IN NATURE of September 12, p. 494, a summary description was given of the remarkable discovery made by Mr. Theodore M. Davis, of Newport, R.I., of the tomb of the famous Egyptian Queen Tii, Thyi, or Teie, mother of the heretic-king Akhenaten, at Thebes. A remarkable point with regard to this discovery has been raised by an "Occasional Correspondent" of the *Times*, who informs us that the supposed remains of the queen, after having been examined by Dr. Elliot Smith, turn out to be those of a young man, at most twenty-five years of age! It is concluded therefrom that the discoverers were mistaken in their attribution of these remains, and that the coffin is not that of the queen at all, but of Akhenaten, whose name appears on it; but this cannot be the case. On the catafalque the inscription definitely states that it was given by Akhenaten to his mother Tii, and the mention of Akhenaten's name only on the coffin need mean also no more than this. The coffin is that of a queen; the diadem and necklace and other objects found are also the parure of a queen, not of a king, and the heads of the canopic jars are portraits of Tii.

The fact that the body found with these things is that of a man would mean simply that, as Prof. Sayce says in a letter on the subject published in the *Times* of September 17, "the mummy of the Queen had been torn to pieces like that of the King; and that, subsequently, when an attempt was made to put the tomb in order, the first mummy that came to hand was thrust into the Queen's jewelry wrappings, and coffin. It was not the first time that the Egyptians resorted to similar measures, and it would explain the otherwise puzzling absence of funeral furniture in the tomb."

In an article published in the *Graphic* of September 14 describing the tomb, I assumed that the weight of Dr. Elliot Smith's medical authority was decisive, and that therefore the body must be regarded as that of a man, at the same time suggesting reasons for this fact more or less similar to those advanced by Prof. Sayce; but the discoverer is by no means convinced that Dr. Smith is right at all. Since penning my article in the *Graphic* I have received a letter from Mr. Davis, giving his reasons for his sturdy belief, in the same terms as one received by Prof. Sayce, who communicates its gist to the *Times* as follows:—"Immediately after the opening of the tomb he had the mummy examined by Dr. Pollock, of Luxor, 'and a prominent American obstetrician. . . . In the presence of the doctor and surgeon, Mr. Ayrton, and one or two other persons, the mummy was opened and the bones exposed. In fact, the mummy had absorbed so much moisture that it could not be unwrapped, but it yielded to the touch and disintegrated to such an extent that there was no difficulty in exposing the bones from end to end. The pelvis was admitted to be the criterion of the sex. Both doctor and surgeon instantly agreed that it was the pelvis of a woman. The surgeon made a most thorough examination, and explained to us why it was a woman's pelvis, and what the difference is between the pelvis of a man and a woman. He practically stated that the 'greater breadth of the pelvic arch gives one of the most easily appreciable points of contrast between the male and female pelvis; the pelvic arch in the female forms an angle of from 90° to 100°, while in the male it averages from 70° to 75°.'" To me Mr. Davis writes:—"In any event, I shall exhaust the question of the sex of the pelvis before conceding Dr. Smith's opinion."

If, however, Dr. Elliot Smith is really right, and the body is that of a man, the fact does not in any way affect the discovery. The tomb, catafalque, coffin, canopic jars, diadem, &c., are those of Tii, and the bones found were in some way substituted for hers. They cannot be those of Akhenaten, as he must have been a middle-aged man when he died. H. R. HALL.

Use of the Word "Telephotography."

NATURE of August 29 contained an article by Dr. Shelford Bidwell entitled "Practical Telephotography." May I enter a protest against the use of the word "telephotography" to describe the method of transmitting pictures to a distance? Without wishing to go into the merit of the term, I would point out that it has been applied for years to photography by means of a lens consisting of a negative as well as a positive element, as in the well-known "telephoto" lens of Dallmeyer. There is already an extensive literature in which the term "telephotography" is used with this meaning, and to employ it now to describe something totally different can only ultimately result in confusion. Would it not be better to employ the term customarily employed, viz. "phototelegraphy"? R. CHILD BAYLEY.

20 Tudor Street, London, September 7.

I BELIEVE that the word "telephotography" was coined by myself, and first appeared at the head of an article published in NATURE on February 10, 1881, in which an account was given of the earliest attempt to transmit photographic pictures by electrical means. The term was at the time generally adopted by the Press, and has found its way into several books of reference. In the "Century Dictionary" (1900) telephotography is defined as "the art (not yet attained) of producing a photograph, distant and invisible from the camera, by means of electrical connections with a suitable apparatus near the object." No other meaning is given.

The word was not employed in the sense in which it appears to be now current among photographers until at least ten years later, the date of Mr. Dallmeyer's invention being 1891; but I have no great affection for my neologism, and propose in future to write "telegraphic photography," thus avoiding the possibility of confusion. "Phototelegraphy" I take to mean signalling by flashes of light, as in heliography. SHELFORD BIDWELL.

Beechmead, Oatlands Chase, Weybridge, September 13.

DOUBLE STARS.[1]

PROF. BURNHAM tells us in the preface to the first mentioned of these works that when he was attracted to the subject of double stars he had to draw the main part of his information from an early edition of Webb's "Celestial Objects." A useful book, no doubt, and one which has given many an amateur his first insight into a fascinating study, but its modest dimensions compared with those of the ponderous tomes the titles of which appear at the foot of this column may serve to remind us of the progress that has been made since that book occupied a prominent place as a recognised authority. It is in no small measure due to the difficulties arising from this scantiness of information that Prof. Burnham experienced in his early days that we owe this magnificent compilation. In those far-away times it was necessary to collect the history of double stars, to make manuscript copies of all the catalogues that could be obtained, to note carefully all that was published; and though this necessity may no longer exist, these manuscript catalogues have been kept posted up to date, and it is the final and complete outcome of this long-continued work that has now found its way into the printers' hands. We therefore get the results of accumulated experience in the form that the author has found most useful.

The catalogue gives the approximate coordinates of 13,665 stars, the position angle and distance at a given epoch, the magnitude of the components, and such other information as can be pressed into a single line. The value of such a work consists in its completeness. It may be confidently assumed that some information concerning every star recognised as double within the area under review previous to 1906, will be found here. All who have worked with incomplete or disconnected catalogues will know how to appreciate the usefulness of this compilation. In no department of astronomical research is the literature more scattered. Amateurs have contributed much to double-star measurement, and their observations are necessarily distributed through many channels. To collect and make available these many sources of information is a task of no common difficulty, and is perhaps only possible to one who has narrowly watched the growth of the material and sifted the details as the observations appeared. Alertness, industry and a keen interest in the subject were as necessary as access to publications or orderly method of arrangement. No one was better equipped for the task than Prof. Burnham, and we may be grateful that he has accomplished it.

The notes to the catalogue will be of greater interest to those who are concerned in the attainment of astronomical results than is the catalogue itself. Here are recorded a sufficient number of measures to show the motion where there has been any relative change, and so far as possible its character and amount, or to exhibit the unchanged relation of the components where no motion has been detected. References to the original places of publication, which would be used in subsequent calculations, are given for each star. The author gratefully acknowledges that he has been given a free hand in the selection of observations and comments, and he adds that he "has omitted nothing that in his judgment would be worth giving." Here the author assumes the position of a critic, a position for which he is admirably fitted by his long training and close study. Many will be prepared to surrender their judgment

[1] "A General Catalogue of Double Stars within 121° of the North Pole." By S. W. Burnham. Pp. lv+256 (Washington, D.C.: Published by the Carnegie Institution, 1906.)

"A General Catalogue of Double Stars." Part ii. Notes to the Catalogue. Pp. viii+257-1086. (Published by the Carnegie Institution, 1906.)

and accept his ruling. All will be cautious how they dissent from his expressed opinions. But it seems to us that to recommend the wholesale rejection of a large number of published measures of double stars is a drastic proposal, from which a less stern critic than the author might well recoil. It may be admitted that the possessors of small telescopes have always struggled to measure objects for which their instruments were unfitted. Indeed, a double-star observer never seems happy unless he is trying to measure something he can see very imperfectly. But simple dissatisfaction with the manner in which an observation has been made does not offer any adequate criterion for the rejection of doubtful observations, and we can hardly accept the assertion "that there need be no difficulty or hesitation in deciding as to the proper material to be used." This, as it stands, is a hard saying, and we may very well doubt if we have correctly understood the author.

He is on safer ground when he declines to deduce any inferences which might be based on the grouping of statistics. He is at present content to collect facts and to regard as premature any attempt to establish, or even suggest, theories on the limited information at command. The remark is made that very little has been done in the way of finding close pairs below the ninth magnitude, and that the effect of recent discovery in this direction may controvert the conclusions drawn from the older measures. This may doubtless be true, but the lack of sufficient data has seldom prevented the adoption of a working hypothesis. Certainly when Prof. Burnham sums up what has been accomplished in a century of double-star observing the results seem somewhat meagre for theory building, and emphasise the necessity for that careful and systematic measurement upon which he insists. There are only eighty-eight systems for which orbits have been found, and of this number only thirty-four can be regarded as of any value. As to the remaining fifty-four systems, the periods and "all the elements of the orbits are wholly uncertain and worthless. They cannot be regarded even as approximations . . . and in some instances it is not certain that they are physical systems at all." This severe criticism can be justified. Perhaps some of these indecisive results and the eagerness to build upon unsuitable observations may be traced to the influence of Herschel, and the apparent success that attended his ingenious device for deriving an approximate orbit. More rigorous methods have, however, given results of scarcely greater trustworthiness, and the tendency now is to leave double-star orbits severely alone.

It may be of greater practical utility to note that our knowledge of double stars has suffered from the want of organisation among observers. As the author puts it, "Since the observations of Struve the work of micrometrical measurement of double stars has not been wisely distributed. A vast amount of time has been practically wasted in the duplication of measures of the prominent and familiar pairs and in observing objects which need no attention except at long intervals." But Prof. Burnham may here be reminded that it is not enough to suggest that the working lists of double stars should be more carefully selected. What is wanted is authoritative leadership and sympathetic guidance. Such an influential position the writer of these books might worthily occupy. His competency no one would question. The necessity for cooperation among astronomers and the judicious husbanding of resources is becoming more and more recognised. The beneficial effect of organisation in coping with large masses of work is acknowledged. Isolated and unmethodical labour is accompanied by many evils, but none more noticeable than that of overlapping and needless duplication. These evils cannot be entirely avoided, but they can be reduced to a minimum.

Overlapping may to some extent be beneficial. An example is supplied by the very admirable work which Mr. Lewis has lately published through the Royal Astronomical Society. But it is not often that two experts work on so nearly parallel lines. Mr. Lewis has done in a very thorough and masterly manner for the Struve stars what Prof. Burnham has accomplished for a larger number. Mr. Lewis's work may be the more efficient, in the sense that it enables us to dispense with a larger number of original authorities, but there would have been no great difficulty and some advantage in combining the merits of both compilations. It is not necessary to give illustrations of the way in which observations are duplicated. It is difficult to quote instances in which independent lines of investigation are being pursued. The Lick Observatory has made the search for close double stars of feeble magnitude peculiarly its own. In this department is doubtless found an admirable employment for large optical power. Mr. Burnham has added many new doubles to our catalogue, but apparently finds a sufficient field for his energy in the re-measurement of recognised doubles. Throughout the United States a vast number of observers are interested in double stars, but in their work it is impossible to recognise any well-developed plan. On this side of the Atlantic, besides the excellent work that is being done at the Royal Observatory, which again demands large aperture, we have an army of amateurs, headed, we may say, by Mr. Maw, the late president of the Royal Astronomical Society, whose contributions to the general store would be increased in value if designed to form part of a definite scheme. Too often double-star measurement is the refuge of the leisured amateur, who finds in this kind of work an agreeable occupation. Such irresponsible observers stand particularly in need of direction, and if some scheme of cooperation could be formulated, Prof. Burnham's intimate acquaintance with the subject would be of immense assistance. He has admirably arranged the material that is to be observed; he has made us apprehend the extent of the field of labour and the abundance of the harvest; he has shown what can be done by unwearying industry and painstaking perseverance; let him complete his work by organising the labourers and infusing into their work system and continuity.

FOOD INSPECTION AND ADULTERATION.

SIR JAMES CRICHTON BROWNE, as president of the Association of Sanitary Inspectors, delivered last week the customary address at the annual meeting of the association. His remarks, devoted largely to the question of purity in foodstuffs, were a forcible presentation of matters which, well known to those concerned in the problem of food-control, deserve the serious attention of a wider circle, since as consumers and as citizens all are interested in the points brought forward.

The most important topic dealt with was that of a pure milk supply. It is "the primary and paramount food question." There is no need to enter here into details of adulteration, but it may be stated that according to the Local Government Board reports ten per cent. of our milk is either adulterated with water or impoverished by the abstraction of fat, or both; whilst a much larger proportion is so manipulated as to leave it only just within the official limits taken as criteria of genuineness. Moreover, the practice of sophistication appears to be extending.

Unfortunately, however, milk is a product which, naturally, varies much in quality. As a consequence there are difficulties, well known to those who administer the Sale of Food and Drugs Acts, in the way of preventing the manipulation mentioned. To avoid punishing the innocent some latitude must be allowed to the guilty—and the guilty take full advantage of it. It does not follow that less latitude should be given. Careful consideration will show that as regards the official "standards" by which milk is judged, the balance is held as evenly as is practicable between the consumer on the one hand and the producer on the other.

At the moment, what seems to be the most pressing question of milk supply is the matter of cleanliness. Whether the milk is genuine or whether it is watered, at least the introduction of filth ought not to be tolerated. Dirty byres, dirty cows, dirty hands; an atmosphere of dust and micro-organisms; tuberculous udders and uncleanly churns; these may each and all have a part in contaminating the foodstuff which, as Sir James puts it, "enters into the diet of a vast majority of the population, and forms the almost exclusive food of its most susceptible units." There is here a very real need for improvement. Nor does it appear certain that any new legislation is necessary. The Public Health Act and the Dairy, Cowsheds, and Milkshops Order would perhaps suffice as regards the machinery; but there is often local reluctance to put the machinery in motion.

In the matter of butter, to which Sir James devoted a part of his address, the hands of the authorities will be materially strengthened by the new Butter and Margarine Act. It was quite time. The chief malpractices to which this article of food is subjected were described some months ago in the columns of this journal (NATURE, vol. lxxiii., p. 466). One or two examples from the report of the principal chemist of the Government Laboratory may be cited to illustrate the recent history of the matter. During last year a creamery in this country was visited under the authority of a search-warrant, and the process of adulterating butter with lard was found in full swing on the premises. Other such places are known to use condensed milk for incorporation with butter. Again, an unscrupulous individual was found offering for sale a process for the "scientific" manipulation of butter by blending it with beef-fat or lard; and eventually he was indicted for inciting to commit a misdemeanour. He was sent for trial, but the Old Bailey never saw him; the authorities had to be content with estreating his bail for 800*l.*

As remedial measures Sir James Crichton Browne mentions provisions that were either previously existent or have been included in the Butter and Margarine Act of last session. The importer is held responsible for the genuineness of the butter he imports, and must find his remedy against the foreign producer. All butter factories must be registered, and be subject to inspection. Any oils or fats found that are capable of being used in the adulteration of butter are to be considered as intended to be so used unless the contrary is proved, and their presence constitutes an offence under the Act. Though not all that could be wished, the measure will be a valuable one in many respects, and should do much to check fraudulent manipulation of butter.

But a much more drastic and far-reaching enactment is just now coming into force in the United States, and the working of one of its provisions in particular will be watched with much interest in this country. Its effect is to ensure that articles of food and drugs shall be labelled so as to show the purchaser, within limits, exactly what the articles are. The description must not "be false or misleading in any particular," whether as to composition, quality, origin, or what not. Thus an article must be stated on the label to be "prepared with glucose," "coloured with sulphate of copper," "dyed with aniline dye," or to be "composed of fragments and scraps from a mushroom cannery," and so on, as the case may be. Moreover, in the case of certain drugs—morphia, cocaine, chloral, chloroform, and others—the proportions must always be stated on the label. If the preparation is found not to agree with the description it is deemed to be "misbranded," and offends against the Act. It is too early yet to say exactly what the effect of this compulsory candour will be, but obviously it affords a powerful means of enforcing commercial honesty. This, however, is not all that is being done. So long as a substance is left undefined, so long is it possible for a "trade custom" to be alleged in defence of malpractices. Witness, for instance, the discussions upon "what is whisky?" and "what is brandy?" which have recently arisen in this country. Hence the new American law is being supplemented by a series of schedules defining the various food products and fixing certain "standards" in respect of them. The appointment of a committee to draw up similar regulations for the United Kingdom has been urged, but at present little more has been done in the matter.

Another point of much importance touched upon by Sir J. Crichton Browne is the open or veiled antagonism of some local authorities to anything like reforming zeal on the part of their medical officers, analysts, and inspectors. The personal interests of influential councillors may clash with the public welfare, and an official may find his tenure but short if he becomes too zealous. How, it is asked, can a public official act impartially if the fearless performance of his duty brings him into the position of having to prosecute his employers?

"Vice," says Sir James, "is mind in the wrong place." Perhaps our present system of local government often puts men in the wrong place.

C. SIMMONDS.

SCIENTIFIC WORK IN INDIA.

THE Asiatic Society of Bengal continues to make satisfactory progress, its membership having increased from 343 in 1904 to 407 in 1906. In his annual address for the latter year the president, Sir A. Frazer, Lieutenant Governor of the Province, expressed his disappointment that so few civilians and members of other services have joined the society. He suggested that the society did not make itself sufficiently known; that the increasing use of English in Bengal discourages the use of the vernacular tongues; but he chiefly attributes the lack of official interest in the work to what he calls "the prevalence of mere officialism." He therefore proposes to appoint a joint committee of savants and officials to investigate the question, and to endeavour to bring about more satisfactory relations between the society and the services.

It is well that the attention of the authorities has been directed to this important subject. Such a committee is, however, hardly likely to throw much new light on the matter. The causes enumerated by the president have no doubt tended to increase the prevailing indifference felt by Indian officials to scientific inquiry and the study of the people, their languages, superstitions, and beliefs. But, in spite of the cheerful optimism of the Lieutenant Governor, the causes of this failure lie nearer home than he would be disposed to admit. All services naturally take their tone from their leaders, and, as a matter of fact, the Indian Government has always regarded investigations, scientific or literary, beyond the immediate range of official routine, with some degree of suspicion. They claim all the time and powers of mind which their servants possess for their own special work; they have hitherto been unable fully to realise the value of a personal knowledge of the country and its people; they suppose that any studies of this kind tend to divert attention from the continuous desk work, the compilation of statistical reports which they consider the main duty of the civilian, or the supervision of his men which is the business of the soldier. With this is combined the impression that men of genius are out of place in the Indian bureaucracy, which prefers the safe person, who meekly follows the codes and circulars of the Revenue Board, to one who is disposed to raise awkward questions and inquire into matters beyond the narrow range of official duties. Hence the scientific inquirer, the linguist, naturalist, or anthropologist, rests under a certain suspicion that he is neglecting his real duties.

Fortunately, the present political situation is tending to modify this old-fashioned official view, and it is becoming obvious that the Government servant needs, above all things, an insight into the little-known beliefs and prejudices of the peasantry, while an officer destitute of scientific training, with no interest in the country and its development, is an unprofitable servant. It may reasonably be suspected that many of the present difficulties in Bengal are due to a fact which Sir A. Frazer mentions incidentally, without apparently realising its importance—that junior officers in Bengal fail to master the vernaculars of the people because most of their work on municipal and other boards is done in association with native gentlemen who prefer that the business should be conducted in English.

In spite of this lack of cooperation on the part of the official classes, the out-turn of the society's work for the past year is excellent. Dr. Annandale continues his studies of the fresh-water fauna, discussing the little-known Polyzoa which are found in fresh and brackish pools, with some undescribed fresh-water sponges from Calcutta and other parts of the country. He also deals with a specimen, recently discovered by accident in the museum, of that rare cat, *Felis tristis*, and Major Anderson describes *Breynia Vredenburgi*, a new Echinoid from the Indian Ocean. Botany is represented by Mr. Burkill's notes on the pollinisation of Indian flowers, with a special account of *Gentiana coronata*. In the zoological field Lieut.-Colonel Phillot deals with various varieties of falcons, and translates the chapters on hunting dogs and cheetas from an Arabic treatise on falconry of the tenth century. The chemical laboratory of the Presidency College contributes notes on a new way of preparing mercurous iodide, and on nitro-ethane as a solvent of iodoform.

The anthropological and numismatic supplements are as interesting as usual, and the materials collected in the late Tibetan expedition are being worked up by Rai Sarat Chandra Das and other native scholars.

The society also continues its useful series of independent memoirs. M. M. A. Gruvel contributes a learned monograph on "Cirrhipèdes operculés de l'Indian Museum de Calcutta," and Mr. E. R. Watson discusses the fastness of the indigenous dyes of Bengal. On the ethnographical side Mr. E. H. C. Walsh contributes a paper on the coinage of Tibet, and Dr. Annandale and Lieut.-Colonel Phillott, in the second part of their "Miscellanea Ethnographica," deal with Malayan weapons and the plan of a Persian gentleman's house. The most important contribution to this department is the monograph by Mr. R. B. Bainbridge on the Saorias of the Rajmahal Hills. These are but an isolated fragment of a widely-spread, broken tribe found in Orissa, Chota Nagpur, Western Bengal, Madras, and the Central Provinces. The author speaks rather vaguely of their ethnical character. He seems to identify them with the Malé, and he adds that the Santals call them Munda and the Hindus Paharia or hillmen. He notes that they combine, as many Dravidians do, a high nasal index with dolichocephaly, but, in opposition to Sir H. Risley, he endeavours to distinguish them from typical Dravidians, like the Santals and Oraons, and suggests that among the Saorias the original Dravidian type has become modified by admixture with Aryan blood. But considering the isolation of their territory from the plains of Bengal, cross-breeding with high-caste Hindus does not seem probable. The author is obviously well acquainted with the people whom he describes, but his lack of literary skill and of anthropological training makes his memoir disappointing in comparison with the accounts of the same people by Sir H. Risley and Colonel Dalton. At the same time, he has collected much useful information on their social customs and religion which will furnish a basis for a full account of the tribe by some more competent writer.

THE CULLINAN DIAMOND.

THE Cullinan diamond, which the Transvaal Government, acting upon the proposition of the Prime Minister, General Botha, has recently decided to present to the King, was discovered at the Premier Mine near Pretoria, in the Transvaal, on January 25, 1905. The stone was found projecting from the side of the open-working or excavation in the "pipe" area about 18 feet from the surface. After a preliminary cleaning it was found to weigh $3024\frac{3}{4}$ carats, or 1·37 lb. avoirdupois; consequently it is more than three times the weight of the largest diamond previously known—the famous stone found in 1893 at Jagersfontein, in the Orange River Colony, which weighed 972 carats. A few days after its discovery the stone was examined and measured by Dr. F H. Hatch and Dr. G. S. Corstorphine, who published a description of it in the Transactions of the Geological Society of South Africa (vol. viii., pp. 26–7, 1905) and in the *Geological Magazine* (April, 1905, pp. 170–2).

According to this description the stone measures 4 by $2\frac{1}{2}$ by 2 inches. It is bounded by eight surfaces; four of these are faces of the original octahedral crystal, and four are cleavage faces parallel to the octahedron. Evidently the stone is a portion only of the original crystal, which had the shape of a distorted octahedron. The original octahedral faces are distinguished by typical striations, the bands varying in width from 0·1 to 0·4 centimetre, by mammillations and by triangular pittings, like deeply-etched figures, the largest of which has a side of 0·65 cm. On the other hand, the cleavage surfaces are characterised by greater smoothness and consequently by a more perfect reflection of light. Parallel to the largest cleaved surface there is an air layer between two internal cleavages, producing a "rainbow" or Newton rings.

The crystal is of remarkable purity. Two spots are visible, one on the surface, the other about 1 cm. within the crystal. The colour approximates to a blue-white. The stone was named after the chairman of the Premier Diamond Company. It is the joint property of the company and of the Transvaal Government, the latter being entitled to a share in the profits made by the company.

NEW LABORATORIES AT QUEEN'S COLLEGE, BELFAST.

On Friday last, September 20, the buildings recently erected to provide much-needed additional accommodation for the scientific departments of Queen's College, Belfast, were formally opened. These buildings include the Donald Currie laboratory and lecture-room for chemistry, the Musgrave laboratories for pathology and bacteriology, the Jaffé laboratory for physiology, the Harland laboratories of physics and engineering, and rooms for the departments of biology, pharmacology, and surgery.

Lord Kelvin had promised to visit the city of his birth and early life in order to perform the opening ceremony. Unfortunately, a few days before the date fixed, the sudden and serious illness of Lady Kelvin made it impossible for him to fulfil his engagement. Lord Kelvin sent to Belfast the text of the address which he had prepared for the occasion, and this was read to the meeting by his nephew, Mr. James Thomson, whose father, Prof. James Thomson, formerly occupied the chair of engineering in the college. The buildings were declared open by Sir Otto Jaffé, chairman of the committee in charge of the "Better Equipment Fund," and a prominent benefactor of the college. The meeting was afterwards addressed by Sir Christopher Nixon, vice-chancellor of the Royal University of Ireland, and by Prof. Letts.

In the beginning of his address Lord Kelvin traced the development of university education in Belfast from the foundation, about 1815, of the "Academical Institution," of which the collegiate part was afterwards merged in the Queen's College. He expressed the hope that the college would soon receive the full status of an independent university. After enumerating the laboratories to be opened on that day, the address proceeded as follows:—

Now that you have them open and ready for use, what are you going to do with them? Your chiefs in the different departments, professors, assistant professors, assistant workers, and students, will, I am sure, soon give very good and useful answers to that question. None of your chiefs will be likely to follow the example of a good old university professor of a bygone age in the sister island, who was the happy official possessor of many very fine and costly instruments, in which he took great pride. He devoted himself whole-heartedly to keeping them in order.

Your seven laboratories extend over the whole field of lifeless matter and of matter associated with life. We may be sure that in none of them will there be any lack of useful occupation. Personally, I need hardly say, I envy most the workers in the laboratories of physics, chemistry, and engineering.

At the present stage of the era which commenced with Henri Becquerel's discovery of radio-activity in salts of uranium and in metallic uranium, the very thought of physics and chemistry, a now united science, compels us to think of radium, in which Madame Curie discovered the element of Becquerel's wonderful radiation. I hope the physical and chemical laboratories of Queen's College, Belfast, will try to find if the radium element does occasionally explode into fragments. If they find that it does, the laboratories will, I trust, hold an official conference with the professors of Greek and logic, and come to a conclusion whether or not it is a convenient fiction to call the radium element an atom. It may remain quite convenient to continue calling radium an element. Indeed, I well remember a time in Belfast when we used to call earth, air, fire, and water "the four elements."

Whatever may betide, I hope the physical and chemical laboratories of Queen's College will be full of radio-activity until we have more intimate knowledge of radium than we have of iron, with its magnetic quality.

I have many happy recollections of Queen's College in the 'fifties and 'sixties, when my brother was professor of engineering there. What would he not have given for the admirable and useful engineering laboratory of which Queen's College takes possession to-day?

I have somewhat later recollections of Queen's College, full of personal and scientific interest, when Thomas Andrews was making his immortal discoveries in it regarding the continuity of the gaseous and liquid states, now celebrated throughout the scientific world. I well remember, too, his showing me, on a promisingly practical scale of magnitude, the electrical transmission of power through a pair of copper wires, from one Gramme dynamo driven by hand to another taking the work from it. No doubt Andrews showed this to his students at a time when, by most engineers and scientific men, engineering applications of electromagnetism were looked on as chimerical fancies of ingenious, non-practical professors or other weak persons. Who can say whether the seed thus sown, about 1870, or 1871 or 1872, through university action in the north of Ireland, may not have germinated in the Portrush electric railway, which has given to Ireland the first historic title to the utilisation of water-power by electric transmission to many miles, instead of to a few yards, as shown to the students of Queen's College in Andrews's lecture-room?

PROF. L. F. VERNON-HARCOURT.

The death of Prof. Vernon-Harcourt, following so soon after that of Sir Benjamin Baker, not only deprives the civil engineering profession of another illustrious member, but leaves experimental science the poorer for the loss of one of her most devoted sons. The branch of civil engineering work with which Prof. Vernon-Harcourt was most closely associated was that concerned in the maintenance and construction of waterways. Harbours, docks, rivers, canals—all and everything, in fact, which appertains to the provision and improvement of routes and termini for water-borne traffic is included under this head. In this special domain Prof. Vernon-Harcourt was an acknowledged authority, and the treatises thereon which came from his pen, and the opinions which he expressed, invariably carried with them that conviction which is the rightful due of sound knowledge and ripe experience.

He came of distinguished ancestry. The son of an admiral, the grandson of an archbishop, he could scarcely fail to leave his mark in any profession he might take up. A brilliant career at Oxford (he graduated in 1861 with a first class in mathematics, and the following year in natural science) was followed by three years of steady, persevering study in the practice of civil engineering under the late Sir John Hawkshaw. Then came ten years of responsible executive work, first at the South-West India Dock, then on Alderney Breakwater, on Rosslare Harbour, and the railway to Wexford. Finally, in 1878, he established himself as a consultant, with offices in Westminster, and four years later he was appointed professor of civil engineering at University College, London. His active connection with University College was maintained practically up to the time of his death.

Prof. Vernon-Harcourt will perhaps be best remembered by his writings, which have won for their author a deserved and unquestioned reputation. In 1882 appeared "Rivers and Canals" (second edition, 1896), followed in 1885 by "Harbours and Docks," in 1891 by "Achievements in Engineering," and in 1902 by "Civil Engineering as applied to Construction." All these works are characterised by lucidity of style and soundness of thought, and they are to be found to-day on the bookshelves of most practising engineers. In addition thereto, Prof. Vernon-Harcourt contributed to the "Encyclopædia Britannica," and wrote copiously for various learned societies—the Institution of Civil Engineers, the Royal Society, the

Society of Arts, and the International Association of Navigation congresses. He was president of the mechanical section of the British Association meeting of 1895, and a number of distinctions were conferred upon him from time to time, including a commandership of the Imperial Franz-Josef Order of Austria-Hungary, in recognition of his services on an International Jury on Canal Lifts.

There is no novel or startling departure in theory or practice, no gigantic masterpiece of constructive skill, associated with Prof. Vernon-Harcourt's career, but his name will long be held in respectful remembrance by those who can understand and appreciate the solid and enduring character of his unobtrusive work. His investigations in 1886 in regard to the Seine estuary, and the patient care with which, from a number of artificial models, he deduced the probable effect of various systems of training works, commanded the attention and interest of the profession, such that his position as an expert authority on fluvio-maritime works henceforward became preeminent. In 1896 he made an inspection of the River Hooghli, and drew up for the Calcutta Port Commissioners a valuable report on the means of improving the navigable channel. Only last year he was consulted by the Mersey Docks and Harbour Board in regard to certain training works proposed for the estuary of the Mersey.

Prof. Vernon-Harcourt did not reach the allotted span of man, and the announcement of his death at the age of sixty-eight is received on all hands with unfeigned expressions of sorrow and regret.

NOTES.

THE celebration of the centenary of the Geological Society of London is to commence this morning with a reception of delegates by the president, Sir Archibald Geikie, K.C.B., F.R.S., at the Institution of Civil Engineers. The history of the society is traced in a review which appears elsewhere in this number, and we hope to give an account of the centennial celebrations in our next issue. The president will deliver an address this afternoon on the state of geology at the time when the Geological Society was founded, and a banquet will be held at the Hôtel Métropole this evening. To-morrow will be chiefly devoted to visits to museums, galleries, &c., concluding with an evening reception at the Natural History Museum. On Saturday, short excursions will be made to places of geological interest within easy reach of London; and on Monday the visitors will divide into two sections, one of which will go to Oxford, the other to Cambridge. At both universities there will be further hospitalities, and honorary degrees will be conferred upon a few of the guests.

THE fourteenth International Congress of Hygiene and Demography was opened at Berlin on Monday in the presence of the Crown Prince and representatives of the Diplomatic Corps, the Prussian Ministry, the Berlin Municipality, and other official bodies. The congress was formally welcomed in the name of the Emperor William by the Prussian Minister of the Interior, Herr von Bethmann-Hollweg.

THE Scottish Arctic Expedition under Dr. Bruce arrived at Tromsö on September 22, all well. Dr. Bruce's companion, Mr. H. Johansen, will stay at Spitsbergen for the winter, together with Mr. Lerner. The *Times* correspondent at Ottawa reports that Dr. Stefansson, of the Anglo-American Arctic Expedition, has arrived at Victoria. He left Captain Mikkelsen and the other members of the expedition well on Herschel Island in July.

A CONFERENCE for the purpose of discussing subjects connected with the work of museums and art galleries and kindred institutions will be held at the Royal Museum and Art Galleries, Salford, on Friday, October 18, and will be attended by members of the Museums Association and other persons interested in museum work.

THE Berlin correspondent of the *Globe* states that during the ensuing four months, that is, from now to January 15, the German Army authorities intend to carry out an important series of experiments in wireless telegraphy at Metz and Strasburg, and at the six leading fortresses of Königsberg, Thorn, Danzig, Posen, Cologne, and Mainz. One thousand reservists, who have served as military telegraphists, have been called up to work with the military telegraphists now serving with the Army.

SPEAKING at Liverpool on September 19, at the Liverpool Imperial Products Exhibition, Mr. Haldane, M.P., again took the opportunity of urging the importance of a scientific foundation for our Empire. He reminded his hearers that the secret of prosperity, the secret of winning the fruits of the earth, lies in mind, in knowledge, and in the direction applied to the energies which abound around us, and can be turned to the service of man. What is true of ordinary industry is true of the great enterprise of making the best of the possibilities of those vast tracts of the world which constitute the British Empire.

THE official results of the International Balloon Race of September 15 show that six balloons travelled more than 800 kilometres before descending. The following particulars are given, among others:—

Order	Name of Balloon	Cubic capacity, metres	Nationality	Hour of ascent	Hour of descent	Distance travelled, kilometres
				Sunday	Monday	
1	Pommern ...	2,200	Germany ...	17 48	22 30	935
2	Le Cognac	1,700	Switzerland ...	18 02	18 03	870
3	Zéohir ...	2,200	Great Britain	17 09	17 30	860
4	Britannia ...	2,200	Great Britain	17 43	18 06	840
5	Bamler ...	1,437	Germany ...	18 37	18 30	830
6	Milano ...	2,000	Italy	17 07	14 30	810

THE autumn meeting of the Iron and Steel Institute was opened at Vienna on Monday in the hall of the Austrian Society of Engineers and Architects. The Ministers of Commerce and Agriculture, with their Under-Secretaries of State and many prominent officials, as well as the general managers of the principal Austrian iron works, were present to welcome the institute. Sir Hugh Bell, the president, returned thanks for the cordial welcome extended to the members by the Austrian Government and the civic authorities. A selection of papers was then read and discussed. On Monday evening a special performance at the Imperial Opera House was arranged. On Tuesday the morning was devoted to the reading and discussion of papers, and the afternoon to a visit to the Imperial Palace at Schönbrunn. To-day, September 26, will begin the excursions to the works to be visited in (1) Bohemia; (2) Styria; and (3) Moravia and Silesia.

THE second Engineering and Machinery Exhibition at Olympia was opened on September 19 by Sir Alexander Kennedy, F.R.S. The body of the hall and part of the annex are filled with the stands of engineering and other firms closely connected with engineering, but the chief feature of the exhibition is the fine collection of machine tools. The British machine-tool manufacturers are well represented, and hold their own with the American and

Continental firms, which could not have been said of the previous exhibition. The importance and adaptability of electric driving is well illustrated by the machine-tool section, and individual operation is greatly in evidence. This is especially the case in one exhibit, as the whole of the machines are individually driven, and the absence of complicated belting as compared with neighbouring exhibits adds greatly to the attractiveness of the machines. Modern electric-tool equipment of every description is well represented, and the heavier machines are also provided in most cases with electric motors, such as plate-bending, girder notching, shearing machines, as well as pumps, winches, &c. Motor starters, iron-clad switches, and electric fittings suitable for workshop use are also exhibited. The exhibition should do much towards helping the electrical industry in workshop practice. Power is obtained for all the motors driving the various machinery shown from the local borough supply, and no independent steam units are employed, their place being taken by single-phase motor generators supplied direct at 2200 volts, converting to 220 volts continuous current.

WE learn from the Allahabad *Pioneer Mail* of September 6 that the programmes of work of the various scientific departments for the current year, as settled by the Board of Scientific Advice, have been published. The following points are of general interest:—(1) schemes have been completed for the establishment of a central research station and agricultural colleges at Poona, Lyallpur, Cawnpor, Bhagalpur, Coimbatore, Nagpur, and Mandalay, and a staff of three European specialists has been sanctioned for each; (2) new agricultural stations are to be started (*a*) at Aligarh for the improvement of cotton, (*b*) at Partabgarh for the study of rice and sugar-cane, (*c*) at Jullundur, (*d*) at Bassein, and (*e*) at Bhagalpur and Bankipur (Bengal). The special investigations connected with the improvement of Indian cottons and wheats will be continued, but the scheme for the improvement of Indian tobacco will largely remain in abeyance until the appointment of a specialist for this purpose. The study of sugar-cane diseases and of practical measures for the suppression of cotton boll-worm in the Punjab will also be continued. The lead mines of the southern Shan States, the tin deposits in Mergui, Tavoy and Karenni, the oil beds in the Irrawaddy valley and the Arakan districts, the volcano of Popa in the Myingyan district, Burma, the copper beds of Singhbhum, and the manganese mines in the Central Provinces, are all to be the subject of geological investigation.

DR. A. GRAHAM BELL has erected on his estate at Benin Breagh, N.S., a tower, 80 feet in height, built of the tetrahedral cells which he invented to secure great strength and lightness in the construction of kites. The engineer was Mr. F. W. Baldwin, of Toronto, who stated at the opening ceremony that the tower weighs less than five tons, and will carry a weight of 50,000 lb.

FROM the report for last year we learn that the collections in the Albany Museum, Cape Colony, are making exceptionally rapid progress, the number of specimens received in the zoological department being in excess of that in any previous year. It is likewise stated that the value of the institution as a means of education is also steadily increasing.

WE have received a copy of a report on trials of the South African locust-fungus in India, by Messrs. E. J. Butler and H. M. Lefroy, issued by the Agricultural Research Institute, Pusa (Bulletin No. 5 of 1897), and published at the Government Press, Calcutta. Unfortunately, little or no success has attended the attempt, the effects of the fungus on several species of locust being *nil*, while in the case of the migratory locust of the north-west such effects as were produced appear to be of no practical value. As regards the last-mentioned species, the authors observe that "the conditions of nature are much more in favour of the insect, and against the fungus, than those under which the experiments were made, and if we can only anticipate a small percentage of infections the method will certainly fail."

THE trophy shown in the accompanying illustration is offered by the *Scientific American* for competition for heavier-than-air flying machines. In order that the competition might be held under the auspices of experts, the trophy has been given under a deed of gift to the Aëro Club of America, to be competed for annually by both American and foreign inventors. The first competition was announced to be held at the Jamestown Exposition on September 14 for a flight of 1 kilometre in a straight line, but the result has not yet reached us. The competition is to be progressive in character, that is to say, if the flight of the predetermined distance has been accomplished this year, next year a longer flight will be required. After every competition the name of the winner will be inscribed on the trophy. If it is won three times in different

The *Scientific American* flying machine trophy.

years by any competitor, the trophy will become his personal property. This fine example of the silversmith's art is of real beauty. From a green onyx base with a silver cartouche rises the massive silver trophy, measuring 32 inches over all. At the summit, projected away from the earth, is an aëroplane in high relief, standing away from the silver globe, with its frame held together by silver guy ropes. The trophy is valued at 500*l*.

THE life-history of a trypanosome infesting the alimentary canal of a leech (*Pontobdella muricata*) parasitic on skates and more rarely angler-fish is discussed by Miss M. Robertson in the Proceedings of the Royal Physical Society of Edinburgh, 1906–7, part iii. Possibly, despite a marked disparity in point of size and appearance, this trypanosome may be the earlier stage of *Trypanosoma raiae*, but this has still to be confirmed. After describing in detail (with a number of coloured illustrations) all that is at present known concerning the development of the trypanosome in the leech's intestine, the author proceeds to discuss its methods of division, which exhibit considerable diversity. Some of such divided individuals suggested the conjugation of a male and female element (gamete), but further examination negatived this interpretation, and showed that division is the sole factor in the phenomenon. This suggests caution in regard to other alleged instances of conjugation among Protozoa, although theoretical considerations render it probable that such a process really occurs at some stage of development.

IN connection with the preceding paragraph, reference may be made to a paper by Miss H. D. King, in the June issue of the Proceedings of the Academy of Philadelphia, on a new sporozoan parasite (*Bertramia bufonis*) found in "Bidder's organ"—a rounded body at the fore-end of the testis—of the common American toad. The interest of the discovery lies in the fact that hitherto scarcely any sporozoans have been recorded in amphibians; but, as the author observes, these creatures are probably as much subject to parasitic infestation as other vertebrates, and they may accordingly be expected to yield many new forms if thoroughly examined.

FROM an article on the history of the tomato, contributed by Mr. W. Dürkop to *Naturwissenschaftliche Wochenschrift* (September 1), it appears that the plant was introduced into Europe, probably into Spain or Portugal, from Peru, shortly before the year 1560, and was first cultivated for its ornamental appearance. Fruits of different colours and shapes were grown in the sixteenth century, but the cultivation declined until the last century, when the fruit came into favour as an esculent.

MR. T. H. GATES has published in the *Botanical Gazette* (February and July) two interesting papers dealing with the cytology of *Oenothera Lamarckiana* and the mutant *Oenothera lata* raised by de Vries. The author investigated the development of the anther in *Oenothera lata*, but was unable to discover why the pollen fails to mature, although it appears to be connected with the early disintegration of the tapetal cells. The pollen of *Oenothera Lamarckiana* was used for raising a hybrid in which the sporophyte stage showed twenty or twenty-one chromosomes, thus differing remarkably from the parents, which both contain only fourteen chromosomes in this stage.

THE July number of the *Indian Forester* opens with a brief appreciative notice, contributed by Mr. S. Eardley-Wilmot, referring to the work of the late Sir Dietrich Brandis, the founder of the Indian Forest Department, and friend of many senior officers in the service. A record of the flowering of the bamboo *Cephalostachyum pergracile* in Lower Burma is reported by Mr. E. V. Ellis. The flowering, although not quite complete, was observed over several hundred acres, and the plants were of two different ages, but neither mature. Gregarious flowering over a few acres had been noted previously. Mr. A. M. Burn-Murdoch communicates a note on damar collection in the Federated Malay States, and Mr. M. Hill provides an account of the introduction of the mahogany tree, *Swietenia mahagoni*, into India.

THE first translator into modern Persian of Morier's famous novel, "Haji Baba," was Haji Shaikh Ahmad-i-Kirmani, a member of the so-called "heretical" sect of the Babis. He retired from Persia to Constantinople in order to continue his studies, and when the Sultan became alarmed at the assassination of the late Shah, Nasr-ud-din, the Turkish authorities basely surrendered the Babi to his hereditary enemies, by whom he was slain at Tabriz. When his version of "Haji Baba" reached Ispahan, it was welcomed with enthusiasm by the Persians as the first great novel written in their language; but when they became acquainted with the English original it ceased to be popular, and was regarded as a satire on all grades of Persians from the Shah downwards. This translation has now been reprinted in Calcutta by Lieut.-Colonel Phillott, Secretary to the Board of Examiners, who has added a brief grammar of modern Persian and a body of valuable notes explaining, not only the slang and popular expressions which abound in the book, but many usages, superstitions, and beliefs of the people. In its present form the book is certain to become popular among all who desire to learn, not so much the classical language, as that now spoken in Persia.

AN exhaustive monograph on the asbestos and manganese ore deposits of Ilocos Norte, by Mr. Warren D. Smith, is published in the *Philippine Journal of Science* (vol. xi., No. 3). The deposits occur in the northern portion of the island of Luzon, and are of considerable extent. The region is of special interest from the varied character of the geology. More diverse features are exhibited than in most parts of the archipelago. The region is primarily one of metamorphism, and this metamorphism is regional rather than local.

AN interesting note by Prof. Omori on the tilting of the ground during a storm appears in the August Bulletin of the Japanese Imperial Earthquake Investigation Committee. On October 10 and 11, 1904, a cyclone, the centre of which passed over the sea to the east of Tokio, was accompanied by a tilting of about $3\frac{1}{2}''$ towards the area of low pressure; on January 10 and 11, 1906, the track of a cyclone centre passed over land, close to Tokio, from south-west to north-east, and was accompanied by a tilting, first to the east and afterwards, as the low pressure passed eastwards, to the westward, the total change of inclination being about $2''\cdot87$. In the latter case the ground rose under the area of low pressure, in the former it sank. The difference is attributed to the fact, recorded in a previous paper, and noticed in NATURE of November 3, 1904, that the sea-level commonly rises by more than the amount necessary to compensate for the diminution of barometric pressure, so that the resulting pressure on the sea bottom is actually greater with a low than with a high barometer. This number of the Bulletin also contains, among other papers, a note on the long-distance records of the Turkestan earthquake of August 22, 1902, in which we notice that the word "mean" seems to have a peculiar significance in Japan, as the mean value is tabulated of a group of two observations, one of which is excepted!

THE engineering experiment station of the University of Illinois has published a Bulletin (No. 13), by Dr. N. Clifford Ricker, professor of architecture, describing an extension of the Dewey decimal system of classification applied to architecture and building. The decimal classification has been largely adopted in libraries in Europe and America, and the proposed extension should prove useful to architects and engineers for classifying collections of lantern-slides and photographs, and for a card index to technical periodicals.

THE Director-General of Indian Observatories has issued a memorandum, dated August 8, with reference to the probable monsoon rainfall during August and September, 1907, based on data obtained since the publication of the previous memorandum of June 8. Among the chief factors taken into consideration were the excess of pressure in South America in July, while in the Indian Ocean the deficiency still persisted. It has previously been pointed out that these conditions are favourable to Indian rainfall, and Dr. Walker thinks it likely that the total amount during August and September will reach or exceed the average.

SEPTEMBER has so far proved exceptionally fine over the entire country, and the whole period since the 5th or 6th of the month has been almost entirely rainless. At Greenwich rain fell on each of the first five days, the aggregate measurement being 0·44 inch, but no rain has fallen subsequently, the dry weather continuing practically for three weeks. At Yarmouth the rainfall to September 25 was 0·23 inch, whilst the average for the month is 2·41 inches, and at both Clacton-on-Sea and at Dover the rainfall amounts to 0·27 inch. The rain has been heavier and more frequent in the north, and at Sumburgh Head there have only been three days without rain, the total measurement to September 24 being 2·64 inches, which is only 0·68 inch short of the average for the whole month. Much mist or fog has prevailed during the past week in many parts of the country, and radiation frost has occurred at night. At Greenwich the exposed thermometer on the grass fell to 24°·7 on the morning of September 23, and there have already been four frosts in the open, as shown by the exposed thermometer, since the commencement of the month. A change in the type of weather is in progress, and the steadily falling barometer foreshadows the setting in of unsettled conditions.

IN accordance with the decision of the International Union for Cooperation in Solar Research that a re-determination of the wave-lengths of certain standard lines should be carried out by independent observers by the interference method of Drs. Fabry and Perot, Mr. A. H. Pfund, of Johns Hopkins University, has, according to a note in the *Physical Review* for August, recently measured the iron lines, and has obtained values which differ from those of Fabry and Perot by less than one part in a million. Mr. Pfund is now engaged in measuring the wave-lengths of the titanium lines.

THE *Zeitschrift für Instrumentenkunde* for August contains a short account, by Dr. von Rohr, of the life and work of the late Dr. S. Czapski, of Jena, so well known for his masterly article on Abbe's theory of optical instruments in Winkelmann's "Handbuch der Physik." He was born in 1861, and after a university education became Abbe's private assistant in 1885. He possessed a wonderful power of grasping the essential points of anything new brought to his notice, and Abbe found in him a friend to whom he ultimately entrusted the publication of his theories.

TWO papers from the pen of Dr. L. A. Bauer which have appeared recently serve to remind us of the prominent position which the United States is taking in the extension of our knowledge of the magnetic state of the earth. The first, in the *Technology Quarterly* for June, summarises the recent results obtained from a detailed survey of the United States and from the voyages of the survey ship *Galilee* across the Pacific. The second is the official report of the department of research in terrestrial magnetism of the Carnegie Institution of Washington, and deals with the voyages of the *Galilee* from October, 1905, to October, 1906, in greater detail. From the latter we gather that the charts of the Pacific at present in use give variations of the compass less than the true value by 1° or 2°, a very serious defect from the navigator's point of view.

SOME curious observations made a few years ago by Dr. A. Heydweiller as to the electrification of the human body by the bending or stretching of the knee or elbow joint receive their explanation in a paper by Drs. S. Tereschin and A. Georgiewsky in the *Physikalische Zeitschrift* for September 1. According to the latter, the electrification produced is due entirely to friction of the foot of the person experimented on on the insulating stand on which he is placed, or, if he is clothed, to the friction between body and underclothing or between under and overclothing. For the electric charges produced in these circumstances the human body is comparatively a good conductor.

IN the *Revue scientifique* for August 31, Dr. C. Féry gives a short illustrated account of the new methods of determining high temperatures in industrial operations. For temperatures up to 700° C. he recommends a thermo-electric couple of iron-constantan, from that to 1300° C. one of platinum and its alloys, in each case in combination with a self-registering arrangement. Where the thermo-couple would be injured if brought into direct contact with the source of heat, he advocates the use of his own pyrometer, in which the radiation from the source is concentrated by a concave mirror on to the thermo-junction. For sources of small dimensions at temperatures above 900° C., optical pyrometers, *e.g.* Wanner's, are the most useful.

THE question of the improvement of the "small power load," to which electric supply companies and borough electricity committees are perforce paying more attention at the present time than heretofore, is raised in an article by Mr. H. S. Hatfield in the *Electrician* of September 13. The difficulties attendant on the development of the small power load, and the inability of the private lighting consumer to avail himself of the offer of cheap power, have been up to the present very great, owing to the fact that the supply must be separately metered, and it is necessary either to instal duplicate wiring or to use submeters. The cost of a separate service generally bars the use of heating and power appliances by the small consumer. The submeter system is free from the objection of first cost to a great extent, and the meters may be removed and used elsewhere, but so far this system has not been adopted to any extent. The objections to the submeter system have been that, although the capital expended on meters would not be irrecoverable, still the cost of four or five trustworthy meters would be considerable; also the average electricity meter is very unsightly. A new submeter which overcomes a great many of the objections of the existing meters is, however, now obtainable, and should help largely towards the development of the small power load. The meter is of the mercury-electrolytic type, and has been proved to be very accurate; it fits over the ordinary two-pin wall plug. It is an inexpensive matter to fix this meter in several rooms wherever a consumer may wish to employ a heating appliance, and he is able to read the meter without trouble and know exactly what his radiator or kettle—as the case may be—is costing him.

UNDER the title "Probleme der katalytischen Forschung" (Leipzig: Veit and Co., price 1.20 marks) Dr. Gertrud Woker has published in pamphlet form an inaugural address delivered at the University of Bern. A suggestive review is given of such questions as the nature of the catalytic changes occurring in the oxidation of sulphur dioxide by nitrous fumes in the chamber process of making sulphuric acid, the problems of autoxidation, the action of the so-called oxydases within the organism, and the nature of the transformations brought about by enzymes in general; finally, the relationship between toxins and anti-toxins is discussed as a phenomenon of physical chemistry governed by the law of mass action.

THE first meeting of the new session of the Entomological Society of London will be held on Wednesday next, October 2, when a paper will be read on the butterflies of Mauritius and Bourbon by Lieut.-Colonel N. Manders.

WE have received from Messrs. F. Darton and Co. their illustrated price list of standard meteorological and other instruments. Some useful notes are given for the benefit of students and others, together with a list of text-books recommended; the latter might be revised with advantage. Before establishing new stations, observers would do well to consult recognised meteorological authorities, especially as regards the installation and proper exposure of the instruments.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN OCTOBER:—

Oct. 1. 18h. Jupiter in conjunction with the Moon. (Jupiter 1° 11′ S).
2. 12h. 58m. Minimum of Algol (β Persei).
4. Saturn apparently without rings.
5. 9h. 47m. Minimum of Algol (β Persei).
8. 6h. 36m. Minimum of Algol (β Persei).
14. 17h. Mars in conjunction with the Moon. (Mars 1° 47′ S.).
18. 6h. Saturn in conjunction with the Moon. (Saturn 2° 13′ N.).
18–22. Epoch of October meteors. (Radiant 92° + 15°.)
22. 22h. Mercury at greatest elongation, 24° 20′ E.
26. 19h. Venus in conjunction with α Libræ. (Star 0° 5′ S.).
28. 8h. 18m. Minimum of Algol (β Persei).
29. 9h. Jupiter in conjunction with the moon. (Jupiter 1° 41′ S.).

SPECTRUM OF DANIEL'S COMET (1907*d*).—Photographs of the spectrum of comet 1907*d*, taken with a Zeiss prismatic camera, were obtained by Herr H. Rosenberg at the Göttingen Observatory on August 9, 11, and 14, with exposures of twenty-five, twenty-eight, and eighteen minutes respectively. The results of the measurements of the spectrograms are uncertain to about ±10 Ångström units, but certainly show that the spectrum includes the chief hydrocarbon and cyanogen bands, with a continuous spectrum extending from about 505 $\mu\mu$ to 370 $\mu\mu$. The brightest bands are those coinciding with the two heads of the third cyanogen band at $\lambda\lambda$ 3883 and 3872 respectively; the third strongest band of the seven measured coincides with the fourth carbon band at λ 4737. Two bands at $\lambda\lambda$ 4055 and 4035 are as yet unidentified. The photograph of August 9 showed bands at 473, 438, 423, 404, and 388 $\mu\mu$ in the spectrum of the comet's tail, all of which were apparently of equal length and strength.

A continuation of the ephemeris of this comet, computed by Herr J. Franz from Dybeck's elements, appears in the same journal (*Astronomische Nachrichten*, No. 4200, p. 401, September 12); the following is abstracted therefrom:—

Ephemeris 12h. (M.T. Berlin).

1907	α (true) h. m.	δ (true) ° ′	$\log r$	$\log \Delta$	Brightness
Sept. 25	11 4·8	+5 47·1	9·8550	0·2085	4·89
29	11 21·9	+4 32·1			
Oct. 3	11 37·7	+3 20·7	9·9264	0·2453	3·00

THE LOWELL EXPEDITION TO THE ANDES.—A second communication from Prof. David Todd to Dr. W. J. S. Lockyer gives additional information concerning the work of the Lowell expedition, of which Prof. Todd is in charge. It appears that at the chief station of the expedition, Alianza, more than 7000 photographs of Mars were obtained during the period June 17 to August 1. Prof. Lowell's discussion of these will form a most important addition to areography, as they show, covering a complete round of the planet, the changing appearances of the two polar caps, a multitude of "oases," and hundreds of the "canals," many of which are plainly in the geminate form.

The photographed images of the planet, as enlarged by the Gaertner camera, are of about three-sixteenths of an inch diameter, and will admit of much further enlargement. Exposures of about two seconds were given on Seed and Cramer plates.

SEPTEMBER METEORS.—The appearance of several bright meteors during the present month is reported from various quarters, but no details of the paths are given. One very fine one was seen at South Kensington by Mr. H. E. Goodson at 11h. 20m. on September 9. The meteor itself disappeared behind a house-top, but left a splendid trail which persisted for fully one-quarter of a minute. Judging from this trail, the direction of the meteor's flight was along a line from β Ursæ Minoris, passing half-way between θ and ι Draconis. The meteor was very brilliant and swift, and was followed almost immediately by a less bright one, which pursued nearly the same path.

PHOTOGRAPHS OF PHŒBE.—Using the 30-inch reflector of the Greenwich Observatory, Mr. Melotte has obtained a series of photographs of Phœbe, Saturn's ninth satellite. The results derived from provisional measurements of the plates show that Dr. Ross's ephemeris, published in the second edition of the American Ephemeris for 1907, is essentially correct (the *Observatory*, No. 387, p. 366, September).

SOLAR ACTIVITY AND TERRESTRIAL PHENOMENA.—We have received from MM. Cirera and Balcells, of the Tortosa Observatory, Spain, a discussion of the relations observed to exist between the variations of solar activity and of terrestrial magnetism and electricity during the first three months of this year.

From this discussion the observers arrive at the following conclusions:—(1) the solar activity increased in January, passed a maximum in February, and decreased during March; (2) the regions of activity exhibited motions in the opposite direction to the sun's rotation; (3) the variations of activity often commenced in the chromosphere. Regarding the correlation of these variations with magnetic and electrical perturbations, the following conclusions were arrived at:—the perturbations either coincided with the appearance of a region of activity on the eastern limb of the sun, with the passage of such a region over the sun's central meridian, or with an extraordinary increase of activity near to the central meridian.

On March 22 an observed strong perturbation coincided, in time, with the central-meridian passage of a region which had been active during the previous rotation of the sun, and on certain dates in January and February the perturbations were more intense on the meridian passage of a region which, having been active before, was increasing in activity.

Three excellent drawings of the great January to April (1905) sun-spot made by Prof. Mascari are reproduced in No. 7, vol. xxxvi., of the *Memorie della Società degli Spettroscopisti Italiani.*

THE JUVISY OBSERVATORY.—An interesting description, illustrated with photographs, of the Juvisy Observatory appears in the August and September issues of the *Bulletin de la Société astronomique de France.* The observatory was founded in 1883 by M. Flammarion, and is principally engaged on planetary observations.

BOTANY AT THE BRITISH ASSOCIATION.

THE time of Section K was considerably occupied in joint meetings with other sections. Thus there was a joint discussion with Section D on "The Physical Basis of Heredity," of which an account will be found in "Zoology at the British Association" (NATURE, September 19, p. 530), and another with Sections D and L on "The Teaching of Biology in Schools," which is described in "Education at the British Association" (NATURE, September 12, p. 505).

A third joint meeting was held, with Sections C, D, and E, to hear an address by Prof. Conwentz, the Prussian State Commissioner for "Naturdenkmalpflege," on "The Preservation of Natural Monuments." Prof. Conwentz explained that the phrase "natural monuments" was new in Germany as well as in England, but we should recognise that there could be monuments of nature as well as of art. The constant inroads of cultivation and of industrial undertakings have led, and are leading, especially in countries with crowded populations, to the disappearance of scientifically interesting and even unique natural objects and types of scenery. A widespread feeling has arisen that as much as possible should be done to prevent such destruction, and this has recently led, not only to much local effort directed towards this end, but in Prussia to the institution of a special State department under the Minister of Education for the purpose of directing and coordinating such efforts. This department (of which the lecturer is the head) has no funds allotted to it for the actual purchase of land bearing natural monuments, nor is it considered that purchase is the right procedure except in special cases. The aim is rather to get private owners interested in the natural monuments on their property, and to induce them to be responsible for their safeguarding and preservation. In the case of Government land, the Forestry Department cooperates by making regulations prohibiting the felling of unique trees, the total clearance of particular types of woodland, &c. Prof. Conwentz's department is prepared to initiate all effort of this kind in Prussia. Its activity has already, during the single year of its existence, met with considerable success. Many areas of primitive marsh and water, heath and woodland, often containing rare and interesting characteristic species of animals and plants, have been saved from destruction, and arrangements made for their permanent preservation. The necessary work falls under three heads:—first, the cataloguing of the natural monuments of the country; secondly, the mapping and scientific description of such monuments; and thirdly, the undertaking of appropriate means for their preservation.

Prof. Conwentz directed attention to the numerous organisations in this country the work of which tends towards this general object, but pointed out that none of them have precisely the same ends in view as his Prussian department. He particularly mentioned the Commons Preservation Society, the Kyrle Society, the National Trust for the Preservation of Places of Historic Interest and Natural Beauty, and the Central Committee for the Survey and Study of British Vegetation. He suggested that the last-named organisation might add the preservation of British vegetation to its objects, and also that efforts in this direction might be helped by the British Association. He pointed out that love for and care of the characteristic natural scenery of the homeland was one aspect of true patriotism, and should act as a check on the purely materialistic development of modern civilisation. The lecture was illustrated by a beautiful series of lantern-slides showing types of protected scenery in Germany, and also of many British examples of a similar kind.

Discussion on the Cytology of Reproduction in the Higher Fungi.

This occupied most of Monday morning, August 5. Three papers were read, and were followed by a discussion.

In the first paper Miss Fraser and Miss Chambers described the development of the ascocarp in *Aspergillus* (*Eurotium*) *herbariorum.* The archicarp consists of a unicellular trichogyne, a unicellular ascogonium, and a septate stalk. An antheridium, divided into a stalk and antheridial cell, is present, and usually fuses with the trichogyne; both structures are cœnocytic. After normal fertilisation or its equivalent, the ascogonium becomes septate and produces ascogenous hyphæ. A sheath is developed, and finally asci are formed. In these, nuclear fusion takes place, and three divisions follow, giving rise to the nuclei of the eight spores.

The authors regarded the genus Aspergillus as primitive, and related its archicarp to that of other groups of Ascomycetes. They pointed out that the male organ closely resembles the antheridium of discomycetous forms; on the other hand, if the antheridial cell, instead of fusing with a neighbouring archicarp, were set free from its parent hypha, it would scarcely differ from the spermatium of the Pyrenomycetes. They held, with Wolfe, that a similar development had taken place among the Florideæ, and regarded the Ascomycetes as a monophyletic group.

Miss Welsford's paper dealt with fertilisation in *Ascobolus furfuraceus.* She confirmed Harper's statement that the archicarp, or scolecite, originates as a row of uninucleate cells. These subsequently become multinucleate, and one increases in size and gives rise to ascogenous hyphæ. Nuclei migrate into this cell and undergo fusion before passing into its branches. Miss Welsford regarded this process as a form of reduced fertilisation, and suggested two interpretations—either (1) the scolecite is a multicellular female organ and the fusions are those of female nuclei in pairs, or (2) the ascogenous cell only is female, the other cells of the scolecite being vegetative and representing a functionless trichogyne and stalk; in this case fertilisation probably consists of the union of a female and a vegetative nucleus.

In the third paper Miss Fraser gave an account of the cytology of *Humaria rutilans.* In this species sexual organs are not developed, but a reduced form of fertilisation obtains, the nuclei of the vegetative mycelium fusing in pairs. Asci are developed from hyphæ which contain fusion nuclei; these show sixteen chromosomes, the sporophytic number, in their mitoses. In each ascus three nuclear divisions take place; the first is heterotype, the chromosomes dividing *transversely*, and the second homotype. These bring about a reduction, related here, as in all other investigated organisms, to normal or reduced fertilisation. During the prophases of the heterotype division, a second nuclear fusion occurs; Miss Fraser suggested a mechanical explanation for this process, and showed that it was occasionally omitted. The sixteen chromosomes which are present throughout the meiotic phase represented the reduced number for two nuclei. The fusion in the ascus is compensated by a peculiar process of reduction taking place in the third division, and termed by Miss Fraser *brachymeiosis.* Sixteen chromosomes are formed from the spireme, and eight pass *without fission* to each daughter nucleus. The reduced number for one nucleus thus appears.

The author considered that this process probably occurred in connection with other asexual fusions also. She related her observations on *Humaria rutilans* to the facts described for Phyllactinia (Harper, 1905) and other Ascomycetes. In conclusion, she pointed out the close analogy between the two fusions in the life-history of Humaria, and suggested that the type of compensating reduction (whether meiotic or brachymeiotic) might be usefully employed to differentiate between sexual and asexual fusions.

The discussion was opened by Prof. Farmer, who agreed that the spermatium of the Florideæ, and no doubt of the Ascomycetes, was closely related to a freed antheridium. He suggested the existence of a further analogy in connection with the events which follow fertilisation. In Ascomycetes a second nuclear fusion takes place in the ascus; in the Florideæ cell fusions occur, but the nuclei are indifferent or repelled. The cases described by Miss Fraser in which ascus nuclei continued their development without fusion might be regarded as intermediate. Prof. Farmer emphasised the dual aspect of nuclear fusion; the process was not primarily originated to associate paternal and maternal characters, but possessed a deep physiological significance.

Prof. Blackman also accepted the theory put forward as to the phylogeny of the male organ. He regarded the variety of female organs among Ascomycetes as difficult to reconcile with their monophyletic origin. The occurrence of both cœnocytic and uninucleate structures was a specially difficult point. With regard to the sexuality of the Ascomycetes, a fairly complete series now existed, including Pyronema (Harper, 1900) and other forms with normal fertilisation; Lachnea (Fraser, 1907) and *Humaria granulata* (Blackman and Fraser, 1906), where the nuclei of the ascogonium fuse in pairs; Ascobolus, where fusion is probably between a female and a vegetative nucleus; and *Humaria rutilans*, where sexual organs are lacking and the vegetative nuclei fuse. Prof. Farmer, in a recent paper, had grouped such various forms of reduction under the general term pseudapogamy, but Prof. Blackman felt that a more detailed classification was required. A further stage would be that in which no fusion took place, and one would then expect a corresponding difference in the divisions in the ascus.

Prof. Blackman accentuated the importance of *Humaria rutilans* as the first case in which the behaviour of the chromosomes in asexual fusions had been elucidated, and dealt with the difference between synaptic and non-synaptic reduction, associating the latter with the fusion of undifferentiated nuclei. In Humaria there is no physiological difference between the two fusions, but the first is obviously the relic of a normal fertilisation. He regarded the definition of a sexual fusion as dependent on the origin of the process, and not on the subsequent behaviour of the nucleus.

Prof. Hartog considered the attempt to differentiate between fusions of sexual and of vegetative nuclei in the ascogonium as puerile, since the pronuclei lose their distinctive sexual characteristics before fusion. He pointed out that brachymeiosis differs from other known types of division in that a sorting, but no splitting, of the chromosomes takes place, and referred to the unexplained fusions of three gametes in the Volvocineæ.

Dr. Darbishire spoke of the complex structure of the multicellular ascogonia of Lichens, and Prof. Buller suggested that a study of the phenomena of spore distribution might throw light on the phylogeny of the Ascomycetes.

Miss Fraser, in replying, dealt with various points raised during the discussion, and pointed out that the difficulty of relating cœnocytic with uninucleate forms was lessened by the occurrence of both states in the scolecite of Ascobolus.

Physiological Papers.

Prof. H. E. Armstrong read a paper by Dr. E. F. Armstrong and himself on "Enzymes, their Mode of Action and Function," which, it is understood, will shortly be published in the *Annals of Botany*. The authors pointed out that the distinctive feature of the chemical changes going on in the bodies of organisms was the fact that they are under the *control* of the action of the bodies called enzymes. Great progress had been made in our knowledge and activity of these bodies within recent years, one of the outstanding conclusions being that all chemical equations involving their action are to be written as reversible changes. It has for a long time been usual to think of ferment action as mainly concerned with destructive metabolic action, but it is probable that the constructive activity of enzymes is really far more important biologically. The authors illustrated the probable structural relations of enzymes to the organic substances upon which they act by reference to the structural formulæ of various sugars, showing that when a given enzyme can act upon several different substances it is because it can work upon a group of atoms common to all these, and in each case holding together the other groups. In the case of albuminoids a complex enzyme is required, but the conception of a skeleton which can only be packed with atoms in a particular way enables us to see that it is unnecessary to assume a mechanism so complex as the structure that has to be produced. It is probable that we should conceive of the constructive activity of enzymes in this way—that the enzyme is a skeleton on which the complicated organic body can be built up. Dr. E. F. Armstrong replied to some questions put by Prof. Reynolds Green and others.

Prof. Bottomley communicated some results of his experiments on the inoculation of nitrogen-fixing bacteria in plants other than the Leguminosæ, and stated that tomatoes had been made to produce a greatly increased crop by this means, the bacteria having been first cultivated in tomato-juice; in wheat the bacteria had been induced to establish themselves in the cortex of the root, though no nodules like those on the roots of Leguminosæ are formed. The economic possibilities of these results, if capable of further development, are sufficiently obvious. Prof. Farmer remarked that this was a case in which we ought to have concluded that if the organism could be cultivated outside the plant it could be got to live upon other plant-cells containing carbohydrates. It had been shown that rusts could be induced to live on different hosts by special training. It was known that wheat can go on for an unlimited number of years producing about thirteen bushels to the acre, but this would probably be much exceeded without manuring if the wheat plants, by the aid of these bacteria, were enabled to fix atmospheric nitrogen.

Mr. F. Darwin read a paper on the cotyledon of Sorghum as a sense organ. It was directed towards confirming the belief that the cotyledon is the seat of geotropic sensitiveness, evidence for which was given in a paper read before Section K at Dover (1899), and published in the *Annals of Botany*. The results given in the present paper were obtained partly by Czapek's "glass-boot" method and partly by an adaptation of Piccard's centrifugal method. The conclusions, though not perhaps finally convincing, are strongly in favour of the view that the cotyledon is the geosensitive region. The paper also contains observations on the traumatic and heliotropic curvatures of Sorghum.

Morphological Papers on Pteridophytes and Pteridosperms.

Prof. Bower read a paper on the embryology of Pteridophytes, embodying the result of his recent work on this subject. He pointed out that there are two types of pteridophytic embryo:—(1) the Lycopod type, which agreed with the Bryophytes in having a suspensor; and (2) the fern type, in which there is no suspensor. The main point he wished to bring out was that there is a definite polarity in the embryo defined at once by the first segmentation, the centre of the "epibasal segment" forming one pole coinciding with the stem apex. On the other hand, the polarity of the embryo with regard to the axis of the archegonium is quite variable, as is the number and time of origin of the first leaves and roots, and also of the haustoria and protocorms. In Isoetes there is no suspensor; the initiation of the polarity is changed, and is even variable within the species. The embryo of Isoetes is inverted as compared with an ordinary Lycopod embryo, but is otherwise in line with the other Lycopods. The initial polarity of *Botrychium obliquum*, according to Lyon's account, is also exactly inverted as compared with Ophioglossum. Goebel's position, that the organs of a plant are laid down in the most suitable positions according to circumstances, is not confirmed by the study of embryos. After the first segmentation the polarity is definitely fixed. There was an interesting discussion, in which Dr. Scott, Prof. Oliver, Prof. Weiss, and Mr. Worsdell joined, and which displayed a general agreement with the author's conclusions.

Mr. Gwynne-Vaughan contributed a striking paper on the real nature of the so-called tracheids of ferns. The author was led by some observations on fossil Osmundaceæ to investigate the pitting of the xylem elements of modern ferns, and was led to the unexpected result that the "pits" are really quite open, placing the cavities of adjacent elements in free communication, while the pits themselves communicate with one another in the thickness of the wall, a "pit-closing membrane" being quite absent. In other words, the wall of the typical xylem element of a fern consists of corner columns joined by pairs of separate horizontal bars. In development the corner columns and bars are gradually lignified, while the pectic substance forming the rest of the primitive wall becomes granular and disappears. In *Pteris aquilina* the substance joining the two bars of each pair remains, though the pits themselves are open. The author exhibited preparations fully demonstrating the facts described in his paper.

Prof. F. W. Oliver read a paper on the structure and affinities of *Physostoma elegans* (Williamson), a pteridospermous seed from the Coal-measures, in which he gave a full description of the seed in question. Williamson afterwards called it *Lagenostoma physoides*, and it is certainly closely allied to the Lagenostomas. Nevertheless, it possesses certain curious and unique features which well warrant its separation, and lead to the conclusion that it represents one of the most primitive types of pteridospermous seed as yet discovered.

Mr. D. M. S. Watson described the cone of *Bothrodendron* (*Lepidodendron*) *mundum* as practically a Lepidostrobus with the radial extension of the sporophylls very much reduced, a state of things that would be expected from a consideration of the vegetative organs. It appeared that there had been a confusion with Miadesmia, the block containing the latter plant also having fragments of two other Lycopod cones, of which this is one. The idea of an immediate connection with Spencerites must be given up. In the course of the discussion Prof. Weiss remarked that we now know Bothrodendron more completely than any other fossil Lycopod.

Papers on Schizophyta.

Mr. David Ellis read a paper on the phylogenetic connections of the recent addition to the thread-bacteria, *Spirophyllum ferrugineum*, Ellis, in which he showed that the new species links the iron-bacteria with the genus Spiromonas, and suggested that the definition of Migula's order Chlamydobacteriaceæ should be modified so as to include both of these genera.

Mr. B. H. Bentley read a paper on cell-division in Merismopedia, in which he described a process like karyokinesis in the cells of this genus. The paper was somewhat adversely criticised by Mr. Wager.

Ecological Papers.

Prof. Yapp communicated a paper by Prof. H. H. W. Pearson (Cape Town) describing a botanical excursion to the Welwitschia desert. The conditions obtaining in this desert (German South-West Africa) are remarkably severe—the annual rainfall varies from zero to 3 cm., the illumination is very intense, and surface deposits of saltpetre and other salts are frequent. This severity of conditions, which must affect the germination of seedlings, results in an extreme paucity of vegetation. One may sometimes walk for miles without seeing a single flowering plant, while as regards species, in the British territory of Walfisch Bay, the total phanerogamic flora, excluding that of the Khusib river-bed, probably does not number more than twelve species. Welwitschia itself has a range extending from 14° to 23° S. latitude. It seems to prefer more or less sheltered and sloping valleys at an elevation of about 100 feet above sea-level. The author gave some interesting observations respecting the pollination of Welwitschia, adducing evidence to show that it is largely effected through the agency of a parasitic hemipterous insect (Odontopus), which is apparently never absent from the plant.

By comparing the Welwitschia plants of known age at Kew with the youngest seen in Damaraland, Prof. Pearson estimates that the latter cannot be less than forty to fifty years old. From this it follows that the conditions necessary for the successful germination of the seeds of Welwitschia occur but rarely. As there are not wanting indications that the rainfall of this area was once considerably in excess of the present one, it is to be feared that the effective reproduction of Welwitschia is now more rare than formerly, and that, with the continuance of the climatic conditions at present prevailing in western Damaraland, the species is doomed to become extinct in its native region.

Prof. R. H. Yapp gave a paper on the hairiness of certain marsh plants. A considerable number of plants found in damp or marshy habitats possess a more or less dense covering of hairs. Many of these plants, however, show seasonal differences in respect of hairiness. Thus the leaves formed in spring on low-growing shoots are usually small and glabrous, while the later leaves, especially those on the erect flowering shoots, are larger, and increasingly hairy. *Spiraea Ulmaria* was referred to in some detail. In spring this species successively forms glabrous, partly hairy and densely hairy leaves. The partly hairy leaves show a regular distribution of the tomentum on their lower surfaces, the leaves decreasing in hairiness from above downwards, while the margins are generally more hairy than the central parts of the lamina. This distribution of hairs is suggestive, in view of the fact that if *Spiraea ulmaria*, var. *denudata*, an entirely hairless variety, be grown in an exposed situation, its leaves suffer more than those of the hairy form, and that the withering due to exposure first begins in those parts of the leaf which, in the hairy variety, are the first to be covered with the tomentum.

Other Papers.

Mr. R. P. Gregory read a paper on the inheritance of certain characters in *Primula sinensis*, in which he dealt with experiments on the inheritance of long and short styles, leaf form, colour of stems and petioles, and, lastly, of flower colour. While some of these characters obey simple Mendelian rules, the colour inheritance presents very complex problems which are by no means completely elucidated. Two distinct classes of whites in flower colour were separated. Sutton's "Snowdrift," with pure green stems, is a true albino, but in all the other races of white-flowered plants a character occurs which inhibits the development in the flower of a colour potentially present in the plant. The results of crossing these "dominant whites" with coloured flowers are complex. Various partial explanations of the observed results were suggested by the author.

Local Papers.—A paper on Charnwood Forest, illustrated by particularly beautiful lantern-slides, was read by Mr. W. Bell, the local secretary, in which the scenery and vegetation of the forest were treated descriptively and historically, and by a comparison of old lists of species with those found at the present day the effect of drainage and cultivation on the native flora was brought out.

Mr. A. R. Horwood read a paper on the disappearance of certain cryptogamic plants from Charnwood Forest within historic times. In this paper the great impoverishment of the lichen flora was particularly noticed, and was attributed largely to the effect of smoke, a similar phenomenon to that observed in the region affected by the Lancashire and Yorkshire smoke-cloud.

Semi-popular Lecture.—Prof. Weiss delivered the semi-popular lecture on "Some Advances in our Knowledge of the Pollination of Flowers." The lecturer dealt with the newer work on this subject, and discussed its bearing upon the older views of the mechanisms of pollination.

Excursions.

By invitation of Mr. C. C. Hurst, an excursion (in conjunction with Section D) took place to Burbage to examine the results of his experiments on Mendelian heredity in rabbits, sweet-peas, &c., and also to witness a demonstration of the inheritance of eye-colour in man, for which about 100 school children from the families studied by Mr. Hurst were assembled. Most unfortunately, rain to some extent interfered with the success of these extremely interesting demonstrations, but Mr. Hurst very kindly repeated them in Section D at a later period of the meeting. The allelomorphic pair of characters in eye-colour studied by Mr. Hurst are the presence or absence of brown pigment on the front of the iris. Eyes with the former character are called *duplex*, with the latter *simplex*. "Duplex" is dominant to "simplex."

A successful excursion to Charnwood Forest, under the guidance of Mr. Bell, took place on the Saturday (August 3), and an excellent idea of the vegetation of the uncultivated portions of the forest was gained by the members of the section.

ECONOMIC GEOLOGY IN THE UNITED STATES.

STRIKING evidence of the work which the United States Geological Survey is carrying on for the direct advancement of mining interests throughout the country is afforded by a batch of eight Bulletins recently received. These Bulletins cover 1562 pages, and are copiously illustrated with plates and coloured geological maps. The most valuable of the series is Bulletin No. 315, dealing with contributions to economic geology in 1906, the object of which is to secure prompt publication of the economic results of investigations made by the survey. This Bulletin deals with the metals, structural materials, and other non-metals. A separate bulletin will be issued later dealing with survey work on coal, lignite, and peat. In investigations of ores during the year, reports are given by Mr. W. Lindgren on an interesting group of thin veins carrying wolfram in Boulder County, Colorado, which now constitute one of the most important sources of tungsten in the country; by Mr. H. S. Gale, on some new deposits of the uranium and vanadium-bearing mineral carnotite, which occur in the upturned Dakota sandstones east of the coal basins in Rio Blanco County, Colorado, deposits of importance as a further possible source of radium; and by Mr. G. F. Kay, on the deposits of silicate of nickel near Riddles, in Oregon. Much work was done in connection with iron ores, and reports are given on the red ores of the Birmingham district, Alabama, by Mr. E. F. Burchard; on the brown iron ores of the Russellville district, Alabama, by the same author; and on the grey iron ores of Talladega County, Alabama, by Mr. P. S. Smith. Mr. A. C. Spencer describes the magnetite deposits of Pennsylvania, and Mr. S. H. Ball the important iron-ore district at Hartville, Wyoming, and the titaniferous iron ore of Iron Mountain, Wyoming. An interesting investigation was made on glass-sands by Mr. Burchard. He gives the results of chemical and physical tests, not only of glass-sands now in use, but also of sands from undeveloped deposits which seem available for use as glass-making material. Prof. A. H. Purdue deals with the recently discovered phosphate fields of Arkansas, and Messrs. F. B. Weeks and W. F. Ferrier describe a new and important phosphate district at Montpelier, Idaho, in the western United States. The discovery has opened up a new industry in the West.

The progress of investigations of the mineral resources of Alaska in 1906 is dealt with in a separate report (Bulletin No. 314). An increase of nearly 50 per cent. in the value of the gold output of 1906 over that of the previous year is the best evidence of the advancement of the mining industry in Alaska. Copper mining has undergone a rapid expansion, and other mineral deposits, such as coal, marble, tin, and gypsum, have also received considerable attention. The progress has consisted in the development of the older districts rather than in discoveries of new mineral fields.

The Juneau gold belt, Alaska, forms the subject of a separate report by Mr. A. C. Spencer (Bulletin No. 287). This belt comprises the mainland strip of south-eastern Alaska from Berners Bay on the north-west to Windham Bay on the south-east, together with Douglas Island. The ores met with are mainly gold, though silver is usually present in small amounts. At the mines of the Treadwell group in Douglas Island, the methods of mining employed represent the highest possible attainment in the successful working of low-grade ores. For the last few years the average value of the material passing through the mills has been only about 8*s*. per ton.

The zinc and lead deposits of the Upper Mississippi Valley are described in great detail in a report by Mr. H. Foster Bain (Bulletin No. 294). The presence of ore deposits in this region was well recognised as early as 1687, but the early work was restricted to lead mining, the zinc ores being disregarded. The rise in the price of zinc ore in 1899 attracted attention to the district, and since 1903 its development has been rapid. The author gives an account of the present condition of the district and a statement of ideas relating to the formation of ores. The geology of the district is simple. The region is one of unmetamorphosed, little disturbed, sedimentary rocks of Palæozoic age, and there are no igneous rocks nor recent ones near it. The ore-bearing rock is a massive dolomite. The ores, consisting of blende, smithsonite with galena and marcasite, occur in crevices, in honeycomb masses, in pitches and flats, and as disseminations. The ore bodies are doubtless due to concentration or reconcentration through the action of underground waters.

A geological reconnaissance in south-western Nevada and eastern California is described by Mr. Sydney H. Ball (Bulletin No. 308). Ore deposits in the area described appear to be confined to the Palæozoic rocks, the post-Jurassic granitoid rocks, and the older Tertiary rocks.

The economic geology of the Independence quadrangle, Kansas, is described by Mr. F. C. Schrader and Mr. Erasmus Haworth (Bulletin No. 296), who present the substance of what is known concerning the distribution, occurrence, and development of petroleum and natural gas in the quadrangle, and note briefly the more important industries growing out of these natural resources. Mr. F. C. Clapp describes the economic geology of the Amity quadrangle, Eastern Washington County, Pennsylvania (Bulletin No. 300). The main interest in this area, which is situated near the centre of the north end of the Pittsburg coalfield, lies in the facts that it has been the seat of extensive petroleum and natural gas development, and that it is almost entirely underlain by at least one valuable seam of bituminous coal.

In the last report to be noticed Mr. E. C. Sullivan discusses the interaction between minerals and water solutions, with special reference to geological phenomena (Bulletin No. 312). Although not directly the result of geological field work, it has an important bearing on such work in that it is a chemical investigation of some of the problems most frequently met with in the study of the origin of ore deposits. Some of the changes that take place at ordinary temperature when water solutions are brought into contact with rock-forming minerals have been investigated. The result has been to make it apparent that chemical reaction between natural silicates and salt solutions is a very general phenomenon, taking place to a decided extent immediately upon contact, and that the outcome is mainly an exchange of bases in chemically equivalent quantities between solid and solution. The metal of the dissolved salt is precipitated, and an equivalent quantity of silicate is decomposed, and its bases enter the solution. Salt solutions as decomposing agents are much more active than pure water, and are comparable with acids in this respect.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Two courses, open free to teachers in London schools, have been arranged at Bedford College for Women (University of London) for the Michaelmas term; they are:—(1) "The Organisation of Nature-study Courses in London Schools," lecturer, Miss M. R. N. Holmer, Saturdays, 10.30, beginning October 5; (2) "Geology for Teachers of Physical Geography," lecturer, Dr. C. A. Raisin, Wednesdays, 6 p.m., beginning October 9.

IN connection with the garden produce, poultry, and honey competitions of the Kent County Council and of the National Potato Society at the South-Eastern Agricultural College, Wye, Kent, on Wednesday, October 2, a conference will be held, when an address will be given by the principal, Mr. M. J. R. Dunstan, to be followed by discussion.

SIX lectures, open to the public without payment or ticket, on the "History of Statistics and the Nature and Aims of Modern Statistical Methods," will be given at

University College by Mr. G. U. Yule on Wednesdays at 5.30, commencing Wednesday, October 9. A course of ten lectures will be delivered on Saturday mornings, beginning on Saturday, October 12, by Mr. F. L. Grant, on "Recent Developments in the Teaching of Arithmetic." This course is open, without fee, to all teachers in London schools. Teachers wishing to attend should apply for forms to the executive officer, London County Council Education Offices, Victoria Embankment, W.C. Forms should be returned by Monday next, September 30.

At the autumnal meeting of the Association of Chambers of Commerce, held at Liverpool last week, the following resolution was carried:—"That it is of the highest importance that the education of boys be continued after leaving school; that employers be urged to use their influence in inducing boys to attend evening classes and to give facilities for such attendance; that in every locality there should be schools provided for secondary and commercial education and for teaching the scientific and artistic principles underlying local industries to boys and domestic economy to girls." The association also carried unanimously a resolution urging the Government to bring in at an early date, as foreshadowed in the King's Speech in 1905, a measure for the conversion of the Board of Trade into a Ministry of Commerce on modern and representative lines.

The "Scholarships and Training of Teachers' Handbook" for 1907–8, just issued by the London County Council, gives particulars of the Council's scholarships and other scholarships open to London children, together with regulations for the admission of pupil teachers, bursars and student teachers, and for admission to training colleges, and a list of London secondary schools. The county scholarships of the Council provide a complete scheme under which a boy or girl may proceed by various stages from the public elementary school to the highest grades of education, whether at a university, technical college, or other institution providing advanced training for a professional career. The scholarships consist of junior county scholarships (ages of candidates, eleven to twelve), intermediate county scholarships (ages fifteen to seventeen), and senior county scholarships and exhibitions (ages, nineteen to twenty-two years). The first class (awarded to all candidates—about 2000—who reach scholarship standard) provides free education at public secondary schools approved by the Council, and a maintenance grant of 6*l*. a year; the second (not less than 100 scholarships), free education at approved secondary schools or technical colleges up to a fee of 25*l*. a year, and a maintenance grant of 25*l*. or 30*l*. a year; and the third class (fifty scholarships) provides a maintenance grant of 60*l*. a year for three years, and tuition and examination fees up to 30*l*. a year. In awarding these senior scholarships, regard is paid to the past successes of the candidates, the financial need, and the recommendations of the teachers under whom the candidates have worked. All candidates for scholarships may be required to present themselves for medical examination, and no award is confirmed if a candidate is found physically unfit to take advantage of a scholarship. In addition to the junior, intermediate, and senior scholarships, the Council awards a number of technical, industrial, and other scholarships, particulars of which are given in the handbook. All the scholarships are confined to candidates resident in the administrative county of London whose parents have incomes not exceeding 160*l*. a year in the case of the junior scholarships, and 400*l*. a year in those of the intermediate and senior scholarships.

SOCIETIES AND ACADEMIES.

Paris.

Academy of Sciences, September 16.—M. A. Gaudry in the chair.—Observations on the electrical action of the sun and moon: Albert **Nodon**. This work was carried out at the observatory on the Pic du Midi, at an altitude of 2877 metres. The results generally confirm those obtained at lower altitudes; the sun induces a positive electric charge varying from 1 to 6 volts per minute, according to the state of the atmosphere. The solar charge is absorbed by passing through a cloud or layer of moist air. The full moon produced a positive electric induction analogous to that of the sun.—A new flying apparatus called the gyroplane: Louis **Breguet**, Jacques **Breguet**, and Charles **Richet**. The lifting force is supplied by rotating planes, driven by a 40 horse-power motor. The apparatus sustained its own weight, together with that of a man (540 kilograms in all), for one minute at a height of 0·6 metre above the ground, and descended slowly as the velocity of the plane was reduced.—A method for the rapid estimation of carbon and hydrogen in organic substances: Pierre **Breteau** and Henri **Leroux**. The vapours driven off by heating the boat containing the substance in a current of oxygen are burnt by an electrically heated spiral of platinum wire, a diagram of the arrangement being given. It is claimed that the time required for a combustion is only from fifteen to forty minutes, according to the nature of the organic substance. No test analyses are given.—The conservation of the arterial pressure in man after the application of high-frequency currents in the form of autoconduction: J. **Bergonié**, André **Broca**, and G. **Ferrié**. The apparatus used gave a frequency in the solenoid of between 400,000 and 410,000, with effective intensities of between 15 and 20 amperes, or from seven to ten times greater than those described up to the present. The conditions for the most advantageous use of the apparatus are given, together with details of experiments on ten subjects. The net result is that high-frequency currents are without action on the arterial pressure.—Remarks on the preceding communication: M. **d'Arsonval**. A discussion of the possible sources of the discrepancies between the results given by the authors of the preceding paper and those of earlier observers.—The agents of coagulation of the milk contained in the juices of *Broussonetia papyrifera*: C. **Gerber**.—The light-receiving terminations in the compound eyes of the Muscidæ: Pierre **Vigier**.

PROBLEMS OF ANCESTRY.

Vorträge über botanische Stammesgeschichte, gehalten an der Reichsuniversität zu Leiden. Ein Lehrbuch der Pflanzensystematik. By J. P. Lotsy. Vol. i., Algen und Pilze. Pp. iv+828. (Jena: Gustav Fischer, 1907.) Price 20 marks.

THE motive inspiring the production of this important work is indicated on the title-page in the "motto" quoted from Coulter:—

"The most difficult as well as most fascinating problem in connection with any group is its phylogeny. The data upon which we base opinions concerning phylogeny are never sufficient, but such opinions usually stimulate research, and are necessary to progress."

Its pages show how stimulating the inquiry has been to the author, and we have seldom met with a book more likely to awaken inquiry in its readers or to suggest further research. Very different values may be placed on the conclusions as to the phylogeny of several of the groups, and on the characters regarded as of chief importance in forming the system of classification, and further information on many points is very desirable; but there can be only one opinion as to the manner in which the information is conveyed to the reader. Under each group is an admirably clear and full, yet concise, statement of the investigations that have been made upon it, and of their results, while an extensive classified bibliography refers the student to the original and full sources of information. Numerous illustrations, original or after those of the best monographs, add greatly to the usefulness of the work, and to its worth as an exponent of the most recent researches into the structure and cytology of the algæ and fungi.

The form of the book appears somewhat artificial, its substance being divided into thirty *Vorlesungen* of very unequal length, *e.g.* that on Exoascineæ (xxvi.) of four pages, and that on Basidiomycetes (xxx.) of eighty-eight pages. As these could scarcely have each been the subject of a single lecture, and as the longer *Vorlesungen* in some cases include several groups, this arrangement does not appear so convenient as the more usual division into chapters and sections.

The course of lectures opens with the discussion of what constitutes a living being, and of the agreements and differences between plants and animals, but very soon passes to the consideration of the simplest organisms as individual "energids," the multiplication of these, and the bodies built up of the combinations of "energids." An outline of the scheme of classification given early in the first lecture derives all plants from Protomastigina, and traces the supposed derivation of the several groups from these early forms, and their relations with one another. The system of classification of the green algæ is stated by Dr. Lotsy to be largely based on that set forth by Blackman and Tansley in 1902 in the "New Phytologist." Great importance is attached to the number and arrangement of the cilia borne by the reproductive cells, or at least by the male gamete; and these characters are employed in tracing the relationships between widely different groups, *e.g.* the Isokontæ are regarded as representing the ancestral condition of the Pteridophytes and seed-plants.

Scarcely less importance is given to the study of the "energids," or very simple units of individual life, the progress being traced from the monoergid to the polyergid organisation within the larger groups, with resultant advance in complexity of structure. That the conception is one of much value in stimulating inquiry cannot be disputed, but it may be questioned whether it is not carried too far in practically identifying the energid with the nucleus. The very different behaviour of the nuclei of the reproductive cells within a single family, and even within a single genus at times, especially among fungi, may well suggest the need of caution in such matters.

It is stated in the preface that the plan of the work was resolved on after perusal of a lecture by Dr. Hugo de Vries, in which a higher plant is regarded as a double organism. Dr. Lotsy was led to endeavour to trace out in theory how the return to the stage of a single organism is effected, and thus arrived at the conception of the two generations denoted as x and $2x$. The book before us embodies the effort to determine the extent of each of these generations, and in which groups of Thallophyta it is possible to detect them, the essential distinction between them being the well-known reduction in the number of chromosomes in the nuclei of the one generation to one-half those of the other. With this as a clue, Dr. Lotsy seeks to determine the relations of gametophyte and sporophyte in the Thallophyta, extending to these the conception of the alternation of generations so familiar in its applications to the Archegoniatæ. He shows a remarkable familiarity with the results of the most recent as well as of the classical researches into the structure and reproduction of the various families, and applies his leading ideas in a very consistent and able manner. We think that the known is still too limited to permit of a secure foundation being laid for the universal employment of such a criterion; but such a theory, applied with the author's thoroughness and width of view, must stimulate further investigation, and thus do excellent service in the study of botany. The doubts that must be felt with regard to the validity of some of the assumptions and conclusions will themselves lead to inquiries that must advance knowledge still more effectively. Several very important discussions of wide interest are introduced in relation to certain groups that illustrate them, *e.g.* that on the asexual cells and the gametes in Chlamydomonas leads to the consideration of the part taken by the nuclei in inheritance and artificial development of the egg under the stimulus of inorganic salts in solutions. Volvox gives further occasion of discussion on heredity, as does also Hydrodictyon, in which the effects of sugar and other substances on the methods of reproduction receive notice, and the relations of the x and $2x$ generations are compared with what occurs in Uredineæ. Illustrations of similar kind are introduced from among animals also. The functions of the various structures in cells are also discussed; *e.g.* the "vacuole" in Codiaceæ leads to the consideration of its nature, of the "tonoplasts" of de Vries, and of the granules of which protoplasm is built up. So under the bacteria their relations to other organisms as foes or as friends, and their importance in many and different aspects, are well set forth.

But it is needless to multiply examples of the many questions of extreme interest that find a place in the book, such as the existence and significance of "physiological species" among parasitic fungi, the very complex series of forms and relations to their hosts in Uredineæ, and others too numerous to mention.

Nor is it possible in a brief review to attempt to supply any adequate notice of the system of classification employed, or of the links shown or suggested to exist between the groups. The algæ and the fungi are not kept apart, but are grouped together into a system under the ideas explained above. In conclusion, we have to express the hope that this volume may in no long time be followed by the other two, which are to treat of the archegoniate and seed-forming plants. The author has earned the gratitude of botanists by placing within their reach an altogether stimulating book which should do much to win new workers to the absorbingly interesting Thallophyta.

THE COMMERCIAL USE OF PEAT.

Peat, its Use and Manufacture. By P. R. Bjorling and F. T. Gissing. Pp. xii+173; illustrated. (London: C. Griffin and Co., Ltd.) Price 6*s*. net.

THIS book contains a practical account of the different methods of preparing peat for commercial purposes, and of the uses to which peat can be applied. In NATURE of April 18, 1901, the attention of our readers was directed to the peat industry of Sweden, and its use there as fuel for generating steam both for stationary and locomotive engines; also in the number of May 31, 1900, to the exhibits at the Vienna Exhibition of that year of carpets, blankets, and clothing made from this material.

According to the authors of the book now under notice, there are $3\frac{1}{2}$ million acres of peat land in Great Britain and 6 million acres in Ireland. The peat varies in depth from 2 feet to 40 feet. Peat is also abundant in Canada, Denmark, Holland, Germany, Russia, and other countries.

The chief importance of this material at the present time is its value as fuel in districts where coal is scarce. Its great bulk as compared with coal, and its high percentage of water, have, however, hitherto proved obstacles to its extended use. The valuable portion of fuel is its carbon content, and in this respect peat is inferior to coal. An average sample of peat contains 42·7 per cent. of carbon, 4 per cent. of hydrogen, 27·4 per cent. of oxygen, 1·6 per cent. of nitrogen, and 2·4 per cent. of ash. In some specimens the carbon reaches as much as 66·55 per cent. of carbon. Wood contains 52 per cent. of carbon, brown coal 66 per cent., Swedish coal 78 per cent., and English steam coal 81 per cent.

The following results are given of the testing of peat fuel as against coal at Horwich, in Lancashire, under a steam boiler. Coal got up steam to 10 lb. pressure in 2h. 25m., and to 25 lb. in three hours. Peat fuel got up steam to 10 lb. in 1h. 10m., and to 25 lb. in $1\frac{1}{2}$ hours. Twenty-one hundredweight of coal maintained steam at 30 lb. pressure for $9\frac{3}{4}$ hours, whilst $11\frac{1}{4}$ cwt. of peat fuel maintained steam at the same pressure for 8 hours.

Peat has been used on the Bavarian railways for more than sixty years, and has been found economical. It is claimed for peat that, being free from sulphur, it has a much less detrimental effect on the heating apparatus than coal or coke. As regards cost, pressed peat costs 7*s*. 4*d*. per ton, Saxony coal 4*s*. 9*d*., and Ruhr coal 5*s*. 5*d*.; but if cost of carriage be taken into consideration, the peat is 7*s*. 4*d*. against 8*s*. 11*d*. and 9*s*. 8*d*. for the coal.

Experiments were made on the Hartford and Springfield Railway, when a locomotive engine ran in express time 52 miles with 14,000 lb. of peat; and it was found that two-thirds of a ton of peat was equal to one ton of coal for locomotive purposes. Several other trials made with peat for locomotive purposes are given by the authors, and there is no doubt in countries where coal is scarce and peat plentiful the peat bogs may be utilised with very great advantage.

Gas has also been made from peat with very successful results, and in Sweden it has been used for regenerating, puddling, and open-hearth furnaces for the last thirty years. It has also given very satisfactory results for illuminating purposes in Ireland. From a single pound weight of peat one hour's light can be produced; in some peat there is as much as 14,000 cubic feet of gas per ton. In Sweden a ton of peat was found to yield 9295 cubic feet of gas of twenty-four candle-power, a ton of English coal tested at the same time yielding 7063 cubic feet of gas of fifteen candle-power, the by-products being also largely in favour of the peat. Paraffin for candle-making is also distilled from peat.

Another use to which peat has been largely applied is in the manufacture of paper, which dates back in Ireland to 1835. Yarn for weaving purposes is also made from peat. There is now being sold by Messrs. Doré and Son, of London, underwear manufactured from peat. It is also considered an excellent material for bandages and surgical purposes. The other uses to which peat can be applied are numerous, even alcohol being obtained.

The greatest problem encountered in the manufacture of peat fuel is the extraction of the moisture from the peat. There are three general processes in use—air, pressure, and heat. The former is best in a country where a sufficient period of dry weather can be counted on. The various methods resorted to are described by the authors of this book, and illustrations of the machinery given. The latest process for converting peat into fuel is by electricity, which has been tried in Ireland. The peat, after being raised from the bog, is delivered into a rotary hydro eliminator, in which it is subjected to a gradually increasing pressure. The eliminator is continuous in action, the wet material passing in at the top and leaving it at the bottom in a partially dried condition. It is then passed on to the electrifying machine, where an alternating electric current is passed through it, and is then again passed on to a kneading and moulding machine. The cost of manufacturing fuel by this process is such that it can be sold at a large profit. The fuel produced is hard, dense, and comparatively smokeless. Electro peat coal averages 30 cubic feet to the ton, ordinary coal averaging 45 cubic feet.

BOOKS ON WIRELESS TELEGRAPHY.

A Handbook of Wireless Telegraphy; its Theory and Practice. By Dr. J. Erskine-Murray. Pp. xvi+522. (London: Crosby Lockwood and Son, 1907.) Price 10s. 6d. net.

Notions générales sur la Télégraphie sans Fil. By R. de Valbreuze. Pp. vi+169. (Paris: *L'Éclairage Électrique*, 1907.)

THERE is a story, probably apocryphal, of a learned professor who undertook to edit the writings of a colleague. At the end of the first paragraph he started to write a footnote, with which he proceeded until he had completed a treatise in several volumes of far superior value to the work he was supposed to be editing. Dr. Erskine-Murray has adopted exactly the opposite system in writing his "Handbook of Wireless Telegraphy," as the following rough summary of its contents will show. He apparently started out with the good intention of writing the book himself, and in the first few pages has succeeded in presenting from a somewhat original point of view the similarities and differences between the various known systems of telegraphy. But on the ninth page appears the first sign of weakness in a half-page verbatim quotation from Sir Oliver Lodge; there is little harm in this, it is true, or in the quotation of equal length from Von Bezold three pages farther on. But it represents apparently the incubation stage of a disease which subsequently develops alarming severity. At p. 17 we find it establishing a firm hold in a five-page quotation from Hertz. Then for a time all goes smoothly, and we read a description of the earlier wireless telegraphy experiments from the author's own pen with feelings of relief. But on the sixty-second page there is a serious relapse in the form of a quotation twenty-eight and a half pages long from a paper on coherers published by Dr. Eccles in the *Electrician*. At the end of this quotation we are told that the results may be summarised in a few words—the summary occupies sixteen lines. We would suggest that in the next edition of the handbook Dr. Erskine-Murray retains only the summary and gives the necessary reference to the original paper.

After such an experience we are not surprised at meeting on p. 100 the first of three successive quotations occupying, with a dozen or so lines of interpolated reference, more than twenty pages; on p. 124 a three-page quotation from a paper by Lieut. Tissot; on p. 129 five pages from a paper by Mr. Duddell. Then, after a brief rest, comes a twenty-page description of the Lodge-Muirhead system from an article by Mr. Marillier in the *Electrician*, and immediately after this twelve pages descriptive of tests on the Fessenden system, including some very uninteresting official correspondence; and so the handbook proceeds to a finish with two more quotations fourteen and fifteen pages long respectively, and nine others varying from one and a half to six pages in length. The only thing that causes surprise in the latter part of the book is that, when Dr. Erskine-Murray refers to Euclid's "well-known work on geometry" in support of his contention that the *surfaces* to be kept clean in relay contacts are "thin, very thin," he resists the temptation to quote at length from that authority (with kind permission of the author).

It is hardly necessary to say that when in a book of 318 pages, 140 are verbatim quotations from other writers, the whole is not particularly coherent. With all due respect to Dr. Erskine-Murray, we submit that this handbook is a striking example of how not to write on wireless telegraphy or any other subject. Books on scientific or technical subjects have a quite definite function to fulfil, distinct from that fulfilled by publications in scientific journals or papers. One does not look to them for new discoveries, or rarely even new theories, but one expects, in a handbook at least, to find a clear *résumé* of existing facts and theories welded together into a consistent whole possessing some sort of literary as well as scientific homogeneity. He who takes up this handbook with such expectations is destined, we fear, to grievous disappointment, though he may find much of intrinsic value and interest, particularly, for example, the seventeenth chapter, on theories of transmission.

M. de Valbreuze's book is of a different stamp; there is nothing in it very novel, either in subject-matter or treatment, but it gives from start to finish a clear and carefully-thought-out account of electric-wave telegraphy. The author starts in a manner rather characteristic of French writers by a fairly full account of the most elementary electrical and magnetic principles. In fact, it is not until half-way through the book that we are introduced to wireless telegraphy proper. Nevertheless, room is left for a summary of the more important researches and descriptions of the leading systems. Though in no sense an advanced treatise, the book is likely to prove of interest to the expert as well as to the beginner; at least, it can be read through without tedium, and can be recommended to all who, possessing little or even no electrical knowledge, are anxious to become acquainted with the leading principles and practice of wireless telegraphy.

