In consequence of these proceedings, the Transvaal authorities at once set to work to accumulate armaments, and they succeeded in procuring vast quantities of artillery and military stores. The British Government would undoubtedly have been entitled to insist that these armaments should cease. It was obvious that they could only be directed against Great Britain; and no nation is bound to allow another people to prepare great armaments to be employed against itself. The criminal folly of the raid prevented the British Government from making this demand. It could not say that the Transvaal Government had no cause for alarm when British officers had attempted an invasion of its territory and had been treated rather as heroes than as criminals at home. Ignorant of the strength of Great Britain, and elated by the recollection of their previous successes, the Boers themselves believed that a new struggle might give them predominance in South Africa. The knowledge that a large portion of the population of Cape Colony was of Dutch extraction, and that public men at the Cape sympathized with them in their aspirations, increased their confidence. In the meantime, while the Boers were silently and steadily continuing their military preparations, the British settlers at Johannesburg—the Uitlanders, as they were called—were demanding consideration for their grievances. In the spring of 1899, Sir Alfred Milner, governor of the Cape, met President Kruger at Bloemfontein, the capital of the Orange Free State, and endeavoured to accomplish that result by negotiation. He thought, at the time, that if the Uitlanders were given the franchise and a fair proportion of influence in the legislature, other difficulties might be left to settle themselves. The negotiations thus commenced unfortunately failed. The discussion, which had originally turned on the franchise, was enlarged by the introduction of the question of suzerainty or supremacy; and at last, in the beginning of October, when the rains of an African spring were causing the grass to grow on which the Boer armies were largely dependent for forage, the Boers declared war and invaded Natal. The British Government had not been altogether happy in its conduct of the preceding negotiations. It was certainly unhappy in its preparations for the struggle. It made the great mistake of underrating the strength of its enemy; it suffered its agents to commit the strategical blunder of locking up the few troops it had in an untenable position in the north of Natal. It was not surprising, in such circumstances, that the earlier months of the war should have been memorable for a series of exasperating reverses. These reverses, however, were redeemed by the valour of the British troops, the spirit of the British nation, and the enthusiasm which induced the great autonomous colonies of the empire to send men to support the cause of the mother country. The gradual arrival of reinforcements, and the appointment of a soldier of genius—Lord Roberts—to the supreme command, changed the military situation; and, before the summer of 1900 was concluded, the places which had been besieged by the Boers—Kimberley, Ladysmith, and Mafeking—had been successively relieved; the capitals of the Orange Free State and of the Transvaal had been occupied; and the two republics, which had rashly declared war against the British empire, had been formally annexed to the dominions of the Queen.

Boer War, 1899.

The defeat and dispersal of the Boer armies, and the apparent collapse of Boer resistance, induced a hope that the war was over; and the Government seized the opportunity to terminate the parliament, which had already endured for more than five years. The election was conducted with unusual bitterness; but the constituencies practically affirmed the policy of the Government by maintaining, almost unimpaired, the large majority which the Unionists had secured in 1895. Unfortunately, the expectations which had been formed at the time of the dissolution were disappointed. The same circumstances which had emboldened the Boers to declare war in the autumn of 1899, induced them to renew a guerilla warfare in the autumn of 1900—the approach of an African summer supplying the Boers with the grass on which they were dependent for feeding their hardy horses. Guerilla bands suddenly appeared in different parts of the Orange River Colony and of the Transvaal. They interrupted the communications of the British armies; they won isolated victories over British detachments; they even attempted the invasion of the Cape Colony. Thus the year which concluded the century closed in disappointment and gloom. The serious losses which the war entailed, the heavy expenses which it involved, and the large force which it absorbed, filled thoughtful men with anxiety.

The close of 1900.

No one felt more sincerely for the sufferings of her soldiers, and no one regretted more truly the useless prolongation of the struggle, than the venerable lady who occupied the throne. She had herself lost a grandson (Prince Christian Victor) in South Africa; and sorrow and anxiety perhaps told even on a constitution so unusually strong as hers. At any rate, towards the close of 1900 it was reported, in well-informed circles, that Her Majesty was not enjoying her usual health. About the middle of January 1901 it was known that she was seriously ill; on the 22nd she died. The death of the Queen thus occurred immediately after the close of the century over so long a period of which her reign had extended. That reign witnessed the greatest industrial triumphs which the world had ever seen; the expansion of the Anglo-Saxon race and the development of Anglo-Saxon rule in every quarter of the globe. Commencing in a period of great internal suffering, it ended at a time of unusual prosperity; and of all the remarkable facts in the reign, there is, perhaps, nothing more noteworthy than these: during the first five years of it poverty and crime in England attained their maxima; while, during the last five years of it, the pressure of poverty and the burden of crime were reduced to the lowest proportions which had ever been known. The vast expansion of the empire, and the marked improvement in the condition of the people, were due to causes with which the Queen herself had no direct concern. But in other respects the Queen rendered services to the country of the highest importance. In the first place, her own example exerted a beneficial influence on all who surrounded her. The atmosphere of the court, which had been injuriously affected during the reigns of her immediate predecessors, was purified by her influence and her conduct. The tone of society was insensibly raised by her example, and it is not too much to say that she left her country better than she found it. The Queen's public conduct, moreover, was as much above criticism as her private life. It would, perhaps, be an exaggeration to say that she invented constitutional government; but she practically determined by her example the right course for constitutional sovereigns to pursue. Though, throughout her reign, she exercised a great and increasing influence on the counsels of her ministers, she never identified herself with any minister or any party. Each of the ten men who successively filled the first place in her counsels, was able to rely on the same loyal and unwavering support, and each of them was ready to acknowledge the debt that was due to her judgment and her experience.

The death of the Queen.

