PATIENTS IN MENTAL INSTITUTIONS, 1940

INTRODUCTION

Previous enumerations.—The history of the collection of mental institution statistics by the Bureau of the Census was briefly discussed in the 1939 annual volume, and will not be repeated here. In its present form, the enumeration has been annual since 1926, and this is the fifteenth census. This report was prepared by Grace C. Scholz, Chief of Mental Institutions Statistics, under the supervision of Halbert L. Dunn, M. D., Chief Statistician for Vital Statistics, and Forrest E. Linder, Ph. D., Assistant Chief Statistician.

Arrangement of the report.—This volume has been arranged in the same format as the reports of the past 2 years. Part I consists of "Patients in Hospitals for Mental Disease," part II consists of "Patients in Institutions for Mental Defect and Epilepsy," and part III presents combined data on mental defectives and epileptics under treatment both in hospitals for mental disease and in institutions for mental defect and epilepsy.

Period covered.—The data reporting the patient population of institutions cover either the calendar year 1940 or the fiscal year that ended during that calendar year. Most State institutions find it more convenient to report for the fiscal year, since their data are customarily compiled for their own reports on this basis. Financial data always cover the fiscal year.

Summary statements.—In the collection, processing, and presentation of these data, the primary consideration throughout has been type of control of institution. Nevertheless there are numerous approaches that might be made to a census of hospitalized mental patients. It is important to know the types of patients that come under the supervision of State hospital systems, of the Veterans' Administration, or of hospitals under other types of control. However, an over-all picture of the distribution of hospitalized mental patients might also be made from point of view of sex, clinical diagnosis, age distribution, geographic distribution, and from other considerations as well. To make possible a ready approach to the characteristics of all hospitalized patients with mental disease, or of all patients institutionalized with mental deficiency and epilepsy, from each of these various aspects, total sections have been compiled for mental disease in part I and for mental deficiency and epilepsy in part II, and other consolidations can be made from data presented throughout the report.

From these tabulations a few conclusions and comparisons may be brought together in summary. Male patients under supervision of all hospitals for mental disease at the end of 1940 outnumbered females 7 to 6, while male admissions outnumbered females in the ratio of 7 to 5. During the course of the year there were 55 discharges and 31 deaths per 100 patients admitted to State hospitals. The remainder may be accounted for by patients transferred to other hospitals, deaths of patients on parole, and by patients who remained in the hospital, thus contributing to its gradual growth. There were nearly three times as many first admissions to mental hospitals as there were readmissions. At the end of the year, 3.6 persons per 1,000 of the total population and 4.8 persons per 1,000 population aged 15 years and over in the United States were in mental hospitals. Few children under 15 years of age develop mental disease. At the end of 1940, 97.8 percent of all patients in hospitals for mental disease were in public hospitals (State, veterans', county, and city). Of total admissions during the year, 83.3 percent were admissions to public hospitals; 16.7 percent, to private hospitals. The rate of first admission to all hospitals for mental disease increased steadily through 74 years of age. The largest diagnosis of first admissions among individual mental disorders was dementia praecox (schizophrenia), with 19.3 percent of all; however, the two psychoses of old age. senile psychosis and cerebral arteriosclerosis, comprised 19.8 percent of all first admissions.

For mental deficiency and epilepsy the number of males under supervision of institutions slightly outnumbered females (4 to 3.9); for admissions the ratio was 9 males to 7.5 females. Mental defective diagnoses among institutionalized patients were five times more numerous than epileptic. During the year there were 46 discharges and 21 deaths per 100 admissions to State institutions. There were more than nine and a half times as many first admissions as readmissions. At the end of the year nearly 0.8 persons per 1,000 of the total population, and nearly 0.9 persons per 1,000 population aged 5 years and over, were in residence in an institution for mental defect or epilepsy. At the end of 1940, 96.5 percent of all patients in institutions for mental deficiency and epilepsy were in public institutions (State and city). Of total admissions during the year, 91.1 percent were admissions to public institutions; 8.9 percent, to private institutions.

Ratios to general population.—Population figures used as the base for computing rates for trend figures in this report are estimates made by the Bureau of the Census for the intercensal periods 1920-1929 and 1930-1939. Rates of hospitalization and of first admission for 1940 data are based on the population enumerated in the 1940 census (as of April 1). In the computation of rates based on selected age ranges of the population, the age distributions of the population obtained in the 1940 census have been used.

Various procedures have been employed in the computation of rates, and certain exceptions have been made. These are noted to make clear their general implications. Rates of hospitalization and first admission are based on State of hospitalization rather than on State of residence of the patient before hospitalization. These rates are based on total population figures, as well as on the population aged 15 years and over in the case of mental disease, and on the population aged 5 years and over in the case of mental defect and epilepsy. Few patients younger than 15 years are hospitalized for mental defect or epilepsy. In computing these adjusted rates, the entire patient population has been used; those under 15 or 5 years of age, as the case may be, have not been excluded. The proportion of the population in these lower age ranges varies considerably from State to State, and the crude rates present somewhat altered relationships from those in which limited population age ranges have been employed.

Because of wide variation in policies of discharge, and in laws determining the length of parole before discharge, rates of readmission and discharge should be cautiously interpreted, particularly in making interstate comparisons. These rates are probably more meaningful for a trend study in a single State over a limited period.

Median ages have been computed by diagnosis for first admissions and deaths, in each instance in which there were more than 100 patients with a single diagnosis. The median duration of hospital life of patients who died in the hospital has also been computed by diagnosis. The median ages should not be taken to be indicative of life expectancy of patients with these disorders, nor of the relative effectiveness of hospital treatment. They indicate simply the median ages of first admissions, or deaths, as the case may be, of patients who come under the jurisdiction of the hospitals of each special type of control. Because the population source of patients in hospitals under different types of control (e.g., State, county and city, or veterans') differs in various ways, such as age range and sex distribution, the median ages and median durations of hospital life before death in these hospitals may be expected to differ.

Acknowledgment.—The generous cooperation of each of the institution superintendents and of the various State and Federal officials through whom data were supplied is gratefully acknowledged. Without their help in making returns accurate and complete, this report would lose much of its value.

[&]quot;When the values of a variable are arranged in order of magnitude, the "median" is a value so selected that 50 percent of the total number of cases lie above it and 50 percent below it.

PART I. PATIENTS IN HOSPITALS FOR MENTAL DISEASE

INTRODUCTION

Scope of the data.—The data in part I of this report are devoted to State, veterans', county, city, and private hospitals for mental disease. There were 179 State and 2 Federal hospitals in 1940, and, of this total, 3 State hospitals did not report. The 2 Federal hospitals, St. Elizabeths Hospital in the District of Columbia, and Morningside Hospital in Oregon, the latter privately owned but hospitalizing the mentally diseased of Alaska for the Federal Government, were included with the State hospitals in compiling tabulations, as in previous years. Patients were also reported in 26 of the 27 veterans' hospitals, 80 county and city hospitals, and 187 private hospitals. The data for 7 psychopathic hospitals, 6 under State and 1 under county control, were reported separately, as were data for patients in psychiatric wards of general hospitals.

Significance of the data. - The true prevalence and incidence of mental diseases in the population can be gauged only in part by numbers of hospitalized patients or of admissions to hospitals during the year. Usually, there are higher hospitalization rates when facilities are available in greater abundance, when they are readily accessible, and when the type of treatment that a hospital provides is well thought of in the community. Even in a State with superior hospitalization facilities, there are many persons with mental disorders who receive treatment from private psychiatrists, visit out-patient clinics, or achieve the minimum degree of adjustment to their environment necessary to obviate psychiatric treatment. These patients do not enter into the present study. Acutely disturbed patients, however, will find hospitalization unavoidable. It is not likely that the mental disorders of hospitalized patients will display the same proportionate diagnostic distribution as the total number of mentally ill in the community. For example, it is probable that general paresis, psychosis due to new growth, or psychosis with organic changes of the nervous system will ultimately require hospitalization, but a patient mildly disturbed with certain types of dementia praecox (schizophrenia) may never approach a point where hospital commitment is necessary.

The purpose of this enumeration is to provide information as to the extent of provision and use of hospital facilities, both public and private, for the mentally ill in each State; to furnish a measure of the quality of treatment that is afforded, insofar as it is indicated by expenditures and by the personnel of the hospitals; and to set forth a distribution of the types of mental disorder of incoming patients, both first admissions and readmissions, the prognosis of each psychosis as measured by rates of discharge, and an indication of the degree of fatality of each. Influences upon the data of administrative practices, such as the extensive use of a parole system, the length of period of parole and its relationship to readmissions, the use of the practice of family care, et cetera, are noted.

Treatment of the data.—The report deals initially with a combination of information from hospitals under State, veterans', county, city, and private control. Following this presentation of combined material, more detailed analysis is given of data for State hospitals for mental disease. In conclusion the data for veterans', county and city, private, and psychopathic hospitals, and for psychiatric wards in general hospitals, are presented separately.

ALL HOSPITALS FOR MENTAL DISEASE

In the following tables a composite presentation of the data secured from all hospitals for mental disease is made. It should be borne in mind that State, county, and city hospitals on the whole draw their patient population preponderantly from within State boundaries. For veterans' or private hospitals this is not necessarily true. The 26 reporting veterans' mental hospitals were located in 23 States, and the State of hospitalization of the patient in at least one-fourth of the cases did not coincide with the State of residence of the patient before hospitalization. Those States in which veterans' hospitals are located are credited with somewhat increased rates of hospitalization and of first admission. To a lesser degree, because fewer patients are involved, the rates are influenced by private hospital patients also. Consequently, the total hospitalization and first admission rates that are presented for each State are in error to the extent to which veterans' and private hospital patients have migrated across State boundaries.

Private hospitals for mental disease in 31 States and the District of Columbia have responded to this enumeration. Reports were not received from some hospitals to which forms had been sent, and undoubtedly there were other hospitals to which forms had not been addressed. Since many States do not have a central system of hospital registration, the Bureau of the Census may not have obtained a complete list of private hospitals for every State.

County hospitals were reported in only seven States and city hospitals in five. The patient population in some of these hospitals was large. Failure to take these patients into consideration resulted in a distorted comparison of public provision of facilities for the mentally ill. In Wisconsin, for example, more than three-fourths of mental patients in custody in public hospitals were under care in county hospitals. State hospital figures alone were necessarily inadequate. Although some private and county hospitals did not respond to this enumeration, their patient populations were known to be comparatively small. We have every reason to believe that the patient population in hospitals for mental disease as reported in these tables, with the exception of those hospitals known to be missing, is substantially complete.

Movement of patient population.—At the end of 1940 State hospitals were credited with 86.1 percent of patients on the books of all hospitals for mental disease; veterans' hospitals cared for 5.6 percent of the total; county and city had 6.1 percent; and private hospitals, 2.2 percent. On the whole these figures point to a trend over some years of increasing State and Federal care of hospitalized patients with mental disease. State hospitals reported 902 patients in family care at the end of 1940. No hospitals under other than State control have adopted this practice.

A greater proportion of patients on books were on parole or other absence status from State hospitals than from hospitals under any other type of control. Parole may be defined as a period of trial during which a patient attempts adjustment to community life, and may last from 30 days to 3 years, depending upon State law. In the interim the patient is retained on the hospital books in order to facilitate his readmission should it at any time prove necessary. Patients who were absent from the hospital during a holiday period or on temporary trial visit have in some instances been included in this category.

In most States a 1-year period of parole is observed. It is apparent that the length of time during which a patient may return to a hospital without recommitment will influence to a great extent the rates of readmission to that hospital. This factor should be borne in mind in interpreting interstate variation in rates of readmission.

The greater the number of social workers a hospital is able to employ, the larger will be the number of paroled patients who may be given the benefit of follow-up care in their own homes. Close periodic check on the activities of paroled patients is important. It may be observed that those States with the largest number of paroled patients are either more progressive in their attitudes toward the care of mental disease, or else their hospitals are so severely overcrowded that it has become necessary to place patients on parole as quickly as possible in order that others in more urgent need of hospitalization may be admitted.

At the end of 1940 there were 532,999 patients on the books of all hospitals for mental disease. There was an increase of nearly 15,000 patients in the course of the year. At the end of the year there were 473,058 patients in hospitals, an increase of nearly 12,000 over the number of patients in hospitals at the beginning of the year.

There were more admissions (150,906) to all hospitals during the year, than there were separations (135,940) during the same period. Veterans' and private hospitals had disproportionately large shares of readmissions. The hospitals maintained by the Veterans' Administration, because of more adequate bed capacity than most State hospitals, provide for readmission of patients less acutely ill. It is also evident that more patients in veterans' hospitals have types of mental disorder that require frequent readmission. Private hospital patients are, in many cases, not so severely disturbed as those admitted to a public hospital. Many times a mildly psychotic patient remains unhospitalized unless he is able to pay for his treatment.

The continuous increase in the number of patients hospitalized for mental disease is due to a variety of factors. Despite an ever-increasing number of beds provided for the care of mental patients, there is no lessening of the promptness with which they are filled. Increasing urbanization makes necessary the hospitalization of many chronic patients, since the aged and infirm are not so readily cared for in a city environment as they may be in a rural locality. As the prevalence of mental disorders is greater among those of more advanced years, the fact that the median age of the general population is steadily advancing will ultimately be responsible for a tremendous increase in the incidence of mental diseases, that is, unless methods of prevention and treatment of old-age psychoses undergo a revolutionary change.

City and county hospitals for mental patients were maintained in 10 States, but the number of patients they cared for constituted a considerable proportion of the total in only 4. Seventeen States had no private hospitals reporting mental patients in 1940.