We have already, on more than one occasion, commented in Nature on the number of books which have been written on wireless telegraphy. Each year sees fresh ones added to the list, and still an insatiable public, its imagination fired by the mysterious mechanism of this newest art, is, Oliver Twist like, asking for more. The two volumes before us show how, in different manners, this craving may be allayed.

Maurice Solomon.

OUR BOOK SHELF.

Machine Design. By Prof. Charles H. Benjamin. Pp. vii+202. (London: Archibald Constable and Co., Ltd., 1907.) Price 8*s.* net.

FEW men are more qualified to speak with authority upon the experimental side of machine design than the author of this little book. Indeed, we are inclined to the opinion that it might well have been entitled "Experimental Machine Design," since it deals almost exclusively with Prof. Benjamin's classical experiments upon the behaviour of certain machine parts when tested to destruction. Our general opinion of the book can be summed up in a very few words—"excellent as a sample." We trust, however, that it is but a sample of what the author intends to give to the engineering world in the near future.

Regarded, however, as a general treatise on machine design, we are bound to confess that it is somewhat disappointing, since such a very small portion of the book is devoted to the correct proportioning of even the commonest constituent parts of machinery. The faults of the book are faults of omission rather than of commission; to a large extent the matter given is original and cannot fail to be of great value to designers of machinery. The analytical treatment of some of the problems dealt with is both new and ingenious.

We have noticed a few slips, but they are mostly unimportant. On p. 6 the modulus of elasticity for crucible or tool steel is given as 40,000,000 lb. per square inch. We have tested a great many specimens of such steel, but have never obtained a value of more than 32,000,000 lb. On pp. 11 and 74 the torsion modulus of a square shaft is given as $d^3/4{\cdot}24$, but according to St. Venant, Lord Kelvin and others, this should be $d^3/4{\cdot}81$. The value given for the elliptical section is also in error; it should be $ba^2/5{\cdot}1$.

The experimental investigations of Prof. Benjamin on the bursting strength of cast-iron cylinders, the strength of flat plates, gearing, fly-wheels, and pulleys are of the greatest interest. If only designers of machinery would take to heart some of the lessons taught by these experiments, we should less frequently hear of the disastrous failures of fly-wheels, &c. We trust that he will continue his researches in many directions and incorporate them in a future edition.

On the whole, the illustrations are good. They are clear without giving too much detail, which is so often a fault in many books of this type; but in some instances the diagrams are crude, and are, indeed, incorrect. For example, the stuffing-box shown in Fig. 36 is not such as one would expect to find in a treatise on machine design.

Some of the friction experiments quoted were carried out in a very crude fashion, and the results are liable to be very misleading. For an example of this see p. 107. Except for the minor faults that we have pointed out, we can heartily recommend the book to students and draughtsmen generally.

Flowers and Trees of Palestine. By Miss A. A. Temple. Pp. xii+172. (London: Elliot Stock, 1907.) Price 6*s.* net.

ARISING out of a tour in Palestine, Miss Temple has compiled for the benefit of other travellers a list of the principal plants of the country. The list, which is arranged alphabetically, furnishes the popular and scientific names, also the localities; certain features of some of the genera and species are added, but they are of little determinative value. Preceding the list are four chapters containing an account of the characteristic flowers, thorny, tropical, and subalpine plants, and of the trees. A number of good illustrations are provided which are taken from the author's photographs.

Miss Temple discusses the interpretation of the Biblical names, following as her guides in this matter Canon Tristram and Dr. Post. The interpretations are obscure, although there is unanimity in most cases. The identification of "the lilies" has given rise to controversy. The author favours the view that the flower signified especially as the "lilies of the field," is *Anemone coronaria*; Dr. Post for another reference inclines to the gladiolus; these flowers are more probably signified than *Lilium chalcedonicum* and *Lilium candidum*, which are found, although rarely. It seems unnecessary to introduce Acanthus for any reference to "nettles," and Jew's mallow is generally understood to be *Corchorus olitorius* or *capsularis*, not *Corchorus trilocularis*. Otherwise, except for one or two obvious mistakes, the identifications are acceptable. Although the information in the descriptive chapters is slight and lacks continuity, the reader can, with the help of the illustrations and the list of plants, obtain a fair idea of the brilliant nature of the flora, and the traveller should be able to identify the more conspicuous plants.

Familiar Indian Birds. By Gordon Dalgliesh. Pp. viii+71; illustrated. (London: West, Newman and Co., 1907.) Price 2*s.* 6*d.* net.

THAT many persons in India, especially new arrivals, feel the want of an easy means of identifying the commoner birds of the country is indisputable, and this want the author of the booklet before us has endeavoured to supply—largely in the form of reprints from notes in scientific and other journals. In the main, the notices are interesting and to the point; but there appears a lack of judgment in regard to the species selected for mention. The omission of the adjutant stork is a glaring instance of this; while in the section on herons it is obvious that the egret or "paddy-bird" should have figured as the main heading, in place of the ordinary British heron. Then, again, it is a mistake to have selected such birds as the heron, moorhen, and barn-owl as the subjects for pictorial illustration, when so few characteristic Indian species are depicted. Neither can much be said in praise of the illustrations themselves, that of the myna being specially poor. By the time the book reaches a second edition, it may also be hoped that the author will have learnt to write sentences of a more grammatical type than the one standing second in the account of the jungle-babbler, or the third and fourth (taken together) on the seventh page. R. L.

Progressus Rei Botanicae. Vol. i., part iii. Die Fortschritte der Immunitäts- und Spezifizitätslehre seit 1870. By R. P. van Calcar. Pp. 110 (533 to 642). (Jena: Gustav Fischer, 1907.)

THE third and final part of the first volume of this publication, issued under the auspices of the International Association of Botanists, is assigned to a survey of the study of immunity, compiled by Dr. R. P. van Calcar. Due credit is given to botanists for the early conceptions of the theory, and the gradual evolution of the subject by pathologists is traced up. The author presents an explicit and critical account of the experiments and views elaborated by Metschnitoff, Ehrlich, and Pfeiffer; he describes the phenomena of agglutination, and discusses the arguments in connection with toxins and antitoxins, the taxonomy of the tubercle bacillus and the *rôle* of ferments. Although the field has been explored chiefly from a medical point of view, a knowledge of the general theories regarding the action and nature of bacteria is also required by plant pathologists, and the summary is eminently suitable to a botanical publication.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

Science and Government.

No one will contest the principle that it is in every way desirable that the State should support liberally such kinds of scientific work as are beyond the means of private institutions or individuals. It is, for example, a scandal that the relatively small sum is not forthcoming which would bring our Ordnance Survey into touch with modern geodesy; but the importance of such matters will not be appreciated until the literary atmosphere in which our statemen and officials are reared is penetrated by a scientific way of thinking. Nor is there at present any widely spread educated opinion which might react on the Government. A member of the House of Commons stated in his place that the sooner coal is exhausted the better, as electricity will do its work. One of our important journals thinks it plausible that the Jamaica earthquake should have been predicted in Europe by the "weather plant," and that telegony may have some bearing on marriage with a deceased wife's sister.

But I am by no means convinced that the *argumentum ad hominem* contained in your issue for September 12 is very helpful. Taking the revenues of the United States and of the United Kingdom as approximately equal, the disparity between an expenditure of (say) $2\frac{3}{4}$ and $\frac{1}{4}$ millions on "science" is at first sight overwhelming; but a little analysis of the figures will, I think, put a somewhat different construction upon them.

Of the total, the Department of Agriculture and that of Commerce and Labour take 2,107,670*l.*, or say two millions. It is assumed that the whole of this goes to scientific work. It would be less inaccurate to describe it as applied to technical purposes; but even that would not quite correctly state the position.

The United States Department of Agriculture publishes an annual report in a bulky volume. Its contents deal largely with purely administrative matters; the rest is mostly educational, even popular, and can scarcely be regarded as adding much to agricultural science. Nor is it intended to do so. The object of the department is rather to disseminate and apply existing knowledge than to add to it by advanced research. The explanation is obvious; agriculture is the fundamental industry of a country which is still largely in the condition of an undeveloped estate, and cultivation is carried on by a population which is to a considerable extent only imperfectly instructed in the art. Agriculture in the United States is far from having reached its intensive stage; this may be illustrated by the fact that while the mean production of wheat in the United Kingdom is thirty bushels to the acre, in the United States it is only thirteen.

The expenditure of the United States Government on Agriculture is rather a political necessity than the outcome of sympathy for science. All other industries are protected by a tariff; but protection is useless for agriculture which has to export its surplus produce, and it is probable that by restricting the imports by which the exported produce is paid for, protection diminishes the exchange value of what the farmer produces. The United States Government is therefore compelled practically to subsidise the farmer in various indirect ways—by the free distribution of seed, for example—as it cannot directly protect him. The writer in Nature has omitted to set out in comparison what is done for agriculture in the United Kingdom. The Board of Agriculture and Fisheries has a vote of 130,355*l.*, and the Irish Department of Agriculture and Technical Instruction one of 190,146*l.*, or 320,481*l.* in all. Now the area of the United Kingdom is one-thirtieth that of the United States; but our State expenditure is per square mile $4\frac{1}{2}$ times as great. It should be noted that this includes Kew and the Ordnance Survey.

But this is not the only omission on the *per contra* side of the account which appears to me likely to be extremely misleading to foreign readers of Nature. I shall not attempt to make Table II. complete, as I have not the means at hand. But there is no mention of the Royal College of Science (including the School of Mines) in London or of the similar institutions in Dublin; one of the science museums, the Government Laboratory, the Standards Department, the Patent Office Library, the Oxford Forest School, the Botanic Gardens at Edinburgh and Dublin, and the research work of the Local Government Board. Nor should the ethnographic department at the British Museum (Bloomsbury) be overlooked.

The first three heads in Table I. represent what the United States Government does for pure, *i.e.* for non-technical, science. They amount to 382,690*l.*, after deducting the casual and temporary item of 250,000*l.* for building; but a further deduction of 107,000*l.* must be made for surveying public lands and forest reserves, as these are merely administrative services. This brings the expenditure on pure science down to 175,090*l.*, an amount which does not strike me as anything to be particularly proud of.

The fact is that the attitude to science of American statesmen is not very different from that of our own; indeed, on the whole, I doubt if it be not even less sympathetic. The Smithsonian Institution has become an independent trust something like our British Museum, and the fact may be recalled that it owes its foundation to the munificence of an Englishman. It is by no means liberally subsidised by the Government. Nor has the United States any national botanic establishment on the scale of Kew.

What one would like to find imitated in this country is the noble idealism which impels those who are possessed of great wealth in the United States to place it at the disposal of the community for the advancement of learning. Our own Royal Society might be entrusted with funds which it would know how to apply to purely scientific purposes. This would be more useful than giving of medals and scholarships to distribute. Our ancient universities, Oxford and Cambridge, are in urgent need of endowments, which would enable them to strike out their own line unhampered by the purely educational aims of the colleges; but State aid dries up the streams of private liberality, and brings with it the cramping atmosphere of official supervision. W. T. Thiselton-Dyer.

Witcombe, September 17.

Sir W. T. Thiselton-Dyer agrees, at all events, that the attitude of British statesmen towards science leaves much to be desired. Statistics can, of course, be treated in many different ways, but, despite the criticisms in the above letter, the general conclusion of the article referred to remains substantially correct. The data are avowedly incomplete; only those who have attempted to collate the material scattered throughout Government publications appreciate wholly the difficulty of the task.

Although Sir W. T. Thiselton-Dyer maintains that but a small part of the grant to the U.S. Department of Agriculture is devoted to scientific research, the facts of the case seem to support the conclusions of the article. For the fiscal year ending June 30, 1905, the expenditure on investigation work alone, exclusive of the salaries of permanent officials, was at least 201,000*l.* The annual report for 1905–6 of our Board of Agriculture and Fisheries on the distribution of grants for agricultural education and research shows that the grant for agricultural research amounted to 355*l.*! Since "agriculture in the United States is far from having reached its intensive stage," there is surely less need for grants in aid of agricultural research there than in this country.

Grants to colleges and universities were omitted intentionally—and special attention was directed to the omission—since this subject has been dealt with so often in Nature; consequently, the administration by the Board of Agriculture of the Treasury grant for the purposes of agricultural education, much of the work of the Irish Department of Agriculture and Technical Instruction, the activities of the Royal Colleges of Science in London and Dublin, and the university colleges, fell outside the scope of the article. Had the subject of grants for higher educational purposes been under consideration, an equally great disparity between the amount provided from public funds in the United States and in this country would have been exposed. The latest report of the U.S. Commissioner of Education deals with the year ending June 30, 1905. The total income for that year of American institutions of university rank, excluding benefactions, amounted to 8,355,000*l*., an increase of 289,200*l*. over the preceding year, and of this amount 23·6 per cent. was from State appropriations and 6·9 per cent. from Federal appropriations. That is, more than 2,506,500*l*. was provided from American public funds for higher education during the year with which the report deals. A very generous estimate of the amount provided here from public funds for higher education of every kind, including the Royal Colleges of Science of London and Dublin, the universities and the university colleges, would be to place it at a quarter of a million pounds sterling, so that the British case is in no way improved by importing the question of the amounts provided for higher education.

Sir W. T. Thiselton-Dyer is doubtful only about the greater belief of American statesmen in the need for the introduction of scientific methods in the solution of problems of government, but of the need of scientific ways of thinking on the part of our legislators he is quite convinced, and that is really the important matter.

A. T. S.

The Interpretation of Mendelian Phenomena.

Apropos of the discussion on the interpretation of Mendelian phenomena, may I seek enlightenment on one or two points from your readers? Mendelian phenomena are possible only when reproduction is bi-parental. They cannot occur, of course, when it is parthenogenetic. I believe I am right in thinking that Mendelian workers suppose or hope that they have found a master key to the problems of heredity. Now, I am able to understand that the study of alternative inheritance may ultimately shed a light on the function of sex, but I find it difficult to conceive how it can shed a light on any other biological problem of importance; for example, the problems of the alleged transmission of acquirements, of the causation of variations, of the retrogression of characters which have lost selection value, and of the mode of development (whether or not by the recapitulation of the phylogeny). All these problems are of at least equal importance to the problem of sex. I have sought information from my Mendelian acquaintances, but I am always told that we must await the accumulation of data—a somewhat Micawber-like attitude, as it seems to me. I hope I make myself clear. The information I seek would be contained in the answer to the following question:—If Mendelism has a bearing on any biological problem save that of sex, what is that problem? If, as I anticipate, no one is able to name another problem, I venture to suggest that Mendelians are engaged in nothing more than the investigation of sex.

Mendelian phenomena have been observed principally in crossed artificial varieties of animals and plants. Crossed natural varieties usually blend their characteristics. This is conspicuously the case with man, the animal who, so far as is known, has crossed more often than any other, and whose hybrids may be observed up to the tenth or twelfth generation in South America and elsewhere. It has been said that "human skin-colour is the only character that is known to blend perfectly"; but this statement is certainly incorrect. With the exception of eye-colour, and possibly one or two other traits, such as the Mongolian eyelid, human hybrids appear to blend every character as perfectly as skin-colour. The transmission of no character is Mendelian. Thus mulattos have the black eye of the negro, and when they breed *inter se* continue to reproduce it indefinitely. There is no segregation. May I mention one other fact which is of considerable interest, but which seems to have escaped the attention of Mendelian workers? Crossed artificial varieties usually reveal latent characters in abundance. I am aware that the correctness of the term latency has been disputed, but it will serve to indicate what I mean. So far as I have been able to ascertain, no single instance of a latent character resulting from the crossing of natural varieties has been recorded. Certainly crossed human varieties reveal no such traits. A very significant passage bearing on this matter may be found in "Animals and Plants" (vol. ii., pp. 24–5). It would appear, then, that characters become latent only under conditions of artificial selection, that is, when mutations are selected. It has been maintained that nature also selects only mutations, but, to say the least, this has not been demonstrated as yet.

Bearing in mind, then, the facts that latent characters appear only when artificial varieties are crossed, and that crossed natural varieties usually blend their characters, the question arises whether Mendelians, so far from investigating even the whole problem of sex, are engaged in anything more than the investigation of those abnormalities of sexual reproduction which occur under conditions of artificial selection.

G. Archdall Reid.

Southsea, September 17.

On Correlation and the Methods of Modern Statistics.

Prof. Karl Pearson's letter in Nature of September 19 gives me a welcome opportunity of explaining what was not intelligible in the condensed report of my remarks in the discussion at Leicester, on methods of modern statistics.

Prof. Pearson communicated to the Royal Astronomical Society (Monthly Notices, May, 1906) a paper by Miss Winifred Gibson, giving an account of a research conducted in the statistical laboratory of University College, London. The first part of this paper discussed the relation between parallax and magnitude of the stars. I confessed to some misgivings as to the astronomical value of the results, and raised two questions, first, as to the method, and second, as to the matter.

Prof. Pearson thinks that I am on safer ground in the second than in the first. I will therefore examine first his reply to my second point, which was that the parallax material contained in Newcomb's table (appendix to "The Stars") is quite unsuitable for discussion by a general statistical method, since it relates very largely to stars selected for investigation because of abnormal proper motion.

Prof. Pearson "fancies that astronomers have been guilty of a considerable amount of circular reasoning. They start from the hypothesis that magnitude is very closely related to parallax. . . . The fundamental hypothesis that the brighter stars are much the nearer as yet awaits statistical demonstration. . . . Surely the hypotheses of high relationships between magnitude and parallax and proper motion are of sufficient importance to deserve *proof*, rather than to be taken as axiomatic." In this matter Prof. Pearson is under a misapprehension. Astronomers do not believe that magnitude is very closely related to parallax; very obviously it is not. But they do believe that parallax is somewhat closely related to proper motion. There are seventeen stars in the sky brighter than mag. 1·5, and their parallaxes have been determined with the heliometers at the Cape and at Yale. Here are the results.

Seven have proper motions (on a great circle) less than 0″·1 per annum:—

	P.M.	Parallax	Mag.
	″	″	
Canopus	0·00	0·00	-1·0
Deneb	0·00	0·00	1·3
Rigel	0·01	0·00	0·3
Betelguese	0·03	0·02	0·9
Antares	0·03	0·02	1·3
Achernar	0·09	0·04	0·5
β Centauri	0·09	0·05	0·8
Mean	0·04	0·02	0·6

Six have proper motions between 0″·1 and 1″·0:—

	P.M.	Parallax	Mag.
	″	″	
Aldebaran	0·19	0·11	1·1
Regulus	0·27	0·02	1·3
Vega	0·36	0·11	0·1
Capella	0·43	0·09	0·2
Pollux	0·64	0·06	1·2
Altair	0·65	0·23	0·9
Mean	0·42	0·10	0·8

Four have proper motions greater than 1″·0:—

	P.M.		Parallax		Mag.
	″		″		
Procyon	1·25	...	0·30	...	0·5
Sirius	1·31	...	0·37	...	−1·4
Arcturus	2 28	...	0·03	...	0·3
α Centauri	3 67	...	0·75	...	0·2
Mean ...	2·13	...	0·36	...	−0·1

It is clear from the first group that low magnitude alone has no very close association with large parallax, and in the other groups Arcturus is the only star with considerable proper motion that has not a considerable parallax, as parallaxes go.

I think that in forming his low estimate of the established relation between parallax and proper motion Prof. Pearson must have been misled by Miss Gibson's results. She has calculated the correlation between parallax and the *separate components* of the proper motion in right ascension and declination, and so has naturally obtained a smaller result than if she had used the whole proper motion in seconds of arc on a great circle, as is usually done.

I have plotted the material used by Miss Gibson in two ways, parallax against magnitude and parallax against proper motion on a great circle, and it seems to me that the second diagram shows considerable correlation.

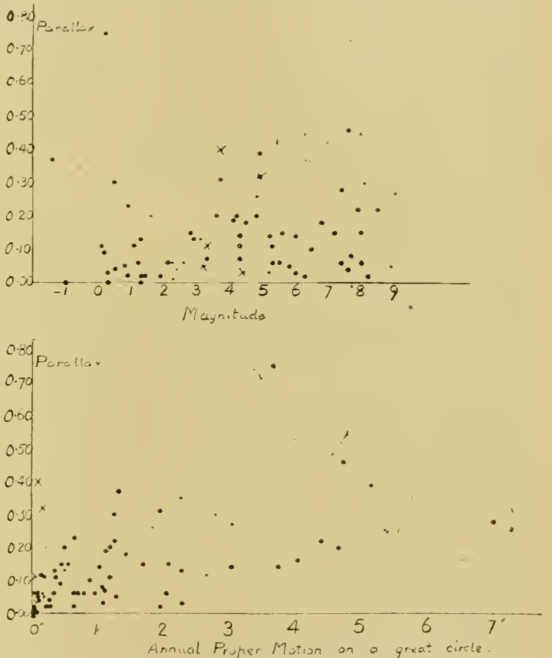
Some of the parallaxes are marked by Newcomb as doubtful; these I have shown by smaller dots. Five which depend on absolute right ascensions observed with the meridian circle may be considered too doubtful for use in this discussion; I have struck them through with a cross.

The seventy-two parallaxes grouped in means by whole magnitudes give a "curve of regression" with three peaks and two valleys, to which Miss Gibson thinks that it might be possible to fit a quartic curve. I suggested a simpler explanation, and Prof. Pearson asks for details of the reason why this curve of regression has such a switchback form if it is not real. It is easy to answer this question. Consider, for example, the second-magnitude group; it contains six stars, only one of which has a moderately large proper motion. Four of the stars were observed in the early days of photography as part of the late Prof. Pritchard's scheme to determine the parallaxes of all second-magnitude stars. One of the stars is Polaris, of small proper motion, observed just because it is Polaris; the sixth is α Gruis, of small proper motion and parallax. The group contains no star specially selected in anticipation of finding a large parallax, and naturally the mean of the group is small, because it is more or less representative of the second-magnitude stars in general.

On the other hand, the fourth-magnitude group includes several stars observed because of large proper motion, η Cassiopeiæ, τ Ceti, 70 Ophiuchi, and is helped out by a large parallax assigned to η Herculis which is certainly spurious. Hence the mean parallax of the group is large.

And so on. It would be tedious to examine each group in detail, but the almost fortuitous value of the mean parallax for each of these small magnitude groups is amusingly illustrated by the first two. The first contains two stars, parallaxes 0″·37 and 0″·00; mean, 0″·19. The second contains five stars; four have parallaxes of 0″·09, 0″·00, 0″·03, and 0″·11, but the group is translated from the valley to the peak because the fifth parallax is 0″·75. This, the largest known parallax, belongs to the double star α Centauri, the components of which have magnitudes 0·4 and 1·9. We might add the fainter component to the second-magnitude group discussed above; this would bring the mean parallax of the group up with a bound from 0″·08 to 0″·18, make a new peak, and remove one of Prof. Pearson's difficulties.

Probably there is no need to justify more minutely my remark at Leicester that a statistician who attacks astronomical problems must be as intimately acquainted with technical astronomy as with the use of his modern statistical tools. If any doubt remains, it will be dispelled by reading further in Miss Gibson's paper. "The next stage in the work was to inquire whether magnitude was more markedly correlated with any other character than parallax. Colour suggested itself as a character for which definite data were available. In vol. ix. of the 'Annals of the Cape Observatory' will be found a catalogue from which the colour of 159 stars can be extracted. . . ." Prof. Pearson quotes in his letter one of the results of this section, "that colour and magnitude are related at least as closely as parallax or proper motion and magnitude." And Miss Gibson concludes "that we have a suggestion, even if it be only of the vaguest kind, that the bulk of the lucid stars may belong to a separate universe within which magnitude is not mainly determined by parallax or distance, but is more closely associated with colour, and thus probably with chemical or physical conditions." On examining the basis of this far-reaching suggestion about the "bulk of the lucid stars," one is struck with the remarkable fact that "white had no frequency in the record"! A search in the Cape volume shows that the list in question is entitled "Coloured Stars observed during the Revision of the 'Cape Photo-



Correlation between (1) parallax and magnitude; (2) parallax and annual proper motion on a great circle, for the seventy-two stars in Newcomb's Table.

graphic Durchmusterung.'" This revision was chiefly an examination of all cases in which stars found in other catalogues are missing from the C.P.D. Sometimes they were hidden by photographic defects; sometimes they were variable or had large proper motion; in a great many cases they were red, and photographically faint. Hence attention was concentrated upon a particular class of stars, near the limit of the C.P.D., which had escaped registration owing to some abnormality, generally redness. This specially selected material has been further specialised, for at the top of the list we read:—*Very few stars of a lighter shade than deep yellow have been recorded because of their frequency*. And this is the material from which Prof. Pearson and Miss Gibson extract their conclusions about the stars in general.

I think that an astronomer may be allowed to express his dissent from these applications of modern statistical methods.

I should like, in conclusion, to refer briefly to the theoretical point:—Should not the correlation ratio be used in preference to the coefficient of correlation? The former expresses the degree of approximation to a smooth curve, the latter the approximation to a straight line. It will rarely happen that the curve of regression for two absolutely correlated astronomical quantities is a straight line, and the range of the quantities is generally so large that we are concerned with much more than an elementary portion of the curve. It appears to me, therefore, that it would be better in all treatment of astronomical statistics to use the correlation ratio. ARTHUR R. HINKS.

Cambridge Observatory, September 23.

The Relation of Man to the Animal World.

IN the short notice given of my "booklet" in NATURE of September 12 on the "Relation of Man to Animals," the writer seems quite to have misunderstood the object of my writing it. I am aware that an author has no right to discuss a fair criticism with a reviewer, but in the present case, when the latter says that he is at a loss to discover the object and aim of my pamphlet, I trust you will allow me to give its true explanation to your readers.

I may state in a few words that if we read the report of the Vivisection Committee which has been lately sitting, we shall see that there are witnesses who confess their ignorance of the many kinds of cruelty being inflicted on animals in their very midst. This ignorance has always been considered a very important point with the advocates of experimentation as showing that the anti-vivisectionists shut their eyes to everything connected with the use of animals except that which is for the attainment of knowledge. This knowledge some of their leading advocates declare is no value.

When I was chosen by my college to give an address on the subject before the Church Congress, I made the present position of the animal world my basis of argument for experimentation. This feature of the question is considered most important at the present time, and therefore I have very willingly re-published and expanded it in my pamphlet. This is my sole object of writing it. It would be quite out of place to give my own opinion as to our treatment of animals generally; in fact, it would be of no value considering the difference of opinion on the subject, and especially at the present time, when vegetarianism seems largely increasing.

Hampstead, September 27. SAMUEL WILKS.

Meteoric Shower, from near β Aurigæ.

ON September 27 at 9h. 54m. I saw a very swift meteor of about $1\frac{1}{2}$ mag. shooting through Cygnus, and leaving a streak of about 10° near α and γ Cygni. The sky was clouding over at the time, and a portion of the luminous course of the meteor must have been hidden, but the observed path was from $306\frac{1}{2}° + 45°$ to $299° + 32\frac{1}{2}°$.

The line of flight traced far backwards carries us to the point $88° + 43°$, and this, I believe, formed the radiant position of the object. There are showers from near β Aurigæ in August, September, and October, and later months also supply indications of activity in the same centre. This particular system of Aurigids appears to be unusually rich from about September 21 to 27. On 1879 September 21 I recorded eight meteors from a radiant at $87° + 43°$, and on 1878 September 25 the radiant near β Aurigæ was re-determined from five meteors. The members of this stream are exceedingly swift, and they usually leave streaks, their appearance being very similar to that of the Leonids. W. F. DENNING.

Bishopston, Bristol, September 28.

A New Stratigraphical Fact in the Thames Basin.

IT will interest geologists to learn of the occurrence in this neighbourhood, below the Tertiary plateau gravels, of a bed (not a boulder) of marly, lignitiferous, glauconitiferous limestone, full of fossils, about the Upper Eocene or Oligocene age, of which there can scarcely be a doubt. Fuller particulars are reserved for a later communication either to NATURE or the *Geological Magazine*, when the fossils have been exactly identified and the investigation completed.

This is, I believe, the first definite record in the Thames basin of pre-Miocene strata younger than the Upper Bagshot Sands. A. IRVING.

Bishop's Stortford, September 25.

Bees' Stings and Rheumatism.

IT appears to be a familiar and widespread belief in many countries that the stings of bees act both protectively and as a cure for "rheumatism." I have recently been able to collect some definite evidence in support of the belief in question.

This is of interest and importance, not only on general grounds, but also on account of the connection which I believe to exist between rheumatic fever and an abnormal production of formic acid (the acid of bee poison) in the human body (*British Medical Journal*, September 19, 1903, and May 25, 1907).

May I, therefore, be permitted to request any of your readers who possess information on the subject, and are willing to assist the present inquiry, to favour me with answers to the following questions?—

(1) Are you acquainted with the belief that bees' stings cure and prevent rheumatism?

(2) Do you know of any case in which rheumatism is believed to have been cured by this means?

(3) Do you know of any person who suffers from rheumatism although frequently exposed to the stings of bees? E. W. AINLEY WALKER.

University College, Oxford, September 27.

The Country Child in Education.

IN your interesting *résumé* of the educational meetings at the British Association in NATURE of September 12 (p. 505) one could not help being struck by the absence of any allusion, near or distant, to the *country* child.

I suppose it is correct to say that, physically, country children are, or will be, the backbone of the nation. If half as much were done educationally for them as is lavished on the town—and particularly the London—child, they would speedily become the nation's brain.

Manual training in all its branches, cookery lessons, swimming baths—what effect would these not have on our slow but sturdy village youngsters? With them nature-study is coming along—but even gardening lessons on scientific principles are all too rare.

Our school buildings and furniture in country districts slowly improve, but our playgrounds are still mostly loose beach, utterly useless for physical exercises or organised games.

It is time for enlightened educationists to urge the needs and claims of the country child. H. J. GLOVER.

Council School, Westham, Sussex, September 18.

[We hope this matter will not be lost sight of in arranging the agenda for next year's meeting of the Educational Science Section of the British Association.—ED. NATURE.]

THE CENTENARY OF THE GEOLOGICAL SOCIETY OF LONDON.

UNDER the presidency of Sir Archibald Geikie, K.C.B., the celebration of the centenary of the Geological Society of London has been carried out with conspicuous success. While the proceedings throughout were characterised by an air of dignified gravity, a feeling of quiet enthusiasm pervaded the meetings. On no previous occasion have so many illustrious geologists been gathered together from all quarters of the globe, and a noteworthy feature in the assembly was the presence of many women who have achieved distinction in the pursuit of geology.

Although the actual date of the foundation of the society was November 13, 1807, it was necessary to hold the centenary meetings a little in advance of the actual birthday, in order to suit the convenience of the foreign members and correspondents, as well as the visitors from abroad and from all parts of the British Isles, who have university duties that commence in October.

The apartments of the Geological Society at Burlington House had undergone a great transformation. Easy-chairs and lounges, curtains and floral decorations served to make attractive the otherwise sombre-looking chambers. The council room, with its historic geological portraits, was set apart for the ladies. The museum, usually so desolate, was the principal reception-room, and it became a busy and animated scene where conversation and writing were seasoned with the fragrant odour of tobacco. Exhibits of certificates of membership of some of the great geological masters, early MSS. and published maps, and other documents of interest were displayed in cases or suspended from the walls. For all these arrangements so happily carried out, the society was indebted to the indefatigable labours of Prof. Watts and Prof. Garwood, the secretaries, to Mr. Belinfante, assistant secretary, and the other permanent officials, and to Mr. F. W. Rudler.

Thursday, September 26, was fixed for the main centenary proceedings, and the fine meeting-room of the Institution of Civil Engineers was courteously placed at the service of the society for the reception and the president's address. At 11 a.m. the delegates were received in the alphabetical order of their countries, and it was arranged that one representative only of each country should speak. Space will neither permit of the insertion of a full list of the delegates who came, nor of any record of the eloquent and warm-hearted remarks with which they accompanied their presentations of the addresses of congratulation to the president. It was to be regretted that no time or opportunity could be given for the display of these elaborate and beautiful documents, but no doubt a special exhibition of them will be made at some future meeting of the society.

Austria-Hungary was represented by Dr. Tietze, director of the Imperial Geological Survey; the Argentine Confederation by Prof. Aguirre, of the University of Buenos Aires; Belgium by M. Mourlon, director of the Geological Survey; Denmark by Dr. Steenstrup; Egypt by Capt. Lyons, director of the Geological Survey; France by Prof. Gosselet, Prof. Barrois, and Prof. de Lapparent; Germany by Prof. Zirkel, Prof. Credner, and Prof. Rothpletz; Greece by Prof. Skouphos; Holland by Prof. Wichmann and Dr. Molengraaf; Italy by Prof. Hughes (who spoke in the absence of Prof. de Lorenzo); Japan by Prof. Omori; Mexico by Dr. Aguilera, director of the Geological Survey; Norway by Prof. Brögger, and Dr. Reusch, director of the Geological Survey; Portugal by Prof. de Lima; Russia by Dr. Tchernyshew, director of the Geological Survey, Prof. Pavlow, Prof. Lœwinson-Lessing, and Dr. Sederholm, director of the Geological Survey of Finland; Sweden by Prof. Nathorst and Dr. Gunnar Andersson, director of the Geological Survey; Switzerland by Prof. Heim and Prof. Baltzer; United States by Dr. Hague, Prof. Iddings, and Prof. Morris Davis; Canada by Prof. Adams; India by Mr. La Touche; South Africa by Mr. Rogers and Dr. Hatch; Australia by Prof. Hill and Mr. Johnston; New Zealand by Mr. Denham.

Numerous delegates represented the universities, the scientific societies, institutions, and field-clubs of Great Britain and Ireland, and on their behalf Prof. Sollas and Prof. Hughes made brief remarks, the latter speaking in Latin the address of congratulation from the University of Cambridge. Mr. A. B. Kempe represented the Royal Society, and Lord Avebury the Society of Antiquaries.

An interesting incident was the award to Sir A. Geikie of the gold medal of the Institution of Mining and Metallurgy, which was handed to him by Mr. C. J. Alford, in recognition of the services rendered by the Geological Society to the mining industry.

In the afternoon the president delivered his address on "The State of Geology at the Time of the Foundation of the Geological Society." He dwelt especially on the important aid towards the foundation of the science of geology given by Guettard and Desmarest in France, by Werner in Germany, by Hutton and Jameson in Scotland, and by William Smith in England. The results of their labours gradually attracted more and more attention, as did also the controversies that arose between the followers of Werner and Hutton, the one school (the Neptunists) attributing too much to the influence of water, the other (the Plutonists) attributing too much to the agency of heat. Thus it came about that a number of earnest students well versed in mineralogy determined to meet together and gather facts in illustration of the new science of geology. In due course they established the Geological Society of London, to the origin and history of which reference has already been made in the pages of NATURE (September 26, p. 537). G. B. Greenough, one of the founders, was the first president, and his geological hammer with a whalebone handle was exhibited by a relative, Mrs. Bowen-Colthurst, of Dripsey Castle, co. Cork. To this interesting relic Sir Archibald Geikie directed brief attention.

In the course of his address he pointed with pride to the publications of the society, and concluded by expressing the opinion that they might with confidence look forward to a career in the future not less successful and useful than that which they were now met to celebrate.

A hearty vote of thanks to the president, proposed by Prof. de Lapparent, was seconded by Prof. Rothpletz.

In the evening a brilliant assembly gathered in the Whitehall Rooms of the Hotel Metropole for the official banquet. The company numbered 291. The president was supported by two veteran geologists, on his right Prof. Gosselet, and on his left Prof. Zirkel. It is noteworthy that not a single peer, baronet, or bishop was present among the fellows of the society or its guests. A brief grace was said by Prof. Bonney, hon. canon of Manchester, and the company then proceeded to the consideration of the menu. The card was illustrated by portraits of Greenough, the first president, and of Sir Archibald Geikie, but, curiously enough, the date of the meeting was printed 1908 instead of 1907. The toasts were taken without interruption at the conclusion of the dinner. Those of the King and of the heads of foreign States were proposed by the president. Then followed the Geological Society of London, proposed by Prof. de Lapparent, with response by the president;

the Universities and other Educational Institutions by Prof. Bonney, and reply by Prof. Credner; the Academies and Learned Societies by Prof. Miers, and reply by Prof. Barrois; the Geological Surveys by Prof. Lapworth, and reply by Prof. Heim; Engineering and Mining Institutions by Prof. Hughes, and reply by Prof. Beck; the Delegates and other Guests by Dr. Marr, and reply by Prof. Stevenson; and the Ladies by Prof. Watts, and reply by Prof. Walther.

On Friday, September 27, visits were paid to the British Museum at Bloomsbury and to the Natural History Museum at South Kensington, to the Geological Survey and Museum of Practical Geology at Jermyn Street, and to the Victoria and Albert Museum at South Kensington. Demonstrations on objects of interest were given by the officers at these institutions, and especial interest was manifested in the new model of Assynt in the north-west Highlands (recently added to the Museum of Practical Geology), which was explained by Dr. B. N. Peach. A number of the foreign and colonial visitors were also invited to St. Paul's Cathedral, and were conducted through the edifice by Canon Scott Holland and Dr. Grabham (delegate appointed by the Royal College of Physicians). The party was afterwards entertained at tea by Dr. Grabham in the Chapter House.

In the evening the foreign and colonial delegates were entertained at dinner at the Criterion Restaurant by the Geological Society Club. This club was founded in 1824 by Buckland, Fitton, Greenough, Lyell, Warburton, and others, with the object of affording to a limited number of the leading members of the society an opportunity of dining together on the evenings of the society's meetings. The proceedings on the present occasion lacked some of the exuberance and animation that we read of in early records of the club, when Buckland and Sedgwick and other geological giants of old made merry. On the present occasion, however, the proceedings had to be curtailed.

The party, as in the case of the official dinner, was photographed, and a congratulatory telegram was sent to the distinguished veteran and past president, Dr. H. Clifton Sorby, now in his eighty-second year, and still engaged in scientific research. It may be mentioned that other veteran fellows of the society, Prof. T. Rupert Jones, now eighty-eight, and the Rev. Osmond Fisher, in his ninetieth year, bear testimony to the healthy character of geological labour. Nor should we forget the father of the society, the Rev. W. H. Egerton, a brother of the late Sir Philip Egerton, who was elected a fellow in 1832, and at the age of ninety-six is still rector of Whitchurch, in Shropshire. A letter received from him during the present year, in which he mentioned that he had been a pupil of Buckland, was exhibited in the society's museum.

After the club dinner the party proceeded to the conversazione, which was held at the Natural History Museum. There a numerous company was received by the president in the Central Hall, and the proceedings were enlivened by a good programme of music, performed by the string band of the Royal Engineers.

During the week prior to the centenary reception a number of excursions were made with the view of exhibiting to the foreign members, correspondents and others who came from abroad, the main features of British geology. The longer excursions were arranged to occupy a week.

The Palæozoic formations were seen in the English Lake District, famed for the early researches of Sedgwick; in South Wales, where Murchison established some of his Silurian divisions; and at Bristol, Weston-super-Mare, and Cheddar, amid geologic scenes described by Buckland and Conybeare. The Jurassic and Cretaceous rocks were viewed along the Dorset coast at Lyme Regis, Bridport, and Weymouth, a region full of associations with the work of De la Beche and Buckland; and in the Isle of Purbeck at Lulworth and Swanage, where Thomas Webster in early days so admirably depicted the geological structure. The excursion to the Isle of Wight was abandoned, while that proposed for the Edinburgh district was replaced by one to the north-west Highlands, to Assynt, Inchnadamph, and Loch Glen Coul for the purpose of studying the displaced rock-masses brought forward by the Glen Coul and Moine thrusts. This last excursion was the more appropriate considering that the long-looked-for Geological Survey memoir on the North-west Highlands, embodying the researches of Dr. Horne, Dr. Peach, Dr. Teall, Mr. Clough, and other colleagues, has just been published under the editorship of Sir Archibald Geikie.

Some shorter excursions for two days were made to May Hill, Westbury-on-Severn and the Forest of Dean, to Derbyshire, and to the Crag District of Suffolk.

On Saturday, September 28, there was a series of day excursions, all well attended, to the Northampton iron-ore district, to Aylesbury, to Dover, to Box Hill, Leatherhead and Dorking, to Reading, to Erith and Crayford, and to Sudbury. Thus opportunity was given of seeing many important and interesting geological sections.

On Monday, September 30, and following days, the foreign and colonial visitors were entertained at the Universities of Oxford and Cambridge. At Oxford the degree of D.Sc. *honoris causa* was conferred upon Prof. Charles Barrois, of Lille, Prof. Albert Heim, of Zurich, Prof. Alfred Lacroix, of Paris, Dr. Albrecht Penck, of Berlin, Dr. Hans Reusch, of Christiania, and Prof. (Geheimrath) Ferdinand Zirkel, of Leipzig. At Cambridge the degree of Sc.D. *honoris causa* was conferred upon Prof. Waldemar Christofer Brögger, of Christiania, Prof. (Geheimrath) Hermann Credner, of Leipzig, Prof. Louis Dollo, of Brussels, Prof. Albert de Lapparent, of Paris, and Prof. Alfred Gabriel Nathorst, of Stockholm. Prof. (Geheimrath) Heinrich Rosenbusch was unfortunately prevented from attending.

All the recipients of the degrees are foreign members of the Geological Society. Thus was honour done to the society and to many of its distinguished representatives abroad.

H. B. W.

THE FOURTEENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THE fourteenth International Congress of Hygiene and Demography, which meets every four years, was held this year in Berlin from September 23 to September 29, under the presidency of Prince Heinrich zu Schönaich-Carolath, the vice-presidents being Profs. Rubner and von Mayr. It was organised in nine sections, comprising every branch of hygiene and demography—bacteriology, parasitology and preventive medicine; general, industrial and school hygiene; port-sanitary and military and naval hygiene; dietetics, life-saving and statistics. Some 4000 members of all nationalities attended the sittings, and were received everywhere with the utmost courtesy and kindness. The meetings were held in the Reichstag buildings, which are central and admirably adapted for the purpose. The question naturally suggests itself, would the British Government pursue the enlightened policy of placing the Houses of Parliament or similar buildings at the disposal of such a congress meeting in England?

The weather throughout was delightful, and many social functions, including excursions, receptions by Prince Heinrich and the British Ambassador, a banquet, a gala performance at the Opera, concerts, &c., served to make the time pass pleasantly. In addition, visits were organised to all the principal scientific institutions, and were much appreciated. These included the laboratories of the Imperial Board of Health and of the University, the hospitals, sanatoria, schools, &c. It is impossible to do more than glance at a few of the more important communications; the full papers will be published hereafter in a volume of Transactions.

There was an important debate on tuberculosis, and some difference of opinion existed as to the most usual mode of infection in man. Prof. Arloing, of Lyons, discussed the question of the existence of different types of the tubercle bacillus. He said that he had become convinced that the bacillus of this disease is but one, and that the species or types described by several observers are but temporary races or varieties, the apparent fixity of which does not survive the conditions of their surroundings. He considered that:—

(1) The types are rarely defined in a perfect manner; (2) they are blended together in an almost indefinite series of individuals which in growth, shape, and virulence admit of a gradual passage from one to the other; (3) variability is sufficient to explain the usual characteristics of tuberculosis in Mammalia and in birds; (4) there would be real danger, from the medical as well as the hygienic point of view, in making such unstable differences a basis for laying down principles for the prophylaxis of tuberculosis.

Dr. Ravenel, of Philadelphia, considered that:—

(1) The alimentary tract is a frequent portal of entry for the tubercle bacillus.

(2) The tubercle bacillus is able to pass through the intact mucous membrane of the alimentary tract without producing a lesion. This takes place principally during the digestion of fats.

(3) The bacilli pass with the chyle through the lacteals and thoracic duct into the blood, which conveys them to the lung, where they are retained largely by the filtering action of the tissues.

(4) Infection through the alimentary tract is especially frequent in children.

(5) Milk from tuberculous cows is the source of infection in many cases. Our present knowledge does not enable us to state the exact proportion of cases of tuberculosis due to this cause, but it is probably considerable.

Prof. Flugge, of Breslau, said that he had performed experiments which showed that tuberculosis could be communicated to animals by inhalation, and that the dose of bacilli required to infect by the respiratory tract was very far less ("millions of times") than that required to infect by the alimentary tract. The mode of infection in man doubtless varied, and children may be infected by the digestive tract by tuberculous food, particularly milk, but the most extensive source of infection is the number of droplets of tuberculous expectoration coughed up by consumptives; these float in the air and serve as sources of infection to others. Prof. Ribbert, of Bonn, and Prof. v. Schrötter, of Vienna, also from the evidence of autopsies considered inhalation as the chief mode of infection in man. Prof. Calmette, of Lille, believed that in the young, infection by the digestive tract, particularly by tuberculous milk, is the most frequent, and attached little or no importance to dry dust containing tubercle bacilli as a source of infection.

Another important discussion was on typhoid and paratyphoid infections of man and the campaign against typhoid fever. Prof. Löffler, of Greifswald, discussed the classification of the causative micro-organisms of these diseases, and their isolation and differentiation by means of sugar nutrient media containing a small percentage of the anilin dye malachite green. Dr. Lentz, of Berlin, pointed out that the bacteria of typhoid and paratyphoid fevers pass by the lymphatics from the digestive tract to the spleen, bone-marrow and blood, and are excreted by the kidneys, in some cases for long periods. Of great importance also are mild cases, sometimes amounting merely to slight indisposition; though the individual may be but little, if at all, ill, he at the same time excretes the bacillus, and thus may be a source of infection to others. Some of the paratyphoid fevers of man seem to be caused by organisms which produce diseases in the lower animals. Anti-typhoid inoculation was discussed by Prof. Wright, Col. Leishman, R.A.M.C., and Dr. Muschold. The latter, from Prussian statistics, considered the method very promising.

Plague naturally attracted some attention, and Dr. Giemsa, of Hamburg, discussed the best methods of ridding ships of rats. He preferred to expose the hold to a mixed gas, produced in a generator, consisting of 5 per cent. carbon monoxide, 18 per cent. carbon dioxide, and 77 per cent. nitrogen. Dr. Strong, of Manila, discussed the subject of preventive inoculation in plague. He considered that this was the mode of combating the disease which held out the most likelihood of success, and made out a strong case for the use of living but attenuated cultures of the plague bacillus as the prophylactic material. Prof. Gaffky, of Berlin, considered the spread of plague to be due primarily to rats, vermin transmitting the bacillus from rat to man.

In a paper on insects as carriers of disease, Dr. Dönitz pointed out that the ticks are intermediate hosts of spirochætæ and piroplasmata; the parasites pass through a developmental stage, and it is not until this has occurred that they can again infect man and animals. He referred to the present lack of knowledge concerning the structure and developmental history of the ticks, and to the confused nomenclature of these insects now existing.

Many papers were devoted to a consideration of parasitic protozoa. Dr. Doflein discussed the nature of spirochætes, as to whether they are bacteria or protozoa, and their mode of division. Prof. v. Wasielewski, of Heidelberg, believed that all parasitic protozoa can act occasionally as pathogenic agents. The Leishman-Donovan body of the Indian disease kala-azar seemed to be a flagellated protozoon; the piroplasmata also seemed to be allied to the flagellates. Prof. Hewlett, of London, considered the parasites of the different malarial fevers to be distinct species, and the piroplasmata, or some of them, to be more nearly allied to the hæmoflagellates than to the hæmosporidia.

The campaigns against malaria and yellow fever were fully discussed. Prof. Ross, of Liverpool, gave a history of the institution of anti-malaria measures and of their results in Sierra Leone, Lagos, Federated Malay States, Panama, and Ismailia; Prof. Savas, of Athens, described the malaria campaign in Greece; and Prof. Celli, of Rome, that in Italy. The latter advocated drainage, mechanical means to render the mosquitoes innocuous, *e.g.* by the use of netting, &c., and the regular prophylactic use of quinine. Prof. Agramonte, of Havana, described the epidemiology of yellow fever and the campaign against the disease in Havana. He considered that the results obtained in the control and extinction of recent epidemics of this disease confirm the truth of the doctrine of mosquito transmission in its propagation.

Under the heading of dietetics, the subject of the necessary minimum of proteins for alimentation naturally came up for discussion. Prof. Forster, of Strassburg, gave the following as his conclusions:—

(1) Besides albumen, fat, and carbohydrates, man requires for his nourishment certain substances which are contained in animal and vegetable food in varying quantities. These substances are both in quantity and quality related to the nitrogenous ingredients of food.

(2) Digestive and other ferments, the internal secretions, protective matters, &c., are nitrogenous substances or descendants of such; their production must therefore be dependent to a certain extent on the intake of albumen and the conversion of the same in the body.

(3) Until the relations both of quantity and of quality are better understood, it will be advisable for general biological and hygienic reasons to favour an ample proportion of protein in practical nutrition, and not to limit the amount of protein to the minimum with which nitrogenous equilibrium can apparently be maintained.

The alcohol question also was to the fore, but a somewhat guarded opinion seemed to be expressed regarding its supposed evil effects when used in moderation. Dr. Triboulet, of Paris, considered that alcoholic drinks had an unfavourable action in cases of tuberculosis, and that alcohol diminishes resistance and predisposes to tuberculosis. Dr. Moeli, of Berlin, considered that alcohol is not a food, is not necessary, and in many cases is detrimental, and that its use should be discouraged in every way, not only by teaching the masses the evil effects of its use, but by instituting other interests so that the lack of it should not be felt.

Industrial diseases, particularly lead and mercurial poisoning, and those arising from dust, strain, &c., were the subject of several papers, and many suggestions were made to mitigate these evils. Lighting, ventilation and water supplies were also dealt with, and likewise statistics. According to Prof. Ballod, the recent Prussian mortality tables show that as regards mortality the country has a decided superiority over the towns, but that this superiority is only distinctly noticeable among the male sex, and at ages 40–50 years the towns appear to be slightly more favourable than the country.

At the general meeting telegrams of congratulation were received from the German Emperor and Empress, Lord Lister, and others, and three special lectures by English, French, and German men of science respectively were delivered. Dr. Haldane discussed his researcheson the effects of high pressures and temperatures in underground workings on man. No ill effects result with pressures below about three atmospheres, but above these, unless the pressure is increased or decreased step by step, as the case may be, grave effects may be produced. As regards temperature, it is the wet-bulb temperature which determines the suitability of atmospheric conditions in mines. The optimum wet-bulb temperature is below 27° C., the maximum that can be sustained without danger being 31° C. Prof. Chantemesse (Paris) discussed the serum treatment of typhoid fever. By growing the typhoid bacillus in a spleen broth medium for a week, heating to 55° C., and injecting into horses, the serum of the latter acquires properties which usually act favourably on the course of the disease when injected into the patient. Thus, in the Paris hospitals from 1901–7, among 5621 cases the mortality was 17 per cent., but during the same period in 1000 cases treated by Prof. Chantemesse with his serum the mortality was only 4·3 per cent. Prof. Schattenfroh, of Vienna, lectured on the hygienic care of water supplies, and the chemical and bacteriological examinations of drinking water. He urged that an international commission should be formed to devise standard methods for carrying out the latter.

The museum arranged in connection with the congress was of the greatest interest. The exhibits of the Imperial Board of Health and of the Institute for Infectious Diseases were especially noteworthy. They consisted of cultivations of pathogenic micro-organisms and drawings and photographs of the same, pathological specimens of tuberculosis and other diseases, series of specimens demonstrating agglutination and precipitin tests for blood, travelling laboratories, &c. All the principal Continental firms showed chemical and bacteriological apparatus, microscopes, and other instruments, and many of the casts showing pathological conditions were marvels of modelling. The exhibit of the Bacteriological Institute of Rio de Janeiro also was a large and comprehensive one, showing what good work is being done abroad, and it is to be regretted that exhibits from the British Empire seemed to be almost entirely wanting.

Demonstrations on the use of apparatus were given, and one interesting exhibit under the microscope was that of living active spirochætes, minute micro-organisms which occur in relapsing fever, syphilis, and certain animal diseases.

THE HARD AND SOFT STATES IN DUCTILE METALS.

WHEN the early craftsmen first observed that the metals they worked in were made harder by hammering, and that the original softness could be again restored to the hardened metal by heat, it probably did not occur to them that any explanation of these useful properties was called for. At a later period, when an interest in the reasons for things became more general, it is probable that hardening was attributed to the compacting of the substance by the driving of its particles closer together so that the mass as a whole became less open or porous. In the same way heat annealing was probably assumed to act by permanently expanding the metal and opening up its texture. So many analogies to these operations were ready to hand from the most common and everyday experiences that it is not surprising that even on closer inquiry this explanation should continue for a time to be accepted as sufficient, the more so as it was obviously true that in some cases unworked metal had an openness or porosity which could be removed by hammering or working. While the researches of chemists on the density of the metals showed plainly that increase of density does not always result from compacting by pressure, these researches were probably too far removed from the ken of those who were most intimately concerned with the working of metals to arouse them to the insufficiency of the existing explanation of hardening.

In the latter part of the past century the views of physicists and chemists on the influence of molecular structure on the properties of matter began to find application in the field of scientific metallurgy. In particular, much attention was directed to the study of the crystalline constituents of alloys and to the influence of heat treatment on their equilibrium. The study of the iron alloys also led to the development of the view that iron itself can exist in several allotropic forms; thus the idea of allotropy was introduced into practical metallurgy.

Mr. G. T. Beilby's researches,[1] which form the subject of the present article, indicate *that all crystalline substances can also exist in a non-crystalline or amorphous form, and that the properties of these two forms are so distinct that they must be regarded as definite allotropic modifications.* Observations on the stability of these forms, and on the conditions under which the one form can pass into the other, confirm this view. As these general principles have been found to apply

[1] "The Hard and Soft States in Ductile Metals." By G. T. Beilby F.R.S. Paper read before the Royal Society on June 27.

without any exception over a wide range of substances, it appears justifiable to conclude that they are universally applicable. The subject is therefore a very extensive one, and the immediate researches which are dealt with here refer to only a small corner of a very wide field.

In the light of present knowledge it would now seem as if the phenomena of the hard and soft states are so striking that they might have been expected to stimulate inquiry into their true meaning at a much earlier date. One of the most obvious of these phenomena has been perfectly familiar ever since metals were first drawn into wire—that is, that the tenacity of the metal is enormously increased by the operation. By the simple operation of wire-drawing, the power of pure soft iron to resist stretching is raised from twenty tons per square inch to more than eighty tons. Recent researches with metals in the highest state of purity have shown that the resistance of gold to stretching may be raised from $4\frac{1}{2}$ tons per square inch to more than 14 tons, while silver and copper are affected to an even greater extent.

Until very recently the adjective "crystalline," when applied to a metal, at once suggested hardness and brittleness, and even yet among practical metallurgists this association of ideas is not easily got rid of. It is no paradox, however, to say that *in the pure ductile metals the crystalline state is actually the soft state.* In what follows it will be shown that a very large part of this softness is directly due to the instability of the crystalline structure. Conversely, the non-crystalline or amorphous state is the more stable mechanically, and is therefore the harder. Not only the softness, but also the malleability and ductility of a metal, largely depend on its crystalline condition. When the metal is mechanically worked, as by hammering or rolling it into sheets or bars, or by drawing it through dies into rods or wires, some of the crystalline is broken down and passes into the non-crystalline form, and as the metal thereby becomes harder it is also reduced to a lower condition of malleability and ductility.

It has been concluded from a long series of experimental observations that in the passage from the crystalline to the non-crystalline state there is an intermediate stage during which the molecules have the freedom and mobility of the liquid state, and that the amorphous state results from the sudden congealing of this mobile phase. It is well known that when a substance passes from the liquid to the solid state, time is required for the molecules to marshal themselves in the orderly formation which is the essential feature of the crystalline state. If a liquid can be congealed with sufficient suddenness, the solid which results is non-crystalline or amorphous, *e.g.* glass, sugar-candy, &c. If we were able to see the actual molecules we may imagine that the amorphous solid would present the appearance of an instantaneous photograph of a liquid in which the molecules would appear as if transfixed in the midst of their rapid movements. It follows from the above that if it were possible in a mass of metal simultaneously to break down all the crystalline units of structure with sufficient suddenness, the whole mass would for an instant be in the liquid condition, and on re-solidification would appear in the non-crystalline state. A little consideration, however, will make it plain that these conditions cannot be fulfilled in the ordinary mechanical operations on metals in the solid state. In a mass of metal, any stresses which are applied mechanically must be applied from the outside, and can only reach an internal point or surface after passing through all the intervening layers. It follows that the breaking down and "flow" of the crystalline elements must take place step by step, so that the mobile condition occurs at successive surfaces within the mass. A wave of mobility can in certain cases be seen as it passes along a stressed rod, but it is instantly followed by a wave of congelation which leaves the metal behind it in a harder and more resistant condition. In some cases a second wave of mobility may be started by the application of a greater stress, but as a rule each successive application of a uniformly increasing stress produces less and less effect. The portions of metal which have yielded and flowed and again congealed protect those portions which still retain their crystalline structure. There appear to be good grounds for believing that even in a gold leaf, in which the metal has been beaten to a thickness of only 1/280,000 of an inch, there are still minute units in the crystalline state which have escaped destruction owing to the protective action of the harder, non-crystalline metal in which they are embedded. Gold wires which have been drawn through a wire plate until they are fifteen times their original length show a microstructure in which deformed and broken down crystals are embedded in non-crystalline substance. *The hardened metal is a complex structure built up of crystalline and non-crystalline substance;* in studying its properties, therefore, it is necessary to remember that no specimen, however drastic may have been its mechanical treatment, can be entirely in the non-crystalline condition.

Though an increase of hardness and tenacity is a very conspicuous feature of the change from the one state to the other, it is only one among a number of equally definite indications of change. A comparison of the heat of solution of a metal in the two states shows that the molecular energy stored in the non-crystalline form is greater than in the crystalline. In this case the difference in solubility which results from this greater energy is further accentuated as the two phases of the metal act towards the solvent as a galvanic couple. A thermoelectric couple made by twisting together the ends of wires in the hard and soft condition is affected by changes of temperature in the same way as a couple made of two different metals would be. In the case of silver a thermocouple of this description can develop an e.m.f. of 27 microvolts for a temperature difference of 83°. *In all these cases the single chemically-pure metal behaves like two distinct metals.*

When hardened metal is heated to a certain temperature, its softness is completely restored. The microscope shows that when this occurs complete crystalline rearrangement has also taken place. The micrographs, Figs. 1 and 2, from the paper by Mr. Beilby read before the Royal Society on June 27, show the two types of structure, the hard and the soft. In Fig. 1 the original crystalline grains have been completely broken down and destroyed by wire-drawing, giving place to masses of deformed and shattered crystal units cemented or concreted together by that part of the metal which has flowed and congealed. In Fig. 2 a new crystalline structure has been developed by heat, and all traces of the other structure have disappeared. This re-crystallisation in hardened metal occurs at a temperature far below the melting point of the metal. In gold the re-crystallisation temperature is about 280°, while its melting point is 1080°; this profound change of structure, therefore, occurs 800° below the melting point.

In the crystalline state the molecules are disposed in sheets or lamellæ of uniform orientation, like soldiers in a battalion. In the liquid state the molecules are in free movement; they do not maintain fixed positions with respect to each other. The effect of sudden congealing probably is to bind the molecules into a rigid mass quite irrespective of any special polar attractions which they may have for each other. They are bound together by the general cohesive force, and their freedom of movement is much curtailed. This is evident not only because they cannot move sufficiently freely to take up the regularly oriented arrangement, but

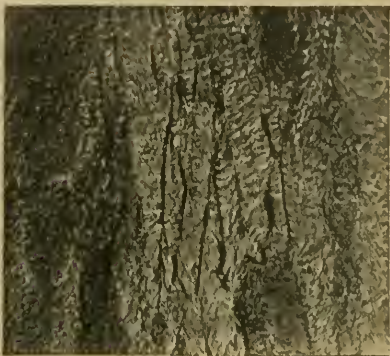


FIG. 1.—Hard-drawn gold wire. Magnification ×700.

also because their elasticity in this state is much less perfect than it is in the crystallised state; the molecules cannot vibrate freely in the amorphous state.

The effect of raising the temperature to the crystallising point is to raise the kinetic energy of the molecules, and therefore to neutralise a part of the cohesive force, thus weakening it and enabling the

FIG. 2.—Hard-drawn gold wire after crystallisation at 280°. Magnification ×700.

molecules to spring into their uniformly oriented position; the crystalline state is thus restored and the internal energy of the mass is reduced. The present observations show that crystallisation occurs over a short and definite range of temperature—short, that is to say, compared with the ranges above and below the crystallisation range. Below the crystallisation range the amorphous or non-crystalline form of the metal is known by direct observations to be perfectly stable down to −180°, while above that range the crystalline form is stable up to the temperature of liquefaction.

The changes in the electrical, mechanical, and other properties, which occur when the crystallisation range is reached, amply confirm the microscopic observations, and all point to the occurrence of an important change in the molecular structure.

By means of an acoustical method it has been found possible to detect the minute changes in elasticity which occur as the temperature is gradually raised to the crystallising range. In this way it has been made evident that there are two distinct stages in the relief of the molecular strains which are caused by hardening. In the first stage no important alteration in the other properties of the hardened metal occurs, while in the second and more important stage the complete restoration of elasticity exactly corresponds with the other changes which occur at the crystallisation temperature.

OCTOBER METEORS.

OCTOBER is a month when meteors are decidedly numerous. They are particularly abundant from October 15 to October 25, and this period includes the well-known shower of Orionids, but the conditions will be unfavourable this year owing to the full moon of October 21.

Early in the month there is occasionally a rich shower near the northern boundary of Boötes at $230°+52°$, and on October 8 there are many meteors from Aries about $42°+20°$, from Auriga, $77°+32°$, and from about this date to October 20 there is a well pronounced morning shower of long-pathed meteors from $154°+39°$.

Before sunrise the observer will also trace radiants at $101°+1°$, $100°+13°$, $108°+13°$, $121°+0°$, $133°+68°$, $133°+48°$.

Thirty years ago, viz. in 1877, during the first week in October there were very well pronounced showers at $133°+79°$ and $313°+77°$; the former gave swift streak-leaving meteors, the latter slow faint meteors.

October furnishes several radiants of Perseids, and one of the most notable of these agrees precisely in its apparent position with the centre of the great display of August Perseids on the date of maximum. Between October 8 and 14 I have recorded a number of slow meteors from a well defined radiant at $45°+58°$.

The principal shower in the last half of October is one of Arietids from near ϵ. On 1877 October 28–November 1, I saw thirty-one meteors from $43°+22°$, and on 1887 October 11–24, forty-five meteors were registered from $40°+20°$. The members of this system are white, rather slow, and occasionally brilliant, with trains of yellow sparks. As they were very active in 1877 and 1887, they may periodically recur at intervals of a decade, and be numerously manifested again in 1907.

W. F. DENNING.

MR. HALDANE ON SCIENCE IN COMMERCE.

A VERBATIM report of the speech on scientific commercial education in relation to the successful pursuit of trade, delivered by Mr. Haldane at Liverpool on September 19, and briefly mentioned in last week's NATURE, appeared in the *Liverpool Daily Post* of September 20. The two main points developed by Mr. Haldane in the course of his remarks were the domination of mind over matter and the value of organisation. Expressed briefly, brain-power was described as the chief factor upon which commercial progress must depend. Subjoined is a summary of the parts of the speech concerned with this subject:—

We live in a time when we shall fall behind in the race if we do not possess as a nation the gift of organisation. Capital has become the instrument in the hands of the directing brain; and the directing brain for huge concerns of to-day is only big enough if it can embrace in its survey the whole of the competing civilisation. Germany, France, the United States, and other countries are pressing us hard, and it is only by the possession of ideas, by the willingness to work as our forefathers never worked, with the same concentration, we can hope to hold our own in the race. At the bottom of great ideas comes great capacity to organise if they are to succeed; and with great capacity to organise great capacity to think. It is the thinker, the man of ideas, who can translate thought into action, that wins the race of to-day—a race far stiffer, far harder, far nobler, than the easy race of our forefathers. Our universities are growing; our tropical schools are starting; our organisation of commerce is going to be on a larger scale; and yet it is none too soon, because other nations are doing the very same thing. So it comes that the great lesson which this nation has to learn appears to be this—to recognise that mind dominates matter, that brains lie at the root of things, and that upon their working out and the results which brains have provided no progress can be made without that secondary but emphatically valuable faculty is added—the faculty of organisation.

The creation of the Committee of Imperial Defence carried scientific principles into the sphere of government, and was the first step toward getting military and naval notions into order. We now have a general staff which is a body, not to exercise command, but to give advice in a thoroughly practical fashion and in a fashion which can be enforced. The speculation may be indulged in whether one of the great reforms of government to which we are coming—because we have been driven to it—will not be the creation in an organised fashion of just such a general staff for departments of government, and not merely for the Army. A concrete instance may be given of the value of scientific advice. In two parts of the dominions of the Crown there are diseases of a terrible character raging at this moment. One is understood, because it has been dealt with by the scientific experts of the Government, but the other is not, because there are no scientific experts to deal with it. The first case is in India, where research work is carried out by experts whom the Indian Government has organised, and who are out working in the subordinate departments of the Government, exercising no authority, but giving advice and reporting to headquarters. These investigators and advisers have brought the plague in India within compass. Then, to give a second case, in one of the West Indian islands, possibly in more, there flourishes what is called tropical anæmia, which, although not fatal to life in the ordinary sense, reduces the working power of its victims by 30 per cent. or 40 per cent. This is a sheer loss to the State, and yet the disease can be and has been combated in other parts of the world. This disease, which also exists in our mines, where it is known as ankylostomiasis, was recently very familiar in Westphalia, and the German Government, working on general staff principles, dealt with the scourge on scientific principles from the beginning. The disease exists in our Cornish mines, but we have not extirpated it as thoroughly as the Germans have.

If people were but aware what can be accomplished and what can be saved to the State, and the extent to which our community can be made more efficient by dealing with these things on a scientific footing, the nation would be wiser and better. This may seem to be the bureaucratic point of view, but when it is founded on science it is the right point of view; and the governments of the future will find more and more work of this kind forced upon them.

THE REV. DR. JOHN KERR, F.R.S.

JOHN KERR, the discoverer of the Kerr effect in magneto-optics, was born at Ardrossan, Ayrshire, December 17, 1824, and received part of his early education at a parish school in Syke. He graduated M.A. with honours in 1849 at Glasgow University, where he greatly distinguished himself, especially in mathematics and natural philosophy. He completed the usual course in theology at the Free Church College in Glasgow, but, instead of entering on a clerical career, became in 1857 mathematical lecturer in the Free Church Normal Training College for Teachers in Glasgow, an institution which has recently passed under the direct control of the Scottish Education Department. Here for forty-four years he trained in mathematics and physics thousands of our youth who afterwards filled important scholastic positions. On his retirement in 1901 his old pupils entertained him at a banquet, when Prof. Magnus Maclean in their name presented him with a tea and coffee service, and made a graceful reference to his great work.

In 1867 Kerr brought out an "Elementary Treatise on Rational Mechanics" (Hamilton, Glasgow), which deserves more than a passing notice. While adhering to the usual mode of treatment at that time, namely, first statics and then dynamics, he introduced what was then a novelty in English books, a separate chapter on kinematics as a preliminary to the chapters on kinetics. Numerous examples are appended to the various chapters, and it is doubtful if among the many more modern treatises of similar standard a better working book for the student exists. Every here and there the physical mind of the author is in evidence, especially in an appendix or "Note," the object of which "is to give a sketch of some of the simpler facts connected with the manifestations of force in nature." Elasticity, cohesion, capillarity, electricity, magnetism, physical optics, and sound are briefly commented on; and the conservation of energy is discussed under that name. The book was written before the formal appearance of Thomson and Tait's "Natural Philosophy," but no doubt under its influence. It is interesting to note that Kerr returns to Newton for the true foundation of dynamics.

In 1875 Kerr published his first paper "On a New Relation between Electricity and Light: Dielectric Media Birefringent" (*Phil. Mag.*, vol. l., pp. 337–348 and 446–458). Accepting the Faraday theory of electric strain, he constructed a remarkably simple form of apparatus in which the ends of two terminals in connection with the open secondary circuit of an induction coil were brought to within a quarter of an inch of each other in the heart of a plate of glass. Nicol prisms were arranged for extinction with their principal axes at angles of 45° with the line of terminals. When the induction coil was set in operation light was restored by the birefringent action of the electrified glass. The investigation was soon extended to liquids, such as bisulphide of carbon, benzol, paraffin, &c. By an extremely neat and simple use of a compensator of mechanically strained glass inserted in the path of the polarised ray, he proved that electrified glass acted upon transmitted light like a negative uniaxal crystal with its axis parallel to the lines of electric force. Quartz acted like glass, but resin acted like a positive uniaxal, as if it were extended along the lines of force. In later papers, published at intervals in the *Philosophical Magazine* between 1879 and 1882, he continued this research with more elaborate apparatus, and extended it to a great many substances, establishing, among other things, the law that the optical effect varies as the square of the resultant electric force.

At the meeting of the British Association in Glasgow in 1876, the president, Prof. Andrews, made a pointed reference to these early experiments of Dr. Kerr, but little dreamed that in a few days the whole scientific world would be positively "electrified" by the announcement of the great discovery known as the Kerr effect. Not only did Kerr announce the discovery, but he demonstrated it with the simplest of apparatus before the meeting of Section A. The paper containing a full account of these experiments was published in 1877 (*Phil. Mag.*, vol. iii., pp. 321–343). The great fact established was that the plane of polarisation of a ray of plane polarised light reflected from the end of the iron core of an electromagnet is rotated under influence of the magnetising current, in a direction contrary to the conventional direction of the current. In a later paper (*Phil Mag.*, vol. v., pp. 161–177) the like phenomenon was established for light reflected from the sides of the magnetised iron. These remarkable experiments form the starting point for a prolonged series of delicate measurements in magneto-optics by several experimenters, of whom we may mention specially Righi, Kundt, Du Bois, Sissingh, Zeeman, and Drude.

On the theoretical side Fitzgerald (*Phil. Trans.*, 1880) was the first to attempt a discussion of the Kerr effect. In this effort he broke "new ground," as Maxwell expressed it; and although the theory was not comprehensive enough, nevertheless (to quote from Larmor, who has himself greatly developed the whole electromagnetic theory) "Fitzgerald's analytical work still remains applicable. The extension to metallic media is now formally made, as Ohm's law indicates, by taking the refractive index to be a complex quantity; with this generalisation the analysis has been extended by various writers, including Lorentz, Goldhammer, and Drude, but most completely by Leathem and Wind, and shown to embrace satisfactorily all the mass of detail that has been brought out in recent years in experimental magneto-optic investigations."

Dr. Kerr's latest paper on this subject (*Proceedings of the Royal Society*, 1894) described experiments on a fundamental question in electro-optics: "Reduction of Relative Retardations to Absolute." In 1888 (*Phil. Mag.*, xxvi., pp. 321–341) he published a well-planned and carefully-executed series of experiments on the birefringent action of strained glass. His last contribution to scientific literature was a note read before the British Association in 1901 on the "Brush Grating and its Optical Action."

Before the great scientific events of his life the University of Glasgow showed their appreciation of Dr. Kerr as an educationist by conferring on him in 1868 the honorary degree of Doctor of Laws. He was elected F.R.S. in 1890, and was awarded a Royal medal in 1898. He died August 18, 1907, after enjoying six years' retirement from official duties in the Normal College. Here, in limited accommodation, with still more limited apparatus, and only by devoting evening hours and precious holidays to research, John Kerr made the discoveries which have linked his name for all time with that of the immortal Faraday.

C. G. K.

NOTES.

Prof. M. H. E. Tscherning, director of the ophthalmological laboratory of the Sorbonne, Paris, has accepted the invitation of the council of the Optical Society to deliver the first Thomas Young oration on Thursday, October 17, and has chosen for its title "The Development of the Science of Physiological Optics during the Nineteenth Century." The oration has been established for the purpose of providing an annual lecture on some subject connected with physical, geometrical, or physiological optics, and thus to further the development of those branches of science with which the name of Thomas Young is intimately associated. The orator is elected annually by the council of the Optical Society from persons eminent in these branches of science or technology.

A very interesting and instructive exhibit has just been added to the public galleries of the geological department of the British Museum (Natural History) in the form of an enlarged wax model of the Silurian arachnid *Eurypterus fischeri*. Remains of these creatures are found in such a wonderful state of preservation in the Upper Silurian strata of Oesel, in the Baltic, that Prof. G. Holm has succeeded in freeing from the matrix considerable portions and mounting them on glass slides in Canada balsam. The original chitin is preserved in an almost unaltered condition, and even the most minute details of the external surface are retained. From these materials it has been possible, under the superintendence of Dr. Calman, to construct the model now exhibited, which is double the natural size, and appears to be between 7 inches and 8 inches in length. The model is temporarily placed in the central hall.

We learn from the *British Medical Journal* that a movement for the foundation of an institution which is to bear the name of Prof. Robert Koch is on foot in Germany, and a committee has been formed with the object of collecting money for the purpose. The chairman is Dr. von Studt, Prussian State Minister; the vice-president, Privy Councillor Althoff; the secretary, Prof. Schwalbe, editor of the *Deutsche medizinische Wochenschrift*; the treasurer, Dr. Paul von Schwabach, General Consul, Berlin. The institution, which is to be applied to the furtherance of research in all directions for the discovery of means of checking the diffusion of tuberculosis, is intended to be a permanent memorial of the discovery of the tubercle bacillus by Prof. Koch twenty-five years ago. Appeal is made for contributions sufficient to make the institution a tribute of gratitude to Koch, similar to those with which the name of Pasteur has been honoured in France and that of Lister in England.

It is announced in the *Times* that the Government has completed negotiations for the purchase of the estate of Inverliver, Argyllshire, with a view to its conversion into a State forest. The estate, which has an area of about 12,530 acres, extends for about nine miles along the western side of Loch Awe, stretching across to Loch Avich. It will be of much value as a centre of education in forestry, and arboriculturists in Scotland are gratified that their desires for the establishment of a demonstration area are about to be realised. The afforestation of Inverliver will at once be proceeded with according to a general scheme, which provides for a certain number of acres being planted each year. The estate will be under the management of the Office of Woods and Forests, and, though it will yield no immediate return, it is expected that it will ultimately cease to be any financial burden to the State.

Mainly at the instigation of the Hon. John Ferguson, C.M.G., the Government of Ceylon has granted to Dr. A. Willey, director of the Colombo Museum, a sum of 3000 rupees (200*l*.) to secure the services of a British anthropologist for the study of the Veddahs during 1908. Dr. C. G. Seligmann, who has made most admirable investigations in British New Guinea, has been invited to undertake this research, and we have the pleasure of stating that he has accepted the commission. The Cousins Sarasin have published a fine monograph on the physical anthropology of these interesting people, in which they have also given valuable information concerning their habits and customs; but the cultural life of these hunter folk has never been thoroughly investigated. Dr. Seligmann will mainly study the sociology and religion of the Veddahs, but he will also make his researches as complete as possible in other directions, and will pay especial attention to the old stone implements of the Veddahs, the recent discovery of which was duly announced in Nature. He will receive cordial assistance from Dr. Willey, who has a practical knowledge of the Veddah country, and with this, and other help and information which will be offered to him, there is every reason to hope for a successful expedition. Dr. Seligmann, who will be accompanied by his wife, expects to sail at the end of November.

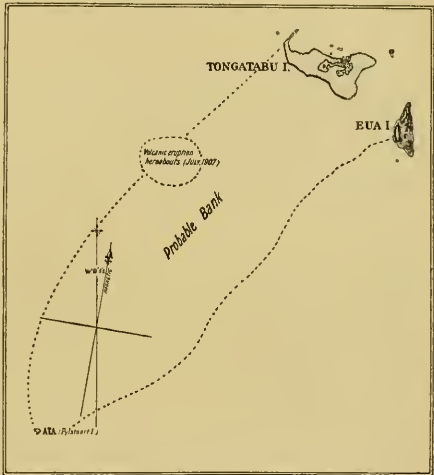
The first exhibition of the Society of Colour Photographers, open free to the public, is being held at the offices of the *British Journal of Photography*, 24, Wellington Street, Strand, W.C. In organising the exhibition the society is appearing before the public for the first time since its formation a year ago, but its first year of active existence opportunely coincides with the appearance of simplified methods of colour photography, already described in these columns.

Dr. W. S. Bruce, Mr. Stewart Ross, and Mr. Gilbert Kerr returned to Edinburgh on Monday on the conclusion of the Scottish expedition to Prince Charles Foreland. Dr. Bruce told a Reuter representative that they have been able to make a detailed survey of the whole of the west coast of Prince Charles Foreland, of the interior with its mountains, and of a considerable portion of the east coast. Good zoological collections have been obtained, including a specially fine set of bird skins, a few seal skins, and the skeleton of a whale. Valuable geological and botanical collections have also been secured. A Reuter representative has also obtained details of the Arctic expedition undertaken by the Duc d'Orléans, who, together with Dr. Recamier, the surgeon and naturalist of the expedition, arrived in England on Monday. The expedition, which was on board the duke's Polar yacht *Belgica*, under the command of Captain de Gerlache, returned to Hammerfest on September 15. The scientific work accomplished will, it is said, prove of great interest.

We have to acknowledge the receipt of a copy of the report of the museums of the Brooklyn Institute of Arts and Sciences for 1906, in which it is stated that the most important additions to the natural history department comprise a collection of sponges and corals made by the late Prof. H. A. Ward in Japan and Australia, and another of shells, late the property of Phebe L. Mumford. Considerable progress has been made in the mounting of realistic groups of mammals and birds, of several of which illustrations are given.

Bulletin No. 5 of the entomological division of the experiment station of the Hawaiian Sugar Planters' Association (published at Honolulu, August 2) is devoted to the sugar-cane leaf-roller, the caterpillar of the moth *Omiodes accepta*. The moths of this genus are regarded by Sir George Hampson as inseparable from Phryganodes, but this is not accepted by Mr. O. H. Swezey, the author of the report, who states that they agree more nearly with the diagnosis of Nacoleia. The caterpillars are very destructive to grass crops, rolling up and glueing together the edges of the blades, and then devouring the softer tissues.

Captain T. H. Tizard, F.R.S., assistant hydrographer of the Admiralty, sends us a copy of a notice to mariners, issued on September 14, relating to a volcanic eruption near the Tonga or Friendly Islands, South Pacific Ocean. The notice states:—"Information, dated July 29, 1907, has been received through the Government of the State of Victoria, that the Government of the Tonga Islands has given notice that a volcanic eruption is in progress about



Volc.nic eruption near the Friendly Islands.

thirty miles south-west of the western point of Tongatábu (Niuanofo)." The approximate position of the disturbance is lat. 21° 25′ S., long. 175° 45′ W. All the information received has been given in the notice, but probably fuller details will be eventually published. The accompanying illustration from Admiralty chart No. 3421 shows the approximate position of the eruption, and also that it appears likely that a bank runs south-west from Tongatábu towards Pylstaart Island, and that the eruption is situated near the edge of this bank.

According to the report of the Government Museum and Connemara Library, Madras, for the year 1906–7, issued by the Educational Department of Madras, July 19, the erection of a new room for the prehistoric collection made by Mr. R. B. Foote is in contemplation. Considerable progress has been made in the anthropological and ethnological section, both in the matter of collections and publications. Unfortunately, the superintendent, Mr. E.

Thurston, has to deplore the loss, by theft, of a number of valuable gold and silver coins, mostly consisting of Roman Imperial solidi and denarii.

In the third part of vol. ii. of the *Agricultural Journal of India* Mr. H. M. Lefroy gives coloured illustrations, with descriptive letterpress, of the various developmental stages of the two species of Indian locusts. Of these, the north-west locust (*Acridium peregrinum*) is normally a migratory species, inhabiting dry districts, and giving rise to annual swarms. The Bombay locust (*A. succinctum*), on the other hand, is typically a native of the moist Western Ghats, and only occasionally assumes migratory swarms, the members of such flights assuming an abnormal red colouring. In the description of these different phases, on p. 241, the references to the figures are unfortunately incorrect. As to the black-spotted grasshopper (of which figures are also given), there is no evidence of its ever assuming migratory habits. The proper identification of migratory locusts from different parts of the country is a matter of some importance in connection, not only with the distribution of the species, but with agriculture.

In the *Journal of Economic Biology* (vol. ii., No. 2) Mr. E. R. Burdon publishes particulars regarding the efficacy of spraying spruce trees in winter to destroy the Chermes or aphids that cause the pine-apple galls. The wash consists of an emulsion of soft soap and paraffin or a solution of soft soap. Dr. R. S. MacDougall communicates the results obtained in rearing broods of the pine-sawfly, *Lophyrus pini*, from unfertilised eggs, and Mr. C. G. Hewitt presents an account of the life-history of the root maggot, *Anthomyia radicum*.

In his annual report for 1906–7, Mr. J. H. Hart, superintendent of the Botanical Department, Trinidad, notes that there has been a large demand for sugar-canes, cacao and rubber plants, also for young cedar, Honduras and native mahogany trees. A considerable quantity of budded stock of various citrus fruits was distributed, and an attractive variety of seedless orange, locally raised, was secured and budded, according to usual practice, on sour-orange stock to avoid the root-rot that is prevalent in the island. Hevea, Funtumia, and Castilloa were the rubber plants chiefly in request; the consignments of Castilloa rubber from Trinidad and Tobago attained to commercial quantities, and realised good prices. A number of camphor seedlings were successfully raised from imported seed, and date palms have received attention. A list is given of more than twenty palms that flowered in the gardens at St. Clair during the year.

The scientific papers in the *Kew Bulletin*, No. 8, consist of a decade of diagnoses of new plants from the herbarium, an article by Mr. G. Massee on degeneration in potatoes, another on the cricket-bat willow by Mr. W. J. Bean, and a note by Mr. N. E. Brown defining the genus Pergularia. Mr. Massee refers to the experience of growers that "seed" potatoes often fail to form sprouts, and attributes the sterility to two causes, *i.e.* to arrest of development of the vascular system in the tuber, and to a want of sufficient diastase. The information regarding the willows is based on the collaboration of the cricketer, Mr. John Shaw, with the Rev. E. R. Linton, a leading exponent of varieties of willows. On this authority Mr. Bean states that *Salix alba*, var. *caerulea*, bearing pistillate flowers, yields the best timber, and that *Salix viridis* is suitable, although inferior to the former. Since, under favourable conditions, trees grow to a merchantable size in twelve years, the cultivation affords a prospect of profitable remuneration.

The "Flora of the Presidency of Bombay," prepared by Mr. T. Cooke, makes good progress, as the fourth part of the second volume, issued in July, deals with the concluding orders of the dicotyledons from Urticaceæ to Ceratophyllaceæ, the gymnosperms and the monocotyledons from Hydrocharitaceæ to Typhaceæ. Under the Urticaceæ the genus Ficus is prominent with eighteen species, one, *Ficus Talboti*, being endemic. Only two gymnosperms, *i.e. Ephedra foliata* and *Gnetum scandens*, are regarded as indigenous; the conifers, ten in number, and the two cycads noted are exotic, although *Cupressus glauca* receives the name of the Goa cypress. The Orchidaceæ, with thirty-one genera, include a number of species confined to the western peninsula, and several are endemic. The Scitamineæ and Palmæ contain numerous economic plants, many of them introduced, that are briefly described. Mr. Cooke has also given a key to Drummond and Prain's identifications of species of Agave and Furcræa.

The writer of the article on "Archæological Discoveries in Egypt," which appeared in Nature of September 12, desires to add that when the article was written nothing was yet known of the results of Prof. Petrie's excavations, which were therefore not mentioned. Since the proofs were corrected, the annual exhibition at University College has been held, and has shown that Prof. Petrie's discoveries of this year, though by no means very exciting, have been interesting enough. The best things found are some splendid interments of the Twelfth Dynasty, with fine coffins and models of ships, &c., in perfect condition, from a tomb at Rîfa, near Asyût. From other tombs in this neighbourhood Prof. Petrie recovered an interesting series of what he calls "soul-houses," which are the small clay models of dwellings often found in tombs of the VIth–XIIth Dynasty period. They are well represented in our museums, but Prof. Petrie has obtained some new and fine types. Prof. Petrie also excavated at Gîza.

We have received a long letter from the Rev. J. W. Hayes, West Thurrock Vicarage, Grays, Essex, with regard to the so-called "twin-chamber denehole" at Gravesend, recently described in the *Times*, and referred to in our notes on September 19 (p. 522). According to Mr. Hayes, the two chambers were originally two distinct deneholes, each with its own shaft, and being in close proximity were brought into communication by a breach in the dividing wall, made after the excavation of the chalk. There is no true platform in either cavern, but a great quantity of sandy loam occupies the floor. In Mr. Hayes's opinion, the pick-marks on the roughly hewn walls could have been made only by an implement of metal, not by one of horn, bone, or flint; whilst he believes that the caves were certainly not used either as a dwelling or as a storehouse for grain.

In a communication to the *Ceylon Observer* of August 10 Mr. J. Pole records the discovery of numerous Palæolithic stone weapons on hillocks at Imboolpittia, Ceylon. Similar discoveries have been made by the brothers Sarrasin, who have hitherto monopolised the study of that interesting forest race, the Veddahs. Mr. Pole, on rather shadowy grounds, attempts to connect the implements which he has discovered with the same tribe.

An interesting report on the borax deposit of Lake Salinas, Peru, has been published by Mr. A. Jochamowitz (*Boletin del Cuerpo de Ingenieros de Minas del Peru*, No. 49). The so-called lake is dry for the greater part of the year, and the borax deposit is about 3 feet in thickness. It consists of ulexite, containing 30 per cent. of boric acid. The bed is impermeable, so that water cannot reach the lake at places where borate occurs. The borate is extracted by means of shallow pits, which become filled with water when the borate is removed. Reports have also been issued by Mr. W. Turner and Mr. J. J. Bravo on the geology of the River Chillon (*Boletin* No. 48), and by Mr. H. C. Hurd on the water supply of the valley of Lambayeque (*Boletin* No. 47).

The current issue of the Proceedings of the American Philosophical Society (vol. xlvi., No. 185) covers two hundred pages, and contains seventeen papers of very varied interest. The most important memoir is a detailed account of the geology of the San Francisco peninsula, by Mr. Roderic Crandall. It describes the Montara granite, the Franciscan series, the Merced series (Pliocene), the Pleistocene beds, the serpentines, the igneous intrusive rocks, and the schists represented on the peninsula. The age and origin of the rocks are discussed, and an excellent coloured geological map is appended. Another paper of great interest is that by Mr. E. B. Titchener and Mr. W. H. Pyle on the effect of imperceptible shadows on the judgment of distance. Careful experiments show that such shadows, raised almost to the limit of perceptibility, exert no influence upon the judgments of distance by five observers. Mr. M. D. Ewell gives the results of a preliminary study of some modern micrometers. He collected a number of stage micrometers, and measured five to ten spaces on each with great care. The results show that no advance in precision has been made during the last twenty-five years. Indeed, the results do not seem to equal those of the former period. The papers of chemical interest deal with the measurement of the action of water on metals, the production of synthetic alcohol, and the association theory of solutions.

The September number of *Symons's Meteorological Magazine* contains a useful paper by Mr. R. H. Curtis on the distribution of bright sunshine over the British Isles. Two forms of recorder have been in general use, the photographic and burning instruments; their records frequently differ considerably, and not always in the same direction. For the sake of uniformity, the Meteorological Office now only publishes records from the burning instrument, and these alone have been used in Mr. Curtis's discussion. Latitude being an important factor, we naturally find that the sunniest parts of the United Kingdom are the most southern, the annual total of hours' duration decreasing from 1900 hours in the Channel Islands to 1200 over the north of Scotland. A very clear map shows, however, that the lines of equal duration have a strong tendency to follow the coast lines both in east and west, and that a large portion of the central area of England and of the south-west of Scotland is adversely influenced by smoke and dust; in winter the largest totals of sunshine are obtained in the south-west. A great part of Ireland, central Wales, and the Highlands of Scotland are still very inadequately represented by sunshine recorders.

September has proved an exceptionally fine and dry month over the entire kingdom, and in England the period without rain continued for about three weeks. Of the stations reporting to the Meteorological Office, the least measurement of rain for the month was 0·28 inch at Yarmouth, which is only 12 per cent. of the average, whilst at Bath the percentage was 18, and at Liverpool 19. At many places in different parts of the kingdom there was less than 50 per cent. of the average. In London the aggregate measurement was 0·58 inch, which is 28 per cent. of the normal. The total measurement of rain since the commencement of the year is deficient, except in the extreme north and west. In London the deficiency amounts to 4·88 inches, and, so far, April is the only month with an excess of rain; the greatest deficiency in any month is 1·48 inches, in September. The duration of sunshine so far this year is, in London, fourteen hours more than the average, the excess occurring in January, February, March, and September. There were in all during the six summer months from April to September sixty-one days at Greenwich with the temperature 70° and above, and only two days with a temperature of 80°. The only years since 1841 with fewer days of 80° and above are 1860, when the thermometer did not once touch 80°, and 1862 and 1879, when there was only one instance of so high a temperature. The type of weather which prevailed with such persistence throughout September has now completely changed, and with October rains have become general.

A summary of the paper on the effects of heavy pressures on arc spectra, communicated by Mr. W. J. Humphreys to the American Physical Society, appears in the *Physical Review* for June. Pressure seems to increase the width of all lines and displace most of them towards the red by amounts approximately proportional to the pressure. The extent of the shift varies from line to line, and is practically independent of the amount of material used. The intensities of some lines are increased, of others decreased, by the pressure.

Mr. E. F. Northrup directs attention in the *Physical Review* for June to the magnitude of the forces exerted by the parts of a non-electrolytic liquid carrying an electric current on each other, and describes several striking experiments in illustration. One of these consists in sending a large current through a narrow channel of mercury connecting two small reservoirs of mercury. With a current of 800 amperes a V-shaped depression half an inch deep formed at the centre of the channel, the mercury flowing into the reservoirs. A slight increase of the current broke the continuity of the mercury in the channel. On the liquid flowing together again the circuit was re-made, the arrangement thus constituting a slow and irregular interrupter.

In the *Physikalische Zeitschrift* for September 15 Dr. K. E. F. Schmidt has an article on the "barretter," *i.e.* the bolometer when used to detect and measure rapid electrical oscillations. He shows that by enclosing the instrument in an oil bath the necessity for using two similar instruments is obviated. The "barretter" in series with a galvanometer of low resistance forms one arm of a resistance bridge, the other arms of which are wound so as to have considerable inductance, and thus confine the oscillating current to the "barretter," the terminals of which are connected to the circuit in which the oscillations are to be measured. The oscillating current heats the fine wire of the instrument, and thus disturbs the balance of the bridge by a measurable amount. The conditions for maximum sensitiveness are considered by Dr. Schmidt, and the results expressed in the form of curves.

Under the title "Grandeur et Décadence des Rayons-N: Histoire d'une Croyance," M. Henri Piéron gives in the

Année psychologique (vol. xiii., p. 143) a review of the history of the mysterious *n*-rays from the time when their discovery was first announced by M. Blondlot in 1903. A complete bibliography of the subject is appended which comprises in all 176 original papers, very unequally distributed as regards date, nineteen being published in 1903, 139 in 1904 (103 in the first half of the year), seven in 1905, and fifteen in 1906. After the surprising statement had been made that it was possible to chloroform metals, and thus, by a process of anæsthesia, destroy their power of emitting the rays, and largely in consequence of Prof. R. W. Wood's letter in NATURE (vol. lxx., p. 530) throwing doubt on the existence of the rays, the *Revue scientifique* instituted an inquiry to ascertain whether other physicists who had worked on the subject had succeeded in verifying the remarkable statements made by MM. Blondlot, Charpentier, and Jean Becquerel. This inquiry, which has been briefly referred to in NATURE (vol. lxxi., pp. 113, 132, 157), showed that practically all those who had attempted to establish even the existence of the *n*-rays had entirely failed. A simple method of settling the question once and for all was then proposed by the *Revue scientifique*. A number of wooden boxes of exactly the same size and appearance were to be sealed up after enclosing in some of them small pieces of lead, in others rods of tempered steel, the latter being one of the recognised sources of the rays. It was to be left to M. Blondlot or his assistants to ascertain by experiments, made in presence of a committee of witnesses, which of the boxes contained the active material. This crucial test was, however, declined by M. Blondlot, who stated that "the phenomena were far too delicate for such a trial," and left "everyone to form his own opinion on the *n*-rays either from his own experiments or from his confidence in those of others." The subject was thus withdrawn from the region of fact and transferred to that of opinion. It is significant that from this time forward publication of further experiments practically ceased. A few attempts were made to obtain photographically objective evidence of the existence of the rays, but these did not withstand the test of criticism. It appears now established that the *n*-rays and their wonderful effects had no real existence, but that the results published in so long a series of papers were due to illusion caused by a species of auto-suggestion based on preconceived ideas. The matter forms, indeed, one of the most curious chapters, not only in the history of physical science, but also in that of psychology.

PAGES 1–78 of vol. ix. of the Proceedings of the Washington Academy of Sciences contain a very useful compilation, by Mr. James W. McBain, of all the experimental data referring to the quantitative measurement of electrolytic migration. Abstracts are given of all papers bearing on the subject between the years 1814 and 1905, the numerical results being summarised in the form of tables. In the introduction a brief discussion is given of the probable degree of accuracy of the determinations, of the errors introduced by the use of diaphragms and by the methods of calculation adopted; the interpretation of the results is also dealt with, a number of anomalous cases which are not in accord with the prevalent theory of solutions being considered separately, as well as the questions of hydrated and complex ions. The matter is arranged chronologically, but for convenience of reference indexes of substances and authors are appended. The compilation appears to be very complete, and its value is enhanced by the fact that a very large number of the papers bearing on the subject have titles which give no indication that they contain experiments on electrolytic migration.

MESSRS. J. GRIFFIN AND SONS, LTD., have sent us a specimen of their new Bunsen burner, which they call an "Improved Teclu Burner." The Bunsen, as a matter of fact, is a slightly modified Marshall burner, the chief feature of which was that the air passes up from beneath the burner instead of being drawn in at the sides of the tube. The gas, on the other hand, passes in at the side, and not up the centre. The novelty in the burner is the arrangement for regulating the air supply, which is cone-shaped. We have tested the burner, and find it gives a good non-luminous flame, and can be turned extremely low without striking back. Even when at its lowest the flame is quite non-luminous.

THE new session of the Institution of Mechanical Engineers will be opened on Friday evening, October 18, when a paper on the indicated power and mechanical efficiency of the gas-engine, by Prof. B. Hopkinson, will be read.

OUR ASTRONOMICAL COLUMN.

NEW ELEMENTS AND EPHEMERIS FOR COMET 1907*d*.—The following set of elements has been calculated for comet 1907*d* by Herr Kritzinger, from observations made on June 15, July 20, and August 28:—

$$\begin{aligned} T &= 1907 \text{ September } 3{\cdot}9792 \text{ M.T. Berlin.} \\ \left.\begin{aligned} \omega &= 294^\circ\ 21'\ 37{\cdot}7'' \\ \Omega &= 143^\circ\ \ 2'\ 33{\cdot}7'' \\ i &= \ \ 8^\circ\ 58'\ \ 6{\cdot}1'' \end{aligned}\right\} & 1907{\cdot}0. \\ \log q &= 9{\cdot}709663. \end{aligned}$$

This appears in No. 4201 of the *Astronomische Nachrichten* (p. 15, September 20), and is followed by a daily ephemeris computed therefrom by Herr Spohn; the following extract gives the calculated positions and magnitude for every eighth day:—

Ephemeris 12h. (M.T. Berlin).

1907	α 1907·0 h. m.	δ 1907·0 ° ′	log *r*	log Δ	Magnitude
Oct. 3	11 38·5	+3 17·9	9·9265	0·2458	6·9
11	12 6·9	+1 6·3	9·9908	0·2776	7·4
19	12 31·7	−0 49·9	0·0472	0·3051	7·8
27	12 53·6	−2 30·8	0·0967	0·3290	8·1
Nov. 4	13 13·2	−3 58·9	0·1399	0·3492	8·5

The magnitudes are derived from the magnitude at the time of discovery, which is taken as 8·0.

An ephemeris extending to December 30 is given by Herr J. Franz in No. 4200 of the *Astronomische Nachrichten* (p. 401, September 12).

An excellent reproduction of Mr. Plaskett's photograph, obtained at Ottawa on July 20, appears as the frontispiece to the current issue of the Journal of the Royal Astronomical Society of Canada (vol. i., No. 4).

SEPTEMBER METEORS.—A magnificent bolide was observed at South Kensington by Mr. F. E. Baxandall at 10.40 p.m. on September 19. Its path lay from near Saturn, where it first appeared, to a little south of Cassiopeiæ, where it was seen to explode and divide into two well-defined portions. The object was intensely brilliant, and travelled very slowly along its path of nearly seventy degrees.

THE ELECTRIC ACTION OF THE SUN AND OF THE MOON.—The results of some experiments on the electric action of the sun and moon, carried out by Dr. Nodon on the summit of the Pic du Midi, appear in No. 12 (September 16, p. 521) of the *Comptes rendus*, and are exceedingly interesting. Using an aluminium-leaf electrometer, so insulated that a charge of 1500 volts was retained for a week, Dr. Nodon found that the sun induced a positive charge, which varied considerably from one moment to another between one and six volts per minute. This charge was completely absorbed by clouds passing before the solar disc, but showed itself when a black card coated with paraffin was interposed between the sun and the instrument. An earth-connected metal screen absorbed the charge.

Dr. Nodon's experiments also indicated that the potential of the soil depends upon the variable electrical state of the upper layers of the atmosphere, for when the indicated potential of the solar charge received remained constant, that of the soil was also constant, but with a varying solar potential the terrestrial potential varied several hundred volts per minute, attaining its maximum when the former ceased to manifest itself. This action is much less marked at sea-level than at the altitude of the summit of the Pic du Midi. It is suggested that the rapid variations of the terrestrial potential may indicate approaching tempests, storms, and even earthquakes, and actual observations by Dr. Nodon tend to confirm this. With this method improved, prognostications of atmospheric and seismic troubles may become possible. On August 21, between 8 p.m. and 10 p.m., Dr. Nodon also detected a positive induction produced by the full moon analogous to the solar charge, and varying from one to five volts per minute.

Perth Catalogue of Standard Stars.—In "A Catalogue of 420 Standard Stars, mostly between 31° and 41° South Declination, for the Equinox 1905·0, from Observations made at the Perth Observatory, Western Australia," Mr. W. Ernest Cooke, the Government astronomer of Western Australia, appears to have done an excellent piece of work, though one might wish that the details had been given somewhat more fully.

When some of the South American observatories failed to fulfil their engagements with reference to the International Photographic Chart of the Heavens, the gap was to some extent bridged by the Perth Observatory undertaking to observe the zone 32°–40° S. The catalogue plates for this zone are now practically complete, but the measurement of the star images and the necessary reductions are delayed by the want of a sufficient number of known stars to furnish the plate constants. For this reason it is proposed to observe some 10,000 stars, appropriately scattered throughout the zone, and for reasons which are not explained the method of absolute determinations has been abandoned in favour of zonal observations. Unfortunately, Auwers's catalogue, which has been accepted as the basis of the system, does not contain a sufficient number of standard stars, and it has been necessary to choose others to act as secondary standards, and to observe these repeatedly. The present catalogue gives the places of 420 stars, which will be adopted as fundamental in the zone reductions.

The number of observations of each star is usually ten, and, judged by the probable error of a single observation, the accuracy of the mean result should be sufficient for the purpose.

VIENNA MEETING OF THE IRON AND STEEL INSTITUTE.

The autumn meeting of the Iron and Steel Institute was held in Vienna on September 23 and 24, under the presidency of Sir Hugh Bell, and was largely attended, there being about 450 members present. The proceedings opened with addresses of welcome by the chairman of the reception committee, by the Minister of Agriculture and Mines as representative of the Austrian Government, by the Mayor of Vienna, and by the president of the Austrian Society of Engineers and Architects, in the building of which the meeting was held. The addresses of welcome, which were delivered in German, having been translated by the secretary, Mr. Bennett H. Brough, the president, Sir Hugh Bell, responded in an eloquent German speech, and incidentally announced that the Archduke Frederick of Austria, who had acted as patron of the reception committee, had accepted honorary membership of the institute. The technical business then began.

Mr. W. Kestranek read the first paper. It recorded the progress made in the Austrian iron industry during the twenty-five years that have elapsed since the institute last met in Vienna. In 1882 Austria-Hungary produced 600,000 tons of pig iron, and the annual output has now risen to 1,900,000 tons. The country suffers from a scarcity of coking coal. It has nevertheless been able to maintain its position among the iron-producing countries of the world.

In the second paper read, Prof. H. Bauerman described the Erzberg of Eisenerz, the largest of the series of mineral deposits associated with the Palæozoic rocks of the eastern Alps. The raw ore averages 38·73 per cent. of iron, and the calcined ore 50·68 per cent. The ore is obtained by quarrying, the entire face of the deposit being laid out in a series of steps or terraces, fifty-eight in all, varying in height from 33 feet to 43 feet, giving a total depth of working faces of about 2000 feet. The present annual output is about 1,600,000 tons. The mining of iron ore on the Erzberg has been carried on from very early times. Traditionally, the workings date back to the eighth century, but there are no authentic records older than A.D. 931.

A paper on steel and meteoric iron was read by Prof. F. Berwerth (Vienna). The paper was prepared by way of introduction to the meteorite collection of the Imperial Natural History Museum, where opportunities are afforded for the study of meteoritic iron masses under conditions unequalled elsewhere. Meteoritic falls from 615 different localities are represented in the collection by 2075 specimens, the total weight of which is 3½ tons. Of these, 232 falls are iron meteorites, weighing together more than 2½ tons. The author's descriptions show that meteoritic iron and steelworks' steels are results of essentially similar chemical and physical causes.

Prof. J. von Ehrenwerth (Leoben) read a useful paper on the determination of the total quantity of blast-furnace gas for a given make of pig iron. The method proposed should prove of great value in view of the increasing importance of the waste gases as an economic factor in iron smelting, more particularly since their successful application in driving gas-engines makes it necessary that closer control should be exercised in their disposal.

At the present time there is a constantly increasing number of cases in which industrial practice is profiting by the application of the laws of modern physical chemistry. Some examples of conclusions dealing with the metallurgy of iron which may be arrived at in this way were given in a lengthy paper contributed by Baron H. von Jüptner (Vienna). He dealt more particularly with the laws of chemical equilibrium as applied to metallurgical chemical processes.