The reign of the Queen may, perhaps, be divided into three periods. During nearly the whole of the first period, from 1837 to 1862, she had her consort by her side, and was largely influenced by his advice. The Prince's stiff and reserved manners, however, diverted attention from his many admirable qualities; and the court hardly enjoyed the full measure of popularity which it deserved at the time and which it acquired later on. During the second period, from the death of the Prince Consort to the earlier 'eighties, the sorrow which had fallen on the Queen induced her to withdraw from the more prominent duties of her position; the people grew accustomed to the absence of their sovereign, and forgot or were unaware of the many great services which she was rendering to them. Even during these years of mourning, however, the Queen's sympathy with suffering made a profound impression on the nation; and if in some respects she lost ground as a ruler, she gained the affection of her subjects by her many excellent qualities as a woman. But it was not till her jubilee of 1887 that the people generally became thoroughly acquainted with the great qualities of their sovereign. The Queen herself saw with surprise the admiration and love which her presence everywhere excited. Thenceforward she emerged more and more from her retirement, and made exertions, which were the more remarkable from the growing infirmities of her age, to display her gratitude for her people's appreciation. She acquired in these years a popularity which no British sovereign, and perhaps no sovereign in the world, has ever enjoyed; and, partly through her connexion with the ruling houses of Europe, and partly in consequence of the authority bestowed by age and experience, she exercised an influence abroad almost as great and beneficial as that which she exerted at home.

The long period over which her reign extended was, in one sense, the most remarkable in the history of the world. So far as the English-speaking races were concerned, it witnessed a material and moral progress which has no parallel in their annals. During her reign the people of Great Britain doubled their number; but the accumulated wealth of the country increased at least threefold, and its trade sixfold. All classes shared the prevalent prosperity. Notwithstanding the increase of population, the roll of paupers at the end of the reign, compared with the same roll at the beginning, stood as 2 stands to 3; the criminals as 1 to 2. The expansion abroad was still more remarkable. There were not 200,000 white persons in Australasia when the Queen came to the throne; there were nearly 5,000,000 when she died. The great Australian colonies were almost created in her reign; two of them—Victoria and Queensland—owe their name to her; they all received those autonomous institutions, under which their prosperity has been built up, during its continuance. Expansion and progress were not confined to Australasia. The opening months of the Queen's reign were marked by rebellion in Canada. The close of it saw Canada one of the most loyal portions of the Empire. In Africa, the advance of the red line which marks the bounds of British dominion has been even more rapid; while in India the Punjab, Scindh, Oudh, and Burma are some of the acquisitions which were added to the British Empire while the Queen was on the throne. When she died one square mile in four of the land in the world was under the British flag, and at least one person out of every five persons alive was a subject of the Queen.

Material progress was largely facilitated by industry and invention. The first railways had been made, the first steamship had been built, before the Queen came to the throne. But, so far as railways are concerned, none of the great trunk lines had been constructed in 1837; the whole capital authorized to be spent on railway construction did not exceed £55,000,000; and, five years after the reign had begun, there were only 18,000,000 passengers. The paid-up capital of British railways now exceeds £1,100,000,000; the passengers, not including season ticket-holders, also number 1,100,000,000; and the sum which is annually spent in working the lines considerably exceeds the whole capital authorized to be spent on their construction in 1837. The progress of the commercial marine was still more noteworthy. In 1837 the entire commercial navy comprised 2,800,000 tons, of which less than 100,000 tons were moved by steam. At the end of the reign the tonnage of British merchant vessels had reached 13,700,000 tons, of which more than 11,000,000 tons were moved by steam. At the beginning of the reign it was supposed to be impossible to build a steamer which could either cross the Atlantic or face the monsoon in the Red Sea. The development of steam navigation since then has made Australia much more accessible than America was in 1837, and has brought New York, for all practical purposes, nearer to London than Aberdeen was at the commencement of the reign. Electricity has had a greater effect on communication than steam on locomotion; and electricity, as a practical invention, had its origin in the reign. The first experimental telegraph line was only erected in the year in which Queen Victoria came to the throne. Submarine telegraphy, which has done so much to knit the Empire together, was not perfected for many years afterwards; and long ocean cables were almost entirely constructed in the last half of the reign.

These are some of the more striking changes which have taken place in the period with which this article is concerned. Concentrated as they have been in the years which have been covered by a single reign, they impart additional importance and interest to the age of Queen Victoria. On personal grounds her memory will be consecrated in history as that of the best of sovereigns; on imperial grounds her reign will be recollected for the extension of the British Empire, the expansion of the British race, and the material and moral progress of the British people. (s. w.)

English Law (History of).—In English jurisprudence "legal memory" is said to extend as far as, but no farther than the coronation of Richard I. (Sept. 3, 1189). This is a technical doctrine concerning prescriptive rights, but is capable of expressing an important truth. For the last seven centuries, little more or less, the English law, which is now over-shadowing a large share of the earth, has had not only an extremely continuous, but a matchlessly well-attested history, and, moreover, has been the subject matter of rational exposition. Already in 1194 the daily doings of a tribunal which was controlling and moulding the whole system were being punctually recorded in letters yet legible, and from that time onwards it is rather the enormous bulk than any dearth of available materials that prevents us from tracing the transformation of every old doctrine and the emergence and expansion of every new idea. If we are content to look no farther than the text-books—the books written by lawyers for lawyers—we may read our way backwards to Blackstone (d. 1780), Hale (d. 1676), Coke (d. 1634), Fitzherbert (d. 1538), Littleton (d. 1481), Bracton (d. 1268), Glanvill (d. 1190), until we are in the reign of Henry of Anjou, and yet shall perceive that we are always reading of one and the same body of law, though the little body has become great, and the ideas that were few and indefinite have become many and explicit.

Beyond these seven lucid centuries lies a darker period. Nearly six centuries will still divide us from the dooms of Æthelbirht (*circ.* 600), and nearly seven from the Lex Salica (*circ.* 500). We may regard the Norman conquest of England as marking the confluence of two streams of law. The one we may call French or Frankish. If we follow it upwards we pass through the capitularies of Carlovingian emperors and Merovingian kings until we see Chlodwig and his triumphant Franks invading Gaul, submitting their Sicambrian necks to the yoke of the imperial religion, and putting their traditional usages into written Latin. The other rivulet we may call Anglo-Saxon. Pursuing it through the code of Cnut (d. 1035) and the ordinances of Alfred (*circ.* 900) and his successors, we see Ine publishing laws in the newly-converted Wessex (*circ.* 690), and, almost a century earlier, Æthelbirht doing the same in the newly-converted Kent (*circ.* 600). This he did, says Beda, in accordance with Roman precedents. Perhaps from the Roman missionaries he had heard tidings of what the Roman emperor had lately been doing far off in New Rome. We may at any rate notice with interest that in order of time Justinian's law-books fall between the *Lex Salica* and the earliest Kentish dooms; also that the great Pope who sent Augustine to England is one of the very few men who between Justinian's day and the 11th century lived in the Occident and yet can be proved to have used the Digest. In the Occident the time for the Germanic "folk-laws" (*Leges Barbarorum*) had come, and a Canon law, ambitious of independence, was being constructed, when in the Orient the lord of church and state was "enucleating" all that was to live of the classical jurisprudence of pagan Rome. It was but a brief interval between Gothic and Lombardic domination that enabled him to give law to Italy: Gaul and Britain were beyond his reach.