Discharges made directly from all hospitals (53,560) were more numerous than discharges of patients on parole (35,967). There is considerable interstate variation in practices observed with respect to discharge. States that discharge all of their patients directly from the hospital are generally those in which facilities for after-care of paroled patients are meager, or those in which the area from which the patient population of the hospital is drawn, is wide and inaccessible.

Deaths of patients in the hospital are maintained separately from deaths while on parole, because it is appropriate that deaths which do not occur within the hospital should not be charged to the hospital.

Trend in hospitalization.—It is desirable when expressing rates of prevalence of hospitalized mental diseases to base them only on the proportion of the population that is liable to the risk of hospitalization. Children below the age of 15 years rarely receive mental hospital care. (Less than 0.3 percent of patients reported to be in residence in State hospitals for mental disease were under 15 years of age in 1939.) In the accompanying table 2, however, only crude rates of hospitalization expressed per 100,000 of the population are presented. These rates are based on annual intercensal population estimates or population enumerated as of April 1, 1940.

At the end of 1940 the rate of hospitalization for all hospitals for mental disease, per 100,000 of the population, was 359.3, an increase of 8.3 points over the rate at the beginning of the year. Incomplete reporting in 1940 accounts for the slightly decreased rate from 1939 to 1940. Rates have not been computed for some of the years in which an enumeration was made, because data from other than State hospitals were not collected.

Beginning with 1933 the number of patients in State and veterans' hospitals increased considerably—in State hospitals by more than one-fourth by the end of 1940; in veterans' hospitals the number of patients more than doubled in the same period. In county, city, and private hospitals, however, the number of patients has remained fairly uniform throughout.

¹ Estimated as of January 1 of the corresponding year for 1923, 1926-1940; enumerated as of April 1, 1940 for 1941.

Number of patients reported at the end of the year 1940.

Incomplete reporting, see footnote to tab's 1.

Patients in county and city hospitals included with Veterans'.

⁴ Rate not computed.

Rates of hospitalization. — At the end of 1940 the rate of hospitalization for all hospitals for mental disease, per 100,000 of the total population, was 359.3. At the beginning of 1940 there was a slight decline from the 1939 rate; however, in 1939 there was complete reporting of State hospitals, and in 1940 three State hospitals and one veterans' hospital were not included. percent increase in the rate of hospitalization has been smaller in recent years probably because the provision of facilities for the mentally ill in some of the more populous States is more nearly adequate now than it ever was before. hospitalization rate per 100,000 of the total population, when considered by State, was highest in Massachusetts (588.2) and New York (583.1). The rate for the District of Columbia (934.7) has been excluded from this comparison since its mental hospital, St. Elizabeths Hospital, admits patients not only from the District of Columbia but from all parts of the country. Its facilities must allow for the care of patients who would otherwise be treated in Army, Navy, Marine, or Veterans' Administration hospitals. The lowest rate of hospitalization, per 100,000 of the total population, was in New Mexico (171.9). Since one hospital in Mississippi has not reported for this year, the State rate (72.5) has not been considered in these comparisons.

The vast majority of the resident patient population of mental hospitals is over 15 years of age (99.7 percent of the patient population of State hospitals in 1939). Accordingly, rates of hospitalization have also been computed based on the general population aged 15 and over. In computing these adjusted rates, the entire patient population has been used; those under 15 years of age have not been excluded. The hospitalization rate for the United States based on the general population aged 15 years and over was 479.3. The two States with the highest rates per 100,000 of the population aged 15 years and over were Massachusetts (752.0) and New York (734.4), as was the case when the total population was used as the base of the rate. The proportion of the population under 15 years in Massachusetts (21.8 percent) was larger than the like proportion in New York (20.6 percent). As a result of this differential the adjusted rate in Massachusetts was 17.6 points higher than New York's rate, as compared with a difference of 5.1 points between the crude rates of the two States. In the areas in which the proportion of children in the population is large, the relationship of the rates in that area to the United States rate, when adjusted by the limited age base 15 years and over, will be altered most. This is true of the South. In the South Atlantic division the hospitalization rate based on the total population (315.2) is 87.7 percent as high as the rate in the United States, while the rate based on the population aged 15 years and over (445.4) 1s 92.9 percent of the corresponding rate in the United States. A truer comparison is obtained when hospitalization rates are based only on that proportion of the population liable to the risk of hospitalization for mental disease.

First admissions.—The classification of mental patients by psychosis, or by type of mental disease, is important in a statistical study of the mental diseases. The classification used is that adopted by the American Psychiatric Association in 1934. Because the terminology differs somewhat from that used earlier than 1935, an exact comparison of the statistics in this report with those of 1934 and earlier years is not possible for certain groups of psychoses. The arrangement is such, however, that direct comparisons can be made among the major psychoses.

This classification divides mental disorders into two major groups, those with psychosis and those without psychosis. The group "With psychosis" is further subdivided into 21 special groups of psychoses, with an additional group for "Other, undiagnosed, and unknown." The group "Without psychosis" is subdivided into 7 definite groups of mental disorders, with an additional group indicated as "Other, unclassified, and unknown."

First admissions include all patients admitted for the first time to any hospital for mental disease, public or private, wherever situated, except to an institution providing temporary care only, such as the psychiatric ward of a general hospital.

Rates of first admission.—The presentation of rates of first admission for each State is similar in form to that used in the case of rates of hospitalization. The rate of first admission per 100,000 of the total population was 80.5. In 1939 the rate was 84.8 and in 1938, 85.1. Undoubtedly part of the decline in rate in the present year may be accounted for by incomplete reporting of hospitals. Nevertheless, there appears to be an actual decline in the rate of first admission.

The rate of first admission varies, not so much in accordance with the number of patients requesting admission, as with the volume of facilities available to accommodate them. When hospital facilities are inadequate, the number of unhospitalized patients, for whom hospital beds are not available, accumulates. In recent years there has been a general expansion of hospital facilities, and this group of patients, who might have been hospitalized sooner, have been admitted for treatment. First admissions accordingly become more and more a direct reflection of the immediate incidence of mental disease.

Rates of first admission, per 100,000 of the total population, were highest in Vermont (126.9) and Maryland (123.8). The District of Columbia rate (155.5) has again been excluded from the comparison. Rates of first admission have also been computed per 100,000 of the population aged 15 years and over. The rate for the United States was 107.4. Adjustment of the rates from the total population base to the base of the population aged 15 years and over, has altered the rank order of State rates in several instances. Those rates that appeared among the highest or lowest in the range, however, were sufficiently dispersed and had sufficiently similar proportions of the population under 15 years of age, so that their rank order in both distributions did not differ to a considerable extent.

Age-specific rates. -The first admission rate to all hospitals for mental disease has been computed per 100,000 of each respective age group of the population in 5-year intervals from 15 years through 74 years. There was an almost steadily increasing rate of first admission in each succeeding 5-year interval. The rate for those patients under 15 years was based on the entire population under 15. It is probable that these patients should all be grouped in the age range 10 to 14 years, but since the specific ages were not known, this assumption was not made. The rate increased from 2.5 per 100,000 population under 15 years to 307.5 per 100,000 population aged 70 to 74 years. The age category of 70 to 74 years is so large because more than 40 State hospitals were unable to indicate the age of patients on first admission by 5-year age intervals above 70 years of age, and these patients have all been placed in the 70 to 74 age range. For patients aged 75 years and over, the rate per 100,000 was 200.6. It is probable that most of the patients of unknown age may be placed in the age category of 75 years and over.

¹Enumerated as of April 1, 1940. ²Incomplete reporting, see footnote to table 1. Population rates for United States and individual States based on total population figures. ³Rate not computed.

TABLE 4. - FIRST ADMISSIONS TO STATE, VETERANS', COUNTY, CITY, AND PRIVATE HOSPITALS FOR MENTAL DISEASE, AND RATE PER 100,000 POPULATION, IN EACH AGE GROUP: 1940

AGE (IN YEARS)	All first admissions	Rate per 100,000 population in age groups	AGE (IN YEARS)	All first admissions	Rate per 100,000 population in age groups
All ages 1	105,989	80.5	40 to 44	10,418 10,177	118.4 123.9
			50 to 54	8,930	123.8
Under 15	828	2.5	55 to 59	7,042	121.2
15 to 19	4,225	34.2	60 to 64	6,327	134.2
20 to 24	7,271	62.9	65 to 69	5,715	150.1
25 to 29	9,171	82.6	70 to 74 2	7,859	307.5
30 to 34	9,930	96.8	75 and over	5,230	200.6
35 to 39	10,669	111.4	Unknown	2,197	(3)

Distribution of mental disorders. — Of the total of 105,989 first admissions to State, veterans', county, city, and private hospitals, 90,940, or 85.8 percent, were diagnosed as with psychosis. In State hospitals the proportion of total first admissions with psychosis was 87.5 percent; in veterans' hospitals, 71.0 percent; in county and city hospitals, 93.6 percent; and in private hospitals, 78.9 percent.

For all hospitals combined the largest number of first admissions, 20,457, or 19.3 percent, were diagnosed as with dementia praecox (schizophrenia). Cerebral arteriosclerosis claimed the next largest number of patients, 12,319, or 11.6 percent, and manic-depressive psychosis with 10,433 patients, or 9.8 percent, was third in size.

General paresis was responsible for the admission of a greater proportion of patients to the veterans' hospitals (13.5 percent) than to all hospitals combined (6.8 percent). First admissions with general paresis to veterans' hospitals (638) exceeded those with dementia praecox (schizophrenia) (588). In county and city hospitals senile dementia was responsible for many first admissions (12.0 percent of the total). In these hospitals a large number of patients have been indicated as with other, undiagnosed, and unknown psychoses, principally because many hospitals in Iowa and Wisconsin were not able to specify the clinical diagnosis of their admitted patients. In private hospitals manic-depressive psychosis (2,338 patients) was responsible for nearly the same number of first admissions as was dementia praecox (schizophrenia) (2,371 patients). Patients with involutional psychoses were responsible for 7.3 percent of total first admissions to private hospitals as compared with 4.3 percent of the total to all hospitals combined. The proportion of patients admitted with alcoholism without psychosis was high for private hospitals, 13.2 percent; and high also for veterans' hospitals, 12.0 percent; while the proportion for all hospitals combined was 6.7 percent.

¹Incomplete reporting, see footnote to table 1.
² The age range 70 to 74 years contains patients reported as 70 and over by those hospitals unable to indicate ages in 5-year intervals for patients over 70 years. Rate not computed.

STATE HOSPITALS

It was the practice in each of the annual enumerations of mental patients prior to 1939, to request more detailed data from State hospitals for mental disease than from hospitals under other types of control. Because the same kind of information has been collected for so many successive years, the data have undoubtedly attained a greater degree of accuracy than those from hospitals under other than State control. In 1940 there were 181 State hospitals and all reported, except one Mississippi State Hospital and the Arizona and Montana State Hospitals.

Movement of patient population.—At the end of 1940 there were 458,845 patients on books of State hospitals, 236,161 male and 222,684 female. Of this total, 88.1 percent, or 404,293 patients, were in hospitals; and 11.9 percent, or 54,552 patients, were absent. The vast majority of those absent were on parole or other absence status (53,650). However, there were 902 patients in family care.

Family care has gradually come into more general use during the past decade, but data reporting the practice were not collected until 1937. In most cases these patients are not yet ready for discharge: in some instances there may be no one in whose custody they can be placed. More personal contact is possible in a small family unit, and the socialization of an individual may be more readily brought about there than in hospital life. At the end of 1940, six States made use of the practice of family care in their State hospitals. They were Maine, Massachusetts, Rhode Island, Connecticut, New York, and Maryland. From the viewpoint of the clinician, this type of treatment is beneficial for the carefully selected patient. It is attractive also from a financial aspect. Although it costs slightly more to maintain a patient in family care than it does to maintain him in a hospital, the capital expenditure for providing new beds for the mentally ill who could not otherwise be accommodated, far exceeds the cost of family care.

Trend in hospitalization.—The hospitalization rate for State hospitals, expressed per 100,000 of the total population, increased from 217.2 in 1926 to 307.1 in 1941 (based on reports at the end of 1940), or more than 40 percent during the 16-year period. In 1926 the data included 163 of the 165 hospitals. In 1940 the number of hospitals had increased to 181, with 178 reporting.

The rate of hospitalization includes neither patients in family care nor those on parole or otherwise absent. These groups contained 11.9 percent of total patients on books at the beginning of 1941. The frequency of use of the practice of parole has not altered considerably during this 16-year period; the percent that patients on parole or otherwise absent constituted of total patients on the books has shown a gradual but slight increase.

1926	272,716	246,486	217.2			26,230	9.6	

¹ Prior to 1937, patients "In family care" were included with patients "On parole or otherwise absent." ² Estimated as of January 1 of the corresponding year for 1926-1940; enumerated as of April 1, 1940 for 1941.

Rates of hospitalization.—The hospitalization rate for patients in State hospitals for mental disease was 307.1 per 100,000 of the total population at the end of 1940. The rate per 100,000 of the population aged 15 years and over was 409.6. By State the highest rate, expressed per 100,000 of the total population, was in New York (547.6), and the second highest in Massachusetts (529.8). When the rates were adjusted to the base of population aged 15 and over, the New York rate was 689.7 per 100,000; the Massachusetts rate, 677.4. Wisconsin and the District of Columbia have been excluded in this consideration because, in Wisconsin, the State hospitals cared for only one-fourth of the total patient population in public hospitals. The situation in the District of Columbia, as has been explained in the preceding section, is unique. New Mexico's rate (171.9) is lowest among State hospitals, as was the case in the distribution of all hospitals for mental disease.

The proportion that absent patients comprised of total patients on the books of State hospitals was 11.9 percent in the United States. The proportions ranged from 0.4 percent in South Dakota to 38.1 percent in Wisconsin and 30.0 percent in Virginia. Proportions of patients absent but on books of the hospitals were highest in the South Atlantic (16.1 percent), Mountain (15.7 percent), and Pacific (15.6 percent) divisions.