In a paper read before the institute last May, Mr. C. E. Stromeyer (Manchester) mentioned several failures of steel plates and structures, which appeared to indicate that certain qualities of mild steel might have the property of changing their nature with age. In a supplementary paper he gave the results of further experiments. They have not revealed a test which will discriminate between trustworthy and treacherous qualities of steel, but they have nevertheless established the fact that mild steel does possess ageing properties, and that certain practices which are still fairly common amongst engineers are not free from dangerous possibilities.

Four papers were read on the subject of hardening steel. Mr. C. O. Bannister (London) and Mr. W. J. Lambert (Woolwich) dealt with the case-hardening of mild steel, giving the results of some observations on the microstructure of cemented bars, on the depth of hardness, and on the carbon contents. The results do not throw much light on the manner in which the carbon penetrates the metal, but the authors consider that the solid solution theory is capable of offering a satisfactory explanation. Mr. G. Shaw Scott (Birmingham) also contributed a paper on case-hardening. He considered that nitrogen in some form is necessary for the practical performance of case-hardening, and suggested that ammonia, whilst being the prime agent in any change, may lead to the formation of cyanogen, which acts as a carrier of carbon to the metal to be carburised. Nitrogen, he concluded, should be added to the list of elements which cause iron to take or retain the γ form; and since γ iron combines more readily with carbon than does α iron, the action of nitrogen on the iron would appear to be sufficient to explain its beneficial effect during the early stages of the process of case-hardening. Throughout the research burnt leather, which is in general use in trade circles in England, was employed as the standard case-hardening material.

The results obtained in practice during the hardening of steel depend upon the conditions under which the transformations of the metal take place, and particularly on the duration and the temperature of the heating, the energy of the quenching bath, and the size of the pieces quenched. The part played by each of these factors was discussed in a lengthy paper contributed by Mr. L. Demozay (Paris). The last paper on hardened steels, contributed by Mr. Percy Longmuir (Sheffield), was somewhat controversial in character. He stated that no metallographical investigation yet published has been of the least service as a guide to the thermal treatment of high-speed steels, and that comparatively little information has been given on the hardening or tempering of carbon steels. The diversity of structure in normal and abnormal products quenched under unsuitable conditions explains to some extent the attitude of practical men towards the microscope, but instead of leading to condemnation it should rather lead to recognition of the value of microscopical examination. Diversity indicates wasters, whilst uniformity denotes correct hardening conditions. The ideal structure, or lack of structure, of commercially hardened carbon steels is produced only in a certain range of quenching temperature, which varies according to the composition of the steel and the contour of the piece to be hardened. Temperatures outside this range result in more or less crystalline patterns, which in the smallest of sections vary from field to field. Although certain of these patterns may give the appearance of special constituents, they are in reality the product of an abnormal quenching temperature, and steels containing them, although hard, are useless for cutting or resisting abrasion.

A paper was then submitted by Mr. B. H. Thwaite (London) on the economic distribution of electric power from blast furnaces. The scheme he proposed is to pool the waste gases from all the furnaces of an iron-making district and to transmit the electrically transformed energy to a central distributing station.

The last paper submitted was by Mr. F. J. R. Carulla (Derby), who described a new blue-black paint as a protective covering for iron. In the preparation of iron and steel rods for wire drawing and galvanising, as also in the preparation of plates for tinning, the iron is kept for a time in a bath of acid to remove the scale. When hydrochloric acid is used, a solution of chloride of iron is obtained, and many methods have been devised to utilise these solutions. It is now suggested that ammonia might be employed for the precipitation of the oxide of iron, seeing that the value of the ammonium chloride is greater than that of the ammonia employed. The blue-black precipitate is a valuable addition to the list of pigments that can be employed with advantage for the protection of structural ironwork.

During and after the meeting the institute was received with lavish hospitality. The members and the ladies accompanying them were entertained at banquets by the Austrian iron trade and by the Municipality of Vienna; they were taken to luncheon on the top of the Schneeberg, to afternoon tea at the Imperial Palace of Schönbrunn, and to a special performance at the Imperial Opera House. They were honoured with a reception at Court, and the council lunched with the Archduke in his palace. On September 26 and 27 the members were divided into three groups, to visit the iron mines and works in Bohemia, Styria and Moravia, and Silesia respectively. Altogether the meeting was without doubt the most enjoyable and the most instructive recorded in the institute's annals.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

MR. ANDREW CARNEGIE has given a donation of 10,000*l*. towards the establishment of a technical college at Aberdeen.

MR. ARTHUR ACLAND is to distribute the medals and prizes of the Royal College of Science in the lecture theatre of the Victoria and Albert Museum this afternoon (October 3) at four o'clock.

AT Oxford on Monday the honorary degree of Doctor of Science was conferred upon Dr. Ludwig Mond, F.R.S., who was nominated for the degree at the last Encænia, but was prevented by ill-health from attending then to receive it.

A COURSE of free lectures to teachers, entitled "The Native Races of the Empire," will be given by Dr. A. C. Haddon, F.R.S., at the Horniman Museum, on Saturday mornings from October, 1907, to May, 1908, beginning on October 12. Admission will be by ticket only, to be obtained from the Clerk of the London County Council, County Hall, Spring Gardens, S.W.

THE mayor of the borough of Bethnal Green appeals for assistance for the Bethnal Green Free Library, which is supported entirely by voluntary subscriptions. The great want of the present time is a new and enlarged building in a more prominent position, to accommodate the increasing number of readers and provide reading-rooms for boys and girls. Mr. G. F. Hilcken, the librarian, will be glad to receive donations or subscriptions.

ANNOUNCEMENTS of the following scholarship awards have reached us:—University of London: University College—Bucknill scholarship of 135 guineas, T. C. Graves; entrance exhibitions of 55 guineas each, P. V. Early and B. Woodhouse. Guy's Hospital Medical School—Senior science scholarships for university students, 50*l*., J. G. Saner; junior science scholarships, 150*l*., J. F. Mackenzie; 60*l*., R. D. Passey. Entrance scholarships, 100*l*., C. S. L. Roberts; 25*l*., G. D. Eccles; 25*l*., G. F. Romer.

THE programme of university extension lectures for the coming session has just been issued by the University Extension Board of the University of London. A three years' course on the evolution of mankind as seen in the development of industries and institutions will be carried on at University College, the first term's work being taken by Prof. Lyde on geographic control of human evolution, while Dr. Slaughter will lecture in the Lent term on forms of primitive society, and Dr. Haddon in the summer term on the distribution of races. The course of work on human evolution as seen in the child and the race, brought to a successful conclusion last session, will be repeated at the Goldsmiths' College, New Cross, Dr. Chalmers Mitchell giving the earlier lectures and Dr. Slaughter and Dr. McDougall taking the later lectures.

AMONG recent developments connected with the Northampton (Polytechnic) Institute, London, E.C., referred to in the calendar for the session 1907–8, particular mention should be made of those in the department of technical optics. The most noteworthy of these developments is a course on the production and measurement of light, which is being given to both day and evening students by the electrical engineering and applied physics department and by the department of technical chemistry jointly. The lectures and laboratory work in the electrical engineering department deal with all the various kinds of electric lamps, glow, arc, and luminescent; with the problems of the production of light, and photometry, and general questions of radiation. In the technical chemistry department the subject is taken up from the chemical side, and the whole subject of incandescent lighting dealt with. The properties of rare metals and rare earths, their production, extraction, and use for all kinds of incandescent lighting, both gas and electric, are fully dealt with, and the production of metallic filaments for electric glow lamps is thoroughly studied. In the technical optics department four new classes especially suitable for artisan students have been started. There are also special classes for the instruction of kinematograph operators, which it is hoped will place this kind of work upon a sound scientific basis.

THE calendar of University College, London, for the session 1907–8, which has just been issued, contains many new features. There is a sketch of the history of University College by Dr. Carey Foster, together with a full statement of the statutes and regulations under which the college is now governed in its new position as an integral portion of the University of London. It also contains a set of plans that show the uses to which the extension of buildings is being put. It appears that the space now available for university purposes is greater by one-third than it was last session. Among the most striking features of the new developments are the following:—the institution of a new department of geology with geological museum, rock museum, and research room; the enlargement of each of the engineering departments and of the drawing office; the enlargement of the department of applied mathematics, and the provision of special rooms to be known as the Galton research laboratories in connection with the Eugenics Institute founded by Mr. Francis Galton. The calendar also contains a section setting forth in full the arrangements for post-graduate courses of lectures and arrangements for research work. The opportunities for research work are full and ample, and the regulation with regard to admission is such that no one qualified to undertake research work ought to be debarred therefrom. It appears from the summary of students that there were no fewer than 171 post-graduate and research students in the college last session, consisting of 140 men and thirty-one women.

At the annual meeting of the governors of the Glasgow and West of Scotland Technical College on September 24 Mr. G. T. Beilby, F.R.S., was unanimously elected chairman of the governors in succession to the late Sir William Robertson Copland. As a chemical technologist, Mr. Beilby enjoys a world-wide reputation. In industrial circles his name is more particularly associated with the Young and Beilby retort, and with a process for the manufacture of potassium cyanide. The introduction of the former revolutionised the process of shale distillation, and enabled the industry to emerge successfully from the struggle for existence; by means of the latter invention he has been instrumental in retaining an important industry in this country. As an investigator in the regions of pure science, Mr. Beilby has also established his reputation, his valuable researches on the surface structure of metals having attracted widespread attention. The second section of the new buildings for the college is in course of erection, and is expected to be ready for occupation in the session 1908–9; operations on the third section, which will complete the buildings as originally planned, will be undertaken immediately. The accommodation provided in the new buildings has enabled the college to extend its work in various directions. Recognition has been given to the importance, in a large engineering centre, of the study of fuels and their applications, and a very complete equipment has been provided in the department of technical chemistry for valuing fuels and illustrating the methods of controlling their use. This consists of calorimeters of all the various types for use with solid, liquid, and gaseous fuels, all the commonly used forms of pyrometer, and an experimental gas producer. Another feature of this department is the plant which has been installed for giving instruction in the methods of conducting technical experiments. The equipment includes grinding mills, filter and hydraulic presses, a hydro-extractor, a small refrigerating plant, pumps, an air liquefier, a steam-jacketed pan, and a double-effect vacuum evaporator plant. The laboratory in the department of motive-power engineering has been fully equipped, and in designing the equipment the object has been, not merely to provide for the illustration of principles set forth in the lecture course, but also to promote the industries of the district by obtaining information ahead of current practice. In addition to the ordinary steam, gas, and oil engines, there are several pieces of plant of special interest; with one of these engines experiments are being made from which it is hoped that information will be obtained to settle the much disputed points in the initial condensation *versus* valve leakage controversy. In the equipment of the other laboratories equal care has been shown, and every effort has been made to render them suitable for the needs of a great centre of industry.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 20.—"The Fluted Spectrum of Titanium Oxide." By A. **Fowler.**

The author has previously shown that nearly all the dark flutings which are characteristic of the spectra of Antarian or third-type stars correspond with flutings obtained from compounds of titanium.

The first part of the present paper gives an account of experiments which indicate that the flutings in question are produced by a compound of titanium with oxygen, and not by the vapour of the metal itself. The most conclusive evidence on this point was afforded by titanium chloride, which, in the absence of oxygen, did not show the Antarian flutings, although the occurrence of another group of flutings, attributed to the chloride itself, indicated that the conditions were not unfavourable for their production if their existence depended only upon the presence of titanium. Experiments with metallic titanium also showed that the Antarian flutings were only produced in the presence of oxygen.

The result is of some importance as indicating that the source of the fluted absorption in the Antarian stars is at a temperature low enough to permit the formation of a chemical compound, and also as demonstrating the presence of oxygen, of the existence of which in these stars there is otherwise no direct evidence. The investigation has lately gained additional interest in consequence of Prof. Hale's discovery of some of the less refrangible flutings in the spectra of sun-spots.

The second part of the paper contains a revised and extended table of wave-lengths, based upon photographs taken with much greater dispersion than that previously employed. For the first heads of the more prominent groups of flutings the wave-lengths tabulated are 4584·62, 4761·08, 4954·78, 5167·00, 5448·48, 5597·92, 6158·86, and 7054·5. All of these are strongly marked in the stellar spectra, that in the extreme red having lately been photographed by Slipher and Newall. Two of the stellar bands, however, about wave-lengths 5862 and 6493, do not appear to be sufficiently accounted for by titanium oxide. Photographs of the spectrum are reproduced in the paper.

Received July 4.—"The Effect of Pressure upon Arc Spectra. No. 1. Iron." By W. Geoffrey **Duffield.**

The first part of the paper contains a description of the mounting and adjustment of the large Rowland concave grating in the physical laboratory of the Manchester University. The feature of this is the stability of the carriages carrying the grating and camera, and the novel construction and attachment of the cross-beam, which secure the absence of any disturbance which might be caused by bending or sagging.

The second part describes experiments made with a pressure cylinder designed by Mr. J. E. Petavel, F.R.S., in which an arc is formed between metal poles opposite a glass window, through which the light is examined by means of the grating spectroscope. A system of mirrors allows the image of the arc, however unsteady it may be, to be kept almost continuously in focus upon the slit.

Two sets of photographs of the iron arc in air have been taken for pressures ranging from 1 to 101 atmospheres (absolute), and the results are given below for wave-lengths $\lambda = 4000$ Å.U. to $\lambda = 4500$ Å.U.

I. *Broadening.*

(1) With increase of pressure all lines become broader.

(2) The amount of broadening is different for different lines, some almost becoming bands at high pressures, and others remaining comparatively sharp.

(3) The broadening may be symmetrical or unsymmetrical; in the latter case the broadening is greater on the red side.

II. *Displacement.*

(1) Under pressure the most intense portion of every line is displaced from the position it occupies at a pressure of 1 atmosphere.

(2) Reversed as well as bright lines are displaced.

(3) With increase of pressure the displacement is towards the red side of the spectrum.

(4) The displacement is real, and is not due to unsymmetrical broadening.

(5) The displacements are different for different lines.

(6) The lines of the iron arc can be grouped into series according to the amounts of their displacements.

(7) Three groups can in this way be distinguished from one another; the displacements of Groups I., II., III. bear to one another the approximate ratio 1 : 2 : 4. (The existence of a fourth group is suggested by the behaviour of two lines, but further evidence is needed upon this point; 1 : 2 : 4 : 8 would be the approximate relations existing between the four groups.)

(8) Though all the lines examined, with two possible exceptions, fall into one or other of these groups, the lines belonging to any one group differ to an appreciable extent among themselves in the amounts of their displacements.

(9) The relation between the pressure and the displacement is in general a linear one, but some photographs taken at 15, 20, and 25 atmospheres pressure give readings incompatible with this relation. Other photographs at 15 and 25 atmospheres present values which are compatible with it.

(10) The abnormal readings are approximately twice those required by the displacements at other pressures, if the displacement is to be a continuous and linear function of the pressure throughout.

(11) On the photographs showing abnormal displacements the reversals are more numerous and broader than they are on plates giving normal values, and there is some evidence in favour of a connection between the occurrence of abnormal displacements and the tendency of the lines to reverse.

III. *Reversal.*

(1) As the pressure is increased, reversals at first become more numerous and broader.

(2) The tendency of the lines to reverse reaches a maximum in the neighbourhood of 20 to 25 atmospheres, and a further increase in pressure reduces their number and width.

(3) Two types of reversal appear on the photographs, symmetrical and unsymmetrical.

(4) Within the range of pressure investigated, the reversals show no tendency to change their type.

(5) In the case of unsymmetrically reversed lines in the electric arc, the reversed portion does not in general correspond to the most intense part of the emission line, being usually on its more refrangible side.

(6) The displacements of the reversed parts of the unsymmetrically reversed lines of Group III. are about one-half the displacements of the corresponding emission lines. Indeed, the reversed parts of the lines of Group III. fall approximately in Group II.

(7) No relation between the order of reversal and the frequency of vibration, such as exists in the spark, has been observed in the iron arc for the ranges of wave-length and pressure examined.

IV. *Intensity.*

(1) The intensity of the light emitted by the iron arc is, under high pressure, much greater than at normal atmospheric pressure.

(2) Changes in relative intensity of the lines are produced by pressure. Lists of enhanced and weakened lines are given.

PARIS.

Academy of Sciences, September 23.—M. Henri Becquerel in the chair.—The red disease of the pines in the Upper Jura: E. L. **Bouvier.** This disease attacks *Abies pectinata* and leaves Picea untouched, and during the last year has assumed alarming proportions in the Jura. A fungus would appear to be the cause of the disease, and as this attacks pines only, it is proposed as a remedial measure to plant no more pines, but to replace them with Picea. Trees that are attacked should be cut down, since their vitality is already destroyed.—Parthenogenesis without oxygen. The elevation of the parthenogenetic larvæ of Asteria up to the perfect form: Yves **Delage.** The author has repeated the experiments of Loeb on the influence of the absence of oxygen, but cannot confirm them; oxygen does not appear to have the influence accorded to it by Loeb. The preparation of the solution for the development experiments has been simplified, and now consists of 300 c.c. of sea water, 700 c.c. of a solution containing 388 grams of saccharose per litre, 0·15 gram of tannin dissolved in a little water, and 3 c.c. of a normal solution of ammonia. The eggs, extracted from the ovary, are placed for one hour in 50 c.c. of this solution, then placed in sea water, two or three times renewed by decantation in order to remove all traces of the reagent. After eighteen hours the vessel swarms with living larvæ. Details are given of all the sea-urchins which have reached the fully developed stage, including one abnormal specimen possessing hexameral symmetry.—The series of methylation of ethyl alcohol from the point of view of the aptitude of isomerisation of the haloid esters: Louis **Henry.** The change of an alkyl halide into an isomer usually means the transference of the halogen atom to a carbon atom combined with a smaller number of hydrogen atoms than the original carbon atom.—The Daniel (1907) comet and its spectrum: Henri **Chrétien.**—Special iron castings, and more especially castings containing nickel: Léon **Guillet.** The net result of this, together with the previous work on the same subject, is that elements such as nickel, aluminium, and silicon, which dissolve in the iron, favour the formation of graphite. Elements which form a double carbide with cementite oppose the formation of graphite (manganese, chromium).—Experimental researches on the lesions following compression and crushing of the sensitive ganglia: G. **Marinesco** and J. **Minea.**—Memory in *Convoluta roscoffensis*: Louis **Martin.** Specimens of Convoluta removed from the seashore and placed in a jar in the laboratory oscillate for a certain time in synchronism with the time of the tides. Under certain conditions, which are described in detail, this memory disappears.—Contribution to the study of the lower valley of the river Ain: J. B. **Martin.**

HIGHLAND SPORT.

The Wild Sports and Natural History of the Highlands. By Charles St. John. Pp. xx+314. (London: John Murray, 1907.) Price 2s. 6d. net.

THE appearance of a reprint of the ninth edition of "The Wild Sports of the Highlands," first published sixty-one years ago, is sufficient proof of the permanent merit of that delectable book, but hardly affords a pretext for a set review of one so well and widely known. More to the point, perhaps, to recall the personality of the author, with which his many readers are less familiar than they are with his writings. A great-grandson of Lord Bolingbroke, the Tory Minister of Queen Anne and Secretary of State to the Old Pretender, Charles St. John became a clerk in the Treasury in 1828, where he proved a distinct failure. His heart was in the open air; his uncle, the second Lord Bolingbroke, lent him a lodge in Sutherland, where he had the good fortune to win the affections of Miss Ann Gibson, a Newcastle banker, whom he married in 1834. His wife not only brought him some money, but hearty sympathy in his devotion to sport and natural history.

In these pursuits the St. Johns might have passed their placid lives known to few except shepherds, gillies, and such venturous sportsmen as had discovered the splendid resources of the moors of Moray and Sutherland, had not Cosmo Innes, Sheriff of Moray, made acquaintance with the recluse and become impressed with his knowledge of woodcraft and wild animals Why, he asked, did not St. John turn his abundant leisure to account by writing on his favourite subjects? St. John laughed at the notion, saying he was quite pleased if he could manage to reply intelligibly to his few correspondents; but in the end Innes persuaded him to try his hand, so that, during the winter of 1844-5, St. John composed a few little essays on sport and natural history. One of these, entitled "The Muckle Hart of Benmore," Innes shaped into an article for the *Quarterly Review*, which so much delighted the editor, Lockhart, that St. John, stimulated by an unexpected honorarium, set to work in earnest, and before his early death in 1853, at the age of forty-four, he had completed the work presently under notice, "A Tour in Sutherlandshire," two volumes, published in 1849, and "Natural History and Sport in Moray," published ten years after the author's death. Death is the crowning act of all field sports, and St. John was an adept in pursuit; but it was from the by-products, so to speak, of a day's fishing, shooting, or stalking that he drew keenest delight—the behaviour, the attitudes, the natural traits of beast and bird. He found out for himself many secrets which are now well known to every field-naturalist. Here is one, for instance, with which all gamekeepers are familiar, but the cause of which remains still to be elucidated.

"It is a curious fact, but one which I have often observed, that dogs frequently pass close to the nest of grouse, partridge, or other game, without scenting the hen bird as she sits upon her nest. I knew this year of a partridge's nest which was placed close to a narrow footpath near my house; and although not only my people, but all my dogs, were constantly passing within a foot and a half of the bird, they never found her out, and she hatched her brood in safety."

Here, again, is a note the truth whereof is slowly gaining ground, although it has had to fight its way to acceptance through half a century of incredulity.

"With regard to the mischief done by owls, all the harm they do is amply repaid by their utility in destroying a much more serious nuisance in the shape not only of the various kinds of mice, but of rats also; these animals being their principal food and the prey which they are most adapted for catching."

There has been a controversy in the *Scotsman* lately about the food of the water-ousel or dipper, opinion appearing to be equally divided upon the question whether that bird devours the spawn of fish. The late Prof. Newton, Frank Buckland, and other good observers stoutly defend the dipper against the accusation, but St. John entertained no doubt about its truth. It is certainly difficult to undersand how a carnivorous bird, searching for food at the bottom of the water, should be so discriminating as to reject the ova of trout and salmon and feed only on aquatic insects and their larvæ. Prof. Newton, however, wrote with much confidence on this subject.

"By the careless and ignorant it is accused of feeding on the spawn of fishes, and it has been on that account subjected to much persecution. Innumerable examinations of the contents of its stomach have not only proved that the charge is baseless, but that the bird clears off many of the worst enemies of the precious product."—("Dictionary of Birds," p. 668.)

On the other hand, St. John's adverse verdict does not seem to have been based on actual observation.

"The water-ousel is supposed to commit great havoc in the spawning beds of salmon and trout, uncovering the ova and leaving what it does not eat open to the attacks of eels and other fish, or liable to be washed away by the current; and, notwithstanding my regard for this little bird, I am afraid I must admit that he is guilty of no small destruction amongst the spawn. . . . Notwithstanding the bad name he has acquired with fishermen, I never could make up my mind to shoot him."

It is a pity that grave charges like this should be laid upon such slight evidence. It must be a very feeble or poor-spirited eel that cannot help itself to as much spawn as is good for it without employing the dipper as pioneer. The question ought to be settled once for all by examining the contents of the stomach of a water-ousel shot among spawning salmon.

St. John's pages well bear re-perusal. They are charged with the free air of the moor and the loch, and, greatly as nature students have multiplied since his day, none of them gives more direct insight than he does into the *vie intime* of wild animals.

B B

SOCIOLOGICAL SCIENCE.

(1) *Sociological Papers.* Vol. iii. (1906). Published for the Sociological Society. Pp. xi + 382. (London: Macmillan and Co., Ltd., 1907.) Price 10s. 6d. net.

(2) *Heredity and Selection in Sociology.* By G. Chatterton-Hill. Pp. xxxii + 571. (London: Adam and Charles Black, 1907.) Price 12s. 6d. net.

(1) THIS volume is quite equal in interest to either of its predecessors. Among the papers which it comprises, those contributed by Dr. Archdall Reid and Mr. A. E. Crawley are of preeminent interest, owing partly to the merit of the papers themselves, partly to the discussions which followed, and the written communications elicited from English and foreign authorities. Dr. Reid took as his subject "The Biological Foundations of Sociology." The present evolution of civilised man is, he maintained, mainly against disease. Intellectual power in a nation depends almost entirely upon the environment of the individuals that make up the nation—in fact, upon education. Education ought to make the pupil think instead of overtaxing his memory. In particular, medical students should study heredity. Until doctors as a body are masters of what is known on this subject, the medical profession will never occupy the place that properly belongs to it. Dr. Reid's statement of his case was at once trenchant and guarded, and the criticisms fell mostly wide of the mark. But is there not, in addition to the evolution against disease on which he lays so much strees, a moral evolution going on? There is everywhere a great demand for honest men. Steadiness and trustworthiness are the qualities which modern civilisation most requires. In the lowest stratum of society, from which the casual labourers mainly come, such things are perhaps not important enough to have survival value. But in all the strata above the very lowest the qualities of steadiness and trustworthiness are those which pay, are those which enable a man to bring up a family; and men and women who are deficient in them sink lower or are eliminated altogether. Dr. J. L. Tayler's paper on the study of individuals (individuology) and their natural groupings (sociology) is to some extent an answer to Dr. Reid's. Instead of finding in disease an influence which strengthens the race, he holds that slums favour barbaric types, whereas with higher social conditions, while diseases testing physical endurance are destroyed by hygienic developments, others arise that test mental tenacity and strength.

Mr. A. E. Crawley's paper on the origin and function of religion is one of great interest. He holds that the problem of religion is a psychological problem, and that the general culture of the savage is entirely religious. Religion is a "psychic tone or temper or diathesis." The religious emotion consecrates all such elemental concerns as birth, puberty, marriage, sickness, death, and burial. It is, in fact, the "affirmation and consecration of life." Religion, therefore, rests on a basis of individualism, though the heightening of the individual life leads to an expansion of individuality, and so to sympathy and altruism.

In a written communication Prof. Starbuck points out that not only religion, but art, morality, and philosophy, heighten and deepen life. The feeling of awe in the presence of a supersensuous reality is an essential part of religion.

We have space for little more than a bare enumeration of the other papers:—"A Practicable Eugenic Suggestion," by Mr. W. McDougall; "The Sociological Appeal to Biology," by Prof. J. A. Thomson; "A Suggested Plan for a Civic Museum and its Associated Studies," by Prof. Patrick Geddes; "Sociology as an Academic Subject," by Prof. R. M. Wenley—an interesting account of sociology in America; "The Russian Revolution," by G. de Wesselitsky; "The Problem of the Unemployed," by Mr. W. H. Beveridge—a short, sensible paper followed by a discussion in which Mr. J. A. Hobson and Mr. Rider Haggard took part; "Methods of Investigation," by Mrs. Sidney Webb; "The So-called Science of Sociology," by Mr. H. G. Wells.

(2) From beginning to end this is a very interesting book. It is the result of much thought on great subjects, and it is written in clear and forcible style. But many of the questions discussed are highly controversial, and it is only to be expected that among competent critics there will be not a few who will come to different conclusions or who will remain unconvinced.

Part i. is introductory, and consists of a general account of evolution. The author is a strong believer in Weismann, whose doctrines he vigorously champions. The criticism suggests itself, that since it is a cardinal doctrine of Weismann, accepted unconditionally by our author, that, as soon as natural selection ceases to work, degeneration sets in, it would have been better to give more evidence of this from the organic world. On the other hand, too much, in the opinion of the present writer, is made of germinal selection—a hypothesis which rests on a very unsure foundation.

In part ii. we get to the heart of the book. Its title is "Social Pathology," and in it our author deals very ably with some of the most difficult problems of modern civilisation. Among the most civilised nations suicide, insanity and syphilis are increasing. There is, besides, much inverse selection, elimination, that is, of many who under more natural conditions would be best fitted to survive, while, on the other hand, an artificial environment brings about the survival of the weak and sickly. No doubt there is much reason for our author's somewhat desponding tone. But is not suicide, however clumsy its operation, one of the means by which the unfit are eliminated? And does not drink remove thousands of the most weakly before they have propagated their kind? Though it degrades the individual, does it not keep up the physical strength of the race? The survival of the weakly has undoubtedly a deplorable effect. Altruism and science strive to keep every child that is born alive until it attains to manhood or womanhood. Here is the fountain-head of the physical degeneration of civilised races. Still, Mr. Chatterton-Hill is, perhaps, over-pessimistic. There is still an enormous amount of elimination; not far short of fifty per cent.

of our population die before the average age of marriage.

The possible remedies for the diseases of our social system are discussed. The increase of suicide, we are told in the very interesting discussion of the subject, is due to want of integration. We live in an age of rampant individualism, for which, however, socialism supplies no remedy. Religion has not the hold on man that it once had. Family life is less strong than it was, and tribes and village communities are things of the past. Men make away with themselves because they have no strong ties and no strong interests. In times of political commotion there are fewer suicides, apparently because there is plenty to think about. To a great extent the theory of want of integration explains the facts. But is our author right when he maintains that Roman Catholicism is a stronger integrating force than Protestantism? Is not the form of faith rather a symptom than a cause? The most go-ahead races have seceded from the church of Rome. The Roman Catholic peoples are more primitive and less industrial; and in this, as in most social questions, there are many factors to be taken into consideration. But however much we may disagree with some of Mr. Chatterton-Hill's conclusions, the book is a book to be read. **F. W. H.**

OUR BOOK SHELF.

British Rainfall, 1906. *On the Distribution of Rain in Space and Time over the British Isles during the year* 1906. By Dr. H. R. Mill. Pp. 100+280. (London: Edward Stanford, 1907.) Price 10*s*.

THE present volume is the forty-sixth of this valuable and unique publication; it gives, in various forms, the results of observations made at 4267 points in the British Isles. The plan of the work is the same as last year, being divided into two parts:—(1) original papers and organisation reports, (2) monthly and yearly rainfall tables, particulars of wet periods, and observers' notes on the principal meteorological occurrences of the year.

Dr. Mill gives an interesting discussion of the great snowstorm of December 25–26, 1906, illustrated by two maps; one of these shows the rate of movement across the country with greater detail than has probably been previously attempted. The area covered by the storm extended from the north-west of Scotland to the English Channel, the advance being least rapid in the north, where it was 12½ miles an hour, and most rapid in the south, where it was about 19 miles an hour; a motor-car could have kept out of the storm without exceeding the legal speed limit.

The frontispiece is a coloured map showing very clearly the relation of the rainfall of 1906 to the average of 1870–99. Generally speaking, the fall over the whole country in 1906 was near the average; Scotland had a pronounced excess, and Ireland a scarcely less pronounced deficiency. The timely revision and publication of such a mass of materials is only rendered possible by the interest taken by the staff in the work and by some valued voluntary assistance. The usefulness of the undertaking is recognised by such public bodies as the Meteorological Committee, the Metropolitan Water Board, and others, who pay for the information they receive, but the main burden of expense has been hitherto borne by the observers and those interested in rainfall investigations. We agree with Dr. Mill in thinking that no piece of work of equal magnitude is done so cheaply.

Le Feste Giubilari di Augusto Righi. Pp. vi+143. (Bologna: Nicola Zanichelli, 1907.)

THIS little work is a *Festschrift* in honour of Prof. Righi, giving an account of the ceremony recently held to celebrate the completion of his twenty-fifth year of university teaching. This period really expired in 1905, but it was decided by the committee organising the *fêtes* to postpone the celebration so as to make it coincide with the inauguration of the new Institute of Physics at Bologna, which is placed under Prof. Righi's charge. The ceremony actually took place on April 12. Prof. Righi delivered his first lecture in the new building, choosing for his subject the "Hypothesis of the Electrical Nature of Matter." Prof. Blaserna, on behalf of the subscribers, then presented the lecturer with a bust of himself in bronze. Congratulatory letters and telegrams received from all parts of the world were subsequently read. The *Festschrift* contains Prof. Righi's lecture printed in full, together with all speeches, letters, &c., received; it is illustrated with many photographs of Prof. Righi and of the new institute. A complete list of Prof. Righi's scientific publications, numbering two hundred and seventeen in all, and a chronological review of his career are appended.

The Half-tone Process. By Julius Verfasser. Fourth edition. Pp. 348. (London: Iliffe and Sons, Ltd., 1907.) Price 5*s*. net.

THE author describes his work in a sub-title as being "a practical manual of photo-engraving in half-tone on zinc, copper, and brass, with a chapter on three-colour work." In preparing the new edition he has thoroughly revised the work, and added to it so that it describes as far as possible the making and proofing of half-tone blocks as at present practised. The subject is treated in a strictly practical way, obsolete methods and historical details find no place in it, nor does the author venture into the future. Apparatus that every worker must buy is not described with excessive minuteness, but such information as is necessary for using it to the best advantage is clearly set forth. No theoretical considerations are introduced, except in connection with such matters as the cross-lined screen and the management of electric arc lights, and then only in the simplest manner as being the best guide to the intelligent use of the apparatus. After ten chapters on appliances, the author describes with all necessary formulæ the operations of making the negative, printing, etching, finishing, mounting, and proofing the plates. The chapter on the three-colour half-tone process assumes a general knowledge of the principles involved, and refers only to the additional manipulation necessary. The two examples of three-colour work are not much credit to the process, but the other illustrations, which are numerous, are useful and good.

The Alphabet of the Universe: Notes for a Universal Philosophy. By Gurney Horner. Pp. 44. (London: Hayman, Christy and Lilly, Ltd., 1907.) Price 1*s*. net.

THE aim of the author of these "skeletonic and informal notes" is "to find the one objective 'Something'—a quest in which humanity has hitherto been baffled and defeated." He is so obviously convinced that notwithstanding "the failure of Plato, Aristotle, and all later philosophers," he has really solved "the problem of the *Method* of the Universe" that he may perhaps be forgiven for allowing his "epoch-making discovery" to be announced in language which inevitably prompts the cautious reader to assure himself that he has not been entrapped by the advertisement of a new patent remedy. Mr. Horner appears to be entitled to the credit of having arrived twenty-five years ago at the now fashionable doctrine that man is essentially a behaving animal—or, as he expresses it, that "man's life is made up simply of a series of acts"—and of having anticipated the Pragmatists in the deduction "that acts form the only proper basis of philosophy." Unfortunately, he has shown in these pages no competence to construct upon this basis anything with which, even in these hard times, philosophy should be asked to allow her name to be connected.

The More Important Insects Injurious to Indian Agriculture. Memoirs of the Department of Agriculture in India, vol. i., No. 2, Ento. Se. Pp. 139+v; 80 figures. By H. Maxwell-Lefroy. (Pusa: Agricultural Research Institute, 1907.) Price Rs. 3.

THE above-named paper is a very excellent foundation for the young economic entomologist in India to work upon. The chief insects known to be injurious to crops in India are briefly described in systematic order.

The method of treatment of this subject is novel, and might well be copied by others compiling similar lists.

The technical name of each pest is given, and then one or two references of interest and a short, concise description of the insect follows. Short notes of the distribution, biology and food plants are appended, and finally the writer's opinion as to the status of the insect as a pest. A large number of the adults are figured, and in a few instances the larvæ also.

Showing the backward state of economic entomology in India is the fact that only four aphides are placed in this list. A sound foundation is, however, being laid, and we are glad to learn that a supplementary list is to follow when the material is available. In all 131 pests are dealt with, some of which are well known in Europe, such as the diamond-back moth, the turnip moth (*Agrotis segetis*), the large cabbage white, convolvulus hawk moth, the corn aphis, cabbage aphis, and thistle aphis.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The "Friar's Heel" or "Sun Stone."

IN an old number of *Notes and Queries* (4, v. 598) E. Dunkin asks "why the 'Friar's Heel' at Stonehenge is so named," and the only answer I can find in the bibliography of Stonehenge (*Wilts Archaeological Magazine*, vol. xxxii.) is as follows:—"It may have been called the Heel stone," observes Prof. Flinders Petrie, "from A.S. *helan*, to hide or conceal, just as a cromlech at Portisham, Dorset, is called the 'Hel-stone.'"

The word *Heal* or *Hele* is used in N. Wiltshire in this sense. "When the ground is dry and hard and the wheat when sown does not sink in and get covered up at once, it is said not to *heal well*" (Dartnell and Goddard, "Glossary of Wiltshire Words," 1893), but this meaning is more applicable to the cromlech than to the upright stone at Stonehenge.

Modern researches as to the date of the erection at Stonehenge point to a time when a Celtic word rather than an A.S. word would have been in use, and it has occurred to me that the word *Heol*, which is the Breton word for *the Sun*, may be an explanation of the name of the stone in question, as it is the stone used for the observation of the rising sun at Midsummer. It would be interesting to learn from Celtic scholars what equivalent Celtic word was in use in Britain when *Heol* was the word used in Brittany, and whether *Heol* or *Hel* would be the Cornish form of the Welsh word for the sun. The Rev. J. Griffith tells me "that *houl* is the oldest Welsh form of the word—then *heil*, and now in literary Welsh *haul*."

The foolish mediæval legend of the devil flinging the stone at a mocking friar and hitting him on the heel is evidently of very late date, but it is singular that a similar legend is attached to the "Hel Stone" in Dorsetshire, where the story is that the devil, playing at quoits in the island of Portland, flung the Hel Stone across to Portisham (see Hutchings' "Dorset," i., 554).

There is another Hel Stone near, so called in common with the cromlech at Portisham, and it stands in a small combe to the north of Long Bredy hut; it is a rude mass about 7 feet high and 7 feet wide, whilst the capstone of the cromlech at Portisham is 10 feet by 7 feet by $2\frac{1}{2}$ feet (Warne's "Ancient Dorset," pp. 111–135).

By the time the legends of the "Friar's Heel" and Hel Stone were invented, the old language would have been a thing of the past, but possibly the old name lingered in the memory of men wholly ignorant of its significance, giving rise to the traditions.

October 4. T. STORY MASKELYNE.

The Double Drift Theory of Star Motions.

PROF. J. C. CHAMBERLIN'S planetismal hypothesis has given geologists a great deal of matter for thought, and on the whole the phenomena with which they are acquainted appear to fall into line when the earth is considered as a body that has always been solid. The cosmical aspect of the question, which Prof. Chamberlin introduced in advancing his hypothesis, geologists are unable to judge, and they are waiting until astronomers give them an opinion before adopting the hypothesis on the larger scale. On the planetismal hypothesis our stellar system is a disc the edge of which is the Milky Way; beyond lies another stellar system, the so-called nebula in Andromeda, for all the most distant stars in the neighbourhood of the nebula appear to be this side of the luminous disc. If our stellar system is of the same nature as that of the nebula in Andromeda, then it must be a spiral nebula with two equivalent arms originating from a central core and winding spirally round the centre in approximately the same plane. Suppose our sun had experienced a gravitational drag and was moving at a less rate than the general average of the other stars, or suppose its spiral course was steeper than the general average, and hence its angular velocity less, then an observer regarding the rest of our stellar system from our planet would see the stars near the centre of the spiral travelling in two directions, those on this side of the centre travelling from right to left, and those on the other side in the reverse direction. Is this not a possible explanation of Prof. J. C. Kapteyn's double-drift theory of star motions? It explains why the two systems travelling in opposite directions should be of equal composition and proportions, but it necessitates that in the region of the sky opposite to that in which the double drift has been observed the drift should be simple.

The explanation also presupposes that our stellar system was once more closely aggregated, and because there is no central core to our system it must be of less bulk than that of the nebula of Andromeda. The two stellar systems, once consisting of closely packed stars and more or less spherical, travelling in opposite directions and approaching each other within reach of the action of gravitation, would have experienced disruption, each throwing out equal equatorial prominences on the same principle as that which produces the tidal bulges. On the nearer approach of the two systems to each other, the smaller of the two, our stellar system, would have experienced the entire disruption which has reduced it to the tenuity which it exhibits, whereas the larger stellar system, the nebula in Andromeda, would have been enabled to keep its central core.

The Origin of Radium.

IN an earlier communication to NATURE (September 26, p. 544) I mentioned some experimental proof which had been obtained of the existence in uranium minerals of a new radio-active element differing from those which have previously been identified. More conclusive evidence of the individuality of this new substance has now been obtained through the examination of the properties of its α radiation. The α rays which it emits are much more readily absorbed by aluminium than the α rays from polonium, with which it has been directly compared. Their apparent range in air determined by the scintillation method is less than 3 centimetres, and a more accurate determination is somewhat difficult, since it has not yet been found possible to obtain the new substance entirely free from thorium. Certain operations are now being carried out with considerable quantities of a uranium mineral containing no thorium which it is hoped will result in the separation of a highly active preparation of the new body free from other radio-active substances. The short range of the α particles is, however, sufficiently characteristic to serve as a definite means of identification.

The new substance also gives out a β radiation which is much less penetrating and more easily absorbed than that from uranium, the value found for the coefficient of absorption being about 1·8 for aluminium.

Experiments which have been carried out with the view of obtaining a quantitative separation of this new element from small quantities of very pure uraninite have given results which are in good agreement with one another, and which indicate that the activity of the new element in equilibrium with radium is about 0·8 of the activity of the radium itself with which it is associated. This is about the value to be expected if the new substance is intermediate between uranium and radium when the ranges of the α particles are taken into consideration.

The name "ionium" is proposed for this new substance, a name derived from the word "ion." This name is thought to be appropriate because of the ionising action possessed by this element in common with the other elements which emit α radiations.

Sloane Laboratory, Yale University, New Haven, Conn., September 21.

Excretion from Plant Roots.

THIS subject, discussed at intervals over the greater part of a century, has been recently revived. Mr. Pickering has suggested that the effect produced by one plant on another is probably due to the indirect action of bacteria. Dr. Russell attributes it to chemical changes in the soil, whilst Schreiner and Reed in America (Bulletin of the Torrey Botanical Club, June) and Mr. Fletcher in India have described experiments tending to show that some deleterious substance is excreted from the root. The questions incidentally raised by these several experimenters are not all identical, because, as Mr. Pickering points out, his work has to do with initial stages of growth, while that of others relates to subsequent development.

So far as *excretion* is concerned, it seems to be almost excluded as a possible explanation, because it would demand open orifices in the root which do not exist. There is nevertheless another line of thought which may have a more likely bearing on the subject. I refer to ionised changes such as occur when hydrogen chloride forms inside the red-blood corpuscle and sodium carbonate on the outside, or when sodium hydrate forms in the blood and hydrogen chloride in the stomach. Both these changes are due to the selective power of the living cell wall; and similarly it is probable that the cell wall of the root exercises a like property, and that the substances called plant foods do not pass into the root cell as such, but suffer change. Thus it is explained why the liquid outside the root becomes more basic, that on the inside more acidic (Hall and Miller, Proc. Roy. Soc., 1905).

May it not be equally possible that, owing to such changes, harmful substances may be formed in the soil solution?

Pleochroic Halus.

IN the March number of the *Philosophical Magazine* I gave reasons for believing that the pleochroic halos of certain micas are referable to the radio-activity of the enclosures which are invariably associated with the halos. I cited in favour of this view the facts that all minerals definitely recognisable as forming the centres of halos are radio-active; that the perfect sphericity of the halo in a medium such as mica precluded any explanation involving diffusion or segregation of colouring matter, and that there was a very exact agreement between the known effective penetrability of α rays in media of this density and the maximum radius attained by the halo. I subsequently found, by examination of specimens kindly lent to me by Dr. Teall, that the same reasoning was applicable to halos formed in cordierite.

When first conceiving this idea, I started experiments on cleavage flakes of biotite to ascertain if halos could be induced by enclosing between the flakes specks of radium bromide. For some two months I kept these preparations under observation, but no change was apparent. They were then put aside in view of experiments which necessitated my abstention from any contact with radio-active preparations.

Within the last few days Dr. Teall has directed my attention to the (independent) work of O. Mügge, of Königsberg i. Pr., which appears in the July number of *Centralbl. für Min.*, in which a coloration was successfully induced in cordierite by application of radium, a coloration agreeing in properties with the halos in cordierite. This sent me back to my slides, and I find that a brown coloration has now developed around the larger radium specks. These stains have all the appearance of halos save that the radius is greater and the boundary less defined, differences at once explicable on the fact that the rays here travel in air before entering the mineral, and hence possess a greater, and at the same time a less sharply defined, range of effectiveness. The coloration is faintly pleochroic, the direction of greatest absorption agreeing with that of some naturally occurring halos present in the flakes.

There is, of course, nothing in these observations to prove that the effects observed are obtained in the precise manner in which radio-active enclosures appear to affect mica. It may be that sufficiently intense β radiation may produce effects which in the mineral are almost certainly referable to α rays. Still more protracted observations will be required to differentiate between the rays. However this may be, the cumulative evidence seems to leave no room for doubt that these extraordinary halos are indeed due to radio-activity. In these halos we have, I believe, the only instance so far observed in nature in which the presence of radium can be determined by direct eye observation of a radio-active effect.

Geological Laboratory, Trinity College, Dublin, September 30.

Apus cancriformis in Great Britain.

SINCE the publication of Baird's "Natural History of the British Entomostraca" (1850), no record of the occurrence of *Apus cancriformis* in the British Isles has, so far as I am aware, been published. Mr. Scourfield, in his "Synopsis of the British Fresh-water Entomostraca" (Journ. Quekett Micr. Club, [2], ix., 1904), remarks of this species:—"it is doubtful whether this ought to be included in any modern list of British Entomostraca."

It is therefore of great interest to know that *Apus cancriformis*, so long lost to observation, has actually reappeared in this country. It was found, during last month, by my friend Mr. Frank Balfour Browne, in some numbers in two small shallow pools on Preston Merse, near Southwick, in Kircudbrightshire. These pools, he believes, may be somewhat brackish, as they are probably occasionally covered by the sea. The specimens which he was good enough to send me were all females, mostly of a good size, and bearing eggs.

ROBERT GURNEY.

Sutton Broad Laboratory, Catfield, Great Yarmouth, October 6.

WHEN THE REINDEER LIVED AT MENTONE.[1]

OF all Quaternary sites associated with the remains of man none is more important than that constituted by the grottoes of Grimaldi. The deposits are of great depth, and rich in archæological and anthropological remains. They exhibit, moreover, a perfect continuity, and enable us to review in definite order the events of a remote and extended period. It is fortunate that the explorations were undertaken by such savants as Villeneuve, Boule, and Verneau, and that the results of their labour have been enshrined in so noble a work as that under notice. The book is in three folios; the first furnishes us with a full topographical description and historical account of the locality, which takes its name from Charles Grimaldi, Prince of Monaco, in the fourteenth century. The rocks which contain the caves are of superior Jurassic formation, and from their rose-red colour have been denominated the Baoussé Roussé, or Balzi Rossi. They originally projected as a V-shaped mass into the Mediterranean, the apex of the V being the Baoussé de Torre, at the foot of which are two caves, the Barma Grande and the Barma della Cippia di Ponte. On the western side of the projection, passing from the Baoussé de Torre, we meet in order La Grotte du Cavillon, La Grotte de Florestan, L'Abri Lorenzi, and La Grotte des Enfants. On the eastern side are La Grotte du Prince and two other caves of minor importance. The caves all open by high, narrow ogee mouths towards the Mediterranean (Fig. 1). They are filled with deposit to the height, in some cases, of 40 metres. In this deposit foyers can be recognised; a foyer is defined as a surface which, from the presence of cinders or products of industry, may be regarded as affording evidence of man's presence.

So far back as the middle of last century the caves were known to contain deposits of scientific value. "Some time before 1848" Prince Florestan I. of Monaco had dispatched a box of earth from one of the caves to Paris for examination. From that time onward numerous workers directed their attention to the caves, particularly Prof. Forel in 1858, and M. Rivière from 1871–1895. In 1882 Prince Albert of Monaco carried on investigations, and issued explicit instructions as to the methods to be employed, instructions which left nothing to be desired on the score of precision. During these excavations human skeletons were found, the first on March 26, 1872, by M. Rivière, in La Grotte du Cavillon, at a depth of 6·55 metres below a layer of stalagmite. The year following three skeletons were found in the Barma della Cippia di Ponte; in 1874 and 1875 two young skeletons were found in La Grotte des Enfants, and no less than seven were obtained from La Barma Grande.

Meanwhile, much discussion had arisen as to the age of the deposits. M. Rivière attributed them to the Quaternary period. M. Mortillet, on the other hand, regarded them as Neolithic, largely, however,

FIG. 1.—General view of the grottoes of Grimaldi. Seen from the sea.

[1] "Les Grottes de Grimaldi (Baoussé-Roussé). Tome i. Fasc. 1, Historique et Description. By M. L. de Villeneuve. Pp. 70. Tome i. Fasc. 2, Géologie et Paléontologie. By Prof. Marcellin Boule. Pp. 71–156+plates. Tome ii. Fasc. 1, Anthropologie. By Dr. René Verneau. Pp. 212+plates. (Imprimerie de Monaco, 1906.)

on the unsubstantial ground that the dead had been designedly interred. Three polished stone axes in the Genoa Museum from the collection of Prof. Pérès were believed to be derived from these caves. Rivière himself had obtained from this site a polished axe-head and a ring or disc *en jayet*. During the discussion it was shown that the axes in the Genoa Museum came from Nice, and there was strong probability that the axe and ring found by Rivière lay on the deposit rather than in it. All went to prove that further and more precise excavations were necessary before the age of the deposit could be definitely fixed. It is with these later investigations that the second and third folios are concerned.

The second folio is divided into three sections. In the first the various cave-beds are described with their petrographical characters; a list of the fossils found in each bed is given. The second section is concerned with the marine formations observed at the entrance and in the interior of the caves, and with the geographical changes which have taken place in the bed of the Mediterranean during Quaternary time. An interesting attempt is made to correlate the movements of the level of the Mediterranean with the movements of the ice, and to show that great glacial invasions are coincident with great positive movements of the sea, while interglacial periods correspond to negative movements. It is suggested that the negative movement of the Inferior Pleistocene was possibly able to re-establish relations between the large Mediterranean islands and the neighbouring continents, and that in this way may be explained the similarity in the contemporary fauna and palæolithic tools of south Europe and Africa. The third section of the folio is devoted to the study of the fossil animals which have been discovered during the excavations. It throws light on the fauna during successive periods, and discloses the danger of dating deposits from implements alone, for in these caves Moustiérien implements are found in association with a Chelléen fauna.

The illustrations, which form a very marked feature of the work, show sections of the caves, and clearly demonstrate the positions of the foyers and skeletons. The bathymetric charts of the Mediterranean are deserving of special mention.

The third folio is largely devoted to anthropology, but to some extent partakes of a *résumé*. The human skeletons are described in great detail, and are compared with each other, with Cro-Magnon Man, with the Negro, and with the European of to-day.

All the skeletons save two conform, with but slight variation, to the Cro-Magnon type. They resemble that type in stature, which is high, and in the shape of the skulls, which latter are dysharmonic, the crania being long while the faces are low and wide. The nose is leptorhine, depressed at the root, yet projecting sharply from the face. The orbits are rectangular and microseme; the supraciliary eminences are faintly developed; the mandible is robust, possessing a prominent chin. Certain negroid traits are noticeable in the skeletons; the proportions of forearm to arm, of leg to thigh, of lower limb to upper limb, resemble those found in the Negro and differ from those in the European. The two skeletons above referred to as not conforming to this type were discovered on June 3, 1901, in La Grotte des Enfants (Fig. 2). They were found at a depth of 8·5 metres, and are the most ancient human remains from these caves, although it should be remarked that a skeleton of the Cro-Magnon type was found in the same cave at a depth of 7·8 metres. The two skeletons were those of an old woman and a boy. The skulls are of the usual type in being dysharmonic, the cranium long, the face low and wide. The orbits are microseme, the forearm and leg relatively long. They differ from the type in

FIG. 2.—Skeletons of an old woman and a boy, from La Grotte des Enfants.

stature, which is not high, in the nose being platyrhine, in the face being prognathous, with the chin *fuyant*. On these grounds the two skeletons are separated from the rest and regarded as constituting a special type—the Grimaldi type. Before accepting such a separation, it should be remarked that little importance can be attached to stature when one of the examples is a boy, the other an old woman. Again, the skulls were obtained in a more or less fragmentary state, and the platyrhinity and prognathism might quite easily be in part due to the reconstruction. Sex, age, and individual variation might also account for some of the difference. It is unfortunate that more examples—and those examples of adults—are not forthcoming.

One of the most remarkable features of the boy's jaws are the teeth, which form the subject of a special report by Prof. Gaudry.

It will be seen that the work is to an unusual degree exhaustive, and has been performed with an attention to scientific accuracy for which palæontologists cannot be too grateful. The observations are beyond dispute, and the theories advanced are suggestive and worthy of careful consideration. The work furnishes us with the most important collection of data as to the nature and habits of Quaternary Man, since the discoveries in the caverns at Spy. We know that Man, even in the Pleistocene, buried his dead, sometimes on intact foyers, sometimes in holes dug in the floor of the cave, sometimes in rude cists consisting of upright stones supporting horizontal flagstones. Frequently he buried them in beds of ologist iron. In the Barma Grande there is evidence of disposal of the dead by incineration. With the dead were buried such trinkets as necklaces, bracelets and anklets made of perforated teeth, shells, and vertebræ of fish.

As to the people who lived in these caves, we can with considerable confidence correlate them with the Quaternary hunters in the valley of La Vézère, with those whose remains have been found at Laugerie-Basse, Gourdan, Chancelade, and Cro-Magnon. It is probable, however, that the hunters of the Grimaldi Mountains were the earlier.

In conclusion, we can unhesitatingly state that the Grimaldi caves have furnished us with the most complete picture we yet possess of Man's life in Europe during Mid-Quaternary time. William Wright.

MEDICAL EDUCATION AND SOME OF ITS PROBLEMS.

By a time-honoured ordinance, the opening of the medical session at the beginning of October is made the occasion for the delivery of inaugural addresses at the various schools of medicine. In London, medical education is in a somewhat transitional stage, and it may be interesting to inquire whether the addresses delivered shed any light on the problems that have to be solved. At the present time in London there is a need for concentration of the preliminary and intermediate studies, chemistry, biology, anatomy, and physiology, taken during the first two years of the curriculum, and until recently taught in every medical school. Now these are scientific subjects, and could more efficiently and less expensively be conducted in fewer centres with better equipped laboratories than has hitherto been the case. In this way it would be possible for some, at least, of the medical schools to devote all their energies and funds to the professional training of the last three years of the curriculum. Various plans have been suggested for effecting this. Some years ago, a scheme for a central institute at South Kensington for teaching the preliminary and intermediate subjects was inaugurated. It was an ambitious scheme requiring some 200,000*l.* for its realisation, and though in theory a good one, is probably not the best practical one for London. London is too large to have a single centre; and University and King's Colleges, and one or two of the medical schools, have definitely decided to continue teaching the preliminary subjects. Moreover, by a recent vote of the Faculty of Medicine of the University of London, the scheme of a Central Institute at South Kensington has been negatived, and the former policy reversed.

Another scheme is actually in being and seems to be working well, and might be extended; this is the drafting of the Westminster Hospital students to King's College, and of the St. George's Hospital students to University and King's Colleges, for the preliminary and intermediate studies. Speaking of this departure, Dr. Allchin, of Westminster Hospital, in his opening address at King's College, said:—

"When in 1899, after the report of Lord Selborne's Commission on a University for London, the medical demand for a re-constitution of the University took organised and coherent shape, the urgent need that there was for some concentration in medical teaching was always placed among the foremost arguments. The feeling generally among the medical schools at that time—or certainly of the great majority of them—was in favour of some scheme by which certainly the elementary subjects of the curriculum, and to some extent also the intermediate, should be taught at fewer centres, thus leaving the smaller schools at least, on whom the pressure of expenditure was relatively the greatest, free to devote their energies entirely to teaching the later subjects. But so far the University of London has utterly failed to bring about any concentration whatever during the seven years of its re-constituted existence, and, what is almost as serious, it has by the course it has followed converted what was seven years ago a widespread feeling among the metropolitan medical teachers of welcome towards the principle of concentration into one of very considerable hostility towards the principle, and has led to many of the schools resolutely opposing any coalescence. In 1905 a coalescence with regard to preliminary studies was arranged between the Westminster Hospital School and King's College, and has worked satisfactorily. I believe that if the University six or seven years ago, when the medical schools would, for the most part, have welcomed the principle of concentration, had exercised upon the different schools a wise and judicious pressure towards giving effect to this principle, much might have been done in this direction."

Certainly this scheme has much to commend it, and with some financial aid from the University it is difficult to see that an arrangement of this kind would be less efficient than a central institute; it would be far less costly than the latter, and, therefore, more likely to be in working within a reasonable time. The last is an element of some moment, for there can be no doubt that London has suffered by contrast with the splendid laboratories and facilities of the new provincial schools, and students in the London schools have diminished in numbers. Long as the five years' curriculum is for the pockets of those who have to pay the fees, it is none too long for the acquirement of the knowledge required for the pass examinations; in fact, it is the exception for a student to obtain a qualification under about six years. It has therefore been suggested that the curriculum might be lightened by relegating to the school science studies the physics, chemistry, and biology required. This plan commended itself to Sir Douglas Powell in his address at University College. He said:—

"I am myself decidedly of opinion that most, if not all, of the chemistry, biology, and physics required for the ordinary pass examination might, and should be, and in time will be, included in the public-school science studies, and be cleared off before the student enters upon the medical curriculum at all; so that the first two years of the student's time may be given up almost entirely to anatomy and physiology, including some comparative anatomy, so far as it may be illustrative of human anatomy, and some physiological chemistry."

Intimately associated with the question of medical education is that of qualifying examinations. In England, Scotland, and Ireland, there are no fewer than twenty-one bodies which have the power of granting degrees or diplomas qualifying to practise medicine and surgery, and there must of necessity be considerable variations in the standard of, and in the conditions of admission to, these examinations. To bring order out of chaos, the only practicable plan would be the institution of a State examination, which everyone should be required to pass, irrespective of any degree or diploma he should otherwise obtain, as advocated by Dr. Ewart in his address at St. George's Hospital. The London students have a grievance in that the diploma of the Royal Colleges does not entitle the holder to an M.D. degree, and the University of London degree is comparatively inaccessible to the average student. To meet this difficulty, Dr. Allchin frankly contended that the University should grant a degree in medicine accessible under reasonable conditions to the average man, reserving for those who desired them honours examinations more stringent than the pass ones. Sir Douglas Powell also expressed his regret that the diploma of the Royal Colleges could not be signalised by some more definite designation than it now carries. He would make any further work beyond the requirements for the qualifying examinations more strictly post-graduate work. He says:—

"When a man has qualified in his first two years' subjects by passing the required examination, he would do well to proceed to a six months' or a longer course in those subjects for the higher university degrees, and when he has qualified in the second grade and obtained his licence to practise he may proceed to post-graduate clinical, pathological, or other research for his final examinations in those degrees or for the membership of the Royal College of Physicians or fellowship of the Royal College of Surgeons. A university degree and the higher grades of medicine and surgery should be regarded as something beyond and in a sense outside a qualification to practise—as an academic or other distinction for the attainment of which a man may take as long as he pleases, but for which certainly some additional work in each grade or period of his studies should be required."

There is a parallel to this in the case of veterinary medicine, in which the University degree does not take the place of the diploma of the Royal College of Veterinary Surgeons, as it is not a licence to practise, as was pointed out by Prof. Lander in his address at the Veterinary College.

Post-graduation study and research in medical subjects are essential if the practitioner is to keep abreast of recent advances, if the science of medicine is to advance, and the public health to improve. In London, with its seven millions of inhabitants, the supply of clinical material for teaching and research is unique, but there can be no question that it is not utilised nearly to the full extent. The West London Hospital, the London School of Clinical Medicine, the Polyclinic, and a few hospitals are doing excellent work in post-graduate teaching, but if London is to be, as it ought, a great centre for post-graduation work, there must be more coordination and concentration among the numerous special hospitals. The system which makes our hospitals and medical schools dependent on voluntary support has led to the founding of a number of hospitals for special diseases, widely scattered, and therefore largely unavailable for teaching purposes, draining the general hospitals of the particular cases they admit, and using up public subscriptions which might be better utilised. There can be no doubt, on the score of economy alone, that a combination between many of the special hospitals would be of advantage, a view which has been taken by the King's Fund. The poor-law infirmaries also are almost entirely unutilised, yet contain material of the utmost value for teaching and research. Sir Douglas Powell says:—

"I cannot but think further that some affiliative grouping of the great clinical hospitals about the three university centres would be of great value in point of view of financial economy and strength of teaching. It is very possible, too, that special hospitals and infirmaries might be more utilised than they now are for clinical teaching material, and especially for post-graduate teaching."

As regards research, the special hospitals, the poor-law infirmaries, and the hospitals of the Metropolitan Asylums Board offer unique opportunities for clinical and pathological investigation, but are almost unutilised in this respect, and the general hospitals are unable to do what could and should be done in this direction owing to lack of funds. Contrast this state of affairs with what obtains, say, in Berlin—the newest hospital, the Virchow Krankenhaus, has 2000 beds for all kinds of cases, its department for infectious diseases, its pathological institute, with scientific staff, and the research Institute for Infectious Diseases is close by and affiliated to it—and it must be admitted that London makes but a poor show.

In the teaching of hygiene and the necessary curriculum for the diploma in public health, concentration again is eminently desirable. At present nearly every medical school retains teachers, and the requisite expensive equipment, in each case for the instruction of but a few students.

SCIENCE IN THE EAST.[1]

AMIDST the crowded town life of England, physical science outside the laboratory seems to be becoming a thing of the past. The ordinary British physicist concerns himself with the eccentricities of radium, the cosmogony of the ion, and other matters which are at present but names of mystery to most people. The work of the Indian Survey carries with it the sense of open air and large areas. It deals with subjects which appeal, in part at least, to the intelligence of the average educated man.

A great magnetic survey has been in progress for some years. Up to the date of the report by Captain R. H. Thomas, observations had been made at 808 stations, and three more seasons, it was hoped, would complete the field work, except in so far as repetitions of observations might prove necessary or extensions into the hills might be found practicable. The main part of the magnetic report deals with the intercomparison of instruments, but there are also some data as to the diurnal inequalities of declination and horizontal force at several of the fixed observatories erected to assist in the survey work. These inequalities are based on five "quiet" days a month, but the non-cyclic change is not explicitly shown, and there seems no statement as to whether it has been allowed for. The difference between the values for 0 a.m. and 11 p.m. in horizontal force is suspiciously large.

Until the question has been actually investigated, it is unsafe to assume that diurnal inequalities from quiet days are really representative of the ordinary day; the part played by disturbance also varies largely from day to day. Thus, though the inequality data are of much intrinsic interest, it is impossible to say in advance what degree of utility they may possess for survey purposes. From the large differences between the inequalities at the different Indian stations, it is clear that problems of some difficulty will have to be faced when it comes to correcting the field observations for diurnal changes, regular and irregular.

Part ii. gives an account of pendulum observations made by Major G. P. Lenox Conyngham and his

[1] Extracts from narrative reports of officers of the Survey of India for the season 1904–5; prepared under the direction of Colonel F. B. Longe, R.E., Surveyor-General of India. Pp. 127. (Calcutta: Government Printing Office, 1907.) Price 2s. 3d.

party at ten stations, including nine nearly on a meridian passing through Darjeeling. The northmost station, Sandakphú, was at a height of 11,766 feet. The results of this and similar future work promise to be of much interest in connection with the theories proposed to account for the observed large deflections of the plumb line in India, and the deductions made as to the density of the material underlying the Himalayas. The observations at some stations had to be taken in a tent exposed to temperature changes, and one of the chief uncertainties was the determination of the proper temperature correction. Considering that the value of gravity at the base station at Dehra Dun—on which all the other Indian values depend—is arrived at by assuming for Kew the value 981·200 C.G.S., it does seem desirable that some British authority should exist possessing both the apparatus and the scientific knowledge necessary to determine the accuracy of such assumptions. In the meantime, practical geodetic science in the British Empire has to turn for guidance and inspiration to Potsdam, Vienna, or Washington.

Part iii. deals with the report by Mr. J. P. Barker on tidal observations and levelling operations. A good many data are given as to tidal constants at various stations, and there is interesting information as to the degree of accuracy of the predicted times and heights of low and high water. At the open coast stations in 1904 the mean error in the predicted times was only nine minutes, and the mean error in the predicted heights was less than 3 per cent. of the range; but in the riverain stations the errors were nearly twice as large, and there seems room for improvement.

Part iv. describes triangulation in Baluchistan, while part v. deals with survey operations of a rapid kind made with the Somaliland Field Force. The officer in charge of the latter, Captain G. A. Beazeley, and his assistant, Captain C. G. Hunter, evidently had a very stirring time.

One of the duties of the tidal officers seems to be the inspection of anemometers at tidal stations. At first sight the following information respecting the anemometer at Port Blair is rather startling (p. 91):—"On November 19, 1904, the velocity of wind registered . . . was 1112 miles, the greatest on record since December 1, 1897, on which day 918 miles was registered." The *day* is rather an unusual unit of time for velocities, and why the limitation? There are other instances where the method of presenting the facts might be improved upon, but fortunately the absence of a good English style does not necessarily imply a corresponding laxity in scientific accuracy. Another criticism that is likely to present itself to many readers is that the season 1904–5 is becoming now a little remote.

C. CHREE.

PROF. CHARLES STEWART, F.R.S.

ON Friday, September 27, Prof. Charles Stewart, conservator of the museum of the Royal College of Surgeons, died at the age of sixty-seven after a few weeks' illness, following some years of failing health.

Prof. Stewart was a native of Plymouth, where both his father and grandfather had been in practice. Following their example, he too entered the medical profession, being educated at St. Bartholomew's Hospital, and taking his M.R.C.S. in 1862. After some few years spent at Plymouth he returned to London, upon obtaining (in 1866) the post of curator of the museum at St. Thomas's Hospital. Later, in 1871, he became lecturer on comparative anatomy at the same school, and in 1881 joint lecturer with Prof. John Harley on physiology. He also for some years held the professorship of biology and physiology at Bedford College.

During this St. Thomas's period, Prof. Stewart accumulated, by incessant work as a teacher and museum curator, and mainly by direct observation, that vast fund of biological knowledge for which he was so well known, and of which he was so lavish to all who came to him for help in their difficulties. In the comparatively small museum at St. Thomas's, he perfected his natural talent for practical museum work, performing with his own hands all the processes necessary in the preparation and display of anatomical specimens, and gaining a thorough insight into all the minutiæ of museum management. At the same time, the variety of his teaching appointments, embracing anatomy, physiology, botany, and pathology, effectually prevented him from becoming narrow or specialised. Thus, when in 1884 the conservatorship of the Royal College of Surgeons' museum fell vacant, through the appointment of Sir William Flower to the control of the British Museum (Natural History), Prof. Stewart was singled out by his practical experience and wide attainments as Flower's natural successor.

Although during his twenty-three years of office at the College of Surgeons Prof. Stewart supervised and stimulated the growth of all parts of the museum, he made the object of his special care the improvement and completion of that section of the museum—"the physiological series of comparative anatomy"—in which are embodied John Hunter's philosophical researches into the normal processes of life. For the advancement of this great collection of adaptive modifications, Prof. Stewart laboured consistently almost to the day of his death, adding or planning new specimens, lecturing so long as health allowed, and finally editing, and in part writing, the first few volumes of a full descriptive catalogue.

The year after his appointment as conservator he was elected Hunterian professor of human and comparative anatomy at the college, and annually until 1902 gave series of lectures that reflected the work he was doing in the museum, and served as introductions to the several sections of the "physiological series." At this time he also delivered some "Friday evening" lectures at the Royal Institution, and was Fullerian professor of physiology there from 1894 to 1897. In his own way, Prof. Stewart was inimitable as a lecturer. He had an easy flow of language, delivered with a persuasive eagerness that compelled attention, and illustrated by wonderful free-hand drawings on the blackboard. The combined result was a picture, not easily forgotten, of interwoven word and line animated by a charming personality. Unfortunately, his lectures were delivered from the scantiest notes, so that little remains of his original researches except some few papers in the publications of the Linnean Society and in some microscopical journals which give but a feeble idea of his real powers.

Since 1866 Prof. Stewart had been a Fellow of the Linnean Society, and from 1890–4 held the office of president. He was also deeply interested in the Royal Microscopical Society, being one of its secretaries from 1878–82; and he was an original member, and for some years treasurer, of the Anatomical Society. He also was an ardent supporter of the Marine Biological Association. In 1896 he was elected to the fellowship of the Royal Society, and three years later was honoured by the conferment upon him of the degree of LL.D. *hon. caus.* by the University of Aberdeen.

In brief, Prof. Stewart was professionally a successful teacher, a great lecturer, and a master of all museum arts; personally he was the simplest and kindest of men, unassuming to a fault, with a cordial detestation of everything false, presumptuous or sordid. His cheery, youthful manner and lively conversation endeared him to many, even of those who had not the privilege of seeing the deep sympathetic nature beneath.

NOTES.

An extra meeting of the Chemical Society will be held in the theatre of the Royal Institution on Friday, October 18, at 9 p.m., when Prof. Emil Fischer, F.R.S., will deliver the Faraday lecture, entitled "Organic Synthesis and its Relation to Biology."

The honorary secretary of the Hampstead Scientific Society informs us that, by permission of the London County Council, a meteorological station (in connection with the Meteorological Office and the British Rainfall Organisation, Camden Square) is to be established by the society at the flagstaff on the summit of Hampstead Hill. This being the highest point in the neighbourhood of London, some interesting records should be obtained. A small astronomical observatory is also to be placed at the same spot, which it is hoped may be of educational value to students and senior pupils of London County Council schools.

The British military airship travelled on Saturday last from Aldershot to London at the rate of about twenty-four miles an hour, and after circling round St. Paul's Cathedral, headed against the wind on the return journey. Owing to the strong wind prevailing, the descent was made in the grounds of the Crystal Palace at Sydenham. The total distance covered was fifty miles, and the mean altitude was 750 feet.

An exhibition is to be held at the Royal Horticultural Hall, Vincent Square, Westminster, on October 22–26, in connection with the *Model Engineer*, and will include a collection of engineering models of all kinds; electrical, optical, and scientific instruments; technical education apparatus; and lathes, tools, and workshop appliances. Popular scientific lectures and demonstrations will be given each day, and many of the models will be shown at work.

Mr. F. Wood-Jones, Harley Lodge, Enfield, informs us that on November 15, 1905, he set adrift several bottles from the Cocos-Keeling atoll, Indian Ocean (12° 04′ 24″ S., 95° 55′ 19″ E.), containing messages requesting that the finder would let him know the place and time of finding. On May 27, 1906, one was picked up on the coast of Brara, Italian Somaliland (1° 06′ 08″ N., 44° 01′ 52″ E.), and on July 11, 1907, another turned up at exactly the same spot. These facts point to a constant westward current in this part of the Indian Ocean. For both communications Mr. Wood-Jones is indebted to Captain Resident G. Piazza, of Italian Somaliland.

The death is reported on September 22 of Prof. W. O. Atwater, of the Wesleyan University, Middletown, Connecticut. He directed from 1875 to 1877 the Connecticut Agricultural Experiment Station, the first institution of the kind in the United States. In 1888 he founded the experiment station of the Federal Department of Agriculture. Of late years he had directed the special investigations of that department into questions of nutrition. He was joint inventor of the Atwater-Rosa calorimeter for experiments on the metabolic changes going on in the human body; and was the author of a large number of articles and reports on physiological and agricultural chemistry. Prof. Atwater, who was sixty-three years of age, had been practically helpless since he suffered from a stroke of apoplexy two years ago.

News has been received from Dr. Sven Hedin by the Simla correspondent of the *Pioneer Mail*, the communication being dated July 25, from the Mansarowar Lake. Dr. Hedin reports that this last journey from Shigatse to Tok-chen, on the lake, has been richer in results than his previous one from the Aksai Chin to Shigatse, as he has been almost the whole time in inhabited country. His message, of which the following is an extract, appears in the *Pioneer Mail* of September 20:—"The results are 1300 big pages in annotations, 203 sheets of maps, 410 specimens of rock in connection with geological profiles, 700 panoramas, twenty-six astronomical points, the meteorological journal continued three times a day, and passes and camps fixed by boiling-point thermometer; at every river crossing a detailed measurement of the volume of water—the Brahmaputra—has been measured at seven points, and most of the northern tributaries, as well as some of the southern; a collection of plants; a great number of sketches, especially types, the interior of temples, and landscape sceneries. One lake, Amtchok-Tso, has been carefully measured, and an isobathic map made. The height of many peaks has been measured with the theodolite at a couple of places; the height of old beach lines of lakes has been measured."

An appeal for funds to secure the preservation of the "Sarsen Stones" on the Marlborough Downs known as the "Grey Wethers" has been issued jointly by the National Trust for Places of Historic Interest or Natural Beauty, the Wiltshire Archæological and Natural History Society, and the Marlborough College Natural History Society. These sarsen stones are, geologically, the hardened and solidified boulders of a stratum of Eocene sand formerly covering the chalk, which in the course of ages has been denuded of the softer portions. The stones vary in size from small boulders to masses of sixty or seventy tons. For many generations these stones, scattered widely over the downs, have been broken up and used for building and other purposes, mainly of a local character. As there is every probability that the work of breaking up the sarsens will be undertaken soon on a greatly extended scale, an attempt is being made to secure the preservation of some characteristic examples of the stones in their natural condition. The sum of about 500*l.* is asked for in order to purchase about twenty acres of land where there are many of the stones. If the money is forthcoming, characteristic examples of a unique geological phenomenon will be secured for the nation. The donations already received or promised amount to 164*l.* Subscriptions to the fund may be sent to Mr. E. Meyrick, F.R.S., Thornhanger, Marlborough, or to Mr. Nigel Bond, secretary, the National Trust, 25 Victoria Street, Westminster, S.W.

To *Spolia Zeylanica* for August Mr. J. Llewellen Thomas contributes further particulars on hybridising the Ceylon jungle-fowl (*Gallus stanleyi*), a subject on which a note appeared in our columns last year. The new experiments demonstrate that in certain circumstances the hybrids with domesticated fowls are fertile, both *inter se* and with their parents, and under really favourable conditions it is surmised that complete fertility could be established. This being so, Darwin's argument from the infertility of the hybrids that *Gallus stanleyi* cannot be the parent stock of domesticated poultry no longer holds good. The difficulty, however, is to convert this negative evidence into positive proof that the Ceylon jungle-fowl is entitled to occupy that position. An important point in the case is the fact that when domesticated fowls tend to revert to the wild type, the cocks develop red or brown (never black) breasts. As the Indian *Gallus bankiva* is black-breasted, the reversion is thus in the direction of the Ceylonese species, which has a reddish-brown breast in the males.

It is a well-known fact that many lizards inflate the body, the region of the mouth, or special laryngeal sacs, for the apparent purpose either of frightening enemies or as a means of sexual attraction, or perhaps for both together. Examples of this are displayed by the inflation of the body in Lacerta and Phrynosoma, in the expansion of the frills of Chlamydosaurus, and the dilatation of the gular sacs of Metopoceros and other iguanas. Such effects might be enhanced, it is reasonable to suppose, by a swelling-out of the head and protrusion of the eyes. Such a function, according to Dr. H. L. Bruner in the *American Journal of Anatomy*, vol. vii., pp. 1–117, is, however, insufficient to explain the existence in the heads of both sexes of many lizards and snakes of an apparatus of muscles and vascular sinuses for producing excessive blood-pressure, and consequent swelling in this region. In lizards, at any rate, this mechanism is developed for the purpose of aiding in the shedding of the scales, and acts physiologically by accelerating lymph movements, and thus promoting metabolism, and mechanically by stretching the skin over the soft parts. This being so, the probability is that the same factor holds good in the case of snakes and tortoises. In some instances, however, the function may be modified for terrifying or sexual purposes, and it is probable that the ejection of blood from the eyes of the "horned toads" (Phrynosoma) is a special development of the same mechanism.

A Greek pamphlet lately published at Athens (P. D. Sacellarius) under the title of "Αἱ τῶν Lamarck καὶ Darwin Θεωρίαι παρὰ τῷ Ἀριστοτέλει," gives an interesting account of various passages in the works of Aristotle which contain anticipations of modern observations and discoveries. The existence of a placenta in selachians and the sexual dimorphism of certain cephalopods were among the facts well known to the Greek philosopher, who also shows a considerable grasp of the phenomena of correlation, of the influence of external conditions on individual development, and of the rivalry between organisms in which the weakest goes to the wall. It is, however, rightly pointed out that Aristotle, though he had distinctly before his mind the principle of natural selection as propounded by Empedocles, deliberately rejected that principle as a factor in organic evolution. A passage from the "Physics," frequently quoted and almost as frequently misinterpreted, shows conclusively that Aristotle, though no theist, held firmly to the view that the scheme of nature is purposeful and rational; but adaptations, in his opinion, came into existence ready-made, and not by degrees. The difference between this latter position and that of Darwin is clearly emphasised in the present pamphlet, but even here the force of the argument in the passage we allude to does not seem to have been fully realised.

We have received a reprint of the memoir (*Biometrika*, vol. v., part iii.) by Mr. J. F. Tocher on the anthropometric characteristics of the inmates of asylums in Scotland, based on data collected by a survey organised by Mr. Tocher under the Henderson Trust of Edinburgh. The characters observed and recorded were stature, head length, head breadth, and head height, hair colour, eye colour, and nose contour. The data are discussed very fully by Mr. Tocher, with especial reference to the methods of Prof. Karl Pearson; to those not familiar with his methods the memoir will prove somewhat difficult reading, the more so as Prof. Pearson's symbols are frequently used without definition. It is impossible to compare the measured characteristics with those of the sane, since no such survey of the sane population has yet been carried out; as regards hair and eye colour, however, comparisons can be made with the results of a survey of school children, and it appears that the sane and insane differ significantly, the latter being lighter eyed and darker haired than the sane population. The majority of the frequency distributions for measured characters are skew, but not more so than similar distributions, drawn from other sources, for the same characters of sane populations. The whole of the original individual data and measurements, concerning 4381 males and 3925 females, together with correlation tables, are given in an appendix.

The publications of the Natural History Section of the Indian Museum, Calcutta, will in future consist of Memoirs, to be issued periodically, and of Records, which will contain shorter papers on zoology and the allied branches of anthropology, and will be issued, so far as possible, quarterly. The first two numbers of the Records contain many contributions of interest. Captain Lloyd describes a collection of the fauna of the Arabian Sea, which was made in the course of a voyage by the Indian survey ship *Investigator* between Aden and Muscat. Considering that this is new ground, the results are disappointing, only a small number of new specimens having been obtained; but the repeated recurrence of many of the species at different stations is remarkable, and the appearance of the giant isopod, *Bathynomus giganteus*, and the large bilaterally symmetrical hydroid, *Branchiocerianthus imperator* (here recorded for the first time in the Indian seas), is noteworthy. Mr. C. A. Paiva discusses the Hemiptera and Hymenoptera of the Himalayas, and Dr. Annandale, with the assistance of the Rev. T. R. R. Stebbing, continues his reports on the fauna of the brackish pools at Port Canning, to which Mr. R. Gurney adds some further notes on Indian fresh-water Entomostraca. In part ii. the most elaborate papers are that of Mr. E. Brunetti on the revision of the Oriental Stratiomyidæ, and a report on a new large collection of batrachia, reptiles, and fish from Nepal and the Western Himalayas, by Mr. Boulenger, Dr. Annandale, and Mr. Regan. It is not difficult to explain the prevalence of malarial fever in Bengal when we learn that Mr. Chatterjee found within three hours no fewer than 250 specimens of the Anopheles mosquito in the rest-house at Port Canning. It has been suggested that this pest might be destroyed by admitting sea-water into the pools occupied by them; but while there are recorded instances of mosquito larvæ being found in salt water, it has now been ascertained that the brackish pools at Port Canning contain an abundant supply. Here at least petroleum is likely to hold its ground as a remedy.

A practical article on pruning cocoa is contributed by Mr. W. Cradwick to the Bulletin of the Department of Agriculture, Jamaica (June and July), and the diagnoses of two new species of Comocladia are furnished by Dr. N. L. Britton. The report prepared by Mr. F. Stockdale on cocoa-nut diseases in Trinidad, describing a root disease referred to a fungus Botryodiplodia, a leaf disease caused by a Pestalozzia, and a bud-rot disease, is also published.

THE third part of the first volume of the Proceedings of the Association of Economic Biologists is devoted to the papers presented at the meeting of the society held in Cambridge in January. The majority of the papers are represented by abstract or title, but the paper by Mr. E. S. Salmon on the American gooseberry-mildew is printed at length. The author refers to the spread of the disease, and its prevalence in parts of Worcestershire, where the County Council has been taking measures to stamp it out; also he points out the necessity for establishing a sub-department of the Board of Agriculture to look after the fruit industry.

THE latest number of the entomological series of Memoirs of the Department of Agriculture in India (vol. i., No. 5), for which Mr. E. E. Green and Dr. H. H. Mann are conjointly responsible, is devoted to the Coccidæ attacking the tea plant in India and Ceylon. Although thirty species are enumerated, only two or three have so far proved serious pests, but it is stated that with Coccidæ, even more than other phytophagous insects, every species must be regarded as a potential enemy, since, owing to some unforeseen change, dangerous multiplication may ensue. Two new species, *Chionaspis manni*, *Dactylopius theaecola*, and a new variety of *Tachardia decorella* are described.

COMMISSIONED by the New Zealand Government to undertake a botanical survey of the small island of Kapiti, situated in Cook Straits, Dr. L. Cockayne has compiled a highly interesting report describing the various plant formations, and enumerating the indigenous ferns and flowering plants. It is proposed to conserve the island as a sanctuary for native birds and plants, especially for species that are becoming rare. As a shelter for birds, and from an ecological standpoint, the forests are alike important. *Corynocarpus laevigata*, *Dysoxylum spectabile*, *Macropiper excelsum*, *Myoporum laetum*, and *Melicytus ramiflorus* are conspicuous trees. The northern rata, *Metrosideros robusta*, varies greatly, sometimes throwing out arches composed of aërial roots. Other species of Metrosideres generally form lianes, and among them *Metrosideros scandens*, but when growing in the open it assumes a shrubby habit. Allusion is also made to the marked heterophylly of *Lomaria filiformis*, to the cauliflory or production of flowers on the naked stems of several trees, and to many other interesting ecological features.

UNDER the title "Ombre sismiche e rimbalzi sismici," Prof. V. Monti has issued a pamphlet dealing with the phenomenon known as earthquake shadow. He finds that Mount Etna appears to have a protective effect in the case of earthquakes in Sicily, and that, wherever the focus may be situated, places lying on the further side of the mountain do not feel the shock, though others at a greater distance are shaken. Monte Cimone, in northern Italy, seems to exercise a similar protective effect, but the much higher range of the Gran Sasso d'Italia and Maiella has no influence of this nature. He rejects the explanation suggested by Prof. Rizzo in his study of the Calabrian earthquake of September 8, 1905, but offers none in its stead. We may remark that the term shadow is based on the supposition that earthquakes originate in areas of small dimensions compared to that over which they are felt; the term loses its significance if Major Harboe's suggestion of extended origins, noticed in NATURE of April 26, 1906, is accepted.

THE U.S. *Monthly Weather Review* for May contains a full translation, by Dr. O. L. Fassig, research director of Mount Weather Observatory, of M. G. Guilbert's principles of forecasting the weather, submitted to the international competition at Liége, organised in 1905 by the Belgian Astronomical Society, with the view of showing the state of our knowledge of that subject. The jury, which was composed of six well-known meteorologists, unanimously awarded the first prize to M. Guilbert, of Caen, whose forecasts were based upon conclusions drawn from the study of the relation of the theoretical to the actual wind. He claims to be able to predict with precision the displacements and variations of centres of high and low pressure for twenty-four hours in advance, and to foretell the inception and dissolution of storms. Dr. Fassig points out that the rules can readily be put to test, and that the paper should receive the careful consideration of all who make weather forecasts. The subject is referred to in the last Parliamentary Report of the Meteorological Committee, and a valuable discussion of the principles will be found in the *Archives des Sciences* for July, 1906, by M. Brunhes, chairman of the jury of award.

Science for August 30 contains the presidential address of Mr. F. T. Shutt to the section of agricultural chemistry at the meeting of the American Chemical Society held this summer in Toronto. Mr. Shutt's address deals mainly with the virgin soils of the new north-west, showing by analysis their richness in nitrogen, but pointing out how rapidly they become exhausted under the common system of growing successive wheat crops with an occasional bare fallow. He gives figures to show that twenty years of such cultivation has reduced the nitrogen content of the soil down to the depth of 8 inches by no less than 2206 lb. per acre, of which not more than 700 lb. has been obtained in the crop. Although no marked falling off in the yield of this soil is as yet apparent under proper cultivation, chemistry warns the cultivator that a great drop in fertility must inevitably take place unless something is done to replenish the nitrogen. This, Mr. Shutt points out, can be done by the growth of clover, and gives examples of the enrichment of the soil consequent upon the introduction of this crop.

MR. CHARLES A. CULVER, of the University of Pennsylvania, has undertaken a study of the relative efficiencies of the various types of receiving systems in use in wireless telegraphy, and the *Physical Review* for September contains an account of the first part of his investigations. Of the types tested, those consisting of one or more vertical wires are the most efficient, and it seems immaterial whether the component parts are connected together at the lower, upper, or both ends. Partial screening of the aërial produces little effect, while the resistance of the earth between the sending and receiving stations is of prime importance. From a consideration of his own results and those of others, Mr. Culver concludes that the theory of propagation of the waves through the surface of the earth accounts for more of the observed facts than the free ether-wave theory, although it does not at present account for several phenomena encountered in practical work.

REPRINT No. 40 from the Bulletin of the Bureau of Standards at Washington consists of an account of some preliminary measurements of the temperature and selective radiation of the filaments of various kinds of incandescent electric lamps made by Messrs. C. W. Waidner and G. K.

Burgess. They find that at temperatures about 1500° C. platinum departs farthest of all the substances tried from radiating as a perfectly black body, while carbon most nearly approximates to a black body. All the filaments used are thus selective radiators, and are more efficient luminous radiators than a black body, the order being for the same temperature—platinum, tantalum, tungsten, carbon. The superiority of tantalum and tungsten over carbon filament lamps is to some extent due to this fact, which is further emphasised by the higher temperature at which they can be worked, the light emitted varying nearly as the twelfth, while the energy supplied varies only as the fifth, power of the temperature.

THE Health Education League of Boston, Massachusetts, has sent us two copies of new booklets published in continuation of the series noticed in a recent number of NATURE (September 12, p. 508). In one of the booklets (No. 12) Dr. M. H. Bailey deals with "Emergencies," and in the other Miss A. F. Rogers and Dr. J. H. McCollom describe "Microbes: Good and Bad."

A SECOND edition of Prof. J. Reynolds Green's "Introduction to Vegetable Physiology" has just been published by Messrs. J. and A. Churchill. The price of the work is 10s. 6d. net.

A SECOND edition (third impression) of Mr. W. P. Workman's "School Arithmetic," which is a school course adapted from "The Tutorial Arithmetic," has been published by Mr. W. B. Clive.

WE have received from Mr. C. Baker, of High Holborn, London, the October issue of his classified list of second-hand instruments and of new pieces of apparatus recently introduced. The catalogue contains a description of more than a thousand pieces of apparatus, together valued at more than 6000*l*. Those who are contemplating the purchase of microscopes, telescopes, spectroscopes, and other physical apparatus would do well to examine this catalogue.

THE general committee of the Dr. Fream memorial fund has confirmed the following resolution, which was passed at a recent meeting and accepted by the Board of Agriculture and Fisheries:—"That the Fream Memorial Fund shall be invested in the name of the Board of Agriculture and Fisheries or of an official trustee selected by the Board, and shall be administered by the Board of Agriculture and Fisheries, and that the income shall be applied by way of a Fream memorial prize of books to be competed for in each year by students in the science of agriculture, and so that as long as an examination is held by the National Agricultural Examination Board for the national diploma in agriculture the prize shall be awarded to the person who obtains the highest marks in such examination." A sum of about 200*l*. is available for the purpose of the memorial.

PHOTOGRAPHERS will study with interest the new edition of the catalogue of photographic apparatus and materials recently issued by Messrs. Marion and Co., Ltd., of Soho Square, London. The full descriptions and carefully tabulated particulars as to sizes and prices contained in this well-illustrated list should render the choice of material easy and expeditious.

OUR ASTRONOMICAL COLUMN.

THE PHYSICAL NATURE OF METEOR TRAINS.—An interesting discussion of the nature of meteor trains is published in No. 2, vol. xxvi. (p. 95, September), of the *Astrophysical Journal* by Prof. C. C. Trowbridge. Prof. Trowbridge, believing that valuable information concerning the upper layers of the earth's atmosphere may be thereby deduced, has compiled a catalogue of observed meteor trains, and for several years has made a comparative study of the data, at the same time making a study of the phenomena of gas phosphorescence. The discussion of altitudes leads to the conclusion that there is a definite layer of the earth's atmosphere, probably some fifty to sixty miles high, where the conditions are favourable to the production of the peculiar glow constituting a meteor train. Prof. Trowbridge believes that the secondary appearance of duality, so frequently observed in meteor trains, is due to the probable tubular form of the trains. The train itself is probably a tube of gas and particles of meteor dust, rendered phosphorescent by some temperature or electrical effect produced by the meteor's passage. The rate of diffusion and the colour of meteor trains agree with similar phenomena observed in phosphorescent air in the laboratory.

THE PULKOWA ECLIPSE EXPEDITION TO TURKESTAN, JANUARY, 1907.—An interesting account of the expedition dispatched from the Nicholas Central Observatory, Pulkowa, to observe the eclipse of January 13, 1907, is given in No. 18, vol. ii., of the *Mitteilungen der Nikolai-Haupsternwarte zu Pulkowo*. The site chosen for the observation of the eclipse was near the small town of Ura-tyube, in the Samarkand district of Turkestan, and there the various instruments were erected on December 31, 1906. The accompanying illustration, reproduced from the *Mitteilungen*, gives some idea of the conditions under which the observers worked, and shows the instruments in position. The long tube on the left is the coronagraph of 5 inches aperture and 43·5 feet focal length, with which M. Hansky hoped to obtain photographs showing details of the inner corona and prominences; as may be seen, this instrument was pointed directly to the sun's place at the moment of mid-totality. With the photographic refractor of short focus, it was planned to obtain five photographs of the corona with various coloured screens and on different plates. In addition to these, an attempt was to be made to photograph the spectrum of the corona from C to the ultra-violet, and M. Hansky also proposed to carry out photographic photometric researches.

Observing Station of the Eclipse Expedition at Ura-tyube, Russian Turkestan.

Heavy snowfall prevented this programme from being carried out on the day of the eclipse, but some interesting observations of the terrestrial colour effects and the shadow-bands were made. M. Hansky also discusses some observations of the zodiacal light made by him whilst at Ura-tyube.

Daniel's Comet.—The spectrum of Daniel's comet (1907*d*) was photographed, with an objective-prism camera, at the Nice Observatory on several nights during July and August by MM. H. and L. Chrétien, and is discussed by the former in No. 13 of the *Comptes rendus* (p. 549, September 23). A prism of 62° was employed, mounted in front of an objective of 10 cm. aperture and 47 cm. focal length, the spectrum of Capella being photographed on each plate for the purpose of comparison.

The following sets of bands were found, quite sharp and easily measurable, on plates secured on August 16 and 18:—387·0, 388·2; 398·9; 401·2, 402·0; 411·1, 413·8, 419·0; 420·0, 421·3; 425·8, 427·5; 430·1, 431·0, 433·5; and 450·3, 454·2; those at 401, 426, and 450 are very similar in character. The spectrum of the tail comprises three groups of radiations, the mean wave-lengths of which are 401·6, 426·7, and 452·2 respectively. An examination of the plates shows that each of these is composed of two condensations, the separation of each couple being 1·9, 1·7, and 3·9 $\mu\mu$ respectively.

Mr. Gillman, of Aguilas (Spain), has forwarded to us another chart depicting the results of his eye-observations made on September 4, 5, and 11. On the last-named date he was able to trace the tail of the comet to a distance of about 17½° from the head in a direction a little north of west.

The Spectroscopic Binary α Draconis.—Since July, 1906, α Draconis has been under observation at the Dominion Observatory, Ottawa, for radial-velocity determinations, and in No. 4, vol. i. (p. 237, July-August), of the Journal of the R.A.S. (Canada), Mr. Harper discusses the observations, with those of other observers, and derives a set of elements for the orbit of this binary. The observed velocities range from −54 km. to +56 km., and Mr. Harper's elements are as follows:—period = 51·38 days, velocity of the system = −16·7 km., eccentricity = 0·42, longitude of periastron (ω), from descending node = 198°, T = 1906 July 11d. 0h., and semi-major axis = 30,057,900 km.

ENGINEERING AT THE FINSBURY TECHNICAL COLLEGE.

The completion of a new wing of the City and Guilds Technical College at Finsbury was the occasion, on Wednesday, October 2, of a large gathering of distinguished members of the city companies to witness the opening ceremony. Mr. Baker, chairman of the Colleges Extension Committee, in inviting the Lord Mayor to declare the new wing open, gave an interesting account of the history of the City and Guilds of London Institute, which, founded in 1878 and incorporated by Royal Charter in 1900, has raised and expended nearly three-quarters of a million pounds for the promotion of technical education.

The growth of the Finsbury Technical College has for some years necessitated the work being carried on in three unconnected buildings, and in order to bring all departments under one roof, with greatly improved facilities for their work, the institute set aside 10,000*l.* from its reserve fund, and the Corporation and Guilds of London contributed an equal amount, while a generous friend of the college contributed 10,000*l.* for equipment. With this sum the committee was able to carry out a long cherished scheme of centralisation and extension, and it was particularly fortunate in having Sir William White as one of its number to advise on all matters relating to the engineering equipment. Mr. Baker also referred to the long and distinguished connection of Prof. Silvanus Thompson and Prof. Meldola with the college, and in conclusion expressed the pleasure of the company at the presence of the Lord Mayor and Sheriffs to open the new wing.

The Lord Mayor, who was received with great enthusiasm, then declared the building open, and delivered an address to the students on the development of character.

Mr. Yarrow, in proposing a vote of thanks, briefly referred to the advantages which the two-year course at Finsbury offered to students, especially those who had served an apprenticeship in an engineering works, and said that in his opinion the Finsbury Technical College fills a special need, which is not supplied by other existing institutions, excellent though many of these are.

Sir John Wolfe-Barry, chairman of the executive committee, seconded the vote of thanks, and after acknowledgment by Sir William Treloar the company proceeded to view the building. On arriving at the engineering laboratory, the Lord Mayor pressed a button, setting the machinery in motion, and afterwards made a tour of inspection with the company, which included Sir Edward Clarke, Sir William White, Sir John Watney (secretary of the institute), Sir A. B. W. Kennedy (president of the Institute of Civil Engineers), Sir Philip Magnus, M.P., Mr. A. C. Morton, M.P., Prof. Unwin, Prof. Dalby, Mr. T. H. Blakesley, Mr. Ralph Palmer, Mr. S. S. Gladstone, and Mr. Soper (assistant secretary of the institute).

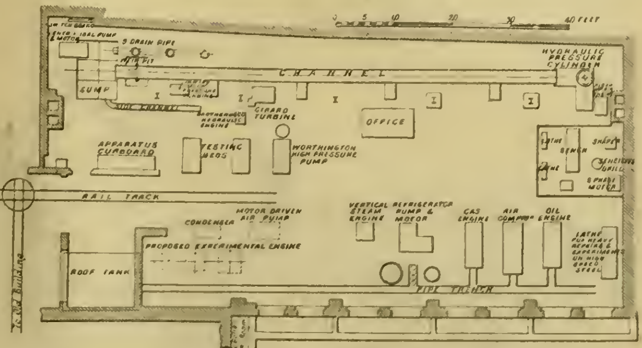

Fig. 1.—Plan of the Engineering Laboratory of the City and Guilds Technical College, Finsbury.

The engineering laboratory, shown on the accompanying plan, is about 100 feet long and 45 feet wide, and is a well-lighted room having walls faced with white tiles from the window levels, those below being brown glazed. Along one side a cast-iron channel of square section, 2 feet wide and 80 feet long, is sunk into the floor. This channel is free from end to end, so that, when occasion requires, the whole length can be utilised for experiments on towing, wave motion, and the like. There are also two smaller channels, parallel to the main one, for draining water into the measuring tanks without disturbing the main channel.

The measuring tanks are six in number, having a combined capacity of about 4000 gallons, and all the water collecting therein can be raised to a tank on the roof by a centrifugal pump delivering 200 gallons a minute against a head of 90 feet; the water is distributed anew by a 5-inch falling main and branches. The usual arrangements of weirs, float gauges, and the like are provided for measuring the water in the channel, and a Venturi meter can also be inserted in the pipe line.

At the other end of the channel is a hydraulic cylinder of special design, capable of giving horizontal and vertical jets up to 2 inches in diameter under any head not exceeding 300 feet. This cylinder is suspended by cross girders over a pit for receiving the vertical jet, and the horizontal jet is directed along the main channel.

The equipment of hydraulic machinery also includes turbines of the Girard and Francis types, and a high-pressure pump for operating an experimental engine of the Brotherhood type.

The heat-engine equipment consists of a representative set of machines arranged along one side of the laboratory, and spanned by an overhead crane capable of delivering a load of 30 cwt. to a lathe at one end. The engines already installed comprise a 12 horse-power "National" gas engine, with special thermometer pockets in the cylinder walls, and arrangements for releasing and shutting down the valves at any moment. This engine can be run on town gas or on suction gas from a producer. A 6 horse-power oil engine has similar thermometer pockets and valve-releasing gear.

An experimental "Linde" refrigerating plant is arranged to work with carbonic acid or ammonia by using interchangeable cylinders. The compressing pump is driven by a motor operating through a worm-wheel gear, so arranged that by disconnecting the pump coupling experiments can be made on the efficiency of worm gearing.

A small vertical steam engine, a petrol motor, a "Rider" hot-air engine, and a pulsometer pump are also included, while spaces are reserved for an experimental reciprocating steam engine of compound or triple expansion type, and an independent condensing plant to be installed at an early date. The steam-raising plant will consist of a Yarrow water-tube boiler, and a separately fired superheater.

An experimental compound air compressor, coupled directly to a motor, has been installed, and is fitted with special arrangements for experimental work. The equipment for testing the strength of materials includes a ten-ton "Buckton" testing machine, a combined bending and twisting machine, and a number of other machines for small-scale experiments. A specially designed machine for compression up to fifty tons will also be installed.

The drawing office, over the engineering laboratory, is a well-lighted room 80 feet long and 34 feet wide, with accommodation for one hundred students.

The college workshops have been recently equipped with the most modern tools, and in addition a special shop for the construction and repair of apparatus is provided in the engineering laboratory. The new wing also contains a lecture theatre and rooms for the staff.

As will be apparent from this brief description, the equipment has been designed with the purpose of giving students a practical acquaintance with as wide a field of engineering as possible. All the machinery and apparatus are of moderate dimensions, easily handled by students without excessive supervision, and at a small cost for running expenses.

While instruction, not research, has been the primary object, there is little doubt that in the future original work can be accomplished which will be of interest and value to the engineering profession.

E. G. COKER.

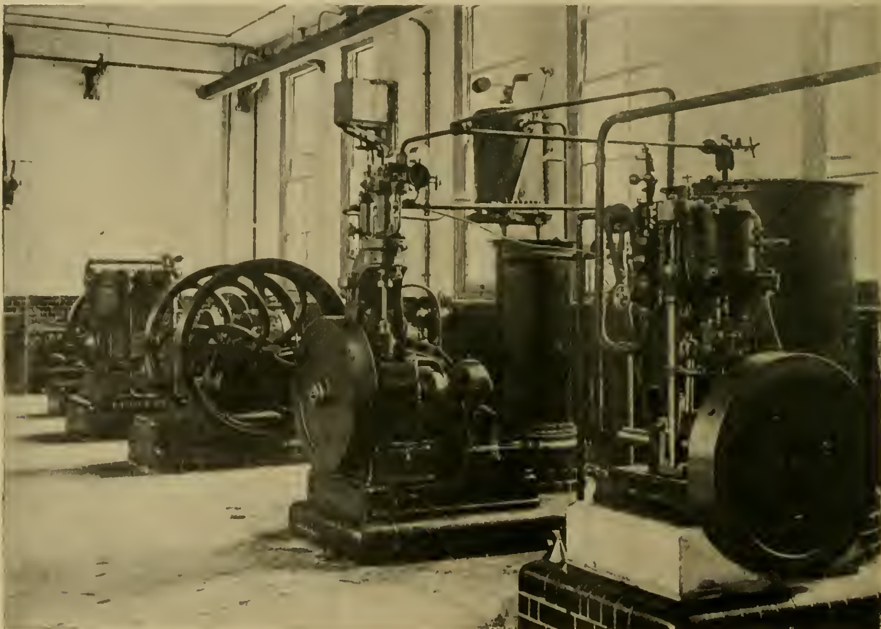

FIG. 2.—View of the Engineering Laboratory showing part of the Heat Engine Equipment.

FORTHCOMING BOOKS OF SCIENCE.

MR. SIDNEY APPLETON promises:—"A Book of Birds," by W. P. Pycraft, illustrated; "Minerals," by L. J. Spencer, illustrated; "Earthquakes," by Prof W. H. Hobbs, illustrated; "The Moon," by G. P. Serviss, illustrated; "The Warblers of North America," by F. M. Chapman and others, illustrated; "The Life and Habits of the Ants," by Dr. L. I. Dublin, illustrated; "Iron and Steel," by Dr. J. R. Smith, illustrated; "Gold," by Dr. J. R. Smith, illustrated; "The Horse: Ailments and

Accidents," by F. T. Barton; "The Dog, in Health, Accident, and Disease," by F. T. Barton, illustrated; "The Cat: its Care and Management," by Mrs. L. Williams, illustrated; and a new edition of "The Manual of Toy Dogs," by Mrs. L. Williams, illustrated.

Mr. Edward Arnold's list includes:—"From the Niger to the Nile," by Lieut. Boyd Alexander, two vols., illustrated; "Hydraulics," by F. C. Lea, illustrated; and "Wood: a Manual of the Natural History and Industrial Applications of the Timbers of Commerce," by Prof. G. S. Boulger, illustrated.

Messrs. Baillière, Tindall and Cox promise:—"Bacteriology of the Eye," by T. Axenfeld, translated by Dr. A. Macnab; "The Spectroscope: its Uses in General Analytical Chemistry: an Intermediate Text-book for Practical Chemists," by T. T. Baker; "Trypanosomes and Trypanosomiases," by A. Laveran and F. Mesnil, translated and edited by Dr. D. Navarro, illustrated; "Blood-stains: their Detection and the Determination of their Source," by Dr. W. D. Sutherland; "Pocket Osteology," by P. Turner; and new editions of "Medical Laboratory Methods and Tests," by Dr. H. French; "Elementary Lectures on Veterinary Science for Agricultural Students, Farmers, and Stock-keepers," by H. Thompson; and "Nature's Hygiene and Sanitary Chemistry: containing also a Special Account of the Chemical and Hygienic Characters of Eucalyptus, Pine, and Camphor Forests, and of some Industries connected therewith," by C. T. Kingzett.