The Anglo-Saxon laws that have come down to us (and we have no reason to fear the loss of much beyond some dooms of the Mercian Offa) are best studied as members of a large Teutonic family. Those that proceed from the Kent and Wessex of the 7th century are closely related to the Continental folk-laws. Their next of kin seem to be the *Lex Saxonum* and the laws of the Lombards. Then, though the 8th and 9th centuries are unproductive, we have from Alfred (*circ.* 900) and his successors a series of edicts which strongly resemble the Frankish capitularies —so strongly that we should see a clear case of imitation, were it not that in Frankland the age of legislation had come to its disastrous end long before Alfred was king. This, it may be noted, gives to English legal history a singular continuity from Alfred's day to our own. The king of the English was expected to publish laws at a time when hardly any one else was attempting any such feat, and the English dooms of Cnut the Dane are probably the most comprehensive statutes that were issued in the Europe of the 11th century. No genuine laws of the sainted Edward have descended to us, and during his reign England seems but too likely to follow the bad example of Frankland, and become a loose congeries of lordships. From this fate it was saved by the Norman duke, who, like Cnut before him, subdued a land in which kings were still expected to publish laws.

Germanic Law.

In the study of early Germanic law—a study which now for some fifty years has been scientifically prosecuted in Germany—the Anglo-Saxon dooms have received their due share of attention. A high degree of racial purity may be claimed on their behalf. Celtic elements have been sought for in them, but have never been detected. At certain points, notably in the regulation of the blood-feud and the construction of a tariff of atonements, the law of one rude folk will always be somewhat like the law of another; but the existing remains of old Welsh and old Irish law stand far remoter from the dooms of Æthelbirht and Ine than stand the edicts of Rothari and Liutprand, kings of the Lombards. Indeed, it is very dubious whether distinctively Celtic customs play any considerable part in the evolution of that system of rules of Anglian, Scandinavian, and Frankish origin which becomes the law of Scotland. Within England itself, though for a while there was fighting enough between the various Germanic folks, the tribal differences were not so deep as to prevent the formation of a common language and a common law. Even the strong Scandinavian strain seems to have rapidly blended with the Anglian. It amplified the language and the law, but did not permanently divide the country. If, for example, we can to-day distinguish between *law* and *right*, we are debtors to the Danes; but very soon *law* is not distinctive of eastern or *right* of western England. In the first half of the 12th century a would-be expounder of the law of England had still to say that the country was divided between the Wessex law, the Mercian law, and the Danes' law, but he had also to point out that the law of the king's own court stood apart from and above all partial systems. The local customs were those of shires and hundreds, and shaded off into each other. We may speak of more Danish and less Danish counties; it was a matter of degree; for rivers were narrow and hills were low. England was meant by nature to be the land of one law.

Then as to Roman law. In England and elsewhere Germanic law developed in an atmosphere that was charged with traditions of the old world, and many of these traditions had become implicit in the Christian religion. It might be argued that all that we call progress is due to the influence exercised by Roman civilization; that, were it not for this, Germanic law would never have been set in writing; and that theoretically unchangeable custom would never have been supplemented or superseded by express legislation. All this and much more of the same sort might be said; but the survival in Britain, or the re-introduction into England, of anything that we should dare to call Roman jurisprudence would be a different matter. Eyes, carefully trained, have minutely scrutinized the Anglo-Saxon legal texts without finding the least trace of a Roman rule outside the ecclesiastical sphere. Even within that sphere modern research is showing that the church-property-law of the Middle Ages, the law of the ecclesiastical "benefice," is permeated by Germanic ideas. This is true of Gaul and Italy, and yet truer of an England in which Christianity was for a while extinguished. Moreover, the laws that were written in England were, from the first, written in the English tongue; and this gives them an unique value in the eyes of students of Germanic folk-law, for even the very ancient and barbarous *Lex Salica* is a Latin document, though many old Frankish words are enshrined in it. Also we notice—and this is of grave importance—that in England there are no vestiges of any "Romani" who are being suffered to live under their own law by their Teutonic rulers. On the Continent we may see Gundobad, the Burgundian, publishing one law-book for the Burgundians and another for the Romani who own his sway. A book of laws, excerpted chiefly from the Theodosian code, was issued by Alaric the Visigoth for his Roman subjects before the days of Justinian, and this book (the so-called *Breviarium Alarici* or *Lex Romana Visigothorum*) became for a long while the chief representative of Roman law in Gaul. The Frankish king in his expansive realm ruled over many men whose law was to be found not in the *Lex Salica* or *Lex Ribuaria*, but in what was called the *Lex Romana.* "A system of personal law" prevailed: the *homo Romanus* handed on his Roman law to his children, while Frankish or Lombardic, Swabian or Saxon law would run in the blood of the *homo barbarus.* Of all this we hear nothing in England. Then on the mainland of Europe Roman and barbarian law could not remain in juxtaposition without affecting each other. On the one hand we see distinctively Roman rules making their way into the law of the victorious tribes, and on the other hand we see a decay and debasement of jurisprudence which ends in the formation of what modern historians have called a Roman "vulgar law" (*Vulgarrecht*). For a short age which centres round the year 800 it seemed possible that Frankish kings, who were becoming Roman emperors, would be able to rule by their capitularies nearly the whole of the Christian Occident. The dream vanished before fratricidal wars, heathen invaders, centrifugal feudalism, and a centripetal church which found its law in the newly-concocted forgeries of the Pseudo-Isidore (*circ.* 850). The "personal laws" began to transmute themselves into local customs, and the Roman vulgar-law began to look like the local custom of those districts where the Romani were the preponderating element in the population. Meanwhile, the Norse pirates subdued a large tract of what was to be northern France —a land where Romani were few. Their restless and boundless vigour these Normans retained; but they showed a wonderful power of appropriating whatever of alien civilization came in their way. In their language, religion, and law, they had become French many years before they subdued England. It is a plausible opinion that among them there lived some sound traditions of the Frankish monarchy's best days, and that Norman dukes, rather than German emperors or kings of the French, are the truest spiritual heirs of Charles the Great.