³Number of patients reported at the end of the year 1940. ⁴Incomplete reporting, see footnote 1 to table 6.

¹ Enumerated as of April 1, 1940. ² Incomplete reporting, see footnote 1 to table 6. Population rates for United States and individual States based on total population figures. ³ Rate not computed.

First admissions.—First admissions include all patients admitted for the first time to any hospital for mental disease, public or private, wherever situated, in or outside of the State, except to an institution providing temporary care only (as the psychiatric ward of a general hospital).

There were 79,449 first admissions to State hospitals for mental disease in 1940, as compared with 81,655 in 1939. The decline can be partly but probably not entirely accounted for by the incompleteness of reporting in 1940. Further discussion relative to this decline may be found in the section dealing with all hospitals for mental disease. The first admission rate per 100,000 of the total population was 60.3 in State hospitals, and the rate per 100,000 of the population aged 15 years and over was 80.5. Adjusted State rates of first admission were highest in New Hampshire (141.5) and Virginia (131.2), and lowest in Colorado (39.5). The District of Columbia and Mississippi were excluded in these comparisons.

Of first admissions, 87.5 percent of the total were diagnosed as with psychosis (69,511 of 79,449). Dementia praecox (schizophrenia) constituted the largest category among single diagnoses of first admissions, numbering 16,433, or 20.7 percent. Cerebral arteriosclerosis, which was responsible for the first admission of 13.5 percent of the patients, ranked second, while manic-depressive psychosis, with 9.2 percent of the total, was third. General paresis, as is usually the case, caused the admission of nearly three times as many male (4,417) as female patients (1,595). Alcoholic psychosis was the diagnosis of nearly six times as many male (2,994) as female patients (527), while alcoholism without psychosis was responsible for the admission of over seven times as many male (3,831) as female patients (517).

The median age of first admissions for male patients with psychosis was 46.0 years as compared with 45.6 years for female patients. For patients without psychosis, the median ages were 38.3 years for male and 35.4 years for female.

2 See footnote 2 to table 4.

Readmissions.—A patient who has previously received treatment in a hospital for mental disease (other than one which provides temporary care only), whether located in the State or elsewhere, and who has been discharged from the books, is designated as a readmission. By a hospital which "provides temporary care" is meant the psychiatric ward of a general hospital.

In 1940 the total readmission rate to State hospitals in the country as a whole was 29.2 per 100 first admissions. The rate has increased steadily in recent years. In 1937 it was 26.1.

For an additional means of comparison the rate of readmission has been expressed per 100 discharges. There was equally wide interstate deviation in readmission rates expressed on the basis of discharges as on the basis of first admissions. For the country as a whole there were 40.4 readmissions per 100 discharges.

The readmission rates, when expressed per 100 first admissions, were highest for manic-depressive psychosis (73.1) and for psychosis with psychopathic personality (56.5). Rates of readmission per 100 discharges were highest among psychoses with epidemic encephalitis (60.8), with dementia praecox (schizophrenia) (54.1), with convulsive disorders (52.8), and with manic-depressive psychosis (51.5).

Rates of readmission are influenced by the degree of hospital overcrowding. When a hospital is unable to accommodate all patients seeking admission and must give preference to the most acutely ill, the rate of readmission is decreased. A less crowded hospital can admit less acutely disturbed patients to begin with, and will have a greater number of persons as possible candidates for readmission.

The development of a system of parole with a sufficient number of social workers to keep in close touch with the patient between the time that he is released from the hospital until such time as he is eligible for discharge will tend to decrease the necessity for readmission. It cannot be too strongly emphasized that any interpretation of rates of readmission must be tempered by consideration of the parole regulations and release practices in each State. 1

The proportion that patients with psychosis comprised of total readmissions was 87.5 percent (82.2 percent for male and 93.6 percent for female). The sex difference may be accounted for by the large proportion of alcoholism without psychosis among male readmissions (10.9 percent). Dementia praecox (schizophrenia) was responsible for the largest proportion of all readmissions (29.8 percent), with manic-depressive psychosis (23.0 percent) next in order; however, in this latter disorder females (30.5 percent) constituted almost twice as large a proportion as did males (16.4 percent).

Some mental disorders are naturally more recurrent than others. While temporarily the patient may be apparently fully recovered, relapses are frequent. The readmission rate based on numbers of first admissions is a measure of the frequency of recurrence of mental disorders. The number of discharges constitutes another reliable basis on which to express rates of readmission since only discharged patients are eligible for readmission.

¹ In some hospitals overnight return of patients on books but not in residence, for the purpose of retaining jurisdiction, is common practice.

Discharges.—When a patient is discharged from the hospital, he is separated from the books, and the hospital relinquishes its supervision over his activities. In some hospitals it is the practice to place all patients on parole first, and to discharge them from parole after a trial period when it appears that the patient is again able to carry on his normal activities. In other hospitals no parole period is employed before discharge, and all patients are discharged directly from the hospital. Generally speaking, those hospitals that are better able to conduct follow-up activities, because of availability of funds and adequacy of personnel, are more likely to retain a greater number of patients on parole.

The terminology used in classifying mental patients according to condition on discharge is defined as follows:

Recovered indicates the condition of patients who have regained their normal mental health, so that they may be considered as having practically the same mental status as they had previous to the onset of the psychosis.

Improved denotes any degree of mental gain less then recovery. Unimproved denotes no mental gain.

without psychosis refers to patients who had no psychosis at the time of admission to the hospital. These patients are not classified as recovered, improved, or unimproved. Such designation would not be meaningful in combination with the condition of psychotic patients, and would tend to confuse the significance of the results for psychotic patients.

There must necessarily be considerable variation of opinion in the measurement of so subjectively determined a factor as condition of a patient on discharge. In all probability, however, there are real differences among the States in the type of patient discharged.

In the country as a whole, slightly more than two-fifths of all patients discharged from hospitals were indicated as improved (male 41.5 percent, female 49.8 percent). Slightly more than one-fourth were recovered, a greater proportion among females (30.2 percent) than among males (23.9 percent). These proportions are larger for females because of the unusually high proportion of male patients without psychosis (24.7 percent as compared with 10.1 percent for female). Condition on discharge was not indicated for nonpsychotic patients.

The rate of discharge of patients with each clinical diagnosis was based on the total number of admissions of the same clinical diagnosis. Transfers were excluded in this consideration and the sum of first and readmissions used as the base. It should be understood, however, that the reported discharges do not indicate discharges of the particular patients reported among admissions. Some discharged patients had undoubtedly been admitted in years previous to the one reported, and some of the admissions have not yet been discharged.

The rate of discharge per 100 admissions for all psychoses was 52.1. Discharge rates were highest for psychosis due to drugs and other exogenous poisons (89.2), psychosis with other infectious diseases (88.9), and psychosis with psychopathic personality (87.1).

The rate of discharge for recovered patients was 17.0 in 1940 as compared with 17.6 in 1939. Rate of discharge of patients with condition improved increased from 27.9 in 1939 to 28.8 in 1940. The rate of discharge for conditions unimproved was 5.1 in both years.

Deaths.—In 1940 there were 31,417 deaths of patients in State hospitals for mental disease (17,671 male and 13,746 female). The ratio of deaths per 1,000 patients under treatment was 68.5 for male and 58.6 for female, 63.8 for both sexes combined. The ratio of deaths per 100 admissions was 30.6 for male patients and 30.7 for female.

The death rate per 1,000 patients under treatment declined from 80.6 in 1926 to 63.8 in 1940, while the death rate per 100 admissions declined from 38.7 in 1926 to 30.6 in 1940. In neither case was the decrease in rate a constant one. The decline probably is largely accounted for by increased capacity of institutions, accumulation of resident patient population, improved methods of treatment, increased life expectancy of the general population, and by the admission of patients less acutely ill.

Of the 31,417 deaths of patients in State hospitals for mental disease, 30,669, or 97.6 percent, were of patients with psychosis. The largest number of deaths occurred among patients with cerebral arteriosclerosis (7,807). The next largest number was of patients with senile psychosis (5,878).

The median duration of hospital life of all male patients was 1 year, 5.3 months as compared with 1 year, 11.6 months for female patients. The median duration of hospital life is reported only for those mental disorders in which there were more than 100 deaths. The median durations were highest for dementia praecox (schizophrenia) and for paranoia and paranoid conditions.

Overcrowding.—During each succeeding year there is a greater number of resident patients in State hospitals. There is a constantly increasing number of beds provided to care for them, but at no time has the number of beds in all State hospitals been sufficient to furnish adequate facilities for all patients. As soon as additional construction is completed, there is a greater influx of patients than the construction was intended to accommodate. Consequently there is almost always a certain amount of overcrowding in practically all State hospitals. It is preferable to express this overcrowding in relation to rated capacity, rather than to numbers of beds, for beds can be crowded into space never intended to hold them. Many hospitals contain one-bed rooms, spaciously constructed, and as a result, hold two or three beds. Day-rooms have been provided in construction plans so that patients may move about unhampered; when it becomes necessary to use these rooms at night for beds that are crowded into the corners as best they can by day, a patient's freedom becomes cramped.

Overcrowding is expressed in terms of the rated capacity and average daily patient population reported by each hospital. During the period 1926 through 1940, there was some variation in the degree of overcrowding in all State hospitals (from 7.1 to 12.7 percent). In 1940 the overcrowding was 9.8 percent. A degree of overcrowding that may not be excessive in some hospitals, may evoke serious problems of administration in others and may make adequate therapeutic care of patients difficult.

Even in those States where a considerable amount of undercapacity was reported, there is no basis for the assumption that all patients in need of treatment were hospitalized. A large percentage of undercapacity may be indicative of a relatively low monetary appropriation made available for hospital use, and consequent lack of use of the hospital facilities that are provided, except when commitment must be resorted to.

¹Incomplete reporting, see footnote 1 to table 6.
²Includes Morningside Hospital, a Federal institution: excluding this hospital, the excess over capacity was 6.0 percent in 1940; -4.6 percent in 1939. 526621

Administrative staff.—In the manual of instructions that accompanied the schedules sent to hospitals requesting data on administrative staff, definitions were given of certain of the types of personnel. They are as follows:

- "Superintendent or chief administrator" indicates the individual responsible for administration of the hospital whether or not he is a physician.
- "Staff physicians" should include all other physicians graded below assistant superintendent and clinical director and above medical interne. "Clinical assistants" should include medical students below the grade
- of medical interne.

 "Graduate nurses" should include only those nurses who have graduated from a school of nursing maintained by a general hospital or by a hospital for mental diseases giving a course covering at least 2 years.

 "Dietitians" should include those persons qualified by either training

"Dietitians" should include those persons qualified by either training or experience who are responsible for the selection, preparation, and serving of all food.

"Social workers" (psychiatric or other trained) should include only persons, regularly employed by the hospital, who look after the interests of hospital and paroled patients. Voluntary workers in this field are not to be included, nor temporary relief workers.

There were 70,195 full-time employees in State hospitals at the end of 1940, and 992 part-time employees. Most part-time employees acted in the capacity of physicians (768, with 699 of these indicated as consulting physicians), dentists (49), and nurses and attendants (35). Most of the remainder of part-time employees were classified as kitchen, domestic, or farm employees.

Detailed data, by State, are presented only for full-time personnel. Male physicians numbered 1,617 and female 212, a total of 1,829 as compared with 1,783 the year previous. The patient ratio per physician decreased to 218.5 in 1940 from 221.0 in 1939.

There were 554 male and 3,698 female graduate nurses as compared with an almost equal number of males (19,657) and females (19,012) among "Other nurses and attendants." There is a considerable lack of male graduate psychiatric nurses. Of all nurses and attendants, nearly 10 percent were graduate nurses. No attempt has been made to differentiate between registered nurses or graduate psychiatric nurses in this total.

There were 60 psychologists and psychometrists in 1940 as compared with 40 in the previous year. There were 155 dentists on a full-time basis as compared with 176 in the previous year. It is difficult, unless one also takes part-time dentists into consideration, to estimate the amount of dental care given to patients

Social workers assume an increasingly important role in the scheme of operation of a mental hospital. There were 349 social workers in these hospitals in 1940 as compared with 289 in the previous year. There were many States in which social workers were retained in one hospital but not in others, and 12 States reported that none were employed. The number of State hospitals, among those reporting, that employed no social workers was 59.

According to the American Psychiatric Association the number of patients per total officer and employee affords one method of comparison of the sufficiency of personnel in each hospital. In the country as a whole there were 5.7 patients per employee, the same as a year previous. The ratio was least adequate in the State of Kentucky (10.0) and best in the State of New Hampshire (3.8). The District of Columbia and Wisconsin have been excluded in this consideration because their hospitals are not directly comparable. Ratios of patients to assistant physicians or to nursing personnel, by State, have not been computed.

Standard maximal ratios of 150 patients per assistant physician and of 8 patients per nurse and attendant have been adopted and recommended by the American Psychiatric Association. The nursing standards were arrived at on the basis of a 12-hour working day. Since that time there has been some change in the hours of duty per day that graduate nurses, other nurses, and attendants

are required to work. To secure information on the hours of duty of nursing personnel, a supplementary query was inserted on the personnel schedule in 1940. This query requested that the number of hours of duty per day be reported for all full-time graduate nurses, other nurses, and attendants.

The total number of graduate nurses reported by State hospitals was 4,252. Of this total, the hours of duty per day were not reported for 256. There were 2,833, or 70.9 percent, on duty for an 8-hour day. This percentage excludes nursing personnel with hours of duty not reported. Fourteen hours or more of duty per day were reported for 13 graduate nurses.