Messrs. G. Bell and Sons' forthcoming books include:—"Darwinism To-day: a Discussion of Present-day Scientific Criticism of the Darwinian Selection Theories, together with a Brief Account of the Principal other Proposed Auxiliary and Alternative Theories of Species-forming," by Prof. V. L. Kellogg; "A Laboratory Outline of General Chemistry," by Prof. A. Smith; and "A Third Year's Course in Practical Physics," by James Sinclair, illustrated.

Messrs. A. and C. Black direct attention to:—"A Treatise on Hydraulics," by Prof. W. C. Unwin, illustrated; "Birds of Britain," by J. L. Bonhote, illustrated; "The Children's Book of Stars," by G. E. Mitton, illustrated; "Suggestion in Education," by M. W. Keatinge; and new editions of "Studies in Fossil Botany," by Dr. D. H. Scott, F.R.S., illustrated; and "Totemism," by Dr. J. G. Frazer.

Messrs. W. Blackwood and Sons have in the press:—"Forest Entomology," by A. T. Gillanders, illustrated; and "In the Footsteps of Marco Polo," by Major C. D. Bruce, illustrated; "The Marshes of Hindustan," by D. Fraser, illustrated; "Elements of Psychology," by Dr. S. H. Mellone.

The list of the Cambridge University Press includes:—Vol. i. of "Sir George Darwin's Collected Scientific Papers"; "Hyperelliptic Functions of Two Variables and the Reduction of the Theory of Multiply-Periodic Functions to that of Algebraic Functions," by Dr. H. F. Baker, F.R.S.; "The Artificial Production of Cold," by Dr. J. A. Ewing, F.R.S.; "Elementary Algebra," by C. H. French and G. Osborn; "Plane Geometry for Secondary Schools," by Dr. C. Davison and C. H. Richards; (Cambridge Tracts on Mathematics and Mathematical Physics): No. 6, "Algebraic Equations," by G. B. Mathews, F.R.S.; (The Cambridge Physical Series): "Inorganic Chemistry," by E. I. Lewis; and a re-issue of "A School Algebra Course," by F. Gorse, part i., "To Simple Simultaneous Equations," with appendix; part ii., "Factors to Quadratic Equations," with appendix; part iii., "Surds to the Binomial Theory," with appendix.

Messrs. Cassell and Co., Ltd., give notice of:—"Trees and their Life-histories," by Dr. P. Groom, illustrated; "The Romance of Medicine," by Dr. R. C. Macfie, illustrated; "The Fairyland of Living Things," by R. Kearton, illustrated; "Denizens of the Deep," by F. M. Duncan, illustrated; "Popular Fallacies," by A. S. E. Ackermann, illustrated; "Structural Engineering," by Prof. A. W. Brightmore, illustrated; "Steel: its Varieties, Properties, and Manufacture," by W. H. Greenwood, illustrated; and new editions of "Iron: its Sources, Properties, and Manufacture," by W. H. Greenwood and A. H. Sexton, illustrated; "Applied Mechanics," by Prof. J. Perry, F.R.S., illustrated; and "The Gun and its Development," by W. W. Greener, illustrated.

The Caxton Publishing Company will issue:—"Birds of Great Britain and Ireland (Order Passeres)," by Dr. A. G. Butler, illustrated.

In Messrs. Chapman and Hall's list we notice:—"The Conquest of Cancer," by Dr. C. W. Saleeby; and "Electrical Engineering Testing," by G. D. A. Parr, illustrated.

Messrs. Chatto and Windus announce:—"A History of Babylonia and Assyria from the Earliest Times until the Persian Conquest," by L. W. King, in three vols., illustrated:—Vol. i., "A History of Sumer and Akkad, being an Account of the Primitive Inhabitants of Babylonia from the Earliest Times to about B.C. 2000"; vol. ii., "A History of Babylon from the Period of the First Dynasty, about B.C. 2000, until the Conquest of Babylon by Cyrus, B.C. 539"; vol. iii., "A History of Assyria from the Earliest Period until the Fall of Nineveh before the Medes, B.C. 606."

Messrs. J. and A. Churchill promise: "A Manual of Prescribing," by Dr. C. R. Marshall; "The Functional Inertia of Living Matter: a Contribution to the Physiological Theory of Life," by Dr. D. F. Harris; and new editions of "Valentin's Practical Chemistry, Qualitative and Quantitative," by Dr. W. R. Hodgkinson; "The Book of Prescriptions," by E. W. Lucas; "The Operations of Surgery," by W. H. A. Jacobson and R. P. Rowlands; "Pathology, General and Special," by Prof. R. T. Hewlett; and "Notter's Theory and Practice of Hygiene," by Lieut.-Colonel R. H. Firth.

The announcements of Messrs. Archibald Constable and Co., Ltd., include:—"The Practical Design of Irrigation Works," by W. G. Bligh, illustrated; "Aërial Flight," by F. W. Lanchester, vol. i., "Aërodynamics"; "India-rubber and its Manufacture, with Chapters on Gutta-percha and Balata," by H. L. Terry; "Electric Power and Traction," by F. H. Davies; "Liquid and Gaseous Fuels, and the Part they Play in Modern Power Production," by Prof. V. B. Lewes; "Coal," by J. Tonge; "Iron and Steel," by J. H. Stansbie; "Town Gas for Lighting and Heating," by W. H. Y. Webber; "Patents, Trade Marks and Designs," by K. R. Swan; "Precious Stones, with a Chapter on Artificial Stones," by W. Goodchild; "The Manufacture of Paper," by R. W. Sindall; "Wood Pulp and its Applications," by C. F. Cross, E. J. Bevan, and R. W. Sindall; "Steam Engines," by J. T. Rossiter; "Glass," by W. Rosenhain; "Electric Lamps," by M. Solomon; "Steam Locomotives," by V. Pendred; "Gold and Precious Metals," by Dr. T. K. Rose; "Electro-metallurgy," by J. B. C. Kershaw; "Photography," by A. Watkins; "Commercial Paints and Painting," by A. S. Jennings; "Brewing and Distilling," by J. Grant; "Electrical Measuring Instruments, Recorders, Meters, &c.," by K. Edgcumbe; "Sewage Disposal Works from an Engineering Point of View," by H. P. Raikes; a translation of Captain Amundsen's book on the *Gjoä* Expedition; "An Introductory Course of Continuous Current Engineering," by Dr. A. Hay; "Plant Physiology and Ecology," by Prof. F. E. Clements, illustrated; "Burial Customs of Ancient Egypt," by J. Garstang; "The Tomb of Ioniya and Toniyou"; "Farm Management," by Prof. F. W. Card, illustrated; "Farm Animals: How to Breed, Feed, Care for, and Use them," by Dr. E. V. Wilcox, illustrated; and "Soils: How to Handle and Improve Them," by S. W. Fletcher, illustrated.

Messrs. J. M. Dent and Co. announce:—"Nature-study," by Prof. J. A. Davis, illustrated.

Messrs. Duckworth and Co. direct attention to:—"The Haunters of the Silences," by C. G. W. Roberts (Studies of Animal Life); "The Interpretation of Nature in Earlier Greek Art," by E. Lowy, translated by W. Fothergill; and a new edition of "Agricultural Botany," by Prof. J. Percival.

Mr. Gustav Fischer (Jena) announces:—"Ergebnisse und Fortschritte der Zoologie," edited by Prof. J. W. Spengel, Band I., Heft 1: "Ergebnisse, Wissenschaftliche, der deutschen Tiefsee-Expedition auf dem Dampfer *Valdivia*, 1898–1899," edited by Prof. Chun, Elfter Band, Zweite Lieferung, "Die Tetraxonia," by Prof. R. von

Lendenfeld; "Forschungsreisen, Zoologische, in Australien und dem Malayischen Archipel," by Prof. R. Semon, Vierter Band, Morphologie verschiedener Wirbeltiere, V. Lieferung; "Vorlesungen über Bakterienenzyme," by Dr. F. Fuhrmann, illustrated; "Handbuch der Arbeiterkrankheiten," edited by Dr. T. Weyl, illustrated; "Handbuch der Technik und Methodik der Immunitätsforschung," edited by Prof. R. Kraus and Dr. C. Levaditi, Erste Lieferung, illustrated; "Handbuch der technischen Mykologie," Vierter Band, "Spezielle Morphologie und Physiologie der Hefen und Schimmelpilze," edited by Dr. F. Lafar, illustrated; "Die Dinosaurier der europäischen Triasformation," by F. Huene, Supp.-Band I., Lieferung 1, "Geologischen und palaeontologischen Abhandlungen," edited by E. Koken, illustrated; "Die Pathologie und Therapie der plötzlich das Leben gefährdenden Krankheitszustände," by Dr. R. Lenzmann; "Die Ursachen der Geisteskrankheiten," by Dr. E. Meyer; "Hausschwamm-Forschungen," by Prof. A. Möller, Heft 1, illustrated; "Versuch einer Phylogenie des Embryosackes und der doppelten Befruchtung der Angiospermen," by Dr. Porsch; "Aus Namaland und Kalahari," by Dr. L. Schultze, illustrated; "Zellen-Studien," by Dr. T. Boveri, Heft 6, "Die Entwicklung dispermer Seeigel-Eier," illustrated; "Festschrift zum XIV. internationalen Kongress für Hygiene und Demographie Berlin 1907," illustrated; "Handbuch der pathogenen Mikroorganismen," edited by Prof. W. Kolle and Prof. A. Wassermann, Zweiter Ergänzungsband, Erstes Heft, illustrated; "Handbuch der technischen Mykologie," edited by Dr. F. Lafar, Erster Band, "Allgemeine Morphologie und Physiologie der Gärungsorganismen, Keimfreimachung und Reinzüchtung"; "Geschichte des Lehrstuhles für pathologische Anatomie und das neue pathologische Institut in Erlangen," by Dr. Hauser, illustrated; "Vorlesungen über Deszendenztheorien mit besonderer Berücksichtigung der botanischen Seite der Frage," by Dr. J. P. Lotsy, Zweiter Teil, illustrated; and "Die Flechtenstoffe in chemischer, botanischer, pharmakologischer und technischer Beziehung," by Dr. W. Zopf, illustrated.

Messrs. R. Friedländer and Son (Berlin) announce:—"Zoologischer Jahresbericht für 1906"; "Die Coniferen-Läuse Chermes: Feinde der Nadelhölzer," by Prof. N. Cholodkovsky, illustrated; "Die Pilzparasiten des Teestrauches," by Prof. N. N. v. Speschnew, illustrated; "Sylloge Algarum omnium hucusque cognitarum," by Dr. J. B. De Toni, five vols., 1889–1907; "Abels Untersuchungen über Schiefsbaumwolle," II. Abt.: Über die Beständigkeit der Schiefsbaumwolle; "Generalregister für Chemisches Centralblatt Jahrg. 1902–6"; and "Das Tierreich," Lief. 24, Cynipidæ, by C. W. Dalla Torre and J. J. Kieffer.

Messrs. Gauthier-Villars (Paris) announce:—"Leçons sur les Théories générales de l'Analyse," by Prof. R. Baire, two vols., vol. ii., "Fonctions analytiques; Equations différentielles; Applications géométriques; Fonctions elliptiques"; "Théorie et Usage de la Règle à Calcul," by M. Rozé, illustrated; "Traité général des Automobiles à Pétrole," by L. Périssé, illustrated; "La Construction d'une Locomotive moderne," by Dr. R. J. Grimshaw, illustrated; "Tables numériques et logarithmiques à l'Usage des Chimistes," by Csakolotos and Mettler; and new editions of "La Géométrie non-euclidienne," by Prof. P. Barbarin, illustrated; and "L'Électricité déduite de l'Expérience et Ramenée au Principe des Travaux virtuels," by Dr. S. Carvallo, illustrated.

Messrs. Ginn and Co. give notice of:—"Principles of Physics," by A. P. Gage, revised by A. W. Goodspeed; "Theoretical Mechanics," by Prof. P. F. Smith and O. C. Lester; and "Geographical Essays," by Prof. W. M. Davis.

Mr. H. J. Glaisher is publishing:—"Anthropometrical Schedules," prepared by J. Gray, and a "Book of Instructions for Taking Anthropometrical Measurements," by the same author.

The announcements of Messrs. Charles Griffin and Co., Ltd., are:—"Practical Calculations for Engineers," by C. E. Larard and H. A. Golding, illustrated; "Mechanical Engineering for Beginners," by R. S. McLaren, illustrated; "Telegraphic Systems and other Notes: a Handbook of the Principles on which Telegraphic Practice is Based," by A. Crotch, illustrated; "A Comprehensive Treatise on Colour Manufacture, comprising the Manufacture, Investigation, and Practical Application of Colouring Matter," by G. Zerr and Dr. R. Rubenkamp, translated by Dr. C. Mayer, illustrated; "The Cotton Weavers' Handbook: a Practical Guide to the Construction and Costing of Cotton Fabrics, with Studies in Design," by H. B. Heylin, illustrated; "The Analysis of Materials used in the Leather Industry," by S. R. Trotman, illustrated; "Soil Bacteria," by Dr. J. Clark, illustrated; "The Principles and Practice of Harbour Engineering," by B. Cunningham, illustrated; "Present-day Shipbuilding, for Shipyard Students, Ships' Officers, and Engineers," by T. Walton, illustrated; "The Design and Construction of Ships," by Prof. J. H. Biles, illustrated, two vols., each complete in itself, and sold separately; "Definitions in Navigation and Nautical Astronomy," by P. Groves-Showell, illustrated; "A Dictionary of Spanish and Spanish-American Mining, Metallurgical, and Allied Terms, to which some Portuguese and Portuguese-American (Brazilian) Terms are Added," by E. Halse, illustrated; "Tropical Medicine, Hygiene, and Parasitology: a Concise and Practical Handbook for Practitioners and Students," by G. E. Brooke, illustrated; "Physico-chemical Tables for the Use of Analysts, Physicists, Chemical Manufacturers, and Scientific Chemists," by J. Castell-Evans, vol. ii., "Chemical Physics, Pure and Analytical Chemistry," in two vols., sold separately; and new editions of "A Manual of Dyeing: for the Use of Practical Dyers, Manufacturers, Students, and all Interested in the Art of Dyeing," by Dr. E. Knecht, C. Rawson, and Dr. R. Loewenthal, two vols.; "Dairy Chemistry for Dairy Managers, Chemists, and Analysts: a Practical Handbook for Dairy Chemists and Others having Control of Dairies," by H. D. Richmond, illustrated; "Road Making and Maintenance: a Practical Treatise for Engineers, Surveyors, and Others" (with important new matter on dust prevention), by T. Aitken, illustrated; "The Metallurgy of Iron," by Prof. T. Turner; "Valves and Valve-gearing: a Practical Textbook for the Use of Engineers, Draughtsmen, and Students," by C. Hurst, illustrated; "A Surgical Handbook, for Practitioners, Students, House-surgeons, and Dressers," by Drs. F. M. Caird and C. W. Cathcart, illustrated; "The Work of the Digestive Glands" (Nobel prize award), by Prof. Pavlov, translated by Dr. W. H. Thompson; and "Outlines of Quantitative Analysis, for the Use of Students," by Prof. A. H. Sexton.

Messrs. G. G. Harrap and Co.'s list contains:—"The Elements of Physics," by S. E. Coleman; "Physics: Theoretical and Descriptive," by Dr. H. C. Cheston, Dr. J. S. Gibson, and C. E. Timmerman; "Special Experiments and Discussions in Introductory Chemistry: with a Plan for the Organisation of the Subject-matter," by Dr. E. P. Schoch; "Physiology: Practical and Descriptive," by B. P. Colton, illustrated; "Case Teaching in Medicine: a Series of Graduated Exercises in the Differential Diagnosis, Prognosis, and Treatment of Actual Cases of Disease," by Dr. R. C. Cabot; and "Manual of Clinical Chemistry," by Dr. A. E. Austin, illustrated.

Mr. W. Heinemann directs attention to:—"The Prolongation of Life," by Prof. E. Metchnikoff, translated by Dr. P. C. Mitchell, F.R.S.; and "Metabolism and Practical Medicine," by Prof. C. von Noorden, English issue under the editorship of Prof. I. W. Hall, in three vols.:—Vol i., "The Physiology of Metabolism," by A. Magnus-Levy; vol. ii., "The Pathology of Metabolism," by C. von Noorden, F. Kraus, A. Schmidt, W. Weintraud, M. Matthes, and H. Strauss; vol. iii., "The Pathology of Metabolism," by C. von Noorden, H. Salomon, A. Schmidt, A. Czerny, H. Steinitz, C. Dapper, M. Matthes, C. Neuberg, O. Loewi, and L. Mohr.

Messrs. Hodder and Stoughton give notice of:—"Electric-power Users' Handbook," by P. H. Brown; (Primers of Industrial Art):—"Tin Enamelled Pottery, including the Majolica of Italy, Spain, and Mexico; Delft Wares of Holland and England, and Stanniferous Faience of France, Germany, and other European Countries"; "Salt Glazed Stoneware, including the Ancient Wares of Germany and the Low Countries, England and the United States, with Characteristic Examples in the Museums";

"Artificial Soft Paste Porcelain, including the Frit Porcelain (Pâte Tendre) of France, Italy, other Continental Countries, and England, with a Chapter on Marks"; and, in conjunction with Mr. H. Frowde:—"Cheap Diets in Tuberculosis," by Dr. N. D. Bardswell and J. E. Chapman; "Diets for the Working Classes," by the same authors; "Fevers in the East: their Clinical and Microscopical Differentiation, including the Milroy Lectures on Kala-Azar," by Prof. L. Rogers, illustrated; "Life Insurance and General Practice," by Dr. E. M. Brockbank; "Medical Sepsis and Oral Sepsis," by Dr. W. Hunter; and "A System of Syphilis," by various authors, edited by Dr. D'Arcy Power and J. K. Murphy, in five vols.

Messrs. Hutchinson and Co. announce:—"Extinct Birds," by the Hon. W. Rothschild, illustrated; "In Wildest Africa," by C. G. Schillings, illustrated; "The World's Birds," by F. Finn, illustrated; "Pets and How to Treat Them," by F. Finn, illustrated; "Wild Life Stories," by S. L. Bensusan; and "The World's Peoples," by Dr. A. H. Keane, illustrated.

Mr. John Lane will issue:—"Some Nature Biographies (Plant, Insect, Marine, and Primeval)," by J. J. Ward, illustrated; "Two Dianas in Somaliland: the Record of a Shooting Trip," by A. E. Field, illustrated; and "Big Game Shooting on the Equator," by Captain F. A. Dickinson, illustrated.

Mr. H. K. Lewis promises:—"Squint and Ocular Paralysis," by Dr. E. L. Hughes; "Opsonic Method of Treatment," by Dr. E. B. Allen; "The Preservation of Infant Life," by Mrs. de Voss (*née* Kanthack); and new editions of "Studies in Blood Pressure," by Dr. G. Oliver; and "Diseases of the Nose and Throat," by Drs. H. Hall and H. Tilley.

Messrs. Crosby Lockwood and Son's list is as follows:—"Chemistry of Gas Manufacture," by H. M. Royle; "A History of Wireless Telephony," by E. Ruhmer, translated by Dr. J. Erskine-Murray; "Magnetos for Automobilists," by S. Bottone; "Earthwork Diagrams," by R. A. Erskine-Murray and Y. D. Kirton; and "Chapters on Paper Making," by C. Beadle, vols. iii. and iv.

Messrs. Longmans and Co. announce:—"Organic Chemistry for Medical Students," by Prof. G. von Bunge, translated by Dr. R. H. A. Plimmer; "Hydraulics," by Prof. S. Dunkerley, vol. ii., "The Resistance and Propulsion of Ships," illustrated; "Electro-physiology of Plants," by Prof. Jagadis Chunder Bose, illustrated; "Systematic Researches in Thermo-chemistry: Numerical and Theoretical Results," by Prof. J. Thomsen, translated by K. A. Burke; "Photo-chemistry," by Dr. S. E. Sheppard; and "The Reduction of Cancer," by Hon. R. Russell.

The list of Messrs. Sampson Low and Co., Ltd., contains:—"Standard Polyphase Apparatus and Systems," by M. A. Oudin; "Stammering, Cleft-palate Speech, Lisping, &c.," by Mrs. E. Behnke; "Chemistry Simplified," by Dr. G. A. Koenig, a course of lectures on the non-metals, based upon the natural evolution of chemistry; and "A Practical Treatise on Friction, Lubrication, Fats, and Oils," by E. F. Dieterichs.

The announcements of Messrs. Macmillan and Co., Ltd., include:—"African Nature Notes and Reminiscences," by F. C. Selous, with a foreword by President Roosevelt, illustrated; "The History of the Pearl," by Drs. Kunz and Stevenson, illustrated; "Atlas Antiquus: Forty-eight Maps in Colours, on a New Graphic Plan, with Explanatory Text in English, the Names of Places, Countries, &c., on the Maps themselves being in Latin, with a full Alphabetical Index," by Dr. E. Reich; "Aphorisms and Reflections from the Works of Thomas Henry Huxley," selected by H. A. Huxley; "Origin and Development of the Moral Ideas," by Dr. E. Westermarck, vol. ii.; "Mining Tables: being a Comparison of the Units of Weight, Measure, Currency, Mining Areas, &c., of Different Countries, together with Tables of Equivalents, Constants, and other Data, for the Use of Mining Engineers and Surveyors," by Dr. F. H. Hatch and E. J. Vallentine; "The Weights and Measures of International Commerce" (being a section of the above larger work printed separately), by Dr. F. H. Hatch and E. J. Vallentine; and new editions of "Elements of the Comparative Anatomy of Vertebrates," adapted by Prof. W. N. Parker from the German of Prof. R. Wiedersheim, illustrated; "Modern Views of Electricity," by Sir Oliver Lodge, F.R.S., illustrated; and "Self-instruction in the Practice and Theory of Navigation," by the Earl of Dunraven, three vols.

Messrs. Methuen and Co.'s list includes:—"A History of Astronomy," by W. W. Bryant, illustrated; "Trees in Nature, Myth, and Art," by J. E. Phythian, illustrated; "The Bee People: or, the Story of a Bee told by Herself," by M. W. Morley, illustrated; "Little Mitchell: or, the Story of a Mountain Squirrel told by Himself," by M. W. Morley, illustrated; "Electric Light and Power: an Introduction to the Study of Electric Lighting," by E. E. Brooks and W. H. N. James, illustrated; "Engineering Workshop Practice," by C. C. Allen, illustrated; and a new edition of "Practical Physics," by Prof. H. Stroud, illustrated.

Mr. Murray announces:—"Heredity," by Prof. J. A. Thomson, illustrated; "Therapeutics of the Circulation," by Sir T. Lauder Brunton, F.R.S.; "Round about the North Pole," by W. J. Gordon, illustrated; and "The South African Natives: their Present Condition and Progress," edited by the South African Native Races Committee.

Messrs. J. Nisbet and Co. promise:—"On Some Common Affections of the Liver," by Dr. G. W. H. White; "On the Diagnosis and Treatment of Surgical Affections of the Knee," by Sir W. H. Bennett; "On Movable Kidney," by W. A. Lane; "On Hip Disease in the Young," by J. Berry; "On Prostatectomy," by J. W. T. Walker; "On Enuresis," by Dr. J. H. Thursfield; "On Some of the Common Affections of the Tongue," by J. Hutchinson, jun.; "Some Clinical Points in the Surgery of the Intestine," by F. C. Wallis; and "Nerve Injuries and their Treatment," by J. Sherren.

The list of the Oxford University Press contains:—"Index Kewensis," Supplement iii., bringing the names down to 1905; "Floral Mechanisms," by Dr. A. H. Church; "Studies in the Medicine of Ancient India," part i., "Osteology of the Bones of the Human Body," by A. F. R. Hoernle; "Lectures on Evolution," by Prof. E. B. Poulton, F.R.S.; "Knuth's Handbook of Floral Pollination," translated by Prof. J. R. A. Davis; and "Solereder's Systematic Anatomy of the Dicotyledons," translated by L. A. Boodle and F. E. Fritsch, and revised by Dr. D. H. Scott, F.R.S.

Messrs. Kegan Paul, Trench, Trübner and Co., Ltd., will publish:—"The Forces of Nature," by Dr. G. Le Bon; and "Introduction to the Science of Electricity," lectures by B. Kolbe, edited and revised by the author for publication in England, translated by J. Skellon, illustrated.

The announcements of Messrs. G. Philip and Son, Ltd., contain:—"'Day by Day' Tellurian and Calendar: a Novel Device illustrating the Elliptical Orbit of the Earth round the Sun, also the Seasons, Day and Night, &c."; "Notes on Maritime Meteorology," by M. W. C. Hepworth; "A Simple Course of Weighing and Measuring, including the Metric System," by H. G. Ashton; and new editions of "Catechism of the Laws of Storms," by Commander J. Macnab, illustrated; and "Trigonometry for Seamen," by the same author.

Sir Isaac Pitman and Sons, Ltd., promise:—"Australian Mining and Metallurgy," by D. Clark, illustrated; and "The Metallurgy of Tin," by P. J. Thibault.

Messrs. G. P. Putnam's Sons announce:—"A Field Book of the Stars," by W. T. Olcott, illustrated; "Alpine Flora of the Canadian Rocky Mountains," by Mrs. C. Schaeffer, illustrated; "Hunting Big Game with Gun and with Kodak: How Wild Animals Look and Live in their Haunts, from Personal Experiences in the United States, Dominion of Canada, and Old Mexico," by W. S. Thomas, illustrated; "The Family: an Ethnographical and Historical Outline, with Descriptive Notes," by Dr. E. C. Parsons; "Alcohol: the Sanction for its Use, Scientifically Established and Popularly Expounded by a Physiologist," by Dr. J. Starke, translated; and "Thinking, Feeling, Doing: an Introduction to Mental Science," by Dr. E. W. Scripture, illustrated.

Messrs. Rivingtons direct attention to:—"Elementary Statics," by W. G. Borchardt, illustrated.

Messrs. Scott, Greenwood and Son announce:—"Modern Flax, Hemp, and Jute Spinning and Twisting," by H. R. Carter, illustrated; "Industrial Alcohol," by J. G. M'Intosh, illustrated; "The Treatment of Paper, for Special Purposes," by L. E. Andes, illustrated; "Celluloid: its Raw Material, Manufacture, Properties, and Uses," by Dr. F. Bockmann, translated, illustrated; "Three Hundred Shades and How to Mix Them," by A. Desaint, plates; "The Paper Mill Chemist," by Dr. H. P. Stevens, illustrated; "Recipes for the Preserving of Fruit, Vegetables, and Meat," by E. Wagner, translated, illustrated; "Pottery Decorating," by R. Hainbach, illustrated; "Manufacture and Comparative Merits of White Lead and Zinc White Paints," by G. Petit; and "Electric Wiring and Fitting for Plumbers and Gasfitters," by S. F. Walker, illustrated.

The Walter Scott Publishing Company, Ltd., direct attention to:—"Race Culture: or, Race Suicide?" by Dr. R. R. Rentoul; and "The Lungs: in Health and Disease," by Dr. P. Niemeyer, translated by B. H. Hall, illustrated.

Messrs. Swan Sonnenschein and Co., Ltd., announce:—"The Port of London and the Thames Barrage: a Series of Expert Studies and Reports," edited by T. W. Barber, illustrated; "The Student's Text-book of Zoology," by Prof. A. Sedgwick, F.R.S., vol. iii., completing the work, illustrated; and a new edition of "Elementary Text-book of Practical Botany for the Botanical Laboratory and Private Student," by Prof. E. Strasburger, translated by Prof. W. Hillhouse

Mr. E. Stanford gives notice of:—"The Elements of Geography," by J. H. N. Stephenson, part i.

The list of the University Tutorial Press contains:—"The Science of Speech: a Full Account of the Structure and Use of the Vocal Organs and the Means of Securing Distinct Articulation," by H. H. Hulbert, illustrated; "The Theory and Practice of Perspective Drawing," by S. Polak; "Certificate Hygiene: a Course of School Hygiene for Teachers, dealing with Sanitation, Physical Training, Food, Drink, Clothing, Fresh Air, Work, Rest, &c.," by R. A. Lyster; and "Junior Chemistry: a Text-book of Experimental Chemistry on Modern Lines," by R. H. Adie.

Mr. T. Fisher Unwin announces:—"Last Hours with Nature," by Mrs. Brightwen, edited by W. H. Chesson, illustrated; "Eliza Brightwen: the Life and Thoughts of a Naturalist," edited by W. H. Chesson, illustrated; "The Matterhorn," by G. Rey, illustrated by E. Rubino, translated from the Italian by J. E. C. Eaton, illustrated; "The Andes and the Amazon: Life and Travel in Peru," by C. R. Enock, illustrated.

The list of Messrs. Vinton and Co., Ltd., contains:—"The Mare and Foal and their Treatment"; "Milch Goats: Breeds and Management"; "Dogs: Breeds and Management"; "Poultry: Breeds and Management"; "Fifty Years among Shorthorns," by R. Bruce; and "The History of Shorthorn Cattle," edited by J. Sinclair.

Messrs. Watts and Co. will issue:—"The Picture Book of Evolution," by D. Hird, part ii.

Messrs. Whittaker and Co.'s announcements comprise:—"The Metric and British Systems of Weights, Measures, and Coinage," by Dr. F. M. Perkin; "Moving Loads on Railway Under Bridges," by H. Bamford; "Principles of Electrical Engineering (Direct Current)," by J. R. Barr; "Steel Works Analysis," by Prof. J. O. Arnold and F. Ibbotson; Whittaker's "Arithmetic of Electrical Engineering"; "Modern Practice of Coal Mining," by D. Burns and G. L. Kerr, parts ii. and iii.; "Electricity in Mining," by P. R. Allen; and "Advanced Text-book on Steam, Gas, and Oil Engines," by J. W. Hayward.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Public Orator, Dr. Sandys, spoke as follows on October 1 in presenting to the Vice-Chancellor the several recipients of honorary degrees on the occasion of the visit of the guests of the Geological Society of London:—

Dignissime Domine, Domine Procancellarie, et tota Academia.

Societatis Geologicae Londiniensis hospites, hesterno die ad nos paulisper advectos, omnes etiam nostrorum hospitum in numero libenter computamus; omnes, scientiarum in hac sede venerabili e tot orbis terrarum partibus praesentes, non sine fraterno quodam animi motu contemplamur. "Saxa et solitudines voci respondent": quanto magis nos, litterarum humaniorum et scientiarum amore imbuti, eorum adventu vehementer commovemur, qui scientia quadam admirabili praediti, etiam ex ipsis saxis rerum naturae veritatem extorquent! Hospitibus nostris omnibus patent hodie Musea nostra, patent Collegia nostra omnia, patent omnium corda. In hoc templo denique honoris, dum hospites nostros omnes, e tot terris advectos, ea qua par est observantia excipimus, nonnullos, gentis uniuscuiusque quasi legatos praecipuos, titulo nostro velut exempli causa decoramus, qui honos aliorum hospitum insignium praesentia illustratus, vestrum omnium plausu sine dubio comprobabitur.

(1) Christiania ad nos misit Universitatis suae Rectorem, geologiae professorem insignem, qui patriae in rupibus et metallis explorandis non sine laude iamdudum exercitatus, Norwegiae australis praesertim de saxis igneis praeclare disputavit. Iuvat videre virum patriae devotissimum, virum Regni novi senatoribus adscriptum, virum denique gentis totius Universitatis legatum auspiciis optimis nominatum.

Doctorum nostrorum in serie primus hodie incedit WALDEMAR CHRISTOPHER BRÖGGER.

(2) Assurgit deinceps Saxoniae explorator indefessus, Universitatis Lipsiensis professor eximius, qui Germania e septentrionali oriundus, palaeontologiae imprimis usus auxilio, Saxoniae in saxis serie perpetua ordinandis diu feliciter occupatus est. Idem geologiae in elementis enarrandis quantum excellit! Rerum naturae in penetralibus suo Marte explorandis quam fortis est! Rerum naturae in miraculis et observandis et explicandis quam subtilis!

Praesentatur vobis Regni Saxonici unus e Consiliariis, geologiae professor Lipsiensis, HERMANN CREDNER.

(3) Progreditur proximus Musei Bruxellensis curator sollertissimus, vir in palaeontologia vertebrata (ut aiunt) investiganda diligentissimus. Meministis arte quali, ossibus immensis ordine apto collocatis, bestiam illam immanem, Iguanodon Bernissartensem, in speciem suam pristinam restituerit, cuius effigiem accuratissime expressam, et zoölogiae in Museo nostro positam, Belgarum Regis liberalitati acceptam rettulimus.

Nostri in Regem illum animi grati testimonium hodie sine dubio libenter audiet unus e ministris eius fidelissimis, LUDOVICUS DOLLO.

(4) Francogallorum respublica maxima, vicinitatis vinculis nobiscum consociata, trans fretum angustum, nonnullis tam formidolosum, ad litora nostra legatum transmisit acceptissimum. Hospes autem noster, qui Normannorum in provincia superiore vallem quandam viridem olim ab oceano denudatam penitus perscrutatus est, in Instituto Catholico Parisiensi geologiam praeclare profitetur. Scientiae vero illius in Actis edendis diu occupatus, Scientiarum ab Academia, viri magni in locum, epistolarum minister perpetuus nuper est electus. Idem stili lucidi perspicuitate et verborum aptorum venustate insignis, opus ingens, summi laboris, summi acuminis monumentum, scientiae suae studiosis dedicavit, cuius in ipso limine professorem quendam Germanum, operis tanti aemulum generosissimum, aperte atque ingenue collaudat, qui, tempore eodem, laudis titulo eodem a nobis iure optima exornatur.

Laudis eiusdem socius merito declaratur ALBERTUS AUGUSTUS DE LAPPARENT.

(5) Germaniae quidem e legatis alterum hodie non sine dolore desideramus, Scandinaviae vero legatum alterum non sine gaudio salutamus. Salutamus professorem, cuius Regem illustrem inter doctores nostros iamdudum libenter numeravimus, cuius popularem insignem, Linnaeum, cum orbe terrarum toto nuper celebravimus. Hodie vero Florae antiquae potius quam hodiernae antistitem decoramus, qui scientiarum ardens amore, saepenumero etiam caeli arctoi frigora fortiter toleravit. Talium virorum auxilio vetera illa poetae Romani verba denuo vera redduntur:—

"Venient annis saecula seris,
Quibus Oceanus vincula rerum
Laxet, et ingens pateat tellus,
Tethysque novos detegat orbes,
Nec sit terris ultima Thule."

Interim velut ultimam Thulen hodie nobis repraesentat doctorum nostrorum illustrium in serie supremus, poli arctoi indagator audax, ALFREDUS GABRIEL NATHORST.

Mr. Augustine Henry, reader in forestry, will deliver his inaugural lecture in the Botany School lecture theatre on Tuesday, October 15, at 5 p.m.

On the nomination of the special board for mathematics, Dr. Glaisher has been appointed an elector to the Isaac Newton studentships until September 30, 1911.

OXFORD.—In the Convocation held on September 30 the degree of D.Sc., *honoris causa*, was conferred upon a number of distinguished foreign geologists who had attended the centenary celebration of the Geological Society, and also upon Dr. Ludwig Mond, who was nominated by the Chancellor for the degree at the last commemoration, but was at that time unable to attend. The following is the text of the speeches delivered by Prof. Love in presenting them for the degree:—

PROF. C. BARROIS.

Aristoteles auctor est ubi hodie terra sit fuisse pontum, ubi pontus terram. Has vicissitudines testantur ipsa e quibus terra constat elementa, φωνήεντα ξυνετοῖσι, sed multorum operam rei ubique incumbentium requirentia ut recte intelligantur. Cum harum rerum investigatores unum in locum aliquando congregari soleant, quo melius quid profectum sit recognoscant, quid egendum sit deliberent, paucos ex eiusmodi conventu laudem singularem adeptos hodie ornat Academia nostra.

Inter Gallos qui geologiæ student fere illustrissimus est Carolus Barrois. Qui vir cum longos saxorum tractus scrutaretur, aliam superficiei structuram esse vidit, aliam medullarum: unde duo saxorum genera distinguere potuit, hæc ignea vi conflata, illa sub vadis, quibus Galliæ pars magna olim opplebatur, sensim concreta. Idem cretæ naturam rimatus, quæ apud nos et apud Gallos perexiguo freto divisos invenitur, nova indicia nactus est unde maris lati et profundi, quo utraque terra olim tegebatur, et incessum et regressum lentum ostenderet.

PROF. A. HEIM.

Qui hodie de vi occulta qua montium iuga super planitiem elata fuerint optime disserunt auctorem sequuntur Albertum Heim. Hic ille est Alpium suarum investigator qui, cum singulorum iugorum, e quibus hæc vasta compages constat, anfractus ramosque perlustrasset, terræ defectus quibus hæ regiones aliquando vexantur, concretas glaciei moles quibus superiora vallium obsidentur, prona montium obteguntur, diligentissime observasset, descriptionem Alpium tabulis pulcherrimis expressam confecit, laboris et fructum et testimonium non pœnitendum.

PROF. A. LACROIX.

Saxorum ignea vi conflatorum varia genera distinguere et quasi in classes distribuere potuit Alfredus Lacroix. Hic ille est qui quattuor abhinc annos monte Peleo vi immani convulso a Galliæ gubernatoribus eo missus est ut nubium ardentium naturam cognosceret: qua in legatione valde periculosa cum appropinquanti exitium flammæ minarentur, mariti virtutem æquavit coniux, quam honoris causa nomino, periculorum olim, nunc laudis socia. Ne multa. Felicissime rem egit vir fortis et sagax, qui harum nebularum natura bene explorata reversus est.

PROF. A. PENCK.

Intercessisse tempora quædam cum terra summo frigore oppressa fuerit nemo nescit. Ultimam quidem ex his quasi periodis, quæ una erat e pluribus quas hic orbis terræ passus est, ex quo animantium sæcula exorta sunt, plurimi pertractaverunt, nemo ex his qui hodie Europam incolunt melius quam Albertus Penck. Cum enim hac periodo exeunte hominem super agros caput extulisse constet, hic noster exstitit qui humani generis vetustatem ultimam illustraret, cum inter variarum gentium instrumentis lapideis utentium tempora et eventus quibus vasti Europæ tractus glacie purgarentur rationem intercedere doceret.

PROF. H. REUSCH.

De Scandinaviæ geologia optime egit Hans Reusch. Qui vir, cum in Norvegia saxa quædam invenirentur innumerabilibus ante sæculis mari terram operiente sensim concreta, deinde vi ignea adeo liquefacta et mutata ut nulla omnino animalium vestigia exhiberent, ipse rationes novas commentatus eiusmodi indicia deprehendit, unde saxorum ætatem colligere potuit. Ostendit etiam Norvegiam vastissimis glaciei molibus antiquitus fere obtectam esse, ex quo patet etiam in vetustate ultima magnis caloris et frigoris vicibus obnoxiam fuisse terram.

PROF. F. ZIRKEL.

Qui illud Scientiæ Naturalis genus pertractant quod ad metallorum saxorumque structuram pertinet Ferdinando Zirkel fere omnia accepta referenda censent, cum microscopo, ut cum physicis loquar, hac in re primus usus sit. Neque satis erat ei nova huic rei studentibus subsidia parare, ipse enim in hoc genere plurimum profecit, cuius doctrinam et peritiam testatur maximus ille de Petrologia liber luculentissime conscriptus.

DR. L. MOND.

"Magnum vectigal est parsimonia" dixit Tullius, quod etiam in Chemia valere sensit Ludovicus Mond. Cum enim id agunt chemici ut certum aliquod elementum a ceteris secernant, restant tanquam rediviva quædam, quæ saepe magni pretii sunt. Multos iam annos hic vir varios modos commentatus est, quibus corpuscula ab aliis spreta, tanquam inutilia, in usum converteret. Ita parcendo dives factus Scientiam Naturalem omni liberalitatis genere coluit. Maximum Londinii laboratorium Humphredo Davy et Michaeli Faraday, Chemiæ et Physicæ auctoribus clarissimis dedicatum, ædificavit et muneribus locupletavit: idem Societati Regali catalogum maximum, in quo omnia ab omnibus in quovis scientiæ genere his centum annis reperta continerentur, conficiendum et typis imprimendum curanti pecunia subvenit.

THE Association of Technical Institutions offers two prizes, each of 25*l.*, for the two best essays, one on "The Bearing of Technical Education on Industrial Progress," and the other on "The Bearing of Technical Education on Agriculture and on Industries of a Rural Character." Particulars of the conditions may be obtained from Dr. Clay, Northern Polytechnic, Holloway, London, N.

A COURSE of eight lectures on "Certain Fundamental Problems in Physiology common to Animals and Plants" will be given by Dr. W. M. Bayliss, F.R.S., at University College (University of London) on Wednesdays, at 5 p.m., beginning October 23. The lectures are open to all students of the University of London; also to qualified medical men and to such other persons as are specially admitted.

PROF. W. C. McINTOSH, F.R.S., professor of natural history in the University of St. Andrews, in July last presented the University museum with 3150 spirit preparations, large and small. The preparations consist of (1) a named series (about 1150 in number) illustrating the marine zoology of St. Andrews—the types of the "Invertebrate Marine Fauna and Fishes" of St. Andrews, 1875; (2) a glazed cabinet illustrating the development and life-history of the salmon of the Tay in ninety-five preparations; (3) a reference series (265 in number) from the trawling expeditions of 1884, each station showing both fishes and invertebrates; (4) a general zoological collection in spirit (consisting of about 1595 specimens), chiefly marine, from Shetland to the Channel Islands, but also including a considerable number of amphibians, reptiles, birds, and mammals; (5) forty-five typical botanical preparations, including a fine series of pitcher plants with their insects.

THE programme of day and evening classes at the Woolwich Polytechnic during the session 1907–8 has been received. The volume contains the usual syllabuses of subjects studied at the polytechnic, and particulars of the examination requirements of London University, Board of Education, and other examining bodies. We are glad to see here and there short notes as to the value of preliminary scientific education to the student of technology. Thus, it is pointed out that a sound knowledge of mathematics is the surest basis for satisfactory progress in mechanical and physical science. In the physical department, all students are required to attend both the lecture and the laboratory course in each class; and students of electrical engineering must attend classes in electricity and magnetism concurrently if they have no knowledge of the principles of electrical science. Systematic courses of study extending over three or more years are arranged in various branches of technology; and the time-tables of these courses should be useful as a guide to serious students. We notice the announcement that the governors are desirous that no young man or woman shall be deprived of the advantages of the instruction given in the polytechnic, on the ground of inability to pay the fees. The principal is authorised to admit students free who desire to attend any of the classes and to work steadily, but are unable to pay the necessary fees.

THE distribution of medals, prizes, and certificates to students of the Royal College of Science on Thursday last was made the occasion of several references to the charter of incorporation of the Imperial College of Science and Technology. The Dean, Prof. W. A. Tilden, trusts that by the end of the year everything will be ready for the transfer of authority which is to take place from the Board of Education to the governing body of the Imperial College on January 1 next. In his address to the students, Mr. A. H. D. Acland said that in the forwarding of technology this country has been lamentably backward. Scientific knowledge is at the very root of the prosperity of the Empire. If determined efforts are made a great national institution will be established of which the country will really be proud. Mr. Acland advised the students to do something to study the great masterpieces of the English language. He remarked that in later life, when they have to make reports, as all men in scientific life must do, they will often find that the study of the English language will not have been altogether useless, even at the present stage of their education. Mr. Acland also advised the students to travel when it is possible for them to do so. Scientific men do a great deal by their interchange of ideas between this and foreign countries to forward that which we all desire—international friendliness. Prof. Dalby, Dean of the Central Technical College of the City and Guilds of London Institute, referred to the union which is to take place between the three colleges; and Sir William White said that to put the charter in practical form it is necessary to recognise all that has been done in the past, to utilise fully all that exists, and to bring the whole of the higher technical instruction into one harmonious and sympathetic working whole.

A STRONG plea for the establishment of a university for Bristol and the West of England was made by Prof. F. Gotch, F.R.S., at the annual distribution of prizes to the students of the faculty of medicine of the University College of that city on October 1. Prof. Gotch pointed out that the geographical position of Bristol, her civic prosperity, and her educational institutions are such that there is no excuse for further delay. It is time for the city to realise that in higher education the organisation of her teaching resources is a matter of momentous importance, and that the way to attain this is to segregate all her scattered educational efforts in a university. Surely the citizens of Bristol are as enlightened and generous as those of Liverpool, Manchester, Birmingham, Leeds, and Sheffield; and the fact that the city has not also a university of its own must be because the difference between a college and a university is not understood. A university possesses greater educational stability, and, in consequence, greater educational efficiency. It segregates all the higher educational enterprises of the district, rivalry gives place to cooperation, general interest is thus awakened, and it is sustained by the knowledge that, having become a working partner in a great enterprise, it must at all hazards be made a success. The credit of the community is then at stake, thus ensuring its proper support; and since the enterprise has, from the educational point of view, attained a new level, it is viewed from a different and a higher standpoint. Another conspicuous feature of a university is the freedom which it enjoys. The possession of the power to give a degree carries with it a matter of enormous freedom. Collegiate teaching has to follow along lines prescribed by those bodies which give degrees, and such prescription stifles educational development, because the teacher has no voice in the matter. A further feature of a local university is the enlargement of the area of educational responsibility. The pride which the citizens of Liverpool and Birmingham have in their universities is due to their proprietary interest in them. A university would thus become the dominant educational force and pride of Bristol and all the surrounding district. The last feature of a university, as distinct from a college, is one which will in the end carry on its broad back all the others: it is prestige. So long as Bristol only possesses a college, she will from the standpoint of higher education have but little general prestige. The fault does not lie with the character of the collegiate teaching, the size of the buildings, or the equipment of the scientific laboratories. So long as the college continues to remain in its present condition, so long will it not only gain no prestige, but may begin to lose what prestige it now possesses. Those who take over wider university responsibilities are felt to be possessed by the spirit of the age, and are duly honoured, whilst those who hesitate to do so are felt to be without this spirit, and lose their position.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, received June 8.—"On Luminous Efficiency and the Mechanical Equivalent of Light." By Dr. Charles V. **Drysdale**. Communicated by Prof. Silvanus P. Thompson, F.R.S.

The paper first directs attention to the fact that the term luminous efficiency requires more rigorous definition. If Q is the total power consumption of the source, R the total radiation $= \int_0^\infty I_\lambda d\lambda$, and L the luminous radiation $= \int_{\lambda_1}^{\lambda_2} I_\lambda d\lambda$, the luminous efficiency is generally taken to mean the ratio L/Q. In many cases, however, the ratio L/R, which has been termed by Nichols the radiant efficiency, is determined. Neither of these definitions is entirely satisfactory from the practical point of view, as a source might apparently be of high efficiency if its radiation were confined within the visible spectrum, but near to either end of the spectrum, where the luminosity is low. A better definition is that of Dr. Guilleaume, which may be termed the reduced luminous efficiency L_λ/Q, where L_λ is the equivalent radiation of the most effective form required to give the same light emission. In order to obtain the latter quantity it is necessary to determine the mechanical equivalent of the most effective luminous radiation which is in the neighbourhood of $\lambda = 0{\cdot}54\ \mu$.

For the measurement of the mechanical equivalent a spectrum was formed by a carbon bisulphide prism, and a combined photometric and bolometric arrangement was made to enable the luminosity of any part of the spectrum to be measured, and the radiation to be compared with that from a glow lamp radiating a known amount of power. By means of a movable screen the radiation from the spectrum or from the source of radiation could be intercepted alternately, and the radiation from the comparison source altered until no effect was observed on changing from the spectrum to the comparison lamp. This eliminated trouble due to drift. Measurements were made both with approximately monochromatic light in the neighbourhood of $0 \cdot 54\ \mu$, and in white light obtained by widening the slit until the whole of the light within the visible limits was collected at the bolometer. The result obtained for the mechanical equivalent was 0·06 watt per candle for the yellow-green light; for white light obtained from an arc the mechanical equivalent was 0·08 watt per candle, and from a Nernst filament as source 0·12 watt per candle, the latter result agreeing almost exactly with that obtained by Ångström for the light of the Hefner lamp. The ideal source of white light should therefore give somewhere about ten candles per watt, and a monochromatic yellow-green source nearly seventeen candles per watt.

June 13.—"On the Identification of Chitin by its Physical Constants." By Miss I. B. J. **Sollas.** Communicated by Prof. W. J. Sollas, F.R.S.

The determination of the physical constants of chitin forms a useful method of identifying it. The specific gravity of chitin from various sources approximates to the value 1·398, a number which represents the specific gravity of chitin precipitated from its solution in strong acid. The refractive index lies between the limits 1·550 and 1·557.

The bristles of Lumbricus, the pupal skin of Pieris and other Lepidoptera, the radula of Mollusca and the shell of Sepia, when freed from mineral matter and easily soluble organic substances, have specific gravities and refractive indices which lie between the same limits as those of chitin from various sources.

June 27.—"The Pressure of Bile Secretion and the Mechanism of Bile Absorption in Obstruction of the Bile Duct." By Dr. Percy T. **Herring** and Dr. Sutherland **Simpson.**

The authors find that the maximum pressure attained by the bile in obstruction of the common bile duct considerably exceeds the figures given by Heidenhain. In the dog, cat, and monkey the average maximum pressure reached in a number of experiments was 300 mm., measured in terms of the height of a vertical column of bile. The highest pressure recorded was 373 mm. bile in a cat.

When the common bile duct is obstructed the bile escapes from the liver by the lymphatics, and in the cat may be seen in the thoracic duct one hour after obstruction.

Evidence is adduced to show that the obstructed bile enters the intracellular plasmatic channels of the liver cells, and passes from them by the natural lymph flow into the lymph channels of the portal spaces. The mechanism of absorption lies in the liver cells, and is not an escape from interlobular bile ducts.

The intracellular plasmatic channels are held to constitute an intermediate system between the blood-vessels and lymphatics of the liver. The "vital" theory of lymph formation is supported.

"On the Relation between the Output of Uric Acid and the Rate of Heat Production in the Body." By E. P. **Cathcart** and J. B. **Leathes.** Communicated by Dr. C. J. Martin, F.R.S.

A diet containing no purine bases, free or combined, was taken by one of the experimenters in equal amounts every three hours during the day, and the output of uric acid during each of the periods of three hours was determined. In this way the average rate of excretion for each period of the day could be ascertained, as well as the daily total. Exposure to cold for about three hours with no voluntary muscular exertions increased the rate of excretion at the time and for some time after (in the first twenty-four hours nearly 50 per cent. above the mean calculated from sixteen successive days), whereas a similar exposure to cold counteracted by muscular activity increased it much less (in the first twenty-four hours about 15 per cent.), and muscular activity without the stimulus of cold (in heavy clothing) for the same length of time diminished it (in the first twenty-four hours about 30 per cent.). The conclusion pointed to is that the endogenous uric acid is in part, and it may be to a considerable extent, a product of the reaction of the body to loss of heat, and that this reaction consists in some form of activity distinct from voluntary movements of the muscles.

"Further Studies of Gastrotoxic Serum." By Dr. Charles **Bolton.** Communicated by Prof. S. Martin, F.R.S.

The serum referred to in this communication was prepared by injecting the stomach cells of the guinea-pig into the rabbit, the blood serum of the rabbit developing toxic properties for the guinea-pig's tissues.

It has been shown that the serum contains, not only a precipitin for stomach-cell proteid, but also separate precipitins for other body proteids. The actions of these precipitins overlap to some extent. There is no agglutinin for the stomach-cell granules, the agglutination which was found to occur being brought about by the precipitins.

The repeated injection of gastrotoxic serum does not produce chronic gastric ulceration, but immunity to the serum is established. The immunity is not only active, but the serum is able to confer passive immunity upon another animal. The tissues of the immune animal are still acted upon by the gastrotoxic serum in the test-tube, the immune substances being present in the blood serum of the animal.

It has been demonstrated that the necrosis of the mucous membrane of the stomach resulting from the injection of gastrotoxic serum is not directly caused by the serum, but is brought about directly by the action of the gastric juice. The cells are functionally damaged by the serum, which renders them susceptible to the gastric juice. The process is thus one of self-digestion. Hyperacidity of the gastric juice increases the tendency to this self-digestion.

Received July 20.—"A Preliminary Summary of the Results of the Experimental Treatment of Trypanosomiasis in Rats." By H. G. **Plimmer** and J. D. **Thomson.** Communicated by Sir Ray Lankester, K.C.B., F.R.S.

The experiments described were undertaken under the direction of the Tropical Diseases Committee of the Royal Society.

The strains of trypanosomes used were a nagana from the original strain brought to England, and a surra from Prof. Lingard in India. The nagana strain kills rats in an average time of 5·5 days, and the surra strain in 6·9 days.

Of drugs experimented with, fifteen chinolin compounds, dichlorobenzidine + acidH, trypanroth, arsenious acid, atoxyl, monophenylarsenic acid, nitrophenylarsenic acid, paratolylarsenic acid, and other arsenic compounds are commented upon, and their effects on the development and course of the diseases stated. Of all the arsenic compounds, and, indeed, of all substances tried singly, atoxyl had by far the most favourable action.

This is the most important substance, so far discovered, in relation to the treatment of trypanosomiasis. In nagana and surra atoxyl causes the entire disappearance of the trypanosomes from the blood, so that rats inoculated with the blood when it was microscopically free from parasites failed to take the disease; but the trypanosomes have invariably recurred, and death was only delayed for a period varying with the dose, and with the time of commencement of the treatment.

When atoxyl is given more continuously or more freely than is required, in cases in which there have been many recurrences, and probably under some other conditions of which we are ignorant, in a certain small proportion of rats so treated a race of trypanosomes is produced which entirely resists atoxyl, and continues to develop and multiply in spite of continued exhibition of the drug. This strain, when inoculated into fresh rats, retains its resistance to atoxyl. Ehrlich, who has produced such a strain in mice, calls them "atoxyl-fest," and we have obtained this atoxyl-proof variety of trypanosome in rats, both in nagana and surra.

In human trypanosomiasis the danger of the production of an atoxyl-proof strain will be at once apparent. For an account of the production and behaviour of these atoxyl-proof strains, and for the results obtained with them, reference must be made to the original paper. Their importance and their bearing on the treatment of human trypanosomiasis by atoxyl is obvious.

Under the heading "Treatment with two or more Drugs," a number of tables are given showing the results of treatment with atoxyl and various mercury compounds, and atoxyl and iodipin. Of the mercury compounds used, the succinimide appears to be the best; it has the great advantage of being unirritating to the tissues, and it will mix with atoxyl without precipitation, and without interfering with the action of the latter.

The results with atoxyl and iodipin are sufficiently encouraging to suggest a further trial of this combination. Several of the animals treated are alive, and apparently well, some as long as five months after inoculation; the duration of the disease has been very greatly prolonged in the great majority of cases, and in some the authors have confidence that a cure has been effected.

PARIS.

Academy of Sciences, September 30.—M. Henri Becquerel in the chair.—Is the use of arsenious acid a preventative against trypanosomiasis? A. **Laveran** and A. **Thiroux.** The authors have repeated the experimental work of Loeffler and Rühs, and come to the conclusion that the use of arsenious acid for trypanosomiasis is not advisable, although in certain cases it may have a useful effect. It cannot be used like quinine against malaria, as the necessary doses of quinine in the latter case are small, not toxic, and can be administered without inconvenience during several months, whilst the doses of arsenious acid which must be administered, either in man or in animals, judging from the doses necessary with the guinea-pig, would be quickly followed by poisonous symptoms. In animals used for food, in particular, the prolonged use of arsenic would have the result of rendering the flesh poisonous.—Researches on the laws of action of light on glucosides, enzymes, toxins, and anti-bodies: Georges **Dreyer** and Olav **Hanssen.** The authors have examined the action of light on two glucosides, saponine and cyclamine; three enzymes, yeast, trypsine, and papayotine; two toxins, ricine and abrine; and one immuno-serum, coli-agglutinine. All these are weakened by the action of light, the ultra-violet rays retained by glass being the chief cause. The action progresses regularly under the action of continuous lighting, the change following very exactly the law of monomolecular reaction.—Transformers with magnetic leakage and secondary resonance for wireless telegraphy: MM. **Gaiffe** and **Gunther.**—Observations on the affinities and evolution of the Chicoraceæ: Léon **Dufour.**—The pluricarpellary origin of the pistil in the Lauraceæ: Marcel **Mirande.**—The function of the spleen in trypanosomiasis: A. **Massaglia.** Trypanosomes collected from the spleen present the same characters as those collected from other parts of the body. This virulence of the trypanosome does not disappear more rapidly in the spleen of animals killed by the trypanosome than in the blood of these animals, and the extract of the spleen does not destroy, *in vitro*, the trypanosomes. The course of the disease surra is the same in a dog from which the spleen has been removed as in the normal animal.—Researches on the chemical nature of the fundamental colouring material of the urine: S. **Dombrowski.** The urochrome is isolated from the urine by precipitation with copper acetate, and from its analysis is shown to contain carbon, hydrogen, nitrogen, sulphur, and oxygen. The sulphur is easily removed by alkalis; the presence of sulphur shows that this body is not derived from the coloured part of hæmoglobin or urobilin, as has been asserted up to the present.—Sodium chloride as a sensitising substance for vegetable ferments: C. **Gerber** and Mlle. S. **Ledebt.** Sodium chloride, in small proportions, accelerates the coagulation of milk by vegetable ferments. It determines the phenomenon when the ferment is present in too small quantities to act alone.

NEW SOUTH WALES.

Linnean Society, August 28.—Mr. A. H. Lucas, president, in the chair.—A preliminary record of the occurrence of Chlamydoselachus in the waters of New South Wales: D. G. **Stead.** The record was based upon portions of a specimen cast ashore some time since in Rose Bay, Port Jackson, comprising the skull and about 150 vertebræ. The specimen measured more than 10 feet in length. Only one species of the genus is known, *C. anguineus*, Garman, from the Sea of Sagami, Japan, as well as from deep waters in the vicinity of Madeira, the Azores, and the coast of Norway, while the length of the largest specimens hitherto known appeared to be about 5 feet.—The resistance of the vegetation of Australia to bush-fires, and the antiquity of the Australian aboriginal: Dr. J. B. **Cleland.** The object of the paper is to suggest that, if it can be proved that the vegetation of Australia has been modified in the course of ages so as to have become more tolerant of bush-fires, and as a result of the frequency of such fires, and if the frequency of such fires can be regarded as due mainly to the agency of man, then there would seem to be some grounds for attributing considerable antiquity to the presence of fire-producing man in that region, and therefore, presumably, to the ancestors of the vanishing aboriginal Australian.—The geology of the Warrumbungle Mountains, N.S.W.: H. I. **Jensen.** In this paper the physiography of the Warrumbungle Mountains district is described, and it is shown that many of its peculiarities are due to *arid erosion*. The mountains may be looked upon as forming a dissected lava conoplain surrounded by an arid erosion peneplain.

CONTENTS.

SUPPLEMENT.

THURSDAY, OCTOBER 17, 1907.

STEREOCHEMISTRY.

Stereochemistry. By Dr. A. W. Stewart. Pp. xx + 583. (Text-Books of Physical Chemistry. Edited by Sir William Ramsay, K.C.B., F.R.S.) (London: Longmans, Green, and Co., 1907.) Price 10s. 6*d*.

THIS book is practically a complete and in many cases a detailed account of the subject of stereo or space chemistry since the foundations of this exceedingly fruitful branch of chemical science were laid by Pasteur and Wislicenus. It is not an historical summary, but a carefully thought out treatise, and one which chemists who have to lecture or teach the subject will find of the greatest use.

The book commences with a short historical introduction. Part i. deals with optical activity, the first section describing the asymmetry of the carbon atom. The author's idea of explaining the effect of polarisation on light by means of a paper-knife and two books is distinctly good. The next chapter deals with inactive compounds, and from this we are led up to the active compounds and the determination of configuration.

Chapter viii., on "other active elements," is a review of the work done upon nitrogen compounds, and also deals with the isolation of active compounds of sulphur, selenium, and tin by Pope and his coadjutors. The first part of the chapter is a survey of cases in which nitrogen is known to show isomerism; the second part is a consideration of the various theoretical explanations put forward upon the configuration of nitrogen compounds. This complex part of the subject would perhaps have been more easy to follow if the author had been able to devote a little more space to the consideration of these theories, but as the references are ample and the book is by no means short, even as it is, Dr. Stewart must be left as the best judge of how much space to devote to each portion of the work. As the author himself says in his preface, stereochemistry is much easier to follow if one has a set of models to work with. It is, in fact, very difficult to study the subject from a book alone, and in Appendix B directions for the construction of stereochemical models are given, one of the simplest methods for making tetrahedra being to cut them out of hard yellow soap, needles being used for bonds.

Steric hindrance is a subject which is very much to the fore at the present time, and one rarely visits a meeting of the Chemical Society without hearing it mentioned. For this reason the chapter on steric hindrance in this book is of particular interest. To a certain extent also interest is added because the author, in connection with his work with Baly upon absorption spectra, has come across facts which in the opinion of the authors are a contradiction to the theory of steric hindrance, Stewart and Baly holding that in the case of the carbonyl group the reactivity is not inherent in the group itself, but depends upon the "nascency" of the radical, this "nascency" being governed by the action of the adjacent groups upon the carbonyl radical. Could not some rather more euphonious name be chosen for the activity of the group than "nascency"? One can perhaps hardly talk about the atomic character of a group; would not activity itself do? It is not unusual to speak of hydrogen, at the moment of its liberation, being in the active form, but one never talks of the "nascency" of hydrogen. Or one might borrow an electrochemical term, and speak of the potential of the group. Thus the potential of hydrogen is high or low, depending upon the surface and character of the electrode from which it is liberated, and the tension or potential of the carbonyl group might be high or low, depending upon the character of the adjacent groups.

Appendix A deals with the relations of stereochemistry to physiology. That the configuration of the groups should affect the physiological action is certainly interesting. Thus when given to rabbits in various ways it was found that in the case of the three arabonic acids more of the lævo- than of the dextro-variety was acted upon, and in the case of the mannoses the dextro-variety appears to be best suited for nourishment. The taste, at any rate to some extent, depends upon the stereoisomeric form; thus in the case of glutaminic acid the dextro-form is sweet, but the lævo-form is tasteless. Furthermore, the toxic action in some cases varies considerably with the different isomeric modifications. For example, *l*-hyoscyamine is almost twice as active in its effects upon the pupil nerve-endings as *dl*-hyoscyamine. This branch of the subject is of great interest, and doubtless the gathering together of these facts will serve to stimulate investigation in this valuable practical part of the subject.

The illustrations are good, some of the half-tone reproductions of models being excellent, and the book itself is well got up. It is decidedly one of the most useful of the series, and Dr. Stewart is to be congratulated upon the completion of a very painstaking work.

F. M. P.

ORIENTAL PLAGUE.

Studies in the Bacteriology and Etiology of Oriental Plague. By Dr. E. Klein, F.R.S. Pp. xv + 301. (London: Macmillan and Co., Ltd., 1906.) Price 12s. net.

THE appearance of this book at the present time is opportune, for plague is ravaging our Indian Empire, some 900,000 deaths having been recorded there from January 1 to May 31 this year. The work is based on Dr. Klein's large experience of the bacteriological examination of cases which clinically and epidemiologically were under suspicion of being plague. Many epizootics among rats on shipboard were also investigated by Dr. Klein, and the results of his examinations are included. The data so obtained, and published in many scattered papers, are thus brought into a convenient form for reference.

In chapter i. a good account is given of the histology of plague lesions and of the distribution of the plague bacillus in the tissues; in chapter ii. the characters of the plague bacillus are described with great fulness, and many valuable hints on staining, &c., will be found here. Dr. Klein believes to be erroneous the view of Calmette that passage of the plague bacillus through a series of animals of a species, while increasing its virulence for that species, diminishes the virulence for other species. The statement is made at p. 29 and again at p. 47 that Hankin described long filamentous modifications of the plague bacillus when the organism is grown on salted media, an observation for which Dr. Klein claims priority. But surely what Hankin did describe was the occurrence of large spherical, spindle- and pear-shaped involution forms on salted media (see *Centr. für Bakt.* xxii., p. 438). Here and in some other places references are omitted, and authors' names are sometimes wrongly spelt, *e.g.* Tideswell for Tidswell, and Simmonds for Simond (p. 154). Chapter iii. deals with the bacteriological analysis of plague material, many valuable practical hints being incorporated, and chapter v. with microbes simulating the plague bacillus. Notable among these are the *Bacterium bristolense* and the *B. myxoides.* The former was isolated from dead rats found on a ship unloading at Bristol, which had come from a plague-infected port. It caused the death of guinea-pigs with a hæmorrhagic septicæmia and enlarged glands, and the bacilli that were present in the lesions were much like the plague bacillus. As a matter of fact, however, cultures showed that the organism was allied to the *B. coli.* The *B. myxoides* was isolated from a case of acute hæmorrhagic febrile disease, which had been notified as possibly one of septicæmic plague. The organism morphologically and in staining properties presented a certain resemblance to *Bacillus pestis*, but it was not pathogenic by subcutaneous inoculation to guinea-pigs and rats, and culturally differed from the plague bacillus. The case was actually one of hæmorrhagic small-pox with a secondary or a terminal infection with this microbe. These examples illustrate the care necessary to diagnose plague bacteriologically. Plague in the rat and in other rodents is discussed in chapters v. and vi. Dr. Klein considers that there may be a type of *B. pestis* occurring in the rat which is less virulent than the ordinary human type. The transmission of plague from one animal to another (chapter vii.) Dr. Klein would ascribe principally to infection by the digestive tract and not to fleas, lice, and other insects, though it must be pointed out that the careful work of Tidswell (Report on the second outbreak of plague at Sydney) and of the Indian Plague Commission (*Journal of Hygiene*, vi., 1906, No. 4) support strongly the latter theory.

Chapter viii. discusses the agglutination reaction and its application to plague; on the whole the test is difficult to apply in this disease, but under certain conditions may be of value. The important subject of preventive inoculation is dealt with in the last chapter but one. The subject of the supposed danger of inoculation during the incubation period is first alluded to, and Dr. Klein remarks that with a prophylactic he has devised there is no risk of this sort. No reference, however, is made to Bannerman's statistics (*Centr. f. Bakt.*, Abt. i., Bd. xxix., p. 873), which seem completely to remove this objection to the use of the Haffkine prophylactic. As the result of his experiments, Dr. Klein says, "I am prepared emphatically to maintain that 10 c.c. of the Haffkine prophylactic is capable of fully protecting a rat against a subsequent lethal dose of living plague culture." Important testimony this to the protective power of the vaccine when India is decimated with plague and the author of the prophylactic treatment is under a cloud in consequence of an unfortunate accident for which we believe he was in no way responsible! Dr. Klein incidentally confirms much of Haffkine's work on the plague prophylactic.

The most interesting portion of this section is that which deals with the preparation of a new form of vaccine material devised by Dr. Klein which consists of an emulsion of the *dried* organs of a guinea-pig dead of plague. The drying deprives the plague bacilli of their vitality, and it was found that 10–15 milligrams of the dried organ powder sufficed completely to protect a rat against a lethal dose of plague bacilli. The final chapter is devoted to a consideration of the modes for the destruction of the plague bacillus, and much useful information on the action of disinfection and disinfectants on this organism is included.

The book, which lacks an index, is profusely illustrated with a number of excellent plates, and we congratulate Dr. Klein on the amount and importance of the work he has done with reference to plague and the plague bacillus. R. T. HEWLETT.

MEMOIRS ON MARINE ANIMALS.

(1) *Anurida.* By A. D. Imms. Pp. viii+99; 7 plates. 1906. Price 4*s.*

(2) *Ligia.* By C. Gordon Hewitt. Pp. viii+37; 4 plates. 1907. Price 2*s.*

(3) *Antedon.* By Herbert C. Chadwick. Pp. viii+47; 7 plates. 1907. Price 2*s.* 6*d.* (London: Williams and Norgate.)

THESE volumes, which form the thirteenth, fourteenth, and fifteenth of the Liverpool Marine Biological Committee's memoirs, are comprehensive studies, admirably illustrated by lithographic plates, of animals common on our shores and readily accessible to the student. The authors and the editor, Prof. Herdman, are to be congratulated on the production of such excellent aids to the study of types of our British marine animals.

(1) Mr. Imms's memoir is a well-arranged and detailed account of the interesting Collembolan *Anurida maritima*, which is common on the surface of the quiet shore-pools and in the crevices of the rocks near Port Erin and at other localities on the British coast. In the description of the habits of the animal attention is directed to the covering of hairs, which, when the animal is submerged, retains a supply of air which serves for respiration (there being sufficient to last the insect five days), and also renders the body incapable of being wetted. Chapters follow on the external characters, integument and coloration, mouth parts, digestive, circulatory, nervous, excretory and repro-

ductive systems and embryology. The author has wisely chosen to describe only the general features of the muscular system; a more detailed account would have been beyond the scope of the present memoir. The ventral tube, characteristic of Collembola, present as a papilliform organ on the mid-ventral aspect of the first abdominal segment, is formed, as is shown by development, by the fusion of a pair of appendages. The various functions which have been ascribed to this organ are set forth. The author records his observations in support of the view that its primary function is that of an organ of adhesion, but he also believes that it plays an important part as a respiratory organ, in virtue of the ease with which blood flows into it and distends its two terminal thin-walled vesicles. He confirms on Anurida the observations of Willem and Hoffmann on other Collembola, that the secretions of two pairs of cephalic glands flow into a ventral groove leading from the head to the ventral tube, which they serve to moisten. In the chapters on the general structure, classification and affinities of the Collembola, the author concludes that there are no grounds for regarding these animals as degenerate; they show affinities with the Thysanura (especially in having a pair of mouth appendages—the maxillulæ—intercalated between the mandibles and first maxillæ), and, by reason of certain generalised features, to the lower Arthropoda. The memoir also contains additional remarks on other marine insects, and an extensive bibliography relating to papers on the Collembola published since Lord Avebury's monograph.

(2) In selecting *Ligia oceanica* for description as a type of the Isopoda, Mr. Hewitt has made an excellent choice, for not only is this the largest British Isopod, but it is intermediate between the aquatic and terrestrial forms. Although specimens are usually found just above high-water mark, in deep cervices of rocks or quay-walls, the author found them at St. Kilda on the top of a hill 450 feet above sea-level, to which altitude the sea-spray often reaches. It was remarkable that most of the examples found at this height were females, which do not descend to sea-level to feed, but probably do so when liberating the young from their brood-pouches, for large numbers of young individuals were found under the rocks between tide-marks, but none at the high level. Following the description of the habits are clear and concise accounts of the external characters, the various systems of organs, and the development. The eyes are described in some detail. In each ommatidium there are two cone-cells, each of which secretes a hemispherical, transparent mass. These two masses, with their flat sides apposed, form the cone on the proximal side of which the cone-cells further produce two subcylindrical accessory cones, an interesting and exceptional feature of the eye of Ligia.

(3) The present volume on *Antedon bifida* is Mr. Chadwick's second contribution to this series of memoirs, his previous one, on Echinus, having been published in 1900. Detailed and useful descriptions, with excellent figures, are given of the various parts of the skeleton and of the three nervous systems and their functions. The other systems of organs and the development are well treated. The author is inclined, but without giving reasons, to regard the sacculi as excretory structures; he holds that the view that they consist of reserve material for use in the regeneration of lost or injured parts is discounted by the fact that sacculi are not present in the allied genus Actinometra, in which, nevertheless, regeneration proceeds quite as actively as in Antedon. The account of the axial organ contains no discussion of the many functions which have been ascribed to it, but the author has observed that, at the breeding season, the epithelial cells lining the tubules of the organ break away and become amœboid, suggesting that at this period, at any rate, the axial organ is a site of formation of amœbocytes.

A LIFE OF SIR WILLIAM FLOWER.

Sir William Flower. By R. Lydekker, F.R.S. Pp. vii+191. (English Men of Science Series.) (London: J. M. Dent and Co., 1906.) Price 2*s*. 6*d*. net.

IT will be long ere the name of William Henry Flower is forgotten by those in this country who are interested in scientific zoology and in the progress and development of zoological museums; and the sketch of his life and work which Mr. Lydekker has put together in the present volume, a small one indeed, though rich in interesting material, will be much valued by those especially who had the advantage of personal acquaintance with the great museum conservator.

As Mr. Lydekker has indicated in his preface, the present work is more devoted to the scientific than to the personal and social side of Sir William Flower's career. Nevertheless, the opening chapter deals with his birth, parentage, education, marriage, general career, and with his lamented death at the age of sixty-seven, in a manner which is both sympathetic and interesting. The remaining seven chapters are devoted to his work as a scientific worker and as a museum conservator or director, and the value of the work which he performed in both capacities is well brought out by the writer of the memoir.

As all zootomists know, Sir William Flower's original work lay almost entirely in the domain of mammalian anatomy and general classification of mammals, and his name will go down to posterity as the discoverer of many new and important facts, and as the propounder of more satisfactory views on many matters of zoological interest. We need only mention his demolition of Owen's classification of mammalia by their brains; his discovery of the fact that in the marsupial dentition only a single pair of teeth on each side is replaced by vertical succession; or his classification of the carnivorous mammalia according to the characters of the base of the cranium. Everyone knows also that Sir William Flower was a first-class authority on the Cetacea, and that in his later years he devoted much attention to anthropological studies.

In the chapters on Sir William's work as conservator of the museum of the Royal College of Surgeons, as director of the Natural History Museum, and on his museum and miscellaneous work, Mr. Lydekker gives a very clear account of the principles on which that work was guided and of the results achieved. The main lines along which Sir William's ideas of the purpose of museums and of their arrangement ran must be approved by all interested in the subject, although as to some matters of detail there may be room for individual differences of opinion. There can be no doubt of the soundness of the principle that the specimens exhibited in the galleries should, so far as possible, form a distinct collection adapted specially to its purpose of instructing the general public, that old and bad taxidermy should disappear from the cases, that specimens should not be crowded together, but that each should be exhibited with a purpose, instructively or "descriptively" labelled, and placed so that it can be properly seen. How far, however, the principle of making such a popular series rather a collection of "labels illustrated by specimens" than a collection of specimens explained by labels should be carried out is a question which it would be out of place to discuss in a notice like the present, as is also the question as to how far "pictorial mounting" ought to be adopted in natural history museums.

Sir William Flower was a strenuous opponent of the unnatural divorce between recent biology and palæontology. Everyone agrees with him now—theoretically—but how many zoologists will take the trouble to look up and read an original palæontological memoir? If they want information on a fossil subject, do they not usually take it and quote it from some text-book at second hand?

In compiling this memoir Mr. Lydekker has done his work sympathetically and well, and has produced a little volume which is worthy of a place on the book-shelves of all British naturalists. R. H. T.

OUR BOOK SHELF.

Sfere cosmografiche e loro applicazione alla risoluzione di Problemi di Geographia Matematica. By Prof. Angelo L. Andreini. Pp. xxix+326. (Milano: Ulrico Hoepli, 1907.) Price 3 lire.

This little book, as its title implies, shows how a class of simple problems in spherical trigonometry can be solved with approximation by mechanical methods. It is a form of exercise which has fallen into disrepute in this country, but practical computers will admit that there are times when an appeal to the globe is not without its uses. Such cases can occur in the transformation of coordinates, when the conditions of the problem make the choice of a quadrant uncertain. The author, however, is not so much concerned in providing assistance for the expert as in instructing the novice.

After tracing the history of globe construction and showing some forms of orrery which explain the motion of superior and inferior planets, the phases of the moon, &c., the author indicates the principal problems for which mechanical solution is possible. Very considerable ingenuity is exhibited in the choice and variety of problems submitted, and by some simple additional apparatus for measuring angles an approach to accuracy is made. In those problems connected with the diurnal rotation of the earth, the latitude of a place is determined by measurements made on the prime vertical, while in those depending upon the annual revolution about the sun the equation of time and the obliquity of the ecliptic find a place. This will give some idea of the range of subjects for which the author finds application. Indeed, not a little of the interest of the book centres in its completeness. We should imagine that no class of problems to which a globe has ever been applied is entirely unrepresented here. As a matter of fact, there is reference to the tides and the establishment of a port, though it is difficult to see how a globe can give any assistance in such matters. A large number of examples are given to be worked by the student, and in another section the manner of solution is indicated.

Electric Light and Power. By E. E. Brooks and W. H. N. James. Pp. viii+372. (London: Methuen and Co., n.d.) Price 4s. 6d.

The best that can be said of this text-book is that it is neither better nor worse than others of its class. The book is apparently intended as a first-year course for students of not very high scholastic attainments; if this is so, we think it covers too much ground. Starting from the very beginning, with experiments with knitting needles, the student is led to the consideration of dynamos, alternators, and motors. Then follow a couple of chapters on lighting circuits and lamps, a chapter on measuring instruments, and finally one on primary cells and accumulators. We doubt if any student can properly master all this material in a preliminary course. In any case, we are strongly of opinion that it is inadvisable that he should try to do so.

Much has been spoken and written on the question of the interconnection between teaching and manufacturing. We cannot forbear quoting one instance from this book, which shows how desirable closer sympathy is. After a very inadequate description of primary batteries, the authors write in reference to the dry cell:—"Economy in first cost is attained in various ways. For instance, a cell recently examined was found to have a solid block of wood nearly three inches thick between the bottom of the cardboard case and the bottom of the zinc cell." It is nothing short of a travesty of teaching to devote even four lines in a text-book, where space is only too valuable, to conveying this sort of information. The authors must have forgotten the excellent definition of an engineer as one who can do for a dollar what any fool can do for five. We pity the young engineer, nourished on this food, who, when asked by his employer to endeavour to reduce first cost, comes forward with a suggestion of this kind. M. S.

L'Hygiène moderne. By Dr. J. Héricourt. Pp. 311. (Paris: Ernest Flammarion, 1907.) Price 3.50 francs.

This book surveys, in an interesting, readable, and non-technical manner, modern views on hygiene. It is divided into four sections—hygiene of the individual, which includes predisposition, tuberculosis, diet, clothing, exercise, and infantile mortality; hygiene of the home, which includes the house and domestic life; hygiene of communities, schools, &c.; and public hygiene, including that of public vehicles, streets, domestic animals, &c. One of the earlier chapters on the arthritic diathesis would be better suited, perhaps, to a medical text-book, and the author seems to be one of those who hold extreme views on the evils of uric acid. On the question of alcohol, the author believes that good wine or spirit in moderation does no harm, and in many cases is beneficial. The kissing of children is rightly condemned, and the condition of the public streets, with their dust, dirt, and spitting, is characterised as a "hygienic scandal." R. T. H.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Advancement of Science.

Some weeks ago Sir Oliver Lodge directed attention to the congestion of work in Section A of the British Association at Leicester. Last week Dr. Chree remarked upon the comparative neglect on our part of such scientific subjects as terrestrial magnetism and the local variations of gravity, which cannot be pursued adequately within the walls of a laboratory, but depend upon observations "in the field." In the meantime, Nature has noted Dr. Mill's protest against the scanty opportunity for the discussion of meteorological subjects at Leicester.

My own experience at Leicester supports Dr. Mill's protest. I do not refer to what happened to my own paper. I have no complaint to make against the officers of the section, who, with the rest of us, were victims of an unworkable system. I refer to the proceedings with regard to the papers by Mr. Petavel and his fellow-workers at Manchester on the investigation of the upper air.

Since the meeting, I have learned that the results of the work of the international week at Manchester (the last week in July) were of remarkable interest as showing in an exceptional manner all the characteristic features of the variation of temperature in the atmosphere up to a height of 20 kilometres. The papers were among a large number on the programme for Tuesday, August 6. When I left the section at three o'clock to attend a conference as the delegate of Section A, they had not been reached. When I returned at half-past four I was told that the proceedings of the section for the year had already been concluded, with the usual votes of thanks. Whether the papers had been read in the interval or withdrawn I do not know, nor is it of much consequence. If the only time to be found for a subject of such general interest is after three o'clock on Tuesday afternoon, it is clear that some change is required.

The sectional proceedings on Tuesday opened with a discussion upon new methods of treating observations, an important practical matter for the observational sciences. In the circumstances, it was evidently desirable that the opening paper should be printed *in extenso*; but the recorder pointed out to me, and quite rightly, that such a proposition could not be entertained by the British Association, because the committee of Section A had adjourned for the year on the previous day.

These things do not make for the advancement of science.

I wish, however, to take up the point raised by Dr. Chree, and to emphasise the fact, already too obvious to those who have to do with such things, that subjects like terrestrial magnetism, seismology, atmospheric electricity, and the physics of the globe generally, without any reference to meteorology in particular, suffer very seriously in this country from the congestion of work in Section A.

On the one side, work is done of which the scientific public know little or nothing. Atmospheric electricity is a flourishing study on the Continent; seismology is now the subject of an international organisation with Government support; terrestrial magnetism has called for expenditure on a large scale for an establishment to replace Kew as the normal observatory. It is desirable that the association should know what is going on in such matters.

There are, moreover, a number of departments of Government the work of which has at least its scientific side. Papers of scientific interest could probably be obtained for the asking, from a number of competent workers, by an energetic president or secretary, animated by the meritorious wish to use the meeting of the association to bring the scientific staff of the various departments into touch with the scientific public; but the officials in charge of such work have not the advantage of academic long vacations. The time spent at the British Association must be taken either from short leave or from duty. The matter must, therefore, be treated in a business-like way, which in present circumstances is impossible.

It would be absurd, for example, for a secretary or an organising committee to ask, let us say, the hydrographer of the Navy for a paper on submarine centres of magnetic disturbance, or the Astronomer Royal for a paper on magnetic storms and sun-spots, or any other aspect of the magnetic or meteorological work of the Royal Observatory. There is the paralysing consciousness that the time for reading the papers would have to be looked for in a general scramble between three and half-past four on Tuesday afternoon. What is true with regard to these distinguished public servants is equally true with regard to distinguished foreign workers in science.

There is provision in the constitution of the association for asking competent persons to prepare reports upon recent progress in particular branches of science. The provision is, unfortunately, a dead letter in the subjects mentioned. One reason at least is obvious—there is no time to listen to such reports, however valuable they might be.

It is time that we recognised that the attempt to include in one section with mathematics subjects like laboratory physics, in which workers are many and in constant intercommunication, and subjects like terrestrial magnetism, atmospheric electricity, and other branches of geophysics, in which workers are few and widely scattered, is disastrous for the one class of subjects; and, judging by the way in which a discussion upon so important a subject as the measurement of temperature by radiation was received at Leicester, it is not too successful for the other class.

Some years ago there used to be a subsection for the outdoor subjects, with the not very euphonious title of "Astronomy and Cosmical Physics"—perhaps astronomy and geophysics might be better. It has disappeared—not on account of any want of success while it lasted. It was simply omitted from the South African arrangements. The circumstances which called it into existence have now become more pressing. Laboratory physics has become more radio-active, and the other subjects have extended their operations. The temporary expedient of a special subsection is not now adequate. One special secretary at least is required in the interest of those branches of geophysics which are not covered by astronomy. The occasional treatment of such subjects in a presidential address would be of real advantage to science in this country.

I ask, therefore, the hospitality of the columns of Nature in order to appeal, in the name of the advancement of science, for the establishment of an independent section of the British Association which shall have sufficient time at its disposal to promote the advancement, not only of meteorology, but also of such subjects as terrestrial magnetism, atmospheric electricity, seismology, and geophysics generally. The briefest consideration of the changes which have taken place since Section A was initiated will show that such an appeal is not unreasonable.

W. N. Shaw.

October 12.

On Correlation and the Methods of Modern Statistics.

I regret that the pressure of work associated with the opening of a new session did not permit of my replying to Mr. Hinks last week. His letter (October 3) is so far satisfactory that it gives evidence that one professional astronomer realises the existence of stellar correlation; but Mr. Hinks will have to advance much beyond "scatter diagrams" before he can hope to get much profit out of modern methods. Further, may I suggest that he would be more just to both Miss Gibson and myself if (1) he read her paper carefully, and (2) he did not suppose that, because we approach the subject from a different standpoint from himself, we are of necessity both very ignorant and very foolish?

At the expense of reiteration, I must again refer to one or two facts. There are, in my opinion, three points of much interest in Miss Gibson's memoir:—

(*a*) The correlation of magnitude and parallax is shown to be low; what correlation exists is shown to depend largely on the sinuosities of the regression curve, and not on a uniform decrease of parallax with magnitude. Miss Gibson's values for the seventy-two Newcomb stars are:—Correlation coefficient, $+0{\cdot}1 \pm 0{\cdot}1$; Correlation ratio, $0{\cdot}5 \pm 0{\cdot}1$. For the 173 stars given in the Yale memoir, Dr. Lee has shown that Correlation ratio $= 0{\cdot}28 \pm 0{\cdot}06$.

Now let us see how Mr. Hinks faces such results. In the report of the British Association discussion, published with his approval in the Royal Statistical Society's Journal, he refers, in the *first place*, to the theoretical question, namely, he speaks of the theoretical possibility that the relation between luminosity and distance is controlled by a logarithmic curve, and makes the suggestion that this curve (although referred to several times in Miss Gibson's memoir) had been overlooked by us, and that accordingly she ought not to have used the correlation coefficient, which might screen under such a value as 0·3 the really perfect correlation which would flow from the logarithmic relation. What was the meaning of Mr. Hinks's appeal to the logarithmic curve if he did not at the British Association suppose Miss Gibson's value of the relationship of magnitude and parallax to be an underestimation? If that appeal was made to show that she ought to have used the correlation ratio, then he had clearly not studied her paper before criticising it. The charge made at the British Association is indirectly repeated in the last words of his letter in NATURE, where he talks about the propriety of calculating the correlation ratio, as if it had not actually been given on p. 452 of the memoir. The divergence between the correlation coefficient and the correlation ratio shows the trained statistician that the sinuosities of the parallax-magnitude curve are not solely humps due to random sampling.

Well, let us come to our one point of agreement at present: "Astronomers do not believe that magnitude is closely related to parallax." I am glad Mr. Hinks accepts this view, and I will refrain from quoting the work of some great astronomers to show that it has not always been their opinion. Mr. Hinks states in his letter that I asked for details of the reason for the switchback character of Miss Gibson's diagram of parallax and magnitude. If he will read my letter carefully, he will find I asked for no such thing. I asked for details of *his* reasoning at the British Association that the dips and humps were produced by selection of proper motions, which is an entirely different point.

He said at Leicester:—"The second peak belongs to stars of the fourth and fifth magnitude; they were not representative of the average star of that magnitude, but had been chosen *because of their exceptionally large proper motion*." I very pertinently asked him why this selection had not also been applied to stars of the second to third and to stars of the sixth magnitudes, and further to demonstrate that if it had been thus applied it could possibly have produced the desired effect. To produce an effect on the correlation of A and B by selecting C, a third character, A and B must both be fairly highly correlated with C, and, further, to produce humps we must show that the selection was concentrated at certain points of the range. Mr. Hinks, to give a logical reply, must therefore show:—(1) that parallax and proper motion are highly correlated; (2) that proper motion and magnitude are highly correlated; (3) that the selection of astronomers has been discontinuous along the magnitude range. Instead of proving (3), Mr. Hinks has pointed out that the "humps" in the curve are due to the presence of individual stars of low or high parallax in the special groups, or rather that *some* of them are. Quite so; any statistician knows that with a population of seventy-two the averages of eleven subclasses will be largely influenced by individuals; but the statistician calls this a result of *random sampling*, and does not suggest discontinuous selection by a third variable with a relatively low correlation to at least one of the two characters. Did Miss Gibson, however, lay any special stress on these humps? On the contrary, she says:—"It is possible that a curve of a somewhat complex character—a quartic curve, for instance—might fit the observations." But she concludes:—"Examining Fig. 1, we see that on the present data nothing better than a horizontal straight line at the mean parallax, or a zero correlation coefficient is likely to be found to fit the observations." I think this will show that we laid no special weight on the humps. On the other hand, the high value of the correlation ratio compared with the value of the correlation coefficient does suffice to suggest that astronomers should be cautious about assuming even a moderately low, but continuously descending relationship between luminosity and distance. The rise in parallax of the faintest stars in Miss Gibson's diagram is again manifest in the Yale results, and is probably not due to mere random sampling. The thirty-six stars of magnitude eight to nine in the Yale data have a parallax nearly three times as great as those of magnitude six to seven, which number thirty-one. Will Mr. Hinks assert here again that the former group have been selected by proper motion and the latter have not?

Let me further remind him that the correlation between magnitude and proper motion has not even been mentioned by him in his argument, and yet this vital relationship, for which I have further determinations, is lower than 0·2. Accordingly, it would need a very high relationship between parallax and proper motion to reduce by a proper motion selection the magnitude-parallax relationship to a small value.

(*b*) The second point in Miss Gibson's memoir was involved in the statement that the correlation between parallax and proper motion was "quite significant and important, but not half-way up the scale of correlation" (p. 449). Mr. Hinks says that I am misled by Miss Gibson's results, and asserts that his scatter diagram shows "considerable correlation." Mr. Hinks is an astronomer, and therefore knows the value of exact numerical work. Miss Gibson obtained in her memoir the value 0·4 for the proper motion components. Does he really suppose that his scatter diagram can demonstrate that the value of the whole proper motion correlation is greater or less than this?[1] My estimate, however, was based, unfortunately for Mr. Hinks, not on Miss Gibson's results, but on determinations of the correlations of proper motion and parallax, which involve not only component, but total proper motion. Actually the Newcomb stars exaggerate the result, and the relation between the two characters is sensibly under Miss Gibson's value. Thus for the Yale stars, when we deal with the *whole* proper motion, it is only 0·36. Mr. Hinks says that Miss Gibson "has naturally obtained a smaller result than if she had used the whole proper motion in seconds of the arc on a great circle as is usually done." If Mr. Hinks had studied the subject of correlation a little more fully, he would have known that one correlation is related to the others, and if he had actually worked out the theoretical relationship between them he would not have attributed the lowness of our estimate of the parallax and proper motion correlation to dealing with component instead of total proper motions. The multiplying factor is, I think, $\sqrt{2/(1+r)}$, where r is the mutual correlation of the components $= 0{\cdot}3$.

Mr. Hinks would support his view of high relationship between parallax and proper motion by *selecting* seventeen stars by magnitude, and leaving the reader to form a mental impression of their correlation. He asserted that our results on seventy-two stars were vitiated by selecting by proper motion, yet he does not hesitate himself to select, not seventy-two, but seventeen stars by magnitude. And what is the result even of this selection? Why, that 40 per cent. of the value he reaches for correlation depends upon the fact that he has not sufficiently counteracted the overwhelming influence due to his inclusion of α Centauri in the seventeen! If he leaves this star out (or reduces its influence by introducing another seventeen stars) the value of the correlation differs from Miss Gibson's value by less than the probable error of the difference.

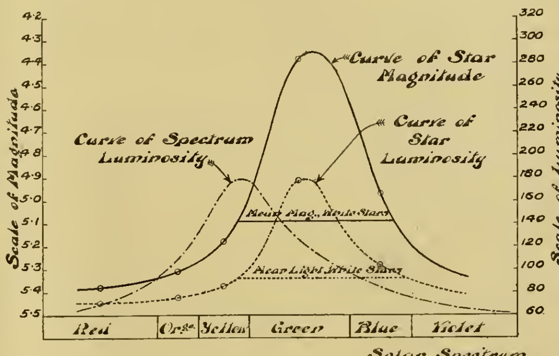
I must now state the conclusion to which I feel myself driven, namely, that astronomers in the near future will not suppose a *very* close, but a "quite significant and important" relationship between proper motion and parallax. The relationship is more intense than that of parallax and magnitude, but, as shown by the Yale data, it is probably less than the value originally fixed by Miss Gibson, and I

[1] For the total proper motion the Newcomb stars give $0{\cdot}58 \pm 0{\cdot}05$.

hold that this relatively low value is the second point her paper has indicated for the first time. Meanwhile, I leave Mr. Hinks to consider whether the proven correlations of both proper motion and magnitude with parallax (under 0·4) have or have not any significant bearing upon the differential method of determining parallax, and upon the fact that more than 20 per cent. of negative parallaxes can be found.

(c) The third point in Miss Gibson's paper was the statement that colours (and probably spectral classes) were more highly correlated with magnitude than distance. Mr. Hinks takes this point as one which will fully justify his criticisms at Leicester. I am of opinion that it is peculiarly a case in which he would have done well to have tempered his judgment by previously asking whether there was no method in our madness. He charges us with three grievous offences:—(1) using a highly selected material; (2) omitting to take into consideration the "white stars"; and (3) deducing from such material sweeping conclusions about the stars in general. He further charges me, *on the basis of this investigation*, with asserting "that colour and magnitude are related at least as closely as parallax or proper motion and magnitude."

In my letter, when making my statement, I made no reference to Miss Gibson's published work, but the fact that I cited the value of the correlation of magnitude and spectral class which is *not* given in the published paper might have warned Mr. Hinks that we held other reductions in our hands. Mr. Hinks asserts that our results would have been modified had we included the "white" stars. Using the 2834 stars of the Harvard Catalogue, of which roughly one-quarter are white ("Annals," vol. xiv.), Miss Gibson worked out more than a year ago the contingency of colour and magnitude; the value was 0·27 (±0·01), as compared with the 0·30 (±0·05) of the list in the Cape Observatory "Annals" previously given by her. Omitting the white stars from the Harvard data, the value is 0·297, agreeing absolutely with the result obtained from the Cape data. Thus we see that Mr. Hinks's suggestion that the Cape Catalogue is worthless, owing to selection of special stars, has no validity at all when we turn to the relationship of colour and magnitude, and, further, the inclusion of white stars produces, as we had logically anticipated, no sensible effect.



But I will go a step further, and reveal another conclusion, which I should naturally have preserved for the present, as the research is as yet incomplete. The mean magnitude of the white stars is almost identical with the mean magnitude of all the remaining truly "coloured" stars; the white star has not a preponderance of any special part of the colour spectrum, and if we wish to investigate the relationship between luminosity and colour we must logically leave out the white stars. The accompanying diagram gives the Harvard stars classed according to colour, with (a) the mean magnitudes of each colour group, and (b) the corresponding luminosity on the assumption that the light of a tenth-magnitude star is unity. It will be seen that the stellar luminosities form a curve very similar to the light-intensity curve of the solar spectrum, but shifted towards the violet end of that spectrum, possibly owing to the fact that the average star is hotter than our sun. On this scale there is clearly no place for the white stars, and the essential feature is that stellar magnitude takes its place in a continuous and definite relation to stellar colour.

I had no intention of anticipating work not yet completed, but Mr. Hinks's contemptuous reference to our omission of the white stars needed to be dealt with. Their inclusion or exclusion makes no difference from the standpoint of the statistical constant; their exclusion is, however, justified by the physical considerations which I have here suggested.

I should wish to say one word, albeit I am afraid it must be a strong one, about Mr. Hinks's further treatment of Miss Gibson and myself. In the paper, to use its own words, a suggestion, "even if it be only of the *vaguest* kind," is made that the bulk of the lucid stars *may* belong to a differentiated system. Mr. Hinks asserts that the basis for "this far-reaching suggestion" is one in which the white stars had no frequency in the record. Will the reader believe that this suggestion, which the writer herself describes as of the "vaguest kind," is not based on the colour correlation at all? Can Mr. Hinks really have criticised the memoir and supposed that even this vague suggestion was based on the 159 Cape stars? The suggestion, such as it is, is based on counts of *all* stars, and results from showing that a continuous curve can be found which describes with remarkable closeness the counts up to the sixth and seventh magnitude, but that beyond this magnitude any formula hitherto proposed fails even approximately to describe the frequency. This result, reached by other investigators, is confirmed by Miss Gibson, and in association with changes in other stellar characters, which occur about the same magnitude, does suggest, I venture to think, that in the vaguest kind of way some differentiation of the stellar system may possibly exist beyond the bulk of the lucid stars. I think Mr. Hinks owes us an explanation of what his statement, that a far-reaching suggestion has been based on stellar statistics from which all white stars have been excluded, really is intended to convey.

In conclusion, may I say that I have learnt from my experience with biologists, craniologists, meteorologists, and medical men (who now occasionally visit the biometricians by night!) that the first introduction of modern statistical methods into an old science by the layman is met with characteristic scorn; but I have lived to see many of them tacitly adopting the very processes they began by contemning. Mr. Hinks is at present in the first stage; but may I remind him that even astronomy owes something to the layman, and express my hope that he may quickly reach a more understanding and sympathetic frame of mind?

The Body of Queen Tii.

Judging from the letter addressed to Nature of September 26 (p. 545), Mr. Hall (like Prof. Sayce in the *Times* of September 17) has been thrown into a state of doubt in regard to the real sex (? and age) of the mummy supposed to be "Queen Tii" by a letter from Mr. Theodore Davis, calling in question the accuracy of my statement that the mummy supposed to be an old lady of at least fifty years is the skeleton of a young man of about half that age.

Let me give a concise account of what I know in regard to this matter. At the end of June of this year Mr. Weigall, the Government inspector in the Service des Antiquités at Luxor, acting on the instructions of M. Maspero, the director-general of that department, sent me a skeleton to be examined and reported on. The skeleton was practically complete, for, although the face, certain ribs, and part of the pelvis were broken, most of the fragments were sent. Mr. Weigall told me that the bones were found in their coffin in a tomb opened by Mr. Theodore Davis in January last, and that they were supposed to be the remains of Queen Tii. Moreover, he has assured me that no possible mistake could have been made, because he himself and Mr. Ayrton had packed the bones, and they were received and unpacked by me in the anatomical department of the Cairo School of Medicine. The fact that the bones were soaked with paraffin wax, and that no other skeleton is known to have been so treated in Luxor, puts their identity beyond all doubt.

The skeleton is undoubtedly that of a young man of about twenty-five years of age.

It does sometimes happen that a skeleton presents features of such an indefinite character that even the most experienced anatomist hesitates before expressing an opinion as to sex; but these bones do not fall into such a category. All of them, and especially the skull, pelvis, and leg-bones, present the male characteristics in such a pronounced or even exaggerated form that a junior student of anatomy would be considered exceptionally stupid if he failed to recognise the sex. The skull is big and heavy-jawed, the frontal sinuses and superciliary ridges are exceptionally large, even for a man, and the mastoid processes are typically masculine; although the skull is exceptionally capacious, the face is disproportionately big. On the evidence of the cranium alone the sex is obvious.

The pelvis exhibits the most characteristic masculine features. The shape of the pubes and the pubo-ischial rami, the size and shape of the subpubic angle (67°), the form of the obturator foramen, the proportions of the pelvic cavity, and the shape of the iliac bones all conform to the definitely male type. The femur also serves to demonstrate the male sex in its size, inclination of shaft, and size of head.

Mr. Theodore Davis and those who have disseminated extracts from his letters have dealt rather unfairly with the two medical men, whose opinions they quote, in giving such wide publicity to statements which could have been made only in the most casual manner by anyone with any medical training whatsoever. It is so absurd as to be altogether incredible that "a prominent American obstetrician" would quote the figures 90° to 100° for the female subpubic (misquoted "pelvic" by Prof. Sayce and Mr. Hall) angle, and 70° to 75° as the average for this angle in the male, with the object of demonstrating the *female* sex of a pelvis *the subpubic angle of which is only* 67°!

But, quite apart from the very obvious male characters of the skeleton, there are even more obtrusive features equally fatal to the possibility of it being Tii's, which could hardly have escaped the observation of a medical man, however casual.

The teeth are practically unworn; three of the "wisdom" teeth had just been "cut," and the fourth was only just emerging from the jaw at the time of death; and a large number of epiphyses on ribs, vertebræ, clavicles, sternum, and pelvis were either separate or in process of joining. In other words, the bones are clearly those of a person of about half the age Queen Tii is known to have reached.

The archæological and historical remarks in Mr. Hall's letter do not concern me.

In a short time I shall publish a full account of this skeleton, with photographs exhibiting the evidences of sex and age, and the points of similarity and dissimilarity to the mummies of Amenhotep III., Yuaa, Thua, Thothmes IV., and perhaps some other royal mummies of the eighteenth dynasty.

G. ELLIOT SMITH.

Anatomical Department, The School of Medicine, Cairo, October 4.

The Interpretation of Mendelian Phenomena.

ALTHOUGH it is impossible within the limits of a short letter to attempt an answer to the question of the bearing of "Mendelism" upon biological problems in general, there are one or two points in Dr. Archdall Reid's letter in NATURE of October 3 which seem to require discussion.

Dr. Archdall Reid begins with the following statements:—"Mendelian phenomena are possible only when reproduction is bi-parental. They cannot occur, of course, when it is parthenogenetic." In the first of these statements the expression "bi-parental" should not be taken too literally, since in the majority of cases of Mendelian inheritance investigated hitherto the method of so-called self-fertilisation has been employed. I hope I may be pardoned for the assertion that the second statement is a little premature. For my own part I shall certainly await the result of experimental evidence upon the point before accepting it as conclusive.

In the absence of Dr. Archdall Reid's definition of what he means by "the problem of sex," I am not sure that I entirely understand the remainder of his first paragraph; but the suggestion may be made that "the function of sex," "the causation of variation," "retrogression of characters," and "mode of development" are less immediately to the purpose in the present condition of biology than the problems of the actual method of transmission of existing characters. Upon the problem of the "alleged transmission of acquirements" Mendel's facts may even be said to throw some light; but in any case it seems rather severe treatment to belittle the importance of a biological discovery merely because it does not immediately lead to the solution of all the most difficult problems which biology affords.

Once more it must be repeated that the appearance of a blended first cross is no criterion of non-Mendelian inheritance. In the case of a problem like that of man, complicated as it is by the fact that he has "crossed more often than any other animal," and further rendered intractable by the circumstance that he is not amenable to experiment, a great difficulty arises in discovering which are the actual allelomorphs concerned. For these natural characters pay no heed to our definitions; so that if an investigator makes the mistake of first rigidly defining the "characters" with which he proposes to deal, and does not keep a perfectly open mind, prepared to revise his definitions in the light of the evidence which experiment alone can afford, he runs a great risk of finding only confusion where a proper analysis would have shown the presence of perfectly definite methods of inheritance. It would be extremely interesting to students of genetics to learn upon what evidence Dr. Archdall Reid bases his positive statement that there is no segregation in the case of the mulatto.

There is certainly occasion for surprise in finding it maintained that "nature selects only mutations"; but that natural conditions lead to the obliteration of a host of mutations is as fair a deduction from the fact that such mutations appear under cultivation as the current deduction that the conditions of cultivation actually cause the occurrence of this kind of variation. We have the testimony of de Vries and others that the former process actually takes place. That the latter process does so is an assumption which still lacks the support of facts.

The Colour of Dye Solutions.