In our own day German historians are apt to speak of English law as a "daughter" of French or Frankish law. This tendency derived its main impulse from Brunner's proof that the germ of trial by jury, which cannot be found in the Anglo-Saxon laws, can be found in the prerogative procedure of the Frankish kings. We must here remember that during a long age English lawyers wrote in French and even thought in French, and that to this day most of the technical terms of the law, more especially of the private law, are of French origin. Also, it must be allowed, that when the law has taken shape in the 13th century it is very like one of the *coutumes* of northern France. Even when linguistic difficulties have been surmounted, the Saxon Mirror of Eike von Repgow will seem far less familiar to an Englishman than the so-called Establishments of St. Louis. This was the outcome of a slow process which fills more than a century (1066–1189), and was in a great measure due to the reforming energy of Henry II., the French prince who, in addition to England, ruled a good half of France. William the Conqueror seems to have intended to govern Englishmen by English law. After the tyranny of Rufus Henry I. promised a restoration of king Edward's law: that is, the law of the Confessor's time (*Lagam Eadwardi regis vobis reddo*). Various attempts were then made, mostly, so it would seem, by men of French birth, to state in a modern and practicable form the *laga Eadwardi* which was thus restored. The result of their labours is an intricate group of legal tracts which has been recently explored by Dr. Liebermann. The best of these has long been known as the *Leges Henrici Primi*, and aspires to be a comprehensive law-book. Its author, though he had some foreign sources at his command, such as the *Lex Ribuaria* and an epitome of the Breviary of Alaric, took the main part of his matter from the code of Cnut and the older English dooms. Neither the Conqueror nor either of his sons had issued many ordinances: the invading Normans had little, if any, written law to bring with them, and had invaded a country where kings had been lawgivers. Moreover, there was much in the English system that the Conqueror was keenly interested in retaining—especially an elaborate method of taxing the land and its holders. The greatest product of Norman government, the grandest feat of government that the world had seen for a long time past, the compilation of *Domesday Book*, was a conservative effort, an attempt to fix upon every landholder, French or English, the amount of geld that was due from his predecessor in title. Himself the rebellious vassal of the French king, the duke of the Normans, who had become king of the English, knew much of disruptive feudalism, and had no mind to see England that other France which it had threatened to become in the days of his pious but incompetent cousin. The sheriffs, though called *vicecomites*, were to be the king's officers; the shire-moots might be called county courts, but were not to be the courts of counts. Much that was sound and royal in English public law was to be preserved if William could preserve it.

The Norman Age.

The gulf that divides the so-called *Leges Henrici* (*circ.* 1115) from the text-book ascribed to Ranulf Glanvill (*circ.* 1188), seems at first sight very wide. The one represents a not easily imaginable chaos and clash of old rules and new; it represents also a stage in the development of feudalism which in other countries is represented chiefly by a significant silence. The other is an orderly, rational book, which through all the subsequent centuries will be readily understood by English lawyers. Making no attempt to tell us what goes on in the local courts, its author, who may be Henry II.'s chief justiciar, Ranulf Glanvill, or may be Glanvill's nephew, Hubert Walter, fixes our attention on a novel element which is beginning to subdue all else to its powerful operation. He speaks to us of the justice that is done by the king's own court. Henry II. had opened the doors of his French-speaking court to the mass of his subjects. Judges chosen for their ability were to sit there, term after term; judges were to travel in circuits through the land, and in many cases the procedure by way of "an inquest of the country," which the Norman kings had used for the ascertainment of their fiscal rights, was to be at the disposal of ordinary litigants. All this had been done in a piecemeal, experimental fashion by ordinances that were known as "assizes." There had not been, and was not to be, any enunciation of a general principle inviting all who were wronged to bring in their own words their complaints to the king's audience. The general prevalence of feudal justice, and of the world-old methods of supernatural probation (ordeals, battle, oaths sworn with oath-helpers), was to be theoretically respected; but in exceptional cases, which would soon begin to devour the rule, a royal remedy was to be open to anyone who could frame his case within the compass of some carefully-worded and prescript formula. With allusion to a remote stage in the history of Roman law, a stage of which Henry's advisers can have known little or nothing, we may say that a "formulary system" is established which will preside over English law until modern times. Certain actions, each with a name of its own, are open to litigants. Each has its own formula set forth in its original (or, as we might say, originating) writ; each has its own procedure and its appropriate mode of trial. The litigant chooses his writ, his action, and must stand or fall by his choice. Thus a book about royal justice tends to become, and Glanvill's book already is, a commentary on original writs.

Royal justice.

The precipitation of English law in so coherent a form as that which it has assumed in Glanvill's book is not to be explained without reference to the revival of Roman jurisprudence in Italy. Out of a school of Lombard lawyers at Pavia had come Lanfranc the Conqueror's adviser, and the Lombardists had already been studying Justinian's Institutes. Then at length the Digest came by its rights. About the year 1100 Irnerius was teaching at Bologna, and from all parts of the West men were eagerly flocking to hear the new gospel of civilization. About the year 1149 Vacarius was teaching Roman law in England. The rest of a long life he spent here, and faculties of Roman and Canon law took shape in the nascent University of Oxford. Whatever might be the fate of Roman law in England, there could be no doubt that the Canon law, which was crystallizing in the *Decretum Gratiani* (*circ.* 1139) and in the decretals of Alexander III., would be the law of the English ecclesiastical tribunals. The great quarrel between Henry II. and Thomas of Canterbury brought this system into collision with the temporal law of England, and the king's ministers must have seen that they had much to learn from the methodic enemy. Some of them were able men who became the justices of Henry's court, and bishops to boot. The luminous *Dialogue of the Exchequer* (*circ.* 1179), which expounds the English fiscal system, came from the treasurer, Richard Fitz Nigel, who became bishop of London; and the treatise on the laws of England came perhaps from Glanvill, perhaps from Hubert Walter, who was to be both primate and chief justiciar. There was healthy emulation of the work that was being done by Italian jurists, but no meek acceptance of foreign results.

Bracton.