There were 2,331 employees reported in the category "Other nurses." Hours of duty were not reported for 351 of these. Of those with hours of duty reported, the largest proportion, 66.6 percent or 1,318 employees, were on duty for an 8-hour day. There were 36,338 attendants in State hospitals. Of those for whom hours of duty were reported, 19,257, or 56.5 percent, were employed for an 8-hour day; and 6,267, or 18.4 percent, were employed for a 12-hour day.

These distributions of hours of employment indicate longer hours of duty per day for a greater proportion of other nurses and attendants than for graduate nurses. The two peak hours of duty per day among attendant nursing personnel are an 8-hour day, which has recently been adopted in many States, and a 12-hour day, which is a carry-over from the practice generally observed at the time the nursing standards were adopted by the American Psychiatric Association. If a standard for nursing personnel on the basis of 12 hours of duty per day is a nurse and an attendant for 8 patients, the standard for 8 hours of duty per day should be a nurse and an attendant for about 5.3 patients. This ratio is approximate because the necessity for increase of supervisory nursing personnel on an 8-hour day basis may not be as great as the necessity for increase in non-supervisory nursing personnel. In making interstate comparison of nursing personnel ratios, hours of duty of the personnel should be taken into consideration.

Expenditures.—Total expenditures in the United States in State hospitals during 1940 were \$144,017,603, an increase of 4.8 percent over the \$137,430,597 expended in 1939, and an increase of 91.6 percent over the expenditure of \$75,154,424 in 1922. Nearly 17 percent of the total in 1940 was spent for additions, improvements, and other expenditures aside from maintenance as compared with 15.3 percent in 1922.

In 1940 more than half (55.6 percent) of total expenditures for maintenance were devoted to salaries and wages, while in 1922 the percentage devoted to salaries and wages was only 40.5 percent. The per capita patient expenditure for this purpose rose from \$109.78 in 1922 to \$167.06 in 1940. Purchased provisions, and fuel, light, and water comprised 20.7 percent and 7.9 percent, respectively, of total expenditures for maintenance in 1940. These proportions did not differ considerably from the proportions expended in 1922. In 1940 the proportion devoted to all other expenditures for maintenance was 15.9 percent as compared with 24.9 percent in 1922.

The total per capita expenditure for maintenance in 1940 was \$300.63. Variation among the States was very marked. The highest per capita expenditure was in Massachusetts—\$424.93; the lowest was in Kentucky—\$147.31. Michigan, Wisconsin, and the District of Columbia were excluded in making these comparisons chiefly because: 1. Michigan's high rate of expenditure for maintenance was due not to expenditures in its State hospitals but to Eloise Hospital in Detroit, which was included in these data. 2. In Wisconsin three-fourths of the patients were cared for in county hospitals. Expenditures for their care were very much less than in the State hospitals for mental disease. 3. The District of Columbia (St. Elizabeths Hospital) receives funds from many sources. This hospital cares for patients paid for by the U. S. Public Health Service, the War Department, the Navy Department, and the Veterans' Administration, as well as for patients for whose care the District of Columbia reimburses the hospital. For this reason it cannot be considered comparable with any of the State hospitals for mental disease.

The amount spent for purchased provisions increased slightly in 1940 as compared with the previous year in spite of less complete hospital reporting, while the per capita expenditure for this purpose declined slightly from \$62.62 in 1939 to \$62.25 in 1940. The decline may have been caused by changes in food costs or by increased production on hospital farms. These provision expenditures did not include a valuation of produce raised on hospital farms. In many hospitals, farm and dairy produce from the hospital grounds comprise a large proportion of the total food consumed. In other hospitals, located within city limits, there is insufficient ground surrounding the hospital on which to maintain a farm, and all food must be purchased. Consequently, there is little interhospital comparability in expenditure reported for purchased provisions.

In this enumeration supplementary questions were included, in addition to the financial statement, to secure the value of food raised on the hospital farm. In some hospitals where accurate figures were not available, an estimate was given. An indication of the number of meals served patients and employees during the course of the year was also requested, because the expenditures that are reported for purchased provisions in most instances include meals provided for both patients and employees.

The value of food grown on the hospital farm was not indicated by each of the State hospitals. A tabulation has been made (table 38) including only those hospitals in which an evaluation was placed on produce from the hospital farm. The total amount reported for purchased provisions by these hospitals was \$17,676,171, while the same hospitals reported a valuation of \$7,092,209 for food grown on the hospital farm. Consequently the proportion of the total value of consumed food that represents a real expenditure for food purchased was 71.4 percent, while 28.6 percent of the total food value was of food produced. The percentages vary considerably throughout the country. This is due not only to variation in the value placed on the food raised, but also to the size of the hospital grounds that can be turned over to farm land. The proportion of the value of total food consumed that had been produced was highest in the Pacific (42.2 percent) and lowest in the West South Central States (20.5 percent).

The number of meals served patients and employees were tabulated for the same hospitals included in the previous discussion. There were reported to be nearly 3 billion meals served patients (98.5 percent of total meals) as compared with 46 million meals served employees during the year.

Of the total amounts received from paying patients, 40 hospitals received direct benefit of all or part of these funds. Seventy-seven hospitals paid the entire amount into the State general fund. In the remaining hospitals in which expenditures were reported, there were either no receipts from paying patients (43 hospitals), or the disposition of the receipts was not indicated (14 hospitals).

TABLE 36. -ANNUAL EXPENDITURES OF STATE HOSPITALS FOR MENTAL DISEASE, WITH PER CAPITA EXPENDITURE: 1940 AND 1939

Based on the average daily patient population, disregarding employee-meals served.

VETERANS' ADMINISTRATION HOSPITALS

In 1940 there were 27 Veterans' Administration hospitals in the United States devoted solely to the treatment of mental patients. Of these, 26 reported and are included in these data. Some general hospitals under control of the Veterans' Administration maintain psychiatric wards. Those that do, 8 in number, have been included in the data reported for psychiatric wards in general hospitals. In few cases is a veteran who requires continued treatment retained in the psychiatric ward of a general hospital for any considerable period of time. Since the veterans' hospitals are located in 24 States, they are generally accessible to any mental patient requiring prolonged hospitalization.

Tabulations giving geographic distribution indicate the data by State of location of the hospital rather than by State of residence of the patient before hospitalization. The veterans' hospitals in Georgia and California were the only reporting hospitals that cared for female patients, but these patients were few in number, and have not been shown separately in the tables in this section.

During the course of the year there was an increase in the patient population on books of hospitals from 28,502 to 29,951. The number of patients on parole or otherwise absent increased from 1,294 to 1,445. Veterans' hospitals do not maintain patients in family care. First admissions (4,715) constituted 47.9 percent of the total admissions during the year (9,843), and readmissions (3,087) constituted 31.4 percent of total admissions; the remainder were transfers. Only in private mental hospitals was the proportion of readmissions as high as in veterans' hospitals.

A veteran with mental disorder rarely experiences difficulty in securing needed hospitalization. He may be cared for in one of the public hospitals of the State in which he claims residence, as well as in a veterans' hospital. It is difficult to determine the number of hospitalized mentally ill veterans, for there may be many in State hospitals, and these data are not available.

The median age of all first admissions to veterans' hospitals was 47.1 years, as compared with 45.3 years in 1939. The single clinical diagnoses with the largest proportions of first admissions were general paresis and dementia praecox (schizophrenia).

There were 3,087 readmissions of patients to veterans' hospitals, 72.9 percent with psychosis. Of the 6,601 discharges, 4,699 (71.2 percent) were of patients with psychosis. More than three-fifths of these (2,859) were discharged with condition improved; 480 were discharged as recovered; 1,087, as unimproved; and 273, as unclassified.

There were 1,106 deaths of patients in veterans' hospitals for mental disease during 1940. The largest number of patient deaths when considered by mental disorder were with psychosis due to general paresis (350), dementia praecox (schizophrenia) (183), and cerebral arteriosclerosis (169).

The median duration of hospital life of patients before death in hospitals falls in the interval between 1 and 2 years. There were only 98 deaths in this category. Because so long a period of time is covered, it does not seem justifiable to assume that the deaths were evenly spaced over this interval. In 1939 the median duration of hospital life of patient deaths in veterans' hospitals was 11.3 months.

Overcrowding is based on capacity and patient population reported by each hospital. Veterans' hospitals reported a capacity of 30,321 and an average patient population of 28,351 with a resulting undercapacity of 6.5 percent. The greatest degree of overcrowding occurred in Pennsylvania, with 4.0 percent excess of population over capacity. The veterans' hospital in Michigan was least filled to capacity (70.2 percent occupied).

There were 11,308 employees in the veterans' hospitals of the United States at the end of 1940; 26 were superintendents, and 326 were assistant physicians. In all, there were 6,392 nurses and attendants, of which 1,039 were graduate nurses, constituting 16.3 percent of the total nursing personnel. This may be compared with the ratio of graduate nurses to the entire nursing personnel in

State hospitals for mental disease, which has never varied considerably from 10 percent. The number of patients per employee was 2.5 as compared with 5.7, the patient load on State hospital personnel.

Expenditures in veterans' hospitals during the year totaled \$21,025,050. Of this amount, \$20,004,761 was devoted to maintenance, with a resulting per capita expenditure for maintenance of \$705.61.

COUNTY AND CITY HOSPITALS

Ten States reported patients in residence in county and city hospitals in 1940. In some of the States the proportion of total hospitalized patients that were in county and city hospitals was small, but in New Jersey, Pennsylvania, Wisconsin, Iowa, and Missouri, they comprised a sizeable proportion of all the hospitalized mentally ill. Patients in these public hospitals, probably in all cases partly State supported, should be considered as complementing the State hospital population.

In general, there are two types of county and city hospitals. 1. In Iowa and Wisconsin, where institutions are largely representative of one type, a patient who is in acute need of intensive therapy is admitted first to a State hospital. If after a period of time it is evident that his condition remains unimproved and that he will be hospitalized for a long period, he is sent to a county hospital. In Wisconsin it is planned that a patient have the benefit of 1 year's residence in a State hospital before being transferred to a county hospital. County hospitals in these States care for continued-treatment or chronic patients. 2. In other States, some or all of the county or city hospitals function precisely as a State hospital. In these instances, they draw their patient population in general from a well-defined area. They may be partly State and partly county or city supported, admitting voluntary patients freely. In many such hospitals a high per capita expenditure and an able administration have resulted in a superior organization.

Of the 32,634 patients on books of county and city hospitals at the end of the year, 29,581 were in hospitals and 3,053 were on parole or otherwise absent. In the entire country there was a larger number of admissions (8,254) than of separations (8,173) during the year. In some States the patient turn-over was small.

There were 3,357 male and 2,494 female first admissions during the year. A small proportion of first admissions were diagnosed as without psychosis (6.4 percent).

Senile psychosis and cerebral arteriosclerosis combined, comprised a larger proportion of first admissions, 21.9 percent, than dementia praecox (schizophrenia), 18.2 percent. These proportions may be compared with the corresponding percentages among State hospital first admissions, 22.2 percent for senile psychosis and cerebral arteriosclerosis combined, and 20.7 percent for dementia praecox (schizophrenia).

The median age of first admissions was 47.2 years. In State hospitals the median age of first admissions was 44.3.

Readmissions (1,652) constituted 28.2 percent of first admissions (5,851). This was a smaller proportion than in State hospitals because the proportion of discharged patients, which constitutes the source of readmissions, was so much smaller. Of readmissions, 6.4 percent (106 patients) were diagnosed as without psychosis.

The number of discharges (4,303) was 74.8 percent higher than the number of deaths in hospitals reported during the year (2,461). More than twice as many patients were reported as discharged in improved condition (1,665 or 38.7 percent) as in recovered condition (658 or 15.3 percent). A large number of discharged patients were included in the category other, unclassified, and unknown, since some hospitals were not able to evaluate the mental status of the patient on discharge.

Overcrowding has been computed on the basis of rated capacity and average daily population reported by each hospital. The overcrowding was 3.7 percent for all county and city hospitals. There was reported overcrowding in Missouri (45.9 percent), New Jersey (17.1 percent), Ohio (13.0 percent), and Tennessee (1.9 percent). The States reporting county and city hospitals not filled to capacity were Michigan (46.9 percent occupied), Maryland (62.5 percent), Iowa (80.0 percent), Pennsylvania (96.4 percent), Wisconsin (96.4 percent), and California (98.7 percent).

Although data were collected dealing with administrative staff and expenditures of county and city hospitals, tables dealing with these factors have not been presented. Hospitals in some of the States, Iowa and Wisconsin for instance, are not entirely for mental patients. In some hospitals the personnel that care for the mental patient population also are employed in that part of the hospital which is the county home. Expenditures that have been reported in some hospitals have been appropriated not only for the care of the mental patients, but also for the care of those in the county home.

PRIVATE HOSPITALS

There was a little less complete reporting from private hospitals for mental disease in 1940 than there had been the previous year. Data are reported in these tables for 187 private hospitals.

At the end of the year there were 11,569 patients on books, of which 10,678 were in the hospitals. The remainder (891) were on parole or otherwise absent, an increase of 77 in the course of the year. Parole or other absence status was employed frequently in certain of the private hospitals and not at all in others. Hospitals in Massachusetts (84 patients), New York (411), and Pennsylvania (301), used this practice most frequently. Of all incoming patients (25,161), 63.5 percent were first admissions (15,974), as compared with 73.8 percent in State hospitals. There were more than twice as many transfers from private hospitals (1,963) as there were transfers to private hospitals (814). It is probable that, when a patient's condition no longer appears to be acute and it is evident that his period of hospitalization will be of long standing, the matter of expense frequently dictates transfer to a public hospital.

Of the 10,678 patients resident in private hospitals at the end of the year, 3,841 were male and 6,837 were female.