IT is generally accepted that the colour of dye solutions depends upon the chemical structure of the dye, and colour changes are usually attributed to some change in constitution; but certain recent investigations on colloidal solutions show that this argument must be accepted with caution. It is well known that colloidal solutions of the metals are highly coloured. Further, it is recognised that many dyes exist in solution in what, for lack of a better term, must be called the colloidal state. Some observations of my own point to the following statement as being true for certain dyes:—

The absorption spectrum of the dye in solution may be either (*a*) a characteristic absorption, consisting of one or more narrow bands and depending on the chemical structure of the dye molecule, or (*b*) a "resonance" spectrum due to colloidal particles, and much more remotely connected with chemical constitution. This spectrum is ill-defined.

The detailed experiments which have led to these conclusions will be communicated in a paper shortly to be published. A word or two is desirable in explanation of the term "resonance" spectrum. By this is denoted the type of absorption exhibited by colloidal metal solutions, glasses, and certain photographically prepared films (F. Kirschner, *Drude's Annalen*, 1904, xiii., 239; Kirschner and R. Zsigmondy, *ibid.*, 1904, xv., 573; K. Schaum and E. Schloemann, *Zeit. wiss. Phot.*, 1907, v., 109). It is probable that all absorption is due to resonance, no doubt, and hence the narrow-band type (*a*), but in this case the resonators would be the molecules or the contained electrons, whereas in case (*b*) the resonance of larger aggregates is the cause of the absorption.

The investigation is to be continued, but a striking case was found in one of the pinacyanols, a class of dyes recently introduced as photographic sensitisers. This dye gives in aqueous solution a flattish, ill-defined absorption, the solution showing all the characteristics of a colloidal solution. In alcohol and organic solvents the absorption was of a narrow-band type, entirely different, and *this spectrum was also obtained by heating the aqueous solution to boiling point.* The behaviour was quite analogous to that of starch, which gives crystalloid solutions at the boiling point. S. E. Sheppard.

The Convection Explanation of Electrolysis.

At p. 12 of a recent text-book entitled "Electrochemistry," by Prof. R. A. Lehfeldt, the author mentions the convection explanation of electrolysis, and states that "Faraday was sufficiently impressed with it to form the hypothesis of *ions*, *i.e.* of charged particles in the liquid travelling under the action of the electric force."

So far from being impressed favourably by this "explanation," Faraday considered it might have a "dangerous influence" and "do great injury to science by contracting and limiting the views of those engaged in pursuing it." He therefore constructed his terminology of electrolysis specially to get clear away from this "explanation."

Again, Faraday did not form a "hypothesis of ions as particles." The word ion refers to the nature of the substance evolved at the electrode, not its dimensions. The ion of Faraday might weigh an ounce or a ton.

The opinions which the modesty of the great observer permitted him to express may be found in the seventh series of his "Experimental Researches." To attribute to him for any purpose, other opinions absolutely alien to these is, I submit, either scientifically reprehensible or grossly careless. J. Brown.

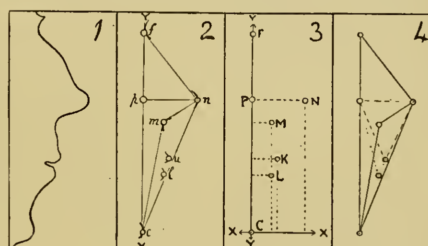
Belfast, August 18.

CLASSIFICATION OF PORTRAITS.

Experiments of various kinds that I have made to define the facial peculiarities of persons, families, and races by means of measurement led to the following results that seem worthy of publication. The most elementary form of portrait will alone be considered here, namely, the outline of the face from brow to chin, as in a shadow or in a silhouette. It contains no sharply defined points whence measurements may be taken, but artificial ones can be determined with fair precision at the intersections of tangents to specified curves. It will be shown that it is easy to "lexiconise" portraits by arranging the measurements between a few pairs of these points in numerical order, on the same principle that words are lexiconised in dictionaries in alphabetical order, and to define facial peculiarities with greater exactness than might have been expected.

The individuality of a portrait lies more in the relative positions of six cardinal features (see the figures below) than in the shapes of the lines that connect them, so long as the general character of the connecting lines is roughly indicated. A few standard types, perhaps ten in all (though I prefer to use more), represent as many concave, convex, and sinuous varieties of outline, between each specified pair of the six cardinal points, as need to be noted. I may recur to this in a future letter.

This will be apparent to the reader's satisfaction if he compares portraits under unfavourable conditions, as through a blurring medium, or out of focus; or, again, if he substitutes connecting links that differ somewhat from the true ones. Consequently my first endeavour was to define accurately six points that should severally be good representatives of the six cardinal features in the outline. Those features the limits of which are vague are expressed by *italic* letters in Fig. 2, and their representative points by the same letters in *capitals* in Fig. 3. The features are these:— *c*, the tip of the chin; *l*, the lower, and *u*, the upper lip; *m*, the hollow between the upper lip and the nose; *n*, the tip of the nose; *f*, the hollow between the nose and the brow. In order to find their respective representative points, proceed as shown in Fig. 2, by drawing (upon tracing paper) a tangent, YY, to both *c* and *f*. Then draw a short tangent to *n* parallel to YY (accidentally omitted in the Fig.). A tangent to



both *c* and *n* intersects the first of these lines at C and the second at N, and determines them. A line drawn from N tangential to *f* determines F. Thus the fundamental triangle CNF is obtained, in which YCFY is used as the axis of Y, and the length of CF (divided into 100 equal parts, here called "cents") determines the scale of measurement. In the life-sized portrait of an adult, 1 cent may be regarded as roughly equivalent to $1\frac{1}{4}$ mm. or to 1/20th of an inch. M, and consequently the triangle CMN, is determined by the intersection of one line drawn from C with another from N, both tangent to *m*. U and L lie at the intersections of tangents drawn in either case, parallel to X and CN respectively. They require less attention than the preceding letters, because *u* and *l* are usually small.

The positions of the six cardinal points may be expressed in either of two ways—(1) as in Fig. 3, by rectangular coordinates, YCY being the axis in Y, and XCX perpendicular to it, the axis in X. Or (2) as in Fig. 4, by triangulation. Here an additional line, NP, drawn perpendicularly from N to YCY, is convenient. I have compared both of these methods, and found each to have its advantages and disadvantages, depending on many variable causes, of which the scale of the portrait is one and the available instrument is another, and am inclined on the whole to prefer the method of coordinates.[1]

In my experiments I have chiefly used the side-view portraits by George Vance, R.A., of his distinguished contemporaries, published in 1809 (2 vols., folio, Longmans), which yielded sixty-eight pure profiles of about one-third the natural size. I lexiconised these in respect to the measures (entered to the nearest cent) of the two coordinates of N and M respectively (4 measures in all), and found, first, that no two of the numerical formulæ were the same, and, secondly, that in two-thirds of them the *smallest* difference between the most nearly resembling pairs was 3 cents in one or more of the four measures. This conspicuous difference, equivalent to between 1/6th and 1/7th of an inch in a portrait of the natural size, could never be due to the inherent imperfection of the art of measurement, but to some gross blunder. It follows that the collection of sixty-eight portraits was lexiconised with remarkable precision. The data were insufficient to enable me to speak with much assurance of the gain that would accrue from taking L and U into additional account, but their correlations with C, M, N, and F, seeming to be very small, the gain ought to be great. I am content to underrate this gain considerably, and to allow only fifteen-fold for it. On that basis a collection of 1000 profiles from brow to chin could be lexiconised and searched with great ease. In 667 cases each portrait would have a clearly distinctive formula; in the remaining 333 there would be doubtful duplicates, and even triplicates, just as in any list of the names of 1000 British persons there would be more than one Smith.

In the report of a committee appointed by the Secretary of State in 1894 (C. 7263, price 10*d.*) to inquire into the best means available for identifying habitual criminals, the following remark appears on p. 18:—"An enormous amount of time is spent in examining the books of photographs. It will be seen from the figures furnished by Chief Inspector Neave that on March 1 last twenty-one officers searched for twenty-seven prisoners—the total time spent being $57\frac{1}{2}$ hours—and made seven identifications. This was an average of more than two hours for each prisoner sought for, and more than eight hours for each identification." A similar search in a lexicon of portraits of the same size would occupy apparently fewer minutes than the above occupied hours.

I will go no further now into the results of my experiments than to say that I have applied the above method to portraits of persons of very different races, and have thus far found it efficient in all of them.

FRANCIS GALTON.

[1] In some cases brevity is very desirable, and may be obtained by regarding only the limits within which the variability of each link most commonly occurs and by dividing the interval between those limits into 8 equal parts. Then 0 would signify all measures below the lower limit, and 9 all above the upper one. The range of the rectangular coordinates to N and M within the limits above explained varies between 12 and 20 cents, so the value of each of the eight equal parts will vary from $1\frac{1}{2}$ to $2\frac{1}{2}$ cents according to the coordinate in question. These "parts" are more suitable for classification than cents, which are too small to be quite trustworthy. But I will not go further here into this question than to add that the 8 rectangular coordinates of M, N, L and U can be described in this way by only 8 figures, and the connecting outlines CL, LU, UM, MN, NF by 5 (or say 10) more, so that a portrait can be expressed (say be telegraphed) in a rude but recognisable form by only 13 (or 18) figures.

WEIGHTS AND MEASURES REGULATIONS.

THE new regulations, which came into force on October 1, apply only to weights, measures, and weighing instruments used for the purposes of trade. They are in some respects rather less stringent than the preliminary draft issued by the Board of Trade in August, 1906, a review of which appeared in these columns last year.

There are but few points of scientific interest in the regulations. Specific instructions as to temperature are now given for the first time to inspectors of weights and measures. Measures of length are to be verified by comparison with a local standard at or near the normal temperature, which is 62° F. for imperial measures. For imperial measures of capacity the standard temperature of their water contents is also 62° F.; for metric measures of capacity it is 4° C.; but metric measures graduated at 15° C. or 60° F. may also be verified for chemical or pharmaceutical purposes, or for volumetric estimations. Measures marked with the temperature at which they are graduated must be tested against measures standardised at the same temperature. An apothecaries' measure, marked with equivalents in weight, is permitted, provided that the words "of water" are marked on it in addition to the denomination.

Certain restrictions are placed upon the weighing instruments to be used by dealers in precious metals or precious stones, retail chemists or druggists, and silk merchants. These traders are permitted to use three kinds of weighing instruments, the first kind being chemical and assay balances provided with means for relieving all the bearings and knife edges, the second being beam scales of a lower order of sensitiveness and accuracy, which must be marked "Class B," and the third being instruments other than beam scales which satisfy the requirements for Class B. The first and third of these types of instruments are not to be marked with a "class."

The requirements of Nos. 69 and 78 of the regulations, prohibiting adjusting contrivances which are not permanently fixed to the weighing instrument, will render some kinds of analytical and assay balances ineligible for official stamping in the future. Traders who use such balances should be careful not to keep them upon their trade premises if unstamped, otherwise they may be liable to forfeiture if they come under the notice of an inspector of weights and measures.

Counter weighing machines of the "accelerating" type are prohibited by the regulations. It is often difficult to distinguish between a vibrating and an accelerating instrument, especially when these are sluggish or have been in use for some time. The requirement prescribed in No. 68 of the regulations that the machine shall balance when unloaded will, however, be sufficient in general to determine this point. When the machine is unloaded, if either of the pans be pressed down and then released, the beam will be set in oscillation about its horizontal balancing position, if the instrument is of the vibrating type; but if the instrument is accelerating, it will be found that one or other of the pans when pressed down will remain down, and the beam, failing to oscillate, will rest out of balance.

Spring balances are somewhat rigorously dealt with, but, on the whole, the Board of Trade has taken a fairly lenient view with respect to these instruments in permitting them to be used for ordinary trade, rather than restricting their use to such purposes as the weighing of postal parcels and passengers' luggage, as is the case on the Continent.

Weights, measures, and instruments at present stamped and in use, but which do not comply with the new regulations, may be continued in use for certain prescribed periods, and, with the exception of a particular type of spring balance, may be re-stamped from time to time.

Appendix 2 contains a useful list of all the denominations of weights and measures which are at present legal in this country. It will be seen from this list that weights of $\frac{1}{4}$ grain, which are frequently employed by chemists in compounding drugs, are not legal for use in trade.

ANCIENT KHOTAN.[1]

DR. M. A. STEIN'S promised scientific publication of the material gathered by him during the course of his first expedition to Chinese Turkestan has now appeared, and has been awarded the distinction of being published by the Clarendon Press, and so under the auspices of the University of Oxford; and worthily: for the importance of Dr. Stein's archæological discoveries is great. The significance of his finds will be found fully explained in two articles which appeared in NATURE on the occasions of the publication of Dr. Stein's first "Preliminary Report" (1901) and of his popular book, "Sand-buried Ruins of Khotan" (1903), which gave so good a general account of his work. It is therefore unnecessary to go over the same ground again now, and we can confine ourselves to a consideration of the fine volumes before us.

The Clarendon Press has produced the book in sumptuous style. The form of the broad page and the size of the type are both good and pleasant to read. The title-page is quite a work of art; as a specimen of a modern title-page with good type, well-sized and well spaced, it is worth seeing. The only fault we can find in the general get-up of the book is that the photographs in the first volume are printed on paper that is somewhat too thin and flimsy, with the result that the half-tone blocks have a somewhat cheap appearance which does not agree well with the fine appearance of the rest of the book.

FIG. 1.—Remains of dwelling completely eroded; Niya site. From "Ancient Khotan."

The same may be said of the first eighteen plates of the second volume, which contains the great body of the illustrations. In one of these also (plate iii.) the upper picture has been printed upside down, which is a pity. But to the rest of the plates nothing but unqualified praise can be given; the coloured ones are very good, especially those reproducing textiles.

From these plates the remarkable character of the art of Niya, Yotkan, and Dandan-Uiliq, having the chief "find-spots" in their chronological order, can easily be grasped. Especially interesting are the wooden remains from Niya, and the pottery and little clay *genre* figures from Yotkan. The strength of the classical tradition which came from Greece to India, and thence to Chinese Turkestan, is very evident to us as we turn over these pictures. Plate lxx., too, shows wooden chair-legs in the shape of the foreparts of sphinxes, with a headdress that reminds us of the triple horn above the heads of Assyrian bulls. Why not? Niya's art came from Gandhāra, and Gandhāra's from Seleucia on the Tigris. The analogy of these excavations to those of Egypt is well shown in such a plate as No. lxxiii., which presents to us antiquities in the shape of musical instruments, carding combs, brooms, hoes, &c., of the same kind as those that may be found on an Egyptian site. In both countries the dryness of the soil preserves objects that elsewhere would long since have perished.

The Kharoshthi letters on wooden boards, and the Chinese written slips found with them, also have a very Egyptian look, and we have a strange note of connection in the Judæo-Persian document written on paper, which was found at Dandan-Uiliq, but which, so far as its language and appearance are concerned, might just as well have been found at Oxyrrhynchus! After all, Tabaristan, where it was written, is not so much farther from the banks of the Nile than from those of the Tārīm. And in the reign of Trajan, long before this document was written, the great Chinese general, Pan-ch'ao, advancing ever westwards from Ch'angan (Si-ngan-fu, then the capital of China), had reached the Caspian, and tried to open up relations with the Romans. So that many a merchant may even in the first century A.D. have known the banks of the Nile, Tigris, Oxus, and Tārīm equally well, and we can well comprehend how classical art influenced that of China by way of the civilisation of which Dr. Stein has discovered the remains in Turkestan.

Dr. Stein's letterpress is very copious, since he includes in his work long dissertations on Chinese and other literary evidence as to the identification and history of the ancient places which he has found. When we say that his success, and that of his coadjutors, in this interesting work has been striking, we do not err; and, on the other hand, several of

[1] "Ancient Khotan; Detailed Report of Archæological Explorations in Chinese Turkestan, carried out and described under the Orders of H.M. Indian Government." By M. Aurel Stein. Two vols.; text and plates. Pp. xxiv+621; pp. vii+119. (Oxford: Clarendon Press, 1907.) Price 5l. 5s. net.

Dr. Stein's finds have amply confirmed the statements of the Chinese official records, especially with regard to the period of the isolation of the "Four Garrisons" of Turkestan after the Tibetans had driven a wedge northwards into the dominions of the T'ang, in the eighth century A.D. To this period belong the ruins of Dandan-Uiliq, while those of Niya, which show the most marked classical characteristics, are five hundred years older. It is at Niya that we find a document sealed with a Chinese and a Greek seal side by side!

The Tibetan evidence contained in graffiti (which Dr. Stein for some reason insists on calling "sgraffiti": "sgraffito-work" is something quite different) at Dandan-Uiliq and Endere is curious. We have apparent references to defeats of the Chinese: "At Pyagpag in the province of Glom-lom this army fought, and a tiger's meal was obtained (*i.e.* many were killed)"; followed by the savage remark, "Now eat until you are fat!" apparently an incitement to go and kill more Chinese. These Tibetan graffiti have been translated by Dr. Barnett, of the British Museum, and Dr. Francke, of Leh; from the transcripts of them and of the

FIG. 2.—Intaglio of a Greek Goddess. From "Ancient Khotan."

Buddhist sutras in Tibetan, also found by Dr. Stein, the curious reader can gain an idea of the sounds of the extraordinarily hideous Tibetan language, which would seem to have served as the model for Swift's Glumdalclitch, Brobdingnag, the Struldbrugs, and the rest of the names in "Gulliver's Travels," not excepting "Houynhnhnm."

The Chinese graffiti are translated by the great French Sinologist, Dr. Chavannes; and Prof. E. J. Rapson, of Cambridge, has begun the translation of the Kharoshthi letters of the Indian maharajas who ruled Khotan in the third century B.C., and of their officials and dependants. Chinese rule seems to have been maintained contemporaneously with that of the maharajas; but what powers were specially reserved to the latter we cannot quite see from this correspondence. Dr. Stein's new discovery (1907), that the Indian kingdom stretched away east to beyond Cherchen and Charkhalik to the Lop-nor, is of great historical importance.

For the details of Dr. Stein's exhaustive description of his discoveries we must refer the reader to the book. The congratulations of all archæologists to all concerned in its making go without saying. And not least congratulatory should be modern Chinese and Japanese literati, to whom the Chinese documents and antiquities of the Former Han and the Great T'ang dynasties should prove of the greatest interest.

H. R. HALL.

INTERNATIONAL METEOROLOGICAL COMMITTEE.

A MEETING of the International Meteorological Committee was held at Paris on September 10 and following days.

The committee consists of seventeen members, appointed at the conference at Innsbruck in 1905. Ten members were present, including the director of the Japanese service. Two places were vacant by death. The principal subjects discussed were the scheme of organisation of international meetings for meteorological purposes; marine charts and weather signals; a number of items of the international daily weather service, including reports by wireless telegraphy; and various propositions concerning the meteorology of the globe, in which were included one on the necessity for observing stations in the regions of centres of action of the atmosphere, another on the necessity for new charts of isotherms for the globe, and a third on the desirability of daily observations from selected stations, in order to trace the course of meteorological changes over the globe.

A number of special commissions were appointed to report upon, or carry out, the various proposals. M. Mascart, president of the committee, was unfortunately prevented by illness from attending the meetings with the exception of one held at his house for the discussion of the question of international organisation. At the close of the session he resigned the office of president, and Dr. Shaw, director of the British Meteorological Office, was elected president. M. Angot, M. Mascart's successor at the Bureau Central, takes his place also as a member of the committee. Dr. Hellmann, director of the Prussian Meteorological Institute, was elected secretary, in succession to Prof. Hildebrandsson, who retires upon his withdrawal from the post of director of the Royal Meteorological Observatory at Upsala. Dr. Hamberg, director of the Swedish Meteorological Office, was elected to succeed Prof. Hildebrandsson as a member of the committee. The other vacant places were filled by the appointment of Dr. Maurer, director of the Swiss office, and Mr. Stupart, director of the Canadian office.

NOTES.

WE notice with regret the announcement made in a Reuter telegram from Paris that M. Loewy, director of the Paris Observatory, and a member of the Academy of Sciences, died there on Tuesday, October 15.

AT 1.17 a.m. on October 11 the Cunard liner *Lusitania* arrived at Sandy Hook, having crossed the Atlantic in 4 days 19 hours 52 minutes. The total distance travelled was 2780 nautical miles, and the average speed was 24·002 knots. The highest day's run was 617 nautical miles.

REUTER'S correspondent at Mombasa reports that Dr. Koch, who has been examining the causes of sleeping sickness, left for Germany on October 15. His investigation camps in Uganda have been taken over by the colonial authorities. It is understood that Dr. Koch's investigations have not led to any fresh discoveries.

THE Peking correspondent of the *Times* reports that an Imperial Edict issued on October 9 orders the Board of Revenue and Commerce forthwith to introduce a uniform system of weights and measures throughout the Chinese Empire, the standards to be fixed within six months.

A remarkable long non-stop railway run was achieved by the Great Western Railway on September 16. A special excursion train, carrying only third-class passengers, the total load weighing approximately 148 tons, was run from Paddington to Fishguard, a distance of 263½ miles, without a stop, at an average speed of 53 miles an hour.

On October 12 the Clifton (Bristol) Scientific Club celebrated its twenty-first anniversary by entertaining Sir William Ramsay and other past members, when Sir William, who was one of the founders of the club, delivered an address on the recent history of chemical science and on the nature of matter. On the previous evening he visited Clifton College, where he gave an account of the experiments by which argon and other gases of the atmosphere were discovered.

We learn from the *Pioneer Mail* that a large meeting was held at Rangoon on September 19 to consider the establishment of a Pasteur Institute in Burma. It was resolved that the institute should be established at Maymyo. A committee was formed with powers to undertake measures preliminary to the formation of the institute. The subscriptions already amount to 80,000 rupees, which secures the success of the movement. Other subscriptions have been promised, which will be sufficient to enable the institute to start on a wide basis.

The announcement that bison are about to be taken from the Zoological Park in New York to Kansas reminds one of the carrying of coal to Newcastle. In the great plains of the Middle West, however, the encroachment of population has practically made these animals extinct. The zoological collections in the east are now to be drawn upon to re-establish, in the Wichita reservation, herds of sufficient size to ensure their permanency.

An exhibition has just been held in Boston, U.S.A., to illustrate the precautions that should be taken against tuberculosis. It included a representation, side by side, of two sleeping-rooms, with arrangements favourable and unfavourable respectively to the growth of the disease. There were also exhibits of tents for open-air treatment. A lecture on hygiene was given during the exhibition.

An exhibition promoted by Lady Aberdeen, as president of the Women's National Health Association of Ireland, with the object of educating the people on the great danger of tuberculosis, was opened at Dublin by the Lord Lieutenant on October 12. The exhibition is intended to be an object-lesson to teach people certain facts contained in Blue-books and the Registrar-General's reports. Its primary object is to reach the women of the country, and to bring these facts home to them as guardians of the home. In opening the exhibition, the Lord Lieutenant read the following message from the King:—"I am commanded by the King to express his good wishes for the success of the Tuberculosis Exhibition, the first of the kind ever held in Great Britain and Ireland, on the occasion of its being opened by you to-day. His Majesty is greatly interested in the problem of checking the progress of this disease, and he trusts that the exhibition may be the means of attracting the attention of the public to the terrible ravages caused by this scourge and to the efforts which are now being made to arrest its progress.—Knollys." After the exhibition has closed at Dublin it will be taken to various parts of Ireland, where lectures will be delivered upon it.

In connection with the indication by the London County Council of houses in London which have been the residences of distinguished individuals, a memorial tablet was, on October 7, erected on 88 Mile End Road, E., where Captain Cook, the circumnavigator, resided at one time. It is probable that his removal to this house took place in 1764, and his wife continued to reside there for some time after his death in Hawaii in 1779. The house does not appear to have been re-built since Captain Cook's tenancy, but it has been converted from a private dwelling-house into business premises by the erection of a shop on the forecourt. The tablet is of encaustic ware, terra-cotta in colour, and bears the following inscription:—"Capt. Cook, 1728–1779, Circumnavigator, Lived Here."

Reference has previously been made in these columns to the progress effected by the Congo authorities in the task of domesticating the African elephant. A recent visitor to the State establishment at Api writes as follows:—"Owing to an unfavourable season no attempt has been made to increase the number of elephants under training. The number in the colony at the present time is twenty-five, of which nineteen are employed in different kinds of work. During the four months of the wet season the elephants are not merely not worked, but are even allowed to rejoin those in a wild state—that is to say, they are turned out into the forest, but they seem to keep apart. They, however, attract some of the wild elephants to the vicinity of the establishment, but these are generally too old and intractable to provide useful recruits. On resuming the regular routine they manifest no indisposition to work, and submit themselves freely to the discipline of the establishment. The African elephant is of short stature, the young elephants at Api averaging from 4 feet 4 inches to 5 feet 7 inches at the shoulder."

The report of the Departmental Committee appointed to inquire and report as to the nature and extent of the benefit accruing to British arts and industries from the participation of this country in great international exhibitions, which has just been issued as a parliamentary paper (Cd. 3772, price 7*d*.), is a document of great interest. The committee found that the evidence it received went to show that international exhibitions are of little use to the textile and other great staple industries of the country. The committee is, however, in favour of the continued participation of this country in all really important exhibitions, owing to the indirect advantages resulting. One aspect of exhibitions to which it is considered that considerable importance should be attached is the effect which they have in encouraging national emulation and in stimulating individual exhibitors to improve their productions. Interesting examples of the effects which particular exhibitions have had on the development of different industries will be found in the evidence of Sir William Preece, K.C.B., Mr. Bennett Brough, and other witnesses. Sir William Preece attributes to the Paris Exhibition of 1881 many of the most important developments of the electrical industry. The exhibition at Paris of certain high-speed tool steels by an American firm is said by Mr. Bennett Brough to have contributed in a large degree to the development of what has become a British industry of great magnitude; and an exhibit by the Courrières Colliery Company, at the mines of which the death-rate from falls of roof was abnormally low, has since led to considerable improvement in the methods of timbering employed and a consequent decrease in the death-rate. The report concludes with important recommendations for securing in future continuity of organisation from exhibition to exhibition, and more effective representation of this country at any exhibition in which the Government may decide to take part.

In the September issue of the *Annals and Magazine of Natural History*, Mr. G. E. Mason describes the remains of a supposed new fruit-bat from Round Island, near Mauritius. The remains, which occur in a guano-deposit, appear to be very recent, and in the October issue of the same journal they are referred by Dr. K. Andersen to an existing species.

Articles on spermatogenesis in the water-beetle (*Dytiscus marginalis*), with remarks on the nucleolus, by Mr. W. D. Henderson, Carnegie research fellow at Aberdeen, and on the embryonic development of *Taenia serrata*, by C. von Janicki, of Basle, appear in *Zeitschrift fur wissenschaftliche Zoologie*, vol. lxxxvii., part iv.

Nos. 1558, 1559, and 1561 of the Proceedings of the U.S. National Museum are devoted to new echinoderms from the North Pacific, Mr. C. L. Edwards describing holothurians in the first of these issues, while free crinoids are discussed by Mr. H. H. Clark in the second and third. Attention is directed to the brilliant and varied colouring of the feather-stars of the multicolour group of Antedon, which exceeds that of all other crinoids. For classificatory purposes this colouring is, however, useless.

The colouring of the interior of the mouths of nestling perching-birds offers, according to Mr. W. P. Pycraft in *British Birds*, No. 5, an almost unknown field of investigation. It is suggested that the bright-coloured membranous margins of the gape are intended as a guide to the parents in feeding their offspring. In addition to this, the interior of the mouth in most nestlings is bright yellow, occasionally marked with black (hedge-sparrow) or white (bearded titmouse) spots on the tongue and palate, and it seems that this bright colouring attains its highest development in nestlings reared in deep shade. If this be confirmed, it seems obviously connected with the feeding process.

The greater part of vol. viii., No. 1, of the Journal of the Marine Biological Association is taken up with descriptions of various organisms collected in August, 1906, by the *Huxley* during a cruise on the north side of the Bay of Biscay. Among these, the most interesting is a second specimen of *Corallium maderense*, this genus of alcyonarians being previously unknown from the area in question. The axis, or "coral," is white, hard, and semi-translucent; and, although not likely to command a high price, in the opinion of Prof. Hickson, this coral might prove, if found in sufficient quantities, to have a marketable value.

In an article on the harm caused to the vision of school children by their studies, published in the *Popular Science Monthly* for July, Prof. W. D. Scott remarks that "the human eye which had been evolved for distant vision is being forced to perform a new part, one for which it had not been evolved, and for which it is poorly developed. The difficulty is being daily augmented. The invention of printing presses has been followed by an increasing number of books, magazines, and daily papers. . . . All things seem to be conspiring to make us use our eyes more and more for the very thing for which they are the most poorly adapted. It requires no prophet to foresee that such perversion in the use of an organ will surely result in a great sacrifice of energy, if not of health and of general efficiency." Certain mitigations of the evil are suggested in the case of young school children.

To the October number of the *Century Magazine* Prof. H. F. Osborn contributes an illustrated article on his experiences in the Fayum district of Egypt while in search of fossil vertebrate remains, with remarks on the nature and origin of the fauna and its bearing on the geographical distribution of mammals. Among the illustrations, special reference may be made to Mr. C. B. Knight's restorations of Arsinoitherium, Hyænodon, and Zeuglodon. In Eocene times the Fayum, in the author's opinion, was a savanna country, partly open, partly covered with scrub, and partly with forest, the temperature being much the same as at the present day. That Africa (when much less extended to the north than at present) was the home of the ancestral proboscideans, sea-cows, hyraxes, and probably hyænodonts, Prof. Osborn is fully convinced; but the absence in the Eocene deposits of remains of ancestral hippopotamuses, ruminants, horses, and rhinoceroses leads to the inference that "none of these quadrupeds had as yet reached Africa; that they were evolving elsewhere, either in Europe, Asia, or North America, and preparing for the great interchange of life which would occur when Africa should again be connected with the other continents." In referring on p. 824 to the *emus* of New Zealand, the author doubtless intended to write *moas*.

In vol. xx., part i., of the Proceedings of the Royal Society of Victoria, Prof. R. J. A. Berry reproduces a photograph of an aged half-caste Tasmanian woman now living on Kangaroo Island, South Australia. She is the daughter of a pure-bred Tasmanian woman by a European husband, and was born on the island about seventy-five years ago. In colour, as well as in her wide nostrils and mouth, weak chin, and dark eyes, she retains strong evidence of her Tasmanian ancestry, but her hair, although distinctly woolly, has departed somewhat from the aboriginal type. The latter is, however, better displayed in one of her daughters, who is, of course, a quarter-caste. The author believes "Mrs. S." to be the oldest surviving half-caste Tasmanian. Prof. Berry accepts the view that the Tasmanians were a branch of the Papuans, and that they reached Tasmania at an early period across Australia, when the continent had a direct land connection with Tasmania. Various cases have been known along the coasts of southern Australia of hybrids between Australian and Tasmanian aborigines, doubtless due to Tasmanians having been carried across Bass Strait by the sealers. The same number of the Proceedings contains a paper by Messrs. Chapman and Pritchard on fossil fish remains from the Australian Tertiaries; it describes seven new species, which are referred to genera which range in time from the Jurassic to the present. There is also the sixth of Prof. Ewart's contributions to the flora of Australia, and a paper by the same author on the movement of the soluble constituents in fine alluvial soils.

The theoretical articles in the fourth part of vol. v. of *Biometrika*, issued in September, include a note by Mr. Francis Galton on "grades and deviates," with a table giving the deviations in the normal curve corresponding to assigned percentiles; this table is due to Mr. W. F. Sheppard, who also contributes a memoir on the calculation of moments. Mr. A. P. di Cesnola gives an account of an investigation as to the action of natural selection in *Helix arbustorum*, by the method of the late Prof. Weldon, shells being ground so as to expose a longitudinal section of the spiral on which measurements can be made, and the frequency distributions compared for the earlier whorls in young and adults. The results show that there is markedly less variation in the adults, and consequently some periodic selection. The records of Prof. Weldon for inheritance in mice are reduced and discussed, so far as regards sex-ratio and size of litter; there is little, if any, inheritance in either case, but the figures exhibit some peculiarities. The remaining articles include investigations by Prof. F. Y. Edgeworth on the average time of absence of wasps and bees from the nest, by Miss Wright, Miss Lee, and Prof. Karl Pearson on the wing dimensions of wasps (*Vespa vulgaris*), and by Dr. J. Brownlee on means of estimating the severity of attack in cases of acute disease. There are a few miscellanea, and a bibliography of literature on biometry and Mendelism relating chiefly to issues of 1906.

On the subject of apogamy in the fern genus Nephrodium, Mr. S. Yamanouchi communicates a preliminary notice of his cytological investigations to the *Botanical Gazette* (August). In the normal gametophyte of *Nephrodium molle* sixty-four or sixty-six chromosomes were counted, and the double number in the sporophyte. In the apogamous developments, the sporophyte was followed from an initial cell, the nucleus of which contained the smaller number of chromosomes, and the same number was found throughout all the stages of the sporophyte.

The first two numbers for the current year of the *Journal Botanique* of the Imperial Society of Naturalists in St. Petersburg contain two papers by Mr. A. Elenkin on lichens. In the earlier he describes three new lichens for the genera Evernia, Aspicilia, and Lecania, all collected in Russia; in the later he discusses the comparative amount of growth in erect and horizontally growing species of close affinity. The description of a new species of Eremurus from China derives its chief interest from the fact that, as the author, Mr. O. A. Fedtschenko states, this is the first record of that genus from China, and a considerable extension of its distribution south-eastwards beyond the previous limit in or near Nepal.

Mr. C. E. C. Fischer contributes to the *Indian Forester* (August) a list of host plants of various species of Loranthus and Viscum observed in the North Coimbatore Division of Madras. It is stated that these parasites are most frequent in dry, deciduous forests at elevations between 3500 feet and 4500 feet, where practically every tree is attacked. The occurrence of one parasite growing on another parasite is recorded. The method of exploiting the trees of *Terminalia Chebula* for their fruits, the myrobalams of commerce, is described by Mr. J. E. C. Turner. The sound fruits become ridged when they are dried in the sun, and the pericarp becomes exceedingly hard; others do not wrinkle, owing to the decomposition attributed to a fungus of part of the mesocarp into a black powder that has a small value for making ink. For sowing, the damaged fruits are preferable, since germination is not hindered by a hard pericarp.

Within recent years an algal disease, known as the "red rust" of tea, caused by *Cephaleuros virescens*, one of the Chroolepidæ, has become a serious pest in the tea districts in India. Dr. H. H. Mann and Mr. C. M. Hutchinson, scientific officers to the Indian Tea Association, after following the course of the disease for some years, have published an account of their observations in the botanical series of the Memoirs of the Department of Agriculture in India (vol. i., No. 6). The growth on the leaf, being usually confined to the surface, would be unimportant, except for the fact that the sporangia there formed provide the means for the spread of the disease. This is effected either by transference of the sporangia as a whole or of the zoospores. The real danger is due to the penetration of the young stems of the tea plant by the alga, when, if the alga prevails, the leaves turn white and the stems are killed.

It is well known that tide curves show that, in addition to waves of very short duration due to wind, and those caused by the regular flow and ebb of the tide, pulsations sometimes called "marine seiches" or "vibrations of the sea" occur, with periods of fifteen to twenty minutes, but differing considerably in various localities (see Nature, January 12 and April 20, 1899). In the *Annuario* of the R. Nautical Institute of Catania, Sicily (vol. i., 1907), Prof. Giovanni Platania contributes an interesting paper on the subject, with the results of some fresh researches made by himself in the Gulf of Catania. Opinions differ as to the origin of these vibrations, which are observed under different meteorological conditions; the author thinks that the principal cause is variations of atmospheric pressure. The micro-barograph recently devised by Dr. Shaw and Mr. Dines for recording the minor and sudden fluctuations of the atmosphere will probably help further to elucidate the phenomenon.

The current issue of the *Central* (vol. iv., No. 12) contains an interesting account of research work carried out recently in the electrical department of the Central Technical College. There is also a well-illustrated description of the cyanide process for the extraction of gold and silver from their ores, written by Mr. Reginald Krall.

The British South Africa Company has issued a copiously illustrated monograph on Rhodesia, covering 120 pages. It contains much information for travellers generally, and for sportsmen in particular. The illustrations have been admirably reproduced, and the five coloured maps are excellent. The volume should prove of special use to teachers as a class-book.

The mode of formation of many placer deposits is not clearly understood, and the source of the gold has not been definitely determined. In view of this uncertainty, a recent paper by Mr. J. B. Tyrrell in *Economic Geology* (vol. ii., No. 4) is of special interest. He describes the conditions that prevail in the Klondike district of Canada, a country of exceedingly rich gold-bearing placers, where the origin and processes of deposition and concentration of the gold into its present position are easily recognised. His investigations show that the district owes its phenomenally rich placers, not to the wearing down of highly mineralised gold-bearing veins, but rather to the favourable conditions of long-continued and uninterrupted concentration from a great mass of rock that contained only very minute quantities of gold.

Three valuable monographs have been issued by the Corps of Mining Engineers of Peru. In *Boletin* No. 51 Mr. F. M. Santolalla describes the mineral resources of the province of Huamachuco. The mineral deposits may be divided into three groups, the veins in eruptive rocks, such as the gold veins of the Toro, the lead-antimony-silver ores of Cerro Negro, and the magnetic iron ores of San Pascual and Potosi de Serpaquino. The coal deposits of the province have been known from time immemorial. In short, the mineral resources might be worked with great advantage if better means of communication were available. In *Boletin* No. 52 Mr. H. C. Hurd investigates two schemes for diverting the waters of the Rio de

Lambayeque. Lastly, in *Boletin* No. 54 Mr. G. Klinge gives the mineral statistics of Peru for the year 1906. The production included 79,969 tons of coal, 70,832 tons of petroleum, 20,226 tons of salt, 2598 tons of borates, 1830 tons of sulphur, 230 tons of silver, 13,474 tons of copper, 2568 tons of lead, 2304 kilograms of mercury, and 1247 kilograms of gold.

M. A. PELLETAN, in the October number of the *Journal de Physique*, expresses his regret that in France there is so much difficulty in finding persons capable of determining the elements of an optical instrument by any of the modern methods. It seems singular that in a country through which a knowledge of mathematics is more widely spread than elsewhere, that knowledge should find fewer practical applications than it does in almost any other country. M. Pelletan suggests the formation of a Government office to which engineers whose knowledge or leisure would not allow them to cope with mathematical difficulties might bring their problems for solution. In the meantime, he gives a clear *résumé* of the general methods of treating geometrical optics which have been developed from Hamilton's characteristic function. These methods are not so well known in this country as they deserve to be, and we have not yet risen to the point of regretting our want of knowledge of them.

THE measurement of the angle between the optical axes of a biaxial crystal has always played an important part in the identification of the crystal, and several methods of making the measurement are in common use. There has, however, been little comparative or critical study of the accuracy of the different methods under different conditions. A considerable portion of the *American Journal of Science* for October is devoted to such a study from the pen of Mr. F. E. Wright, of the Carnegie Institution. During the course of his experimental work, Mr. Wright has constructed a double-screw micrometer ocular with the screws at right angles to each other which he uses to determine the position of any point on the interference figure produced when a thin plate of the crystal is examined in plane polarised convergent light. By this means he is able to obtain more accurate results than were possible with the ordinary micrometer in Becke's method. He advocates the use of the stereographic projection in preference to any other.

AN interesting account of the processes recently devised for liquefying air on an industrial scale, and for extracting oxygen directly from the liquefied product, is contained in an article by Prof. E. Mathias in the *Revue générale des Sciences* (No. 17, p. 697). Particular attention is directed to the method of liquefaction developed by Claude, in which the principle of expansion with the performance of external work has been adopted with remarkable success. The process patented by Thrupp in 1898, and that described by Linde in 1901, are also described. The problem of separating air into its constituents oxygen and nitrogen, which has formed during the past few years so prominent a goal for the endeavours of engineers of all countries, is dealt with at somewhat greater length, the many schemes suggested being considered in detail. Such success has attended the efforts made to separate the gases of the air industrially by liquefaction that the expenditure involved in preparing 1 kilo. of pure nitrogen on the large scale has fallen below a penny. The article is illustrated by nineteen drawings showing the principle of the various types of plant in use.

A SEVENTH and enlarged edition of the translation by H.R.H. Princess Christian of Prof. Friedrich Esmarch's "First Aid to the Injured," with additional illustrations, has been published by Messrs. Smith, Elder and Co., at 2*s*. net.

NEARLY half of the thirteenth edition of Mr. W. H. Harling's illustrated catalogue of mathematical drawing instruments is new matter. Every requirement of the architect, draughtsman, and student appears to be anticipated. The needs of teachers of practical mathematics have been borne in mind, and considerable space is given in the additional pages to particulars concerning instruments for measuring with precision lengths, angles, and other dimensions.

MR. H. K. LEWIS has published a third edition of "Hygiene and Public Health," by Dr. Louis C. Parkes and Prof. Henry R. Kenwood. The present work grew out of Dr. Parkes's "Hygiéne, or Public Health," which appeared in 1899, and was reviewed in NATURE of January 30, 1890 (vol. xli., p. 290). A certain amount of new matter has been introduced into the present edition, but some parts of the previous issue have been compressed and abbreviated. The size of the page, too, has been slightly enlarged.

A FIFTH edition of the late Prof. P. G. Tait's well-known "Properties of Matter" has been published by Messrs. A. and C. Black at 7*s*. 6*d*. The work appeared first in April, 1885, and was reviewed at length in our issue of August 6, 1885 (vol. xxxii., p. 314), by Lord Rayleigh. The present edition has been edited by Prof. W. Peddie, of the University College, Dundee. The recent advance of physical science has necessitated some additions, but these have in every case been placed within brackets and initialed by the editor, so that the original plan of the book has been preserved.

OUR ASTRONOMICAL COLUMN.

A NEW COMET.—A telegram from the Kiel Centralstelle announces the discovery of a new comet by Mr. Mellish on October 13. Its position at 16h. 0m. (Madison-Wisconsin M.T.) on that date was R.A. = 8h. 31m., dec. = 9° 24′ S., and the comet was moving slowly in a north-westerly direction.

This position lies between one-quarter and one-third the distance from ι to C Hydræ, and the comet is apparently travelling towards Canis Minor. At present it rises a little to the south of east at about 2 a.m., and crosses the meridian at 7 a.m.

SUN-SPOT SPECTRA.—At the June meeting of the Royal Astronomical Society, Prof. Fowler announced that he had found a terrestrial origin for the numerous short, hazy lines, known as "band" lines, in sun-spot spectra which have hitherto remained unorigined. These lines, it now appears, are part of an extensive "fluting" spectrum ascribed by Liveing and Dewar, in 1881, to a compound of magnesium and hydrogen (Proc. Roy. Soc., vol. xxxii., p. 190), and investigated by Sir Norman Lockyer.

The brightest fluting begins near λ 5211, and fades off towards the violet; a second includes the well-known hazy spot lines at λλ 5163·2, 5160·1, 5156·8, &c., whilst others begin at λ 5620 and on the violet side of Hβ. A comparison of the laboratory wave-lengths obtained by Prof. Fowler with those observed in the sun-spot spectrum places the identification beyond doubt, and it is estimated that probably several hundreds of the sun-spot "band" lines will be found to agree, in position, with those occurring in the laboratory spectrum (Monthly Notices R.A.S., vol. lxvii., p. 530, June).

Q

The Red Spot on Jupiter.—Mr. Stanley Williams publishes his observations of the Great Red Spot during the most recent opposition of Jupiter in No. 4202 of the *Astronomische Nachrichten* (p. 23, September 30). He records the spot as being as faint as ever it was, and the observing conditions, especially at the commencement of the opposition, were very poor. The rotation period satisfying the observations is 9h. 55m. 42·27s., from 594 rotations, and the longitude is $20°{\cdot}87 \pm 0°{\cdot}23$.

Mr. Williams directs attention to the abbreviated rotation-period which obtained between the oppositions of 1905–6 and 1906–7; during the former it was 9h. 55m. 41·46s., whilst in the interval it was 9h. 55m. 36·25s. This difference is too great to attribute to errors of observation, and indicates a real change in the spot's position. Observations lead to the conclusion that this change of position is in some way due to the large mass of dark material known as the Pyramid Spot, or South Temperate Disturbance, for on three occasions such changes of position have synchronised with the passage of the Disturbance past the Red Spot. The general discussion of a large number of observations of this phenomenon may, as Mr. Williams suggests, throw considerable light on the nature, and possibly the mass, of the Red Spot.

The Proper Motions of Stars in the Cluster Messier 92.—In No. 4165 of the *Astronomische Nachrichten*, Dr. K. Bohlin compared some measures of the stars in the cluster Messier 92, made on an astrographic plate taken at Stockholm in 1898, with those made by Schultz at Upsala in 1873, and found discordances which were attributed to proper motions during the intervening twenty-five years.

Prof. Barnard has had this cluster under observation, with the 40-inch Yerkes refractor, for some time past, and in No. 4202 of the same journal he discusses his observations with the view of testing the theory of proper motions. A comparison of the three sets of measures leads him to the conclusion that the existence of actual proper motions is very doubtful, for the cases of agreement are practically equal in number to those in which the measures do not agree. In a second paper he compares the definite measures made by Schultz of the stars in the bright part of the cluster with those made by himself, and definitely expresses his confidence in the opinion that the discordances are not due to proper motion, but rather to the uncertainty of the measured positions. The knowledge that such uncertainty existed led Prof. Barnard to undertake visual micrometer measures of various clusters with the 40-inch refractor, and he hopes to publish the results of the work in the course of the next twelve months.

The Dominion Observatory, Ottawa.—From notes in the current Journal of the Royal Astronomical Society (Canada), vol. i., No. 4, p. 264, July-August, it is evident that valuable results may be expected from the investigations now being carried out at the Dominion Observatory, Ottawa. The new spectrograph is performing very satisfactorily, and with the one prism gives spectra of first-type stars, in which $H\beta$, $H\delta$, $H\epsilon$, and $H\gamma$ are accurately measurable; $H\gamma$ was the only hydrogen line usable on the earlier spectrograms. Seven spectroscopic binaries are under regular observation, and, in addition to the results already published for α Draconis and ι Orionis, it is hoped that the provisional elements of four other binaries will soon be completed. A new method, a modification of Hartmann's, has been applied to the reduction of the plates with considerable accuracy and a great saving of labour. Experiments, having for their object the production of a flatter field, are being carried out, and it is hoped to obtain a field of 8°, instead of the 2° or 3° at present available. A 6-inch first-quality plane grating has been supplied by Dr. Brashear for use with the cœlostat telescope in solar research. Dr. R. G. de Lury, Mr. R. M. Motherwell, and Mr. J. N. Tribble have been appointed to the staff for work on solar research, micrometer observations, and radial-velocity determinations respectively.

The Perseid Meteors.—A watch for Perseids was kept at Greenwich from August 10 to 13, but very few brilliant meteors were seen, the display, on the whole, being considered a very poor one. The actual numbers of meteors bright enough to be plotted were twenty-seven on August 10–11, sixty-four on August 11–12, and eight on August 12–13. On the last-named night clouds interfered with the observations, but the other two nights were quite cloudless (*Observatory*, No. 387, p. 366, September).

BOTANICAL CONGRESS AT DRESDEN.

The German Botanical Society has this September celebrated its twenty-fifth anniversary at Dresden under the presidency of Prof. Schwendener, who justly emphasised the promptness of publication and value of the contents of the society's journal. Owing possibly to the wording of the invitation to members to contribute papers to the meeting, only one communication was made, by Dr. Winkler, on parthenogenesis in plants. The same botanist aroused great interest, and a short but lively discussion, by exhibiting a growing plant obtained by grafting *Solanum nigrum* with a tomato variety, and by encouraging, to the exclusion of other buds, a composite bud, arising at the point of contact and fusion of the two plants. The resulting shoot shows, from node to node upwards, especially well seen in the leaves, alternately, right and left, the characteristics of each plant. The term "graft-bastard" proposed was objected to by many. No doubt more will be heard of the specimen if it forms flowers. Prof. Bower and Colonel Prain were elected honorary members of the society.

In the earlier part of the week (September 8–15) the Society of Applied Botanists and that of the Systematists held their meetings. The applied botanists were present in force, and many important papers were read. The society by resolution agreed to urge on the Government the necessity of making better provision in many of the technical colleges for botany in its various branches. A few weeks previously the professors in the universities and technical colleges met to form a union, one object of which is to secure greater freedom of action and less Government interference, without, however, loss of Government funds.

Ule's finely illustrated account of the flora of the Brazilian province of Bahia, Hiltner's soil-bacteria investigations, and Lindner's beautiful mould cultures, were outstanding features of this part of the meeting. The systematists made a delightful excursion to the Bohemian Mountains (Rollberg, &c.) to compare their varied flora with the more uniform flora of the Elbe sandstone. On the basaltic Rollberg *Asplenium septentrionale*, *Woodsia Ilvensis*, *Ribes alpinum*, *Allium strictum*, and many other interesting alpines were obtained.

In the following week the German Society for the Advancement of Science and Medicine met also in Dresden. The botanical section was strongly represented under the presidency of Prof. Pfeffer, who contributed a paper on sleep movement in plants, Wettstein one on the phylogeny of the angiosperm flower, Molisch one on ultra-microscopic organisms, while Prof. Drude gave a demonstration in the botanic garden of his cultural work on *Cucurbita Pepo*. He showed a well-established hybrid between *C. Pepo* and *C. institiia*, the fruit having the mottled colour of the latter, the size and form of the former. Throughout Prof. Drude and his assistants, Drs. Schorler, Naumann, and Schwede, did everything possible to ensure the comfort of visitors and the success of the meetings. The forestry school and arboretum at Tharandt were visited; but, owing to sudden illness, Prof. Neger was unfortunately absent. Nobbe's Seed Station, formerly at Tharandt, is now at Dresden under Dr. Simon's direction. The botanical garden at Dresden, though small, shows many interesting features. There are groups illustrating geographical distribution, *e.g.* plants characteristic of South Africa, Australia, &c. The illustrative plants throughout the garden are kept small to economise space. By using differently coloured labels, the periods of introduction into European cultivation of our garden plants are indicated.

T. J.

WATER AND ICE, TO-DAY AND IN THE GLACIAL EPOCH.

MR. G. K. GILBERT'S survey of the Niagara Falls (see NATURE, vol. lxxv., p. 607) is not to stand alone. In the "Summary Report of the Geological Survey Department of Canada for 1905" (Ottawa, 1906) Dr. J. W. Spencer promises a full account of the Niagara district, which he is agreeably confident will reveal "discoveries of the greatest importance" (p. 91). Soundings have been made in the gorge below the falls, in areas previously untested, and wells have been sunk to prove the depth of an interesting buried channel, filled with glacial drift.

In contrast with this region of attractive turmoil and erosion, Mr. T. W. Kingsmill takes us to the lower Hwangho, in China, where the river "is prevented by the laws of hydraulics from excavating its bed, and has in consequence to flow on the surface" ("The Hydraulics of Great Rivers Flowing through Alluvial Plains," Shanghai, North China Herald Office, 1906). If once this great body of water effects a breach in one of its banks, it "shows no disposition, when the flood subsides, to return to its bed, but invariably finds some easier course to the sea." The Hwangho, according to Mr. Kingsmill's interesting historic sketch, broke its right bank in 1854, and from that date to 1870 wandered over a wide stretch of country, depositing a layer of sand from 6 feet to 8 feet thick. In Horan, not far from Mangtsin, 250 feet of river-alluvium, thoroughly pervious to the water above it, were passed through in sinking for a coal mine. Much of the drainage thus reaches the sea by underground channels, and the main river actually diminishes in volume below Mangtsin. The extensive deposits that are forming in the Gulf of Pechili, at the rate of 208,000 tons per day (p. 31), increase the difficulty of controlling the river in the interior. We learn that fishermen on stilts may be met with out at sea miles before the low coast is sighted. Mr. Kingsmill's suggestions for correcting the stream are enlivened by the printing of a discussion of them by Mr. Tyler. Mr. Kingsmill proposes to continue banking up the river; Mr. Tyler would organise floods at selected points, and let the river build its huge conoidal plain under proper supervision. The silt would then be disposed of in an orderly manner, and the river-bed would cease to rise. The titanic struggle of man with the Colorado River (NATURE, vol. lxxv., p. 501) suggests, however, that Mr. Tyler's dumping-grounds might at times get more water and less silt than they were prepared for.

There are many districts that have been assailed by diluvial flooding and deposition in comparatively recent times, where now desiccation has set in, with the accompaniment of the formation of löss and sand-dunes. The extremely uncomfortable conditions that prevailed in Europe at the close of Glacial times are shown by Prof. Steinmann to have been paralleled in South America ("Uber Diluvium in Süd-Amerika," *Monatsberichte d. deutschen geol. Gesell.*, 1906). The author believes that the vast extent of fluvio-glacial deposits, which have filled up the hollows of the Cordillera and spread so freely over Patagonia, can only be accounted for by a series of glacial epochs. He sees, moreover, in the level expanses of calcareous mud round the salt-lakes of Bolivia and Argentina the evidences of former fresh-water lakes, in which Bythinia flourished. "The traces of the last ice-age may be followed across the equator as far as Cape Horn." The climatic differences that prevail at the present day are now shown to have existed, both in Europe and South America, during the melting of the last ice-sheets; and "hence we shall do well to discard all attempts at explaining glacial epochs that are not of a universal character."

In a paper furnished with an abstract in French ("Till Fragan om Ost-Finmarkens Glaciation och Nivåförändringar," *Bull. Comm. géol. de Finlande*, No. 18, 1907), Herr V. Tanner describes the course of the ice in Finmark in glacial times as being from S.W. to N.E., and traces the variations in the sea-level by observations on terraces cut in the rock and on gravelly raised beaches. While the ice was melting from the land, the continental mass was rising, and thus offered a more and more extended front to the action of the waves.

While the terminal tongues of glaciers in Alberta and British Columbia have not in all cases shown a marked retreat in recent years, Messrs. George and W. S. Vaux prove that the ice-masses have become greatly reduced (*Proc. Acad. Nat. Sci. Philadelphia*, December, 1906, p. 568). The Illecillewaet Glacier has withdrawn about 250 feet in eight years; but its annual rate of recession is becoming slower, and its rate of flow is now actually greater than in 1899. Conical moraines appearing through the ice on the Wenkchemna Glacier (p. 577) are witnesses of the immense amount of ice removed in recent times by surface-melting.

FIG. 1.—Margin of the Malaspina Glacier, August 11, 1906, showing mingling of moving ice-blocks with trees still in leaf.

The famous Malaspina Glacier of Alaska has, however, started on a new career. Prof. R. S. Tarr ("Second Expedition to Yakutat Bay, Alaska," *Bull. Geographical Society of Philadelphia*, January; see also *Bull. Geol. Soc. America*, June) describes the rapid and unexpected changes that are taking place in it, and in certain other glaciers close to its eastern margin. Crevassing has occurred in previously quiescent and moraine-covered masses, accompanied by a marked advance. Prof. Tarr found that the alder and cottonwood trees growing on the Malaspina Glacier developed their leaves in 1906, but were then in part swallowed up and over-ridden by the active ice. The scene of visible movement, with falling trees and ice-blocks, and sliding soil from the moraines, is paralleled by the attack of the adjacent Atrevida Glacier on its marginal forest. Other glaciers as yet have not been influenced; and Prof. Tarr refers these remarkable movements to the shaking of the district by the earthquakes of 1899, or even of some earlier date. The fall of masses of snow into the gathering-grounds would thus have taken seven years to influence the ice-front; but the author points out that the crushing of the resisting masses in the lowlands is just what might be expected from a sudden addition of snow to the reservoirs in the hills. Changes of level, moreover, amounting to as much as 47 feet, took place in Alaska in 1899, and these may in part account for local variations. The description of the broad alluvial fan of the Hayden Glacier, with its streams changing in position and depth from day to day, is impressively interesting, as an illustration of the rate at which our own "glacial gravels" may have been distributed.

Perhaps Prof. Tarr's remarkable but modest paper will be hailed by M. Edouard Piette as an argument in favour of his more startling views ("Déplacement des Glaces polaires et grandes Extensions des Glaciers," Saint Quentin, 1906, pp. 36). M. Piette attributes the glacial climate of the northern hemisphere to the release of ice-masses by earthquakes at the pole. He urges that this would be assisted by the uprush of volcanic vapours and hot springs along the fissures, while cataclysms like that of the Straits of Sunda would fling the ocean waters irresistibly against the polar ice-cap. The Atlantic continent from Ireland to Iceland fell in about the same time by an "affaissement définitif," and the whole ice sped southward, leaving the pole for a time free. We confess that we can read M. Piette's paper far more sympathetically, now that we have the advantage of Prof. Tarr's conclusions; but there is a whirl of death and horror about his description of the great catastrophe that reminds us of the old diluvial theories, to say nothing of Dante's second circle. We read, moreover, that icebergs nowadays (p. 6), running aground on the coasts "d'Irlande ou d'Ecosse, y déterminent des froids intenses, capables de geler la végétation." Such a phenomenon would attract thousands of excursionists, and would surely be mentioned in our veracious daily papers.

The erosive power of glaciers is clear, wherever joints or any other planes of division in a rock are so arranged as to slope up against the direction of movement of the ice. "Plucking" then becomes a feature of the district. But, even on ice-smoothed surfaces, signs of rock-fracture under the pressure of the glacier are occasionally found. Prof. G. K. Gilbert discusses these "crescentic gouges" (*Bull. Geol. Soc. America*, vol. xvii., 1906, p. 303) as due to the presence of subglacial boulders. A line of type omitted on p. 313 renders one of the sentences obscure; but the argument put forward is that ice must have "greater power of resistance [to flowage] than some students have been disposed to admit. . . . The more rapid the flow the stronger the resistance. Therefore the crescentic gouges . . . may testify also to the relative rapidity of glacier movement." Prof. Gilbert's photographic illustrations are excellent, as are those of subglacial potholes in a subsequent paper on moulin work (*ibid.*, p. 317), in which it is pointed out that such moulin-hollows may be bounded during their formation on one side by rock and on another by the ice, leaving a rock-surface with flexuous incurvings when the glacier has disappeared by melting.

Prof. R. S. Tarr ("Glacial Erosion in Alaska," *Popular Science Monthly*, vol. lxx., 1907, p. 99) discusses the broader features of glacial erosion as displayed in hanging valleys. He postulates, in common with other writers, a considerable deepening of the main valley by ice; but may we not presume that the lateral valleys were largely developed and cut back by the frost-nibbling, under glacial conditions, on which Profs. Penck and Davis lay such proper stress? A main valley, with feeble lateral tributaries, may be occupied up to a certain level by ice, which widens it, deepens it somewhat, and wears back the poorly developed projecting spurs. The lateral valleys are at the same time rapidly weathered back under the new and more strenuous conditions of high-level erosion, and rocky cirques are formed at their heads in place of confluent stream-grooves. Tributary ice gathers in each lateral hollow, and the erosion above it, and also below it where a rushing stream emerges on the crevassed main glacier, cannot operate below the level where the two masses unite; and finally, if melting is rapid, hanging valleys are left, which will in time be cut down by ordinary weathering to the level of the main valley-floor. If the main glacier diminishes by ablation slowly, the tributary glaciers and their subglacial streams cut down their valleys to keep pace with the falling surface, and these valleys finally cease to be of the hanging type, though showing glaciated floors. This seems to have been the case in much of central Connemara. This is not the place, however, to attempt to modify the theory of the deepening of glacial valleys so brilliantly put forward by Prof. W. M. Davis. Suffice it that Prof. Tarr disposes successfully of several of the fantastic theories put forward to account for a phenomenon of very wide occurrence in glaciated areas.

In the *Verhandlungen der schweizerischen naturforschenden Gesellschaft*, St. Gallen meeting, 1906, pp. 261–307, Herr J. Früh, of Zürich, writes a general essay, "Ueber Form und Grösse der glazialen Erosion," illustrated by personal observations on the topography of Switzerland. Hanging valleys, Alpine lakes, and "Uebertiefungen" are discussed, and useful references are given to Davis, Penck, and Brückner.

Lastly, we must not forget the work of water in its immense circulatory systems below the surface. The investigation of the "Underground Water Resources of Alabama," by Mr. E. Allen Smith (Geological Survey of Alabama, Montgomery, Alabama, 1907), has provided us with a neatly bound volume which is in many ways a guide to the geology of the State. The conditions favouring underground flow and the emergence of springs are discussed in pp. 32 to 63 in a manner that will interest engineers in general, as well as the ordinary citizen between the Tennessee River and the Gulf of Mexico. The great region for artesian water-supply in Alabama lies along the band of Cretaceous limestone, the Selwa Chalk, which passes just south of Montgomery. Several medicinal springs occur among the Tertiary strata towards the Gulf, including one (p. 320) that has been said to give protection against malarial fever.

G. A. J. C.

ENDOWMENTS FOR SECONDARY EDUCATION.

WHILE writing this article the following questions have been in mind:—(1) What are the number and extent of the educational endowments of our great public and other endowed schools? (2) What were the intentions of their founders? (3) How far are such intentions at present realised? (4) Can the endowments be made more generally available so as to increase their benefit to the public with the minimum departure from those intentions?

The answer to the two latter questions must be that it is largely a question of degree; from the nature of the case an expression of opinion, not a precise estimate, is all that can be attempted. The first two questions relate to definite matters of fact, the answers to which *ought* to be ascertainable, but are only approximately to be determined. A better reply to (1) would be forthcoming had either the late or the present Government fulfilled their promises to obtain a return, to be presented to the House of Commons, giving statistics of the finance of all endowed schools. We are informed that the Charitable Trusts Division of the Board of Education is considering the details to be sought in such inquiry, and it is to be hoped that considerations of its cost will no longer be allowed to stay its fulfilment. In the meantime, the following condensed account, based on such materials as were obtainable, is submitted as calculated to correct some of the grosser errors prevalent with regard to the subject of our ancient endowments. The writer wishes to acknowledge his indebtedness to the writings of Mr. A. F. Leach (Charity Commissioner) and to the courteous help of the officials at the Education Board, of course without implying that they have any responsibility for the statements which follow.

Endowed Schools before the Reformation.

The records included in Mr. A. F. Leach's book entitled "English Schools at the Reformation" (Constable) show that 200 grammar schools at least, and more probably

300, flourished before the Reformation. The majority of these were abolished or crippled by the Government of Edward VI., who, by the strange irony of fate, is commonly credited with founding many of our endowed schools. Generally, it is correct to say that a King Edward VI. school means a foundation which was maimed by Edward VI., *i.e.* by the actual regent at the time. These schools were of various types, some existing as independent institutions, while many were connected with one of the following:—cathedral churches, monasteries, colleges, hospitals, guilds, or chantries. The endowments varied widely, Eton and Winchester having well-paid masters and seventy scholarships apiece, while Launceston paid an old man 13*s.* 4*d.* a year to teach young children. In addition to public schools and grammar schools there were choristers' schools and elementary schools. What we now call secondary education existed in fact, though not in name; with scholarships tenable at the schools, and exhibitions thence to the universities. According to the above authority, the boys were mainly of the middle classes, with younger sons and poor relations of the upper classes, and occasionally bright boys from the real poor. The character of the learning certainly supports this contention, Latin, dialectic and rhetoric, being taught up to a standard fitting the youth of sixteen to eighteen years of age for entrance to the university. Without entering into details (which it were easy to do), it can be asserted that the English schoolboy of the sixteenth century was immeasurably superior to his successor at the present day in respect to knowledge of Latin. Further, it appears to be true, alike of the past and the present, that, given good *quality* of education, the numbers seeking to avail themselves of its provision will take care of themselves. In round numbers, we find in the England of 1546 a population of two and a half millions, with 300 grammar schools, or one school for 8300 people. This compares well with the one school for 23,000 of the year 1865. One is tempted to wonder, though of course it is mere idle and somewhat melancholy speculation, what would have resulted had some wise statesman developed these disconnected but useful, and, for their day, efficient, institutions into an organised system of national education. Should we have become as a nation more scientific and artistic, but less robust and individual? As facts are, and as they have to be faced, the opportunity was lost, destruction and spoliation took the place of development, and to-day we are left with endowments, not indeed to be despised, but utterly inadequate to provide a tithe of the cost of higher education of the country.

1864 TO PRESENT DAY.

Under the chairmanship of Lord Clarendon, a commission of inquiry reported in 1864 on "The Revenues, Management, Instruction, and Studies of Eton, Charterhouse, Merchant Taylors', St. Paul's, Westminster, Winchester, Harrow, Shrewsbury, and Rugby." In 1868, the date of the Public Schools Act, there were 2956 scholars in these nine schools, and their net aggregate income, including exhibitions, was about 65,000*l.* a year. In 1905 the number of scholars was 4100, and their income, as to which only partial information is accessible, has increased in far larger proportion than the number of scholars. The position of Eton and Winchester Colleges is one of such independence that the Board of Education has no information as to their present financial position. They are undoubtedly wealthy, and their national importance makes periodical audit and publication of financial statements the more desirable. In 1890 the gross income of St. Paul's School endowment was stated to be 15,426*l.* A recent question raised by a member of the House of Commons has fortunately led to an investigation of the case of Harrow School. Here it appears that the endowment is worth about 1000*l.* annually, roughly half of which goes to the lower school of John Lyon, and the rest might easily be spent on clerical, legal, and office expenses connected with the foundation. In short, Harrow School is supported by the fees of the pupils. If any reader of this article should have been under the delusion that our ancient endowments are vast stores of unused or misused wealth, this fact may prove one step in his disillusionment. It is to be hoped that the Board of Education will give us information about the income of the remaining five schools. Not being subject to the Endowed Schools Acts, they are not included in the Roby Return of Charitable Foundations presented to the House of Commons in 1892 (and reprinted in the Report of the Secondary Schools Commission of 1895). It does not appear from the reports of either the Clarendon or the Schools Inquiry Commission that the segregation of these schools was justified on any clear legal, proprietary, educational, or national ground. The following extract from the Clarendon Report is of interest:—

"Are the classes by whom these benefits are now enjoyed the same as those for whom they were originally intended? There is no doubt that the collegiate schools were primarily though not solely designed for the assistance of meritorious poverty; the independent grammar-schools primarily though not solely for the benefit of some particular town, village, or neighbourhood. . . . Speaking generally, it must be said that the difficulty of assigning a precise meaning to the word poverty, the doubt what class of persons, if any, at the present day really answers to the ***pauperes et indigentes scolares*** of the Lancastrian and Tudor periods, and the further doubt whether poverty is not after all best served by giving the widest encouragement to industry, coupled with the interest which every school has in collecting the best boys from the largest surface, have tended, and will continually tend, to render the qualification of indigence practically inoperative. We do not think it necessary to recommend any change in this respect."

One more extract refers to local privileges, often the right to gratuitous education:—

"The question we have to consider is, whether the maintenance of the local privileges in favour of these persons, and of the few permanent residents who desire a public-school education for their sons, is recommended either by respect for the founder's intentions or by any other sufficient reason. We think that it is not." (We may note that "these persons" refers to immigrants attracted to the town or village by cheap education through the foundation.)

Following the "Clarendon" Commission there was "The Schools Inquiry Commission" under Lord Taunton's chairmanship, which reported in 1867 on all the remaining schools, numbering 100 first-grade and 247 second-grade endowed grammar schools, including twenty-two in Wales. Of these, a few have ceased to exist or have become elementary, while occasionally the endowment has become a bursary or scholarship. Perhaps one-seventh have thus been lost to secondary education; the remaining six-sevenths still form to-day the core of the public secondary education of England.

Despite the remarkably able character of the commission and its arduous labours, we cannot altogether rely on the accuracy of an important part of the information contained in its voluminous report and minutes of evidence (twenty-one volumes), that part, viz., which purports to give the ancient history of the foundations. The commissioners mainly relied for this history on the earlier reports of the commissioners for inquiry concerning charities, 1818 to 1837. In a chronological list of schools given in his "English Schools at the Reformation," Mr. A. F. Leach assigns a different date from that given by the commission in a large majority of cases, differences amounting in some cases to centuries! As Mr. Leach is probably our best authority on this subject, we can feel but little confidence in the findings of the commission with regard to the original documents, deeds, and charters, particularly of the older foundations. This consideration does not, of course, affect the accuracy of their statements as to the position of the endowments in 1867, but it gives some support for further amendment of the Public Schools Act of 1869, which was avowedly based on the Taunton Report. Apart from amendments in detail, this Act governs most of our grammar schools to-day.

The powers of the Charity Commission to establish and amend schemes, which were transferred to the Board of Education by an Order in Council in 1901, were powers under the 1869 Act. For example, head and assistant masters are dismissible "at pleasure" in nearly all endowed schools at this day, because the law of 1869 so enacts. Its importance may be indicated further from the fact that during 1905 alone there were 649 orders made, 470 relating to secondary and 179 to elementary education, by the Board in its exercise of these powers. Returning to the 1867 report, we find that there were in England and Wales 782 distinct foundations, 820 schools, 36,874 scholars, and annual income 210,000*l.*, exclusive of the nine great schools. Including these, but excluding elementary schools, we have 40,000 scholars and an income of 277,000*l.* a year. This was for a population of twenty-one millions. In an appendix is an interesting table showing the estimated number of boys (eight to fifteen years) of upper and middle class parents to be:—in towns, more than 15 per thousand; and in rural districts, 11 per thousand. Local inquiries made the number of boys in day schools other than elementary to be 16 per thousand of the population, so that private schools were responsible for the greater number. It is known that the standard represented by "secondary education" in most of these schools (public and private) was very low, in many cases decidedly below that of a good board school in the last decade.

In 1895 the Commission on Secondary Education, under the chairmanship of Prof. James Bryce, reported that for seven selected counties the number of boys was 2·48 and of girls 3·6 per thousand of the population in endowed and proprietary schools. In London the proportion of boys was slightly higher, that of girls decidedly less. Nor could it be seriously contended that private schools made up by their number, size, and efficiency for this most serious state of affairs. It has to be acknowledged that the attempt to leave secondary education to be provided by private enterprise and endowments has had disastrous effects. The great improvement made in the last decade, though in part due to a raising of the tone and standard of teaching in schools, both private and endowed, could not have advanced so far as has already been the case; still less could it make the needful progress we hope for in the immediate future, without the aid of the national exchequer and the local rates. It may be thought that by pooling the endowments and re-distributing them the expense to the rate-payer and tax-payer might have been avoided. The writer is not of this opinion. Some re-distribution would undoubtedly be of advantage, by making the endowments more generally available, and thus much benefit might accrue, as a comparatively small addition to the funds of a struggling school will often make a relatively enormous increase in its efficiency; but unfortunately the sums available are far less than is often supposed. The precise amount is not readily ascertained. The annual reports of the Charity Commission give no information on the subject; the "Statistics of Public Education in England and Wales," published by the Board of Education, despite its comprehensive title, merely deals with grant-aided schools; the balance-sheets of county education committees usually omit to give the endowments of the schools aided; and the inquirer has to fall back upon the Roby Return.

The return gives the gross income for the year 1890 of each individual charitable trust, but does not specify which part, if any, is educational. The 1895 Bryce Commission Report adds notes on the apportionment of each trust to educational and other uses, but often the directions are hopelessly intricate. No digest or summary is attached to these documents, and the present writer must be held responsible for the following statements, based on a rough analysis of the return:—In 1890 the number of foundations the endowments of which could provide entirely for the education of 100 boys (at 18*l.* per annum) was thirty-five; moreover, the number of boys and girls being educated at the schools of each foundation exceeded the number which the endowment alone would suffice to educate efficiently, the difference being made up by fees at the more expensive schools, and in other cases partly by fees and partly by Exchequer and local grants. When it is considered that in 1905 the Board paid grants amounting to 211,254*l.* on 51,779 scholars in 575 secondary schools, that these schools had in addition 30,000 scholars not earning grants, and that the annual increase in grant-earning scholars is estimated to be 30,000, it is obvious that no large measure of financial relief to the community is to be found in re-distribution of endowments. What has happened is rather the inverse process; the municipal authorities have rescued impoverished schools with too meagre endowments.

THE NEAR FUTURE.

The control exercised by the Board of Education over schools aided by grants of public money has greatly increased during the last two years, and is destined to become more and more penetrating. It is inevitable that this development of bureaucratic influence should bring with it the usual concomitant advantages and evils. To make the most of the advantages, and to minimise the evils of centralisation should be our goal. We want local public interest in our schools, and a strong profession of teachers. One of the worst results of the extreme regard paid to the "individuality" of our schools has been to produce a body of schoolmasters suspicious of, if not hostile to, organisation, even of their own profession. This unfortunate sentiment is happily growing weaker, and will become evanescent as soon as it is realised that the schools themselves are becoming subject to a common authority, with its potency for good or ill to all under its sway. What the country as a whole needs is a proper devolution of responsibility to local education committees, with reservation to the central authority of certain functions the performance of which locally is open to serious objection. Among the latter may be placed the training of teachers, and the inspection of schools as regards conditions of health, while the local authorities should supply statistical information required by the Board. Each endowed school should have a board of governors, including members representing the local authority, and while the management of the school should be entrusted to the governors by the scheme, it should nevertheless be the duty of the latter to present to the former a yearly budget. Any pooling and re-distribution of endowments might be so limited as to preserve the benefits of each foundation to the area of the local authority in which it exists. This would largely limit the vehement opposition usually raised to any proposal to translate an endowment to a populous centre from a village where it is wasted, at the same time fulfilling in a reasonable manner the intention of the pious founder to provide for the native inhabitants of the place he endowed. For the smaller endowments (by far the greater number of those existing) this plan implies the extension of that municipalisation of endowments for which a precedent was set at Derby last year. With reference to the larger endowments, a word of caution is not out of place.

The leading public schools of England are among our most important national assets. Dating, as some of them do, from six, seven, or even eight centuries back, they have the advantage of unrivalled traditions, of inestimable value in influencing their character and tone. It would be a disastrous policy to destroy these for the comparatively trivial pecuniary gain to be achieved; but the question of reforming their constitution raises important questions of principle, which cannot be more than hinted at in this article. It appears to the writer that some mild infusion of democratic influence might be of mutual advantage to the schools and the neighbouring communities. There appears to be justice behind the claim for admission of fit boys from every social rank, and although such admission would only be of real benefit to the exceptional boy of poor parentage, the principle is not to be lightly disregarded. By sacrificing their "splendid isolation" and becoming associated with the national system of education, the great schools would be more truly doing their duty to the country, and the benefits reaped from their association with schools of all grades would not all be on the side of the humbler institutions. For these and other reasons one may hope that the Government will proceed with part ii. of the Education Bill (1906), which was dropped last year, a reprint of which those interested may find in "The Schoolmaster's Year-book for 1907" (Sonnenschein). Briefly, it conferred upon the Board enlarged powers to make new schemes and to amend old ones, with considerable simplification of procedure. Universities and their colleges were excluded from the operation of the Bill, and the segregation of the great schools of the 1868 Act was to be continued by their reservation from the more sweeping clauses; indeed, Eton and Winchester would only be affected so far as their governing bodies consented. Safeguards relating to the religious character of certain foundations were introduced, although Clause 16 states, and very rightly, that "in making a scheme regard shall be had primarily to the educational advantages to be derived from the scheme." May we not hope that the matter will be discussed and legislated upon in this spirit?

G. F. Daniell.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The next combined examination for sixty-six entrance scholarships and various exhibitions at Pembroke, Gonville and Caius, King's, Jesus, Christ's, St. John's, and Emmanuel Colleges will be held on Tuesday, December 3, and following days. Mathematics, classics, and natural sciences will be the subjects of examination at all the above-mentioned colleges. A candidate for a scholarship or exhibition at any of the seven colleges must not be more than nineteen years of age on October 1, 1907. Forms of application must be sent in on or before Tuesday, November 26.

Mr. A. H. Lees, of King's College, has been appointed to the studentship in medical entomology for the period of one year. The studentship was recently established on the basis of a grant from the "Tropical Diseases Research Fund," administered by the Colonial Office. Mr. Lees will pursue research under the direction of the Quick professor of biology.

Of the four fellowships awarded last week at Trinity College, two were for classics; one of the remaining two was awarded to Mr. A. S. Eddington, senior wrangler in 1904, and first class, first division, part ii. of the mathematical tripos, 1905; and the other to Mr. V. H. Mottram, first class, part i. of the natural sciences tripos, 1903, and first class (physiology) in the same tripos, part ii., 1905.

Mr. A. Wood, who took his degree in chemistry and physics in 1904 as an advanced student, has been elected to a fellowship at Emmanuel College.

Mr. A. Berry, of King's College, has been appointed chairman of examiners for the mathematical tripos, part i. (old regulations), 1908.

At a Congregation to be held to-day, the honorary degree of Doctor of Science will be conferred on Prof. Emil Fischer, of Berlin.

Liverpool.—Prof. J. Reynolds Green, F.R.S., lately professor of botany to the Pharmaceutical Society of Great Britain, has been elected to the Hartley lectureship in plant physiology, recently instituted in the botanical department through the generosity of Mr. W. P. Hartley, of Aintree.

Dr. J. H. Grindley has been appointed principal of the Government School of Engineering at Ghizeh, Cairo. The school is under the Egyptian Ministry of Education for the training of engineers for the various departments of the Egyptian public works.

Mr. W. MacGregor Wallace has been elected lecturer on applied mechanics in place of Dr. Grindley (resigned).

Manchester.—The honorary degree of Ph.D. has been conferred upon Prof. Ernest Rutherford by the University of Giessen.

The following appointments have been made:—Dr. C. H. Weizmann, lecturer in chemistry; Mr. J. N. Pring, demonstrator in electrochemistry; Mr. F. H. Gravely, assistant lecturer and demonstrator in zoology. Mr. Frank Howson has resigned the position of demonstrator in physiology on his appointment to a similar post at the Armstrong College.

Dr. R. S. Hutton, on leaving Manchester, is resigning his position as lecturer in electrochemistry and assistant director of the physical laboratories, but has been appointed a special lecturer in electrochemistry.

The Herter lectures before the medical department of the Johns Hopkins University are to be given this session by Prof. E. A. Schäfer, F.R.S., professor of physiology in the University of Edinburgh, at the end of April, 1908.

We have received the current issue of the year-book of the Michigan College of Mines. It covers 136 pages, and contains full details of the courses arranged for the session 1907–8. The courses are admirably planned, and the situation of the college in the copper- and iron-ore district of Michigan, where its students live in a mining atmosphere, has brought to the institution a large measure of success.

Under the will of the late Dr. Nathaniel Rogers, the Senate of the University of London offers a prize of 100*l.*, open for competition to all members of the medical profession in the United Kingdom, for the best essay or dissertation setting forth the results of original investigations made by the candidate on any medical pathological subject during the preceding two years. Candidates will be permitted to present papers published during the preceding year as the dissertation. The essay or dissertation, by preference typewritten or printed, must be sent in not later than May 1, 1908, addressed to the clerk of committees at the University.

The prospectus for the session 1907–8 of the Belfast Municipal Technical Institute should prove of real assistance to intending students seeking guidance in planning their courses of work. It is quite clear from the volume, which runs to nearly 250 pages, that the chief object of the institute is to provide instruction in the principles of those arts and sciences which bear directly or indirectly upon the trades and industries of Belfast, and to show by experiment how these principles may be applied to secure industrial advancement. The classes are designed to assist persons engaged during the day in handicrafts or business, and desire to supplement the knowledge gained in the workshop or warehouse. The time-table of classes is published as a separate pamphlet, and with it a sensible letter of advice to students from the principal of the institute, Mr. Fras. C. Forth, indicating several directions in which students can assist the staff to secure success in the work of the various departments. Arrangements have been made for full courses of study in the various branches of science, art, technology, and commercial subjects.

Among the advanced lectures on scientific subjects announced in connection with the University of London to be held during the present session may be mentioned a course of eight lectures, by Mr. A. D. Hall, on the function of the mineral constituents of the soil in the nutrition of plants, to be given at the Chelsea Physic Garden on dates to be announced later. Mr. J. B. Leathes commenced a course of eight lectures on October 15 at the University physiological laboratory on problems in animal metabolism. At the same place four lectures on the construction of diets in health will be commenced by Dr. E. I. Spriggs on November 8. Three lectures on the principles of classification will be given at University College by Mr. G. A. Boulenger, F.R.S., beginning on October 28, and three lectures by Mr. J. T. Cunningham on sexual dimorphism, beginning on November 18. The University reader in meteorology will deliver at the University a course of twelve lectures on meteorological organisation and methods of dealing with meteorological observation, commencing on October 21.

The *Electrician* for October 11 contains an interesting description of the electrotechnic institute of the Technical University in Karlsruhe (Baden), by Mr. Stanley P. Smith. The writer describes the general lay-out and equipment of the institute buildings, which were specially designed for the various branches of engineering carried on within them, but the description mainly deals with the electrotechnic institute itself. The cost and equipment of this building was between 2700*l.* and 2800*l.*, and from the plans and description given there is no doubt that it is very perfectly arranged and fitted up. The general idea of the curriculum followed is also given, and it will be of interest to both engineers and others to note that the course at Karlsruhe includes political economy and labour problems. There is also a greater tendency in Germany for the various branches of engineering to be treated by professors who are also engaged in practical work. On another point the institution at Karlsruhe differs from the colleges in this country, namely, the students themselves. There appear to be no student organisations, and the sociability so characteristic of an English college is almost entirely wanting.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 27.—"The Annealing of Copper, with Special Reference to Dilatation." By Prof. T. **Turner** and D. M. **Levy**. Communicated by Prof. J. H. Poynting, F.R.S.

The authors have employed a special form of extensometer, in conjunction with a Le Chatelier pyrometer, in order to trace the changes in the length of metallic rods during the process of annealing, and have thus obtained continuous curves connecting dilatation and temperature. The rods, which were $\frac{1}{4}$-inch in square section and 35 inches long, were uniformly and regularly heated in a gas-fired furnace. The chief feature of the apparatus was the use of water-cooled copper tubes for connecting the rod with the extensometer, a plug of non-conducting material being used to prevent any cooling of the end of the rod by the water. By this method the whole of the rod was in the furnace and uniformly heated, while the rest of the system was maintained at a constant temperature. The water-cooled tube attached to one end of the rod was firmly clamped, the other being free to move. On to this tube was screwed a brightly polished brass disc, against which pressed a finely rounded projection attached to the short arm of a bell-crank lever, which, traversing a scale, indicated the expansion of the rod.

The scale was divided into millimetres, each millimetre representing 1/1200-inch expansion, corresponding to a magnification of 48 : 1. The suitability and delicacy of the apparatus were ascertained by testing bars of wrought iron and steel; from the former a regular line was obtained, while the latter gave a curve showing a marked change of volume at the critical point (about 690° C.), thus agreeing with Le Chatelier's results obtained by an entirely different method. Hard-drawn copper bars gave a perfectly regular line, similar to that obtained with wrought iron; annealed copper also gave a straight line. Experiments on rods of brass of different composition, on gun-metal, and on phosphor bronze gave similar results.

It thus appears that the change from the hard, elastic condition of worked copper and copper alloys to that of extremely soft metal is not accompanied by any alteration in length. On the other hand, it is known that allotropic changes in an element, such as occur in pure iron at about 880°, or such chemical constitutional changes as occur in iron-carbon alloys at critical temperatures, are accompanied by marked alterations in volume, and the authors therefore conclude that the changes brought about by mechanical work, or by annealing of worked metals, produce only internal re-arrangement of the metallic molecules, but are of a different order from the chemical and physical changes, such as are correctly regarded as allotropic.

"Experiments on a New Kathode Dark Space in Helium and Hydrogen." By F. W. **Aston**. Communicated by Prof. J. H. Poynting, F.R.S.

This paper is a description of a new dark space, close up to the kathode and inside the Crookes dark space, discovered by the author while investigating the length of the latter phenomenon in helium, and later found to be exhibited in a less marked degree in hydrogen. The length of the new dark space, which under measurable conditions varies from 0·2 mm. to 1·0 mm., is almost unaffected by the pressure of the gas, but varies roughly with the inverse square root of the current density.

Careful observations show that *the fall of potential across the new dark space is constant* for the same gas under all observed conditions, and is in helium 30 volts, in hydrogen 15 volts. The phenomenon may be accounted for by the supposition that the energy required to ionise a molecule of helium is a definite quantity, and that an electron liberated from the surface of the kathode virtually at rest must fall freely through a definite potential in order to acquire that energy, so that the new dark space may be regarded as *the distance through which the electrons fall in order to attain sufficient energy to ionise the gas by collision with its molecules.*

The intense blackness of the new dark space in pure helium bears out this theory, by which also the following effect was predicted:—Since the behaviour of electrons liberated from molecules of the gas by collisions should be the same as that of those derived from the kathode, if the ionisation just beyond a potential distance from the kathode of 30 volts is sufficiently concentrated there will be a further maximum of ionisation—and therefore of light—just beyond a potential distance of 60 volts, another beyond 90 volts, and so on, each getting less definite than the previous one, so that the light in the Crookes dark space should be striated in appearance. By suitable adjustment of conditions, several successive striations can be seen and photographed in helium. Combining the potential differences obtained from the length of the new dark space with the accepted values of e and m for the electron, the following values of the energy required to ionise and the velocity of the ionising electron are obtained:—

Hydrogen ...	$1·7 \times 10^{-11}$ ergs	$2·25 \times 10^{8}$ cm. per sec.
Helium	$3·4 \times 10^{-11}$,,	$3·2 \times 10^{8}$,,

Not the slightest indication of the phenomenon has yet been observed in any other gas.

Received July 5.—"The Dispersion of Double Refraction in Relation to Crystal Structure." By Dr. T. H. **Havelock**. Communicated by Prof. J. Larmor, Sec.R.S.

In this paper the object is to consider to what extent it is possible to regard double refraction, whether produced artificially or occurring in natural crystals, as due simply to an æolotropic distribution of similar particles. The ordinary theory of double refraction amounts to considering the medium as a collection of crystal molecules in cubical order, all the varieties of dispersion being postulated of the single particle; and similarly in artificial double refraction, the æolotropy is assumed to originate wholly in the individual molecule, and to be effected through the quasi-elastic force under which the polarisation electrons are supposed to vibrate. On the other hand, a theory which confines the effect to a re-arrangement of the molecules in space will express the result by a modification of the effective electric force operative at each particle. From this point of view the author develops a theory of the optical properties of a homogeneous assemblage of isotropic particles. If the medium behaves like a uniaxal crystal, it is found that the double refraction, equal to the difference between the two principal indices, is proportional to $(n_0^2-1)^2/n_0$, where n_0 is a mean value measuring the refractive index of a medium composed of the same particles in the same density, but arranged in simple cubical order.

This gives a law of dispersion of the double refraction, provided the dispersion of the mean index n_0 is known. The formula is applied first to the double refraction produced artificially in simple isotropic media. Experimental data are available for the dispersion of the double refraction produced in carbon disulphide by an electric field, and these results are found to agree well with the formula given above.

In the case of natural crystals, where the effect is larger, the theory indicates that the quantity

$$(n_1^2-1)^{-1}-(n_2^2-1)^{-1}$$

should be independent of the wave-length, n_1 and n_2 being the ordinary and extraordinary indices of the crystal. This relation is found to hold very well for quartz over a wide range, and gives in this case the equation

$$n_2^2-n_1^2=0·01441(n_1^2-1)(n_2^2-1).$$

It follows, further, that the double refraction decreases in absolute value with the mean index n_0, that is, it decreases in general with increasing wave-length. This is the rule of dispersion in most actual crystals, but there are various exceptional cases of anomalous dispersion, and to cover these a modified theory of uniaxal crystals is given in the following terms. The molecules (or crystal units) of the medium are not necessarily to be supposed ellipsoidal in shape, but are optically æolotropic, so that the subsidiary equations connecting the polarisation of a particle with the effective electric force are æolotropic, with an axis of symmetry; the particles are supposed to be arranged in a homogeneous assemblage, such that the effective cavity may be taken as a spheroid of small ellipticity with its axis of symmetry coincident in direction with that of the crystal unit. Hence an explanation is given of the anomalous dispersion of the double refraction in regions free from absorption, that is, when a medium composed of the same crystal units arranged in regular cubical order would give regular dispersion. The theory is considered finally in its general application to dispersion in biaxal crystals.

The author has attempted to connect the varieties of dispersion of double refraction with the structure of the crystal under the following assumptions. The crystal unit contains vibrating electrons, so that their combined effect is expressed by three principal equations connecting the polarisation of the unit with the effective electric field; if, then, these units are arranged in regular cubical order, we have a medium with principal refractive indices along three fixed directions in space, and in this case it is assumed that there is regular decrease of the double refraction with increasing wave-length in regions away from absorption bands; but considering in general any other homogeneous assemblage, the effect is expressed by a change in the effective electric field acting on the crystal unit; this effect is estimated by supposing, as a sufficient approximation, that the effective cavity is slightly ellipsoidal instead of being spherical. Thus differences of packing of the crystal molecules are represented optically by variations in the ratios of the axes of the effective cavity and in their directions in space compared with the polarisation axes of the individual unit. Combining these assumptions, it is shown that they are sufficient for a descriptive theory covering the varieties of dispersion of double refraction found in natural crystals.

PARIS.

Academy of Sciences, October 7.—M. Henri Becquerel in the chair.—The spectrum of the Daniel comet, 1907*d*: Jean **Bosler**. The spectrum of the nucleus of the comet was photographed on the nights of August 8 to 9, 18 to 19, and 19 to 20, with exposures of forty minutes, one hour, and one hour and ten minutes. Details are given of the lines observed, which appear to indicate the presence of hydrocarbons and cyanogen. There are also some lines of which the origin is uncertain.—Trigonometric series: Marcel **Riesz**.—The execution of a geodesic chain of precision in the Savoy Alps: Paul **Helbronner**. Particulars are given of the immediate objects of the survey, together with a list of the thirty-three stations, mostly mountain peaks, proposed to be included in the survey. Of these, twenty-six were completed between June 12 and September 28.—Spectroscopes with mirrors: Maurice **Hamy**. The substitution of mirrors for objectives is often used in spectroscopes. The present note gives a study of the theory of the best position to give the face of the last prism or grating to obtain a field of images as flat and as extended as possible.—The thermoelectricity of nickel; the influence of foreign metals: H. **Pécheux**. Three specimens of nickel were studied, the chemical analysis of each being determined. Couples were formed of each of these with pure copper, and the thermoelectromotive forces studied for a temperature range of 640° C. The curves of electromotive force of the three couples were not parallel, but the results are comparable, differing only by about 0·25 per cent. on the average. The simultaneous existence of copper and cobalt in a specimen of nickel produces the most marked deviations of E.M.F.—Phenyl migrations in the aromatic iodohydrins by the elimination of HI from the same atom of carbon: M. **Tiffeneau**. The theory developed in previous papers regarding the migration of the phenyl group in compounds of the type

(Ar)R—C(OH)—CHI—R′

has been extended and confirmed by a study of the corresponding ether oxides.—The phases of development of the Epicaridæ; experimental verification of the nature of the Microniscidæ: Maurice **Caullery**.—The presence of Tyroglyphinæ in the long bones of the wings of birds: E. L. **Trouessart**.—The existence of statoblasts in the scyphistome: Edgard **Hérouard**.—The necessity of cultures in the study of the gonococcus: A. **Guépin**. The absence of the gonococcus, and of any other pathogenic microbe, can only be admitted as proved after negative results have been obtained from systematic cultures.—Some new fossil plants from the travertine of Sézanne: René **Viguier**.

DIARY OF SOCIETIES.

FRIDAY, OCTOBER 18.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—The Indicated Power and Mechanical Efficiency of the Gas Engine: Prof. B. Hopkinson.

THURSDAY, OCTOBER 24.

WAY-SIDE FRUITS.

Wild Fruits of the Country-side. By F. Edward Hulme. Pp. x+221; illustrated. (London: Hutchinson and Co., 1907.) Price 5s. net.

THE subject of this book is one that may be most conveniently studied in the autumn season, when so many trees are in a fruiting condition. Mr. Hulme has written 212 pages, which are illustrated with thirty-six full-page coloured drawings, prepared by the author, and twenty-five half-tone pictures, which are reproductions from photographs. There are three chapters, and the species of plants are grouped into these chapters as follows:—Chapter i., plants of the hedgerows; chapter ii., trees of the forest; and chapter iii., plants of the moorland, the meadow and the stream.

The notes vary in length according to the estimated importance and interest of the species, and the text is largely composed of quotations from the old writers on the folk-lore of the species, and medicinal uses to which parts of the plants have been applied. The author attempts to trace in most cases the derivation of the names, and, in addition, supplies brief descriptions of the structure of the flowers and fruits. We have nothing but praise for the coloured plates, which in all instances appear sufficiently faithful to nature to enable the novice to identify the fruits, notwithstanding the drawings lack such botanical details as can only be shown after dissection of the fruits, and illustration of the sections. Those representing the common spindle tree (*Euonymus europaeus*), hawthorn (*Crataegus oxyacantha*), sweet briar (*Rosa rubiginosa*), and oak (*Quercus Robur*) are especially commendable.

Having said so much as to the merits of the book, we cannot be silent in respect to its defects. The text has evidently been written hurriedly, and the composition needed more careful revision than has been exercised. The following sentence, for instance, is not more ambiguous than many others that might be selected from each chapter. On p. 13, in respect to the privet (*Ligustrum vulgare*) the author writes:—

"After these somewhat offensive or altogether delightful flowers succeed the berries, and these, if unmolested by the blackbirds, thrushes, bullfinches, and other birds to whom they are acceptable, remain on the plant throughout the winter."

The punctuation is reproduced faithfully. Or, as on p. 203:—

"Large tracts have, however, of late years been ploughed up, a proceeding little to the benefit of anyone, and, so far as it goes, destructive of a wild beauty that might well have been suffered to remain, and which we, Staffordshire-born, can only regret the loss"!

On p. 14, in a sentence which refers to the privet, the word *generic* has been made to read *genuine*. On p. 52 the yew (*Taxus baccata*) is referred to as "a genuine ancient Briton," but on p. 57 it is also described as "a welcome and sturdy guest," which is surely suggestive of an exotic species rather than "an ancient Briton."

The use that is made of capital letters is altogether inconsistent. In the headings all the specific names commence with capitals, a practice which is indefensible when applied to botanical nomenclature, yet on p. 181 *Viscum cruciatum*, when printed in the text, has no capitals, not even one for the generic name.

We can see no reason for the author adopting the out-of-date name *Sarothamnus* for the common broom, the correct name for which is Cytisus. The plant should be invariably described as *Cytisus scoparius*. The list of illustrations at the commencement of the book has probably escaped the author's revision after the type was set. This would explain the generic word Rubus being misspelt Robus in three instances, and scoparius misspelt scaparius.

The subject of this work is an extremely interesting one, and notwithstanding the imperfections we have mentioned, the book may be recommended to those who are about to spend a holiday in a country district, or to students in schools, but especially to those who desire to acquire some knowledge of the folk-lore connected with some of the commonest fruiting plants in our native flora.

COSMOLOGICAL SPECULATION.

Two New Worlds. (1) The Infra-World; (2) The Supra-World. By E. E. Fournier d'Albe. Pp. ix+157. (London: Longmans and Co., 1907.) Price 3s. 6d. net.

THE first part of this book is an elaboration of an analogy already familiar to the scientific public. The Infra-world is a universe in which an earthly atom is a solar system: the positive atom is its sun, the electrons are its planets. The author points out that the scale of distances in our own and the infra-world is approximately in the ratio $10^{22}:1$, this being the ratio of the average diameters of our solar system and an atom. Further, the infra-year, measured by the period of revolution of an electron about its positive atom, is, for a particular case, reduced by the same factor. In this coincidence Mr. Fournier finds justification for regarding the world of atoms as a veritable universe on a smaller scale.

The detailed account of the Infra-world which is presented in the first six chapters, though interesting in itself, is perhaps to be regarded mainly as preparing the way for the conception of a Supra-world, in which our solar system functions as an atom. It is not possible here to discuss the reasoning by which the author seeks to establish the existence of ultra-galactic universes; the arguments he employs are simple and reasonable, and will appeal strongly to the reader who is willing to be guided by probability in a region where logical certainty is at present unattainable. It is sufficient here to remark that the author's presentation of the Supra-world is based on the assumptions:—

"(1) That the material universe is infinite in three-dimensional space, and eternal both in the past and the future.

"(2) That the law of gravitation holds good throughout infinite space and time.

"(3) That the luminiferous ether has the same properties throughout space."

The Infra-world, our own universe, and the Supra-world are represented as three links in a chain of indefinite extent.

We learn from the preface that this book contains "an attempt to penetrate the mystery of space and time with the help of the most modern resources of scientific research." Mr. Fournier's success in achieving this object must depend upon what is required of one who penetrates a mystery. Certainly, the relativity of space and time could scarcely be more clearly and forcibly brought home than is done in these pages.

The limits of this notice do not permit a discussion of the author's speculations regarding the interrelation of "personality" in universes of different orders. The chief value of this work undoubtedly consists in the point of view which is here presented—a point of view which is valid for anyone who accepts the author's proof of the existence of universes of the next lower and higher orders to our own, whether he prefer to interpret conscious or subconscious activity in terms of motion, or matter in terms of consciousness.

Though necessarily incapable of verification, these speculations, which are well and clearly expressed, will hardly fail to evoke something more than a passing interest.

F. L. USHER.

CHEMICAL METHODS IN MEDICINE.

The Chemical Investigation of Gastric and Intestinal Diseases by the Aid of Test Meals. By Dr. Vaughan Harley and Dr. Francis W. Goodbody. Pp. viii+261. (London: Edward Arnold, 1906.) Price 8*s.* 6*d.* net.

THE continual increase in our knowledge of the physical mechanisms of the body necessitates a corresponding increase in the complexity of the methods which the physician has to employ in his endeavour to locate the seat of disease and to determine its character. Every year the medical man has therefore to start his career with expert knowledge of instruments and methods that were not dreamed of by his predecessors, and every year the extent of his armamentarium is added to by the growth of our knowledge of diseases. Many of these methods which the present-day practitioner has to acquire are physical, such as the use of the thermometer, of the stethoscope, the ophthalmoscope, and the various other instruments which have been devised for throwing light into the cavities of the body.

Until recently his chemical methods were practically limited to the testing of the urine for sugar and for coagulable protein. Disorders of digestion were, and in many cases still are, treated purely empirically. Yet it cannot be a matter of indifference whether any given derangement of digestion has its primary seat in the stomach, the bowel, or the nervous system, whether it is accompanied with increase or diminution of the acid secretion of the stomach, or whether it is attended by an absolute failure on the part of the alimentary canal to assimilate in proper proportion to the food which is presented to it. It is of no use to label a series of drugs as good for indigestion, to administer them one after another, in default of knowledge on such important points as these. It is to aid the practitioner in his investigation of gastric and intestinal diseases by the latest methods that this book has been written.

Prof. Harley and Dr. Goodbody confine themselves entirely to the chemical methods, and even here are eclectic in treatment, mentioning only the methods which they have found during twelve years' trial of practical value.

It is to be hoped that the publication of this book may help to render more general the application of science to practice in the treatment of this important class of disease, since the book contains records of a number of analyses made by the authors on different patients, which furnish a useful guide to the results which may be expected in practice.

It is impossible to avoid the impression that the increased technical knowledge required for the diagnosis and treatment of disease must tend more and more to specialism along certain lines, and must handicap the private patient as compared with his poorer brother who is treated in a hospital. Without the resources of skilled assistance and a well-equipped laboratory, it is impossible for a busy practitioner to make all the investigations which are necessary to determine the diagnosis and to control the treatment of a number of cases of diseases. It is possible that in future years every consulting physician will regard a hospital for observation, and a private laboratory with skilled assistants, as necessary adjuncts to his consulting-room. At the present time, if the disease be one of doubt or difficulty, the pauper in the hospital has a better chance of enjoying the benefit of the latest discoveries than has the private patient.

We have no doubt that practitioners, whose time is not already entirely absorbed by the round of visits, will find this book of considerable value. It will not have failed of its object if it teaches such men to carry out a proper investigation of the gastric contents in cases of disordered digestion instead of simply guessing at the causation of the disorder. In one or two places the authors are hardly explicit enough for the purposes of those men who are working out the methods by themselves. Thus, on p. 31, no idea is given of what the colour-changes on titration of the gastric juice consist when dimethyl-amido-azo-benzol is used as an indicator, nor is the rationale of Töpfer's method for determining the acidity of gastric juice made sufficiently clear. These and a few other slight drawbacks can easily be amended in a subsequent edition.

WILD LIFE AND ADVENTURE.

Wild Life in Australia. By W. H. D. le Souëf. Pp. xv+439; illustrated. (Christchurch: Whitcombe and Tombs, Ltd.) Price 7*s*. 6*d*. net.

The Life-Story of a Squirrel. By T. C. Bridges. Pp. vii+230; illustrated. (London: A. and C. Black, 1907.) Price 6*s*.

Adventures in the Great Forests. By H. W. G. Hyrst. Pp. 330; illustrated. (London: Seeley and Co., Ltd., 1908.) Price 5*s*.

Heroes of Pioneering. By E. Sanderson. Pp. 352; illustrated. (London: Seeley and Co., Ltd., 1908.) Price 5*s*.

IN re-publishing, with considerable additions, the series of natural history articles which originally appeared in the *Victorian Naturalist* and the *Emu*, the author of "Wild Life in Australia" has assuredly been well advised; for within this unassuming little volume is to be found a valuable store of information concerning the animals and plants of various districts in Australia. The province of Victoria, the Riverina district of New South Wales, the islands of Bass Strait, Queensland, and Western Australia are in turn discussed; and in each case the treatment of the subject is full of interest, although the amount of space devoted to each district is by no means large. The most important observations in the book are those relating to the life-history of the duckbill or platypus. Many of our readers will recall that in 1901 Mr. G. Metcalfe, at a meeting of the Zoological Society, denied that the platypus lays eggs. Mr. le Souëf, on the other hand, definitely states that at the end of October the creature lays one or two eggs, which are of elongated form and furnished with a leathery shell. The egg is believed to be soon hatched, and the newly-hatched young is naked, and about one inch in length. A nest and broken eggshell were, according to the author, forwarded to Dr. P. L. Sclater. The point in dispute may now be regarded as settled. Mr. le Souëf adds that the platypus is a good climber, and that when on land it folds inwards the portion of the web projecting beyond the toes, so that the latter may be enabled to obtain a grip of the surface.

So far as the naturalist is concerned, "The Life-Story of a Squirrel" is effectually condemned by the illustrations, which (although of passable excellence from the conventional standard) represent the squirrel as being wholly red above, with long ear-tufts, at all seasons. In the winter scene facing p. 142 the characteristic grey flanks are not shown; while in the plate facing p. 32, which is stated in the text to represent a larch, and must therefore, as the tree is in leaf, indicate summer, the squirrel is likewise shown with ear-tufts and the chestnut tail of winter. The text is not of a nature that commends itself to our taste, or, it may be added, to that of certain young people to whom we have shown the volume. For our own part, we like either a sound book on natural history or a good novel; the attempt to combine the two does not appeal to us.