A great constructive era had opened, and its outcome was a large and noble book. The author was Henry of Bratton (his name has been corrupted into Bracton), who died in 1268 after having been for many years one of Henry III.'s justices. The model for its form was the treatise of Azo of Bologna ("master of all the masters of the laws," an Englishman called him), and thence were taken many of the generalities of jurisprudence: maxims that might be regarded as of universal and natural validity. But the true core of the work was the practice of an English court which had yearly been extending its operations in many directions. For half a century past diligent record had been kept on parchment of all that this court had done, and from its rolls Bracton cited numerous decisions. He cited them as precedents, paying special heed to the judgments of two judges who were already dead, Martin Pateshull and William Raleigh. For this purpose he compiled a large Note Book, which was discovered by Prof. Vinogradoff in our own day. Thus at a very early time English "common law" shows a tendency to become what it afterwards definitely became, namely "case law." The term "common law" was just being taken over from the canonists by English lawyers, who used it to distinguish the general law of the land from local customs, royal prerogatives, and in short from all that was exceptional or special. Since statutes and ordinances were still rarities, all expressly enacted laws were also excluded from the English lawyer's notion of "the common law." The Great Charter (1215) had taken the form of a grant of "liberties and privileges," comparable to the grants that the king made to individual men and favoured towns. None the less, it was in that age no small body of enacted law, and, owing to its importance and solemnity, it was in after ages regarded, and is by English lawyers regarded at the present day, as the first article of a statute book. There it is followed by the "provisions" issued at Merton in 1236, and by those issued at Marlborough after the end of the Barons' War. But during Henry III.'s long reign the swift development of English law was due chiefly to new "original writs" and new "forms of action" devised by the Chancery and sanctioned by the court. Bracton knew many writs that were unknown to Glanvill, and men were already perceiving that limits must be set to the inventive power of the Chancery unless the king was to be an uncontrollable law-maker. Thus the common law was losing the power of rapid growth when Bracton summed the attained results in a book, the success of which is attested by a crowd of manuscript copies. Bracton had introduced just enough of Roman law and Bolognese method to save the law of England from the fate that awaited German law in Germany. His book was printed in 1569, and Coke's head was full of Bracton.

The comparison that is suggested when Edward I. is called the English Justinian cannot be pressed very far. Nevertheless, as is well known, it is in his reign (1272–1307) that English institutions finally take the forms that they are to keep through coming centuries. We already see the Parliament of the Three Estates, the Convocations of the Clergy, the King's Council, the Chancery or secretarial department, the Exchequer or financial department, the King's Bench, the Common Bench, the Commissioners of Assize and Gaol Delivery, the small group of professionally learned judges, and a small group of professionally learned lawyers, whose skill is at the service of those who will employ them. Moreover, the statutes that were passed in the first eighteen years of the reign, though their bulk seems slight to us nowadays, bore so fundamental a character that in subsequent ages they appeared as the substructure of huge masses of superincumbent law. Coke commented upon them sentence by sentence, and even now the merest smatterer in English law must profess some knowledge of *Quia emptores* and *De donis conditionalibus.* If some American states have, while others have not, accepted these statutes, that is a difference which is not unimportant to citizens of the United States at the dawn of the 20th century. Then from 1292 comes the first "law report" that has descended to us. It is the precursor of the long series of Year Books (Edw. II.–Hen. VIII.) which runs through the residue of the Middle Ages. Lawyers, we perceive, are already making and preserving notes of the discussions that take place in court: French notes that will be more useful to them than the formal Latin records inscribed upon the plea rolls. From these reports we learn that there are already, as we should say, a few "leading counsel," some of whom will be retained in almost every important cause. Papal decretals had been endeavouring to withdraw the clergy from secular employment. The clerical element had been strong among the judges of Henry III.'s reign: Bracton was an archdeacon, Pateshull a dean, Raleigh died a bishop. Their places begin to be filled by men who are not in orders, but who have pleaded the king's causes for him—his serjeants or servants at law—and beside them there are young men who are "apprentices at law," and are learning to plead. Also we begin to see men who, as "attorneys at law," are making it their business to appear on behalf of litigants. The history of the legal profession and its monopoly of legal aid is intricate, and at some points still obscure; but the influence of the canonical system is evident: the English attorney corresponds to the canonical proctor, and the English barrister to the canonical advocate. The main outlines were being drawn in Edward I.'s day; the legal profession became organic, and professional opinion became one of the main forces that moulded the law.

The study of English law fell apart from all other studies, and the impulse that had flowed from Italian jurisprudence was ebbing. We have two comprehensive text-books from Edward's reign: the one known to us as *Fleta*, the other as *Britton*; both of them, however, quarry their materials from Bracton's treatise. Also we have two little books on procedure which are attributed to Chief-

Justice Hengham, and a few other small tracts of an intensely practical kind. Under the cover of fables about king Alfred, the author of the *Mirror of Justices* made a bitter attack upon king Edward's judges, some of whom had fallen into deep disgrace. English legal history has hardly yet been purged of the leaven of falsehood that was introduced by this fantastic and unscrupulous pamphleteer. His enigmatical book ends that literate age which begins with Glanvill's treatise and the Treasurer's dialogue. Between Edward I.'s day and Edward IV.'s hardly anything that deserves the name of book was written by an English lawyer.

14th and 15th centuries.

During that time the body of statute law was growing, but not very rapidly. Acts of Parliament intervened at a sufficient number of important points to generate and maintain a persuasion that no limit, or no ascertainable limit, can be set to the legislative power of king and Parliament. Very few are the signs that the judges ever permitted the validity of a statute to be drawn into debate. Thus the way was being prepared for the definite assertion of parliamentary "omnicompetence" which we obtain from the Elizabethan statesman Sir Thomas Smith, and for those theories of sovereignty which we couple with the names of Hobbes and Austin. Nevertheless, English law was being developed rather by debates in court than by open legislation. The most distinctively English of English institutions in the later Middle Ages are the Year-Books and the Inns of Court. Year by year, term by term, lawyers were reporting cases in order that they and their fellows might know how cases had been decided. The allegation of specific precedents was indeed much rarer than it afterwards became, and no calculus of authority so definite as that which now obtains had been established in Coke's day, far less in Littleton's. Still it was by a perusal of reported cases that a man would learn the law of England. A skeleton for the law was provided, not by the Roman rubrics (such as public and private, real and personal, possessory and proprietary, contract and delict), but by the cycle of original writs that were inscribed in the Chancery's *Registrum Brevium.* A new form of action could not be introduced without the authority of Parliament, and the growth of the law took the shape of an explication of the true intent of ancient formulas. Times of inventive liberality alternated with times of cautious and captious conservatism. Coke could look back to Edward III.'s day as to a golden age of good pleading. The otherwise miserable time which saw the Wars of the Roses produced some famous lawyers, and some bold doctrines which broke new ground. It produced also Sir Thomas Littleton's (d. 1481) treatise on Tenures, which (though it be not, as Coke thought it, the most perfect work that ever was written in any human science) is an excellent statement of law in exquisitely simple language.