PSYCHOPATHIC HOSPITALS

In the following tables data are reported for seven psychopathic hospitals: Boston (Mass.), Syracuse (N. Y.), and Colorado Psychopathic Hospitals: Iowa and Galveston (Tex.) State Psychopathic Hospitals; Cook County Psychopathic Hospital, and the Psychiatric Institute of the Chicago State Hospital (Ill.). The New York State Psychiatric Institute and Hospital, previously tabulated in this section, has been included with State hospitals this year and will be in the future. Patients reported in this section have not been included in totals reported for all mental hospitals given in the first part of this report. However, if it is desired that data in both sections be combined, the format of the tables has been arranged so that this can readily be done.

Several factors should be borne in mind if these data are combined with other mental hospital data. Various practices are observed in the statistical designation of an admitted patient in the psychopathic hospitals and in the State hospitals in the same States. In Boston, Syracuse, and Colorado Psychopathic Hospitals, and in the Psychiatric Institute of the Chicago State Hospital, a patient who has been designated as a first admission is designated as a readmission upon each subsequent admission to a State hospital for mental disease. In Iowa and Galveston Psychopathic Hospitals, and in Cook County Hospital, a patient upon admission is designated as a first admission on his first entry to that particular hospital for treatment. However, upon the first subsequent admission to a State hospital, he is again termed a first admission. This difference in usage of terminology does not make for ready combination of these data with State hospital data, since undoubtedly some patients recorded as first admissions in Iowa, Texas, and Illinois are duplicated in both sets of statistics.

It is believed by some that patients cared for in psychopathic hospitals in those States in which they are maintained, as well as in psychiatric wards of general hospitals where that type of treatment is available, are similar to those patients with transient mental disorders, in most cases not sufficiently disturbed for State hospital care. Many States reported neither psychopathic hospitals nor psychiatric wards in general hospitals. Whether in this eventuality the patient seeks admission to a State hospital or whether he remains unhospitalized is a moot question.

Movement of patient population. — At the end of the year there were 668 patients on the books of psychopathic hospitals, 535 in residence and 133 on parole or otherwise absent. The total number of admissions was 10,988. Obviously there was far greater turn-over in psychopathic hospitals than in other public hospitals for mental disease. Of all admissions, 77.6 percent were first admissions. The number of admissions by transfer was small (33), while the number of separations by transfer (5,511) constituted over half of all separations (10,976).

Dementia praecox (schizophrenia) was responsible for the largest number of first admissions to psychopathic hospitals (1.946). Alcoholic psychosis had the second largest frequency (1,186). This latter diagnosis was given to a characteristically large proportion of male first admissions. By far the largest number of first admissions with alcoholic psychosis was reported in Massachusetts and Illinois, 1,105 of a total of 1,186.

The median age of all first admissions to psychopathic hospitals was 40.4 years as compared with more than 44 years in State hospitals.

The clinical diagnoses with large numbers of first admissions were also responsible for large numbers of readmissions. Of psychotic patients discharged. 9.1 percent were indicated as with condition recovered, 27.3 percent were improved, and 38.3 percent were unimproved. There were 1,425 discharges without psychosis. These proportions may be compared with the corresponding proportions in State hospitals for mental disease, 32.6 percent recovered, 55.3 percent improved, and 9.9 percent unimproved.

There were 193 deaths of patients in psychopathic hospitals during the year, and 186 of the patients were diagnosed as psychotic. Of all the deaths, 182, or 94.3 percent, occurred within less than 1 month of hospital residence. Only Digitized by Google

1 death took place after more than 6 months of hospital residence. This is an indication of the limited period of time that psychopathic hospitals retain patients in residence.

Overcrowding.—In all of the psychopathic hospitals combined, the bed capacity was 83.5 percent occupied. The percentage of occupancy of hospitals was 92.0 percent in Texas, 88.1 percent in Massachusetts, 83.3 percent in New York, 77.8 percent in Illinois, and 60.0 percent in Iowa. In the Colorado hospital, the number of patients more nearly approximated the rated capacity.

Ordinarily a psychopathic hospital is undercapacity. A certain proportion of the patients are probably emergency admissions, the number varying from time to time for each hospital. It is likely, however, that most admissions are of voluntary patients, or of patients whose types of mental disorder will advance study in some specialized phase of research activity. Effective research would be difficult in a hospital harassed by problems of overcrowding.

Administrative staff.—There were 95 physicians, including 11 internes, in psychopathic hospitals at the end of 1940, 26 more than had been reported the previous year. There were 6 psychologists and psychometrists, 3 in Massachusetts. Of the total nursing personnel (432 employees), 155 were graduate nurses, and they constituted 35.9 percent of the total. This proportion may be compared with the 9.9 percent found in State hospitals for mental disease. There was 1 full-time dentist reported. The number of resident patients per employee was 0.7 as compared with 5.7, the proportion in State hospitals for mental disease.

Expenditures.—Per capita expenditure for maintenance was available for six of the hospitals reporting. The average for the country was \$2,253.84. By State, the per capita expenditure ranged from \$1,416.27 in Texas to \$3,309.72 in the Iowa State Psychopathic Hospital. Of the total amount spent for maintenance, a larger proportion (66.9 percent) was devoted to salaries and wages than is customary in State hospitals for mental disease (55.6 percent in 1940).

TABLE 62.—EXPENDITURES OF PSYCHOPATHIC HOSPITALS, WITH PER CAPITA EXPENDITURE FOR MAINTENANCE, BY STATES: 1940

PSYCHIATRIC WARDS OF GENERAL HOSPITALS

Previous data on the patient population in psychiatric wards of general hospitals were collected in 1933 and again in 1939. At the end of 1933 there were reported to be 1,608 such patients. At the end of 1940 there were 5,056 patients reported in psychiatric wards of general hospitals. Of the total number of hospitals addressed, 71, or 87.7 percent, reported. It may be that there were other general hospitals that maintained psychiatric wards which were not included in this enumeration. In these data we have endeavored to include all general hospitals that give treatment for mental disorders, and to exclude those that retain a mental patient in custody only until he may be transferred elsewhere.

The patient turn-over is even larger than in psychopathic hospitals. Total admissions during the year numbered 73,150. Because of the fact that the definitions of first admissions and readmissions as they are employed in mental hospitals are not used in general hospitals, it was deemed advisable to combine all admissions and report only total figures.

Of separations from the hospitals during the year (72,421), 67.6 percent, or 48,985, were discharged; 28.4 percent, or 20,552, were transferred to a hospital for mental disease; and 4.0 percent, or 2,884, died.

The number of admissions reported in table 64 (73,735) does not agree with the number reported in table 63, (73,150). It is customary for some hospitals to diagnose a patient on discharge rather than on admission. In these instances the number of patients for whom clinical diagnoses were reported agreed with the number of discharges rather than with the number of admissions. Usually, however, the number of admissions to and of discharges from one hospital do not vary widely.

Of all admissions to hospitals during the year (73,735), 44,139 were diagnosed as with psychosis. The largest number of those without psychosis (29,596) was diagnosed with alcoholism (17,552).

¹ Cook County Psychopathic Hospital not included since the data are not available.

PART II. PATIENTS IN INSTITUTIONS FOR MENTAL DEFECT AND EPILEPSY

INTRODUCTION

Scope of the data.—Part II of this report is devoted to patients in State, city, and private institutions for mental deficiency and epilepsy. These data report patients in 76 of the 85 State institutions listed with the Bureau of the Census, in 2 city institutions, and in 56 private institutions.

In three States in the West South Central and Mountain divisions (Arkansas, Arizona, and Nevada), no separate institutions are maintained for mental defectives and epileptics, but special provision is made for them in a designated section of the State hospitals for mental disease. While the number of private institutions reporting is only 70.0 percent of total private institutions addressed, the percentage of privately institutionalized patients included in these data is undoubtedly much greater, since more complete cooperation is received from larger institutions whose statistical departments are more developed.

Significance of the data.—As in the case of hospitalized patients with mental disease, the data presenting information concerning institutionalized mental defectives and epileptics do not show the true prevalence and incidence of persons with these deficiencies in the entire population. Not all individuals recognized as mentally deficient or epileptic require institutionalization. Adequate social adjustment to a simple routine may be attained by some mentally deficient individuals more satisfactorily outside than inside an institution. The following tables present data only for those mental defectives and epileptics in institutions established specifically for their care. In the preceding section, it was pointed out that hospitals for mental disease care for mentally defective and epileptic patients in varying proportions throughout the States. Some are also found in prisons, reformatories, almshouses, and in homes for the aged.

The provision of facilities in institutions for mental defect and epilepsy shows wider interstate variation than in hospitals for mental disease. The bed capacity made available for these patients, particularly in the South, is meager. It has been found that as the proportion of Negroes in the general population increases, the rate of hospitalization of Negro mental defectives and epileptics decreases. Frequently a Negro mental patient may secure admission to a hospital for mental disease, but not to an institution for mental defectives and epileptics. For uniform interstate presentation of data relating to these institutionalized patients, statistics for patients in institutions for mental defectives and epileptics have been combined in part III with those for patients of this type in hospitals for mental disease.

Treatment of the data.—In the first section of part II the data treat of patients in institutions under all types of control. They indicate movement of patient population, resident patient population, and first admissions during the year. Following this summary presentation, more detailed information is given for State institutions. In conclusion, separate data are reported for city institutions and for private institutions.

In most instances, statistics for mental defectives and epileptics are presented separately. This separation is relatively simple for clinical data, but is difficult for capacity, administrative personnel, and financial expenditures. Nevertheless, an attempt has been made to segregate institutions caring solely for mental defectives, and those caring solely for epileptics, from those that maintain a combined patient population. More complete explanation of the method of separation will be included with the discussion of these data.

Institution officials were requested as heretofore to classify patients according to the primary cause of admission. The rules for such classification are set forth below:

1. If the case history shows that the patient was primarily mentally defective and that epilepsy developed at a later period, the patient should be reported on the schedules for mental defectives.

- 2. If the case history shows that the patient was primarily epileptic and that mental deterioration developed at a later period, the patient should be reported on the schedules for epileptics.
- 3. In all cases where epilepsy is definitely present, and where insufficient data are available to determine the patient's previous mental status, even though mental deficiency is not established, the patient should be reported on the schedules for epileptics.

ALL INSTITUTIONS FOR MENTAL DEFECTIVES AND EPILEPTICS

Movement of patient population.—The presentation of data for all institutions for mental deficiency and epilepsy must necessarily be abbreviated, since the entire set of schedules was not forwarded to private institutions. Nine of the State institutions, comprising approximately 6 percent of the patient population in State institutions, failed to send in schedules reporting these data. They were: Department for Defective Delinquents, Massachusetts; Institute for Male Defective Delinquents, and Woodbourne Institute for Defective Delinquents, New York; Indiana Village for Epileptics, Indiana; Rosewood Training School, Maryland; District of Columbia Training School, Laurel, Maryland; Training School for Mental Defectives, Georgia; State Colony and Training School, Louisiana; and Northern Oklahoma Hospital, Oklahoma.

Although those State institutions not reporting numbered nine in 1940, as compared with seven in 1939, the patients that were reported in this enumeration total more than those reported for 1939. An estimate of the total patient population in 1940 and in 1939 indicates that there was consistent increase in patient population, as has been evident during the past years. A minimal approximation of 112,000 may be made for the total number of patients in institutions reporting and in those not reporting at the end of 1940.

At the end of 1940 there were 118,021 patients on books of all institutions reporting; a slightly larger proportion were male patients. These patients represent an increase of 3,650 over the number of patients on books reported at the beginning of the year. Of the total, 104,784, or 88.8 percent, were in the institutions. There were 13,237, or 11.2 percent, absent, of which 419, or 0.4 percent, of total patients on books were in family care, and 12,818, or 10.9 percent, were on parole or otherwise absent. The number of admissions (12,677) was slightly larger than that reported the previous year (12,432). There was a slight decrease in separations; there were 9,027 during 1940, whereas there had been 9,237 during 1939. Notwithstanding the expected decrease due to decline in the number of institutions reporting, admissions and separations, which necessarily depend to a large extent on the facilities that are available, may be expected to vary from year to year.

There was an increase in both the mentally defective and the epileptic institutionalized patient population during the course of the year, the proportionate increase in the former diagnosis being approximately one and a half times the proportionate increase in the latter.

At the end of 1940, 96.1 percent of all patients in mental defective and epileptic institutions were in institutions under State control, 0.5 percent were in city institutions, and 3.5 percent were in institutions under private control. Private institutions had a small number (162) on parole or visit.

For mental defective patients, the proportion of resident patients at the end of the year in State institutions was 96.2 percent. The proportions of total mental defective admissions and separations in State institutions alone were 94.3 percent and 92.6 percent, respectively, larger in both cases than the proportions for the total patient population. For epileptics the proportion of resident patients at the end of the year in State institutions was 97.3 percent, and the proportions of all admissions and separations of epileptics from State institutions were 95.4 percent and 95.6 percent, respectively.

Of admissions, 90:7 percent came to State institutions, but only 87.8 percent of all patients separated from institutions were released from those under State control. Patient-stay is longer in public than in private institutions.

Patients transferred to a State or a city institution or admitted there for the first time are more likely to be in need of prolonged hospitalization. The large turn-over of patients in private institutions is due to patients who are diagnosed as neither mentally defective nor epileptic. These patients are probably classified under the clinical diagnoses, postencephalitis, psychopathic personality, or psychosis with primary behavior disorders. Patients of this type who cannot afford treatment in a private institution may be excluded from institutions under State control because of lack of facilities. Severe over-crowding of State institutions has necessitated the maintenance of waiting lists from which patients most acutely in need of care are admitted when there is a vacancy.