Of the two remaining volumes mentioned above, a brief notice must suffice, seeing that both are based on more or less well-known stories of travel and adventure or on striking historical events, and appear to be mainly intended for boys. In both instances the authors are to be congratulated on their selections and on the interesting style in which these are placed before the public. In his preface Mr. Hyrst records a protest against the destruction of forests which is proceeding only too rapidly in many parts of the world, quoting a statement to the effect that seven acres of primeval forest are felled to meet the requirements of the paper-maker for a single day's issue of a New York journal. Adventures in the great forests of the world, ranging from Major Stedman's expedition in Surinam in 1772 to the journeys of Speke and Grant, Winwood Reade, and other comparatively modern African explorers, are recorded in a style which should attract all juvenile readers. Mr. Sanderson carries his readers further backwards in time, commencing with Sir Walter Raleigh in Virginia, and continuing his narrative down to the establishment of British supremacy in Rhodesia and Nigeria.

OUR BOOK SHELF.

The Collected Mathematical Works of George William Hill. Vol. iv. Pp. vi+460. (Washington: The Carnegie Institution, 1907.)

THE fourth volume of Hill's mathematical works brings the re-publication of these papers up to date, and a little beyond it; for it includes four memoirs that have not appeared elsewhere, and are of very considerable interest. It is, indeed, difficult to overstate the interest of the whole volume—at least, to those occupied in the subjects treated of. Newcomb, in his "Reminiscences," permitted himself a good-natured grumble at Hill's "lack of the teaching faculty." It seems to us that for true instruction as to what the problems of celestial dynamics actually require, and what are the most hopeful ways of approaching them, nothing has appeared since Laplace's "Mécanique Celeste" that so well deserved study as these four volumes. One cannot do them justice in a brief notice. Generally we should say their unique force is a force of character, a serious purpose to adhere only to real problems, to which great analytical facility, with clearness and fastidious elegance, and immeasurable patience are subservient.

Passing over the minor papers, and one of much interest not hitherto published—No. 84, "On Dynamic Geodesy"—the chief part of the volume is engaged in the attempt to find integrals of the planetary equations of motion which shall be valid for an indefinite lapse of time, and so supply some conclusive information as to the permanent future stability, and equally as to the past history of our system. This may be said to be the problem of vital interest at the present time in this branch of astronomy. Construction of tables of the actual motions of the planets is so far perfected that their remaining interest is almost wholly technical. On the other side, if we may take the opinions expressed by Hill in No. 60, "Remarks on the Progress of Celestial Mechanics since the Middle of the Century," the efforts of even very brilliant analysts have not succeeded in throwing much light upon the problem of representing the motions by more general integrals.

Without claiming too much for what Hill himself here contributes, his memoirs are instructive as giving almost a history of the efforts, extending over many years, of his patient and trenchant mind to effect some real advance. The ideas to which he most recurs are those of Delaunay and Gyldén, to both of which it is evident that he attaches high value.

The paper No. 79, "Integrals of Planetary Motion Suitable for an Indefinite Length of Time," supplies a solution of the problem in outline, but in complete and not in unfinished outline, so far as it is illustrated by the system of Jupiter and Saturn.

The volumes are published by the Carnegie Institution of Washington. Vol. iv. contains an index, but it is of the perfunctory character that makes it little more than a list of names; Delaunay's name is followed by a list of no fewer than eighty-three reference numbers, without other clue; it would be shorter and equally useful to write DELAUNAY—*passim*.

R. A. S.

Stray Leaves and Some Fruit on Cancer, based upon Physiologic Chemical Principles. By Henry D. McCulloch. Pp. 49+3. (London: John Bale, Sons and Danielsson, Ltd., 1907.)

THE title of Dr. McCulloch's book is original, and there is no doubt as to the "stray leaves," but in our opinion there is very little "fruit," and we find very little of either "physiologic" or "chemical" principles in the foundation of the heterogeneous collection of quotations which form the bulk of the book—if, indeed, it can be said to have any foundation whatever.

In the present state of the cancer question, such undigested material can only be another obstacle to the real study of this most difficult of problems. A particular form of protozoal infection is assumed without any proof, or mention of work on this theory, as the cause of cancer; and the author thinks that "by proper culture, and introduction to the leucocyte, a vaccine or perfect remedial agent, vicariously prepared in a living animal, will be possible."

Dr. McCulloch makes an attempt to explain the *rôle* of the leucocyte in the natural production of specific vaccines in cancer. Certain leucocytes being phagocytes eat up the opsonised microorganisms under certain conditions, and return to the lymphatic glands and there degenerate; their remains are propelled to the "gland reservoir," where a chemical dissociation and rearrangement of their constituents is brought about, and are finally converted into the immunising agent. This occurs in the early stages of cancer, which are not recognisable. When these conditions fail, the leucocytes perform segregation, and hence the metastasis in the cancer growth.

The dissociation and rearrangement which occur, according to the author, are said to be brought about by enzymes. No doubt these play a part in the process, and it might have been thought that the author would have made an attempt to try to isolate them, or, at any rate, determine what enzymes were present. The assumption of an enzyme is not sufficient proof for its presence, since enzymes are specific in their actions, by which means they are identified. A "nascent enzyme" has not yet been described. The author has also introduced "hormone" in the hope that the word may help to explain the unknown.

The presence of so many quotations might have included the following, by a distinguished physiological chemist:—"The less a physiologist knows about chemistry, the greater is his inclination to work at the most difficult chemical subjects—the proteins and ferments. If even this subject be not sufficiently obscure to him, he can study the phenomena of coagulation. He feels most at home in the still more obscure subject of the pathology of coagulation and of the ferments; it is good to fish in the dark! *These authors have built up a literature which no one can become master of, and which is only a drag and a brake to science.*"

In this book of quotations, Dr. McCulloch finishes up with one in Sanskrit, of which he gives a voluminous interpretation, which appears to have even less to do with cancer than many of the many others of which the book is made up.

R. H. A. P.

Helianthemum Canum (L) Baumg. und seine nächsten Verwandten. By Dr. E. Janchen. Pp. 68. (Jena: Gustav Fischer, 1907.) Price 2.50 marks.

Helianthemum canum is a highly variable species, and therefore one for which it is difficult to define the limits. In the volume of Engler's "Pflanzenreich," dealing with the Cistaceæ, Dr. W. Grosser differentiates two varieties that are each again subdivided into several forms. The herbarium worker may follow such a splitting of interrelated forms, but it is extremely unlikely that he could separate them in the field where intermediate forms would probably be found. Dr. Janchen puts forward an alternative limitation of *Helianthemum canum*, and one or two nearly related species. Broadly, he merges in *canum* part of the species recognised by Grosser as *marifolium*, and maintains *italicum* and *rupifragum* as independent species. There appears to be considerable support for Janchen's arrangement, and the adoption by Grosser of two varieties under different species as *H. canum v. marifolium* and *H. marifolium v. canum* is decidedly confusing, but the determinations of Dr. Janchen are also based solely on herbarium material, although a crucial test could be obtained either by a study of the plants as they grow or by cultivating them from seed. Undoubtedly, such methods are arduous but not impossible, as all the plants under discussion are European. It is only right to add that Dr. Janchen himself recognises the necessity for determining the systematic limits in such variable species by the methods indicated.

Limnologia: Studio Scientifico dei Laghi. By Dr. G. P. Magrini. Pp. xv+242; illustrated. (Milan: U. Hoepli, 1907.) Price 3 lire.

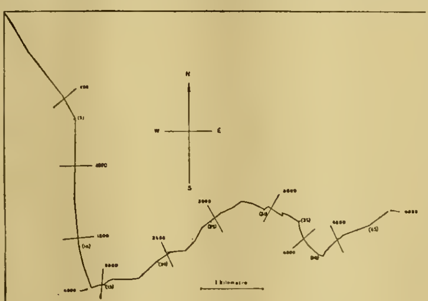
THIS valuable little work forms Nos. 372–373 of Hoepli's well-known scientific series of manuals. As the title implies, it deals entirely with the phenomena of lakes, and is intended to be preliminary to a somewhat similar work on the much larger subject of oceanography. Limnology owes its name to Prof. F. A. Forel, whose standard monograph on the Lake of Geneva is recognised as a model in this branch of inquiry. The present volume deals more particularly with the geographical and physical sides of the question, touching but very lightly on the more difficult subject of biology; it summarises the methods of observation which experience has shown to be the best, including descriptions of the instruments used, the improvements recently introduced in them, and the principal results hitherto obtained. The occurrences of *seiches* are attributed partly to the sudden cessation of wind which had been previously blowing over the lake, and partly to small differences of pressure at various points of the lake (acting on the water as on the mercury of a barometer); it is, however, pointed out that although it may be possible to indicate some of the causes that produce *seiches*, it is very rare that the particular cause of any individual *seiche* can be precisely determined. An appendix contains a list of the positions and areas of the principal Italian lakes. The author admits his especial indebtedness to Profs. Forel and Delebecque, to whose works, and to those of Prof. Chrystal and others, frequent references are made in the compilation of this useful manual.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

Upper Air Research in Egypt.

The Helwan Observatory (under the Survey Department of Egypt) has recently acquired apparatus to enable it to join in the study of the upper regions of the atmosphere. As a commencement, some fifteen ascents of small "pilot" balloons were made during the month of August. On three occasions the balloons were watched to a height of 5000 metres, but rather a large percentage of the balloons used burst at much lower altitudes. A better type of balloon has been ordered, and it is hoped that observations may be regularly made with them up to 5000 metres or 6000 metres. The balloons are of 2 feet nominal diameter, and are filled with dry hydrogen made from zinc and sulphuric acid. They are observed as they ascend by two observers at the ends of a base line 1 kilometre in length. The theodolites are of the very convenient type made by S. and A. Bosch, of Strassburg, specially for this work. The result of a month's work shows that at this season the surface wind (N. to N.W. as a rule) is from



PILOT BALLOON Aug 27th 1907

HELWAN. EGYPT

LAT 29° 52' N. LONG 31° 20' E GR

heights in metres

interval in minutes from the start

1000 metres to 2000 metres thick. Above this there is a layer of varying thickness of winds from W. to W.S.W., whilst above 4000 metres other winds are reached, but the number of observations is at present too few to generalise about this region. An interesting ascent is shown in the figure, which represents the horizontal projection of the flight of a balloon on August 27, with contours showing the position of the balloon at intervals of 500 metres. In this case, above the stratum of S.W. wind there was a layer of N.W. winds, whilst above this a S.W. current was again entered.

Besides this study of the winds, kite ascents will very shortly be commenced. The apparatus acquired for these consists of a winch of the pattern designed by Mr. W. H. Dines, F.R.S., driven by a Crossley petrol engine of 4 horse-power. The observatory is indebted to Mr. Dines and also to Mr. J. E. Petavel, F.R.S., who watched the manufacture of the winch and introduced many minor alterations which use of a similar machine at Glossop had suggested. The machines are housed in an iron building on the flat desert plateau behind the observatory.

During the September international days (September 4, 5, and 6) five ascents of pilot balloons were made. The height to which they were followed varied between 2500 metres and 3300 metres.

Newton's Rings in Polarised Light.

An erroneous statement regarding the above-mentioned subject is made in Preston's "Theory of Light" (p. 363, 1901 edition) and also in Edser's "Light" (p. 519, 1902 edition). As the error is a rather serious one, it seems worth while to point it out.

When the rings are seen between two lenses of the same substance, by light polarised perpendicularly to the plane of incidence, reflected at an angle greater than the polarising angle of the substance, it is stated that the centre of the rings is bright. That this is wrong can be seen. For :—

(1) Stokes has shown from the principle of reversibility that, whatever be the nature of light, the centre of the rings seen between lenses of identical refractive indices is black at all incidences of the light.

(2) Since the centre of the rings is black *at all incidences* for common light and for light polarised in the plane of incidence, it follows by resolution that it is also black when the light is polarised in a perpendicular plane.

(3) When the angle of incidence is less than the polarising angle, the coefficients of reflection *in glass* and *in air* at the bounding surfaces of the two media are opposite in sign. It is argued that, on increasing the incidence, the coefficient of reflection *in air* changes sign as the polarising angle is passed, and therefore at such incidences the two coefficients agree in sign, and destructive interference no longer takes place. Really, however, it appears from Fresnel's formula (coefficient $= -\tan(i-r)/\tan(i+r)$) that both the coefficients change sign as the incidence passes through the polarising angle, and therefore continue to differ in sign, as can be directly shown from the principle of reversibility. Destructive interference does, therefore, take place.

(4) I have shown by experiment that the statement is not true.

(5) Airy has shown (Lloyd's "Wave Theory," p. 178, and Jamin's "Optique Physique," p. 503) that when the two lenses differ in refractive index, the centre of the rings seen in light polarised perpendicularly to the plane of incidence is white only when the incidence lies between the angles of polarisation of the two media. Outside these limits the centre is dark.

C. V. Raman.

Science Association Laboratory, Calcutta, September 12.

Mr. Raman's criticism of the statement made on p. 519 of my "Light for Students" is quite justified. Some time ago I noticed the error myself, and devised the following experiment, to which the same objections cannot be raised, while at the same time it is more easily performed than that in which two lenses of different refractive indices are used.

An ordinary black tea-tray is filled with tap water, and the surface is then touched by the end of a glass rod which has been dipped in oil (I find that the heavy paraffin oil used for engine lubrication answers well). The oil spreads over a fairly large area, Newton's rings being exhibited round the edge of this. On viewing the colours through a Nicol at an angle slightly greater than 45° no change is produced when the light transmitted is polarised in the plane of incidence, but on turning the Nicol through a right angle the colours change to their complementaries. In this case the light is reflected from the lower surface of the film at an angle slightly greater than the angle of polarisation for that surface, while it is reflected from the upper surface of the film at an angle less than the polarising angle. I presume that if Lloyd's single mirror fringes were observed through a Nicol, a similar change would occur on rotating the Nicol; I should be obliged if anyone who has tried this experiment would let me know whether this actually occurs. Edwin Edser.

Thermodynamics of Diffusion.

In his review of "Thermodynamics" (Nature, July 25) and again in the *Philosophical Magazine* for July, Mr. Burbury directs attention to a result stated by me regarding the gain of entropy resulting from slow diffusion of gases at constant pressure and temperature.

May I direct attention to the context in connection with which this result is stated in "Thermodynamics" (§§ 124, 126, 156)?

It cannot be deduced from the laws of thermodynamics or the definitions of a perfect gas (§ 124). These leave the change of entropy in the form of an undetermined constant.

It must necessarily be based entirely on experimental evidence (§§ 126, 156). It is in all probability *approximately* true for actual gases, but of this the experimental physicist is the only competent judge. As applied to "perfect gases" it should be regarded, in common with Boyle's law, as one of the "definitions of a perfect gas," a definition selected partly on account of its simplicity and partly on account of its approximate agreement with the properties of actual gases (§ 156).

An irreversible transformation does not, *ipso facto*, imply a gain of entropy. Unless a compensating transformation exists (§§ 50, 51), and unless the final result involves nothing more than a loss of available energy, we have no justification for applying the methods of thermodynamic analysis. If diffused gases could never be separated, we should have an instance in point; but do such exceptions exist?

Mr. Burbury asks why should different gases behave differently from different portions of the same gas? This question must be decided by the experimental physicist, subject to some further condition, *e.g.* that the gases are in the presence of a liquid which dissolves one of them or of a membrane which is permeable to one of them only. In other words, the matter resolves itself into the question, Why should the conditions of equilibrium of a gas in such circumstances depend on its *partial* pressure instead of on the total pressure of the mixture?

If the experimental physicist had told me that the total pressure, and not the partial pressure, was the determining factor, I should have asserted that no entropy was gained by diffusion, and should have written zero as the value of my constant C.

But then we should have no vapour of water in our atmosphere unless the temperature rose above the boiling point of water. These, generally speaking, are the views which the book was intended to convey; but may I direct attention to the large number of open questions in thermodynamics that have hitherto only received scanty attention in the hands of mathematical physicists?

G. H. BRYAN.

IN the passage in my review to which Prof. Bryan takes exception I had in my mind his definition of available energy at p. 35 and p. 43:—"The available energy of a system *under given conditions* is the quantity of energy which *under these conditions* can be converted into work"; and in the same passage the conditions are also spoken of as "external" conditions. Let the system consist of two gases occupying equal halves of a cylinder, both at the same temperature and at pressure p, separated by a piston impervious to either, and the whole surrounded by air at the same pressure p. It seems to me to be impossible under those conditions to convert any of the energy of the system into work; but if it can be done, it must be possible to explain how. The context of p. 125 does not seem to me to explain it.

S. H. BURBURY.

The Nomenclature of Radio-activity.

THE name "ionium" which Dr. Boltwood proposes for the new radio-active element, of which he announces the discovery in NATURE of October 10, is open to serious objections. I do not mean merely linguistic objections—it is too late to consider them; beside such a hybrid as "ionisation" the philological barbarity suggested by Dr. Boltwood is insignificant; but it is a first principle of scientific nomenclature that a name should connote some of the distinctive properties of the thing named. A thoroughly satisfactory system for naming radio-active elements has not been put forward, but that adopted by Prof. Rutherford in designating the members of the series descended from radium is at least better than none.

According to this system, the products arising successively from the disintegration of a radio-active element are denoted by the name of that element followed by the letters X, A, B, C, &c. The principle of this plan has been adopted by universal consent in the nomenclature of the products of radium, thorium, and actinium, but for historical reasons slight divergences from the simplest form of the system have been permitted. Only one disintegration product of uranium (other than the radium series) has been known hitherto; its name, uranium X, is in accordance with Prof. Rutherford's nomenclature. Dr. Boltwood now announces the discovery of a descendant of uranium subsequent to uranium X; it appears to me desirable that this product should be known as uranium A, and should not be given any purely fanciful and meaningless name such as its discoverer suggests.

NORMAN R. CAMPBELL.

Trinity College, Cambridge, October 12.

On Correlation and the Methods of Modern Statistics.

IN my last letter (October 3, p. 566) I ventured to express the modest hope that "an astronomer may be permitted to dissent from these applications of modern statistical methods." Prof. Pearson refuses the desired permission with such warmth of language and wealth of argument that I find it difficult to make a suitable renewal of the request. Perhaps I may be allowed to confine my reply to the point of most general interest.

With regard to the supposed relation between magnitude and colour, Prof. Pearson wishes "to say a strong word" about my criticism of a conclusion respecting the bulk of the lucid stars, which I said was based on a record in which the white stars had no frequency. I have re-read Miss Gibson's paper, and am unable to see that my criticism in any way misrepresents the facts.

In section (3) of her paper Miss Gibson discusses the relation between magnitude and colour, basing her results upon the Cape list of 159 stars, from which all stars less coloured than deep yellow are excluded.

In section (4) she fits various types of frequency curve to statistics of counts of the lucid stars. In this part of the paper there is no mention whatever of colour or spectral type.

At the end of section (4) we have the conclusion, to which I ventured to take exception:—"Thus we have the suggestion, even if it be only of the vaguest kind, that the bulk of the lucid stars may belong to a separate universe within which magnitude is not mainly determined by parallax or distance, but is more closely associated with colour, and thus probably with chemical or physical condition." The phrase "*but is more closely associated with colour*" is undoubtedly there. If it does not arise from section (3), its origin is "wrop up in mystery"; if it does arise from section (3) my criticism was not so unjustifiable as Prof. Pearson would with strong words call upon the reader to believe.

ARTHUR R. HINKS.

Cambridge Observatory, October 18.

New Zealand Birds.

DURING the past twenty-five or thirty years many reports have been published in regard to the extinction of New Zealand birds, and an impression has gone abroad that our avifauna, with its striking peculiarities and its wealth of interest to ornithologists, will soon be lost. Some time ago, when I was inquiring into the results of the acclimatisation of English birds, I had thousands of circulars distributed in all parts of the colony, and on those circulars I placed questions dealing with the position of the native birds. When the circulars were returned to me I found that every native bird was accounted for, in some cases in many different districts.

I feel, therefore, that I am able to sound a brighter note than has been sounded by most writers on New Zealand ornithology. From personal observations, I can say that several species the extinction of which was announced twenty years ago are fairly plentiful, and are increasing. I may mention specially the stitch-bird (*Pogonornis cincta*), the bell-bird (*Anthornis melanura*), the North Island robin (*Miro australis*), and the tui (*Prosthemadera novae zealandiae*).

I do not know of a single New Zealand bird which we can say with any degree of certainty has become extinct since European occupation of the country, except perhaps the quail (*Coturnix novae zealandiae*), and it is reasonable to suppose that it may still be represented on some flats that settlement has not reached. My inquiries extended only to the mainland; I did not deal with the islands included in the colony's boundaries.

Jas. Drummond.

Christchurch, New Zealand, September 8.

Showers from near β and γ Piscium.

On October 12, at 9h. 50m., I saw a second-magnitude meteor at $346^\circ+3^\circ$, and it appeared to be nearly stationary at that point, but I recorded the object imperfectly, as I was looking toward the western sky at the time.

On October 2, 1902, I noticed a small meteor almost stationary at $345^\circ+3^\circ$, and several others directed from the same point. This shower in Pisces is rather a prominent one in the months of August and September, and it has frequently been observed. The following are some of the determinations of the radiant:—

July 25 to Aug. 12, 1879	$343^\circ+3^\circ$	Weiss	6 meteors
Aug. 10, 1897	345+3	Libert	6 ,,
Aug. 13–16, 1893	347+0	W.F.D.	6 ,,
Aug., 1893	347+0	Corder	6 ,,
Aug. 16–20, 1885	345+0	W.F.D.	7 ,,
Aug. 15–21, 1901	345+0	W.F.D.	7 ,,
Aug. 19, 1900	346+1	W.F.D.	fireball radiant
Aug. 21, 1901	341+5	W.F.D.	meteor radiant
Aug. 21–23, 1879	350+0	W.F.D.	10 meteors
Aug. 24–Sept. 7, 1886	346+1	W.F.D.	5 ,,
Sept. 1–4, 1885	346+0	W.F.D.	9 ,,
Sept. 3–14	346+3	Schmidt	
Sept. 8, 1899	347+3	W.F.D.	fireball radiant
Sept. 14, 1901	345+1	W.F.D.	,, ,,
Sept. 14, 1875	348+0	Tupman	,, ,,
Sept. 15–20, 1876–1879	346+0	W.F.D.	10 meteors
Sept.	344−3	Schmidt	
Sept. 1858–63	346−3	Heis-Neumayer	
Sept. 17, 1885	345+0	W.F.D.	4 meteors
Sept. 17, 1898	343+0	W.F.D.	meteor radiant
Sept. 20–Oct. 4, 1886	347+0	W.F.D.	5 meteors
Sept.–Oct. 1, 1891	345+0	Milligan	
Sept. 27, 1906	347+2	W.F.D.	fireball radiant
Sept. 29–Oct. 2, 1877–1902	347+3	W.F.D.	13 meteors

Possibly several showers may be involved in producing these radiants. As they nearly agree with the radiant point computed for Daniel's comet on September 12, they possess an interest of rather special character, and it is to be hoped that observations will be augmented, particularly at the middle of September.

Bristol, October 14. W. F. Denning.

The "Quaternary" Period.

In Dr. Wright's interesting review of "Les Grottes de Grimaldi," by M. L. de Villeneuve (Nature, October 10, p. 590), I find the following:—"M. Rivière attributed them [the deposits] to the Quaternary period, M. Mortillet, on the other hand, regarded them as Neolithic." Now it is impossible to conceive any defensible use of the word "Quaternary" that does not include the Neolithic. Many authors have condemned the expression on the ground that the Pleistocene and Recent are nothing more than the latest and very subordinate portions of the Tertiary period. For my own part I believe that the great influence which man has already exerted on the character and distribution of the forms of life upon the earth, as well as on the purely physical conditions of its surface and the still greater changes that his activity must occasion even in the near future, are ample justification for marking his effective appearance on the scene by the commencement of a new period in the earth's history, a period the threshold of which we have scarcely passed. If, however, the Quaternary "period" is to be considered to close at the end of the Pleistocene, it becomes so insignificant in comparison with the long ages of its predecessors that it would be better to dispense with it altogether.

John W. Evans.

Imperial Institute, London, October 11.

The separation of the Quaternary period from the Recent period, which begins with the Neolithic, is attributable to the fact that an interruption was supposed to have occurred in Man's occupation of Europe. According to this view, the Recent period begins with his reappearance. Of late years it has been shown that such a view is untenable, and that no such interruption occurred. There is therefore much reason in Dr. Evans's contention that the Quaternary period should be extended to include the Recent period. The term "Quaternary" has, however, a recognised meaning which could not be changed without entering into a discussion of the reasons for the step—a discussion which would be quite outside the province of the writer of a short review.

William Wright.

To Deduce the Polar from the Intrinsic Equation.

I shall be grateful if one of your mathematical readers can give me the polar equation of the spiral which satisfies the condition $\rho s = c$, *i.e.* the spiral the curvature of which is a linear function of the arc. A. B. Porter.

324 Dearborn Street, Chicago, September 19.

The curve in which the *radius* of curvature is proportional to the arc is easily seen to be an equiangular spiral. If, as your correspondent assumes, the radius of curvature is *inversely* proportional to the arc, the problem is more complicated, and it is best in the first instance to express the Cartesian coordinates in terms of a third variable before attempting to form the polar equation. If instead of $\rho s=c$ we write $\rho s=\frac{1}{2}k^2$, we get with the usual notation

$$\tfrac{1}{2}k^2\frac{d\phi}{ds}=s,\ \text{whence}\ \phi=\frac{s^2}{k^2}$$

(choosing axis so that $s=0$ when $\phi=0$).

Put

$$u=\sqrt{\phi}=\frac{s}{k}$$

and we have

$$x=\int ds\cos\phi=k\int\cos u^2du=\frac{k}{2}\int\frac{\cos\phi\,d\phi}{\sqrt{\phi}}$$

$$y=\int ds\sin\phi=k\int\sin u^2du=\frac{k}{2}\int\frac{\sin\phi\,d\phi}{\sqrt{\phi}}.$$

By a suitable choice of origin, the lower limit of integration can be made to be zero in each case.

The integrals are known functions closely allied to the well-known error function. In fact, we have

$$x+iy=k\int_0^u e^{iu^2}du=\frac{k}{\sqrt{i}}\,erf\,u\sqrt{i}$$

To find the polar equation, we first transform the coordinates to new axes of X and Y, making an angle α with the old axes. Thus

$$X=x\cos\alpha+y\sin\alpha=k\int_0^u\cos(u^2-\alpha)\,du$$

$$Y=y\cos\alpha-x\sin\alpha=k\int_0^u\sin(u^2-\alpha)\,du$$

If now r, θ are the polar coordinates, we may adapt the last results to polar coordinates by taking $X=r$, $Y=0$, $\alpha=\theta$. The polar equation is thus the eliminant of the two simultaneous equations

$$r=k\int_0^u\cos(u^2-\theta)du$$

$$0=k\int_0^u\sin(u^2-\theta)du.$$

In terms of ϕ we have

$$r=\frac{k}{2}\int_0^\phi\frac{\cos(\phi-\theta)}{\sqrt{\phi}}d\phi,\quad 0=\int_0^\phi\frac{\sin(\phi-\theta)}{\sqrt{\phi}}d\phi$$

while the inclination ψ of the tangent to the radius vector is given by $\psi=\phi-\theta$.

This method can be applied to find the polar equation of a curve the radius of curvature of which is any function of the arc, but, as in the present example, the integrations cannot always be evaluated in terms of the functions discussed in elementary text-books. G. H. B.

SOME SCIENTIFIC CENTRES.

XI.—THE PHYSICAL LABORATORIES OF MANCHESTER UNIVERSITY.

SIXTY years ago John Owens, fine-spinner of Manchester, left 97,000*l.* "for providing or aiding the means of instructing and improving young persons of the male sex in such branches of learning and science as are usually taught in the English universities, but subject, nevertheless, to the two following fundamental rules and conditions, that the students, professors and teachers . . . shall not be required to make any declaration as to or submit to the test of any of their religious opinions. . . ."

The trustees rented for the purpose of the college a large private house in Quay Street in the city, formerly inhabited by Richard Cobden. The college was opened in 1851, with a staff of five professors, among whom appears the name of Edward Frankland as first professor of chemistry.

Though the chemical laboratory became almost at once very successful, a special fund of 10,000*l.* being raised for its development, it was not until much later that the chair of physics, or, as it was then called, "natural philosophy," was founded, Prof. A. Sandeman being its first occupant. He was succeeded by Prof. R. B. Clifton, F.R.S., now of Oxford, who was again succeeded in 1866 by Prof. William Jack.

On Prof. Jack's removal to Glasgow, Dr. Balfour Stewart, F.R.S., was called from Kew Observatory, where he was then superintendent. A small physical laboratory was opened by him at Quay Street in 1871, when eight students attended for instruction.

In 1873 the college was removed from the city to its present site in Oxford Street, to the fine new building erected from the designs of Mr. Alfred Waterhouse, R.A. The accommodation assigned to the physical laboratory consisted of three small rooms in the basement, quite at the back of the college. With the addition of a private laboratory for the professor, and a workshop, these constituted Prof. Stewart's quarters for experimental work up to his death, which occurred in 1887. Though much of Prof. Stewart's work while at Kew, such as his classic research on the air-thermometer, was of an experimental character, after he came to Manchester he seems to have devoted his attention more particularly to the theories of terrestrial magnetism and of the sun, rather than to laboratory research. The writer, who attended his classes in 1887, remembers how Prof. Stewart displayed an almost affectionate interest in demonstrating the use of certain instruments, such as, for example, the magnetometer, in which he always showed an especial delight.

Photo.] [*Warwick Brookes, Manchester.*

FIG. 1.—Prof. A. Schuster, F.R.S., in his laboratory.

On Prof. Stewart's death, after an illness brought on by an extremely rough sea voyage from Ireland, Prof. Arthur Schuster, F.R.S., who then occupied the chair of applied mathematics in the college, was called to succeed as Langworthy professor of physics and director of the physical laboratories.

Although from time to time the quarters assigned to physics had been considerably enlarged, the demand for a larger laboratory soon became very urgent, and, a generous donor having promised a large sum for the purpose, the council decided to build a new physical institute on a plot of ground close to the main buildings.

An interesting volume[1] has recently been published giving a description of the new physical laboratories and of the work done at the college during the occupation of the chair of physics by Prof. Schuster. It was compiled in commemoration of the twenty-fifth anniversary of his professorship, which was celebrated last summer by a large gathering of his old students and assistants, a specially bound copy being presented to Dr. Schuster by them on the occasion. Its compilation was largely the work of Dr. Hutton, head of the electrochemical department, who recently succeeded Dr. Lees, F.R.S., as assistant director of the laboratory. This book contains plans of the building and some excellent illustrations of the various departments, together with biographical notes and a bibliography of the scientific achievements of the professor, his staff, and pupils during the period named. The frontispiece of the work is a fine portrait of Prof. Schuster, by Lafayette.

As an account of the new laboratory appeared in these columns previous to its opening by Lord Rayleigh in June, 1900,[2] attention will only be directed here to a few of the more important features, and more particularly those connected with the research work.

From his earliest associations with physical science Prof. Schuster had always been specially interested in spectroscopy, having received his inspiration from contact with the foremost pioneers in this branch, Bunsen, Kirchhoff, and Roscoe. Hence it was only to be expected that the facilities for spectroscopic research in the new laboratory should be of a unique character. Probably one of the most important pieces of special apparatus is the large concave grating of $21\frac{1}{2}$ feet radius, of very high quality, specially ruled by the late Prof. Rowland for Dr. Schuster. The mounting, the details of which have been improved by Prof. Schuster, and subsequently by Mr. Duffield, is arranged so that the grating and camera are fixed to carriages, sliding on specially stout iron beams, so connected that as the camera moves away from the plate the grating moves towards it. With this arrangement, as Rowland showed, the different portions of the spectrum are always in focus, whatever the position of the camera on its beam. Mr. Duffield communicated last year to the British Association a preliminary account of a research in which he has been engaged using this equipment, for the study of the effect of pressure on the arc-spectrum of iron, the pressures being varied up to 100 atmospheres.

Other spectroscopic apparatus are a 33-plate echelon-spectroscope by Hilger; a printing comparator for the measuring of spectrum photographs, from the designs of Prof. Kayser; a quartz spectrograph; and a smaller specially mounted concave Rowland grating of one-metre radius.

A very important development of the special work of the laboratory is the department of electrochemistry, which, owing to the efforts of Dr. Hutton and Dr. Petavel, F.R.S., has now established a wide reputation. The details of the equipment have been previously described,[3] but mention must be made of the special electric furnace in which reactions can be studied in gaseous pressures ranging up to 200 atmospheres, and also of the various modifications of the carbon-resistance furnace, designed by Dr. Hutton for different purposes. Accounts of more than one important research undertaken in the department are now in the press.

No record of the physical work at Manchester would be complete without a reference to the long series of painstaking researches by Dr. Lees on thermal conductivity. Alone, and in conjunction with students as collaborators, he has published during the past fifteen years ten papers, many of them of great importance on the subject. He was the first to work with sufficient accuracy to determine with certainty the sign of the temperature coefficient of thermal conductivity in a number of materials, and the value of his work was recognised by his election as a Fellow of the Royal Society last year.

The physical department at Manchester was one of the first to recognise the importance of electrical engineering, and in the old buildings a considerable sub-department was the "dynamo house," where, under Dr. Lees's tuition, many now occupying high positions in the world of electrotechnics received their training. When the department was reorganised on a larger scale, the Hopkinson Memorial Wing was built and equipped by the friends and relatives of the late Dr. John Hopkinson for the purpose. This was placed under the supervision of Dr. R. Beattie. In this house and its annexes are installed a representative collection of all the more important types of modern machines, including specially designed generators for experimental work of all kinds, as well as some machines of historic interest, such as the pair of early alternators presented by Dr. Henry Wilde, F.R.S., to illustrate the property of synchronous running originally discovered by him.

A meteorological station in Whitworth Park, erected by the generosity of the Whitworth trustees, has been splendidly equipped under the care of Dr. C. G. Simpson, and quite recently a kite station at Glossop Moor on the Derbyshire hills has been fitted up under the superintendence of Dr. Petavel with improved Dines apparatus, for winding in and paying out the steel kite-wires, worked by a small engine. This is the most westerly station in Europe for kite-flying, and may therefore acquire considerable importance in the international scheme for the investigation of the upper atmosphere.

Dr. Petavel's researches on radiation and on high-pressure explosions led to his recently being elected to the Fellowship of the Royal Society, and have caused him to be regarded as an authority on both these branches.

After mention of these particular developments of the work of the laboratory, we may note that in the volume referred to, the mere bibliography of the scientific publications of Prof. Schuster and his pupils occupies no less than eighty pages, covering an extremely wide range. Students have been attracted to the laboratory, not only from all parts of England, but from abroad, especially of late years. This is due in some measure to the splendid provision made for research, but undoubtedly in a greater degree to the eminence Prof. Schuster has attained as an original investigator, and pioneer in many important branches of physics. His early work on the discharge of electricity through gases, carried out in the old building with the help of his extremely able private assistant, the late Mr. Arthur Stanton, contributed largely to laying the foundations of the modern theory of the charged atom, which has seen such marvellous developments at the hands of the Cambridge school of physics. His work as an astrophysicist has taken him almost all over the world on eclipse expeditions, and, as a representative either of the British Government or of the Royal Society, to many scientific con-

[1] "The Physical Laboratories of the University of Manchester." A record of twenty-five years' work. Prepared in commemoration of the twenty-fifth anniversary of the election of Dr. A. Schuster, F.R.S., to a Professorship in the Owens College, by his students and assistants. Pp. 142. (Manchester: The University Press.) Price 5s. net.

[2] NATURE, vol. lviii., pp. 621–2.

[3] Hutton and Petavel, Journ. Inst. Elec. Eng., 1903, vol. xxxii. pp. 222–247.

ferences. His influence on the research done by his pupils at Manchester is easily traced, and all of them would acknowledge the inspiration and encouragement of many a half-hour's chat with the professor, perambulating the corridor to and fro in a thoroughly characteristic manner.

Some months ago Prof. Schuster announced his intention of vacating the chair of physics to allow more leisure for the literary work and theoretical research to which he has recently devoted himself more particularly. To the satisfaction of his colleagues at Manchester, it has been decided, however, that his connection with the college shall not cease, but that he will continue to direct some of the research, and the council has therefore appointed him "honorary professor." His place as Langworthy professor and director of the laboratory has been filled by the appointment of Prof. E. Rutherford, F.R.S., of Montreal, who arrived in Manchester a short time ago and organised some researches, though not nominally in charge of the laboratories until the commencement of the October session. Prof. Schuster at present is engaged in the study of the permeability of iron at high temperatures under high pressures, especially with a view to discover the effect of high pressures in changing the temperature, between 800° and 900° C., when the metal suddenly loses most of its magnetism. Pressures up to 1000 atmospheres are contemplated. A second problem under investigation is the effect on the rate of decomposition of radio-active substances of extremely high pressures, such as are met with deep down in the earth's crust. In both these problems the design of the high-pressure portion of the apparatus has been due to Dr. Petavel, and for the latter purpose Mr. Cook, the university mechanician, has succeeded in constructing a combined pump and ram, in which pressures up to 37,000 pounds per square inch can be maintained without perceptible leak over long periods. The effect on radium of pressures up to 2000 atmospheres has been studied, and an account of the experiments will be ready shortly.

The accompanying photograph of Prof. Schuster in the laboratory was taken specially by Mr. Warwick Brookes.

J. A. HARKER.

A NEW METHOD OF COLOUR PHOTOGRAPHY.

THE latest method of colour photography is distinguished as the "Warner-Powrie" process, and is well illustrated at the first exhibition of the Society of Colour Photographers, which will close on October 26. It will presumably be some little time before the plates are generally obtainable, but so far as can be judged from the examples shown and the details of their preparation, it is a process that will offer special advantages. Mr. Powrie has been working at the subject for many years, and has succeeded in producing a triple-coloured lined screen with better and finer lines than has been possible by previous methods, and without either gap or overlap. He discards ruling in favour of a very ingenious method of printing that does away with all need for the troublesome registration that becomes almost impossible with fine lines. The glass is coated with a bichromated colloid, exposed under a black-lined screen that has spaces half the width of the lines, and developed in warm water. This leaves the colloid in lines with spaces of bare glass twice as wide as the lines. By immersion in a solution of a green dye the lines are stained, and by the application of formalin or chrome alum the colloid is made quite insoluble and the dye fixed. The plate is coated again, exposed under the same black-lined screen, the only precaution being that the green lines already made shall be covered with the black lines of the overlying screen. After exposure and development the plate is immersed in a solution of a red dye to stain the second set of lines, and again treated with a hardening agent. The plate is coated once more, and this time exposed alone with its back to the light, so that the red and green lines already made serve to protect the coating from light action. So after development all the remaining spaces are exactly filled with colloid, and this is then dyed blue. The prepared plate is coated with a suitable photographic emulsion, and can be used in a similar way to the "autochrome" plates of Messrs. Lumière, which we have already described. The chief difference between the two apparent by mere inspection is that the colours are in lines instead of as a random grain. But the lines can be made so fine that they are invisible to a normal eye without assistance.

It is obvious that the "autochrome" and the "Warner-Powrie" plates, and any plates in which the surface is apportioned to three colours for colour reproduction, must absorb about two-thirds of the light that would pass through them if the colours were not there. A simple colour, such as red, is produced by a silver deposit that covers the green and blue colours that are in the area that is required to be red, and this area is therefore one-third red and two-thirds black. A print on a "bleaching-out" paper (as the "Uto") would give its colours mixed with a double area of black, and therefore be uselessly dark. It is difficult, if possible, to obviate this with a random distribution of the colours, but Mr. Powrie, with his plates, overcomes the difficulty by separating the plate and the paper with a thin sheet of celluloid or glass, and by two mirrors on opposite sides of the printing frame gets oblique light in two directions, as well as direct light at right angles to the surface, and so causes each coloured line in the plate to give a line on the printing paper three times its width. In this way, each colour—red, green and blue—produces its effect over the whole surface of the paper, the colour patches are continuous (free from black), and what should be white parts are completely bleached instead of being coloured like the original. In the same way, but using ordinary plates, and red, green and blue light separately for the exposures, a separate negative can be obtained of each of the three colours, with a continuous image on each, and these can be used for any method of three-colour printing. A single exposure on a single plate will thus give all that is necessary for the preparation of the three colour records which hitherto have been obtained by separate and generally consecutive exposures on the original.

C. J.

MR. HOWARD SAUNDERS.

IT is with unfeigned regret that we record the death of Mr. Howard Saunders, after a long and painful illness. Mr. Saunders was born in London in 1835, and was therefore seventy-two at the time of his death. He was educated privately—to a great extent at Dr. Gavin Smith's school at Rottingdean, near Brighton, where he is said to have developed that taste for ornithology by means of which he attained eminence in later years. Immediately after leaving school he entered on a business career, and at the age of twenty joined a mercantile house at Callao. Five years were spent by him in Chili and Peru, where archæological studies appear to have chiefly occupied his leisure. In 1860 he crossed the Andes, reaching the headwaters of the Amazons, and descending that river to Pará, in Brazil, where he made his first long halt. Few Englishmen had at that time made a similar journey, which appears to have been fraught with difficulty.

After this journey Mr. Saunders returned to England, and devoted himself to the study of ornithology in real earnest. In South America he had acquired an intimate acquaintance with the Spanish language, so that in the numerous visits he paid to Spain between the years 1863 and 1870 he found himself thoroughly at home. Owing to these frequent visits he became a recognised authority on the ornithology of the Spanish peninsula, and in the year 1869 he published in the *Ibis* the first of a series of important papers on that subject.

To those members of the British public interested in birds, Mr. Saunders is, however, much better known as the editor of the third and fourth volumes of the fourth (and last) edition of "Yarrell's British Birds," the late Prof. Newton, who had edited the two earlier volumes, having found himself unequal to the task of continuing the work, at the rate of issue deemed necessary by the publishers. This work is alone a monument to the extensive knowledge and unflagging industry of Mr. Saunders. In addition to the conciseness and yet fulness of his descriptions, the text of these two volumes is noteworthy on account of the minuteness of detail with regard to the geographical distribution of the various species. The first part of vol. iii. appeared in 1883, and the last volume was completed in 1885.

This, however, was by no means the only work on British birds by Mr. Saunders. In 1887 he published a list of the birds of our islands; and in 1888–9 "An Illustrated Manual of British Birds," which originally appeared in parts, and of which a second edition was issued during the years 1897–9. Terns, gulls, and skuas were a group of birds in which Mr. Saunders was specially interested, and he was engaged by the Trustees of the British Museum to write the volume on this group (Gaviæ) for the famous series of "Catalogues," of which this volume is the twenty-fifth. It was published in 1896. He was one of the contributors to the "bird volume" of the scientific results of the cruise of the *Challenger*, which appeared in 1881, and likewise wrote the article Birds in the "Antarctic Manual." He was also joint-author of the "Birds of Lancashire," and had, indeed, an almost unrivalled knowledge of the county distribution of British birds. His papers in the *Ibis*, in addition to those on the birds of Spain, are numerous, and, needless to say, valuable.

At an early stage in his career Mr. Saunders became a member of the British Ornithologists' Union, at the meetings of which he was a regular attendant, while he also took a large share in the management of that body. He was a Fellow of the Linnean, the Zoological, and the Royal Geographical Societies, and served on the council of each, as well as contributing largely to the publications of the second named. The Society for the Protection of Birds also claimed his interest. For several years (1880–5) Mr. Saunders was secretary of Section D of the British Association; he was also a member of the American Ornithologists' Union, and on the foreign list of the Société Zoologique de France and of several other Continental scientific bodies. In addition to ornithology, Mr. Saunders also took an active interest in geographical research, especially that connected with the exploration of both polar regions. His death will be felt as a personal loss by a large circle of scientific friends, both in this country and abroad. R. L.

NOTES.

THE first Press messages by wireless telegraphy were transmitted by the Marconi system across the Atlantic Ocean, between Ireland and Cape Breton, on October 17. Several congratulatory messages were exchanged between the two continents. The Governor-General of Canada dispatched a message from Ottawa congratulating the King "on the establishment of a fresh link between Canada and the Motherland," to which His Majesty replied on the following day by the same method of communication:—"His Majesty the King to Earl Grey, London, October 18.—I thank you for your telegram. I am delighted that wireless Transatlantic telegraphy should unite the bonds between Canada and the Mother Country so closely.—EDWARD R." The Irish station is situated on a headland facing the Atlantic, about four miles from Clifden, in Galway, and is the largest wireless installation in the United Kingdom. A number of tall masts, arranged in a line facing seawards, contain a network of wires on which messages are received and dispatched. The operators have a telephonic apparatus with a sensitive sounder attached to their ears, and it is their trained sense of hearing and distinguishing the Morse signals transmitted that enables them to detect the signals. It is stated that signals are sent and received simultaneously, and that a speed of about thirty words per minute has already been attained. Full particulars of the modifications in the apparatus and plant which have made the success of last week possible will doubtless be forthcoming in due course. Mr. Marconi and those at work with him are to be congratulated upon their triumph over practical difficulties, and men of science have reason for satisfaction in this remarkable development of means of communication by means of ether waves. The Marconi Company state that any delays in the transmission of messages by their system between North America and the United Kingdom are attributable entirely to delays on the land lines. The company claims that with a private wire from its station at Glace Bay to Montreal, and from the Irish station to London, the service between London and Montreal will immediately compare favourably with the cable service in point of speed.

THE Faraday lecture was delivered by Prof. Emil Fischer, professor of chemistry in the University of Berlin, at a meeting of the Chemical Society held on October 18 at the Royal Institution. Sir William Ramsay, K.C.B., president of the society, was in the chair. An abridgment of the lecture appears in another part of the present issue. At the conclusion of his discourse a medal was handed to Prof. Fischer by Sir William Ramsay as a mark of appreciation by the Chemical Society of his scientific work. Sir Henry Roscoe proposed a vote of thanks to the lecturer, and remarked that the great interest of the lecture is due, not only to the fact that Prof. Fischer is a master of his subject, but also because the application of synthetic chemistry to biology is a subject that at the present time exceeds in interest and importance any other branch of the science. In seconding the vote, Sir James Dewar mentioned that the centenary of the isolation of potassium and sodium by Davy fell on the day following that of the lecture.

THE death is announced of Prof. A. Fürtwangler, professor of classical archæology in the University of Munich, and a prolific writer on archæological subjects.

THE council of the Royal Meteorological Society has awarded the Symons gold medal for 1908 to M. L.

Teisserenc de Bort, of Paris, in recognition of the services which he has rendered to the science of meteorology. The medal was established in memory of the late George James Symons, F.R.S., the founder of the British Rainfall Organisation, and is awarded biennially. The presentation will take place at the annual general meeting of the society on January 15, 1908.

At the sixth annual meeting of the Northern Scientific Club, held at Newcastle on October 17, Sir W. H. White was elected president, and gave an address upon the application of the gyroscope for steadying ships. He showed a working model of Dr. Schlick's apparatus, which, he said, when applied to cross-Channel boats and coasting passenger steamers, would so prevent the rolling of these vessels as to allow persons troubled with sea-sickness to travel on the sea in comfort.

A message was received in New York on October 9 from Dr. Frederick A. Cook, the explorer. It was dated August 26, from Etah, and ran as follows:—"I have hit upon a new route to the North Pole, and will stay to try it. By way of Buchanan Bay and Ellesmere Land, and northward through Nansen Strait over the Polar Sea, seems to me to be a very good route. There will be game to the eighty-second degree, and here are natives and dogs for the task." Dr. Cook's expedition is provisioned for two years, and is wintering thirty miles further north than Commander Peary did two years ago.

The experts of the U.S. Forestry Service, after a fortnight's work on the ground principally affected, are still in the dark as to the origin of the blight that has attacked the white pine of New England during the summer. At Brunswick, Maine, it is feared that the beautiful Bowdoin pines, of which Hawthorne and Longfellow wrote, will soon be a thing of the past. The blighted trees are recognised by the fact that the tips of the needles of this year's growth have turned a peculiar reddish-brown colour, so that the trees look as though they had been scorched. The national Government has established several sample plots, not only at Brunswick, but also at Peterboro, New Hampshire, where a scientific study of the problem is to be carried on.

The Philosophical Institute of Canterbury, New Zealand, is making arrangements for an expedition to some southern islands included in the colony's boundaries. The expedition will be under the leadership of the Hon. R. McNab, Minister of Lands and Minister for Agriculture, who is interested in the history of the islands, and has written an interesting work dealing with the old sealing and whaling days in the islands and the southern part of the mainland. The expedition will be under the auspices of the Government, and will be taken to the islands in one of the Government's steamers. It will leave New Zealand about the end of November or the beginning of December, and will visit the Auckland Islands and Campbell Islands. About twenty New Zealand men of science will take part in the undertaking. They will be divided into two parties, one going to each group. Work will be done in regard to terrestrial magnetism, zoology, geology, and botany, and reports will be prepared dealing with the results of the investigations.

The jubilee of the East Kent Scientific Society was celebrated on October 16 by a conversazione held at the Simon Langton School, Canterbury. Biological, chemical, and physical exhibits were on view, and several interesting demonstrations were provided. The society numbers eighty-six members.

Reuter's correspondent at St. Petersburg states that reports have reached there of an earthquake in Central Asia. On October 21, between 9 a.m. and 10 a.m., a strong but gradually diminishing shock of earthquake was recorded at Katta-kurgan. Other advices state that an undulatory earthquake occurred on October 21 at Samarkand, lasting from 8.45 to 10.30, and causing cracks in many buildings. The dome of one mosque and the minaret of another collapsed.

We learn from the *Agricultural News* of the West Indies that Mr. W. R. Buttenshaw died suddenly in Calcutta on September 9, at thirty years of age. Mr. Buttenshaw, who was a graduate of the University of Aberdeen, entered the service of the Imperial Department of Agriculture for the West Indies as lecturer in agricultural science at Jamaica in 1899, and was appointed scientific assistant in charge of publications at the head office at Barbados in 1903. He left Barbados in May last to take up an appointment as botanist in the Indian Agricultural Service.

Cardiff is now to have a seismograph. Mainly through the instrumentality of Principal E. H. Griffiths, F.R.S., the local Naturalists' Society took the matter up, and approached the City Council with the offer of a seismograph and several other instruments to complete the set belonging to the corporation if only the latter would suitably house and maintain the same. The city fathers, after some demur on the score of economy, have now unanimously agreed to the proposal. An excellent site has been found for the seismograph on Penylan Hill alongside the public observatory, where will also be installed all the instruments necessary for a complete meteorological outfit. This announcement was made amidst applause at the annual meeting of the naturalists on Thursday evening, October 17, by the retiring president, Prof. Haycraft.

The Harveian oration was delivered by Dr. F. Taylor at the Royal College of Physicians on October 18. In the course of his address, Dr. Taylor remarked that Harvey's injunction to search and study out the secrets of nature by way of experiment should be addressed to the lay public, not, indeed, that they may experiment themselves, but that they may promote and forward such experimentation, or at least not hinder and obstruct it. Consideration of the value of experiment and research leads to the reflection how enormous has been the progress, on the one hand, made in medicine in the last few years, and how large, on the other, is our ignorance of natural phenomena in relation to disease and its treatment or control. Dr. Taylor referred to the work of Prof. E. Starling, to whom the Baly medal for the present year has been awarded, on the chemical relations of the functions of the body, as being particularly in accordance with the spirit of Harvey. Two advances which have had important results are the improvements in surgical practice which, initiated by Lord Lister, have led to the present theory and practice of asepsis in surgery, and the advances on the therapeutical side which are intimately connected with the subject of prevention and immunity, and the treatment of disease by antitoxins and the later opsonic methods. The field for research is enormous, the necessity for research patent, and even if the number of workers who can conduct research on the highest lines is limited, whether on social, financial, or moral considerations, there can be no doubt that the medical profession as a body will continue actively to support the maxim contained in Harvey's injunction to search out the secrets of nature by experiment.

FROM Tuesday to Saturday of this week boys of all ages have a delightful opportunity of seeing well-made models of engines, boats, electrical and other devices, and tools used in making them, at the Royal Horticultural Hall. Besides seeing the models at rest or at work, they are able to attend lectures on some of those attractive features in mechanics, physics, or chemistry that made the Polytechnic such a favourite resort in the old days. The *Model Engineer* is to be congratulated on the success of its first exhibition, or at any rate on what ought to be a success, the only misfortune being that, as the younger boys are at school now and the older boys are at work, many who would have attended with delight are perforce out of reach. Our interest in an exhibition such as this is more with its educational aspect than in general with the exhibits themselves. A boy with a mechanical or scientific turn obtains exactly the kind of encouragement which is wanted; his vague ideas as to making something, however fantastic (before the days of bicycles he generally hankered after making a velocipede), are corrected by seeing pleasing things that will really work of every kind of difficulty, from the simplest to the most elaborate, and, what is more important, he learns precision and how to read a drawing, for the instructions given at the exhibition and in the *Model Engineer* are accompanied by proper scale elevations and sections that would do credit to an engineer's office. The boy of the present day has a great advantage over his predecessor owing to the great development and moderate price of small precision tools. These are to be seen in their usual variety; but it is a little sad to notice under the same roof beautiful small precision lathes, with hollow mandrels and draw-in chucks, hailing often from Germany, and old-fashioned designs of cheap lathes with short and solid mandrels. Of course money is the difficulty, and the boy is tempted by the greater capacity of the gap lathe. Perhaps as an educational instrument it has its value. Among the pleasing subjects of lectures is the gyroscope, but, judging from the syllabus, the lecturer has missed the opportunity which the now popular "diabolo" would have given him if his dexterity is equal to his knowledge of demonstrating the laws of precession. We can only repeat our regret that such a treat should not have been arranged for the holidays.

THE *Times* of October 15 contains a further communication from Dr. Stein announcing the results of his work in north-western China during the last few months. Leaving the Lop-nor region, where, at Miran, he had made discoveries proving that in the second century A.D. the Indian kingdom in Turkestan, of which he had previously found such important remains at Niya, between Khotan and Cherchen, extended eastwards almost to the borders of China, Dr. Stein proceeded along the ancient trade-route across the desert of Gobi towards the oasis of Sha-chau, still, as of old, the westernmost outpost of Chinese population and speech. This route has been avoided in modern times until now, on account of its difficulties. Dr. Sven Hedin did not essay it, and it had not been crossed for many years until, not long ago, two British officers from India performed the journey. Their feat was chronicled in the Journal of the Royal Geographical Society, but is not mentioned by Dr. Stein in his letter. The discoverer has found a very interesting relic of ancient Chinese authority in this region in the shape of a previously unknown "great wall" of defence, erected in the early days of Chinese conquest by the Han emperor Wu-ti, at the close of the second century B.C. Dr. Stein traced its course for 140 miles, and found many interesting remains of its original builders and later garrisons in the shape of Chinese records on wood, chiefly referring to matters of military administration, besides numberless miscellaneous antiques, which had been perfectly preserved by the dry climate and soil. Buddhist antiquities of a thousand years later have also been found on sites to the south of this wall, and with these researches Dr. Stein is still occupied.

AN informal conference of representatives of museums, with members of the Museums' Association and other persons interested, was held at Salford, on October 18, by the invitation of the Museums and Libraries Committee of the Salford Corporation, who entertained the visitors. The meeting was well attended, the museums of Liverpool, Manchester, Leeds, Hull, Leicester, Bolton, Chester, and Warrington being represented among others. The afternoon was spent in the inspection of the Peel Park Museum and the recently opened natural history branch at Buile Hill Park, and Mr. B. H. Mullen, curator, afterwards gave a brief account of the recent extensive changes and developments carried out in the Salford museums. Mr. G. A. Dunlop, Warrington Museum, in a paper on the preparation of botanical specimens for exhibition, described in detail processes of drying flowering plants in silver-sand and boxwood sawdust, exhibiting samples of successful results with the latter medium, in which leaves and delicate floral structures were perfectly preserved. The forms were practically permanent; the colour of specimens exposed to the light might be expected to last about two years. An effective dry method of preserving succulent plants was, however, still a desideratum. Mr. H. Murray, Manchester Museum, followed with notes on wet methods of preserving plants for exhibition. Mr. E. E. Lowe, Leicester Museum, read a paper entitled "What should be the Curator's Ideal?" in which he offered evidence of the need for an all-embracing scheme or classification, as of an ideal museum, which should cover the whole field of museum work, and from which curators might select, and by which they might verify and coordinate their work in such sections of the whole as they might severally find it practicable to include in their programmes. Mr. Lowe submitted an outline of some portions of such a scheme, and was encouraged to proceed with the project.

THE first meeting of the new session of the Royal Geographical Society will be held on November 11, when Mr. Mackintosh Bell, director-general of the New Zealand Survey, will give a paper on the Great Douglas Glacier and its neighbourhood. Arrangements have also been made for papers by Dr. Hunter Workman, on the exploration of the Nun-Kun mountain group, in the Himalayas, and its glaciers; Dr. Vaughan Cornish, on the Jamaica earthquake; Mr. A. H. Harrison, on his search for an Arctic continent; and Dr. Tempest Anderson, on his visit to the volcanoes of Guatemala and St. Vincent. Among other papers provisionally arranged are the following:—the Duc d'Orléans, on his exploration in and around Novaya Zemlya; the Count de Lesdain, on his journey from Peking to Darjiling through Central Asia and Tibet; Mr. Laurence Gomme, on the story of London maps; Dr. T. G. Longstaff, on the Trisul district of the Himalayas; Mr. A. W. Paul, on Bhutan; Dr. W. S. Bruce, on his recent expedition to Prince Charles Foreland, Spitsbergen; and Dr. Johnston Lavis, on the influence of volcanic action on some features of the earth's crust. A series of lectures on the geographical conditions which affect the development of the British Empire is being arranged for, one or two of the lectures to be given each session; the lectures at present decided upon are:—on the British Islands, by Mr. H. J. Mackinder, and on Australia, by Prof. J. W. Gregory, F.R.S. Beginning on Thursday, January 23, and continued weekly, a course of six lectures will be given by Dr. H. R. Mill on the geographical distribution of rainfall in the British Islands.

From Mr. John Wheldon we have received a copy of a catalogue of ornithological literature, comprising nearly 1000 books and papers.

A paper by Messrs. W. K. Brook and S. Rittenhouse on the life-history and development of the hydroid *Turritopsis nutricula*, in which both the hydroid-stock and the free-swimming medusas are described, is published in the Proceedings of the Boston (U.S.A.) Natural History Society, vol. xxxiii., No. 8.

In the list of additions to the Zoological Society's menagerie in the Regent's Park, attention may be directed to a specimen of Phillips's dik-dik antelope from Somaliland, the first of its kind ever exhibited in the gardens. A true zebra from Cape Colony is likewise an important addition to the collection.

The council of the Ealing Scientific and Microscopical Society deplores, in its report for the past year, the lack of interest displayed by local residents in matters scientific, and the consequent want of expansion in the membership roll of the society. Unless at least twenty new members are enrolled during the coming year, the society's expenses must be cut down. Among the reports of addresses delivered during the year, attention may be directed to one on the continuity of the germ-plasm, in which an abstruse subject is explained in a remarkably clear manner.

It has long been known that the North American cat-fishes of the genera Noturus and Schilbeodes can inflict painful wounds with the spines of their pectoral fins, but some difference of opinion has hitherto prevailed whether a sac opening by a pore in the axillary region of these fishes is a true poison-gland. In the September number of the *American Naturalist* Mr. H. D. Reed, after careful examination of several species of these cat-fishes, states that the pore, which is the aperture of a gland, is present in all, and that in at least one species the secretions of the gland are poisonous. It has also been found that in species in which the spines are not strongly serrated, glands of the same type are developed on the pectoral and dorsal fin-spines. In these species, in which they attain their highest development, the glands are structurally similar to those of the weaver-fishes.

Among a number of interesting articles in the October issue of *Science Progress*, special reference may be made to one by Mr. F. V. Theobald on the economic relations of birds to agriculture, horticulture, and forestry. Despite the enormous amount of literature on British ornithology, the author is of opinion that our present information concerning the majority of the species is insufficient to admit of a definite pronouncement as to their utility or harmfulness, and that it is consequently necessary to study their food in a much more systematic manner than has hitherto been attempted. Some birds Mr. Theobald does not hesitate to condemn to destruction, among these being the black-cap, blackbird, and sparrow-hawk. Attention may also be directed to an article by Dr. A. Dendy on the pineal gland. Although its wonderful developmental history is fairly well known, we are still ignorant of the function of this organ. To remedy this we require a series of investigations into the physiology of the pineal organs, both in those animals in which they still exist as a sense-organ, and in those in which the epiphysis cerebri has assumed the character of a ductless gland.

The Bulletin of the Johns Hopkins Hospital for September (xviii., No. 198) is longer than usual, and contains a number of important papers on pathological subjects. Prof. W. G. MacCallum gives a short outline of an experimental course in pathological physiology which the students of the Johns Hopkins Hospital have the privilege of attending.

From Messrs. G. W. Bacon and Co. we have received a set of the first part of their "Photographic Nature Drawing Cards," reproducing illustrations of leaves. The size of the prints averages about 5 inches by 3 inches, and on each a single leaf is figured. They are nicely printed, and serve to indicate general shape, outline, and veining, but obviously the advantage lies with natural specimens.

A catalogue recently received of Leitz microscopes contains several new designs and fittings. A novel and improved form of fine adjustment, providing endless movement by means of a cam, is supplied with the better stands; being fitted to the connecting piece between the frame and the tube-holder, it is possible to curve the frame so as to give accommodation for large objects on the stage. In the so-called museum microscope there is a circular drum on which a dozen preparations can be fixed that rotates under the objective. Special features are combined in the mineralogical microscopes, and an opaque illuminator for fitting on the end of the tube has been designed. A pamphlet describing Edinger's drawing and projection apparatus has also been published.

The July number of the *Philippine Journal of Science*, vol. ii., No. 4 of the botanical series, is assigned to the identification of specimens collected by Mr. E. D. Merrill and others on Mt. Halcon, Mindoro. With regard to new plants described by Mr. Merrill, the most notable is a species of Centrolepis providing the first record for the order Centrolepidæ in the Philippines. The order is typically Australian, as four out of six genera are entirely confined to Australasia, and out of twenty species of Centrolepis this and one other only occur outside Australia. Several other plants of the collection bear out the same affinity; *Dianella caerulea, Halorrhagis halconensis*, and *Cladium latifolium* afford good examples. Two new genera are proposed, Halconia under the order Tiliaceæ, and Mearnsia under the order Myrtaceæ. A small parcel of mosses collected on the same expedition was referred to Dr. V. F. Brotherus. His determinations and those of the orchids consigned to Mr. O. Ames are also published.

Dr. Virginia Ridsdale has published a thesis (Lord Baltimore Press, 1906) dealing with the arrangement ot the real branches of plane algebraic curves. The Harnack and Hilbert processes of small variation from specially degenerate curves are applied to curves with the maximum number of branches, and the various possible arrangements of internal and external ovals are discussed. The author concludes that the theorem with which the paper professes to deal can be stated in several alternative forms. This theorem relates to the greatest and least numbers of ovals for a curve of given degree.

The Weekly Weather Report of the Meteorological Office for the week ending Saturday, October 19, states that the rainfall was more than the mean in all districts except Ireland N. In nearly all parts of the kingdom, except Scotland N. and Ireland S., the excess was very large. Several parts of the country recorded falls of much more than an inch within twenty-four hours, and some places more than 2 inches. Most of the heavy falls occurred either on October 15 or 16. At Lincoln (about $1\frac{1}{2}$ miles from the centre of the city) as much as 3·50 inches were recorded on October 16, and at Leith 2·61 inches on October 15, while over a large area of Great Britain measurements of between 1 inch and 2 inches were registered. The largest aggregates for the week were 4·92 inches at Bournemouth and 4·62 inches at Portland Bill.

THE report of the Government Meteorological Department on rainfall registration in Mysore for 1906 shows very clearly, both statistically and graphically, that the district average for the year was somewhat above the mean of the past thirty-seven years in all parts except in Shimoga and Kadur, but was, on the whole, not sufficient to make up for the deficiency of the two previous years. The greatest rain in twenty-four hours was, as usual, at Augumbe (Shimoga), where 15 inches fell on July 21 and $11\frac{3}{4}$ inches the following day. The director, Mr. J. Cook, states that though the interest of the observers in their work has greatly increased in recent years, many of the gauges are still badly exposed.

AN interesting pamphlet by Mr. D. W. Horner, entitled "Observing and Forecasting the Weather: Meteorology without Instruments," has recently been published by Messrs. Witherby and Co., 326 High Holborn (post free, 7*d.*). On reading this booklet we were impressed by the fact that much useful work can be done by the public generally without expense, and with advantage to themselves, by recording their observations as recommended. The greater part of the pamphlet deals with the importance of cloud observations, and the author points out how anyone possessing an ordinary photographic camera may obtain useful pictures of clouds and lightning flashes. To make the chapter on wind more complete, a table of the velocities corresponding to estimated force by Beaufort's scale is given; the equivalents were in general use until very recently, but have been slightly modified by a publication of the Meteorological Office (No. 180, 1906) bearing upon the subject. With reference to the supposed influence of the moon on the weather, the author states that there is "grave reason for doubt" that Sir W. Herschel compiled a table until recently published in almanacs; any doubt on the question was removed by Sir J. Herschel's denial in *Good Words*, 1864.

MESSRS. SANDERS AND CROWHURST have issued a new series of lantern slides from Mr. W. Farren's photographs illustrating wild bird life, taken from nature. The slides include many instructive pictures of birds and their habits. Enlargements of the photographs are also issued.

A SECOND edition, being the third impression, of Dr. R. Wallace Stewart's "Higher Text-book of Magnetism and Electricity" has been published by Mr. W. B. Clive. This edition contains an additional chapter on the electron theory of matter and radio-activity, written by Mr. J. Satterly.

A SECOND edition, which has been revised and enlarged, of Dr. Ernst Cohen's "Vorträge für Arzte über physikalische Chemie" has been published by Mr. W. Engelmann, of Leipzig. An authorised translation of the first edition, by Mr. M. H. Fischer, was published by Messrs. Henry Holt and Co., of New York, in 1903, and the English version was reviewed in NATURE of July 16, 1903 (vol. lxviii., p. 245).

FROM Messrs. Philip Harris and Co., Ltd., of Birmingham, we have received a specimen of their recently introduced students' clinometer and compass. It consists of a silvered dial of some $2\frac{1}{2}$ inches diameter divided into degrees in the two uppermost quadrants, and provided with a pair of sights of the usual folding pattern. About this dial revolves a metal collar carrying a spirit level, to which is affixed an index point indicating the angular elevation of the object under measurement. No fine degree of accuracy can be expected, of course, from a dial of so small a radius, but, with the accompanying compass, the instrument should be found extremely useful in educational work, such as is involved in the practical study of physical geography, inasmuch as it will familiarise the student with the principles of the angular measurements of elevation and azimuth. The clinometer would be simpler to use, it appears to us, and would give greater accuracy, if some method were devised of attaching the collar carrying the level and index to the stand, thereby leaving the sights and dial to move independently of the latter, which could then be accurately levelled at the commencement of the observation and afterwards left undisturbed.

OUR ASTRONOMICAL COLUMN.

MELLISH'S COMET, 1907*e*.—A second telegram from the Kiel Centralstelle informs us that the comet discovered by Mr. Mellish at Madison on October 13 was observed by Prof. Hartwig at Bamberg on October 15. Its position at 17h. 0·4m. (Bamberg M.T.) was R.A. = 8h. 26m. 13s., dec. = 8° 45′ 16″ S., and its magnitude 9·5.

The following are a set of elements and an ephemeris calculated by Miss Lamson from places observed on October 15, 16, and 17, and communicated by Prof. Pickering to the Kiel Centralstelle (Circular No. 100):—

Elements.

T = 1907 September 12·47 (M.T. Greenwich).

$$\left.\begin{aligned} \omega &= 291^\circ\ 42' \\ \Omega &= 55^\circ\ 32' \\ i &= 118^\circ\ 53' \end{aligned}\right\} 1907 \cdot 0$$

$q = 0·973$

Ephemeris 12h. (G.M.T.).

1907	α	δ	Brightness
		° ′	
October 19	8 14·1	−7 0	1·15
,, 23	7 57·7	−4 38	—
,, 27	7 36·0	−1 30	—
,, 31	7 6·8	+2 39	2·06

The brightness at time of discovery (mag. = 9·0) is taken as unity. On October 27 the comet will be about halfway between γ (26) Monocerotis and Procyon, and on October 31 it will be some 2° north of δ (22) Monocerotis. On the latter date the comet will rise a little to the north of east at about 10.30 p.m.

A BRIGHT METEOR.—Mr. W. F. Denning informs us that a fine meteor = ♀ was seen by Miss Irene Warner of Horfield Common, near Bristol, on October 19 8h. 50m. It disappeared close to the star δ Aquarii, near the planet Saturn, and was directed from the north-east region of Cygnus, near α and ε. It was of a fiery yellow colour and formed quite a conspicuous object even in the presence of the nearly full moon.

THE SPECTRA OF SUN-SPOTS AND MIRA CETI.—In the September *Astrophysical Journal* (vol. xxvi., No. 2, p. 123) Father Cortie compares the spectra of Mira Ceti, taken at Stonyhurst during the maxima of 1897 and 1906, with the sun-spot spectrum, and infers therefrom that the temperature of the spot vapours is lower than that of the photosphere, thus confirming the results previously obtained by Sir Norman Lockyer, Profs. Hale and Adams, and others. There are strong reasons for believing that the spectrum-producing vapours of Mira were at a higher temperature during the 1906 than during the 1897 maximum. In the first place the star was brighter, and therefore presumably hotter. Again, the changed intensity of the hydrogen lines and of the characteristic absorption bands also indicates, according to our present knowledge, an increased temperature in 1906. Concurrently, the titanium-oxide bands in the spectrum of Mira were weaker in 1906 than in 1897, and, as these bands are *stronger* in the spot spectrum than in that of the photosphere, it seems reasonable to conclude that the spot vapours are therefore cooler than those of the general photosphere.

The evidence thus afforded by the temperature, and the accompanying spectral, changes of Mira from one maximum to a higher one agrees with Sir Norman Lockyer's temperature classification of the stars wherein similar changes, from type to type, are held to determine the relative positions of the Antarian and Aldebarian groups.

RECENTLY DISCOVERED MINOR PLANETS.—In No. 4205 (October 10) of the *Astronomische Nachrichten*, Prof. Bauschinger gives a list of thirty-four recently discovered minor planets showing the permanent designatory number that has been allotted to each. The last date of discovery given is June 9, 1907, and up to that time six hundred and thirty-five of these objects had been allotted permanent numbers. The present list also gives the provisional designation, the name of the discoverer, the date of discovery, and, where it has been allotted, the proper name by which each asteroid is to be known. A second list gives the elements for the orbit of each minor planet where they have been determined. Fifteen of these objects, which were allotted provisional numbers in 1906–7, have been found to be identical with previous discoveries.

ELEMENTS OF COMETS 1907*a* AND 1907*d*.—A set of parabolic elements for the orbit of comet 1907*a* is published by Signor E. Tringali in No. 4205 of the *Astronomische Nachrichten* (October 10).

The same journal also contains a set of parabolic elements for comet 1907*d*, calculated by Prof. E. Millosevich from observations made on June 16, July 18, and August 22. The results of a number of observations of the latter comet made at the Kremsmünster Observatory during the period July 4 to August 28 are given by Prof. F. Schwab in the same issue. On August 18 the comet was of 2·5 magnitude, and its tail was seen to extend 16° in the direction from λ to γ Geminorum.

THE LIVERPOOL ASTRONOMICAL SOCIETY.—We have received the annual report of this very active society giving a brief *résumé* of the work done and papers read during the session 1906–7. Among the latter, reference may be made to the president's address delivered at the opening meeting by Mr. W. E. Plummer, who, in a most interesting paper, directed attention to a few of the more urgent problems at present facing the practical and the theoretical astronomer.

An excellent photograph of Mr. George Higgs is reproduced as a frontispiece, and that observer contributes a short paper dealing with recent advances in the absolute wave-length measurements of solar radiation. Some curious phenomena were described by Mr. C. T. Whitmell, who supposed the observer to be located on the sun, and from that standpoint surveyed the solar system. Of more practical interest were the papers by the Rev. R. Killip, on the planet Jupiter; Mr. H. Waters, who presented a few notes to beginners in stellar photography; and Mr. F. W. Longbottom, on work with a $12\frac{1}{4}$-inch reflecting telescope of 24-inch focus. The two last-named papers are illustrated by reproductions of photographs, that of the vicinity of γ Cassiopeiæ having been taken by Mr. Waters with a $3\frac{1}{4}$-inch Voigtlander portrait lens of 8 inches focal length mounted on a rough equatorial stand and driven by hand.

A MODERN SUN-DIAL.—The August number of the *Bulletin de la Société astronomique de France* (p. 360) contains an interesting illustrated description of a sun-dial which the author, Vicomte d'Aurelle Montmorin, thinks may suit the modern requirements of the general public. The usual gnomon is replaced by a wire stretched across a rectangular frame, its shadow being cast on to a semicircular dial at the back. The frame is adjustable on pivots to any latitude, and curves engraved on the instrument give the equation of time for every fifth day. Setting screws are provided to adjust for longitude, once for all, and for the equation of time, so that no calculation is necessary, the time being read off directly from the dial, which is divided into divisions of five minutes each. The instrument is very portable, and the author suggests an ingenious arrangement of selenium cells whereby the hours and quarters might be struck on one or two gongs.

FLEAS AND PLAGUE.

SIR LAUDER BRUNTON, F.R.S., delivered the inaugural address at the opening of the twenty-fifth session of the London School of Tropical Medicine on Monday, October 25, Mr. R. L. Antrobus, C.B., Assistant Under Secretary of State for the Colonies, presiding. He described the campaign against mosquitoes in relation to malaria and yellow fever; sleeping sickness, its spread along the lines of commerce in Africa and its transmission by a tsetse-fly; and then proceeded to discuss plague. The ravages of this disease in Europe in the fourteenth century under the name of the "Black Death" were described, and quotations from contemporary writers were given illustrating the terrible condition to which the countries attacked were reduced by the pestilence.

In India at the present moment the ravages of plague, though not so great as those of the Black Death or of the Great Plague in London, are nevertheless dreadful. During the first six months of this year no less than 1,060,000 deaths from plague occurred in India, and out of these 632,000 occurred in the Punjaub, which has a population of only twenty-five millions, that is to say, one in every forty inhabitants in this district has died of plague between January and June.

It has long been observed that great mortality in rats is apt to precede pestilence, and Mr. Hankin suggests that the story of the Pied Piper of Hamelin is a legendary account of a plague epidemic. Simond first suggested that fleas transmitted the virus, and the most convincing experiments have been made by Captain W. Liston, I.M.S., who found that 61 per cent. of white rats and 52 per cent. of Bombay rats contracted plague from fleas which had fed upon infected rats. He then found that fleas would infect guinea-pigs. He further showed that guinea-pigs did not catch plague if they were protected from fleas in various ways, *e.g.* by wire gauze, adhesive fly-paper, &c. His experiments have been confirmed and extended by the Advisory Committee appointed by the Secretary of State for India, the Royal Society, and the Lister Institute, who concluded from their experiments that:—

(1) Close contact with infected animals does not give rise to plague epidemic among guinea-pigs when fleas are excluded.

(2) If fleas are present, epidemic starts at once.

(3) An epidemic may be started when no contact with a plague-infected animal is allowed, when fleas from infected animals are introduced.

(4) Infection can take place without the animal being in contact with the ground. Thus a guinea-pig put in a wire cage and suspended 2 inches from the ground contracted disease.

(5) Aërial infection did not take place if the cage was 2 feet (that is, more than fleas jump) from the ground.

(6) In all the animals thus naturally infected the large proportion, 90 per cent. (nearly), of the buboes were in the neck; 179 animals were examined, and in obtaining fleas from animals 65·3 per cent. were obtained from head and neck.

The great difficulties in the way of preventive measures are ignorance and apathy, to which superstition is often superadded. In some parts of India there is great prejudice against taking life of any kind, but this is not universal, because in some parts goats are offered to Kalee, the Goddess of Destruction. If the Brahmins could persuade the natives that the sacrifice of a dead rat as often as possible to Kalee would avert pestilence, rats would very soon be destroyed, and plague would be at an end.

Cases of plague from time to time arrive at the Port of London, and rats might therefore become infected and start a pestilence in our midst. We are pursuing a foolish policy in allowing rat- and flea-infected districts to exist in the East End of London and other similar places.

THE THIRD "PREHISTORIC" CONGRESS OF FRANCE.

THE third Congrès préhistorique de France was held at Autun (Saône and Loire) from August 12 to August 18, and attracted some 350 adherents, about fifty more than did the congress held at Vannes in 1906. More than 150 archæologists attended the scientific meetings and excursions held at Autun.

The congress was opened in the town theatre, where an address of welcome was delivered by the Mayor of Autun. Then Dr. A. Guébhard and Dr. Marcel Baudouin, the president and general secretary respectively of the congress, made the usual statements, and were followed by the official delegate of the Minister of Public Instruction, Prof. Matruchot, of the Faculty of Paris and director of *Pro Alesia*. Prof. Matruchot congratulated the Société préhistorique de France on the success it has attained, and conveyed to it the compliments of the Government.

On Monday evening, August 12, the congressists attended a reception at the Town Hall at the invitation of the learned societies of Autun, a group of bodies held in high respect in France. The brilliancy of this gathering was enhanced by the presence of numerous professors and men of science from other lands, the list of those present including the names of M. Rutot (Brussels), Prof. Cossina (Berlin), MM. O. Montelius (Stockholm), Valdemar Schmidt (Copenhagen), Count Zeppelin d'Arlehausen (prefect of Lorraine), M. Wassre (Switzerland), MM. Lewis and Dickins (England), M. Peabody (U.S.A.), &c. In addition to several German professors who assisted in the meetings of the congress, there were also present Profs. Adrien de Mortillet (Paris), P. Girod (Clermont-Ferrand), Dr. Henri Martin, M. Edmond Hue, M. Gustave Chauvet (Ruffec), Dr. Baudon, deputy of Beauvais, &c.

Among the subjects discussed should be mentioned that which treated of the prehistoric features of the Eduen country, in which the congress was held, and which was celebrated in the Roman history of Gaul. In the environs of Autun itself is situated the "Champ de la Justice," a Neolithic station which has furnished a number of "finds," and formerly included a fine megalithic alignment, which to-day is totally destroyed. This was visited by those who attended the congress, and there is indubitable evidence that it was formerly an ancient fortified camp, of which only the eastern side of the vallum, which has been investigated by M. Déchellette, remains.

Part of another evening was devoted to each of the walls of the town, and groups of the congressists also visited the Roman remains of Autun, which is surrounded on all sides by primitive ramparts dating from the time of Augustus; the temple of Janus, the sepulchral pyramid of Couhard, and the principal gates, such as La Porte St. André and La Porte d'Arroux, were amongst the sites visited. Then another place of great interest was found in the Roman theatre, at one time an important structure, now a mass of ruins, which, however, forms one of the chief attractions to tourists in Autun.

The principal question on the agenda of the congress was that of prehistoric camps and fortifications, which have been thoroughly examined by the learned president of the meeting, M. Guébhard. These were clearly described and discussed by the president before a large meeting of the whole congress held in the theatre on the evening of August 13. The exposition was rendered more enjoyable by the lantern-projection of more than 130 slides, and was so enthusiastically received by the large audience present that another afternoon was devoted to this complex subject.

Another lantern lecture was delivered, on the afternoon of August 14. by Mr. Lewis (England), his subject being the principal megaliths of England, whilst Mr. F. V. Dickins (England) exhibited a number of photographs of Japanese megaliths taken by M. Goodhan. These photographs were greatly appreciated by the audience, and, in the subsequent discussion, Dr. Marcel Baudouin, the great French authority on the study of megaliths, insisted upon the great interest of the English cromlechs and of the Japanese *allées couvertes*, which belong to a more recent epoch, and of which the funeral ornaments singularly recall those of the Gaulish sepultures.

This meeting concluded with a lantern demonstration given by Dr. Henri Martin, who dealt with the remains, showing traces of utilisation, found at stations of the *Moustérienne* epoch in Charente and Dordogne.

It is not advisable to describe here all the communications discussed at the congress, but it should be recorded that, concerning the megaliths, it seems to be generally admitted in France that the monuments were unquestionably oriented for a set purpose. Dr. Baudouin, who, following Gaillard (of Plouharnel) and many others, scientifically defends this theory in France, stated that the orientation varies from N.E. to S.S.E. in Brittany and Vendée, and clearly refers to the rising sun if one takes into account the latitude of the place and, an important factor, the momentous seasons.

The variation of the orientations indicates that in erecting these monuments all the seasons were considered, although the alignments to the winter sun predominate, as in Brittany, where the most frequent direction is S.S.E. This is in good accordance with the results of the work recently prosecuted in England concerning this important problem. The author also insisted upon the relations between menhirs and dolmens, and showed by an example, *apropos* and indisputable, that the menhirs were really indicators of megalithic sepultures, or of the limits of the necropolis of this epoch. By using two certain holed stones as indicators, he was enabled to discover an *allée couverte* which was buried under the soil, and had until then remained undiscovered. This "find," made with remarkable scientific precision, was received by numerous foreign congressists as a striking example of the value of a theory which many of them still ignore.

The question of the place the Aurignacien stratum should occupy in the classification of Palæolithic industries was also discussed at length, first at Autun by Prof. Girod, then at Solutré itself by Dr. Arcelin, jun., and M. Adrien de Mortillet. One sees that the excavations of Solutré should afford the much-desired solution of this problem, but it is not there, for the stratigraphy of that classical station is very intricate owing to serious landslides, and the consequent over-running, which detracts all meaning from the disposition of the layers laid bare by the recent work of M. Arcelin, jun. This worker believes, however, the *sous-solutréenne* layer to be re-mounted; but M. de Mortillet holds the opposite opinion, and believes that the over-running is real.

The question of forgeries was also discussed, and it was decided that it is necessary to warn prehistorians concerning "finds" in the Charollais country, near Autun. Possibly some of the Neolithic arrows of bizarre shapes are genuine, but it is certain that others are the work of clever forgers.

"Eoliths," the fruitful source of much debate, also came up for discussion. The subject seems threadbare in spite of the frequent writings of M. Rutot. He apparently admits that there are "eoliths" of every epoch of the "Stone age," but the true "eoliths" are those which correspond to the Tertiary deposits and suddenly appear in the Lower Quaternary. This is what may be called, with Dr. Baudouin, the *Préchelléen*, without entering into the detail of the layers.

Four days, instead of three, were this year devoted to the final stages of the congress, the session being augmented by one day for this purpose. In this time all the camps were visited, special attention being paid to the stations of the Iron age. Thus, in the days devoted to the more extensive excursions, the congressists visited Mont Beuvray, near Autun, which, under the name of *Bibracte*, was formerly the central Oppidum of the Aedui. Here are carefully preserved the precious remains of brave Gaulois, of which other specimens were also seen in the

Musée de l'Hotel Rolin. The toilsome journey to an altitude of 810 metres was amply repaid by a good lunch, and, in spite of the rain, by the more artistic pleasure of the grand panorama of surrounding plains and hills which is to be seen from the summit.

This visit to Mont Beuvray, a hill well known to the whole world, since it has justly given its name to an important epoch—the Iron age—recalled the fact that Cæsar once visited this Oppidum, and shortly after protected the Aedui from the Helvetian attack, and also from that of Ariovistus. It was here, too, that the Gauls held the famous general assembly, after the Aedui abandoned the Roman cause, and proclaimed Vercingetorix, the proclamation no doubt taking place near the *Pierre de Vibre.*

The ancient importance of this fortified Eduen camp is also attested by the fact that Cæsar, after the triumph at Alesia, established himself there. After this, Gaul was completely submitted to the Eastern civilisation, and *Bibracte* (with its *Beuvraysien, i.e.* its *industrie du Fer*), some years after the commencement of the Christian era, was completely obliterated by a forest fire. Vestiges of the town have been found by a modern Eduen, Bulliot, and a room in the Musée de l'Hotel Rolin is devoted to the results of the gigantic excavations. These were shown to the congressists by his worthy successor, M. Déchelette, who also exposed, for the congress, several Gaulish habitations, and prepared an exposure laying bare part of the old ramparts of the Oppidum, thus affording the visitors a view of a good example of the constructions of that epoch.

On August 16 an excursion to the boundary of the Côte d'Or and Saône and Loire occupied the attention of the congress, and a number of dolmens in the neighbourhood of Nolay and Decize were examined, but these do not recall anything of those well-known monuments on the borders of the Gulf of Morbihan. This visit showed what becomes of monuments in the centre of France, as those of the Field of Justice, in Saint Pantaléon, near Autun, had already appeared as an ultramicroscopic reduction of those of Menec and of Kerlescant at Carnac.

The evening was devoted to an enjoyable visit to the camp of Chassey, a typical Neolithic fortification occupied later by the Gallo-Romans. In the hands of the late director of the Musée Rolin, Dr. Loydreau, this camp furnished a valuable collection to the museum, and, thanks to the enthusiasm of M. R. Gadant, the room devoted to the collection was solemnly declared open during the visit of the congress. The subject of this second excursion was restricted entirely to the two principal periods of the polished stone epoch.

Looking south from Chassey, the far-away plateau of Aluze may be seen, considered by the Eduens as being the only Alesia possible. This supposition has not, however, prevented M. Etienne Bonneau from preparing his modest work, in spite of many difficulties, on the Siège d'Aluze par J. César.

At the camp of Chassey, of which the northern and southern parts of the vallum remain intact, excavations had been specially preserved, and furnished the visitors numerous fragments of Neolithic pottery and remains of Bovides, &c.

The third day was devoted to the Palæolithic age, to the period of the *pierre taillée*, and to this end the congressists visited the very fine collection made by Arcelin *père* from the classical beds of Solutré, and now to be found in the Musée de Mâcon. The son of the inventor of Solutré, Dr. Arcelin *fils*, was the guide, and had prepared a new cutting of the *Clos du Charnier*, which showed *in situ* the exact stratification of the beginning of *Solutréen*. As has already been mentioned, this visit did not give the key to the thorny question of *Présolutréen* or *Aurignacien*, on which sides are taken by the leaders of the Belgian and French brigades.

But the old school of prehistoric France showed that the Solutré bed has been greatly modified by the earth displacements, and so rendered little assistance to the solution of the Aurignacien problem. Against this the few facts have shown that the layers, as known, of horses, which form the base of the station, appear to be contemporaneous with the *Mousterien*. In fact, it appears, *a priori*, that one such place which had been frequented by the Palæolithic workmen had also been inhabited by the Solutréens. Certain flints, and remains of horses, apparently prepared on the Mousterienne model, have been found by Drs. Arcelin and Baudouin.

On the last day of the excursions a visit was made to the Oppidum d'Alesia, where there are rare traces of the Gaulois (huts, &c.). The epoch appears to be completely the Gallo-Roman, *i.e.* at the end of the Iron age. Here is to be seen the result of two years' assiduous labour, and one sees that if Faith is not able to raise mountains, Science of to-day is able to dig out from their foundations the majestic ruins of several successive Roman civilisations. In face of these works, the question which suggested itself was, "If by some unlikely chance this was not the true Alesia, how is it that a town, having presented such elaborate monuments, has left no trace of itself in the primitive history of France?"

This visit, with that to the two special walls which were seen at *Alise Sainte Reine*, worthily brought the congress of Autun to a close.

As a proof of the enthusiasm aroused, it may be stated that the last excursion attracted more than 100 participants. In spite of the complexity of the excursion programme, and in spite of the large number of adherents, the congress programme was carried out punctiliously.

The splendid organisation of this Congrès préhistorique de France may henceforward remain a model for others. It is to be hoped that its success will be repeated upon the occasion of the fourth congress in 1908, and that a still greater number of foreign workers, more especially the specialists of Great Britain, will be present.

ECONOMIC BIOLOGY AND AGRICULTURE.

A CONFERENCE to mark the inception of a new department of economic biology at University College, Bristol, was held on Thursday, October 17, in the Bristol Museum, the Right Hon. Henry Hobhouse, P.C., taking the chair.

Mr. A. D. Hall, director of the Rothamsted Experimental Station, speaking upon the experimental work at Rothamsted, directed attention to the part played by bacteria in the fixation of nitrogen in the soil. Mr. E. S. Salmon (Agricultural College, Wye) referred to the destructive character and prevalence of fungus pests, and the beneficial results following the use of various spray solutions. Mr. F. V. Theobald (vice-principal Wye College), in dealing with the investigations upon insect pests, urged the importance of each worker making his own observations upon their life-history and habits within the district in which he worked, otherwise much mischief would result from the repetition of misstatements. It has been found, for example, that the winter moth, the wingless females of which are supposed to emerge in the middle of October and ascend tree trunks to lay their eggs, does under certain conditions and in some districts appear earlier, so that grease banding of the trees is in such cases carried out too late, and much damage results.

Prof. J. R. Ainsworth Davis (Aberystwyth), speaking upon economic biology in relation to fisheries, urged a much closer connection between educational work and trade. He also pointed out the need of a fuller knowledge of the movements of food fish, and the importance of organising systematic investigations upon the fisheries of the Bristol Channel and the rivers flowing into it. Mr. T. H. Middleton (Board of Agriculture and Fisheries), speaking upon the public and departmental aspects of economic biology, stated that it is the policy of the Board to subsidise institutions establishing departments of agriculture, recognising that the work of economic biologists is of public benefit, in that all are consumers. The result of disease and unscientific management leads to dearer foodstuffs. The Board has a special interest in the work of biologists, and can be made an effective intermediary between the scientific man and the grower. It is possible that a time will arrive when the Board will be able to do more in support of applied science, and when that time comes consideration will be given to those institutions which have actively worked for the benefit of agriculture, forestry, and fisheries.

Mr. W. R. Barker, chairman of the Museum and Art Gallery Committee, said the committee of that institution recognises the beneficial effect of active cooperation with the University College of Bristol, and to that end is rapidly developing a special section of economic biology for the exhibition of insect and plant pests, and of material damaged by them. Prof. A. F. Stanley Kent explained that the new department has been called into existence by the needs of the west of England, and that applications for help and inquiry have come in rapidly. Valuable research work has already been carried on at the college in matters relating to economic biology, and important results have been obtained in connection with ciders, black-currant disease, and the development of lobsters on the coast of Devon and Cornwall. It was announced that Mr. Richardson Cross has offered land for an experimental station, where investigations upon various crops, manures, &c., can be carried on; additional land has also been offered by Mr. James Sinnott at St. Anne's Park. It is intended that the teaching side of the work shall be kept subsidiary to the advisory, and that the real function shall be to supply information and render help wherever required. Prof. Lloyd Morgan pointed out that academic and national interests in these matters are one, and that the department will directly benefit the community. Mr. W. E. Collinge (Birmingham) described the work of his department in the University of Birmingham, instancing as an example of the work done the yield from two orchards of the same acreage, and only separated by a road. One left unsprayed produced fruit worth 122*l.*; the other, that had been sprayed, produced fruit worth 497*l.*

SYNTHETICAL CHEMISTRY IN ITS RELATION TO BIOLOGY[1]

IT is easy to understand why in its early youth organic chemistry was so closely connected with biology; the materials which the chemist was called upon to investigate were mostly products of animal or vegetable origin. Indeed, carbohydrates, proteins, and vegetable acids served Lavoisier, Gay-Lussac, Berzelius, and Liebig as materials in elaborating the methods of elementary analysis.

The isolation of urea from animal urine by Rouelle, the recognition of uric acid, lactic acid, malic acid, and glycerine by Scheele, the isolation of asparagine by Vauquelin and Robiquet, of morphine by Serturnier, together with many other similar discoveries accomplished during the first ten years of the nineteenth century, are admirable examples of the manner in which the living world was drawn upon and made to yield up its treasure of chemical compounds. The many hundreds of natural organic compounds enumerated in the text-books of animal and vegetable chemistry are proof of the rich harvest since gathered in this field of investigation; but how small is their number when compared with the 130,000 carbon compounds which organic chemistry can boast of to-day. All these, it is known, are either products of the artificial transformation of organic matters occurring naturally or have been completely synthesised from their elements. The accumulation of this huge material, including the elaboration of the necessary methods, has been the main occupation of organic chemists during the past sixty years; and as their discoveries gave rise to much happy speculation, for the time being they took the lead in developing chemical theory.

It is not to be denied that, in the latter half of the last century, owing to the growth of the subject in importance, organic chemistry became separated from biology. It cannot be mere chance that the most famous of Liebig's pupils, A. W. Hofmann, A. Kekulé, and A. Wurtz, did not follow the example of their great teacher, whose chief triumphs were won by the use he made of chemical methods in solving biological problems. Perhaps they were restrained by the feeling that, mainly through his influence, physiological chemistry had been developed into a separate discipline, which should be cared for by men who could devote themselves entirely to its service. Such subdivision of labour undoubtedly has many advantages; the disadvantages would have outweighed these had it precluded interchange of experiences and friendly co-operation of workers in the two fields; the history of both sciences, however, affords ample proof that such has not been the case.

Physiologists have ever been ready to avail themselves of the latest developments of chemical analysis and synthesis, whilst organic chemists have not only been stimulated in many ways by biologists, but their studies have derived much practical aid from biological science. I may instance the modern development of the chemistry of fermentation, which began with the pioneer work of Pasteur, and was greatly favoured by the introduction of Koch's refined bacteriological methods; also the flourishing industry to which the manufacture of medical remedies prepared by synthetic methods has given rise.

But organic chemistry will certainly never be content to act as the mere handmaid of biology. This is impossible, as the theoretical and technical problems which she is already called upon to consider are too numerous, and they cannot fail to increase in number and importance in the future; but I do consider it not only possible, but desirable, that the close connection of chemistry with biology which prevailed in the days of Liebig and Dumas should be re-established, as the great chemical secrets of life are only to be unveiled by cooperative work. I will therefore attempt to indicate the part chemistry can play by reference to cases of which I can claim to have personal experience.

We know that in nature the construction of organic matter begins in the leaves of plants with the conversion of carbon dioxide into sugar, from which many physiologists suppose the complex substances contained in the living cell are formed by further changes in which nitrogen, sulphur, and phosphorus take part.

These transformations are for the most part enveloped in mystery. We know nothing definitely even of the assimilation of carbon dioxide. Of the various hypotheses advanced to explain the change, that advocated by A. von Baeyer has gained most support, namely, the view that the initial product is formaldehyde, glucose being formed from this by a process of polymerisation. Actually both changes have been effected artificially. After it had been shown by Butleroff that on heating formaldehyde with lime water a sugar-like, syrupy product is formed, and O. Loew had improved the method of effecting the condensation, I was able to adduce proof that the complex mixture contains a small quantity of an α-acrose which can be transformed into glucose. As it was known that carbon dioxide could be converted into formaldehyde by more or less drastic means, the preparation of glucose from carbon dioxide thus became a possibility. Recently, Fenton has succeeded in carrying out the reduction of carbon dioxide to formaldehyde at a low temperature in aqueous solution, so that it is now possible to effect the complete synthesis of sugar at temperatures such as prevail in the living plant. But how thorough is the work of the plant in comparison with our laboratory practice; usually when such questions are discussed, the poor yields which our methods give rise to are forgotten!

I need only allude here to recent apparently successful attempts, on the one hand, to effect the reduction of carbonic acid to formaldehyde by means of light, and, on the other, to detect formaldehyde in green leaves, as Prof. Meldola dealt exhaustively and critically with these questions in his presidential address eighteen months ago. I may be allowed, however, to dwell somewhat on one peculiar feature of the natural change, namely, the asymmetric character of the synthesis; according to present experience, and especially the brilliant investigations of H. Brown and Morris, the optically active hexoses of the *d*-series, glucose and fructose, are alone formed.

But from the experience gained in effecting syntheses in the sugar group, as I showed some time ago, it is possible to give a fairly satisfactory explanation of this change. It is only necessary to assume that the condensation is preceded by the formation of an additive compound of

[1] Abridged from the Faraday lecture delivered by Prof. Emil Fischer, F.R.S., at a meeting of the Chemical Society held at the Royal Institution on Friday, October 18.

formaldehyde with some optically active constituent of the chlorophyll granules. I shall give a more precise form to this hypothesis if I say that I consider it probable that the carbon dioxide itself enters into combination in this manner, as there is reason to suppose that the proteins offer sufficient opportunity for its fixation; according to Siegfried, even the simple amino-acids are capable of combining with carbon dioxide. I am inclined to think that this compound with carbon dioxide undergoes decomposition into oxygen and a reduction product, probably a derivative of formaldehyde; the condensation to sugar takes place either in the original asymmetric complex or in one produced from it by a secondary change involving the separation of the formaldehyde and its re-association in some other manner. It may be that the condensation takes place directly or that intermediate compounds, biose or glycerose, are formed. Thanks to the researches of Marckwald, and especially those of Mackenzie, we are acquainted with a whole series of asymmetric syntheses; no one of these, however, is half so complete as that involved in the formation of sugar under natural conditions. Indeed, it is obvious that if the natural process is to be imitated *in vitro*, it will be necessary to alter the methods hitherto adopted in every single detail; difficult as this may appear, it is not altogether impossible.

But even if this be done successfully, the precise nature of the assimilation process will not be finally elucidated. It is to be expected that this will only be accomplished when biological research, aided by improved analytical methods, has succeeded in following the changes which take place in the actual chlorophyll granules.

The carbohydrates elaborated by the plant undergo combustion to carbon dioxide and water in the animal body. The change is easily effected by means of powerful oxidising agents at the ordinary temperature; the natural process, however, must be a very different one, as in the organism oxygen is conveyed to the carbohydrate by oxidising enzymes, and doubtless many intermediate products are formed of which we know little at present.

It would be easy to multiply examples; but these two are sufficient to demonstrate the incompleteness of the explanation of biochemical processes deduced from the data of organic chemistry. The service rendered to biology by chemical analysis and synthesis, which will be rendered by it in even greater measure in the future, is to be sought in other directions.

The ultimate aim of biochemistry is to gain complete insight into the unending series of changes which attend plant and animal metabolism. To accomplish a task of such magnitude, complete knowledge is required of each individual chemical substance occurring in the cycle of changes and of analytical methods which will permit of its recognition under conditions such as exist in the living organism. As a matter of course, it is the office of organic chemistry, especially of synthetic chemistry, to accumulate this absolutely essential material. The chemical constitution of hundreds of carbon compounds which occur naturally has already been determined, and their more important properties have been established; but far more remains to be done. In proof of this, let me briefly direct your attention to the three great classes of substances which predominate in the living world: the fats, the carbohydrates, and the proteins.

It was established at least ninety years ago by Chevreul, in the course of his celebrated investigations into the process of soap-making, that the fats can be decomposed into the glycerine discovered by Scheele and into fatty acids; but the relationship of these latter to one another could not be understood until the conception of homologous series had been evolved in organic chemistry. The classical researches of Berthelot and the discovery of glycol by Wurtz were necessary preliminaries to the establishment of the constitution of glycerine; the final proof that the fats are neutral glyceric salts of the fatty acids was first provided by Berthelot's synthesis. Synthetic methods have made us acquainted with the mono- and di-glycerides and also with mixed triglycerides such as have frequently been met with of late in nature. Nevertheless, the group in which the natural fats are ranged is one in which there are still many lacunæ and many misstatements to be corrected.

The problems afforded by the fats are simple, however, in comparison with those connected with the carbohydrates. The original subdivision of the group into mono-, di-, tri-, and poly-saccharides has been justified in practice. Up to the present time only the monosaccharides have been studied satisfactorily from the point of view of their spatial structure. The growth of our knowledge of the monosaccharides has proved in many ways to be of importance in connection with biological inquiry, especially in enabling us to penetrate the mystery of enzyme action somewhat further.

On contrasting the effects which emulsin and the enzymes in yeast produce on the various glucosides prepared by synthetic methods, I was led to conclude, not only that there was a difference between the two series of optical antipodes similar to that discovered by Pasteur in the course of his studies of moulds, but that very slight changes in configuration were sufficient to inhibit the action of enzymes entirely. I was led by these observations to apply the simile of *lock* and *key* as an expression of the close inter-relationship in configuration which obtains between the enzyme and the substance which it attacks. Similar results were obtained on investigating the behaviour of the stereoisomeric hexoses with yeast, the fermentative power of which we now attribute to an enzyme—E. Buchner's zymase.

The experience gained with the glucosides became of service in studying the polysaccharides. Another outcome of the investigation has been the discovery of distinct enzymes capable of attacking di- and tri-saccharides. As the result of these inquiries, I was able to formulate a rule of general biological significance, namely, that the alcoholic fermentation of a polysaccharide is necessarily preceded by its hydrolysis by some particular enzyme. It was shown, especially in the case of the invertase of *Monilia Candida*, that it is not essential that the enzyme should even be soluble in water.

Unfortunately, but few successful syntheses of polysaccharides have been effected. It is most desirable, therefore, that better methods should be devised, as it is probable that the attack on the dextrins, gums, and similar undeciphered substances is most likely to be successful if made from the synthetic side. It is to be expected that biology would gain much by the discovery and utilisation of such materials; more, perhaps, than it has from the study of the monosaccharides and of the glucosides prepared by artificial means.

The carbohydrate group is that in which use was first made of enzymes as synthetic agents. Such syntheses fascinate the imagination, as they approximate closely to natural processes; but I may point out that they cannot take the place of purely chemical methods, as these latter are so much more under our control and can be varied in so many ways that we are in the position to produce materials which it is quite impossible for the organised world to furnish. Laboratory synthetic methods will be indispensable for a long time to come, not only for preparative purposes, but also as the means of elucidating the structure of complex substances of natural origin.

This contention is applicable to the proteins even more than it is to the carbohydrates; as they are among the most complex substances produced in the living world and are concerned in all the vital activities of the cell, a complete comprehension of their nature must obviously precede the full development of biological chemistry. We distinguish to-day some forty to fifty natural proteins, discovered by the joint labours of chemists and physiologists; but it is to be expected that as the methods of differentiating and separating them are improved, their number will be largely increased.

At present the majority are known only in an amorphous form; some important terms of the group, however, such as oxyhæmoglobin, egg albumin and the albumin of horse serum, excelsin from the Brazil nut, and the edestins from other plant seeds, have been obtained in definite crystals; but, unfortunately, it cannot be decided from their crystalline appearance whether these products are definite substances, as the tendency to form mixed crystals is the greater the more complicated the molecule. Examples in point are afforded by the aniline dyes, the higher fatty acids, and the purine compounds;

and those who have studied the chemistry of the natural silicates will be aware of the extension which mineralogists have been compelled to give to the conception of isomorphism. It would therefore be altogether surprising if the crystallised natural proteins should turn out to be single substances.