Education.

Meanwhile English law was being scholastically taught. This, if we look at the fate of native and national law in Germany, or France, or Scotland, appears as a fact of primary importance. From beginnings, so small and formless that they still elude research, the Inns of Court had grown. The lawyers, like other men, had grouped themselves in gilds, or gild-like "fellowships." The fellowship acquired property; it was not technically incorporate, but made use of the thoroughly English machinery of a trust. Behind a hedge of trustees it lived an autonomous life, unhampered by charters or statutes. There was a hall in which its members dined in common; there was the nucleus of a library; there were also dormitories or chambers in which during term-time lawyers lived celibately, leaving their wives in the country. Something of the college thus enters the constitution of these fellowships; and then something academical. The craft gild regulated apprenticeship; it would protect the public against incompetent artificers, and its own members against unfair competition. So the fellowship of lawyers. In course of time a lengthy and laborious course of education of the mediæval sort had been devised. He who had pursued it to its end received a call to the bar of his inn. This call was in effect a degree. Like the doctor or master of a university, the full-blown barrister was competent to teach others, and was expected to read lectures to students. But further, in a manner that is still very dark, these societies had succeeded in making their degrees the only steps that led to practice in the king's courts. At the end of the Middle Ages (*circ.* 1470) Sir John Fortescue rehearsed the praises of the laws of England in a book which is one of the earliest efforts of comparative politics. Contrasting England with France, he rightly connects limited monarchy, public and oral debate in the law courts, trial by jury, and the teaching of national law in schools that are thronged by wealthy and well-born youths. But nearly a century earlier, the assertion that English law affords as subtle and civilizing a discipline as any that is to be had from Roman law was made by a man no less famous than John Wyclif. The heresiarch naturally loathed the Canon law; but he also spoke with reprobation of the "paynims' law," the "heathen men's law," the study of which in the two universities was being fostered by some of the bishops. That study, after inspiring Bracton, had come to little in England, though the canonist was compelled to learn something of Justinian, and there was a small demand for learned civilians in the Court of Admiralty, and in what we might call the king's diplomatic service. No mediæval Englishman did anything considerable for Roman law. Even the canonists were content to read the books of French and Italian masters, though John Acton (*circ.* 1340) and William Lyndwood (1430) wrote meritorious glosses. The Angevin kings, by appropriating to the temporal forum the whole province of ecclesiastical patronage, had robbed the decretists of an inexhaustible source of learning and of lucre. The work that was done by the legal faculties at Oxford and Cambridge is slight when compared with the inestimable services rendered to the cause of national continuity by the schools of English law which grew within the Inns of Court.

Chancery.

A danger threatened: the danger that a prematurely osseous system of common law would be overwhelmed by summary justice and royal equity. Even when courts for all ordinary causes had been established, a reserve of residuary justice remained with the king. Whatever lawyers and even parliaments might say, it was seen to be desirable that the king in council should with little regard for form punish offenders who could break through the meshes of a tardy procedure, and should redress wrongs which corrupt and timid juries would leave unrighted. Papal edicts against heretics had made familiar to all the notion that a judge should at times proceed *summarie et de plano et sine strepitu et figura justitiæ.* And so extraordinary justice of a penal kind was done by the king's council upon misdemeanants, and extraordinary justice of a civil kind was ministered by the king's chancellor (who was the specially learned member of the council) to those who "for the love of God and in the way of charity," craved his powerful assistance. It is now well established that the chancellors started upon this course, not with any desire to introduce rules of "equity" which should supplement, or perhaps supplant, the rules of law, but for the purpose of driving the law through those accidental impediments which sometimes unfortunately beset its due course. The wrongs that the chancellor redressed were often wrongs of the simplest and most brutal kind: assaults, batteries, and forcible dispossessions. However, he was warned off this field of activity by Parliament; the danger to law, to lawyers, to trial by jury, was evident. But just when this was happening, a new field was being opened for him by the growing practice of conveying land to trustees. The English trust of land had ancient Germanic roots, and of late we have been learning how in far-off centuries our Lombard cousins were in effect giving themselves a power of testation by putting their lands in trust. In England, when the forms of action were crystallizing, this practice had not been common enough to obtain the protection of a writ; but many causes conspired to make it common in the 14th century; and so, with the general approval of lawyers and laity, the chancellors began to enforce by summary process against the trustee the duty that lay upon his conscience. In the next century it was clear that England had come by a new civil tribunal. Negatively, its competence was defined by the rule that when the common law offered a remedy, the chancellor was not to intervene. Positively, his power was conceived as that of doing what "good conscience" required, more especially in cases of "fraud, accident, or breach of confidence." His procedure was the summary, the heresy-suppressing (not the ordinary and solemn) procedure of an ecclesiastical court; but there are few signs that he borrowed any substantive rules from legist or decretist, and many proofs that within the new field of trust he pursued the ideas of the common law. It was long, however, before lawyers made a habit of reporting his decisions. He was not supposed to be tightly bound by precedent. Adaptability was of the essence of the justice that he did.