Some institutions have adopted the plan of placing patients, who have not recovered sufficiently to be paroled or discharged, in private families in the community, other than their own, with remuneration to the family by the institution. This plan, designated as family care, has the object of giving the patient whatever benefit may be derived from the intimate association and closer contacts and relationships possible in a family unit. Since only State institutions maintained patients in family care in 1940, the plan will be more fully discussed in the section dealing exclusively with State institutions.

Trend in institutionalization.—There has been a steady increase in the number of patients in institutions for mental defectives and epileptics during the past 19 years. Comparable data do not extend over a longer period of time for the country as a whole. In this interval the number of patients has more than doubled, while the institutionalization rate, expressed per 100,000 of the total population, has increased by more than two-thirds. By far the largest proportion of increase has been in State institutions. The number of patients in city institutions decreased in 1938 to about one-third of the total in 1923 and to slightly more than one-fourth of the total in 1933. This was due to the discontinuance of some city institutions. Care of the mentally deficient and epileptic is now essentially a State problem. In private institutions the number of patients increased by almost one-third from 1923 to 1939. With fewer private institutions reporting in 1940 the number of patients was smaller than in 1939.

The rates presented in this report differ slightly for the interval 1930 to 1939 from those given in publications prior to the 1939 volume because of the re-estimation of the annual intercensal population figures used in computing these rates.

Rates of institutionalization.—Rates of institutionalization have been presented separately for mentally defective and for epileptic patients. In the United States the institutionalization rate for mental defectives, expressed per 100,000 of the total enumerated population, was 65.9, larger than in 1939, although the reporting was less complete in 1940. Since children younger than 5 years of age are rarely institutionalized for mental deficiency, the rate of institutionalization has also been expressed per 100,000 of the population aged 5 years and over. On this population base the rate for the United States was 71.6. Rates have not been computed for any geographic division in which reports from any State institutions in that division were missing. State rates have been computed in these instances, however. The institutionalization rate was highest in Delaware (159.5 per 100,000 population aged 5 years and over) and lowest in West Virginia (9.2 per 100,000 population aged 5 years and over), when only those States with all State institutions reporting were considered.

Rates for institutionalized epileptics were 12.9 per 100,000 of the total population and 14.0 per 100,000 of the population aged 5 years and over in the United States. The rate was highest in Kansas (50.2 per 100,000 population aged 5 years and over). In some States with all institutions reporting, there were no epileptic patients in residence in institutions for mental deficiency and epilepsy. This does not mean that there were no institutionalized epileptics in these States. Some patients may have been both mentally defective and epileptic, and, in conformity with the definitions previously stated, may have been classified as mentally defective. Some epileptic patients are treated in State hospitals for mental disease.

¹Estimated as of January 1 of the corresponding year for 1925, 1926-1940; enumerated as of April 1, 1940 for 1941.

The Neurological Institution, New York, was included as a city institution from 1925-1936.

Mumber of patients reported at the end of the year 1940. Incomplete reporting, see footnote 2 to table 68.

First admissions. -- First admissions to institutions for mental defectives and epileptics include all patients admitted for the first time for treatment to an institution of this type, whether that institution be under State, city, or private control.

Rates of first admission based on the general population constitute one available measure of determining the incidence of the mental deficiency and epilepsy that requires institutionalization. The measure in this case has a somewhat different meaning from that presented with regard to mental disease. When a patient is mentally ill, it may become urgently necessary to hospitalize him immediately. Mental deficiency is a less variable condition, and there is seldom an imperative need for immediate institutionalization. Consequently, the practice has arisen of maintaining waiting lists for these institutions, and, as beds are made available, patients may be admitted. In presenting rates of first admission for a series of years, it is probable that the comparisons are more indicative of the number of beds made available for new patients in each of these years than of the actual number of mentally deficient patients or of epileptic patients in need of institutionalization.

There were reported 8,166 first admissions of mental defective patients and 1,936 first admissions of epileptic patients in all institutions for mental defectives and epileptics during the year.

The rate of first admission of mental defective patients to all institutions was 6.2 per 100,000 of the total population and 6.7 per 100,000 of the population aged 5 years and over. State rates were highest in Nebraska (14.4 per 100,000 population aged 5 years and over) and in Wisconsin (13.6 per 100,000 population aged 5 years and over). The rate of first admission of epileptics to all institutions was 1.5 per 100,000 of the total population and 1.6 per 100,000 population aged 5 years and over. Rates were highest in Michigan (7.7 per 100,000 population aged 5 years and over) and in Kansas (4.3 per 100,000 population aged 5 years and over).

STATE INSTITUTIONS

In the following tables, data are presented for patients cared for in State institutions. They comprised 96.4 percent of the total number of patients on books of all institutions at the end of the year.

In addition to the factors covered in the preceding section, namely, movement of patient population, resident patients, and first admissions during the year, consideration will also be given to readmissions, discharges, deaths, rated capacity, administrative personnel, and expenditures.

Movement of patient population. -- At the end of 1940 there were 57,597 male patients and 56,130 female patients on the books of State institutions reporting. There was a majority of males in each category in the presentation of movement of patient population, with the exception of the number of patients placed in family care.

Family care. — It is more practicable to place female mentally defective patients in family care, since a woman may be more easily occupied at home. There is a tendency to retain men in institutions until it is deemed advisable to place them on parole or to discharge them. Only a few epileptic patients have been placed in family care. There were only 4 such patients at the end of 1940 as compared with 414 mental defectives. If an epileptic patient is not seriously mentally defective and his convulsions are mild, he may learn to cope with them without seeking institutional aid. Epileptics who come to an institution are usually seriously handicapped and cannot be cared for any more satisfactorily in a strange family than in their own.

At the end of 1940, three States made use of the practice of family care for mentally defective or epileptic patients. They were New Hampshire, Massachusetts, and New York. Four States had no patients absent or on parole at the end of the year. They were Tennessee, Alabama, Montana, and New Mexico. Placing a patient in family care or on parole is one means of determining whether or not he is able to get along in the community while the institution still has more or less supervision over his activities. After a patient has been discharged, the institution can no longer be intimately concerned with his welfare, and should an adjustment be impossible, readmission is the only recourse. States that do not maintain a parole system more than likely employ so few social workers that they cannot be spared for follow-up parole work.

Interstate comparison. - In table 70, movement of patient population by State is given separately for mental defectives and for epileptics. Patients diagnosed as neither mentally defective nor epileptic are not included in this State distribution. In a few States the number reported as neither mentally defective nor epileptic was large, either because these patients were freely admitted or because the reporting was done on the basis of the present clinical condition of the patient. Some patients committed as mentally defective have been found to be mentally normal but emotionally maladjusted.

Some States reported no patients institutionalized with epilepsy. In these States it may be customary to diagnose epileptic patients as with mental deficiency, or to send these patients to a public hospital for mental disease.

Although there were more male (42,015) than female (41,371) mental defective patients institutionalized at the end of the year in the country as a whole, the New England (4,277 male, 4,465 female), Middle Atlantic (12,169 male, 12,653 female), East South Central (1,234 male, 1,250 female), and West South Central (629 male, 1,088 female) divisions reported more female than male patients. The New England division also had more institutionalized epileptic female (664) than male (596) patients. In the West North Central, South Atlantic, and East South Central divisions, the number of females was also slightly larger than the number of males. Nearly as many patients diagnosed as neither mentally defective nor epileptic were institutionalized in the Middle Atlantic division as in all other divisions combined; the vast majority was in the State of New Jersey.

Of 83,386 mental defective and 15,527 epileptic patients in State institutions at the end of 1940, the largest proportions were in the Middle Atlantic and East North Central divisions. Digitized by Google

Trend in institutionalization.—From 1923 to 1941 the institutionalization rates for patients resident in State institutions for mental defect and epilepsy increased from 42.1 to 76.4 per 100,000 of the total population. From 1923 to 1936 there was an almost steadily increasing trend of patients on parole or otherwise absent, from 4,060, 8.0 percent of the total on books in 1923, to 14,463, 13.6 percent of the total in 1936. The most recent data showed fewer patients in family care or on parole or otherwise absent than in 1936, probably only because not all institutions were reported for 1940. The number of patients in family care was 479 in 1937, the first year for which these data were collected, and 419 at the end of 1940 (designated as 1941 in the table). The larger numbers reported in 1938 and 1939 appear to be due to varying interpretations of the definition of family care.

Rates of institutionalization.—At the end of the year there were 100,652 patients resident in State institutions for mental defect and epilepsy. Of these, 83,386 were mentally defective and 16,527 were epileptic. The institutionalization rates for total patients were 76.4 per 100,000 of the total population and 83.1 per 100,000 of the population aged 5 years and over. The former rate was higher than that of the previous year, although the reporting was less complete in 1940. For mental deficiency the rate per 100,000 of the total population was 63.3; and based on the population aged 5 years and over, the rate was 68.8 per 100,000. For epilepsy the rate per 100,000 of the total population was 12.6; and based on the population aged 5 years and over, the rate was 13.6. Rates for geographic divisions were not computed when any State institution data in that division were not reported.

Total rates of institutionalization expressed per 100,000 of the population aged 5 years and over were highest in Delaware (185.4) and Wyoming (171.9). These same States had the highest rates for mental deficiency. For epilepsy, however, rates were highest in Kansas (50.2 per 100,000 population aged 5 years and over) and in New Jersey (38.7).

First admissions.—First admissions to institutions for mental defectives and epileptics include all patients admitted for the first time for treatment to an institution of this type, whether under State, city, or private control.

Rates of first admission.—There were 9,699 first admissions to State institutions for mental deficiency and epilepsy during the year. The rate per 100,000 of the total population was 7.4; expressed per 100,000 of the population aged 5 years and over, it was 8.0. Each total rate was higher by 0.2 points than the combination of the corresponding separate rates for mental deficiency and epilepsy. This difference is explained by the fact that patients diagnosed as neither mentally defective nor epileptic were included in the total.

For the 7,673 first admissions of mental defectives to State institutions, the rate per 100,000 of the total population was 5.8, and the rate per 100,000 of the population aged 5 years and over was 6.3. For the 1,841 epileptic first admissions, the rates were 1.4 and 1.5 per 100,000 based on the total population and on the population aged 5 years and over, respectively.

<u>Mental defect.</u>—The American Association on Mental Deficiency has adopted a classification of mental status of mentally defective patients, which defines the terms idiot, imbecile, and moron as follows:

- An <u>idiot</u> is a mentally defective person usually having a mental age of less than 3 years, or, if a child, an intelligence quotient of less than 20.
- An <u>imbecile</u> is a mentally defective person usually having a mental age of 3 years to 7 years, inclusive, or, if a child, an intelligence quotient of from 20 to 49, inclusive.
- A moron is a mentally defective person usually having a mental age of 8 to 11 years, inclusive, or, if a child, an intelligence quotient of 50 or more. As a rule, the upper limit for a diagnosis of mental deficiency should be an intelligence quotient of 69.

The idiot-imbecile-moron classification is a flexible one, for there cannot always be a clear-cut differentiation of the mental status of an individual patient. The States varied considerably in the distributions of mental status of mentally defective patients. In the entire country nearly half of first admissions, 45.0 percent, were designated as morons (3,398); 31.1 percent, as imbeciles (2,353); and 16.4 percent, as idiots (1,238). The distribution for male and female first admissions did not vary considerably from the total distribution. A more complete break-down of mental defectives by clinical diagnosis indicated 30.2 percent (2,282) of all first admissions diagnosed as with familial mental deficiency. 'Undifferentiated and unknown diagnoses (3,257 patients) constituted 43.1 percent of the total (7,555 patients). Of the other clinical diagnoses, Mongolism (418 or 5.5 percent) and posttraumatic (400 or 5.3 percent) constituted the largest single categories. There was some difference in the causes of mental defect in male and female patients. Familial causes constituted a somewhat larger proportion among female than among male patients, 33.2 percent (1,187), as compared with 27.5 percent (1,095).

The median ages of first admissions were 13.8 years for male patients and 16.2 years for female. For the total of males and females, the median ages were lowest for idiots (male 10.6, female 11.7), next for imbeciles (male 13.3, female 15.8), and highest for morons (male 14.4, female 17.3). Two factors are largely responsible for this: 1. A patient of higher mental status may be kept out of the institution for a longer period of time in an attempt to adjust him to his environment. 2. In an overcrowded institution patients of the lowest mental status must of necessity be given preference on admission.

TABLE 79.—FIRST ADMISSIONS OF MENTAL DEFECTIVES TO STATE INSTITUTIONS, BY MENTAL STATUS AND SEX, BY AGE: 1940

2 Median not computed.

<u>Epilepsy.—A</u> classification of clinical diagnoses of epilepsy has been adopted by the National Association for the Study of Epilepsy (now amalgamated with the American Psychiatric Association). Most patients may be classified as having either symptomatic or idiopathic epilepsy. The remainder must be designated as with epilepsy of unknown cause. The terms are defined as follows:

Under the heading symptomatic are to be included only those cases in which it is decided that the seizures are symptoms of a definite disease.

Under the heading idiopathic are to be included those cases in which the condition is apparently not associated with a disease process, toxic condition, or structural defect.

Under the heading unclassified are to be included those cases in which it is undetermined whether the condition is associated with a disease process, toxic condition, or structural defect.

More than half of all epileptic first admissions were reported as idiopathic (980 of 1,834). Of epilepsy due to idiopathic causes, some cases (92) were associated with psychogenic factors, but most cases (888) were designated as undifferentiated or unknown. Of epilepsy due to symptomatic causes (22.2 percent of all), by far the largest proportion (18.3 percent of all) was due to definite brain diseases. Epilepsy due to toxemic causes totaled only 3.4 percent of all epileptic patients.