Of the numerous attempts to unravel the constitution of the proteins by analytical means, the only method which has given useful results hitherto is that of hydrolysis. Hydrolysis can be effected by acids or by alkalis, and also by digestive enzymes; the products, it is well known, besides ammonia, are albumoses, peptones, and ultimately amino-acids. The wide range of variation in composition of these amino-acids is shown by examining a list of all the substances hitherto prepared from the proteins.

The proportions in which the various amino-acids are obtained from the different proteins vary very considerably. In some cases they are altogether lacking, as may be proved by application of the definite tests for tyrosine, tryptophane, or glycine; but it is worthy of note that, as a rule, the amino-acids isolated from the mixtures produced by subjecting albuminous substances to hydrolysis all occur almost without exception, especially is this true of the important proteins which play the chief part in animal or vegetable metabolism, so that the conclusion must be drawn that none of them can be dispensed with in organic life. With the exception of diaminotrihydroxydodecanoic acid, they have all been so thoroughly investigated that their structure is well established. The majority also have been synthesised, proof of their structure having, in fact, been given in this way. Only oxyproline, histidine, and diaminotrihydroxydodecanoic acid remain still to be synthesised.

With the exception of glycine, all the amino-acids derived from natural sources are optically active; but when prepared by ordinary synthetic methods, as is well known, they are obtained in the first instance in the racemic form. The resolution of the racemoids into their optically active components has been effected quite recently in most cases. Asparagine, however, which is closely related to aspartic acid, had been resolved into the two active forms by recrystallising the inactive synthetic product from water and separating the two constituents mechanically. Moreover, in the case of some other amino-acids, for example, leucine, the antipode of the natural form had been obtained by partially fermenting the synthetic product with moulds. The complete synthesis of the active amino-acids which are obtained from natural sources was first accomplished by the method I introduced based upon the use of the acyl derivatives. The method has been applied with success to the majority of the synthetic products; its extension to the remaining cases, proline, lysine, tryptophane, and cystine, is not likely to be attended with any difficulties.

As the amino-acids are formed from the proteins, not only when these are subjected to the action of hot acids and alkalis, but also at moderate temperatures by the agency of the digestive enzymes, they are to be regarded as the true foundation stones of protein molecules. Opinions adverse to this hypothesis are only occasionally met with; they centre round the arbitrary supposition that complicated atomic re-arrangements may take place during hydrolysis.

Were one inclined to regard such objections as of moment, all the experiments on the determination of the constitution of organic compounds by degradation methods would be useless; moreover, the conclusions which have been drawn in other cases from the results obtained by the dissection of compounds have been too frequently confirmed by their synthesis. It is now possible to make this claim on behalf of the proteins, as it has been found to be possible, by a process the reverse of hydrolysis, to associate amino-acids in such a manner that substances are produced which, in the case of the simpler terms, closely resemble peptones, whilst the more complex resemble proteins.

I have termed these synthetic products *polypeptides*, in view of their relationship to the peptones and to facilitate systematic treatment of the group on the lines of the carbohydrates.

No useful purpose will be served by my giving an account of the synthetical methods on the present occasion, especially as I had the honour, six months ago, of describing to you the preparation of an octadecapeptide derived from fifteen molecules of glycine and three molecules of *l*-leucine, a substance which in its external properties closely resembles many natural proteins. I may say that more than one hundred of these artificial polypeptides have already been synthesised.

Many of them, it is true, belong to the lower stages, but all the amino-acids previously mentioned, with the exception of diaminotrihydroxydodecanoic acid, have been made use of in their preparation. The synthesis of the higher terms has been restricted hitherto to the combinations of glycine, alanine, and leucine; there is not a shadow of doubt, however, that all the remaining amino-acids could be associated in complicated systems with the aid of our present methods. The knowledge of the artificial polypeptides thus acquired has opened up new ways of investigating the peptones and albumoses analytically. During more than fifty years, physiological chemists have endeavoured without much success to isolate homogeneous substances from these ill-defined materials; all the products described by them, however, bear indubitable evidence of being mixtures. By making use of new methods based on the study of the polypeptides, it has been possible during the last two years to isolate and detect with certainty quite a number of dipeptides among the decomposition products of the proteins.

In spite of encouraging successes, I am fully aware of the difficulty of discovering the nature of all the components of the various peptones and albumoses; but in preparing the way for the synthesis of the natural proteins this is not even necessary. Probably the work can be restricted to the reconstruction of the original system from the major products of cleavage formed in the process of hydrolytic dissection. I am indeed venturesome enough to cherish the hope that I may be able to solve this problem in the case of silk fibroin, one of the simplest proteins. To deal with the whole of the proteins will be a gigantic task; so large a number of separate investigations will be necessary that nothing less than the life-work of a whole army of inventive and diligent chemists will suffice to complete it. Probably, too, the unpleasant discovery will be made that the natural proteins as we know them to-day are only to be obtained by mixing the homogeneous artificial products.

I have sketched this prospect merely to indicate the manner in which synthesis must play the leading part in this field of work. The nature of the more complicated carbohydrates, as I have already pointed out, will also have to be determined in the future, I imagine, mainly by the application of synthetic methods. Obviously the conditions are very similar in the case of the dextrins and gums to those met with in the case of the proteins, and starch, which has hitherto been regarded as a homogeneous substance, appears also to come into the same category, according to Maquenne's observations.

Not only do the proteins constitute the major part of living protoplasm, but they appear also to be the material from which the organism prepares its most wonderful agents—the ferments or enzymes. In many of the more thoroughly investigated biological processes their cooperation has been demonstrated, and there is good reason to suppose that they take part in all changes occurring within the living cell. So much is certain, the physiological chemistry of the future will be largely concerned with the study of fermentative changes; many indications that this must be the case are to be met with in tracing its latest developments.

The number of the enzymes has been increased to an extraordinary extent during the last ten years. I may allude to the newly discovered enzymes correlated with the carbohydrates: maltase, lactase, mellibase, trehalase, amygdalase, inulase; to the various oxidases: laccase, tyrosinase; to the lipases, erepsin, enterokinase, arginase, the sucroclastic and glucosidoclastic enzymes, and finally to the zymase of alcoholic fermentation. Much valuable information has been accumulated as to the manner in which they act, as to their formation from zymogens, and as to their assistance by co-ferments and their retardation by chemical agents or by anti-ferments. The specific character of their action, in other words, their dependence on the structure and configuration of the object they attack, has been proved beyond doubt, and favours very definitely the assumption that enzyme and hydrolyte enter temporarily into combination, a conclusion to which H. E. Armstrong and E. F. Armstrong have quite recently again very properly directed special attention; but, unfortunately, we know practically nothing of the composition of the enzymes, as the complete isolation of an enzyme has never been accomplished.

From observations hitherto made, it appears in a measure probable that they are derived from proteins and possess a protein-like character. If this be so, it may be hoped that the experience gained with the proteins will be of service in the investigation of enzymes.

In the meantime, there are other directions in which synthetic chemistry can be of service in elucidating the chemistry of fermentation. In the same way that the artificial glucosides have been of use in establishing the dependence of the action of enzymes on configuration, the synthesised polypeptides are now being used by Abderhalden, Euler, and others to define and measure the activity of the proteoclasts. In a like manner, the synthetic exploration of the purine group has served to direct the recent observations on the fermentative de-amination and oxidation of adenine, guanine, and xanthine. Finally, attention may be directed to the use that has been made of stereochemical considerations in the course of Bertrand's interesting studies of the oxidation of polyhydric alcohols by the sorbose bacterium.

Not only have the methods of organic chemistry proved to be fruitful of results in the case of the proteins, but also when applied to complex derivatives of the latter, such as the nucleo-proteins, for example. Thus we are indebted to the brilliant researches of A. Kossel and his school for our knowledge of no less than four bases of the pyrimidine and purine group obtained by breaking down nucleic acids, and the analytical investigation of the latter has already been carried so far that, in the opinion of H. Steudel, it is to be expected that their synthesis will be effected at no distant date. Similar success may be hoped for even sooner in the case of the lecithins. Structural chemistry, moreover, is slowly acquiring the mastery over cholesterin by making use of the experience afforded by the synthetic study of the hydroaromatic substances.

Besides the old well-known constituents of the animal body, new substances having quite unexpected properties have been added from time to time. Such are iodothyrin from the thyroid gland—discovered by Baumann—and crystalline adrenaline—isolated by Takamine from the supra-renal capsule—minute doses of which increase the blood-pressure. Judging from analytical results and the synthesis effected by F. Stolz, adrenaline possesses a relatively simple structure. In the opinion of the discoverers, this is probably true of the "pancreatic secretin" made known by Bayliss and Starling's researches, which has the remarkable property of liberating enzymes from the pancreas. May it not also be true of the toxins of many infectious diseases and of the antitoxins used in serum therapeutics, the discovery and systematic investigation of which by Behring, Roux, P. Ehrlich and others, are to be reckoned among the greatest achievements of modern biology and medicine?

The methods of organic synthesis will certainly serve to throw light on the nature of all such substances of animal origin. Equally numerous problems await solution in the plant world.

The great success with which the alkaloids and terpenes have been studied during the past ten years is known to all, but it is only too obvious that much still remains to be done when such substances as quinine, morphine, and caoutchouc remain to be synthesised.

Alizarin and indigo are prepared artificially in huge quantities, and we are well informed as to the structure of hæmatoxylin and kindred substances; but our ignorance is correspondingly great of most of the blood colouring matters, as well as of many coloured constituents of our own bodies—of the hair, the skin, and the eye.

The fullest recognition must be accorded, however, to recent investigations on the complex colouring matters of the blood and of chlorophyll, which is distantly related to the former, associated with the names of Schunck, Nencki, Marchlewski, Küster, and Willstätter.

In fine, the aid of synthetical chemistry is required in every direction in arriving at a clear understanding of structure and of change. The methods at our disposal in the laboratory are doubtless altogether different from those which come into operation in the living world, but chemists are already trying to effect changes in carbon compounds by means of so-called mild interactions, under conditions comparable with those which prevail in the living organism. It may suffice to refer to the development of a number of catalytic processes and to the comprehensive studies on the action of light on organic substances undertaken by Ciamician. In fact, the effort is already being made to cooperate with biology; it is clear that a section of the forces of organic chemistry is being directed once more towards the goal from which it set out. The separation from biology was necessary during the past century while experimental methods and theories were being elaborated; now that our science is provided with a powerful armoury of analytical and synthetical weapons, chemists can once more renew the alliance both to its own honour and to the advantage of biology. Indeed, the prospect of obtaining a clearer insight into the wondrous series of processes which constitute animal and vegetable life may well lead the two sciences to work with definite purpose to a common end.

In order, as far as possible, to avoid mistakes in this difficult task and to shield ourselves from the disappointment which is the inevitable consequence of exaggerated hopes, we cannot do better than strive to imitate the great example of Faraday, who always, with rare acumen, directed his attention to actual phenomena without allowing himself to be influenced by preconceived opinion, and who in his theoretical conceptions gave expression only to observed facts.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Public Orator, Dr. Sandys, spoke as follows on Thursday, October 17, in presenting for the degree of Doctor in Science *honoris causa* Geheimrath Emil Fischer, F.R.S., professor of chemistry in the University of Berlin:—

Scientiae chemicae professor Berolinensis, purpura nostra (ut videtis) vestitus, ex insperato nobis hodie paulisper affulsit. Novimus tamen quam subtiliter materiam illam investigaverit, quae cum aqua commixta lanam colore roseo pulcherrimo tingit; novimus, via quam admirabili pedetemptim progressus, sacchari genera multa, aut olim nota aut ab ipso patefacta, in elementa sua prima resolverit, atque atomorum de ordine et positura leges novas illustraverit. Peritis saltem nota sunt plurima alia viri huius inventa, quae scientiae intimae ad ipsa penetralia pertinent. Duo vero laboris eius monumenta multorum oculis sunt manifesta atque aperta. Berolinensibus praesertim patet Institutum illud magnum consiliis eius conditum; talium rerum studiosis ubique terrarum patet opus eius eximium sexies saltem in lucem editum. Virum igitur tam insignem et salvere et valere hodie libenter iubemus, qui Faradaii in memoriam orationem inter Londinienses propediem habiturus est, quique, studiorum communium consuetudine nobiscum consociatus, eo artiore nobiscum vinculo coniunctus est, quod filium suum natu maximum Universitati nostrae in scientia chemica erudiendum haud ita pridem commendavit.

Duco ad vos virum in scientia chemica per orbem terrarum totum illustrem, AEMILIUM FISCHER.

On Tuesday, October 15, Mr. A. Henry, the reader in forestry, gave his inaugural lecture before a large audience. The Vice-Chancellor presided. Mr. Henry dwelt upon the causes which had retarded the scientific development of forestry in Great Britain. He then described the various types of forest and their origin, and the several methods of the management of forests. He also described the rapidly approaching depletion of the forests in the United States and northern Europe, and pointed out the necessity of re-afforesting the waste lands of our country. He dwelt at length on the possible introduction of exotic trees, such as the western larch and the Corsican pine. In conclusion, Mr. Henry described the course he purposed to pursue in developing the teaching and research in forestry in the University.

The number of students who have just matriculated is 1099, as compared with 1021 who matriculated in October, 1906. Of these, fifteen are advanced students.

The number of first-year students studying medicine is 130, as compared with 122 last year and 117 in 1905.

Mr. R. P. Gregory has been appointed university lecturer in botany in succession to Mr. Hill, as from Michaelmas, 1907, until Michaelmas, 1912, and Mr. A. M. Smith has been appointed demonstrator in the same subject for the five years ending September 30, 1912.

The general board of studies will shortly proceed to appoint a university lecturer in advanced human anatomy in succession to Dr. Hill. The annual stipend is 50*l*. Candidates are requested to send their applications, with such testimonials as they think fit, to the Vice-Chancellor on or before November 5.

Oxford.—In a Convocation held on October 22, the honorary degree of D.Litt. was conferred upon Prof. E. Meyer, professor of ancient history in the University of Berlin, in recognition of his work on Egyptian hieroglyphs and researches in Egyptian history and chronology, and his general study of history.

The offer of a sum of about 1000*l*. for the foundation of a prize as a memorial of the late Prof. Weldon, and for the encouragement of biometric science, has been accepted by Convocation. The prize is to be awarded every three years for the most noteworthy contribution during the previous six years to biometric science without regard to nationality or sex, biology being interpreted to include zoology, botany, anthropology, sociology, psychology, and medical science.

Mr. A. A. Read has been appointed professor of metallurgy at the University College of South Wales and Monmouthshire.

At University College (University of London) on October 16, the Chadwick medals for municipal hygiene and engineering were presented to Mr. N. G. Dunbar, Mr. W. D. Reynolds, and Mr. J. R. Wade.

The Lord Lieutenant of Ireland will open the new Municipal Technical Institute at Belfast on Wednesday next, October 30. In connection with the opening, a conversazione will be held in the institute on Friday, November 1.

The third annual general meeting of the Association of Teachers in Technical Institutions will be held on November 9, at 3 p.m., in the South-Western Polytechnic, Chelsea, S.W. The annual report of the council will be presented, and other business transacted.

At Bedford College for Women (University of London), Reid fellowships for research have been awarded to Miss Tchaykovsky and to Miss C. Saunders. Dr. W. H. Willcox has resigned the appointment as lecturer in hygiene, and Mr. J. A. H. Brincker has been appointed temporarily to take his place.

The President of the Board of Education, Mr. McKenna, on October 18 laid the memorial stone of a new girls' high school at Gloucester. The cost of the school buildings alone is to be 13,615*l*. Subsequently, Mr. McKenna delivered an address to a large meeting of persons interested in education, and directed attention to a modern tendency in educational administration by which is being realised the American conception of a single type of public school for all classes of the community.

The report read by the principal, Mr. H. B. Knowles, at the distribution of prizes to the students of the Salford Royal Technical Institute on October 18, referred to several points of interest to administrators of technical institutions. Mr. Knowles directed attention to the fact that the Board of Trade requires that a candidate who seeks to qualify as an engineer in the mercantile marine must have served as an apprentice for at least four years. Time spent in a suitable technical school may, however, be accepted as equivalent to artisan service in the ratio of three years in the technical school to two years' artisan service. The Board of Trade has recognised the day mechanical engineering courses at Salford as giving suitable training for this purpose. During last session all applicants for admission to the Salford institute under sixteen years of age were required to give evidence that they possessed a satisfactory preliminary knowledge of English and mathematics, and, failing this, were advised first to attend special courses preparatory to the work of the institute. Sixty per cent. of the applicants for admission were thus rejected. Courses of study are now arranged suitable for persons engaged in the chief industries of the district, based upon attendance at the institute on three evenings per week.

Speaking at Wakefield on October 17 at a public meeting held in connection with the Wakefield Education Guild, Mr. Haldane said that higher education is of great value to those engaged in industrial pursuits, in fact it is of value to the whole nation. Learning for learning's sake is a great text, and it does not shut out the utilitarian side. The profits of industrial enterprise go to the man of brains, to the man with the power of direction. This shows that it is vital to those engaged in industrial enterprises that they should have command of science and as much knowledge as they can get. Unless knowledge is spread among the people there cannot be equality of opportunity. There is only one leveller, only one man who does anything substantial to make people equal, and that is the schoolmaster. Education in this country will never be right until the elementary school, the secondary school, and the university are linked together. The British people perhaps need education more than any other nation. We are very prosperous; we are very self-reliant; we have magnificent energy; if we had not, we should have been distanced in the race. But we are competing against science and the increasing science which science gives. We are being more and more handicapped in the race, and it is our own individual powers that have enabled us still to get to the goal in front of our competitors. Let us learn before science makes still further advances, and before they are appropriated by foreign nations, to bring ourselves at least up to their level.

SOCIETIES AND ACADEMIES.

London.

Entomological Society, March 2.—Mr. C. O. Waterhouse, president, in the chair.—*Exhibits*.—Commander J. J. **Walker**: Living specimens of the heteromerous beetle *Sitaris muralis*, first re-discovered at Oxford in 1903 by Mr. A. H. Hamm on old stone walls in the vicinity of Oxford inhabited by the mason bee, *Podalirius* (*Anthophora*) *pilipes*, on which it is parasitic in its early stages.—G. T. **Porritt**: Black specimens of both sexes of *Fidonia atomaria* from the Harden Moss Moors, Huddersfield, illustrating the melanic tendency of Lepidoptera in the district.—H. St. J. **Donisthorpe**: *Apion semivittatum*, taken at Deal; *Magdalis duplicata* from Nethy Bridge, the first record of the species for Scotland; *Formica sanguinea* from Aviemore and Nethy Bridge, the first record for Scotland; and *Piezostethus formicetorum*, taken with *Formica rufa* at Rannoch, a species not recorded since 1874.—A. H. **Jones**: A case of butterflies taken this year from Herculesbad, South Hungary, including specimens of *Erebia melas* from the Domogled, which bore a remarkable resemblance to *Erebia alecto*, var. *nicholli*, Oberth., from Campiglio, and *Erebia lefebvrei*, Oberth., also shown for comparison by Mr. H. Rowland-Brown. Mr. Jones also exhibited examples of *Chrysophanus dispar*, var. *rutilus*, and *C. alciphron*, from the neighbourhood of Budapest, both species of great size and brilliant colouring.—Dr. F. A. **Dixey**: Specimens from Uganda of the African Pierine genus Mylothris, showing an almost complete gradation between *Mylothris chloris*. Fabr., and *M. agathina*, Cram.—M. **Jacoby**: Several fine forms of the ab. *ceronus* of *L. bellargus* taken this autumn at Folkestone, and one example of the ab. *cinnides*, Stgr.—Norman **Joy**: A specimen of the rare beetle, *Cryptophagus subdepressus*, Gyll., taken near Garva, Ross, on August 4 last.—W. J. **Lucas**: Two specimens of *Deilephila euphorbiae* bred by Mr. Nicholson and Mr. Summers from larvæ found in Kew Gardens. Mr. Lucas also exhibited several examples of predaceous insects with their prey *in situ*.—H. M. **Edelsten**: Specimens of *Sesia andraeniformis*, bred from pupæ taken in Bedfordshire and Kent, and ova of *Nonagria cannae*, giving an account of its remarkable methods of oviposition.—A. **Harrison** and H. **Main**: Four broods from females of *Pieris napi*, var. *bryoniae*, captured on the Kleine Scheidegg Pass, Switzerland, in July, 1906, showing a wide range of variation.—Prof. T. Hudson **Beare**: A specimen of the rare bug *Lygaeus equestris*, Linn., from St. Margaret's Bay, also specimens of *Hypera tigrina*, Boh., taken in some numbers on the wild carrot at the same locality, and *Apion semivittatum*, Gyll., off plants of *Mercurialis annua*, all taken during the same period at St. Margaret's Bay.—*Papers*.—The species of Hesperidæ from the Indo-Malayan and African regions, described by Herr Plotz, with some new species: Colonel Charles **Swinhoe**.—The butterflies of Mauritius and Bourbon: Lieut.-Colonel Neville **Manders**.—The hibernating habit of the lepidopterous genus Marasmarcha: Dr. T. A. **Chapman**.

PARIS.

Academy of Sciences, October 14.—M. A. Chauveau in the chair.—The transits of Mercury across the sun, and, in particular, on that of November 14 next: G. **Bigourdan**. A review of the various phenomena regarding which further information is desirable, including the visibility of the planet outside the sun, the external and internal contacts, the appearance of the horns and the measurement of their distance.—The summation of Laurent's series: A. **Buhl**.—The invariants of differential systems: Étienne **Delassus**.—A theorem on integral equations: Tommaso **Boggio**.—The analysis of mixtures of air and gas or combustible vapours: Jean **Meunier**.—A new improvement allowing of the rapid detection and estimation of methane: Nestor **Gréhant**.—The reactions in the nickel-plating bath: A. **Brochet**. The causes of the favourable effect of the addition of boric acid to the bath are discussed, and also some peculiarities of the way the anode is attacked.—A vinyl alcohol of the type ArR : C : CH.OH: MM. **Tiffeneau** and **Daufresne**. The substance described in a previous note as anisylcyclopropanol has been found to be methylanisylethenol, $(CH_3O).C_6H_4—C(CH_3) : CH.OH$, the first alcohol of this type to be isolated.—A caoutchouc tree at Tonkin: MM. **Dubard** and **Eberhardt**. The principal characters of the tree are given in detail, and prove that it is a new species of the genus Bleekrodea, and is named *Bleekrodea tonkinensis*. This tree is of great economic interest, as it is the first caoutchouc-bearing tree found in Indo-China. It is abundant, and the rubber produced from it is of the highest quality.—The reception of the light stimulus in the compound eyes of insects, particularly the Muscidæ: P. **Vigier**.—The evolution of the carbon, water, and ash as a function of the age in plants: J. **Tribot**.—The psychophysical law; applications to energetics and photometry: Charles **Henry**.

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), contains the following memoirs communicated to the society:—

March 9.—Determination of absolute values of magnetisation numbers, especially for crystals: W. **Voigt** and S. **Kinoshita**.—Determination of the elastic constants of aragonite: W. **Voigt**.—Interpolation by means of exponential functions: H. **Burkhardt**.—Some properties of the radium atom: E. **Riecke**.

May 11.—Peculiar cases of vibrating membranes: W. **Voigt**.—The influence of internal reflexions on the interference phenomena in doubly refracting crystal plates: H. **Joachim**.

June 8.—The most general concept of the plane continuous curve (second paper): A. **Schoenflies**.—Vibrations of non-uniformly stretched membranes: W. **Voigt**.

July 20.—The so-called general energy equations of the technical theory of rigidity: J. **Weingarten**.

July 27.—Four new letters of Gauss: P. **Stäckel**.

The business communications, part i. for 1907, of the same society include reports on the progress of the publication of Gauss's works and on the Samoa Observatory, together with a memorial discourse on Ludwig Boltzmann, by W. **Voigt**.

DIARY OF SOCIETIES.

THURSDAY, OCTOBER 24.

CHEMICAL SOCIETY, at 8.30.—The Constitution of Phenol- and Quinol-phthalein Salts: a Contribution to the Quinonoid Theory of Colour: A. G. Green and P. E. King.—Poly-ketides: J. N. Collie.—Production of Orcinol Compounds by the Action of Heat on the Sodium Salt of Ethylacetoacetate: J. N. Collie and E. R. Chrystall.—A Simple Gas Generator for Analytical Operations: J. M. Sanders.—Some Double Ferrocyanides of Calcium, Potassium and Ammonium: J. Campbell Brown.—Halogen Determination in Organic Substances: J. Moir.—Racemisation by Alkalis as applied to the Resolution of *r*-Mandelic Acid into its Optically Active Isomerides: A. McKenzie and H. A. Müller.—The Optical Activity of Cyclic Ammonium Compounds: F. Buckney and H. O. Jones.—Keten. A New Anhydride of Acetic Acid: N. T. M. Wilsmore.—The Action of Phosphorus Pentachloride on Hydroxy-trimethyl Succinic Ester. 1 : 2-Dimethyl Trimethylene 1 : 2-Dicarboxylic Acid: H. Henstock and B. E. Woolley.

FRIDAY, OCTOBER 25.

PHYSICAL SOCIETY, at 5.—On the use of Variable Mutual Inductances: A. Campbell.—On Magnetic Oscillators as Radiators in Wireless Telegraphy: Dr. J. A. Fleming.

TUESDAY, OCTOBER 29.

FARADAY SOCIETY, at 8.—On the Electrolysis of Salt Solutions in Liquefied Sulphur Dioxide at Low Temperatures: Dr. B. D. Steele.—Note on the Action of Aluminium Powder on Silica and Boric Anhydride: F. E. Weston and H. R. Ellis.—Reduction of Metallic Oxides by Means of Calcium Hydride: Dr. F. Mollwo Perkin and Lionel Pratt.—A Series-Parallel Lamp Resistance Useful for Electrochemical Work: N. T. M. Wilsmore.

CONTENTS.

THURSDAY, OCTOBER 31, 1907.

THE THEORY OF FUNCTIONS OF A REAL VARIABLE.

The Theory of Functions of a Real Variable and the Theory of Fourier's Series. By Dr. E. W. Hobson, F.R.S. Pp. xvi+772. (Cambridge: University Press, 1907.) Price 21*s.* net.

IT is impossible to read Dr. Hobson's book without reflecting on the marvellous change that has come over Cambridge mathematics in the last twenty years. Twenty years ago Cambridge mathematics was a thing standing by itself, and with its own virtues and defects. Pure mathematics in Cambridge meant Cayley and a few disciples; and Cayley (widely as he read) owed little or nothing to anyone but himself. Certainly he never appreciated the most fundamental ideas of modern Continental analysis. It is probable that he could not have defined a function or a limit in a way which would have satisfied Weierstrass or Dr. Hobson: it is certain that he would have been as incapable as any Senior Wrangler of proving any of the less obvious theorems of convergence. The first signs of the absorption of these ideas are to be found, not in Cayley, but in Stokes.

Now Cambridge has fallen into line. There are no Cayleys, perhaps, but there is quite a flourishing school of pure mathematics, working by what may be called German methods and on German lines, and making up in numbers and soundness for anything that it has lost in distinction. The school of Cayley is dead, and so (what is perhaps even more to be regretted) is the old Cambridge school of applied mathematics: pure mathematics and experiment have combined to kill it, and the Stokes Lecturer in Applied Mathematics writes books like this. We wonder what Clerk Maxwell or even Stokes himself would have thought of it.

However, all this is not Dr. Hobson's fault, and we must not blame him if the reflections which it inspires are not altogether pleasant. And we hasten to congratulate him on the completion of what is, without a doubt, a magnificent piece of work. It would be a fine piece of work even if were a mere compilation; for the subject is one of which there was no systematic account in English, and which no previous English writer had ever really mastered. But the book is far from being a compilation, for Dr. Hobson has made the subject his own, and writes with the air of mastery that only original work can give: and even in French, German, or Italian, there is no book which covers anything like the same ground. Dini (whom Dr. Hobson has obviously taken as his model) has held the field for a long time, and Dr. Hobson can fairly claim to have superseded him.

In taking Dini as his model, Dr. Hobson has made the "theoretically general," rather than what Borel has called the "practically general," his goal. No doubt he had to make his choice, but we must confess that he seems to us to have gone too far. Let us consider his treatment of "double limit problems," for example, problems such as those of the differentiation or integration of an infinite series or an infinite integral (why will he persist in making the uninitiated scoff by his fondness for the word "improper"?). Such problems may be approached from two different points of view. We may ask, "What is absolutely the most general form in which we can state our theorems, when we utilise all the most modern theories of sets of points, Lebesgue integrals, and the like?" This is the point of view of Dini and Dr. Hobson. On the other hand, we may ask, "In what special forms do these problems naturally occur in analysis? What are *the really important cases?* Can we state our theorems in such a way that writers on applied mathematics, or other branches of pure mathematics, when they are confronted, as they continually are, with particular problems of this kind in all conscience difficult enough, will be able to turn to us for a solution of their difficulties?" These questions must be continually before us, if we are aiming at Borel's "practically general" completeness, and even an author who has decided to aim at the other ideal will do well to keep them clearly in sight; and we wish that Dr. Hobson had more often adopted this point of view. He might then have made his book a good deal more useful and attractive for the ordinary worker in the fields of analysis. The latter, as it is, is likely to find himself faced by many theoretical difficulties to which he will not easily find an answer in Dr. Hobson's pages. However, it is perhaps as well that Dr. Hobson should leave something for someone else to do.

But it is time that we said a little of the details of the book. It is needless to say that it is beautifully and almost faultlessly printed. It is a pity, though, that the chapters are so long. Long chapters do not make a difficult book easier to read, nor do they make it easier for the author to arrive at the proper logical arrangement of the subject-matter—as appears very clearly in chapters v. and vi., which had much better have been broken up into half a dozen shorter chapters. We should like to have seen a great many more examples. Summaries of the chapters, too, would have been useful; and the author is too sober in his use of different kinds of type. In a word, he shows too great a contempt for the arts of popularity.

There are seven chapters in all. For the first three, which are of a particularly abstract character, we have practically nothing but praise. The matter is admirably selected and admirably arranged, and Dr. Hobson writes with a lucidity and distinction rare indeed among mathematicians. Nothing could be better in its way, for example, than his terse criticism of the "formal" view of mathematics (pp. 9–10). We cannot entirely agree with the conclusions at which he arrives in the course of the critical discussions of chapter iii, but we can appreciate the clear and temperate manner of his criticisms, advanced, as he says, "with some diffidence, on account of the great logical difficulties of the subject," and in the hope that "they may be of utility as a contribution towards the discussion of questions of great interest which at the present time, cannot be regarded as having been decisively settled."

In chapter iv. we begin for the first time to be bored in places. The four derivatives of a function *are* dull, and no one will ever make them seem anything else; and a good deal of Brodén's work is much more solid than inspiring. Occasionally we do not quite like Dr. Hobson's choice of words—in particular we may instance his use of "indefinitely great," in such phrases as "has indefinitely great values," "the functional value is regarded as indefinitely great," "the lower limit is indefinitely great." Why not, in the last case, simply "there is no lower limit"? Dr. Hobson could reply that he has expressly warned the reader against any such confusion of thought as is sometimes implied in modes of expression such as these; and there is certainly none in his own mind. None the less we wish that he had expressed himself in a different manner.

In this chapter, let us single out for special praise the sections on double and repeated limits (pp. 303 *et seq.*). We particularly like the author's generalisation of the definition of a repeated limit, which enables him to simplify the statements of a number of theorems. We have already said that we do not altogether like the arrangement of the next two chapters. Surely it would have been better to introduce the notion of a series at an earlier stage. As it is, some of the theorems concerning integrals are separated from one another in a rather irritating way. But most of the discussions of particular theorems are admirable. We may mention especially the treatment of the "absolutely convergent improper integral" (pp. 364 *et seq.*), the sections on the transformation of double integrals (pp. 445 *et seq.*), and the account of Baire's theory of the representation of functions (pp. 522 *et seq.*). A few criticisms of details suggest themselves. Is it worth while to define "principal values" if nothing more is to be said about them? There is a curious slip on p. 454, l. 14; obviously the condition stated is not *necessary*: and it is very odd that Dr. Hobson should define *divergence* and *oscillation* in such a way that $1-2+3-4+\ldots$ is a divergent rather than an oscillating series. The last word has not yet been said about Weierstrass's non-differentiable function (pp. 620 *et seq.*). What about $\Sigma a^n \cos b^n x$, where ab is only a little greater than 1? One would expect the function to have no differential coefficient whenever $ab \geqq 1$; but no one seems to have found out whether this is the case or not.

Finally, chapter vii. (Fourier's Series) shows Dr. Hobson quite at his best. The last part, in which he supplies a final touch of rigour to some of Riemann's work, is extremely difficult, but that was inevitable. The remark at the foot of p. 647 is open to dispute. Was not something very much like the theorem, ascribed to Lerch on p. 727, also proved by Stokes? On p. 732, l. 24, for "diminished" read "increased."

A short appendix contains some further critical remarks, in addition to chapter iii. We wish that there had been space for a summary of König's rather watery theories, and the author's neat and convincing reply in the London Mathematical Society's Proceedings. We must confess to a strong temptation to argue with Dr. Hobson concerning the remarks at the top of p. 765, but the temptation must be resisted.

Dr. Hobson has attempted an appalling task. There is no region of pure mathematics (unless it be the theory of numbers) which is quite so difficult as this; certainly none of which the literature is so scattered and so difficult to collate, or in which the writing of a big book requires a greater combination of drudgery and critical insight. All things considered, he has succeeded wonderfully. We can think of no one else who would have done half as well. G. H. H.

LIEBIG AND GÜSSEFELD.

Justus von Liebig und Emil Louis Ferdinand Güssefeld. Briefwechsel: 1862–1866. Herausgegeben von Dr. O. E. Güssefeld. Pp. viii+72. (Leipzig: Johann Ambrosius Barth, 1907.) Price 3 marks.

THIS little book has a twofold interest. To the scientific agriculturist it is interesting as elucidating the history of the introduction of the modern methods of agriculture into Germany, and especially of the introduction of the so-called chemical fertilisers, due largely to the teaching and influence of Liebig; it serves also to throw some sidelights upon the character and habits of Liebig himself, and is therefore of interest to the historian of chemistry. It consists simply of a collection of thirty-eight letters which passed between Liebig and Emil Güssefeld from 1862 to 1866, twenty-two of which are contributed by Liebig, and the whole has been arranged for publication, with explanatory notes and annotations, by the pious care of the son of one of the correspondents.

Emil Güssefeld was a Hamburg merchant, of the conventional type, dealing mainly in coffee and other colonial products. In a fortunate hour he accepted an agency from an American company for the sale in Germany of guano from Baker Island, in the Pacific Ocean, and thereby laid the foundations of a prosperous business in phosphatic manures. Emil Güssefeld indeed stands to Germany in much the same relation that the late Sir John Bennett Lawes stands to this country, and both reaped fame and fortune by the far-sighted enterprise which induced them to give practical effect to the theoretical views of Liebig. As a prudent man, Güssefeld, before undertaking the agency, seems to have consulted Liebig as to the probability that the Baker guano, of the merits of which he was well assured, would find a ready sale among a body of agriculturists who are even more conservative than our own, and Liebig's reply constitutes the first letter in the series. It is in every respect worthy of him—sound, thoughtful, and considerate, and with that note of cautious optimism which the eminently practical mind of the Hamburg merchant could not fail to appreciate. Liebig, as this correspondence abundantly testifies, never spared himself when his interest was aroused, and he was ever ready to give of his best, without fee or thought of reward, when the object commended itself to him. In this large-hearted liberality Liebig resembled Davy, who nearly half a century previously had striven in the same self-sacrificing way to infuse something of the scientific spirit into the oldest of the arts. Liebig's letters are rich in practical advice, business hints, analytical information

—all given with no other thought than of doing what in him lay to further the true interests of agriculture. How greatly Güssefeld benefited by his wise counsel, and what material advantages he gained from Liebig's altruistic interest in the development of the industry of which he was a pioneer in Germany, Güssefeld's letters clearly indicate. His letters, too, indicate his sense of gratitude. He repeatedly pressed upon his distinguished correspondent his earnest desire to make some substantial recompense, but Liebig declined to entertain any thought of pecuniary reward. All Güssefeld could do was to appeal to one of the most characteristic of Liebig's frailties. He was, to quote Dr. O. E. Güssefeld, a "leidenschaftlicher Raucher und wollte schwere und nur gute Zigarren haben." These, we are told, are particularly easy to obtain in Hamburg; and we are assured by Liebig that Güssefeld sent him of the best the city could furnish, and kept him well supplied. There is much virtue in a good cigar; how much German agriculture owes to it may be plainly discerned in this interesting correspondence.

T. E. T.

BOTANICAL WORKS.

(1) *Botanisches Jahrbuch.* Edited by Dr. A. Engler. Vols. xxxvi to xxxix. (Leipzig: W. Engelmann, 1905–7.)

(2) *Das Pflanzenreich.* Edited by Dr. A. Engler. Vols. xxii to xxvi, xxvii and xxix. (Leipzig: W. Engelmann, 1905–7.)

(3) *Recueil de l'Institut botanique.* Edited by Dr. L. Errera and Dr. J. Massart. Vols. i, ii, and vi. (Bruxelles: H. Lamertin, 1906.)

(1) ENGLER'S "Botanisches Jahrbuch" serves mainly as a repository for information on systematic botany and plant geography. The issue is peculiar, as usually three or four volumes are in progress simultaneously, but the irregular appearance of the parts serves to ensure rapid publication of papers containing new identifications. Vol. xxxvi was begun and completed in 1905, but the three succeeding volumes form a simultaneous triad that date from September, 1905, to March, 1907. Throughout the four volumes there are only four instalments of the "Beiträge zur Flora von Afrika," in which special interest attaches to the Orchidaceæ and Asclepiadaceæ mostly collected and described by Mr. R. Schlechter, two new genera of the Podostemonaceæ founded by Dr. A. Engler, the collation of the Combretaceæ by Dr. L. Diels, and the list compiled by Dr. F. Pax of plants collected by Mr. F. Rosen in Abyssinia. Another monograph of a similar nature is concerned with the plants collected by Dr. A. Weberbauer on a tour of exploration over the highlands of Peru, of which a brief outline was given in vol. xxxii, and a map with the two first instalments of determinations prepared by various workers under the editorship of Prof. I. Urban appears in vol. xxxvii. Dr. Weberbauer also contributes two short articles that may be regarded as preparatory to a volume for the series "Die Vegetation der Erde."

The subject of insular floras is enriched by several papers. To a phytogeographical account of New Caledonia, Mr. R. Schlechter has added a systematic account of the flora, and Dr. E. Lemmermann has compiled a list of algæ collected in the Chatham Islands.

Among the summaries representing recent work on individual orders and genera, a general comparative account of the Cornaceæ is presented by Mr. W. Wangerin. The review of the order Valerianaceæ by Dr. P. Graebner affords an indication of a more elaborate commentary to appear in a future volume of the "Pflanzenreich." The genus Anemone forms the subject of a monograph by Dr. E. Ulbrich.

Two papers of more universal interest are provided in the accounts of myrmecophilous plants by Mr. E. Ule and Mr. H. v. Ihering. The symbiotic hypothesis, as well as the view that the hollow spaces in the stems are the result of natural selection, are refuted. The biology of tropical flowers and fruits is discussed by Prof. H. Winkler, and an ecological study of the vegetation on some newly-formed islands in a Swedish lake is described by Mr. S. Birger.

(2) "Das Pflanzenreich" has attained to twenty-nine volumes, of which eight have been published since November, 1905. The volume on the Primulaceæ has been prepared by Prof. F. Pax and Dr. R. Knuth. The genus Primula is remarkable, both for the beauty of the flowers and its wide distribution. From the map provided it will be seen that centres of distribution occur in Switzerland and in the Himalayas, but the richest source lies in western China. Dr. A. K. Schindler has contributed the monograph on the Halorrhagaceæ, from which he excludes the genus Hippuris. Dr. Fr. Buchenau has summarised the fruits of his researches in the volume on the Juncaceæ. The anatomy of the leaves, the germination of the seedlings, and the numerous hybrids are important features of the order. Prof. L. Diels is responsible for the Droseraceæ, that show many interesting characters in anatomy, regeneration, and growth forms. In dealing with the Polemoniaceæ, Dr. A. Brand pays special attention to the work of American botanists. The latest volume by Mr. O. E. Schulz is concerned with the Erythroxylaceæ.

(3) The papers collected in these volumes of the "Recueil de l'Institut botanique" of Brussels constitute a scientific memorial to the late Prof. Errera, as they represent research carried out by him or inspired by his influence. The first volume contains several papers by Prof. Errera on glycogen in plants, and contributions on the same subject by Dr. E. Laurent and Mr. G. Clautriau. In the second volume is published a series of papers dealing with the cycle of nitrogen compounds, including those by Dr. E. Laurent on the reduction of nitrates, and Mr. E. Marchal's account of ammonia formation in the soil by bacteria. Another important collection of papers relates to alkaloids and proteid substances. This series begins with the paper on the localisation and significance of alkaloids in plants, written by Prof. Errera in conjunction with Dr. Maistriau and Mr. G. Clautriau. The next three volumes are reserved for papers published before the year 1903. The sixth

volume, edited by Dr. J. Massart, opens with a contribution by him on the subject of irritability in the higher plants. It also contains the instructive essay by Prof. Errera on the primrose, an account by Miss J. Wéry on the attraction of bees by flowers, and an investigation carried out by Dr. A. Jacquemin on the localisation of alkaloids in the Leguminosæ.

OUR BOOK SHELF.

Les Observatoires astronomiques et les Astronomes. By P. Stroobant, J. Delvosal, H. Philippot, E. Delporte, and E. Merlin. Pp. vi+317; with one chart. (Brussels: M. Hayez, 112 Rue de Louvain, 1907.)

IN collecting and publishing the information contained in this volume, Prof. Stroobant and his collaborators have rendered a service of inestimable value to all interested in astronomy. The purpose of the publication is to permit astronomers of every class to learn readily what is being done in their own line of work, and by whom and where it is being done, and the arrangement of the matter makes this a very simple task.

In the main list all the known observatories are arranged in alphabetical order, and for each one is given the country wherein it is situated, its latitude, longitude, and altitude, the nature and titles of any publication it issues, the names of the director and staff, and, finally, a brief *résumé* of the observatory's history, instruments, and work.

This is followed by a list of astronomical societies arranged in the order of their foundation, a brief statement of particulars concerning each society, such as its meeting place, subscription, number of members, titles of its publications, &c., being given. The chief astronomical reviews are then similarly treated.

An alphabetical list of some 1500 names of individual astronomers gives page references to the list of observatories, which enables one to refer immediately to any person named, and find at once his specialities and resources. Then follow a geographical list of all the places referred to, and a list of the astronomical societies and publications of each country.

The work concludes with a chart of the world, on which the distribution of observatories is shown, and which should be consulted by those who are desirous of founding new observatories. Whilst western Europe and the eastern States of the U.S.A. are thickly dotted with observatories, only seven are shown in the whole of Africa. The southern hemisphere and the torrid zone are remarkably deficient in this respect.

The whole of the work of compilation and publication has been done by the Comité de bibliographie et d'études astronomiques of the Royal Observatory of Belgium. Their names appear on the title page, and they are to be heartily congratulated upon the efficiency and expedition with which they have performed their self-imposed task.

Lese- und Lehrbuch für ländlich-gewerbliche Fortbildungsschulen. By H. Gehrig, Dr. A. Helmkampf, Dr. Th. Krausbauer, and Fr. Stillcke. Pp. vii+343. (Berlin: B. G. Teubner.) Price 2 marks.

IN Germany, as in England and other industrial countries, there is a growing difficulty in keeping country lads in the country, and attempts are being made to stimulate interest in rural matters by giving definite agricultural instruction in certain of the schools.

The present volume is intended for the Fortbildungsschulen, continuation schools at which attendance is compulsory for two or three years after leaving the elementary school. Like other readers in use at these schools, it contains literary and patriotic sections in addition to the purely technical matter. The book opens with a few poems and short prose pieces in praise of a country life, and exalting the husbandman's calling; towards the end comes the section headed "Deutschland über alles," describing some of the glories of the Fatherland.

The technical part covers a very wide range. Some of the readings deal with economic questions, cooperative societies and banks, liquidation of mortgages, the legal position of the workman with regard to holidays, taxes, &c. Others are hygienic, and give rules for bathing, advice about fresh air and tuberculosis, and first aid to the injured. The purely agricultural part occupies about a quarter of the volume, and is distinctly practical. Useful hints on the management of farm stock are given, together with general accounts of soils, crops and manures. There is also a collection of proverbs dealing with husbandry that will help the pupil fix in his mind the instruction he has received. So far the book is very good, both in conception and in execution. But we are not quite clear why the authors should have attempted accounts of apparently extraneous matters like the metallurgy of copper and steel, the theory of the microscope and of the dynamo. The treatment is necessarily vague and general, and the space might well have been utilised for a fuller development of things falling clearly within the scope of the book.

However, a good deal will depend on the teacher. If he is an enthusiastic countryman he will find the book very useful; if not, it may prove rather dull. Whether a reader of this sort will really attract boys to agriculture remains to be seen; the result of the experiment will be watched with great interest by those in this country who are trying to solve the same problem. E. J. R.

La Houille verte. By Henri Bresson. Pp. xxii+278. (Paris: H. Dunod et E. Pinat, 1906.)

THE title of this work, if literally translated, signifies "green coal," and a word of explanation is necessary as to what this combination of words implies. The word "houille" in this sense is intended to convey the idea of energy, more particularly that due to waterfalls and rivers, and the qualifying adjective "verte," as opposed to "blanche," indicates that the sources of the energy are the rivers and watercourses to the exclusion of snow- and glacial-fed torrents.

A book with such a title might be an engineering work or a statistical record; in the present case the latter is the more correct description. Throughout the volume the scientific information is scanty and very elementary. A large part is taken up with a chronicle of the utilisation of water power in the various departments of France; this part comprises 127 pages out of a total of 278. The first half is devoted to "Généralités et Theories," but it must be confessed that the theories are not very serious, and that the generalities are the more prominent.

A large quantity of statistical information is contained in the last fifteen or twenty pages, in which several tables are given showing the volumes of the various rivers and the numbers of hydro-electric installations. These tables will probably be of more interest to the serious student of the subject than all the rest of the book.

The illustrations are fairly numerous, and consist chiefly of landscape scenes; they help to make the book appear lighter, but hardly serve any other purpose.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Transit of Mercury across the Sun's Disc, November 13-14, 1907.

PREMISING that the times given on p. 451 of the Nautical Almanac for 1907 are the Greenwich mean astronomical times of the several contacts in the above transit as seen from the centre of the earth, it may be useful to the readers of NATURE to record the corresponding Greenwich mean astronomical times of the contacts as seen from Greenwich. These times are deduced by the formulæ printed on the above-mentioned page of the Nautical Almanac:—

		d.	h.	m.	s.
External contact at ingress ...	November	13	22	23	24
Internal contact at ingress ...	,,	13	22	26	1
Internal contact at egress ...	,,	14	1	48	10
External contact at egress ...	,,	14	1	50	50

Angle from north point of sun of contact at ingress, 62°; angle from north point of sun of contact at egress, 345°; measured towards the east in both cases.

A. M. W. DOWNING.

H.M. Nautical Almanac Office, October 26.

Origin of Radium.

IN a letter to NATURE (June 6) I gave the experimental evidence which led me to conclude that in ordinary actinium preparations a new substance was present which was slowly transformed into radium. By a chemical method this substance was separated from actinium, and a solution of the latter was obtained which showed no appreciable growth of radium over a period of eighty days. Observations on this solution have been continued over a total period of 240 days, and there is still no detectable increase in the quantity of radium. The growth of radium, if it occurs at all, is certainly less than 1/500 of that observed in other experiments.

In two recent letters to NATURE (September 26 and October 10) Dr. Boltwood has given the results of his later experiments in this direction. He has confirmed my conclusions, and has, in addition, been successful in devising a satisfactory method of separating this new substance from actinium, and has examined its radio-active and chemical properties. He suggests that the name "ionium" be given to this new body, which is probably the immediate parent of radium. Dr. Boltwood is to be congratulated for his admirable work on this very difficult problem, for, apart from the chemical operations, the radio-active analysis required for correct deduction is unusually complicated and difficult.

Dr. Boltwood has not been able to separate the parent of radium from actinium by the reagent employed by me, viz. ammonium sulphide, but has found the use of sodium thiosulphate effective. In explanation of this discrepancy, he suggests that I employed old ammonium sulphide. As a matter of fact, I did not use the ordinary laboratory solution of ammonium sulphide, but added ammonia to the actinium solution, and then saturated it with sulphuretted hydrogen. The complete separation effected in my experiment was, I think, probably due to an accidental production of finely divided sulphur in the solution.

In a letter to NATURE of last week, Mr. N. R. Campbell raised objections to the name "ionium" given by Dr. Boltwood to the new body, from the point of view that every radio-active substance should be given a name to indicate its position in the scheme of radio-active changes. This system is very excellent in theory, but I have found it extremely difficult to carry out in practice. The continual discovery of new products in very awkward positions in the radio-active series has made any simple permanent system of nomenclature impossible. Besides uranium and thorium, twenty-four distinct radio-active substances are now known to exist in radio-active minerals. The number of products still to be discovered is, I think, nearly exhausted. When there is a general consensus of opinion that this is the case, I feel it will be very desirable for physicists and chemists to meet together in order to revise the whole system of nomenclature. There is not much to be gained in doing so immediately, as the discovery of a new product in the midst of a series would entail the alteration of the names of a possible half-dozen others which follow it. At the same time, I think it will be desirable to retain a distinctive name for those radio-active substances which, like radium, have a long enough life to be separated in sufficient quantity for an examination of properties by the ordinary chemical and physical methods. It is probable that the parent of radium fulfils these conditions, and should thus have a distinctive name like radium.

Personally, I do not much like the name "ionium," but for similar reasons neither do I care for the name "actinium." It is not easy to suggest a name that is at once simple and explanatory. I have for some time thought that possibly "paradium" or "picradium" might be suitable for the new substance. The former name suggests that it is the parent of radium, but I recognise that a possible play on words may make it unsuitable. The name uranium A, suggested by Mr. Campbell, in itself innocuous, is open to the objection that in the case of radium, thorium, and actinium the suffix A is applied to the first product of the disintegration of the respective emanations, while no such emanation has been observed in the initial series of changes of uranium.

E. RUTHERFORD.

The Nature of X-rays.

IN a paper published in the October number of the *Philosophical Magazine* (pp. 429–449), Prof. Bragg, after discussing the properties of various electric radiations, arrives at the conclusion that although a beam of X-rays contains some ether pulses, these may not after all constitute the bulk of Röntgen radiation. In place of the usually accepted theory, he proposes the hypothesis that these rays consist mainly of "neutral pairs" (consisting of a positive and a negative particle) each revolving in a plane containing its direction of translatory motion. This, he considers, affords an easier explanation of the properties of the rays, and is not improbable *a priori*.

I do not intend to discuss more than one point here, for it seems to me that the record of a simple experiment is of more value in deciding between the two hypotheses than a series of comparisons or discussion of probabilities possibly could be.

To explain the phenomena of secondary radiation from light atoms, he supposes that a "pair" striking a light and yielding atom does not suffer disarrangement, but may be returned unchanged and constitute a scattered ray. He also supposes that it is liable to be taken up only by an atom revolving in the same plane as itself, and that if ejected again the subsequent rotation and translation will continue to take place in the one plane. The secondary radiation in a direction perpendicular to that of propagation of the primary will then consist of pairs rotating in the plane of the primary and secondary propagations, and the tertiary will therefore be strongest when in the same plane, thus explaining the polarisation effect.

It is important to notice that this theory can only account for the amount of polarisation which I found to exist in a secondary beam from carbon (Proc. Royal Soc., A, vol. lxxvii., 1906), if the assumed relation between the plane of rotation and direction of propagation is an accurate one.

Now it can easily be shown that, according to the ether pulse theory, when an unpolarised X-ray beam is incident on a substance of low atomic weight, such as carbon, the intensity of secondary radiation is at a minimum in a direction perpendicular to that of propagation of the primary beam, and a maximum in, or opposite to, that direction.

On the neutral pair hypothesis, if we only assume that the chance of ejection from an atom is equal in all directions in the plane of rotation, it may as simply be shown that the directions of minimum and maximum intensity are the same as on the previous hypothesis; but whereas on the ether pulse theory the intensity of the secondary rays in the direction of propagation of the primary is double that in a direction at right angles, on the "neutral pair" hypothesis it varies as the cosecant of the angle which the direction of propagation of the secondary makes with that of the primary, becoming infinite along the direction of propagation of the primary. In other words, the intensity of secondary radiation varies as the density of the lines of longitude (or as the secant of the latitude) on a sphere with the secondary radiating mass at its centre, the direction of primary propagation being along the axis.

I have made experiments to test the two hypotheses, using an electroscope to compare the intensities of secondary radiation as nearly as possible in these two directions. Taking into account the finite section of the beams and consequent obliquity of the rays, the ratios on the two hypotheses would be roughly 1·9 : 1 and 8 : 1, assuming perfect scattering and neglecting the effect of tertiary rays in the first case and assuming the plane of rotation to contain accurately the direction of propagation in the second. If the assumption is only approximately correct in either case, the ratio will be somewhat reduced. It is evident that great accuracy in the experiments was not essential. They, however, leave no doubt as to the conclusion, for the ratio of intensities was roughly 1·6 : 1—one that might be expected on the ether pulse theory, and appears impossible on the other. It is possible that with suitable primary rays and thickness of secondary radiator, results showing more perfect scattering will be obtained.

These preliminary experiments, however, to my mind furnish quite conclusive evidence in favour of the ether pulse theory. CHARLES G. BARKLA.

University of Liverpool, October 26.

On Correlation and the Methods of Modern Statistics.

I do not know that much profit is likely to arise from continuing this discussion further; it appears to me to be merely unwrapping considerable convolutions in Mr. Hinks's mental attitude towards Miss Gibson and myself. The chief charge made at the British Association was that we had overlooked a curved regression line between magnitude and parallax—that now appears to have disappeared into limbo. In his first letter to NATURE Mr. Hinks apparently objected to our finding "a quite significant and important" relation between parallax and proper motion, but one not more than half-way up the correlation scale. He has now discovered that "the point of most general interest" is that of colour. He charged us with stating a far-reaching suggestion on the basis of the Cape stars. It turns out now that the element in our far-reaching suggestion is not the *suggestion* at all, but what I am prepared to assert as a fact, namely, that the magnitude of the stars "is not mainly determined by parallax or distance, but is more closely associated with colour, and thus probably with chemical or physical condition." The colour and magnitude correlation is essentially that determined by Miss Gibson, 0·3; the values for the spectral class and magnitude correlations run up according to the classification used to double this value, and even to 0·7. The colour and spectral class correlations reach, as we might expect, a still higher value. Meanwhile, the magnitude and parallax relation in its best determination is 0·28. I agree with Mr. Hinks that this is a point of "general interest," and I am glad that his last letter enables me to assert it, not as "the vaguest of suggestions," which words had reference to the discontinuity of frequency in star counts, but as a fact which may be slightly modified when more data are reduced, but is substantially correct as I have given it.

KARL PEARSON.

The Interpretation of Mendelian Phenomena.

I AM sorry Mr. Lock should mistake what I devoutly hope is a sense of proportion for a desire to belittle Mendelian work. In science clear ideas are of importance, and I wished to elicit something more definite than the vague notion that Mendelism will someday and somehow furnish a master key to the problems of heredity. I made no complaint that Mendelism "does not immediately lead to the solution of all the most difficult problems which biology affords," as Mr. Lock rather extravagantly asserts, but merely asked what conceivable bearing it can have on any problem save that of sex. By the problem of sex I mean the problem of the function of sex—or of conjugation if Mr. Lock prefers. I confess I cannot imagine what light Mendelism has shed on the question of the alleged transmission of acquirements, and as for the "problems of the actual transmission of characters," these, as dealt with by Mendelians, *are* nothing other than problems of sex. That is, Mendelian experiments demonstrate nothing more than the degree in which certain characters (mutations) are transmitted or distributed under, or affected by, conditions of conjugation. Doubtless it is true that the majority of Mendelian cases have been observed in self-fertilised types, but I am not aware that they have ever been observed unless cross-fertilisation had previously occurred. In parthenogenesis the individual arises from an unfertilised ovum; how, then, is segregation possible? What segregates?

The evidence on which I base my assertion that there is no segregation in the mulatto is that of my own eyes. Mulattoes vary amongst themselves, but the blend is usually very obvious, and is reproduced in subsequent generations when breeding is *inter se*. With every infusion of European blood the negro type—skin colour, hair texture, shape of features, and the like—grows fainter, until at length the "touch of the tar-brush" is hardly if at all perceptible; and this blending, so far as I am aware, occurs, not only in all crossed human varieties, but in other natural varieties as well. There may be exceptions; in fact, I believe there are; but blending appears to be the rule in the vast majority of instances.

How can the fact that human races have crossed more often than any other animal complicate the problem? My statement implied, not that every human race is a chaotic mixture of types, nor even that there are no pure types, but only that we have here a very large and varied mass of material on which to found our judgments. Nor did I imply that mutations are especially frequent under conditions of cultivation. I believe they are quite as common in nature. Our hospitals and asylums are full of them—hare-lips, cleft-palates, club-feet, hæmophilia, colour-blindness, deaf-mutism, feeble-mindedness, and so forth. Their inheritance is usually Mendelian, but I never heard of a human mutation that was useful. I implied merely that artificial selection is founded on mutations, and that the striking difference between artificial and natural varieties indicates that natural selection is not founded on them. We know the past and present of man better than that of any other type, certainly of any natural type. Men are fond of noting wonders, and we have a written history of thousands of years; but never yet has the differentiation of a human variety by mutation been recorded. On the other hand, so surely as a human race separates into sections, between which there is little or no intercourse, gradual differentiation sets in, which, under conditions of savage warfare and very restricted intercourse, may be seen in the inhabitants of quite small tracts of country, as in New Guinea. Amongst plants and lower animals parthenogenetic types are particularly rich in varieties. "Thousands of forms may be cultivated side by side in the Botanical gardens and exhibit slight but undoubted differentiating features, and reproduce themselves truly by seed" (de Vries, "Species and Varieties," pp. 59–60). When reproduction is bi-parental, varieties are few if individuals from distant parts of a wide area are able to mate, and proportionately more numerous if intercourse is more restricted. Thus in every valley of Samoa is found a distinct variety of snails; but species of birds, mammals, and fishes which possess considerable powers of locomotion have few varieties. Is Mr. Lock able to conceive any interpretation of all these facts except that under natural conditions fluctuations are selected and inheritance is blended?

He lays stress on the circumstance that man is not amenable to experiment; but man is not the only species that has natural varieties. May I, in turn, lay stress on the fact that it seldom pays the cultivator to select small differences (fluctuations)? Of necessity he selects mutations. The Mendelian experimenter has practically limited himself to the materials so created. He himself chooses for his experiments, and can choose, only glaring differences. In other words, he has, *qua* experimenter, absolutely no acquaintance with the small differences (fluctuations) which normally distinguish mating individuals in natural breeding. He judges the normal from the abnormal, the rule from the exception, and then appeals to earth to note the precision of his methods and thanks heaven he is not as other men, even as mere observers who seek to take the whole of the facts into consideration. Notwithstanding his parade of exactness, his belief that he reproduces natural conditions "is an assumption which still lacks the support of facts." Once more, therefore, let me challenge Mr. Lock and his comrades. If Mendelism deals with any other problem but that of sex, what is that problem? If no other problem can be named, what is the evidence that Mendelism deals with anything more than those abnormalities of sexual reproduction which occur under conditions of artificial selection? As I say, I do not ask for the solution of any problem. I ask only for an indication that Mendelism has any conceivable bearing on it. If the latter question also cannot be answered, then by all means let Mendelians pursue their very interesting studies; but let it be understood that "the new science of genetics" implies, not the study of heredity in general, but only the study of certain curiosities of artificial breeding.

G. Archdall Reid.

Southsea, October 20.

Pagan Survivals and Christian Adaptations.

It may interest some of the readers of Nature to find that the institution of the "kern-baby" (corn-baby) still exists in our island; and a writer in the *Christian World* for October 3 was present at the bringing home, on the last load, of this Pagan institution, and was present at the harvest supper this year, when the effigy was honoured by being placed on the table. It was, presumably, only a survival of olden time, when our ancestors "ate and drank" with their gods—especially the gods of agriculture (Judges, 9, v. 27).

Again, I received a letter the other day from the rector of Fobbing, Essex (formerly rector in the Scilly Islands), informing me, in reply to an inquiry, that the Beltane fires are, up to the present day, lit there on the highest point of the islands on May eve, just as our ancestors lit them in honour of the rise of Baal (or the sun). My informant, who has only left the islands two years, often witnessed the jumping of the youths "through the fire." I should be very pleased to learn of any ancient customs of this kind still carried out on the eves of "May Day," "Easter," "All Hallows," "Christmas," or other solstitial and equinoctial periods, and not heretofore recorded in standard books on the subject. In trying to ascertain the uses of certain stone circles and monster cromlechs this evidence is of great importance, as the early missionaries purposely "adapted" so many of the Pagan festivals to Christian worship. Wales is the most promising field.

The "Quaternary."

In reply to Dr. Wright's comment on my letter (p. 639), I would point out that the restricted use of the word "Quaternary" appears to be confined to anthropologists. Geologists (Sir Archibald Geikie, Prof. Kayser, and Prof. Lapworth, for instance) who employ the term include in it everything from the commencement of the Glacial period to the present time.

John W. Evans.

Imperial Institute, October 25.

THE "MAURETANIA."

The first impression of the *Mauretania* is one of colossal size, the last is wondering amazement at the forethought and design which appear in details, trivial in themselves, but of supreme importance to individual comfort, of the fittings. Only those who saw the ship in the narrow waters of the Tyne can realise her huge dimensions. Eight hundred feet long herself, she floated abreast the builders' yard in a river less than 900 feet wide, which runs in a narrow cleft between low hills. In that narrow valley the great bulk of the ship made a prodigious spectacle, and over the valley before the start on the maiden voyage the smoke from her four great funnels moved like a pall.

In the brief voyage from the Tyne to the Mersey which took place last week, some of the peculiar features of the great ship were revealed. The Tyne is winding and narrow, and on the Tuesday afternoon its course was obstructed by crowds of steamers laden with sightseers. In this difficult passage the handiness of the vessel was at once apparent. Proceeding under her own steam, steered by propellers and the rudder, she was easily manœuvred at the sharp bends. To the writer, who was on the bridge at the time, it was obvious that the great turbines, which in the aggregate can develop 70,000 h.p., can be stopped or started with ease and certainty.

At sea, though the recurrent shocks characteristic of vessels fitted with reciprocating engines are absent, vibration is noticeable, though relatively slight. Generally speaking, it is maximal in the after part and diminishes thence to the bows. The distribution, however, is erratic, regions of maximal vibration often being close to regions of minimal vibration. In the great dining saloon at 22 knots the tremors were barely noticeable, being something like the passage of a vehicle in a street outside. On the other hand, a region of marked vibration was forward of this, about the level of the second funnel.

The cause of the vibration in turbine-propelled ships is not at all obvious, and experts at present seem to be unprovided with a satisfactory hypothesis. The turbines themselves are singularly free from it. Leaning against their great steel shells one is not conscious of a movement. In the shaft tunnels, however, it is very marked. The vibration has been referred to the impact of the water thrown by the blades of the wing propellers against the sides of the ship, to the unequal thrusts which each blade exerts in the course of each revolution, and to the formation of twisting couples between the propellers when they synchronise in certain ways. Inequalities in the thrust arise from the fact that owing to skin friction the water near the side of the ship is dragged bodily along with it. Each blade, therefore, as it revolves, passes through water moving in the direction of the ship to water which, relatively speaking, is still.

The vibrations themselves are markedly periodic, mounting by a long crescendo to a climax, followed usually by complete quiet. This periodic nature unquestionably suggests a dependence upon synchronism between propellers on opposite sides of the ship, and it was found in the case of, I believe, the *Deutschland* that vibration was much lessened when her twin screws were set to rotate respectively at 70 and 80 times a minute instead of both being at approximately the same rate. The whole subject is being investigated on the *Mauretania* by means of the pallograph, which registers at the same time the shaft movements and the vibrations.

As it is not possible to get an indicator diagram of a turbine, the work done is measured on the

Mauretania by torsion meters directly applied to each shaft. Two wheels are fitted on the shaft at some distance apart, each of which in its rotation makes an electrical contact. The contacts are exactly in line, and therefore are coincident in point of time when the shaft is at rest. When the shaft is rotated it suffers torsion, and the aft contact lags behind the forward one. The angle of the lag measures the torsion. The instrument is calibrated by determinations made in the shops of the twist which the shaft suffers from couples of known magnitude. In the navigating house of the *Mauretania* are four dials, on each of which a hand revolves in the direction and at the speed of the particular propeller shaft to which it is attached. It is obvious that the torsion meter might be so adjusted as to give direct records on the bridge of the work of each turbine from moment to moment.

The two most impressive parts of the machinery are the controlling platform, already mentioned, of the engine-room, where a few small levers control the gigantic forces pent up in the long polished barrels of the turbines, and the small, easily manipulated wheel in the wheel-house, which, by means of a small hydraulic motor, controls the enormous steering engine sunk below water level some 650 feet distant!

The plates of the *Mauretania* were delivered rolled to a guaranteed thickness. This is, I believe, a new departure in the building of English merchant ships, and it enabled the builders to save 500 tons of dead weight. The use of silicon steel in the boilers effected a further saving of 500 tons, making a total of 1000 tons, which, reckoned as cargo, represent a gain to the Cunard Company of about 22,000*l.* a year in the earning power of the vessel. An interesting saving in dead weight was also effected in connection with the decoration. The lifts in the well of the main staircase are enclosed by a beautiful piece of metal work adapted from existing sixteenth-century wrought-iron work. It is carried out in aluminium instead of iron, and thereby 20 tons weight is saved. One wonders whether the high affinity of the metal for chlorine and the presence of chlorides in sea air have been adequately taken into account.

The engine-room of the *Mauretania*, despite the absence of the main reciprocating engines, is very closely packed, and the greatest ingenuity is manifested in the arrangements. The four main turbines, each of 15,000 h.p., are controlled from a tiny platform by six small levers. Over the great engine-room steam pipes arch large enough for a boy to walk through, and the exhaust from each low-pressure turbine passes through a "pipe" 14 feet by 16 feet! The distinctive noise of the engine-room is the continuous roar of the steam passing through the main steam pipes. The engine-room, counting main turbines, turbo-generators, and auxiliary engines, holds machinery capable of developing something over 80,000 h.p., and the rotating mass of the main turbines amounts to about 600 tons, and rotates about 200 times a minute.

The gigantic low-pressure turbines receive the steam at nearly atmospheric pressure, which falls to a condenser pressure of about minus 27 inches of mercury. Ingenious gauges are fitted on each turbine, which record the pressure at different steps in the expansion, so that, should some of the blades become stripped, the injury can be at once located.

The stokeholds are so efficiently ventilated by powerful fans as to be cool save when the furnace doors are actually opened, in spite of the presence of 192 furnaces.

The magnitude of the strains which a ship nearly the length of the Houses of Parliament must experience in a heavy head sea is brought to mind by the provision which has been made for bending. The boat deck, together with the deck houses on it, which contain the long suite of public rooms, are cut completely through in three places, so as to allow the ship to give longitudinally.

No description can give the effect of the stately progress of so great a ship down the narrow Tyne. The grey autumn day, the cheering crowds piled on the hill-sides to their summits, and the anxious pilot striving to make his orders heard amid the clamour of steam whistles and fog signals, are vivid recollections. So, too, are the raucous blasts of welcome flung to us from the great headlands as we passed them by. The sombre cliffs of the Pentlands in the grey dawn, Cape Wrath under the autumn sun, lonely light vessels, tiny fishing craft, and liners, each after its own fashion wished us the freedom of the seas.

W. B. HARDY.

THE GEOLOGICAL SUCCESSION IN SOUTH AFRICA.[1]

EVERY year our knowledge of the geological succession in South Africa becomes more extended as a result of the labours of the Geological Commission of the Cape, the Geological Survey of the Transvaal, and the host of private workers who contribute to the Transactions of the Geological Society of South Africa. The newly published Report of the Cape Commission for the year 1906, and the Transactions of the Geological Society for the period January to June of this year, are full of interesting matter. The Cape surveyors have been working in Bechuanaland and Griqualand West, and have thus come into close contact with the work of the Transvaal geologists; for although the operations of the official Survey of the Transvaal have as yet been confined to the Pretoria and Middelburg districts, the Marico district and the neighbourhood of Mafeking have been explored by unofficial geologists in the employ of big land companies. Pioneer work of this nature, although unsanctified by official publication, is not to be contemned, since in many cases it is done, under conditions of considerable difficulty, by enthusiastic geologists and keen observers whose labours have often laid the foundation for the detailed work of the Government surveyors.

The earliest work in Griqualand West was by Mr. G. W. Stow, who communicated some of his results to the Geological Society of London (Q.J.G.S., vol. xxx., pp. 581–680, 1874). Unfortunately, a considerable proportion of his observations was embodied in reports to the Griqualand West Government, which since they were handed in have never emerged from their pigeon-holes. However, his classification of the Griqualand West rocks has, with the exception of the Keis series, been adopted by the Cape Survey. It is as follows:—

Matsap Series...	Quartzites and conglomerates
(unconformity)	
Griquatown Series ...	Magnetite-jasper rocks
Campbell Rand Series ...	Limestone and quartzite
Keis Series	Quartzites and mica schists

[1] Eleventh Annual Report of the Geological Commission of the Colony of the Cape of Good Hope, 1906. (Capetown, 1907.)
Geological Map of the Colony of the Cape of Good Hope. Sheet xlvi. (Published by the Geological Commission, 1907.)
Transactions of the Geological Society of South Africa. Vol. x., January to June, 1907. Pp. 1–68. (Johannesburg, 1907.)

The next step was the tracing by Mr. E. G. Holmes in 1904 from the Transvaal into Bechuanaland of the Black Reef, Dolomite, and Pretoria Series (Trans. Geol. Soc. S.A., vol. vii., p. 130). He followed these well-known Transvaal formations near enough to the original localities of the Keis, Campbell Rand, and Griquatown Series described by Stow to suggest the correlation which was proposed in the following year by Hatch and Corstorphine in their "Geology of South Africa" (p. 311), namely, in the following manner:—

Griqualand West		Transvaal
Matsap Series	=	Waterberg Series
(unconformity)		(unconformity)
Griquatown Series	=	Pretoria Series
Campbell Rand Series	=	Dolomite Series
Keis Series	=	Black Reef Series

Mr. Rogers appears to doubt whether Stow, by his Keis Series, referred to the quartzites which succeed the Campbell Rand Series in downward succession. He therefore substitutes the Transvaal name—Black Reef Series—and with this modification accepts the correlation; but he points out that the Matsap and Waterberg Series present marked points of difference, especially in regard to their volcanic rocks, which are of a more acid character in the latter than in the former.

The Matsap Series is subdivided by Mr. Rogers as follows: an *upper* group of quartzites and sandstones, developed in the Langebergen proper; a *middle* group of quartzites, lavas, and fragmental rocks of volcanic origin; and a *lower* group of quartzites, slates, and conglomerates forming the foothills east of the Langebergen, north of Pad Kloof. The basal bed contains many boulders and pebbles of quartzite, quartz, and red jasper in a quartzite matrix which is sometimes highly ferruginous.

In the Transvaal, Mr. Mellor has recently shown (Trans. Geol. Soc. S.A., vol. x., p. 44) that while the base of the Waterberg System is often marked by the presence of coarse conglomerates, in the Middelburg district a series of acid and intermediate lavas, interbedded with tuffs, agglomerates, shales and sandstones, underlies the usual sandy types of sedimentation. The whole volcanic series attains a thickness of approximately 8000 feet.

The Griquatown Series is divided by Mr. Rogers into an *upper* group, consisting largely of slaty rocks, together with some brown and red jasperoid rocks and thin beds of chert and limestone; a *middle* group, consisting for the main part of the Ongeluk volcanic beds, together with some banded jasper beds; and a *lower* group, comprising banded jaspers, quartzites and mudstones. The conglomeratic rocks that occur at or near the top of the lower group in the Hay district contain "striated and flattened pebbles and boulders," which, according to Mr. Rogers, "certainly owe their characteristic shape and scratches to glacial action" (Rep. for 1905, p. 162). Seeing that these beds belong to a geological period considerably older than the Dwyka Glacial Series (they occur at least 15,000 feet lower down in the succession—even more if the Matsap Beds are considered to be older than the Table Mountain Sandstone), this is an interesting contribution to the fast-growing history of glacial action in the remotest periods of geological time.

The Campbell Rand Series occupies practically the whole of the Kaap plateau. As in the Transvaal, this formation consists mainly of dolomitic limestone with which cherts are often associated. The shales which occur near the bottom of the series were searched by Mr. Rogers without success for fossils. Conformably underlying it is the Black Reef Series, consisting of quartzites, grits, felspathic quartzites, conglomerates, shales, &c. An exact divisional line between the two formations cannot be drawn owing to the alternation of beds of quartzite and limestone near the junction.

The three series—Black Reef, Campbell Rand, and Griquatown—are grouped together by Mr. Rogers as the Transvaal System, a term introduced by Molengraaff for the corresponding series in the Transvaal. The name is scarcely a happy one; but since it has also been adopted by the Transvaal Geological Survey, it will probably remain. Below the Black Reef Series is a basic series of amygdaloidal lavas—the Pniel series of Stow—and this is succeeded by an acid volcanic series to which the Cape geologists have given the name Zoetlief Beds. There is an unconformity between the two series; but Mr. Rogers has decided to include them in one group under the name of the Ventersdorp System, which name is used for the equivalent formation in the Transvaal.

The Ventersdorp, Transvaal, and Matsap Systems lie on a floor of granite and schists, and have been folded during pre-Dwyka times into arches and troughs, the axes of the folds embracing a wide area of low mountains, the principal range of which is the Langebergen. The underlying schists are grouped as the Kraaipan Series; they are equivalent to the Swaziland Series of the Transvaal, and consist largely of magnetitic schists and thin quartzites. The Cape geologists have found no evidence of the granite being intrusive into the schistose formation, although this has been clearly proved in the Transvaal (Abelskop, Monte Maré, &c.). In this connection it is interesting to note that the Geological Survey of the Transvaal has recently recognised that the granite mass which lies north of Johannesburg is younger than the schists of the Swaziland Series (Moodies Series), while it also admits the correctness of the view that it constituted an older floor on which the basement beds of the Witwatersrand Series were deposited (Trans. Geol. Soc. S.A., vol. x., pp. 55 and 57; *cp.* also "Geology of South Africa," p. 93).

Summarising, there is in South Africa, lying on an old floor of schists and granite (which is almost certainly of Archæan age), a succession of sedimentary rocks, older than the Devonian, and including the Waterberg or Matsap, the Transvaal, the Ventersdorp and the Witwatersrand Systems, all separated by strong unconformities. In this accumulation of sediments, which is estimated to have a thickness of between 50,000 and 60,000 feet, not a single fossil has as yet been found.

With regard to the Karroo rocks of the Transvaal, a further step in their elucidation is marked by the conclusion arrived at by the Survey, that the Bushveld Sandstone Series (a succession of red marls, shales, and fine-grained sandstones), together with the overlying amygdaloids, are the equivalent of the Red Beds, Cave Sandstone, and Volcanic Group of the Stormberg Series of the Cape, the Orange River Colony, and Natal (Kynaston, Trans. Geol. Soc. S.A., vol. x., p. 34). The recent discovery by Mr. J. Mitford Bowker, in the Zoutpansberg district near the Limpopo River, of fossil bones, which Dr. Broom has determined to be of Stormberg age, shows that the Bushveld Sandstone Series extended far to the north; for it is found to cross the Limpopo River into the Victoria district of Mashonaland, where coal-seams have been reported to occur in it (Proceedings of the meeting of the Geol. Soc. of S.A. held on June 24, 1907).

F. H. Hatch.

THE ROMANCE OF PHOTOGRAPHY.[1]

ALL phenomena are wonderful in the measure that we are unaccustomed to them, and if quite strange to us they are incredible. The romantic character of the details of any subject is therefore an individual matter, but the author in this particular case assumes no exact, and very little general, knowledge on the part of his readers, and so he is justified in his repeated asseverations of the marvellous character of the various details of the discovery and achievements of photography. We take it that the duty of the writer of such a volume is very largely to rob his subject of its atmosphere of romance by showing its gradual development and the reasonableness of its results. In this the author is successful. He gives no "instructions," but merely tells his story in a readable form and illustrates it well, for every one of the sixty or more illustrations has a definite and sufficient reason for its presence. He treats it in an easy and sometimes, perhaps, rather too discursive manner, giving many apt analogies of the development of photography and of its applications in instantaneous work and kinematography, the making of book illustrations, the photography of the invisible as by means of Röntgen rays or the ultra-violet of the spectrum, and the reproduction of colour.

Telegraphed Photographs. These photographs are just as they were received by the electric telegraph. The left-hand portrait is that of the Crown Prince of Germany, and the other is a portrait of Prof. Korn. From "The Romance of Modern Photography."

One of the most interesting chapters deals with the detection of crime and the identification of criminals, for it is seldom that those who are not engaged in the work itself have the opportunity of seeing examples of photographs taken for these purposes. There is also a chapter on telegraphic photography, described in NATURE of August 19 (p. 445). The accompanying illustration from this chapter is reproduced by the courtesy of the publishers. In another chapter we learn how "the largest photograph in the world," 40 feet long by 5 feet wide, was developed by mounting it face outwards on the periphery of a large broad wheel made for the purpose, and rotating it in a comparatively shallow tank that contained the developer, and find details of many other cases in which great difficulties were successfully overcome. The number of examples given of extraordinary methods of work is considerable, and they cover so wide a field that probably no one who reads the book will fail to find something new to him.

When an author sets out with the avowed purpose of dealing with the romantic side of such a subject, the critic naturally looks for a little exaggeration here and there, and when so many branches of the subject are dealt with he expects to discover a few inaccuracies. It may be true to a certain extent to say that kinematography will enable our descendants to see the incidents in our great battles, but it is a mistake to state, concerning a picture of a group of men in the act of diving, that "the whole detail of this living scene was recorded by the great artist, Light, in one five-hundredth part of a second" by means of a focal-plane shutter, as the narrow slit in the shutter probably took thirty or forty times as long as this to pass over and so expose the surface of the plate. It is also incorrect to state that a Lippmann photograph "must have its mercury background" to view it properly. But the slips of this kind are not very serious and they are very few.

C. J.

M. MAURICE LOEWY.

"RIEN ne saurait exprimer la consternation et l'affliction que la mort foudroyante de Tisserand a répandues autour de lui, car l'amitié, l'estime et l'admiration entouraient comme d'une auréole l'illustre astronome qui s'est éteint dans la nuit de mardi." These words, which M. Loewy spoke at the graveside of his friend and predecessor, Tisserand, may very well be remembered when expressing our sense of the loss which France and science suffer in the sudden removal of the director of the National Observatory of Paris. Even the painful suddenness, which added an increased bitterness to the grief we experienced in the loss of Tisserand, is repeated again with depressing emphasis, for we understand that M. Loewy was struck down while attending a meeting of the Conseil des Observatoires astronomiques.

The director of a great National Observatory does not usually enjoy unfettered discretion in the selection of the lines of investigation to be pursued. In such institutions large pieces of work are not unfrequently undertaken, for the conduct of which both ample time and funds are needed. Too often he who plans does not see the full fruition of his work, and loyalty to the reputation of predecessors and the influences of tradition alike restrict the direction along which activity is possible. The long connection of M. Loewy with the Paris Observatory, previous to his occupancy of the director's chair, would make him particularly anxious to complete, if possible, certainly to forward, two very heavy legacies of work bequeathed to him by former astronomers. One of these was the great Paris catalogue of stars, depending upon meridian observations made within the period 1837–1881, including the re-observation of all Lalande's stars. The complete work, published in four sections, furnishes the places of nearly 35,000 stars, based upon 387,000 single measures. This heavy piece of work was brought to a very satisfactory conclusion under the supervision of M. Loewy, and by its completion the observatory staff is relieved of an oppressive incubus. The other is the International Star Chart, which had its origin under Admiral Mouchez. Not only has this work been prosecuted with ardour at the observatory, but encouragement and assistance were given to all who participated in the scheme, by means of conferences that have been held from time to time in the observatory at the suggestion of the regretted director. To both these projects M. Loewy gave as generous and consistent support as though he were responsible for their introduction.

M. Loewy's more immediate influence on the conduct of the observatory is shown in the steady prosecution of another piece of work, the chart of the moon derived from photographs taken with the equatorial coudé, a form of telescopic mounting with which M. Loewy's name is closely connected. The long focal length, which is one of the advantages secured in this class of telescope, giving an image of the moon more than seven inches in diameter, made this instrument peculiarly suitable for the investigation. The admirable reproductions made from the negatives justify the time and attention that have been bestowed on the enlargements. Concurrently with the issue of the maps there have been published acute dissertations on the physical constitution of the moon, founded on a minute critical study of the lunar surface. This close and detailed examination led the director to conclude that there were evidences of a permanent elongation of the moon's figure towards the earth, and of a surface action tending to diminish the angular velocity of rotation.

But besides the study of the moon's surface, the equatorial coudé has served another purpose. The principle of construction is so well known that it is not necessary to describe it here. But in designing this instrument M. Loewy had in view the possibility of obtaining greater stability than is attainable with ordinary equatorials, and by taking advantage of this stability to measure large angular distances on the celestial sphere. Having determined, by a thorough examination of the theory, the sources of error inherent in the instrument, M. Loewy proceeded to use it for obtaining a new value of the constant of aberration by an entirely novel method. For this purpose he placed a double mirror, formed by silvering two faces of a large prism of glass, in front of the object glass. The double mirror was capable of rotation about the axes of the telescope, so that by reflection from the two silver surfaces the images of two stars in different parts of the sky could be brought into the field side by side, and the distance between them measured in the common plane of reflection. By choosing suitable stars and making the necessary measures six months apart, the quantity measured could be made four times that of the constant of aberration. For greater accuracy the stars selected had the same altitude so as to reduce the effects of refraction to a minimum, but by changing the plan of observation it was possible to investigate the effects of refraction separately. The instrument lent itself to methods of great beauty and ingenuity, displaying both the mechanical ability of the inventor and the varied resources of the mathematician and astronomer. The Royal Astronomical Society fittingly acknowledged its appreciation of the important services M. Loewy had rendered to astronomy by awarding him the gold medal. Needless to say, he was an honorary member of that society as of many others, both in his own country and abroad.

It would not be possible, even if it were desirable, to record all the varied occupations in which M. Loewy was engaged in the course of his scientific career. His position made him frequently the adviser of his Government in many important matters. His services to the Bureau des Longitudes, in his capacity of director of the Connaissance des Temps, will be readily acknowledged. The part he played in various conferences, such as those which arranged the scheme for observing the planet Eros and for securing uniformity in the employment of astronomical constants, has been already mentioned. We can only deplore, in company with the whole guild of science throughout the world, the loss of one who ornamented a dignified position and worthily supported the traditions of the National Observatory. Within the last few years the continuity of its direction has been too frequently interrupted by the loss of its distinguished chiefs. Among these brilliant memories the name of Maurice Loewy will hold an honoured place. Round his grave in respectful sympathy were grouped the representatives of many learned societies. In addition to those of France, there were present members of the Academy of Sciences of Vienna, of the R. Accademia dei Lincei, while the Royal Society of London, as well as the Royal Astronomical Society and the British Association, were represented by Sir David Gill and Major MacMahon.

NOTES.

It is reported that at Monday's meeting of the Paris Academy of Sciences Prof. Lapparent described some experiments by Prof. Bordas upon the conversion of corundum into precious stones by the influence of radium. It is stated that when fragments of corundum were placed in contact with a tube containing radium for a month they changed colour entirely, and were transformed into crystalline varieties of the mineral, some pieces becoming yellow, like topaz; others purple, like amethyst; blue, as sapphire; and red, as rubies. The gems thus produced were submitted to a jeweller, who was unable to distinguish them from precious stones. We shall await with interest the appearance of the *Comptes rendus* of Monday's meeting for particulars of these experiments and results.

The death is announced of Prof. Gustav Adolf Zeuner, the distinguished authority on applied mechanics. Born at Chemnitz in 1828, he was the founder, and editor from 1853 to 1857, of the German journal the *Zivilingenieur*. In 1855 he was appointed professor at the Zurich Polytechnic, of which institution he was director from 1865 to 1868. From 1871 to 1875 he was director of the Freiberg School of Mines, and from 1873 to 1890 he was also director of the Dresden Polytechnic. He retired in 1895. His works included treatises on valve gearing and on the mechanical theory of heat.

Dr. Elis Strömgren, private tutor at the Kiel University, has been appointed professor and director of the Copenhagen Observatory in succession to Prof. T. N. Thiele, retired.

Sir Herbert Maxwell has been appointed chairman of the council of the National Association for the Prevention of Consumption in succession to the late Sir William Broadbent, and Dr. C. Theodore Williams has been elected vice-chairman.

The cup for the winner of the International Balloon Race, to be awarded to the aëronaut landing furthest from St. Louis in a measured straight line, has been won by Herr Erbsloh (Germany), who descended at Annapolis Junction, Maryland, having covered a distance of 874·4 miles.

The death is announced of Mr. T. F. Brown, a recognised authority on the geology of the South Wales coalfield. Mr. Forster Brown was a member of the Institute of Civil Engineers, a Fellow of the Geological Society and of the Surveyors' Institute, and past-president of the South Wales Institute of Engineers.

We are asked to announce that the annual "fungus foray" of the Essex Field Club will take place on Saturday, November 2, at Loughton and Theydon Bois, Epping Forest. The director will be Mr. George Massee, of the Kew Museum. Botanists wishing to be present should communicate with the secretary, Mr. W. Cole, Buckhurst Hill, Essex.

Referring to his letter in Nature (October 3, p. 568), the Rev. Dr. Irving writes to state that his assignment to the Upper Eocene or Oligocene of the fossiliferous limestone discovered in a well-sinking at Thorley, near Bishop's Stortford, was erroneous. The bed in question is probably Lower Eocene, of the age of the Oldhaven beds.

Count G. N. Plunkett, who has just taken office as director of the Dublin Museum of Science and Art, initiated the system of museum "demonstrations" about ten years ago, and has lectured on the arts and artistic crafts, and also on Irish archæology. In the Cork Exhibition of 1903 he organised a nature-study section, the work of more than a hundred schools. He is known outside Ireland through his book on Sandro Botticelli.

The list of lectures to be delivered at the London Institution during the present winter session is varied and comprehensive. Prof. G. S. Boulger takes for his subject the Andes of Peru; Prof. W. M. Flinders Petrie, F.R.S., will describe ancient Egyptian houses; Mr. E. S. Bruce is to explain the coming of the aëroplane, with the aid of experiments and illustrations; Mr. A. R. Hinks will discuss the evidence for life on Mars; Mr. I. S. Scarf takes up the subject of flames; Mr. L. E. Hill, F.R.S., researches on deep-sea diving; Prof. W. B. Bottomley, soil inoculations; and Mr. P. Chalmers Mitchell, F.R.S., ruminating animals. The lectures for juveniles will be delivered during the Christmas vacation by Prof. Grenville A. J. Cole, his subject being three days of open-air geology.

Calabria was subjected to a severe earthquake shock during the evening of October 23. The disturbance, which occurred at 8.30 p.m., seems to have followed the same line and to have been felt throughout the same districts as that of 1905. The centre of the disturbance was located in Monteleone, and its effects seem to have been noticed from Catanzaro to Reggio di Calabria. Reports of varying amounts of damage have been received from Gerace, Sinopoli, Pizzo, Tropea, and other places, which also suffered two years ago. Secondary shocks were felt on October 24; but from observations which have been recorded it is believed that the earthquake of last week was less severe than that of 1905. The shocks on both days were recorded by Prof. Milne's instruments at Shide, in the Isle of Wight, and by Prof. Belar at Laibach, in Austria. The number of victims is variously estimated, Reuter putting the number at 600. The damage is extensive and widespread. Shortly before 6 p.m. on October 28 a violent shock was experienced at Monteleone, Santa Eufemia, Bagnara, and Sinopoli.

Mr. Balfour on October 25 opened the new administrative buildings and two new wards at the Royal Victoria Hospital for Consumptives at Craigleith, Edinburgh. During the course of an address, Mr. Balfour said it is impossible to withhold wonder at the enormous strides which scientific medicine has made in the treatment of consumption in less than thirty years. Referring to future work in this direction, he remarked:—"If we cannot destroy and expel the tubercle bacillus from among us, we can reduce its power to do evil to a degree which may seem to us at the moment to be almost incalculable. We have an example before us of what has been done with regard to typhus. I doubt whether there is a single case of typhus in Edinburgh at this moment; and it may be that our children will live to see the time when consumption will be as little known in their midst as typhus is at this time. We have made the conditions of infection with regard to typhus so small that the power of resistance of the community at large is amply adequate to prevent its making any lodgment of a serious kind in our midst. That is the ideal to which we look forward with regard to tuberculosis." Continuing, Mr. Balfour pointed out that it is a great responsibility resting upon every person to see that the doctrines of modern scientific medicine penetrate, not merely among the well-to-do, but to every class in the community.

According to *Museum News* for October, a figure of a native Australian, carefully modelled by an eminent Washington sculptor, has been placed in the Brooklyn Museum alongside stuffed specimens of the man-like apes, in order to illustrate the wide differences between the latter and the lower races of mankind. Silk-worm-culture and silk-manufacture are now illustrated in the museum by cases of living silk-worms, as well as by exhibits of the more important descriptions of raw silk.

Total prohibition of the use of the plumage of wild birds as articles of dress is regarded by Prof. T. H. Montgomery (Bull. Univ. Texas, No. 79) as the only effectual remedy against what he regards as a mischievous fashion. "It will not do," he writes, "to prevent the killing of our American birds and to allow the importation of foreign ones, for this would be injuring another country, and in the long run, for the sake of greater cheapness, would result in the killing of our native species."

The additions to the Zoological Society's menagerie during September were 149 in number, of which sixty-eight were acquired by presentation and two by purchase, while sixty-five were received on deposit, four by exchange, and ten were born in the gardens. Amongst these, special attention is directed by the secretary to the following, viz. a female giraffe, born on September 20; a male gayal, born on September 6; three harnessed antelopes (*Tragelaphus scriptus*); a nagor antelope (*Cervicapra redunca*); and two side-striped jackals (*Canis lateralis*), from Gambia, presented by Sir George Denton; and a Cayenne kite-falcon (*Leptodon cayennensis*), deposited.

Vol. lxxxviii., part i., of *Zeitschrift für wissenschaftliche Zoologie* contains an exhaustive article on the morphology and life-history of the vine Phylloxera (*Phylloxera vastatrix*), by Mr. H. Stauffacher, of Frauenfeld, Switzerland, illustrated by a coloured plate showing the chief developmental stages and the dimorphic phases of the winged adults. At the conclusion of the article special attention is directed to the origin of these dimorphic phases, which include a larger and a smaller form; diagrammatic illustrations being given of the various theories proposed. According to the author's view, trimorphic nymphs are developed, from which are produced what he terms the α form, β form, and γ form, which in turn respectively give rise to the parthenogenetic generation, to males, and to females.

To the July issue of the Proceedings of the Philadelphia Academy, Mr. E. G. Conklin contributes a paper on the embryology of the gastropod Fulgur, from the point of view of the influence of the yolk on development. The eggs of this genus are remarkable for their large size, the bulk being almost wholly due to the quantity of yolk; and one of the problems to which special attention was devoted is the effect of large or small yolks on the development of the organs of the embryo. For the author's conclusions our readers must be referred to the original paper; but it may be mentioned that after a certain stage the elements of the Fulgur yoke cleave irregularly, a feature which may foreshadow the "meroblastic" eggs of birds and reptiles, in which only a portion of the yolk undergoes cleavage.

We have received copies of a circular issued by the Vigilance Committee of the Fur and Skin Trade Section of the London Chamber of Commerce directed against the alleged practice of certain retailers in wrongly marking, naming, and advertising furs for sale, in violation of the Act of Parliament against "false trade descriptions." The action taken by the committee has already led to satisfactory results, but there appears reason to believe that the illegal practice still continues. Among the scheduled items are musquash and nutria (coypu) fur, sold, "when pulled and dyed," as seal; and nutria, when "pulled natural," sold as beaver. Dyed rabbit fur sold as sable, white rabbit as ermine, and dyed white rabbit as chinchilla, also appear in the list. It is added that purchasers who may have any doubt as to whether furs sold to them are correctly described can obtain expert opinion, free of charge, by forwarding the articles to the offices of the London Chamber of Commerce, Oxford Court, Fleet Street, E.C.

In the introduction to his report on the diatoms collected in the Pacific Ocean on the voyages during the years 1898 to 1904 of the steamer *Albatross*, belonging to the United States Bureau of Fisheries, Dr. A. Mann claims that, as owing to their minuteness diatoms can be transported by slow currents or surface drifts, a tabulation of the species found at different stations would provide useful data for determining the direction and extent of ocean currents. He also quotes several instances to show how different species are confined to, and therefore typical of, distinct localities. The systematic enumeration contains a careful digest and sifting of previous nomenclature. The genera Navicula, Biddulphia, and Coscinodiscus are richest in species, and also provide the larger number of new species. The report is published as vol. x., part v., of the Contributions from the United States National Herbarium.

We have received the annual report of the medical officer of health (Dr. Seaton) of the administrative county of Surrey for 1906. The prevalence of enteric or typhoid fever in the administrative county is the subject of a special report. The incidence of 2093 cases occurring during the last twelve years has been reviewed, and the opinion is expressed that it is doubtful whether even 10 per cent. of the cases can be attributed to the drinking of a polluted or infected water supply, and there seems to be no evident relation between the rainfall, and consequent floods, to typhoid prevalence. Dr. Seaton believes that polluted and infected foods are a much more frequent source of typhoid illness than is even now generally supposed. He also refers to the occurrence of cases which it is impossible to connect with any other case, and suggests the possibility of new origin (*i.e.* apart from human infections) through bacilli other than those which are regarded as the invariable specific causes of typhoid. With regard to this, it may be mentioned that recent German researches have shown that patients may harbour the typhoid bacillus for months after they have recovered from an attack, and that even well persons may occasionally be the hosts of the organism; it seems hardly necessary, therefore, to suggest a *de novo* origin.

Under the title of "The Tuna as a Food for Man," Mr. R. F. Hare and Mr. D. Griffith have provided in Bulletin No. 64 of the Agricultural College, New Mexico, an illustrated account of the varieties of fruit—commonly called prickly pear—grown to a considerable extent in Mexico. The fruits described are species of Opuntia; they have a thin skin more or less covered with spicules, under which is a rind enclosing the pulp and embedded seeds. The pulp alone is generally eaten, but sometimes part of the rind is included. The fruit is relished by the peons and poorer classes, and is harvested for shipment. There is also a local manufacture of products of the nature of honey, sugar-paste, and toffee.

The Quarterly Journal of the Liverpool Institute of Commercial Research in the Tropics, vol. ii., No. 5, contains excellent illustrations of some African fibrous plants from photographs by Mr. J. A. Alexander, formerly of Portuguese East Africa. Dr. E. Drabble furnishes notes on the synonymy, morphology, and fibres of leaves of *Sansevieria guineensis* and *Agave rigida*, also on the seeds of *Myristica angolensis* and fruits of *Lophira alata*. From the latter the natives of West Africa obtain a cooking oil, and the fat of Myristica is suitable for soap-making. Dr. D. Spence contributes articles on the analyses of latex and rubbers, the most important being a discussion of the methods of analysing raw rubbers.

A second hundred of the leaflets published by the Board of Agriculture for free distribution has been completed. They deal with farm and garden crops, insects and fungal pests, and the breeding and management of farm animals. Among recent issues are two containing information on the winter rot of potatoes caused by the fungus *Nectria solani*, and the black rot of cabbage attributed to the bacterium *Pseudomonas campestris*. The Nectria appears on stored potatoes, forming white, and later pink, patches, from which arise crops of spores that spread the disease and reduce the tubers to a fœtid mass. The ascospores developed in the following season can infect growing crops. The cabbage rot is readily distinguished by the black appearance of the vascular bundles along which the bacteria travel. The Sycamore leaf-blotch, caused by species of Rhytisma, so familiar by reason of the black patches produced, is described in another leaflet. An account of the coltsfoot, *Tussilago farfara*, and a note on the Fertilisers and Feeding Stuffs Act, 1906, have also been published.

The King has instituted a new medal for bravery in mines. The Royal Warrant states that the King is desirous of distinguishing by some mark of Royal favour the many heroic acts performed by miners and quarrymen who endanger their own lives in endeavouring to save the lives of others. The new medal will be of two classes, which are to be designated the Edward medal of the first class and the Edward medal of the second class. The ribbon will be dark blue with a narrow yellow stripe on either side.

The *Engineering Magazine* for October is a special number of great interest, devoted exclusively to mining. There are articles on the copper situation in the United States, the production of gold, the mechanical engineering of the mine, the manufacture of steel and wrought iron, asbestos, excavations for the foundations of a modern tall building, electrometallurgical progress, steam production from the cheaper grades of anthracite, underground workings in New York City, and the unwatering of mines in the anthracite region. All these articles are written by leading authorities and are admirably illustrated, and the whole forms a trustworthy review of current practice.

At the first meeting of the new session of the Institution of Mechanical Engineers, Prof. Bertram Hopkinson read an important paper on the indicated power and mechanical efficiency of the gas engine, describing an investigation made with the object of finding whether the indicator power of the gas engine does, in fact, vary so much and is so difficult of determination as the report of the committee of the Institution of Civil Engineers on the efficiency of internal-combustion engines suggests. The conclusions reached were as follows:—(1) If precautions are taken to keep the pressure of the gas supply constant, the diagrams given by the engine are remarkably regular, and whether the engine be missing ignitions or not, it is possible, by the use of a sufficiently accurate indicator, to obtain the indicated power from diagrams within 1 per cent. or 2 per cent. It seems probable that the difficulty experienced by the committee was due either to the essential defects, for this purpose, of the ordinary form of indicator, or to casual variations in the gas supply per suction due perhaps to variation in the gas pressure at the engine. (2) The difference between indicated horse-power and brake horse-power is rather less than the horse-power at no load under the same conditions of lubrication, mainly because of the difference in the power absorbed in pumping. In the particular engine tested by Prof. Hopkinson the error from this cause in obtaining the indicated power would amount to about 5 per cent. The friction is substantially constant from no load to full load, provided that the temperature of the cylinder walls is kept the same, but the influence of temperature is very great.

The current number of the *Quarterly Review* includes an important article, by Mr. Urquhart A. Forbes, on the water supply of the United Kingdom. The importance of treating water supply on broad lines was pointed out by the 1869 Commission on Water Supply, when the adoption of the watershed area as the administrative unit for water supply was recommended. Since the water supply for purposes of navigation is derived from the various watersheds traversed by canals and river navigations, it is desirable that the authority in each watershed should be empowered to exercise some control over canal companies and river trustees with respect to the amount of water to be abstracted from it. Such watershed boards with the powers indicated would be able to carry out the scientific regulation of all water from its first arrival as rain to its disappearance in the ocean. It has been suggested that the staff of the central authority, which would be a department under the Local Government Board, would, in addition to the administrative head, comprise (1) an engineer and assistants, with a special knowledge of geology and water supply, charged with the duty of collecting and digesting for use all the facts requisite for the scientific treatment of our water system; (2) a bacteriologist and a chemist, with a special knowledge of the bacteriology and chemistry of sewage, trade effluents, and water supply, who should be provided with a laboratory for experiments; (3) a staff of inspectors for carrying out its supervisory work with respect to both pollution and waste of water. In addition to the facilities it would provide for the treatment of our water system on scientific principles, the establishment of a central water department offers the best means of restoring order in the present chaotic condition of things.

The great changes wrought by the eruption of April, 1906, necessitated a re-survey of Mount Vesuvius, which has been effected by the Italian Military Geographical Institute. The extreme height of the mountain was determined as 1223 metres above sea-level, as compared with 1335 metres before the eruption; the height of the crater rim has become more irregular, dropping to only 1103 metres on the E.N.E., with a diameter of 725 metres from N.N.E. to S.S.W., and 645 metres from N.W. to S.E. At lower levels the contours have everywhere been enlarged from those of the survey in 1900, and in the Atrio del Cavallo and Valle dell'Inferno the depression has been filled up to the extent of from 5 metres to 50 metres.

In travelling by rail, or still better by steamer, from Lyons to Avignon, a marked narrowing of the Rhone Valley is noticed after Valence, between the pre-Alps of Dauphiné on the left and the singular dark ridge of Coirons on the right. This easterly spur of the central *massif* of France is capped by a thick sheet of basalt, which affords a striking instance of inversion of topography. There is no doubt that, at the close of the Miocene, when the molten rock issued from a vent located near Mount Gerbier des Joncs, it followed one of the channels of the river system of that period. Since that time the eastern border of the central *massif* (Cévennes) has been subjected to strong erosion, increased by the subsidence of the lower part of the Rhone Valley, and the consequent lowering of the base-level. The surrounding Cretaceous and Upper Jurassic limestones have been easily worn down and reduced to gentle slopes. The basaltic flow, about thirteen miles in length and three miles wide, resisted much more successfully the subaërial disintegration. In consequence of this very unequal weathering, what was once a valley is now a long ridge standing 2200 feet above the level of the Rhone. The history of the Coirons may be compared to that of the Scuir of Eigg in western Scotland. Unfortunately, a portion of the sheet of lava of Coirons rests upon the Oxfordian, easily undermined by the head-waters of the lateral torrents; the edges of the volcanic table are liable to break away and to creep down the slopes upon the clayey substratum. The landslip which occurred on October 11 above Moulin-Artige is only an episode in this process of slow undermining, which has reduced the formerly continuous basaltic plateau to the shape of a fish-bone. As a consequence of the torrential rains which occurred in southern France during the first part of October, nearly one million cubic metres of rocks has moved a distance of 900 metres, threatening to block a valley and to form a lake. Such incidents are bound to occur again on both sides of the Coirons, and the suggested re-afforesting of the district will tend to diminish, but not to prevent, all future danger. Perhaps it would be wise to restrict the construction of villages to safer ground.

MR. W. ERNEST COOKE, Government astronomer at the Perth Observatory, West Australia, directs our attention to an exhibition of globe lightning, or a fireball of some sort, which was noticed by two observers on September 7. Mr. Cooke did not himself see the display, but he can certify that about the time mentioned by the observers there was a blinding flash of lightning in the vicinity, followed almost immediately by a heavy crash of thunder. The observers who reported the matter to Mr. Cooke are stated by the *Daily News* of West Australia (September 9) to have described their experience as follows:—In the middle of the reverberation of the thunder a tremendous explosion about 6 feet from the ground was heard, and a momentary flash of blinding intensity was seen. Both saw a lurid red ball, estimated by them as about 4 inches in diameter with a circle of bright yellow flame, with a diameter which seemed to be 18 inches, which graduated in colour until it faded at the edges. As there are only a few authenticated instances of similar displays, it is desirable to place each new instance on record.