A time of strain and trial came with the Tudor kings. It was questionable whether the strong "governance" for which the weary nation yearned could work within the limits of a parliamentary system, or would be compatible with the preservation of the common law. We see new courts appropriating large fields of justice and proceeding *summarie et de plano:* the Star Chamber, the Chancery, the Courts of Requests, of Wards, of Augmentations, the Councils of the North and Wales; a little later we see the High Commission. We see also that judicial torture which Fortescue had called the road to hell. The stream of law reports became intermittent under Henry VIII.; few judges of his or his son's reign left names that are to be remembered. In an age of humanism, alphabetically arranged "abridgments" of mediæval cases were the best work of English lawyers: one comes to us from Anthony Fitzherbert (d. 1538), and another from Robert Broke (d. 1558). This was the time when Roman law swept like a flood over Germany. The modern historian of Germany will speak of "the Reception" (that is, the reception of Roman law), as no less important than the Renaissance and Reformation with which it is intimately connected. Very probably he will bestow hard words on a movement which disintegrated the nation and consolidated the tyranny of the princelings. Now a project that Roman law should be "received" in England occurred to Reginald Pole (d. 1558), a humanist, and at one time a reformer, who with good fortune might have been either king of England or pope of Rome. English law, said the future cardinal and archbishop, was barbarous; Roman law was the very voice of nature pleading for "civility" and good princely governance. Pole's words were brought to the ears of his majestic cousin, and, had the course of events been somewhat other than it was, King Henry might well have decreed a reception. The rôle of English Justinian would have perfectly suited him, and there are distinct traces of the civilian's Byzantinism in the doings of the Church of England's supreme head. The academic study of the Canon law was prohibited; regius professorships of the civil law were founded; civilians were to sit as judges in the ecclesiastical courts. A little later, the Protector Somerset was deeply interested in the establishment of a great school for civilians at Cambridge. Scottish law was the own sister of English law, and yet in Scotland we may see a reception of Roman jurisprudence which might have been more whole-hearted than it was, but for the drift of two British and Protestant kingdoms towards union. As it fell out, however, Henry could get what he wanted in church and state without any decisive supersession of English by foreign law. The omnicompetence of an Act of Parliament stands out the more clearly if it settles the succession to the throne, annuls royal marriages, forgives royal debts, defines religious creeds, attaints guilty or innocent nobles, or prospectively lends the force of statute to the king's proclamations. The courts of common law were suffered to work in obscurity, for jurors feared fines, and matter of state was reserved for council or Star Chamber. The Inns of Court were spared; their moots and readings did no perceptible harm, if little perceptible good.

The Tudor Age.

Yet it is no reception of alien jurisprudence that must be chronicled, but a marvellous resuscitation of English mediæval law. We may see it already in the Commentaries of Edward Plowden (d. 1585) who reported cases at length and lovingly. Bracton's great book was put in print, and was a key to much that had been forgotten or misunderstood. Under Parker's patronage, even the Anglo-Saxon dooms were brought to light; they seemed to tell of a Church of England that had not yet been enslaved by Rome. The new national pride that animated Elizabethan England issued in boasts touching the antiquity, humanity, enlightenment of English law. Resuming the strain of Fortescue, Sir Thomas Smith, himself a civilian, wrote concerning the Commonwealth of England a book that claimed the attention of foreigners for her law and her polity. There was dignified rebuke for the French jurist who had dared to speak lightly of Littleton. And then the common law took flesh in the person of Edward Coke (1552-1634). With an enthusiastic love of English tradition, for the sake of which many offences may be forgiven him, he ranged over nearly the whole field of law, commenting, reporting, arguing, deciding,—disorderly, pedantic, masterful, an incarnate national dogmatism tenacious of continuous life. Imbued with this new spirit, the lawyers fought the battle of the constitution against James and Charles, and historical research appeared as the guardian of national liberties. That the Stuarts united against themselves three such men as Edward Coke, John Selden, and William Prynne, is the measure of their folly and their failure. Words that, rightly or wrongly, were ascribed to Bracton rang in Charles's ears when he was sent to the scaffold. For the modern student of mediæval law many of the reported cases of the Stuart time are storehouses of valuable material, since the lawyers of the 17th century were mighty hunters after records. Prynne (d. 1669), the fanatical Puritan, published ancient documents with fervid zeal, and made possible a history of Parliament. Selden (d. 1654) was in all Europe among the very first to write legal history as it should be written. His book about tithes is to this day a model and a masterpiece. When this accomplished scholar had declared that he had laboured to make himself worthy to be called a common lawyer, it could no longer be said that the common lawyers were *indoctissimum genus doctissimorum hominum.* Even pliant judges, whose tenure of office depended on the king's will, were compelled to cite and

Coke.

discuss old precedents before they could give judgment for their master; and even at their worst moments they would not openly break with mediæval tradition, or declare in favour of that "modern police-state" which had too often become the ideal of foreign publicists trained in Byzantine law.

The current of legal doctrine was by this time so strong and voluminous that such events as the Civil War, the Restoration, and the Revolution hardly deflected the course of the stream. In retrospect, Charles II. reigns so soon as life has left his father's body, and James II. ends a lawless career by a considerate and convenient abdication. The statute book of the restored king was enriched by leaves excerpted from the Acts of a Lord Protector; and Matthew Hale (d. 1676), who was, perhaps, the last of the great record-searching judges, sketched a map of English law which Blackstone was to colour. Then a time of self-complacency came for the law, which knew itself to be the perfection of wisdom, and any proposal for drastic legislation would have worn the garb discredited by the tyranny of the Puritan Cæsar. The need for the yearly renewal of the Mutiny Act secured an annual session of Parliament. The mass of the statute law made in the 18th century is enormous; but, even when we have excluded from view such Acts as are technically called "private," the residuary matter bears a wonderfully empirical, partial, and minutely particularizing character. In this "age of reason," as we are wont to think it, the British Parliament seems rarely to rise to the dignity of a general proposition, and in our own day the legal practitioner is likely to know less about the statutes of the 18th century than he knows about the statutes of Edward I., Henry VIII., and Elizabeth. Parliament, it should be remembered, was endeavouring directly to govern the nation. There was little that resembled the permanent civil service of to-day. The choice lay between direct parliamentary government and royal "prerogative"; and lengthy statutes did much of that work of detail which would now be done by virtue of the powers that are delegated to ministers and governmental boards. Moreover, extreme and verbose particularity was required in statutes, for judges were loath to admit that the common law was capable of amendment. A vague doctrine, inherited from Coke, taught that statutes might be so unreasonable as to be null, and any political theory that seemed to derive from Hobbes would have been regarded with not unjust suspicion. But the doctrine in question never took tangible shape, and enough could be done to protect the common law by a niggardly exposition of every legislating word. It is to be remembered that some main features of English public law were attracting the admiration of enlightened Europe. When Voltaire and Montesquieu applauded, the English lawyer had cause for complacency.

Hale.