For epileptics the median ages of first admissions were 18.7 years among male patients and 17.3 years among female. For symptomatic epilepsy the median age for males was 17.4 years as compared with 14.9 years for females. Apparently patients with epilepsy of known cause were admitted at younger ages than patients with idiopathic epilepsy, in which the median age for males was 19.9 years, and that for females was 18.7 years.

¹ Incomplete reporting, see footnote 2 to table 68.

Readmissions.—Readmissions to institutions for mental defectives and epileptics include all patients who have previously received treatment at an institution of this type, whether under State, city, or private control, and have been discharged from that institution since their previous admission.

In the case of epileptics, readmission usually results from a relapse from the improved condition attained on discharge. In the case of mental defectives, readmission does not necessarily imply regression, but rather the inability of the patient to adjust to conditions in his community.

The most satisfactory methods of expressing readmission rates from the point of view of measuring recurrence of mental deviations are the proportion readmissions constitute of first admissions and the proportion they constitute of discharges. In 1940 the proportion that readmissions constituted of first admissions was 9.9 percent, higher than the previous year (8.0 percent). Since 1922 the proportion has varied between 6.0 and 11.5 percent.

Readmissions constituted 19.7 percent of discharges in 1940. From 1929 when the rate was 29.6 percent to 1934, there was a gradual decrease, although since 1937 the rate has again begun to rise. The present rate, however, is still lower than that reported a decade or more ago. This may indicate that institutions have developed better methods of training individuals to be economically sufficient and socially adjusted, and thus have obviated the necessity for readmission. It may be equally true in some places, however, that overcrowded institutional facilities make it impossible to accommodate all patients seeking readmission, and necessitate preferential consideration of those who have never been institutionalized.

Idiots constitute a somewhat lower proportion among readmitted mental defectives (7.7 percent) than among first admissions (16.4 percent). Idiots and some of the lower-grade imbeciles are less likely to be discharged and hence less likely to have to be readmitted.

While idiopathic epileptics constituted 53.4 percent of all epileptic first admissions, they constituted 71.6 percent of all readmitted epileptics. Most of the readmitted patients with symptomatic epilepsy have been diagnosed as with a definite brain disease (34 of 44 readmissions).

Discharges.—A similar practice was observed in the presentation of rates of discharge as of rates of readmission. In neither instance are rates presented for each State because the figures are not large enough for the computation of reliable rates in every case. There is considerable interstate variation in length of period of parole. After a given length of time a patient may be designated as a return from parole in one State, while in another State, after a like period of time he may be considered a readmission.

Discharge rates have been computed only for the country as a whole. There were 4,886 discharges in 1940. Discharge rates were 45.3 per 1,000 patients under treatment and 45.8 per 100 admissions. In 1922 the rate per 1,000 patients under treatment was 54.1. Since that year there has been considerable fluctuation in the rate. The discharge rate per 100 admissions was 34.9 in 1922.

Mental defect.—Discharges have been grouped into the two age groups "Over 15 years of age," and "Under 15 years of age," with special provision for those discharges that are of unknown age. Those over 15 years of age were grouped, by condition on discharge, as follows: capable of self-support, capable of partial self-support, incapable of productive work, and unknown. These four conditions were defined as follows:

- If the patient is able to retain a position and earn a living during the parole period, enter as "Capable of self-support."
- If the patient is able to earn wages to cover part of the cost of his maintenance during the parole period, enter as "Capable of partial self-support."
- If the patient is entirely dependent on friends and relatives, enter as "Incapable of productive work."
- 4. If the patient's condition on discharge is not known, enter as "Un-known."

Patients under 15 years of age comprised 13.4 percent of all mental defectives discharged. The variation for those areas in which the number of discharges exceeded 100, ranged from 8.3 percent under 15 years in the West North Central States to 16.4 percent in the East North Central States.

Of idiots discharged from the institution, 62.9 percent were over 15 years of age. Of these, 83.9 percent were incapable of productive work.

Imbeciles over 15 years of age comprised 85.1 percent of those discharged, and more than two-fifths of these were incapable of any productive work. One-seventh of discharged imbeciles (14.8 percent) were under 15 years of age.

Morons, who constituted 52.7 percent of all discharged mental defectives, were over 15 years of age in 90.5 percent of the cases. More than five-sixths of those over 15 years of age were capable of partial or complete self-support. Those incapable of any productive work comprised 9.4 percent of morons over 15 years of age, and 9.5 percent of discharged morons were under 15 years of age.

Epilepsy.—Epileptics have been designated as recovered, improved, and unimproved. These conditions were defined as follows:

- "Recovered" indicates the condition of a patient who has regained his normal mental health so that he may be considered as having practically the same mental status as he had previous to the onset of his epilepsy.
- "Improved" denotes any degree of gain less than recovery, which warrants the patient's discharge.
- "Unimproved," as the term implies, denotes no gain.

There were more than three times as many discharges of patients with idiopathic (625) as with symptomatic (197) epilepsy. When rates of discharge per 100 first admissions of the same diagnosis were computed, the ratio for idiopathic epilepsy was 63.8 discharges per 100 first admissions, and for symptomatic epilepsy 48.4 discharges per 100 first admissions. Apparently when a patient's epilepsy is symptomatic in origin the chances of discharge are three-fourths of what they would be if the condition were due to other than a structural defect, toxic condition, or definite brain disease.

Only 5.0 percent of total epileptic patients discharged were designated as recovered; 40.5 percent were with condition improved, and 53.9 percent were with condition unimproved. Patients discharged as recovered constituted 3.6 percent of the total for symptomatic epilepsy, and only 3.0 percent for idiopathic epilepsy. For patients discharged in improved condition, the proportions were 44.2 percent for symptomatic epilepsy and 42.9 percent for idiopathic epilepsy. Very few of the States reported discharges of epileptics with condition entirely recovered.

¹Incomplete reporting, see footnote 2 to table 68.

Deaths.—Deaths of mentally defective patients and deaths of epileptic patients are dealt with separately whenever possible. Only in those instances in which a combination of the data is of administrative significance, such as in the computation of death rates, have total figures been given.

The death rate may be expressed in one of two ways. 1. It may be based on the number of patients under treatment, which is defined as the number of patients resident in the hospital at the end of the year, plus patients discharged from the hospital and from parole, plus deaths in the hospital during the year. 2. The death rate may also be expressed in terms of total admissions (first admissions plus readmissions) to the hospital. Since the number of admissions may fluctuate greatly, a more stable rate is secured in a rate expressed per 1,000 patients under treatment.

In 1940 the death rate per 1,000 patients under treatment was 20.9, a decline from the rate of 22.5 the previous year, and 39.4 percent less than the rate in 1922 (34.5). The explanation probably lies in the fact that institutions now have facilities available for the accommodation of patients less acutely ill, and can retain them for longer periods of institutionalization.

The death rate per 100 admissions was 21.2, slightly less than a year previous. No consistent trend has been exhibited in rates computed on this basis over a period of years.

In 1940 there were 1,489 deaths of mental defectives (792 male, and 697 female). There were 743 deaths of epileptic patients (444 male, and 299 female).

Mental defect.—The median duration of institutional life before death of mental defectives was 7.1 years (7.3 for male, 6.8 for female). As has been evident in previous years, the median duration of institutional life of idiots was lowest (4.5 years for male, 4.6 years for female). Contrary to previous experience, the median duration of institutional life was highest for imbeciles (9.4 years for male, 9.8 years for female).

For morons, the median durations of institutional life were 8.7 years for male patients and 8.6 years for female. In 1939 morons had longer institutional life than imbeciles.

Epilepsy.—The median duration of institutional life before death of all epileptic patients was 8.0 years (7.3 for male, 9.1 for female). On the whole, epileptics tend to have longer total institutional life than mental defectives.

TABLE 98.—DEATHS OF PATIENTS IN STATE INSTITUTIONS FOR MENTAL DEFECTIVES AND EPILEPTICS, AND RATE PER 1,000 PATIENTS UNDER TREATMENT AND PER 100 ADMISSIONS: 1922, 1926-1940

YEAR	All deaths	Deaths per 1,000 patients under treatment ¹	Deaths per 100 admis- sions
1940 2	2,258	20.9	21.2
1959 3	2,582	22.5	22.8
1958	2,546	25.5	22.8
1957	2,905	27.4	23.8

Overcrowding.—In 1940 the normal capacity of State institutions for mental defectives and epileptics, reporting these data, was 92,999. There was an average daily population of 99,086 patients cared for in the institutions reporting, and the excess of population over capacity was 6.5 percent. Excessive overcrowding may indicate a temporary condition to be alleviated by construction under way; however, it should be borne in mind when making interstate comparisons that there is no uniform measure for determination of rated capacity.

It would be desirable if the rated capacity set apart for the care of mentally defective patients and of epileptic patients could be determined separately. Since there are many institutions in the country caring for both types of patients, complete separation has not been possible. However, on the basis of the diagnosis of resident patient population, data are presented separately for mental defectives and epileptics, after arbitrarily adopting the following conditions:

- 1. An institution shall be designated as caring for mental defectives when more than 90 percent of its patient population is diagnosed primarily as mentally defective.
- An institution shall be designated as caring for epileptics when more than 90 percent of its patient population is diagnosed primarily as epileptic.
- 3. An institution shall be considered as caring for both mental defectives and epileptics if 10 percent or more of either diagnosis makes up its patient population. Such institutions have oeen grouped separately.

A similar division of institutions into those that may be considered mentally defective, or epileptic, or as caring for a combined mentally defective and epileptic patient population, was made in 1938 and in 1939. However, the same institutions were not included in each of these groups for each of these years as for the present data. The determination of the institutions to be included in each break-down was based on the distribution of patient population in institutions at the end of the year. Institutions included as epileptic in the tables dealing with overcrowding will also be included as epileptic in the personnel and expenditure sections that follow, and similarly for the other groups of institutions.

On this basis, 47 institutions were considered as caring for mental defectives. They had a normal capacity of 62,103 and an average daily resident patient population of 67,453. The excess of population over capacity was 8.6 percent. The most severe overcrowding occurred in Massachusetts (29.3 percent), Rhode Island (51.1 percent), New York (28.8 percent), Wisconsin (30.6 percent), Kentucky (28.8 percent), and Tennessee (28.4 percent). The lowest degree of occupancy among those institutions reporting occurred in Virginia (76.0 percent occupied).

Eight institutions have been considered as caring solely for epileptics. Their normal capacity was 9,804, and they cared for 10,720 patients. The excess of population over capacity was 9.3 percent. The most severe overcrowding reported occurred in Massachusetts (32.9 percent), while the lowest degree of occupancy occurred in Michigan (95.1 percent occupied).

There were 21 institutions considered as caring for both mental defectives and epileptics. Their normal capacity was 21,092, and they cared for 20,913 patients. These institutions showed a slight degree of underoccupancy (0.8 percent). Nine of the State institutions providing combined facilities for mentally defective and epileptic patients reported underoccupancy. There are several possible explanations. It may be that in some States with combined facilities, the provision was adequate, and the institutions were underoccupied. Other States were probably not doing as complete a job of hospitalization and were barring admission to patients who needed care.

² Incomplete reporting, see footnote 2 to table 68.

Administrative staff.—In 1940 there were 15,774 full-time employees in State institutions for mental defectives and epileptics. In the institutions reporting, there was a total ratio of 6.2 patients to each officer and employee in 1940, as in the 3 previous years. There was a slight increase in the patient load on total physicians. The ratio in 1940 was 310.8 patients per physician as compared with 287.6 in 1939. These figures include superintendents, assistant superintendents, pathologists, staff physicians, and medical internes. Perhaps the comparison afforded by the inclusion of superintendents in this ratio is not entirely adequate because of the large amount of time they must spend in administrative activities.

There was an increase in the number of psychologists in 1940, from 46 the previous year to 52. Undoubtedly the increase would be still greater if the number of psychologists in the institutions that did not report, was available. The number of graduate nurses increased from 411 to 442. The entire nursing personnel of the institution is included in the five categories: graduate nurses, other nurses, matrons and assistant matrons, supervisors and assistant supervisors, and attendants. There were 8,745 of these employees at the end of 1940, as compared with 8,787 the previous year.

The duties of the personnel vary considerably from institution to institution. In some cases the psychologist may be required to perform only routine psychometric examinations, and in other cases his duties may be much more varied and complex. There are many institutions that do not employ psychologists.

A few institutions are small and maintain no physician other than the superintendent on the staff. Evaluation of the amount of therapeutic treatment a patient receives in an institution where the only medical official is responsible for the administration of the institution, as well as for the welfare of its individual patients, is difficult. Consequently, the only personnel ratio that has been employed in this report for interstate comparison is the ratio of patients to total personnel.

There were 52 psychologists reported by 20 States. Their activities may not reach each patient hospitalized in States where the psychologists are employed in institutions other than those in which the patients reside. Social workers were employed in 24 States. Southern and Mountain States were most lacking in this type of personnel.

In addition to full-time personnel, a total of 251 officers and employees were employed as part-time, 123 as consulting physicians. There were 31 dentists on part-time basis, as well as 15 teachers of special subjects and 4 teachers of grade subjects. In the entire country there were vacancies for 19 physicians. A vacancy has been defined as a position for which funds are available but which has not been filled.

Data on administrative personnel are presented in a manner similar to that adopted in the section dealing with capacity. Three separate tables give data for institutions grouped as mentally defective, as epileptic, and as institutions whose patient population is a combination of both types.

The patient load on total personnel was lowest in institutions caring solely for epileptics (4.7), probably because this type of patient requires more constant nursing care. The patient ratio is slightly heavier, 6.2, in institutions caring entirely for mental defectives and highest of all, 7.2, in institutions caring for both types of patient. Many States do not have a sufficiently large epileptic patient population to establish separate institutions for patients of that diagnosis. The patient ratios in institutions that are devoted entirely to epileptic patients are lower in every State than in those institutions devoted to mental defectives in the same State.