MESSRS. GEORGE PHILIP AND SON, LTD., have sent us a specimen of their "New Standard Time Dial" designed by Prof. R. A. Gregory for the determination of the local mean time at any place on the earth's surface, corresponding to the time at the place where the dial is being used. This simple and useful device consists of a stout wooden board on each side of which is printed a clock face showing the hours from noon to midnight and midnight to noon. Within each dial is a rotating disc on which is printed, on the one side, a map of the northern, and on the reverse side a map of the southern, hemisphere. Meridians of longitude are drawn at intervals of 15° on each map, and where a meridian marks a commonly used standard time, such as Greenwich, mid-Europe, or inter-Colonial, it is so designated; the meridian where the date changes from the American to the Asiatic date is also marked. By simply rotating the inner disc until the meridian of a place is opposite to the actual time, as shown on the dial, the corresponding local time at any other place may be read off directly. The device will be found serviceable; and its low price (3*s*. 6*d*. net) should ensure its appearance in all places, especially schools, where the longitude-time problem has to be solved frequently.

Le Radium for September contains an important article by M. Jean Becquerel on the influence of temperature on the absorption of solids. It appears from M. Becquerel's researches that increase of temperature of a solid displaces the absorption bands towards the red end of the spectrum by two or three units of the fifth figure of the wave-length per 100° C., while the bands at the same time increase in width and change in intensity, the width being proportional to the square root of the absolute temperature.

THE communication to the Physical Society of Berlin in which Dr. E. Goldstein announced his discovery of the existence of two independent spectra of each of the elements cæsium, rubidium, and potassium has been reproduced in full in the *Physikalische Zeitschrift* for October 15. The new spectra are produced by powerful condenser discharges, and have not a single line in common with the old, or as Dr. Goldstein names them, the arc spectra. The new lines do not appear to fall into series, and the author suggests that they constitute the "fundamental spectra" of these elements, the arc spectra being due to polymerisation in the metal vapour, which is impossible in the powerful sparks necessary to produce the former.

IN the June number of *Terrestrial Magnetism and Atmospheric Electricity*, Mr. Y. Homma calculates the rates of change of the electrical potential at different distances above the earth's surface on various assumptions as to the distribution of positive charges in the atmosphere, the earth being taken as a sphere. None of the calculated rates of change agrees with the somewhat meagre observations which have been made, and the author points out the importance of further work in this direction.

IN the report of the third Prehistoric Congress of France in NATURE of October 24 reference was made to some photographs of Japanese megaliths, which were said to have been taken by M. Goodhan (p. 649, col. 2, line 3), Prof. W. Gowland writes to say that the photographs were taken by him, and were lent to Mr. F. V. Dickins for exhibition at the conference. The name was printed exactly as it was given by the secretary of the conference, who furnished the report of which a translation appeared in NATURE.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN NOVEMBER:—

Nov. 4. 15h. 33m. to 19h. 14m. Transit of Jupiter's Sat. III. (Ganymede).
10. Saturn's major axis outer ring $=43''\cdot00$, minor axis $=0''\cdot64$.
12. 4h. 11m. Moon in conjunction with Mars. (Mars 0° 58′ S.)
13. 22h. 23m. to
14. 1h. 47m. } Transit of Mercury across the Sun.
,, 10h. 24m. Moon in conjunction with Saturn. (Saturn 2° 26′ N.)
14–16. Epoch of the Leonid meteors. (Radiant 150° + 22°.)
17. 10h. 1m. Minimum of Algol (β Persei).
20. 6h. 50m. Minimum of Algol (β Persei).
,, 4h. 25m. to 5h. 4m. Occultation of δ^1 Tauri (mag. 3·9).
,, 4h. 44m. to 5h. 35m. Occultation of δ^2 Tauri (mag. 4·7).
21. 17h. 6m. to 17h. 54m. Occultation of ζ Tauri (mag. 3·0).
23. 15h. 41m. to 17h. 1m. Occultation of δ Geminorum (mag. 3 6).
25. 20h. 34m. Moon in conjunction with Jupiter. (Jupiter 1° 57′ S.)
29–30. Mercury rises 2h. 2m. before the Sun.
30. 18h. 49m. to 23h. 39m. Transit of Jupiter's Sat. IV. (Callisto).

COMET MELLISH, 1907*e*.—Three observations of Mellish's new comet are reported in No. 4207 of the *Astronomische Nachrichten* (p. 111, October 17). Prof. Hartwig's observation on October 15 showed that the comet was round, with a diameter of 3′ and a central condensation. The magnitude at 15h. 52m. on October 15, as estimated by Prof. Becker at Strassburg, was 9·3.

THE TRANSIT OF MERCURY.—In view of the approaching transit of Mercury (November 14), Mr. W. T. Lynn publishes a letter in No. 388 of the *Observatory* (p. 382, October) in which he directs attention to earlier observations of this phenomenon and to its periodicity. He states that the first authentic observation of the transit was made in 1631 by Gassendi, and was followed by an observation by Jeremiah Shakerly, an Englishman who went to Surat, India, in 1651, for the purpose of observing the transit. Halley observed the 1677 transit at St. Helena, and this led him to suggest that transits of Venus would afford a peculiarly advantageous means of determining the solar parallax, a suggestion that was first carried out officially in 1761.

Mr. Lynn also directs attention to the peculiar commensurability existing between the orbital periods of the earth and Mercury, the former completing forty-six in nearly the same time that the latter completes 191 revolutions; the periods are 16,801 and 16,802 days respectively, and thus transits of Mercury must occur every forty-six years at the same node.

THE PERSEID METEORS.—In No. 4206 of the *Astronomische Nachrichten* (p. 81, October 16) Herr W. Milowanov, of the Kasan University Observatory, Russia, gives an account of the Perseid observations made at Kasan in August, 1906. Two hundred and seventy-two meteor-paths were recorded, by three sets of observers, on August 11, 12, and 13, forty-nine of which were not Perseids. The horary rate on August 11 was 21·5, and on August 12 25·4. The time of observation, the path and the magnitude of each meteor are given, together with a list of the variously estimated radiants; the centre of the radiant for 1906 is given as $\alpha = 43°·5$, $\delta = +55°·0$. The heights of twenty-four meteors are also given, the mean heights of appearance and disappearance being 111 km. (sixty-nine miles) and 73 km. (forty-five miles) respectively.

A RICH NEBULA REGION.—On a plate exposed in the Bruce telescope for three hours on July 10, 1906, Prof. Max Wolf found an extensive nebulous cloud having its centre some $1\frac{1}{2}$ degrees north-east of ϵ_2 Sagittarii. Later observations show that the region is very rich in small nebulæ, a plate exposed on July 16 showing a large number of such objects over a region of forty-eight square degrees. Most of these nebulæ are of Prof. Wolf's class I_1, being round objects with central condensations (*Astronomische Nachrichten*, No. 4207, p. 109).

RAIN-GAUGE EXPOSURE AND PROTECTION.

WHEN during the nineteenth century rainfall observations by means of gauges began to be carried out upon an extensive and scientific system, it was soon discovered that gauges which stood in situations much exposed to the wind invariably indicated a smaller amount of rain than such as were protected from the wind.

The greater part of our knowledge regarding the effects of wind exposure upon the indications of rain-gauges was derived from a careful study of the diminution of recorded rainfall with the elevation of gauges, either upon buildings or poles, above the ground, and an abundance of experimental work carried out during the nineteenth century in many European countries, notably, perhaps, in England, as well as in the United States of America, left no doubt but that this indicated decrease of rainfall with height above the ground was only apparent, and due to the more imperfect catch of rain by the gauges consequent upon their increased exposure to wind.

The well-founded conclusion is that wind interferes with the proper catch of rain by eddying around the mouth of the rain-gauge, and that consequently a rain-gauge should on theoretical principles be protected from wind disturbance if we would know the true quantity of rain that falls upon the ground in its vicinity. Nothing is known as to the mode of formation or of the complexity of these wind eddies, and information respecting these questions could only be suggested through laboratory experiments. When a gauge is elevated above the ground upon a thin pole there is merely the augmented wind velocity to be considered in explanation of the decreased amount of rain it will receive as compared with a similar one upon the ground, but when a gauge is placed upon an edifice or close to the edge of a steep cliff or bank the case is far more complicated through new disturbances introduced by such obstructions themselves to the wind, which has the effect of causing a deficit of rain upon the windward side of buildings and a relative surplus upon the leeward side.

The whole subject, however, of decrease of recorded rainfall with height above the ground has been thoroughly investigated, as mentioned above, in its several relations, so that there offer themselves for discussion, more particularly the methods that have been adopted for protecting rain-gauges from, or of correcting their readings for, wind error.

It was about the year 1889 that Prof. Cleveland Abbe,[1] of the United States, made an exhaustive study of the data

[1] *Monthly Weather Review*, vol. xxii., 1894, p 25, "The Reliability of the Rain-gauge"; *American Meteorological Journal*, vol. vi. p. 241, "The Determination of the Amount of Rainfall.'

at that time available from different parts of the world with reference to the apparent decrease of rainfall with elevation above ground, and relating his data to a law known to meteorologists as Archibald's, connecting increase of wind velocity with square root of altitude for small altitudes above the surface of the earth, showed that the deficit of rain indicated by an elevated gauge was proportional to the square root of its altitude above the ground. From these results Abbe deduced for a rain-gauge in a free, open situation a numerical wind correction which may be explained as follows:—

If a second gauge, in all essential respects similar to the one for the readings of which the correction is to be applied, be placed twice as high above the ground as the latter, the quantity $E \times 2·414 + R = C$, where E is the excess of the reading of the lower gauge above that of the upper, R is the reading of the lower gauge, and C is the corrected reading of the lower gauge; to state this in words, add to the reading of the lower gauge 2·414 times its excess above that of the upper, and the result is the amount of rain which the lower gauge would have caught in the absence of wind disturbances. The validity of this correction, which depends, of course, upon the extent to which for any particular occurrence of wind and rain the necessary assumption of Archibald's law is trustworthy, is doubtless such as to enable at least a close approximation to the true rainfall to be reached. But two conditions must be complied with before the records of two gauges placed at different heights above the ground can thus bear a simple relation to differences of wind velocity corresponding to different amounts of error through eddy action at the mouths of the gauges:—(*a*) the two gauges must be of the same form and dimensions; (*b*) if the lower gauge rests upon the ground, the upper one must be supported on a somewhat thin pole as may not induce, by offering an obstruction to the wind, other disturbances operating at the mouth of the rain-gauge in addition to those due to the gauge itself.

Of the various types of wind-shield for rain-gauges that have been suggested or tried, by far the most serviceable is the protecting funnel jacket[1] originally devised about the year 1879 by Prof. F. E. Nipher, of the United States. This is screwed on to the cylinder of the rain-gauge at such a height that the rim of its broad upper portion lies level with that of the mouth of the gauge, and consists usually of copper gauze for the purpose of preventing or minimising the splashing of water into the gauge from the inner surface. The efficiency of such a protector has been tested, not only by Nipher himself, but by Prof. R. Börnstein in Germany and Dr. H. Wild in Russia, with the result that the contrivance may, on the whole, be regarded as an appropriate means of eliminating, or at all events reducing, injurious wind eddies around the mouth of a rain-gauge, as will be shortly seen. Since the protecting jacket was invented by Nipher it has been improved in various ways, a comparatively recent modification, as used at some of the Russian rainfall stations under the direction of the Central Physical Observatory at St. Petersburg, being capable of being taken to pieces so as to facilitate packing for transport.

Another type of protection contrivance, more accurate than the Nipher jacket, was established about 1880 in St. Petersburg by Dr. H. Wild. This took the form of a rectangular fence enclosure composed of wooden slabs, 2·5 metres in height, at certain equal distances on each side from the rain-gauge, the mouth of which was 1 metre above the ground, and provided with a door for the entry or exit of the observer. A comparison of anemometer observations within and without such an enclosure shows that even during the prevalence of high wind the conditions within approximate nearly to those of a calm, so that a fence enclosure of the dimensions adopted by Wild may be taken as the standard of accuracy for wind-protection contrivances.

[1] *Zeitschrift der Osterreischischen Gesellschaft für Meteorologie*, Band xiv., 1879, s. 250, "Ueber die Bestimmung der wahren Regensmenge mittelst hochaufgestelltes Regensmesser, von F. F. Nipher: *Meteorologische Zeitschrift*, Band i., 1884, s. 381, "Ueber den von Nipher vorgeschlagenen Schutztrichter für Regenmesser," von R. Börnstein; *Bulletin de l'Académie Impériale des Sciences de St. Pétersbourg*, v^{e} série, vol. iii., 1895, p. 193, "Kritische Untersuchung der Angaben freier und geschützter Regenmesser,' von Emil Berg.

Respecting the relative efficiency as protecting agents of the Nipher jacket and the Wild fence, experimental observations have been, and are apparently still being, conducted in Russia, a country, be it noted, where, owing to the large quantities of snow that fall during the colder months of the year, the sources of error in rain-gauge records through wind assume greater magnitude than they do, for instance, in England, where the winter precipitation consists largely of rain. It may be said that, while the Nipher protector is generally well adapted to its purpose for ordinary situations of rain-gauges, it may be with advantage replaced by the fence enclosure in the case of gauges which are unduly exposed to the full force of the wind in unsheltered locations. If the accuracy of the Wild fence be taken as 100, that of the Nipher jacket may approximate to 100 in more sheltered positions, but may be as low as 80 or even lower in such as are quite open to the violence of the wind. It should be added that a Nipher gauge ought to be fitted with some form of heating apparatus adequate to prevent accumulations of snow in winter upon the protecting jacket, from which into the rain-gauge portions of such accumulated snow are liable to be blown.

This brief abstract of the chief methods of diminishing or eliminating the wind error due to rain-gauges would be incomplete were it omitted to mention a process of calculation [1] by which the rainfall figures for a sufficiently long period, as indicated by a gauge at a place which suffers undue exposure to the wind in comparison with another gauge in the neighbourhood, say a few miles distant, at a more sheltered spot that may be regarded normal, may be corrected. The method depends upon the relation subsisting between the amounts of discrepancy in the records of two such gauges during periods of rain and of snow. If the rainfall for a specified time at the sheltered station be represented as 100, and that at the exposed station as $100-A$ for periods of rain and $100-A-B$ for periods of snow, the equation $K=\frac{x+A}{B}$, when solved for x, affords the correction required. The value of K, which for a few localities in Germany has been found to range from 0·13 to 0·22, must be empirically determined for a particular district by establishing two similar rain-gauges close together, or, if possible, side by side, one of which is fitted with an efficient wind-protection contrivance, the other being left free; for a pair of gauges in such close proximity x may be considered to vanish, so that K becomes $=A/B$. The value of K for the locality being thus found, x is solved $=KB-A$, which will, of course, be a *plus* or *minus* quantity according as the true rainfall is slightly greater or less at the exposed than at the sheltered station. This method of calculation, which is applicable in many instances, has been tested by another more direct one involving anemometer readings, whereby the measured quantities of precipitation could be reduced to equal mean wind velocities, and as the two have given most concordant results, it may be concluded that the one briefly delineated above is correct.

Thus at Karzig, in Neumark, the rainfall at an open, wind-swept spot on the outskirts of a forest, though indicated by a rain-gauge as considerably less than that of a glade more than 2 kilometres distant, was found by both processes of calculation to be actually 2 per cent. greater.

To summarise the contents of this article:—

(1) Experimental observations extensively carried out during the nineteenth century in many countries have established the fact that in the measurement of rainfall errors of considerable magnitude accrue from the presence of the rain-gauge during the prevalence of wind, and point to the conclusion that such errors arise from the eddying or rebounding of wind about or from the mouth of the rain-gauge.

(2) The readings of a rain-gauge in a free, open situation may be corrected by means of a method involving their comparison with those of another similar gauge placed at twice the height above the ground.

(3) The most efficient wind-protection contrivances for rain-gauges are the Nipher jacket and the Wild fence enclosure; the latter, though more accurate and advantageous in special circumstances, is generally less used than the former.

(4) The corrected rainfall for a sufficient length of time of a wind-swept spot may in many instances, if the rainfall for the corresponding period of a sheltered spot in the same neighbourhood, say a few miles distant, be known, be determined by means of an equation involving as known data (*a*) the relative amounts of discrepancy in the records of the gauges at the two places during periods of rain and of snow; (*b*) an empirically determined constant K.

L. C. W. Bonacina.

RECENT DEVELOPMENTS IN THE THEORY OF MIMICRY.[1]

The remarkable resemblances that exist between certain insects belonging to widely different orders have long been known to naturalists. Wasps and hornets are imitated by the "clear-wing" moths, the resemblance being so close that it has sometimes deceived for the moment a skilled entomologist. Certain two-winged flies that inhabit the nests of humble-bees are scarcely to be distinguished from their hosts, and the handsome Xylocopas, or carpenter-bees, familiar objects in the tropics, are deceptively copied by two-winged flies found in the same regions.

But it is not only the bees and wasps that are so imitated, nor are the imitating insects to be found only in the ranks of moths and flies. An ichneumon fly in Borneo, belonging to the same order as the bees and wasps, though not in the same sense a stinging insect, is closely copied by a Reduviid bug.

Other instances are numerous. So long ago as the year 1836, the French entomologist Boisduval directed attention to the extraordinary resemblance that exists between certain butterflies which are not at all closely related to each other, belonging, indeed, to groups which are widely distinct. One of these butterflies is a member of the Danainæ, a group of which we have no resident representative in this country; a second is nearly related to our familiar "swallow-tail" of the Cambridgeshire fens; while the third is a Nymphaline, not far removed from our British "White Admiral." The structural differences between these butterflies show the want of real affinity between them in spite of their superficial resemblance. The "cell," for example, of the hindwing is open in the Nymphaline, while in the other two it is closed by a transverse vein. This illustrates the point that these resemblances affect only obvious characters; they are independent of affinity or blood relationship, and leave untouched such morphological features as do not readily meet the eye.

An insect thus resembled by another is spoken of as its "model," the imitating insect is called a "mimic," and the combination of model and mimic or mimics is known as a "mimetic pair" or "mimetic assemblage," as the case may be.

What is the meaning of these resemblances? Many of them were well known to the older naturalists, who, however, had nothing to offer by way of explanation but vague talk about "repetition" and "analogy" in nature. The well-known entomologists Kirby and Spence got so far as to suggest that in some cases the resemblance might be of advantage to the mimic, but in their day it was not likely that the subject should be treated from the evolutionary point of view, and the first really scientific explanation of the matter was given by Bates on his return from his famous visit to the Amazon, now nearly fifty years ago.

Bates had observed that in these cases of deceptive resemblance between butterflies, one member of the pair or of the group was often characterised by abundance of individuals, while the whole group was marked by slowness of flight, conspicuousness of appearance, and immunity from the attacks of insect-eating birds. On these grounds he put forward the suggestion that the mimicking species enjoyed protection from attack by their

[1] An evening discourse delivered at the Leicester meeting of the British Association on August 5 by Dr. F. A. Dixey.

resemblance to their more abundant models, the immunity of which, he thought, was due to the possession of some distasteful quality—probably a scent or flavour disliked by the birds.

Accepting Darwin's view of evolutionary process, he attributed the formation of these resemblances to the accumulation by natural selection of variations in the mimicking species that happened to point in the appropriate direction; so that these mimics had gradually put off the general aspect of the group to which they properly belonged, and had become more or less completely assimilated in outward appearance to the members of an entirely different assemblage; thus sailing, as it were, under false colours, as if a peaceable merchantman were to disguise itself under the rig and ensign of a man-of-war. This is the well-known Batesian theory of mimicry. It was at once, and cordially, accepted by Darwin; while the array of facts from South America on which it was based was soon afterwards shown to be paralleled by corresponding phenomena in the Malayan Archipelago and in South Africa. This was the work of two great naturalists happily still with us, Alfred Russel Wallace and Roland Trimen.

An objection was raised in early times to Bates's view on the ground that it was difficult to account for the first advances towards the formation of a mimetic pattern. This objection was felt in some degree both by Darwin and by Fritz Müller, of whom we shall hear more presently. Darwin and Müller thought that the objection might be met by supposing a considerable original likeness between mimic and model; it can, however, quite easily be shown from forms actually at present existing that a complete series of gradations may occur between the ordinary type of a mimetic genus and its very distinct-looking model or models. The transitional forms, even those exhibiting the earliest stages of mimetic assimilation, are evidently able to maintain themselves (how they do it we shall see later), and they in many cases form a perfect succession of links between extreme forms of the utmost divergence in aspect. Hence it is unnecessary to suppose that a considerable initial resemblance must exist between mimic and model, while the initial stages of the mimetic pattern, however we are to account for them, are not only theoretically possible, but are found to be in actual existence.

The beauty and simplicity of Bates's theory commended it strongly to public acceptance, and it is probable that to this day, when the subject of mimicry is mentioned, it is the Batesian theory that presents itself to most people's minds.

But notwithstanding the immense value of Bates's contribution to knowledge, it is now evident, as we shall see, that he only touched the fringe of a great subject, and that a much wider view is necessary before the facts observed by him, and subsequently by others, can be fully explained.

Those who read Bates's classical paper cannot avoid remarking that he himself was not thoroughly happy about all the facts there recorded. He directs attention to the circumstance that not only do the mimics resemble their models, but that the models themselves often show an extraordinary resemblance to each other. He speaks of "a minute and palpably intentional likeness which is perfectly staggering."

To take an instance: two species of the Ithomiine genus Dircenna, *D. epidero* and *D. rhaeo*, structurally distinct, but almost indistinguishable on the wing, were noted by Bates as being always found together where they occur in the Amazonian region. A moth, *Hyelosia tiresias*, was regarded by Bates as a mimic of *Dircenna epidero*, but it did not escape him that his theory failed to account for the resemblance of the two Dircennas to one another, the subfamily Ithomiinæ, to which they belong, being on good grounds supposed to be generally distasteful. The difficulty becomes still greater when it is realised that not only members of the same presumably distasteful genus, but also members of different genera, all with the same habits and denizens of the same region, bear the same extraordinary likeness to each other. There are, for example, some twenty species of Ithomiines, belonging to no less than seven different genera, all with the same, or very nearly the same, external appearance. But this is not all, for the same mimetic assemblage will be found to include, not only these Ithomiines, but also butterflies belonging to the group of Danaines (genus Ituna) and Pierines (genus Dismorphia), as well as moths of the two widely separated groups of Hypsidæ and Castniadæ, all with a common facies.

If it were merely a case of resemblance between two or more species of the same genus, such as the Dircennas that have just been mentioned, we might be tempted to say that the resemblance was merely due to affinity, and to explain, as Bates did, the circumstance of the constant companionship of the two species by appealing to the "social and gregarious instincts of the group." When, however, we see that not only Dircennas, but Ithomiines generally, Danaines, Pierines, and moths all come into the same mimetic assemblage, the explanation from affinity breaks down. Affinity, no doubt, may help mimicry, but there is no necessary connection between the two. Some members of the company are closely related; others are widely distinct. Bates himself saw clearly enough that his theory of one distasteful and immune form sheltering others which would be attacked if detected would not apply to cases of this kind. If all the species but one of a "homœochromatic" group are to be considered as edible mimics, we should have to account for the fact that they vastly outnumber the model, in which case the mimicry would be more harmful to the model than beneficial to themselves; we should also have to face the improbability of one species of a genus being distasteful and immune, while other species of the same and allied genera were edible and liable to attack. It was plain that the distasteful models did really imitate each other, but why?

All that Bates could do in the face of this difficulty was to fall back, somewhat doubtfully, on the hypothesis of some local or climatic cause acting equally upon the forms of different groups, and in some unexplained way bringing about this strange resemblance between them. In this supposition he was for a time followed by Wallace.

It is not to be denied that there is a certain plausibility at first sight in this view concerning the direct action of external conditions. It is, for example, a striking fact that the members of a mimetic group of very diverse affinities will, as Bates says, every few hundred miles all change their hue and pattern together, "as if by the touch of an enchanter's wand."

There is a well-marked assemblage of this kind, generally characterised by a pattern composed of the three colours red, yellow, and black. It contains, besides moths, butterflies of many diverse groups, Ithomiines, Heliconiines, Danaines, Nymphalines, and Pierines—in some of the latter the female only taking part in the mimetic cluster, a point to which we shall return later on. The members of this assemblage as it occurs in the northern part of Central America—Guatemala to Nicaragua—present in common a remarkable streakiness of pattern, a feature that makes them easily recognisable among the corresponding forms from other regions of the same continent. Passing on to Venezuela, we find among the geographical races, or, if we like to call them so, the representative species, that there replace the Central American forms, a tendency to the breaking-up of the streaks, and a slight encroachment of the red ground-colour upon the yellow of the apex. In Trinidad there occurs a general paling of the ground-colour, due to an increase of yellow pigmentation, and running, as before, through the entire group. Next, taking the corresponding Guiana forms, we find a further breaking-up of the streaks into spots, and also a general darkening, especially of the hindwings, which gives a most characteristic aspect to the whole assemblage. In East Brazil we have a modification which somewhat recalls the Trinidad facies, though here the yellow streak on the hindwing is better defined, and the black of the apex is less broken up. At Ega, on the Upper Amazon, a curious dark chestnut tinge pervades the group, while in Peru a characteristic spottiness takes the place of the streaky pattern we saw elsewhere, and the apex becomes more uniformly dark. Finally, in Ecuador the streaks have all but disappeared, and even the spots have become almost blocked out by a dark infusion which now occupies, not only the apex, but also a large part of the base of the forewing, and the whole, or nearly so, of the hindwing. After a little study of some of the typical members of each of these geographical groups, it becomes easy to pronounce, with a considerable degree of confidence, upon the local habitation of a species that we may never have met with before.

If facts of this kind were the only ones with which we had to deal, there might be some justification for adopting the theory of the direct effect of geographical conditions, but it is now incumbent on us to consider whether this hypothesis of common surroundings producing a common aspect will bear further examination. We will take the instance of a group of ant-like insects caught by Mr. Guy Marshall in Mashonaland on one day on a single plant. All were to outward appearance ants; but while the first four were veritable ants, the next two were bugs, and the last was a locustid, belonging, that is to say, to the order of crickets and grasshoppers. If a common environment has of itself produced the ant-like appearance of the bugs and the locust, why has it not done something towards assimilating the points of structure that do not meet the eye? As a matter of fact there is no such approach. In internal organisation each member of the group preserves the exact characters of its own order.

There is a certain ant-like locustid, possibly of the same species as that last mentioned, in which the body of an ant is, as it were, painted on that of the locust. The constriction between thorax and abdomen, real in the ant, is in the locustid only apparent. Can the external conditions which are supposed to have caused the characteristic shape of the ant actually paint a copy of the ant on the otherwise unaltered body of the locust?

Again, there are cases where the supposed external influence must have acted, if at all, as sculptor instead of painter. In a certain ant-like Membracid (an insect allied to our common "cuckoo-spit") the body of the insect is concealed beneath a shield, which grows backward from the fore part of the thorax. This shield or screen, which is quite separated from the body except along one line of attachment in front, is hewn or moulded, so to speak, into the form of an ant, reproducing even the small swelling in the peduncle which is characteristic of some ants of the region that this insect inhabits.

Another instance, probably familiar, but so much in point that I cannot refrain from mentioning it, is that of the immature form of a Membracid found by Mr. W. L. Sclater in Guiana among a number of leaf-cutting ants. The flat green body and brown head and legs of the Membracid make a very fair copy of the ant engaged in its occupation of carrying home the cut leaf, the picture including, not only the ant, but the leaf as well. Ants are avoided by some enemies, though not by all, and in a procession of ants of this kind it is not likely that an enemy, however sharp-sighted, would readily pick out the Membracid from among its leaf-carrying companions. The idea that external conditions can produce in another insect a copy, not only of the ant, but of the leaf which it carries, needs, I think, only to be mentioned to be dismissed.

Looking at the matter from a slightly different point of view, we may take the instance of the wonderful African butterfly *Papilio dardanus*, no very distant relative of our English "swallowtail." The male of this insect is non-mimetic, while the female occurs in three or four different forms, each of which is a palpable mimic of a separate model. On the theory of direct external causes we have to explain why these external conditions have brought about a resemblance between each form of the female and a separate model of different affinities, while these causes have not been able to prevent individuals of the same species from going off in four or five different directions.

The facts here have been questioned, but as all the diverse forms have been found among the offspring of one individual, there is no longer any room for doubt that they are all really conspecific.

We can get more light on the subject if we return for a moment to our assemblage with transparent wings, the assemblage, that is, which contains the two Dircennas, *rhaeo* and *epidero*.

Now if the effect of transparence, which is common to the entire group, had been the direct result of an external cause, we should expect it to have been brought about in all cases by the same means; but whereas in the Ithomiines the transparence is due to an alteration in shape and diminution in size of the minute scales which normally clothe the wing, in the Pierines the same effect is produced by a mere diminution in size, the shape remaining unaltered. The Danaines of the group owe their transparence to a reduction in the *number* of the scales, not to any alteration in shape or in size; while in the associated moths the effect results, not from any change in size, shape, or number of the scales, but from the fact that the individual scales themselves become transparent, and are sometimes set up vertically, so as to let the light pass between them.

In view of these facts, the investigation of which we owe to Prof. Poulton, it is difficult, if not impossible, to imagine any direct agency which will produce the same visual effect by all these different means. The likeness is superficial; the real difference is profound. The common features, if we may so express it, are only meant to be looked at. They must stand in relation to vision of some sort; and to whose vision, we may well ask, if not to the vision of would-be enemies? Natural selection will attain the desired end by any means that come to hand, and these observations of Poulton seem to put every other explanation in this case out of court. If we may be allowed to use, without prejudice, teleological language, we may say that these resemblances have been brought about by natural selection for a mimetic purpose. Any variation, whether in size, shape, number, transparence, or position of scales, which leads in the required direction, will be preserved; and the final result, though to ordinary vision identical in all cases, will bear evidence, on close examination, of the manner, different in each individual case, in which it has been effected.

But, it may be said, many of your instances are simply cases of Batesian mimicry, and for them we can allow the sufficiency of natural selection; it is the other cases which want explaining. This is quite true, but a great point is gained if we have shown that, in many of these cases, neither affinity nor the direct agency of external conditions will account for the facts, while natural selection will do so if only we can find out why it should be an advantage for these distasteful types to form themselves into groups. If we *can* bring both kinds of mimicry under one cause, we are bound to do so. The old logical canon, the "razor of Occam," applies here. "Entia non sunt multiplicanda praeter necessitatem"; in other words, having found an adequate cause for one case of a given phenomenon, we are not at liberty to go out of our way to seek another cause for a second case of the same phenomenon. We must first try if the cause already established will not meet the requirements of the situation.

What we have to do, then, is to prove, if we can, why it should benefit these *distasteful* forms of various affinities to fall into homœochromatic groups, groups, that is, essentially similar in outward aspect. For a long time the key to the puzzle eluded discovery; it was at last found by Fritz Müller.

This admirable naturalist, working, like Bates, in South America, put forward in the year 1879 a suggestion which, when developed into its full consequences, has revolutionised our conception of the whole subject.

His suggestion rested on the assumption (since shown, mainly by Lloyd Morgan, to be correct) that birds have no instinctive knowledge of what forms would be suitable for food and what should be avoided, so that each bird has to gain its knowledge by experience. Hence a certain number of distasteful forms must be sacrificed by each generation of birds until these enemies have learned to leave such forms alone. In other words, each distasteful form has to *pay a tax* for its immunity.

Now if two distasteful species resemble each other so closely that birds or other enemies do not distinguish between them, the disagreeable experience gained by tasting an individual of one species will be applied to the benefit of the other, and so each of the two species will only need to contribute a portion of the tax, instead of each paying the whole—a consideration which, I think, will go home to most of us. And what is true of a combination of two species will be equally true of a larger assemblage; the greater number of forms that can be got to share the tax, the better for all. Hence the formation of these large "inedible associations," or, as they might be called, Müllerian groups. I do not wish to be understood as saying that the Batesian and Müllerian theories are mutually incompatible. They are *supplementary* to each other, and there is ample room for true mimicry beside or within the ranks of the Müllerian associations.

Though the theory of which I have just given an account is really quite simple, it has never been so generally understood and appreciated as that of Bates. May I, at the risk of being tedious, try to illustrate the relation between the two?

Imagine a large box of sugar-plums, and a schoolboy given *carte blanche* to help himself from it as he likes. Imagine, further, that the sugar-plums are of different colours and flavours, and that some of them are flavoured with an essence which the boy does not like—we will say aniseed. Further, let all the aniseed sugar-plums be coloured pink. The boy will soon find out that the pink sugar-plums are unpleasant to his taste, and *after a trial or two* they will be left until all the others have been disposed of, or, if sufficiently disagreeable, they will be refused altogether. The pink colour is here an *aposeme*, to use Prof. Poulton's term, or the visible mark of a distasteful character.

Suppose a few pleasantly flavoured sugar-plums to be coloured pink like the aniseed sugar-plums. These, if there are not so many of them as to destroy the impression of nastiness associated with pink, will also be left. This represents Batesian mimicry. The few pleasantly flavoured sugar-plums share in the protection afforded by the pink aposeme.

Now for Müllerian mimicry. Let us suppose that there are *two* flavours disliked by the boy, say aniseed and peppermint, and that the sugar-plums with these flavours are coloured pink and green respectively. The boy would have to try both pink and green before he learned to avoid them. Perhaps two of each, two of the pink and two of the green, *i.e.* four in all, would be sufficient to complete his education in this respect; but if *both* kinds of disagreeable sugar-plums were coloured pink, a trial of two only, instead of four, would be sufficient to protect all the rest, of both flavours, aniseed and peppermint, from the boy's depredations. In other words, the tax paid by each would be halved, and so with larger numbers. Hence the advantage of a common aposeme for *distasteful* objects, whether sugar-plums or butterflies.

This illustration refers only to the relation between the two theories. It says nothing, of course, as to the means by which the sugar-plums originally became coloured and flavoured; but what we *have* done is to show the advantage to be gained by Müllerian association, and therefore to supply the required motive power for natural selection.

Müller's suggestion was brought to the notice of British naturalists by Prof. Meldola in the year of its first publication, and in its further developments at the hands of Meldola himself and of Poulton it was accepted both by Wallace and by Trimen, the two naturalists who had done most by their own observations to confirm the validity of the supplementary (though earlier-devised) theory of Bates.

Fritz Müller had spoken chiefly of the resemblance between two butterflies, Ituna and Thyridia, belonging to distinct subfamilies, but it was soon pointed out by Prof. Meldola that the general likeness between members of the same distasteful family groups came easily under the same principle.

In order to appreciate this point fully, let us consider the common European Vanessas, the Peacock, Red Admiral, large and small Tortoiseshells, Camberwell Beauty, &c., several of them familiar objects in our own country. We see at once that though there is certainly a family likeness between them, they are distinguishable from one another at a glance; no one would think of taking one of them for another. Contrast this with a similar group of closely allied species, known to be distasteful, from a part of the world where competition is keen, for instance, the Acræas of Africa. Of these, four or five species may be taken on the same day, looking all alike while on the wing, and practically indistinguishable from one another without close examination. Or take a group of Euplœas, another distasteful genus, from the Oriental region. Here again we may have some five separate species, all quite distinct, but so much like one another that it needs much more than a casual glance to distinguish between them.

These and similar cases were shown by Meldola to be easily explicable on the basis of the Müllerian theory of mutual protection by the adoption of a common scheme of warning colours on the part of inedible forms, and the possibilities of the theory were still further expanded by Poulton, who pointed out that in any given region the fewer independent schemes of warning coloration there were to learn, the better chance there was of the protection they afforded being effective; so that the same simple warning badge, such, for instance, as the alternate black and yellow rings on the body of a wasp, might be employed by insects, like the caterpillars of the Cinnabar moth, which are widely separated from the wasp in point of affinity. The aposeme, or signal to an enemy to keep his distance, may be recognised and obeyed even when hoisted by insects which have little else in common between them. A great part of the significance of the facts that we have noticed depends, of course, on the circumstance that the members of each of these closely assimilated groups inhabit the same geographical areas. We do not find an Eastern Euplœa resembling an American Heliconius, or an Ithomiine from Brazil recalling an African Acræa. As a further illustration of what Poulton has aptly named "synaposematism," or the adoption of a common warning badge on the part of distasteful forms, we may take the wonderfully diverse assemblage that centres round the conspicuous and distasteful beetles belonging to the genus Lycus. This assemblage, in South Africa, contains wasps, Braconids, moths, a bug, and a two-winged fly, besides beetles belonging to three or four different families. I have myself seen several members of this group, heterogeneous in affinity though wonderfully similar in hue and pattern, on or about one tree at East London, in South Africa. Be it remarked that they were all conspicuous insects, and exposed themselves freely, so that there could be no question of a common cryptic coloration. The assemblage, beyond doubt, is mainly if not entirely synaposematic.

We have now reached what may at any rate rank as a preliminary generalisation, that is to say, that the resemblance between distasteful forms is to their advantage, and is an adaptation brought about by natural selection. Following the approved logical method of Mill and Jevons, we ought next to see what consequences are involved in the hypothesis we have formed, and then to make a fresh appeal to the facts for verification or the reverse.

(1) It is obvious that in Batesian, or true mimicry, the advantage is all on the side of the mimic. Experience gained by tasting the mimic would be used to the injury of the model. While, therefore, there is every inducement for the mimic to seek safety by approaching nearer and nearer to the aspect of the model, there is no reason for the model to assimilate itself to the mimic, but rather the contrary.

In a Müllerian association, on the other hand, the benefit is mutual. Each fresh accession to the group is a source of strength, not of weakness. Everything is in favour of the formation of such groups as rapidly and on as large a scale as possible; hence there is nothing to impede, and everything to promote, the free interchange of characters all round, each member being able to act, so to speak, *as both mimic and model*. This, we saw, could not happen in the case of Batesian mimicry.

Now does this interchange of characters, as a matter of fact, ever take place? If it does, it will be, of course, a confirmation of our theory.

One of the most characteristic features in the subfamily of Pierines, or "white butterflies," is the possession of red or yellow spots, streaks, or patches on the underside of the hindwing, near the base. These marks reach a high state of development in some members of the Eastern genus Delias, and relics of them are to be seen in the common white butterflies of our own country.

Now no one who accepts mimicry at all will be inclined to doubt the existence of a mimetic relation between *Heliconius guaricus* and the Pierine *Pereute leucodrosime*. How has it been brought about? The dark colour and red band are not at all characteristic of Pierines, and have no doubt been copied from the Heliconius; but the Pierine red spots have passed the other way, being taken up by the Heliconius from the Pierine. This, I believe, was the first case of mimetic interchange noticed.

Another instance. White is not an ancestral colour in Heliconius; it *is* ancestral in the Pierines. The Pierine *P. locusta* falls by its undersurface into mimetic association with the group of Heliconius represented by *H. alithea* and *H. galanthus*. The white colour has passed from Pieris to Heliconius; the dark, in great measure, from Heliconius to Pieris.

Much the same has happened in the case of *Heliconius leuce* and the female of *Pieris noctipennis*. These two have undergone reciprocal change. The white comes from the Pieris, the black from the Heliconius.

There is another case where two species belonging to widely separated sections of the same subfamily are in question. The hindwings of the island form of the Pierine *Huphina nerissa* have been drawn away into imitation of the hindwing of *Ixias baliensis*, also a Pierine; while the forewing of the Ixias, leaving the usual aspect of its genus, has been assimilated to the forewing of Huphina.

Another good example of interchange is afforded by the "swallowtail" *Papilio rex* from Uganda, which is in undoubted mimetic relation with the Danaine *Melinda formosa*. The brown at the base of the forewings is a Danaine character adopted by the Papilio; the pale areas at the base of the hindwings are a Papilionine character adopted by the Danaine. Each has in one of these respects acted as a model to the other. The two African genera Mylothris and Phrissura, the species of which form a parallel series of mimetic pairs analogous to the Ithomiines and Heliconiines of tropical America, furnish what is probably another instance of the same phenomenon. For this mutual approach by a process of give and take on both sides, Prof. Poulton has proposed the apt term "diaposematism," the idea of reciprocity being conveyed by the Greek particle "dia."

Let us now look at the working of this reciprocal principle in another direction.

It is well known that where the sexes differ in the extent to which they are protected, whether by power of concealment or by other means, it is almost invariably the female that has the advantage. This was pointed out long ago by Dr. Wallace, and was, no doubt rightly, attributed by him to the fact that the continuance of the life of the female, as the guardian of the early stages of the future brood, was of greater importance than that of the male to the welfare of the species. So we find many cases in which the female alone is mimetic, not the male. Shall we say that "Nature abhors the unprotected female"?

We have already noticed the case of *Papilio dardanus*, with its non-mimetic male, and three or four different forms of female, each form in mimetic relation with a Danaine model.

The case of the Pierine *Leuceronia argia* is in many respects parallel to that of the Papilio. Again we have a non-mimetic male, and several different forms of female, each being in mimetic relation with another butterfly of quite different affinities.

Once more: the female of the Nymphaline butterfly *Hypolimnas bolina* falls into mimetic association with Danaines and with a Papilio, leaving its own male outside the group. It will be remembered, also, that much the same thing occurs with certain of the South American Pierines which we considered in an earlier part of the present lecture.

These instances are sufficient to show the readiness of the female, as distinct from the male, to enter a mimetic combination.

Bearing these facts in mind, when we look at such a combination as that of *Papilio iphidamas* with *Euterpe approximata*, we shall have little or no difficulty in recognising that here we have an analogous case. The sexes of the Euterpe (a Pierine) and the female of the Papilio all resemble each other, while the male of the Papilio stands apart. We have just seen how readily the female of a given species may be drawn away into a mimetic relation apart from its own male, and we have every reason to suppose that the same has occurred here, only that in the case of *P. dardanus*, *L. argia*, and *H. bolina* the pull has been mainly or entirely away from the *dardanus*, *argia*, and *bolina* standard, while here there is no doubt that the female Papilio has pulled the Pierine away from the usual Pierine standard, though it has in turn been pulled away from its own male. The male, it is true, belongs to a synaposematic group of its own, but the female has joined the stronger combination. The pull has been mutual between female Papilio and Pierine, and the association must therefore be Müllerian.

(2) Here is one more piece of evidence. We have seen that from the nature of the case the attraction (so to call it) in a Müllerian assemblage acts, or may act, in all directions, for each member of a Müllerian group is potentially both mimic and model.

It ought then sometimes to happen, if the Müllerian theory is correct, that although one dominant species, distinguished perhaps for its hardiness and distasteful qualities, may act as the centre of a group, influencing all the other members, yet that these other (subordinate) members of the group should show signs of having influenced each other, apart from the dominant species.

Does this ever happen? Certainly it does.

Limnas chrysippus, a Danaine, is one of these dominant forms, numerous in individuals, hardy, conspicuous, proved to be distasteful, and accompanied by mimics wherever it goes. Among its mimics in Africa are an Acræa, and a Lycænid (allied to our common blues). Now it is quite evident that there is a mimetic relation between the Acræa and the Lycænid apart from that which exists between them both and the Limnas. In short, they resemble each other in some respects more than either of them resembles the common model. Hence one or other of these two, or perhaps both, must be distasteful, and therefore there must be a Müllerian element in the whole group, if, indeed, it be not entirely Müllerian.

It has been pointed out by Prof. Poulton that many beetles, belonging to different families, are all in a sense mimics of the hymenopterous group of the Mutillidæ, and yet they have become assimilated to each other in non-Mutilloid points.

Facts of this kind prepare us for a further consideration of great importance, with which I shall conclude.

(3) We find that it is impossible to regard the mimetic assemblages of a given region as so many isolated groups. As a matter of fact, though there are certain dominant forms which act, so to speak, as centres of attraction, we often find that the mimetic forms constitute a nexus, models of the most dissimilar aspect being held together, as it were, by a kind of connection which runs from group to group, gradations from one group to another being formed in the most unexpected ways. From the nature of things this point is difficult to illustrate within the limits of a lecture like the present; a few examples may suffice.

Starting from a white Pieris of ordinary aspect like *P. phaloe*, we can pass by easy stages through *P. calydonia* ♀ and *P. demophile* ♀ into a well-marked distasteful group of which the Ithomiine *Aeria agna* is a good example. From *P. demophile* ♀ we can also pass through *P. viardi* ♀ to the pattern of *Heliconius charitonia*, or in yet another direction by way of *P. tithoreides* ♀ to *Heliconius atthis* and *Tithorea pavonii*. *P. calydonia* ♀, again, gives us a fresh starting point from which to proceed by way of *P. kiçaha*, *P. pandosia*, and *P. leptalina* up to a well-marked Ithomiine group typified by *Napeogenes inachia*. We have already seen how *P. locusta* ♂, which presents the Pierine characters of *P. phaloe* in an intensified form, comes into association with another group of Heliconii, while the same butterfly forms an early link in the chain which leads up by easy gradations through both sexes of various species of Perrhybris (another Pierine genus) to the red, black, and yellow Müllerian assemblage we have already considered. From an intermediate stage in this latter series, exemplified on the undersurface of *Perrhybris lorena* ♀, we get a passage to yet another Heliconiine scheme of coloration, that shown by *H. aranea*. Here, then, we have groups centring round protected Heliconiines and Ithomiines of the most varied aspects, all held together and linked up with white butterflies of the ordinary Pierine facies by a network of almost imperceptible gradations.

As a final illustration, let me direct your attention to the series formed by *Papilio iphidamas* ♀, *Euterpe approximata*, *E. bellona*, *E. nigrina* (underside), and *Heliconius venusta*.

We have only to examine a gradated series like this to see how difficult it is to account for it on Batesian lines. There is the common aposeme, the yellow patch on the dark forewing, running right through; but if the Papilio is the model for all the rest, why should these Euterpes, which are Pierines, mimic a mimic (the Heliconius) instead of going to the model itself (the Papilio)? If, on the other hand, we regard the Heliconius as the model, we are met by exactly the same difficulty, only that it is reversed. Now we know that some at least of these intermediate forms are numerous in individuals, and as soon as the Müllerian principle is admitted we can see how easily forms protected by distastefulness can arrange themselves into a gradational series of this kind. For every distasteful form tends to protect other forms on each side of itself; hence the existence of these transitional stages is just what we should expect. This group represents in miniature what is everywhere to be found when we examine a tropical butterfly fauna from the point of view of mimicry, and I think we have here discovered the answer to an objection that met us at the outset, namely, the difficulty of accounting, on the principle of natural selection, for the existence of these intermediate forms, including the initial mimetic stages. Whether or no the difficulty is a real one in the way of the Batesian theory, in view of the Müllerian principle it is non-existent.

The comparison may perhaps be allowed between these mimetic groups, each with its own type of coloration, and the solar and stellar systems. Sometimes, as in the solar system, there is one central member of the group dominating the whole and influencing its attendant planets to an extent in comparison with which the force they themselves can exercise is insignificant. At other times, as in the systems of double and multiple stars, there are bodies more nearly equal in mass and importance bound together by mutual attraction into a single combination, where each one effectively controls and is controlled by the rest. Could we imagine irregular wanderers through cosmic space which from time to time get drawn within the limits of some established system, we might in them find an analogy to certain species which seem to hover on the outskirts of mimetic groups, undecided, as it were, whether to throw in their lot with one association or another.

What result have we been able to reach to-night? Starting from the fact, long recognised by naturalists, of the wonderful likeness borne to each other by certain insects of widely different affinities, we have found that the first rational explanation of the phenomenon was given by Bates, who nevertheless did not conceal from himself that his interpretation left many of the observed facts unaccounted for. The fertile suggestion of Fritz Müller went far to supply what was still wanting. Expanded by Meldola and by Poulton, accepted by travelled naturalists like Wallace and Trimen, the Müllerian generalisation has proved a powerful means of interpretation of many complicated relationships. We have seen reason for concluding that such rival attempts at explanation as those which allege affinity, or geographical and climatic conditions, as adequate causes for the phenomena before us, break down on serious examination; and we have applied the final test of arguing deductively from the premises, and finding, on a fresh appeal to the facts, that our results are in accordance with expectation.

This verification, we saw, is concerned with the three chief topics of (1) the interchange of characters, or diaposematism; (2) the influencing of subordinate members of mimetic groups by one another; and (3) the nexus of protected conspicuous forms which may overspread a whole zoological continent.

I think no one who has paid attention to the facts that have been before us can fail to recognise that here, as everywhere in organised nature, the principle of adaptation is paramount. No scientific explanation of adaptation that really meets the case has yet been offered except natural selection. Whatever bearing the principle of adaptation by selection may have on the question of the origin of species—I for one venture to think that it has a very important bearing—it is a principle which cannot in fairness be ignored.

In what has been said I have tried to be explanatory rather than controversial, though it has not been possible to avoid altogether points that have given occasion for dispute. Those who are conversant with the subject will know that many questions of interest have been left unnoticed; but I trust that in this survey, necessarily brief, I have said enough to show how much of biological importance and interest is involved in the really great subject of mimicry.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr. R. C. Punnett has been re-elected to the Balfour studentship for one year from Michaelmas, 1907.

A grant of 50*l*. from the Balfour fund has been made to Mr. W. E. Agar in furtherance of his expedition to the Paraguayan Chaco.

A proposed change in the Previous Examination, which may be of far-reaching importance, will be voted on by the Senate next week. At the suggestion of the Board of Examinations, a paper on elementary heat and chemistry will be set in part ii. of the Previous Examination as an alternative to the papers on Paley's "Evidences" and elementary logic. The Board also proposes the substitution of a single combined paper on arithmetic and algebra for the present separate papers on these subjects in the same examination.

The Special Board for Mathematics has issued an important report with reference to the constitution of the board. Owing to the new regulations, the examiners and moderators will in future be nominated by the board. The representatives of the college on the board given them in past years by the nomination of the moderators will thus disappear. The board considers it advisable that there should be direct representation of the mathematical lecturers of the University and of the colleges; it is therefore suggested that two members be nominated each year at a meeting held of the lecturers in subjects for the mathematical tripos.

The reforms which the board of mathematics have introduced into the University in the last four years are numerous and far-reaching. They include a complete revision of the mathematical tripos, the recognition that the teaching of mathematics should be correlated with that of physics and engineering, the establishment of a qualifying examination in mechanical sciences, re-casting of the mechanical sciences tripos, and reforms in the mathematical special examination for the ordinary degree.

Dr. Hobson has been re-elected president of the Cambridge Philosophical Society. The new vice-presidents are Prof. J. J. Thomson and Mr. S. Ruhemann. The new members of the council are Prof. T. B. Wood, Prof. B. Hopkinson, Dr. Searle, and Mr. W. E. Dickson. Mr. H. F. Newall has been re-elected treasurer, and Mr. A. E. Shipley, Dr. E. W. Barnes, and Mr. P. V. Bevan secretaries.

OXFORD.—The Romanes lecture will be delivered by the Chancellor of the University, Lord Curzon, All Souls' College, on Saturday, November 2, at 2.30, in the Sheldonian Theatre. The subject of the lecture will be "Frontiers."

Mr. J. S. C. Douglas, Christ Church, Radcliffe travelling fellow, has been elected to the Philip Walker studentship in pathology.

The London Day Training College, Southampton Row, W.C., will be opened by the Earl of Rosebery on Saturday, November 2, at 3 p.m. The ceremony will be conducted by Mr. H. Percy Harris, chairman of the London County Council.

Dr. W. Goodwin has been appointed head of the chemical department of the South-Eastern Agricultural College (University of London), and Mr. B. N. Wall head of the agricultural department. A new department of soil bacteriology is being established under the charge of Mr. C. T. Gimingham. A conference of hop-growers will be held on November 27 under the chairmanship of Mr. E. C. Lister-Kay, when papers on fertilisation of hops, eel-worms, and hop-drying will be communicated.

At the annual general meeting of the Old Students' Association at University College (University of London), Dr. Tempest Anderson was elected president of the association for the year 1907–8. The annual dinner of the association will be held on Thursday, December 5. The new wing that has recently been added to the college will be completed by that time, and will be open to inspection. Former students of the college who desire to be present should communicate with Mr. George A. Aitken at 42 Edwardes Square, Kensington, W.

Prof. L. F. Vernon Harcourt, who died on September 14, bequeathed 1000*l.* to the Institution of Civil Engineers in memory of the many advantages he had derived from its library and lectures, to found a yearly or biennial (in the discretion of the institution) lecture, medal, premium, or prize, in connection with river, canal, or maritime engineering. The residue of his property he left to his wife for life, and after her death to the University of Oxford, if there shall have been founded there in the lifetime of himself and his wife a school of engineering or mechanical science, 1000*l.* for the promotion of the teaching of engineering science there. He also bequeathed 200*l.* to University College, London, for a yearly prize in civil engineering.

The new laboratories of the scientific departments of the College of Liberal Arts of Boston University have now been opened in the building formerly occupied by the Harvard Medical School. We learn from *Science* that the top floor is occupied by the departments of astronomy, physics, and mathematics, and comprises large and small lecture-rooms, laboratories, and offices; a large part of the basement is also given over to physics. The chemical and biological departments occupy the second floor, and consist of large, well-lighted class laboratories, private laboratories and store-rooms, professors' rooms, and an amphitheatre for the larger classes. The two domes for the telescopes of the astronomical department are situated on the roof, and are not quite completed. The equipment of all the laboratories is new, and was purchased in part by special funds given to the University for that purpose. The scientific departments are under the same directors as last year.

The report for the year 1907 on secondary education in Scotland, prepared by Dr. J. Struthers, the permanent secretary of the Scotch Education Department, has just been published. It appears that instruction in experimental science continues to make headway steadily. The schemes of study submitted to the department for approval often show a tendency to attempt a larger volume of work than can be accomplished satisfactorily in the time allotted to the subject, and teachers find difficulty in treating inductively the more advanced subjects included in the school course of physics and chemistry. The chief examiner reports a large increase in the number of candidates presented at the examination for leaving certificates. It is exceedingly satisfactory, the report continues, to know that in more than 50 per cent. of the schools the examiners were able to accept the teacher's list without change or modification of any kind. This is a sure sign of the growth of that mutual confidence between teachers and examiners which is essential to any really healthy system of examination.

The scientific training of the pharmacist was the subject chosen by Prof. Meldola, F.R.S., for the inaugural address upon the occasion of the opening of the present winter session of the School of Pharmacy. From the lecture we gather that for the two examinations of the school the passing of which qualify the student as a pharmacist, a period of fifteen months' training is all that is required. The standard of the examinations themselves is unquestionably high, and too high, in the opinion of Prof. Meldola, for so short a period of training, creating the danger of the instruction of the school degenerating into a "cram." It appears, however, that at present no knowledge of the action of drugs is demanded of the pharmacy student, although a most intimate acquaintance with the methods of physical and chemical analysis is demanded of him. There can be no doubt that legally great responsibility rests upon the pharmacist, in that if he cannot make his own preparations he is expected to know how they are made and how to assure himself that the products he dispenses are of the nature and substance demanded. In Germany a more thorough and a more prolonged scientific training is necessary before a legal qualification in pharmacy can be obtained, and in this country certain universities have, after a prolonged and thorough curriculum, granted degrees in pharmacy. In conclusion, Prof. Meldola suggested that the Pharmaceutical Society should demand of those students entering the school a higher standard of general education and some specific scientific training either in addition to or in the place of the present three years' apprenticeship, or, in other words, that more attention should be given to the scientific status of pharmacy, even if this has to be done at the expense of its commercial aspects.

SOCIETIES AND ACADEMIES.

Paris.

Academy of Sciences, October 21.—M. H. Becquerel in the chair.—The transits of Mercury across the sun, and in particular on that of November 14: G. **Bigourdan.** A discussion of the various phenomena which have been observed in connection with the transits of Mercury, together with suggestions regarding instruments, &c., for use in the coming transit.—Some formulæ relating to the minima of classes of quadratic forms, binary and positive: G. **Humbert.**—The spawning of the cod in the south of the North Sea: Alfred **Giard** and C. **Cépède.** The authors criticise the views put forward by T. Wemyss Fulton in a recent paper on the same subject. The spawning of the cod in the Pas-de-Calais, the south of the North Sea, and the Baltic takes place in winter, the maximum being produced towards the middle of February, or a month earlier than indicated by Fulton. There is no indication of there being two spawning seasons in certain localities.—The installation of a large astronomical instrument at the summit of the Pic du Midi: B. **Baillaud.** This was carried out in 1906 and 1907 with the assistance of officers and men of the French artillery. Observations will be commenced in August, 1908.—Observation of the Mellish comet (1907*c*) made with the bent equatorial of the Observatory of Lyons: J. **Guillaume.** The comet appeared on October 17 as a diffuse nebulosity of about 35″ diameter, with a faint central nucleus. Its lustre is about that of a star of the tenth magnitude. The apparent positions of the comet and comparison stars are given.—Observations of the new comet (1907*e*) made at the Observatory of Marseilles with the Eichens 26 cm. equatorial: M. **Borrelly.** Similar observations made on October 17 and 18.—Integral equations: E. **Goursat.**—The integrals of the differential equation $y' + A_2y^2 + A_3y^3 = 0$: Pierre **Boutroux.**—The variation of the mass of the electrons in the interior of the atom: H. **Pellat.**—The formation and preparation of aluminium carbide: Camille **Matignon.** Four methods of preparing this carbide without the use of the electric furnace are described: heating a mixture of aluminium powder and lampblack in a Perrot gas furnace for twenty minutes, inducing the reaction to start at a point in the same mixture by the addition of iodine or sulphur, the use of the oxy-acetylene blow-pipe, and by the interaction of aluminium and hexachlorobenzene. In the first two cases the purity of the product was tested by treating with water and analysing the methane produced.—A delicate method for the detection of nickel in the presence of cobalt: Z. **Tchougaeff.** A direct comparison of the dimethylglyoxim reagent suggested by the author some years ago with the reagent recently proposed by M. Pozzi-Escot (ammonium molybdate) shows that the latter is much inferior in delicacy, and under certain conditions may also give rise to a precipitate with cobalt.—Syntheses in the camphor group. The complete synthesis of campholene: G. **Blanc.** The starting point of this synthesis is ethyl malonate, and the sodium derivative of this, treated with γ-bromodimethylbutyric ester, $CH_2Br.CH_2.C(CH_3)_2.CO_2C_2H_5$, gives the ester of 1:1-dimethylbutane-1:4:4-tricarboxylic acid. This is saponified and the acid heated, giving ααδ-trimethyladipic acid, the anhydride of which, slowly distilled at the ordinary pressure, is converted into 1:1:4-trimethyl-*cyclo*pentanone-5. This with magnesium methyl iodide gives the corresponding tertiary alcohol, and the latter spontaneously loses water on distillation, giving a hydrocarbon identical in boiling point, density, and refractive index with campholene from β-campholenic acid.—Sodium anilarsenite in syphilis: Paul **Salmon.** This substance is sold commercially under the name of atoxyl, and by its use comparatively large quantities of arsenic can be administered with comparative impunity. A physiological comparison of three commercial specimens, two amorphous, one well crystallised, showed that no appreciable differences could be detected. It was noteworthy that whereas in animals poisonous symptoms in the medulla were not infrequent, no such untoward effects were observed in man. Of 181 syphilitic subjects, only about 15 per cent. showed intolerance of the drug.—The causes of trypanolytic crises and relapses which follow: A. **Massaglia.** From experiments *in vitro* it is concluded that the crises are due to the formation of an anti-body in the blood of the animals infected by trypanosomes; a small number of the parasites escape destruction and grow accustomed to the action of the anti-body, and it is to these parasites which escape that the relapses are due.—The true accelerating action of sodium fluoride on the coagulation of milk by vegetable ferments: C. **Gerber.**—A preliminary sketch of the geology of Dahomey: Henry **Hubert.**—The displacements of the maxima of the positive and negative anomaly of gravity relatively to the configuration of the earth: Giulio **Costanzi.**

DIARY OF SOCIETIES.

FRIDAY, NOVEMBER 1.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Resumed discussion by Capt. H. R. Sankey on Prof. Bertram Hopkinson's paper on The Indicated Power and Mechanical Efficiency of the Gas-engine.

GEOLOGISTS' ASSOCIATION, at 8.—Conversazione.

MONDAY, NOVEMBER 4.

ARISTOTELIAN SOCIETY, at 8.—The Presidential Address on The Methods of Modern Logic and the Conception of Infinity: Rt. Hon. R. B. Haldane.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—The Determination of Indigotin in Indigo-yielding Plants: Cyril Bergtheil and R. V. Briggs.—Analysis of Indigo (Part iii) and of the Dried Leaves of *Indigofera arrecta* and *Indigofera Sumatrana*: R. Gaunt, F. Thomas and W. P. Bloxam.

TUESDAY, NOVEMBER 5.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Address by the President, Sir William Matthews, K.C.M.G., and Presentation of Medals and Prizes awarded by the Council.

SOCIOLOGICAL SOCIETY, at 8.—The Evils of Cities: a Study of the Degeneration of Communities, and of the Deterioration of their Individuals: Prof. Geddes.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Presentation of the Huxley Memorial Medal to Dr. E. B. Tylor.—On Methods of Determining the Stature and taking other Measurements of the Living Person: Prof. D. J. Cunningham, F.R.S.

WEDNESDAY, NOVEMBER 6.

ENTOMOLOGICAL SOCIETY, at 8.—On some of the Butterflies of Tobago: Dr. G. B. Longstaff.—On a Large Series of Nycteribiidæ (Parasitic Diptera) from Ceylon: Hugh Scott.

SOCIETY OF PUBLIC ANALYSTS, at 8.—Discussion on the Sealing of Samples.

THURSDAY, NOVEMBER 7.

ROYAL SOCIETY, at 4.30—*Probable Papers*: The Effect of Pressure upon the Arc Spectra of Metals: W. Geoffrey Duffield.—The Diurnal Variation of Terrestrial Magnetism: Prof. A. Schuster, F.R.S.—The Electric Discharge in Monatomic Gases: F. Soddy and T. D. Mackenzie.—On the Measurement of Temperature in the Cylinder of a Gas Engine: Prof. H. L. Callendar, F.R.S., and Prof. W. E. Dalby.—Note on the Association of Helium and Thorium in Minerals: Hon. R. J. Strutt, F.R.S.

RÖNTGEN SOCIETY, at 8.15.—The Presidential Address, The Production of High Frequency Oscillations, with Demonstrations: W. Duddell F.R.S.

LINNEAN SOCIETY, at 8.—The Origin of the Di-trimerous Whorls among Flowers of Dicotyledons: Rev. George Henslow.—Unrecorded Acari from New Zealand: Albert D. Michael.—On *Ænigmatistes africanus*, a new Genus and Species of Diptera: R. Shelford.—*Exhibits*:—A copy of Hudson's "Flora Anglica," 1778, with numerous annotations by the Rev. William Kirby: Alexander Stevenson.—Abnormal Stem of *Eucalyptus salmonophloia*, F. Muell., from West Australia: Dr. A. B. Rendle.

CHEMICAL SOCIETY, at 8.30.—Gaseous Nitrogen Trioxide: H. B. Baker and Mrs. M. Baker.—The Atomic Weight of Tellurium: H. B. Baker and A. H. Bennett.—The Isomerism of the Double Sulphites of Sodium and Potassium: M. H. Godby.—Studies in the Camphane Series, Part xxiv, Camphoryldithiocarbamic Acid and Camphorylthiocarbimide: M. O. Forster and T. Jackson.—The Vapour Pressures of Triethylamine, of *sym*-Trimethylpyridine, and their Mixtures with Water: R. T. Lattey.—Liquid Triethylamine: R. T. Lattey.—The Action of Sulphuretted Hydrogen on Solutions of Sodium Hydrosulphite: F. S. Sinnatt.—The Alkyl Compounds of Gold. Diethylauric Bromide. Preliminary Note: W. J. Pope and C. S. Gibson.—Note on the Constitution of Homoeriodictyol: F. B. Power and F. Tutin.—The Interaction of Methylene Chloride and the Sodium Derivative of Ethyl Malonate: F. Tutin.—Preparation of Aliphatic Nitro-compounds by the Interaction of the Alkyl Iodides and Mercurous Nitrite: P. C. Rây and P. Neogi.—Some Mercury Derivatives of Camphor: J. E. Marsh and R. de J. F. Struthers.—Contribution to the Chemistry of the Terpenes. II. The Oxidation of Limonene with Chromylchloride: G. G. Henderson.—The Synthesis of Acridines and Phenonaphthacridines: Tetra- and Hexa-methylacridines: Dimethylphenonaphthacridines: Dixylylmethylenediamines: A. Senier and A. Compton.

FRIDAY, NOVEMBER 8.

ROYAL ASTRONOMICAL SOCIETY, at 5.

MALACOLOGICAL SOCIETY, at 8.—Description of a New Species of Clathurella, probably from Ceylon: H. B. Preston.—On the Mollusca of Birket-el-Qurun, Egypt: C. A. Smith.—*Turbo granoliratus* (New Guinea); *Sistrum chrysalis*, *Purpura bougei*, *Natica bougei* (New Caledonia); *Urosalpinx walkeri*, *Listra walkeri* (N. W. Australia); *Amalthea coxi* (Port Stephens); *Pitaria elata* (Sierra Leone); all new species: G. B. Sowerby.—Note on the Originals of the Illustrations for E. M. da Costa's "Historia Naturalis Testaceorum Britanniæ," London, 1778: Alex. Reynell.

PHYSICAL SOCIETY, at 8.—Discussion on Mr. Campbell's Paper on the use of Variable Mutual Inductances.—A Graphic Method for Stream-lines and Equipotential Surfaces: L. F. Richardson.—On the Lateral Vibrations of Bars Supported at two Points with one end Overhanging: Dr. J. Morrow.

CONTENTS.

SUPPLEMENT TO "NATURE."

DENATURED ALCOHOL.

Denatured or Industrial Alcohol. By Rufus Frost Herrick. Pp. x+516. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1907.) Price 17*s*. net.

THE tax-gatherer, nowhere a *persona grata*, by some strange irony of circumstance finds that one of the most convenient modes of raising revenue is to tax that which, proverbially speaking, maketh glad the heart of man. Nevertheless, this fact rather detracts from his general unpopularity than adds to it, at least with all right-thinking communities. For alcohol, unlike certain much-advertised pens, is not an unmitigated boon and a blessing; there are some people, indeed, who, if they had their way, would tax it out of existence altogether.

Without entering on the vexed question as to whether alcohol, in its manifold forms, is or is not of alimentary value, it is universally agreed that if articles of food and drink are to be taxed at all, human nature being what it is, there is no more convenient substance by which to raise a revenue than the spirit of wine. But the industrial value of alcohol is hardly less important than its potable value. It is the starting-point in the manufacture of a great variety of useful and beneficent products, and it has special merits as a fuel and as a solvent. The tax-gatherer-in-chief, that is the Chancellor of the Exchequer, of every civilised State is, therefore, confronted with the problem how to raise a due amount of revenue from alcohol without hampering or crippling those industries which need alcohol in their manufacturing operations. This country was the first to attempt to settle this difficulty by introducing the system of what is called "denaturing" the alcohol, that is, so treating it as to render it practically worthless as an article of drink without materially impairing its application to industrial purposes or materially increasing its cost to manufacturers. The effective solution of the problem is by no means an easy matter. An efficient denaturant must fulfil certain necessary conditions. In the first place it must render the spirit nauseous, even when used in comparatively small quantity. Secondly, it must not be capable of being easily removed by distillation or by mechanical or chemical treatment; next, it must be capable of ready and certain detection, even if present in very small quantity; and, lastly, it must not affect the industrial value of the spirit. The ideal denaturant has not yet been found, but by general consent of all who have studied the question (and it has been inquired into and reported upon by the revenue authorities of nearly every country), the method suggested by the late Mr. George Phillips, and first adopted in Great Britain about half a century ago, has been found in practice to be on the whole the most convenient and suitable. It consists in adding to the spirits a certain quantity of wood-naphtha, or crude methyl alcohol, which, if containing a sufficient quantity of the associated pyroligneous products, renders the alcohol practically unpotable, except perhaps to the hardened dipsomaniac, who, like Porson, will drink even ink if it intoxicates, and who, to the extent that he is a curse to himself and society, must be treated by special means. Alcohol thus denatured, although not wholly released from revenue control, can be supplied for industrial use free of duty and without any charge to the user beyond the cost of "methylation."

With the spread of manufacturing industry, especially of chemical and pharmaceutical products, and in consequence of the increasing stress of competition, it was but natural that this question of the relations of alcohol to industry on the one hand, and to the revenue on the other, should be the subject of frequent inquiry, and for some years past an agitation was kept simmering in this country to effect the relaxation of the conditions under which duty-free alcohol may be employed in industry. It culminated in a departmental inquiry, and a considerable body of evidence was accumulated which had the unlooked-for result of entirely disproving the allegation that the attitude of the revenue authorities was in the least degree answerable for the position in this country of those industries which are concerned with, or are dependent upon, the use of alcohol. At the same time, the inquiry was not only of benefit to manufacturers in this country by opening their eyes to the real causes which affected their industries, but resulted in some substantial concessions to them. For although the contentions on which they originally based their demands were hardly supported by such evidence as they were able to adduce, it was found that the cost of "denaturing" might be materially reduced without risk to the revenue, and, what was of more importance to manufacturers, that the Treasury could afford to grant a considerable rebate to industrial alcohol. It is too soon, perhaps, to draw conclusions as to the operation of these concessions, or as to their commercial effect. It is, however, quite certain that if the results are not commensurate with anticipation, the fault will not rest with the inland revenue authorities.

All these matters are treated at length in the volume before us, which is, if we mistake not, the first treatise in our language on the subject to which it relates. Of course, much has been written on the methods of manufacture of alcohol, and Mr. Herrick's book contains little on this point which is not already familiar to distillers. Nor is it to be expected that what he has to say respecting the value of alcohol as an illuminant and as a fuel, or as a source of power, contains much original matter. But his compilation will be welcomed by all who are concerned in these subjects, and especially by those mechanicians who are interested in alcohol as a source of light and power. Mr. Herrick has been at some pains to put together all available information in the confident expectation that his countrymen will not be slow to turn it to account.

"It is the hope and belief of the author that we Americans can solve for this country the problem of Denatured Alcohol in such a successful manner that all the world may secure, from the results we here attain, uses and benefits much greater than those heretofore achieved."

As America has only known anything of denatured alcohol since the beginning of this year, Mr. Herrick's anticipation has all the enthusiasm and optimism of inexperience. At the same time, we shall look with interest to the realisation of his belief. Meanwhile we commend his book to the attention of those older nations to whom the problem of denatured alcohol has been familiar for generations past, in the hope that their energies may be quickened and their inventive genius stimulated by its perusal.

WATER AND WATER POWER.

Hydraulics. By Prof. S. Dunkerley. In two volumes. Vol. i., Hydraulic Machinery. Pp. vii+343. (London: Longmans, Green, and Co., 1907.) Price 10*s.* 6*d.* net.

HYDRAULICS, the practical side of the science of hydrodynamics, is a subject of no little interest and importance, not only from a technical, but also from an historical point of view. The energy contained in running water was one of the earliest sources of power utilised for the service of man. Water-wheels date back to a remote age, and are no doubt coeval with windmills. It is interesting to note that water power and wind power share the unique distinction of being found in nature "ready made," in which respect they stand apart from other motive agencies, which have to be generated.

It is mainly within a comparatively recent period that the capabilities of hydraulic power for industrial purposes have been thoroughly and systematically exploited. No little of the initiative in this matter was due to the genius and enterprise of the late Lord Armstrong, whose inventive mind was, he tells us, first set to work in this direction on the occasion of a journey through the Craven district of Yorkshire in 1836. He was then struck by the large number of mountain streams descending the steep slopes of the hills and expending their energy to no apparently useful purpose. Applying himself to the problem with characteristic energy, he became the pioneer and founder of the modern system of hydraulic power transmission, which has had such an enormous vogue during the past fifty years; and although at the present time its popularity is threatened by the growing importance of its junior rival, electricity, yet there still remains a vast field of usefulness for it which it can never wholly lose.

Prof. Dunkerley is thoroughly qualified to deal with a subject of this kind, requiring, as it does, a combination of close mathematical reasoning with practical common sense. He divides his material into two volumes, the first of which, and the one now under review, is entirely concerned with the theory of hydraulics in its relation to machinery. Dealing primarily with fundamental principles, he lays down the laws which have been demonstrated by experiment, and then proceeds to describe the means of their practical application.

Admirable, however, as is Prof. Dunkerley's work in its general scheme, we find that it bears here and there several traces of a slight lack of care in preparation, and some mistakes (due most likely to an imperfect scrutiny of the proof-sheets) which it would be well to correct in future editions. In certain parts the book would appear to have been compiled somewhat disconnectedly, and without that sustained continuity of reasoning and progressive demonstration which constitute features of a scientific treatise no less essential than accuracy of detail and clarity of diction. The author frankly admits that one article (p. 192) is out of its proper sequence, and it seems to us that other sections might have been more advantageously arranged. For instance, we venture to suggest that it would have been preferable for article 62 to follow directly after article 34, to which it appertains, and there is no apparent reason why the frictional resistance of bends and elbows should be dealt with in widely disconnected sections on pp. 56 and 87.

Over and above some evident misprints of an ordinary type, one or two strange inaccuracies seem to have crept in. The rendering of Kulter for Kutter (the familiar name of the Swiss experimentalist, who with Ganguillet propounded the well known formula now commonly known as Kutter's formula) is surely a *lapsus plumae* of rather more than ordinary significance, seeing that it occurs no less than four times, and is nowhere given correctly. The formula for bends, quoted on p. 87 as that of Weisbach, and presumably covering the general case, is certainly incomplete, and should read:—

$$h_b = m \cdot \frac{v^2}{g} \cdot \frac{\theta}{\pi},$$

where, for circular culverts,

$$m = 0{\cdot}131 + 1{\cdot}847\left(\frac{r}{R}\right)^{\frac{7}{2}},$$

θ being the angle of deflection. Even supposing the expression intended only to apply to rectangular bends of circular section (which is not expressly stated, and cannot be strictly inferred), the essential power index is lacking.

We mention these points in no carping and fault-finding spirit, but simply by way of enabling such few blemishes as there are to be removed. It is infinitely more pleasant to direct attention to the really commendable features, which are not a few. A number of worked examples are inserted throughout the book. These have been so carefully selected, and are so eminently helpful, that the author is to be congratulated upon their introduction. Then, too, he has been at pains to choose for his illustrations instances of some of the more recent applications of hydraulic science to engineering and commercial operations, instead of confining himself to old-fashioned types. A predilection for naval appliances is no doubt due to his past association with the Royal Naval College at Greenwich. In chapter iii. there are very full details of the hydraulic gun brake and of the method of operating bulkhead doors. Other articles worthy of mention are those relating to the hydraulic ram (pump), the Gutermuth valve, and the various adaptations of the centrifugal system of pumping, including the turbine. A good portion of the book is devoted to chronicling Prof. Osborne Reynolds's researches, including an article on the theory of lubrication. We do not notice any allusion to Prof. Hele-Shaw's experiments in stream line flow, but possibly this is reserved for the second volume, which is announced to deal with the resistance and propulsion of ships.

Altogether, there is a great deal to commend this book to students and others interested in the practice of hydraulics. The type is clear, the setting good, and the diagrams are very distinct. There is a large amount of new matter, and some old matter presented in a new light, and to those who are desirous of possessing a record of Prof. Reynolds's investigations, the volume forms a much readier source of reference than the original papers and the proceedings of various learned societies in which they are embodied.

COMPARATIVE ANATOMY OF THE LABYRINTH.

The Labyrinth of Animals, including Mammals, Birds, Reptiles, and Amphibians. By Dr. Albert A. Gray. Vol. i. Pp. x + 198; 31 plates. (London: J. and A. Churchill, 1907.) Price 21*s.* net.

ONE turns away from the examination of this work with a mixed feeling in which admiration is tempered with disappointment. In the volume under review the author reproduces thirty-one excellent stereoscopic photographs of exquisite preparations of the inner ear of various species of mammals—structures which hitherto have been left unexplored owing to the grave technical difficulties involved in their preparation. These difficulties the author has overcome by the application of a new technique whereby the delicate and complicated membranous labyrinth is freed from its surrounding bone, and clearly exposed as a transparent body, perfect in form and texture. Besides the photographs of these structures, which are novelties to the anatomist, the author gives scores of accurate measurements relating to the fenestra ovalis, the semicircular canals, and the cochlea; careful records are given of the development of the perilymph system, of the degree of twisting of the cochlea, of the pigmented areas on the ampullæ and lamina spiralis, and of the form and size of numerous other structures. The technique, the industry, and the field of fresh observation compel our admiration; it is when one comes to consider how far this research has really advanced our understanding of the inner ear that a feeling of disappointment creeps in. What Dr. Gray has really succeeded in showing is, that the mammalian labyrinth—if the monotreme form be excluded—is almost identical in form and arrangement in all; the variations shown relate only to minor details. That is what one ought to expect, seeing how strictly the organ subserves the same function in all—at least so far as it serves as an organ of hearing. But as part of the mechanism of balancing and of orientation, one might expect a greater degree of variation in structure than Dr. Gray has actually found. In the case of the sloth the semicircular canals are certainly peculiar in form. From the data of comparative anatomy one is frequently able to obtain valuable suggestions of the functional meaning of obscure structures, but in this respect Dr. Gray's inquiries, so far as can be seen at present, are remarkably barren.

Dr. Gray is of opinion that many of his observations may afford indications of the relationship of one mammalian order to another. He divides the forms of cochlea into flat conical and sharp conical. To the sharp type belong the Carnivora and Rodentia, while Primates, Ungulata, Sirenia, Cetacea, Insectivora, and Cheiroptera possess the flat type; the Edentata show an intermediate form. Unfortunately one knows so little of the real meaning of the twisting of the cochlea tube that it is hazardous to say at present what importance should be attached to its form. Amongst marsupials, Dr. Gray found both forms of cochlea to occur. He is inclined to attach a taxonomic value to the size of the perilymph space in the semicircular canals, a wide space being, in his opinion, the primitive form. The seal, for instance, has a wide perilymph space, while the sea-lion, like the land Carnivora, has a very narrow one, from which he concludes that the seal must have branched off from the primitive Carnivora stock while this space was still wide, whereas the sea-lion dates his departure from the period at which this space had already diminished in the land forms. To estimate the worth of such an observation one wishes to be quite certain that the size of the perilymph space has no functional significance, and, secondly, that the wide form is really the primitive mammalian form. Man and all the monkeys possess an ample perilymph space, whereas in the lemurs it is of small size. The slow loris differs from the typical lemur in many points so far as regards the anatomy of the inner ear, but here again one wishes to know how much of this difference is really due to a difference in function, and how much is really due to a difference in descent.

While expressing an unqualified admiration for the results obtained by the application of Dr. Gray's technique, one must also admit that it is a technique with very serious limitations. The finer structures of the ear, the organ of Corti and the nerve-endings cannot be thus examined, and are only to be explored by the old, laborious and accurate method of sectional reconstruction. A. K.

BRITISH WILD LIFE.

The Woodlanders and Field Folk: Sketches of Wild Life in Britain. By John Watson and Blanche Winder. Pp. xii + 304; illustrated. (London: T. Fisher Unwin, 1907.) Price 5*s.* net.

THE demand for books on country life and popular natural history (and from the number of volumes on these subjects issued nowadays from the press it may be assumed that such demand is large) is a healthy sign of the times. A *sine quâ non* with such books is, however, that they should be fairly accurate and reasonably up to date. Whether the volume now before us fulfils these conditions we will leave our readers to judge for themselves after perusal of the following extracts and comments.

In the chapter headed, not very happily, "A Miniature British Fauna," it is stated (p. 109) that "British voles are diminutive beavers"; while on the next page we are told that there are three British species of these rodents—the water-vole, field-vole, and bank-vole. Now to call the water-rat, or water-vole, a beaver is bad enough, but to include the short-tailed field-mice, or field-voles, under the same term is a positive absurdity. With such lack of knowledge it is not surprising to find the authors completely ignorant of the existence of the Skomer Island and Orkney voles. Again, it is a little late in the day to refer (pp. 113–114) to the bank-vole as having only recently been recognised as a species, especially when mention is made of Yarrell's description of it "as lately as 1832." While excluding "voles," the authors class the dormouse among mice, stating that we have four representatives of that group—the dormouse, the harvest-mouse, the long-tailed field-mouse, and the house-mouse. What may be the authors' views as to the systematic position of rats we dare not venture to guess!

In connection with mice, we may refer to the statement (p. 109) that, "with one exception (the harvest-mouse), the long-tailed field-mouse is the smallest British mammal," the shrew-mice being totally forgotten! As regards the matter of sizes of animals the authors are, indeed, very casual, as on p. 249 they tell us that the rock-dove is the smallest of the British pigeons, although they include in that group the turtle-dove, as they likewise do the passenger-pigeon!

Other instances of carelessness or want of knowledge occur in the statement that the fur of the water-shrew is warm brown (p. 110), and the mention of silver fox where white fox is obviously intended (p. 37). If true, the statement that otters feed mainly on crayfish (p. 101) is new to us; while we are startled by the suggestion on p. 67 that British cuckoos occasionally incubate and hatch their eggs. In using the term loon (p. 206) to designate the grebes, the reader should have been informed that it is generally applied to the divers; or if that information was considered superfluous, it was surely unnecessary to suggest (p. 101) that most persons are ignorant of the fact that owls reject the waste portions of their food in the form of pellets.

Owing to its many errors the naturalist will be very disappointed with the volume; while the nature-student who desires to use it as a source of information will find that he has much to unlearn.

The illustrations of scenery and of nests of birds in their natural situations are for the most part good, and many of them excellent. As for the photographs of stuffed birds among pseudo-natural scenery, perhaps the less said the better; but if such artificial pictures are used, it would be well to see that the toes of the birds are made to grasp the boughs on which they are placed, instead of sticking out in an aimless manner, as in the photograph of the turtle-dove facing p. 252. R. L.

POPULAR ORNITHOLOGY.

(1) *Birds I have Known.* By Arthur H. Beavan. Pp. 256; illustrated. (London: T. Fisher Unwin, n.d.) Price 2s.

(2) *A Ready Aid to Distinguish the Commoner Wild Birds of Great Britain.* By David T. Price. Pp. 62. (London: Gurney and Jackson, 1907.) Price 1s. net.

(3) *Birds of the Countryside: a Handbook of Familiar British Birds.* By Frank Finn. Pp. xvi+190; illustrated. (London: Hutchinson and Co., 1907.) Price 5s. net.

(4) *The Useful Birds of Southern Australia.* By Robert Hall. Pp. xvi+306; illustrated. (Melbourne: T. C. Lothian, 1907.) Price 3s. 6d.

(1) THAT there is an increasing interest taken in wild birds by amateurs is abundantly proved by the steady stream of books on the subject intended for the use of beginners which issues from the publishers. Perhaps there is no better way of fostering their interest than relating one's lifelong experience of birds, and Mr. Beavan has done this very pleasantly in "Birds I have Known." Beginning with his childhood, when he lived in a "dreary London square" which could not repress his ornithological instincts—these finding an outlet in the parks, rare visits to the Zoo, and to Margate, where he made the acquaintance of a living gull—the author passes on to his school-days. They were schooldays under the old, hard system. To read of them should make the modern boy contented with his lot, although he may perhaps long for the greater amount of liberty and the greater opportunities for training the powers of observation enjoyed by boys before games were put before everything else. But he will follow with delight the author's adventures in search of birds' nests, and his experiences with tame hawks and owls, &c. Later, in the holidays, this particular boy found his way to Leadenhall Market, with its then rich show of ruffs and reeves, avocets, godwits, and rare waterfowl, at which he used to gaze long and admiringly. Altogether the progress of the young ornithologist, with the real, keen love of birds in him, making the best of not very favourable conditions, is admirably traced. But the author soon went to sea, and succeeding chapters take us among ocean birds, and recount his experiences of birds "during many years in many lands and over many seas." Here he deals "with Nature like an open book," "uncomplicated by references to scientific theories as to the origin and distribution of species." And very good reading these chapters are, although home-staying bird-lovers may find their chief pleasure in those upon Cornish and London birds. But wherever made, the personal observations of a keen bird-man are always worth reading by his fellows, and really are a great help to the younger ones. Mr. Beavan has certainly known a great many birds. The frontispiece is a reproduction of one of Wolf's incomparably beautiful pictures of eagles. The rest of the illustrations seem to be original, but will hardly escape criticism to-day.

(2) Even nowadays, under the narrowing influence

of primary education and the counter attractions of cheap holiday outings and cigarettes, some of our ploughboys grow up knowing the names of nearly all the birds around them, without having even seen a book on the subject; and a generation ago such knowledge was general among them. But there are now many educated people, it appears, who would like to be able to recognise the birds they meet with, and having come to mature years without knowing anything about them, seek for a short, if not a royal, road to that knowledge. For them a pocket key has been cunningly devised by Mr. Price. In the second part will be found short descriptions of about one hundred of the commoner British birds, written specially for the observer with a field-glass, dealing therefore with habitat, flight, and characteristic habits rather than with details of plumage. In order, however, that it shall not be necessary to search this part of the volume from beginning to end in the process of identification, the first part has been devised. In this part—which might be called an index—under seven headings, each heading constituting a certain locality, and in two columns (for winter and summer), will be found lists of the species that are likely to be seen in such localities.

"By dividing these lists into groups according to the size of the species, and by adding a two-word description of each, it is hoped that but two or three species will remain as possibilities. The descriptions of these will then be found in the second part on the page indicated."

The idea has been very well carried out, and we are sure the little book will be a help to those for whose use it is intended; but we confess to having our doubts as to whether anyone who *wants* such a key for use in the field will ever know his birds as well as our ploughboys. The single illustration explains the meaning of the names of the different portions of a bird's plumage.

(3) Mr. Finn's stouter volume is also intended to help the beginner to identify birds, but the subject is dealt with more fully therein. It is a handbook, not a key, although the descriptions here again are of the bird as it catches the eye at a distance as well as close at hand—its general colour, shape, and peculiarities of motion and cry. The book is primarily intended to serve as a means of identification of the birds most conspicuous in life or literature, free or in captivity in this country; and the easiest method of learning to know birds, in the author's experience, is to identify those which first catch the eye, and then learn their relations. To this end he has arranged the species dealt with according to the circumstances under which they are likely to be first met with. As most of his readers will be more interested in "the bird in the bush" than in that in the hand, he has cut the descriptions of the species as short as possible, so as to facilitate identification. Here again the birds are grouped according to their locality, the chapters being subdivided in some cases for summer and winter. The complete and pleasing, though concise, account of the general life habits of the different birds (and the nesting habits of those that breed in this country) seems well calculated to help the novice to acquire the knowledge he desires. There are directions for encouraging the presence of desirable birds, by the provision of nesting-boxes, food, and water, as well as for the rearing up of orphaned or deserted young birds—directions which will, of course, be quite as useful for birds taken out of the nest. Finally, to give the reader some idea of classification, at the end of the book there are enumerated and briefly diagnosed all the natural families of birds occurring in our islands, even where these are only represented by casual stragglers.

For the dozen coloured plates we have the highest praise. Many of the black and white illustrations are most interesting and novel, *e.g.* one showing the peculiar appearance of pea-pods torn to pieces by hawfinches. But those of captive birds (so apt to look ragged and dejected) and stuffed groups are not always so happy. We hardly think the photographs of the "house martin," the missel thrush and fieldfare can be much aid to identification, nor can we, by the way, fall in with the statement that the martin seems more common in England than the swallow nowadays. But we do not know where else you can get so many good and interesting bird-pictures for so little money.

(4) Those who are interested in the economic aspect of ornithology, especially the good, or harm, done by birds in the course of the satisfaction of their hunger will profit by a perusal of Mr. Hall's careful treatment of the subject in his account of some of the birds of southern Australia. The book will be welcomed also by those who would like to get some idea of what manner of birds inhabit the far distant island continent, and learn something of their habits. There is, of course, a raven, crow, and kestrel, which for some reason, like the Americans, they will call a sparrow hawk. But the birds on the whole are so utterly different from ours that it comes as a surprise to find a meadow pipit of the same genus as ours, and it is interesting to compare the habits of the two birds. There are no less than six kinds of cuckoo in South Australia, but they do not call "cuckoo," and their notes do not in the slightest degree resemble those of our northern bird—they are described as high-sounding, as weird, and as melancholy. But these cuckoos are just as troublesome to their small neighbours, "upsetting hundreds of family arrangements." The pallid cuckoo chooses open nests like that of the fantail for this purpose; the other species distribute their favours among the wide, open, cup-shaped nests and those with a side entrance. The fan-tailed species and two bronze species choose 75 per cent. of dome-shaped nests, while the square-tailed cuckoo is content with 50 per cent., and the remaining half of open nests. The whole of the account of the cuckoos is most interesting, and the home life of some of our best-known cage-parrots may be learned in this pleasant little book. It concludes with some account of birds which have been introduced. The goldfinch and song thrush are naturally well spoken of; nothing bad is yet known there about the greenfinch or the skylark, and the blackbird's character is much what it

is with us. Few introduced species have succeeded in firmly establishing themselves, and not all of them have been a success in other ways. The starling has already taken to turning out of their nesting holes certain useful native species, and the author says "certainly a part of the cost of upkeep in every well-settled district will need to be expended on the annual subjection of sparrows and starlings." Altogether the acclimatisation of birds in Australia does not seem to have been attended with very encouraging results. The book is, of course, mainly intended for use in the colony. It is nicely illustrated.

O. V. A.

AN UNFREQUENTED ITALIAN COAST.

The Shores of the Adriatic; the Italian Side. By F. Hamilton Jackson. Pp. xiv+358; illustrated. (London: John Murray, 1906.) Price 21*s.* net.

OF the hundreds of English-speaking tourists who annually visit Italy, the great majority consider that they have "done" the Adriatic when they have seen Venice, while a few are attracted a little further afield by the curio shops of Ravenna or Rimini or the postage stamps of San Marino. In exploring the coast-line from Brindisi to Udine by gradual stages, omitting Venice, Mr. Hamilton Jackson has opened up a region practically unknown to English and Americans. There is a good deal of French, Italian, and German literature regarding this part of Italy of which a fairly long list is given in the preface, but English writings are few in number, and this circumstance alone would afford sufficient justification for the publication of the present book, if indeed any justification should be needed.

The district is one of great historical interest. It has been occupied by Greece and Rome, raided by Saracens and Turks, invaded by Gauls, and the southern part conquered by the Normans, of whose methods of strategy an interesting narrative forms part of the first chapter. It comprises the province of Apulia, the Abruzzi, the Marche, Emilia (Romagna), and Venetia. Geographically, the most important feature along the coast-line is the Monte Gargano, with its shrine of Monte Sant'Angelo, founded by Constantine. From its prominent position it was for a long time a Saracenic stronghold, and still retains its name of Monte Saraceno.

It is with the architectural beauties, in particular the churches, that this book mainly deals, and the illustrations are an important feature. In these days of "process blocks" line drawings come as a pleasant change and relief from the monotonous "half-tone" illustrations. Mr. Jackson has made use of both forms of illustration. A number of photographs, mostly taken by Mr. J. Cooper Ashton, are reproduced in the form of plates, while the illustrations in the text show the advantages of pen and ink sketches for bringing architectural details into due prominence. The dual mode of illustration has undoubtedly served another useful purpose. In the narrow streets of an Italian town there are many buildings which cannot possibly be got into the field of view of a camera fitted with even the widest angle lens, and we may be fairly sure that if the author had trusted to photography alone many of the choicest and most picturesque bits would never have figured in this book. Of the difficulties of taking photographs when boys will persist in standing in front of the camera we have an example on p. 165, while the arrival at Brindisi described on p. 33 gives a familiar instance of the way the English traveller is imposed on in Italy when he keeps to the beaten track. On the other hand, the author speaks warmly of the courtesy shown him by officials and others in regions where English tourists are practically unknown. As a set-off against this advantage, Mr. Jackson had to put up with somewhat rough and primitive accommodation in places, and his photograph of an interior under the title "Stable and house in one, Foggia," gives some insight into the insanitary conditions prevailing in many of these unenlightened little Italian towns.

Of the buildings of interest, the following rough summary may give some general idea:—At Bari, cathedral, church of San Nicola, with treasury, King Roger's Castle; at Bitonto, church of San Valentino; at Terlizzi, eleventh century church; at Giovenozzo Molfetto, Trani, Troja, Lucera, cathedrals; at Barletta, church of Santa Maria Maggiore; on Monte Sant'Angelo, the grotto church, with fine bronze doors dating from 1006; San Clemente in Casauria, church; Ascoli Piceno, Roman bridge and prison, churches of SS. Vincenzo and Anastasia, San Giacomo, San Francesco; at Ancona, arch of Trajan, cathedral of San Ciriaco, with beautiful panels, church of Santa Maria della Piazza; at Rimini, bridge of Augustus, church of San Francesco, castle of Sigismond Malatesta; at Ravenna, mausoleum of King Theodoric, cathedral, tomb of Galla Placida, church of San Vitale; at Pomposa, abbey church of Santa Maria, with great campanile; Chioggia, a picturesque town on two canals easily reached from Venice; at Treviso, cathedral; at Udine, cathedral and excursions to Cividale, with its picturesque bridge, castle, churches of San Martino and Santa Maria in Valle. It would be impossible to quote the author's descriptions of these and other objects of interest, but the above list will afford some idea of what there is to be seen by anyone who will follow in Mr. Jackson's footsteps, while the stay-at-home reader will certainly, as the author claims, by reading the descriptions and examining the figures, obtain an insight into Italian art which will be quite new to him.

A number of plans of churches and cathedrals are inserted in the text, in addition to the other figures. There is, however, one point which is too often overlooked by writers of books of travel. A map, however rough and sketchy, of the district traversed greatly adds to the interest. It is true that most people have a map of Italy in their possession, and it must further be admitted that the towns follow each other in fairly regular order along the coast, so that the descriptions can be followed fairly well in any case. At the same time, a very useful purpose would be served by having a map in the book itself. If only on the ground of convenience, it would be consulted more frequently than an atlas, and the reader would acquire a better knowledge of the geography of the interesting and practically unspoilt towns that Mr. Jackson has so ably brought before our notice. This is the only fault, and that not a serious one, that can be found with this charming and delightful book. On the other hand, the vivid descriptions recall to our mind the bright colours of a southern town, the shouts and gesticulations of the populace, and last, but not least, the scent of burnt incense in the churches and the unsavoury odours of narrow Italian streets.

G. H. Bryan.

SCIENCE AND PRACTICAL BREEDING.

Farm Live Stock of Great Britain. By Robert Wallace. Fourth edition. Pp. xxxi+758. (Edinburgh: Oliver and Boyd, 1907.) Price 16*s.* net.

THIS edition of Prof. Wallace's handbook cannot fail to be of value to owners and to students of the history and management of stock. The illustrations are a special feature of the book; more than 400 of them are excellent reproductions of photographs, and had the animals been taken in a position which would admit of measurement, and a scale provided, the collection would have been of unique value.

After a chapter on wild cattle, in which the various herds recorded are referred to, and, where possible, described, there follow nine chapters on breeds of cattle. The origin and history of these breeds, their points, character, and management are well set forth; but what is of special interest is the attention devoted to variation, to the development of special qualities and of new types, to the influence of climate, and to the results of crossing. Chapters on the breeding and management of calves, on grazing cattle, and on the house-feeding of cattle follow, and this section concludes with two valuable chapters on dairying.

Pigs are somewhat perfunctorily dismissed in two short chapters.

Six chapters are given to the horse. Extinct and wild horses are briefly referred to, and a few inconclusive words said on the subject of the origin of our domestic breeds. Clydesdales and shire horses are more fully treated than are any of the other breeds, as must be expected in a book of this kind, but the space devoted to horses is meagre, and the treatment accorded them not comparable to that given to cattle and sheep.

On sheep there are eight chapters, in which the various breeds are separately and, as a rule, fully treated, while four short chapters contain advice as to the management of sheep, their feeding, the parasites which infest them, and the diseases from which they suffer.

The author claims in writing this book to have kept "in view not only the interests of one special breed, but also its connection with other breeds and the position it occupies in the great live stock economy of the country." This is a high aim, and, if he has not entirely succeeded, either to the satisfaction of certain special breeders or to that of the advanced student of live stock economy, his work is valuable, and will be of real service to those who follow him in their efforts to attain this end.

To readers of Nature it is to the first chapter in this book, on the principles of breeding, they will turn with special interest, and it is disappointing to find that the author has failed to give an account which adequately represents the results attained by modern scientific workers or the influence such work must exert on the future development of the breeding industry.

It is not from books, he says, that a student can learn to master the peculiarities of different breeds or the constitution of different animals; a long apprenticeship as a practical breeder is essential for such knowledge and for the success of the stock-owner. That is undoubtedly true, but one may surely have expected the professor of agriculture in Edinburgh to point out in his book that the scientific principles which govern the right application of all practical experience are of no less importance; to emphasise the fact that a scientific training which teaches the practical observer what to look for, how to sift his observations, how to apply his knowledge effectively, is necessary for the student of the subject, and a sound knowledge of the scientific principles of breeding essential for the highest success of the modern stock-owner. This omission is greatly to be deplored.

W. H.

A NEW DICTIONARY OF SOLUBILITIES.

Solubilities of Inorganic and Organic Substances. By Atherton Seidell. Pp. x+367. (London: Crosby Lockwood and Son; New York: D. Van Nostrand Co., 1907.) Price 12*s.* 6*d.* net.

DURING the thirteen years which have elapsed since the publication of Comey's "Dictionary of Chemical Solubilities," so great an activity has been shown in the determination of solubilities as to necessitate a new compilation of the data. As it is impossible to tell whether the solutions used in most of the earlier determinations were saturated in contact with a single definite solid phase, a considerable degree of uncertainty characterises such values. At the time when Prof. Comey's "Dictionary" was written it appeared inadvisable in the majority of cases to attempt to select from the discordant results of different observers the most trustworthy values for any particular substance, but the author of the present work points out that such a discrimination can now be made with advantage. In general, the values he gives were chosen by calculating the available determinations to a common basis, and plotting the data so given on squared paper. A comparison of the curves obtained, together with a consideration of the experimental details, usually furnished clear evidence for a trustworthy selection.

One advantage of this system is that the results are expressed in a uniform manner throughout; usually the solubility is given for regular intervals and in terms of weight of dissolved substance per given weight of solvent or of solution. In all cases where it is possible, the nature of the solid phase is clearly defined.

The value of such a work of reference must be determined by two factors, its completeness and its accuracy. As regards the former, there is little doubt that great pains have been taken to search thoroughly the literature of the past twenty-five years; concerning the latter, an opinion can only be formed after the book has been for some time in constant use. It is to be regretted that more care has not been given by the author to his nomenclature. On the same page we have acetamide and acetamid; acetanilide, acetanilid; anilin and aniline. The names of many organic substances appear curiously disjointed; for example, Tri Chlor Acetic Acid, Di Phenyl Amine, Epi Chlor Hydrine. It is unfortunate that the author considered it advisable to give to substances the names "found in the original papers," because this has led to the introduction, for example, of such terms as toluyl acid, anis acid, and napthion acid for the well known toluic, anisic, and naphthionic acids. Phenyl thiocarbimide is found under the German disguise of "Senföl"; suberic acid is, however, given its correct name, and is not seen masquerading as "Cork acid."

In several cases it would appear that the author does not know the German equivalents of the names of very well known organic compounds; quinine and chinin are regarded as different substances, and the data given under these two headings are quite different, being derived from different sources. Glycollic acid is termed glycocholic acid. Misprints of names are numerous.

Such blemishes, occurring with extraordinary frequency, are very unfortunate in a book which must have involved great labour in its preparation, and is bound to be widely used. The author in his preface modestly craves "all indulgence for errors and omissions," thus in a manner disarming criticism. The value of future editions of this work will greatly be enhanced if the nomenclature be carefully revised.

W. A. D.

A TEXT-BOOK OF OCEANOGRAPHY.

Handbuch der Ozeanographie. By Dr. Otto Krümmel. Vol. i. Die räumlichen, chemischen und physikalischen Verhältnisse des Meeres. Pp. xv+526. (Stuttgart: J. Engelhorn, 1907.) Price 22 marks.

THE treatise on oceanography published in Ratzel's "Bibliothek geographischer Handbucher" in 1884 has remained the standard work on the subject. Few branches of science have made more progress, absolutely and relatively, during the last twenty years than those which concern our knowledge of the sea, and the book has been seriously out of date for a considerable time. A new edition is therefore practically a new book, and a new standard treatise on oceanography will be hailed with relief by every student of the subject who has toiled more or less successfully to keep up with the unfailing streams of original memoirs which have issued from almost innumerable sources in recent years.

Prof. Krümmel's new volume, issued in the same series, which is now under the editorship of Prof. Penck, takes the place of vol. i. of the older treatise, written by the late Prof. von Boguslawski. Its general scope is the same, inasmuch as it treats of the form and distribution of the seas and oceans, the formation and composition of deposits, and the physics and chemistry of sea-water, and leaves dynamical questions to be dealt with in vol. ii., which in the older treatise was written by Prof. Krümmel himself. But the arrangement of the different parts, and the space devoted to each, are, of course, widely different. A comparison of the two works brings out in an unusually striking manner the enormous advances which have been made in the comparatively short interval, and places in their proper perspective the great contributions made, amongst others, by Murray in the concluding volumes of the *Challenger* reports, by Pettersson, Nansen, the deep-sea and Antarctic expeditions and the cable-ships, and the smaller researches in home waters which have culminated in the institution of the International Council for the Study of the Sea. It may be added that a comparison also makes clear the immense complexity of many problems which once seemed comparatively simple, and the urgent need, on economic as well as scientific grounds, for continued independent and combined effort in exploration and research.

Detailed description of the contents of Prof. Krümmel's book is impossible in the space at our disposal. The author gives an account under each head of the methods of observation employed by the chief investigators, more particularly in the most recent work, states the quantitative or distributive results arrived at, and applies them systematically to the description of special phenomena or of special geographical divisions. The amount of labour involved by this method is, of course, enormous, and the compression of the results into a volume of 526 octavo pages has been done with masterly skill. Criticism is by no means wanting, and we note with satisfaction that Prof. Krümmel has been able to retain many of the earlier observations, which, with their obsolete methods and cruder equipment, have sometimes been regarded as unworthy of comparison with those of the high precision more recently attained. Controversial questions concerning the application of these observations to the discussion of dynamical questions will doubtless be dealt with in vol. ii., the publication of which we await with interest. For the present it suffices to record the debt which all oceanographers owe to Prof. Krümmel for placing at their disposal so vast and orderly a store of material.