A supplementary query similar to that made of hospitals for mental disease was made of all State institutions for mental defect and epilepsy, relative to hours of duty per day of nursing personnel. The data have been assembled separately for each of the five types of nursing personnel reported: graduate nurses, other nurses, matrons and assistant matrons, supervisors and assistant supervisors, and attendants. Hours of duty per day ranged from 7 hours to 14 hours and over. In table 110 the data are presented by these five types of nursing personnel, and by hours of duty per day, for each of the three groups of institutions in which personnel data are given (institutions for mental defectives, institutions for epileptics, and institutions that care for both mentally defective and epileptic patients).

There were 30l graduate nurses reported in institutions for mental defectives, 91 in institutions for epileptics, and 50 in institutions for both mental defectives and epileptics. In institutions for mental defectives, 211, or 73.5 percent, were on duty for an 8-hour day, as compared with 76, or 87.4 percent, in institutions for epileptics, and 16, or 37.2 percent, in institutions for both kinds of patients. In this third type of institution, 10 graduate nurses (23.3 percent) worked a 10-hour day, and 17 (39.5 percent) worked a 12-hour day. These percentages are exclusive of personnel for whom the hours of duty were not reported.

Those employees reported as "Other nurses" were for the most part on duty for an 8-hour day. There were 335 matrons and assistant matrons reported, 247 in mental defective institutions, ll in epileptic institutions, and 77 in combined institutions. Most of those in mental defective institutions worked an 8-hour day, while most of those reported by institutions for both mental defectives and epileptics worked a 10-hour day. Of the 367 supervisors and assistant supervisors reported in all these institutions, 267 were in mental defective institutions, 56 in epileptic institutions, and 44 in combined institutions. Hours of duty varied considerably. Most attendants with hours of duty reported worked an 8-hour day. Among those reported in institutions for both mental defectives and epileptics, there were peak hours reported for both 10 and 12 hours of duty per day.

¹ Incomplete reporting, see footnote 2 to table 68.

Expenditures.—In 1940, in the country as a whole, \$27,961,023 was spent for maintenance of patients in the State institutions for mental deficiency and epilepsy, reporting in that year, and an additional \$5,116,236 was spent for additions and improvements. This latter amount was a little less than the amount spent for additions and improvements in 1939.

The total per capita cost of maintenance was \$291.13 in 1940 as compared with \$288.05 in 1939, an increase of 1.1 percent. This may be compared with an increase of 1.7 percent from 1937 to 1938 and of 1.6 percent from 1938 to 1939.

The distribution of institutions for mental defectives and epileptics, and of institutions caring for both types of patient, as given in the sections reporting overcrowding and personnel, are also used for reporting expenditures. The per capita expenditure for maintenance in institutions for epileptics was \$318.88 as compared with \$297.67 in institutions for mental defectives, and \$251.55 in institutions for both types of patient. In institutions for epileptics the percent decrease from the amount spent in 1939, \$322.94, was 1.3 percent. In institutions for mental defectives, the per capita expenditure in 1939 was \$298.54, and the decrease from 1939 to 1940 was 0.3 percent. In institutions where both types of patients are cared for, there was an increase of 1.0 percent over the 1939 expenditure (\$248.97).

Interstate comparison indicates a higher per capita expenditure for maintenance in institutions for epileptics than in institutions for mental defectives, in each State in which both types of institutions were maintained, except in New York and Texas.

The increase in the total per capita cost of maintenance in all State institutions in the United States is reflected in the amount of money that was spent for salaries and wages. The increase in the per capita amount spent for salaries and wages in all institutions, from \$152.04 in 1939 to \$154.25 in 1940 was 1.5 percent. This is greater than the increase in the total per capita expenditure for maintenance (1.1 percent).

In all institutions, 53.0 percent of the total expenditures for maintenance was spent for salaries and wages. When institutions were considered by type (mental defective, epileptic, or mixed) the largest proportion of the total was spent for salaries and wages in epileptic institutions (56.9 percent), the next highest proportion was in institutions for mental defectives (53.2 percent); and in institutions where both mental defectives and epileptics were cared for, the proportion was lowest (49.2 percent).

Expenditures for provisions, and for fuel, light, and water, and expenditures for other operations and maintenance did not change considerably from the previous year.

It is difficult to compare the amounts of money spent for food from year to year for as large an area as the country as a whole, because of the varying amounts of produce raised on the institutional farm. This produce is not included in the amount of money reported as expended for provisions. The reported amount represents actual expenditures for provisions purchased. The amounts spent for items necessary to maintain the institutional farm are divided among the categories: salaries and wages; fuel, light, and water; and other expenditures, wherever these items may be included most appropriately.

To secure more complete information on the value of food served in institutions, an additional item of information was secured relative to expenditures in 1940. It was requested that the actual or estimated value of products raised on the institutional farm be reported. This information was not available to every institution. In table 115 data are reported on the value of food consumed in all institutions in which a valuation was placed on food produced. The actual or estimated value of food produced has been added to the actual cost of provisions purchased, and from the total of these two values, the per capita value of food consumed per annum is reported for certain States. In compiling this information, separation of the data has been made into the three groups of institutions: institutions for mental defectives, institutions for epileptics, and institutions for both mental defectives and epileptics.

In institutions for mental defectives the per capita value of food consumed was \$80.43, as compared with \$87.62 in institutions for epileptics, and \$84.84 in institutions for both mental defectives and epileptics. In institutions for mental defectives, 31.3 percent of the total value of consumed food was raised on institutional farms. In epileptic institutions the corresponding proportion was 33.8 percent, and in institutions for both types of patients the proportion was 34.4 percent.

Information was also secured in 1940 for the number of meals fed to patients and the number fed to employees, when the reported expenditures were allotted to cover both. Of those institutions reporting these data, 88.1 percent of all meals served during the year were fed to patients and 11.9 percent to employees. In State hospitals for mental disease the proportion of meals fed to patients was considerably higher.

In 1940 data were requested to determine whether funds received from paying patients were devoted to hospital use or paid into the State general fund. Of those institutions reporting, 16 indicated that funds received from paying patients were devoted entirely to hospital use, while 1 institution indicated that part of these receipts was devoted to the institution and part went directly to the State fund. In 25 institutions these funds were paid directly to the State treasury. There were no receipts from paying patients in 22 institutions, and in 12 institutions there was either no indication of the disposition of the funds, or there was no report received.

CITY INSTITUTIONS

There are two city institutions for mental defectives and epileptics, one in Missouri, the other in Louisiana. At the end of 1940 there were 512 patients in these two institutions, and no patients were on parole or other absence status. Of the patients in residence, 265 were male and 247 were female. There were 54 admissions during the year, and 63 separations. The patient turn-over is small. Most of the patients who were first admissions during the year were classified as morons (20 of 34). There were reported 20 readmissions, 31 discharges, and 4 deaths.

There were 98 employees on a full-time basis and 22 part-time employees reported. There were 4 physicians on a full-time basis, 2 of whom were superintendents and 2 staff physicians. The other full-time employees reported were: 1 laboratory technician, 7 teachers, 1 social worker, 2 nursing supervisors, and 83 clerical and domestic personnel. Part-time employees were: 13 consulting physicians, 2 dentists, 4 principals and teachers, 2 attendants, and 1 domestic employee.

During 1940, \$212,663 was expended for the maintenance of the two institutions, and \$183,561 for additions and improvements. Per capita expenditure for maintenance was \$438.38 in Missouri and \$174.42 in Louisiana.

PRIVATE INSTITUTIONS

In 1940 there were 56 private institutions, either proprietary or nonprofit, reported as caring for mental defectives and epileptics. This was slightly smaller than the number reported in 1939. Many of these institutions also reported patients classified as neither mentally defective nor epileptic. There was a slight increase reported in the total number of patients on the books of private institutions, from 3,692 at the beginning to 3,782 at the end of 1940. The number of mental defectives increased more than the number of epileptics in this period. Few private institutions practiced placing patients on parole or other absence status. There was a small patient population turn-over among mental defectives and epileptics but considerable turn-over among those patients classified as neither mentally defective nor epileptic. As has been indicated, these patients are generally diagnosed as postencephalitic, with psychopathic personality, or with primary behavior disorders.

Among mental defective first admissions (459), the patients whose mental status was reported as idiot (60) comprised 13.1 percent of the total. In State institutions the corresponding ratio was 16.4 percent. Generally, it is less common for a child whose mental status is as low as that of idiot to be placed in a private institution. Since no amount of habit training can bring about improvement, and the treatment resolves itself into the administering of custodial care, such children are generally sent direct to a public-supported institution. At best, the lines of demarcation between degrees of mental status cannot be clear-cut.

First admissions of symptomatic epileptics (16) were less than half as numerous as those of idiopathic epileptics (41). In State institutions, approximately the same ratio exists.

The number of first admissions diagnosed as neither mentally defective nor as epileptic (428) was nearly as large as the number of first admissions of mental defectives (459), and considerably larger than the number of first admissions of epileptics (95). More than three-fourths of first admissions of patients neither mentally defective nor epileptic were in New York State in a single institution that cares for a large number of aged and infirm patients.

PART III. CONSOLIDATED DATA FOR MENTAL DEFECTIVES AND EPILEPTICS

INTRODUCTION

Scope of the data.—In part II of this report, data are presented for mental defectives and epileptics in institutions established especially for their care. In part III the data assembled on this same type of patient in hospitals for mental disease have been added to this information.

The distribution of all first admissions to hospitals and institutions, whether under State, veterans', county and city, or private control, is given separately for mental defectives and epileptics. The age distributions of first admissions are presented for State, veterans', county, and city hospital and institution patients, but not for patients in hospitals or institutions under private control. Data for readmissions, discharges, and deaths are also available for all but private hospitals and institutions.

Significance of the data.—Considerable misinterpretation is possible in interstate comparison of the care provided for mental defectives and epileptics when those in hospitals for mental disease are not included. Several States in the Mountain division provide no separate State institutions for such patients. In past years, as well as in 1940, these States have not been listed in the report of mental defectives and epileptics in institutions because the State hospitals in which these patients were institutionalized chose to report all their census data on schedules provided for hospitals for mental disease.

In the South the hospitalization of the Negro presents another problem. In the South Atlantic division only Virginia provides a separate institution for the care of Negro mental defectives and epileptics. Negro patients who require institutionalization must seek admission to a hospital for mental disease. Complete racial break-down of the data would be most desirable. This is not possible in the present report. Nonetheless, combined hospital and institution figures are more representative of the whole situation than institution data alone.

Treatment of the data. — Data for mental defectives and epileptics are presented separately by State and geographic division. In each case figures for institutions for mental defectives and epileptics are shown separately from figures for hospitals for mental disease.

First admissions.—Of the 9,671 mental defective first admissions, 8,048 (83.2 percent) were admitted to institutions for mental defectives and epileptics; 1,623 (16.8 percent), to hospitals for mental disease. Of the 2,394 epileptic first admissions, 1,929 (80.6 percent) were first admissions to institutions; 465 (19.4 percent), to hospitals for mental disease. For both types of patients, the proportions admitted to institutions and to hospitals were 82.7 percent and 17.3 percent, respectively. There is greater turn-over of mental defectives and epileptics treated in hospitals for mental disease. Perhaps these patients are not so seriously handicapped to begin with, or it may be that they are transferred later to institutions if they require lengthy care.

The rate of first admission of mental defective patients to hospitals and institutions was 7.3, and of epileptic patients it was 1.8 per 100,000 of the total population. When based on the population aged 5 years and over, the rates were 8.0 for mental defectives and 2.0 for epileptics. These rates may be compared with those presented in part II for mental defective and epileptic first admissions to all institutions where the rates, expressed per 100,000 of the population aged 5 years and over, were indicated to be 6.7 for mental defectives and 1.6 for epileptics.

The median age of all mental defective first admissions was 16.2 years, as compared with a median age of 28.2 years in hospitals and 14.8 years in institutions. For all epileptic first admissions, the median age was 19.5 years, as compared with 28.1 years in hospitals and 18.1 years in institutions.

¹ Incomplete reporting, see footnote to table 1 and footnote 2 to table 68.

Readmissions.—Readmission data were available only for public hospitals and institutions. Of all mental defective readmissions, 36.1 percent were to hospitals for mental disease. The corresponding percentage for mental defective first admissions was 16.8 percent. A similar situation prevailed among epileptics, with 37.6 percent of all readmissions to hospitals for mental disease as compared with 19.4 percent of first admissions to these same hospitals. This relationship holds in many States.

Of the 1,174 readmitted mental defectives, 750, or 63.9 percent, were to public institutions for mental deficiency and epilepsy and 424, or 36.1 percent, to public hospitals for mental disease. Epileptic patients readmitted to public hospitals for mental disease numbered 121 (37.6 percent) as compared with 201 (62.4 percent) to public institutions for mental defectives and epileptics.

Discharges.—Slightly more than three times as many discharges of mental defectives were made from institutions (3,832) as from hospitals (1,204), although the mental defective patient population in institutions was proportionately much larger (almost nine times as large in 1939). Of the 1,257 epileptic patients discharged, 887 were discharged from institutions, and 370 from hospitals, a ratio of 2,4 to 1, as compared with a ratio of almost 8 to 1 among resident epileptics (in 1939).

Apparently mental defective and epileptic patients in hospitals are more likely to be discharged than those in institutions.

Deaths.—There were 1,824 deaths of mental defectives in all public institutions for mental patients. More than 80 percent of these were in public institutions for mental deficiency and epilepsy. Of all epileptic deaths, 87.3 percent occurred in public institutions (743 of a total of 851 deaths reported).