The common law was by no means stagnant. Many rules which come to the front in the 18th century are hardly to be traced farther. Especially is this the case in the province of mercantile law, where Mansfield's (d. 1793) long presidency over the King's Bench marked an epoch. It is too often forgotten that, until Elizabeth's reign, England was a thoroughly rustic kingdom, and that trade with England was mainly in the hands of foreigners. Also in mediæval fairs, the assembled merchants declared their own "law merchant," which was considered to have a supernational validity. In the reports of the common law courts it is late in the day before we read of some mercantile usages which can be traced far back in the statutes of Italian cities. Even on the basis of the excessively elaborated land law—a basis which Coke's Commentary on Littleton seemed to have settled for ever—a lofty and ingenious superstructure could be reared. One after another, delicate devices were invented for the accommodation of new wants within the law; but only by the assurance that the old law could not be frankly abolished can we be induced to admire the subtlety that was thus displayed. As to procedure, it had become a maze of evasive fictions, to which only a few learned men held the historical clue. By fiction the courts had stolen business from each other, and by fiction a few comparatively speedy forms of action were set to tasks for which they were not originally framed. Two fictitious persons, John Doe and Richard Roe, reigned supreme. On the other hand, that healthy and vigorous institution, the Commission of the Peace, with a long history behind it, was giving an important share in the administration of justice to numerous country gentlemen who were thus compelled to learn some law. A like beneficial work was being done among jurors, who, having ceased to be regarded as witnesses, had become "judges of fact." No one doubted that trial by jury was the "palladium" of English liberties, and popularity awaited those who would exalt the office of the jurors and narrowly limit the powers of the judge.

But during this age the chief addition to English jurisprudence was made by the crystallization of the chancellor's equity. In the 17th century the Chancery had a narrow escape of sharing the fate that fell on its twin sister the Star Chamber. Its younger sister the Court of Requests perished under the persistent attacks of the common lawyers. Having outlived troubles, the Chancery took to orderly habits, and administered under the name of "equity" a growing group of rules, which in fact were supplemental law. Stages in this process are marked by the chancellorships of Nottingham (1673-5) and Hardwicke (1737-56). Slowly a continuous series of Equity Reports began to flow, and still more slowly an "equity bar" began to form itself. The principal outlines of equity were drawn by men who were steeped in the common law. By way of ornament a Roman maxim might be borrowed from a French or Dutch expositor, or a phrase which smacked of that "nature-rightly" school which was dominating continental Europe; but the influence exercised by Roman law upon English equity has been the subject of gross exaggeration. Parliament and the old courts being what they were, perhaps it was only in a new court that the requisite new law could be evolved. The result was not altogether satisfactory. Freed from contact with the plain man in the jury-box, the chancellors were tempted to forget how plain and rough good law should be, and to screw up the legal standard of reasonable conduct to a height hardly attainable except by those whose purses could command the constant advice of a family solicitor. A court which started with the idea of doing summary justice for the poor became a court which did a highly refined, but tardy justice, suitable only to the rich.

Equity.

About the middle of the century William Blackstone, then a disappointed barrister, began to give lectures on English law at Oxford (1758), and soon afterwards he began to publish (1765) his *Commentaries.* Accurate enough in its history and doctrine to be an invaluable guide to professional students and a useful aid to practitioners, his book set before the unprofessional public an artistic picture of the laws of England such as had never been drawn of any similar system. No nation but the English had so eminently readable a law-book, and it must be doubtful whether any other lawyer ever did more important work than was done by the first professor of English law. Over and over again the *Commentaries* were edited, sometimes by

Blackstone

distinguished men, and it is hardly too much to say that for nearly a century the English lawyer's main ideas of the organization and articulation of the body of English law were controlled by Blackstone. This was far from all. The Tory lawyer little thought that he was giving law to colonies that were on the eve of a great and successful rebellion. Yet so it was. Out in America, where books were few and lawyers had a mighty task to perform, Blackstone's facile presentment of the law of the mother country was of inestimable value. It has been said that among American lawyers the *Commentaries* "stood for the law of England," and this at a time when the American daughter of English law was rapidly growing in stature, and was preparing herself for her destined march from the Atlantic to the Pacific Ocean. Excising only what seemed to savour of oligarchy, those who had defied King George retained with marvellous tenacity the law of their forefathers. Profound discussions of English mediæval law have been heard in American courts; admirable researches into the recesses of the Year-Books have been made in American law schools; the names of the great American judges are familar in an England which knows little indeed of foreign jurists; and the debt due for the loan of Blackstone's *Commentaries* is being fast repaid. Lectures on the common law delivered by the present Chief-Justice of Massachusetts (O. W. Holmes) may even have begun to turn the scale against the old country. No chapter in Blackstone's book nowadays seems more antiquated than that which describes the modest territorial limits of that English law which was soon to spread throughout Australia and New Zealand and to follow the dominant race in India.

Long wars, vast economic changes, and the conservatism generated by the French Revolution piled up a monstrous arrear of work for the English Legislature. Meanwhile, Jeremy Bentham (d. 1832) had laboured for the overthrow of much that Blackstone had lauded. Bentham's largest projects of destruction and reconstruction took but little effect. Profoundly convinced of the fungibility and pliability of mankind, he was but too ready to draw a code for England or Spain or Russia at the shortest notice; and, scornful as he was of the past and its historic deposit, a code drawn by Bentham would have been a sorry failure. On the other hand, as a critic and derider of the system which Blackstone had complacently expounded he did excellent service. Reform, and radical reform, was indeed sadly needed throughout a system which was encumbered by noxious rubbish, the useless leavings of the Middle Ages: trial by battle and compurgation, deodands and benefit of clergy, John Doe and Richard Roe. It is perhaps the main fault of "judge-made law" (to use Bentham's phrase) that its destructive work can never be cleanly done. Of all vitality, and therefore of all patent harmfulness, the old rule can be deprived, but the moribund husk must remain in the system doing latent mischief. English law was full of decaying husks when Bentham attacked it, and his persistent demand for reasons could not be answered. At length a general interest in "law reform" was excited; Romilly and Brougham were inspired by Bentham, and the great changes in constitutional law which cluster round the Reform Act of 1832 were accompanied by many measures which purged the private, procedural, and criminal law of much, though hardly enough, of the mediæval dross. Some credit for rousing an interest in law, in definitions of legal terms, and in schemes of codification, is due to John Austin (d. 1859) who was regarded as the jurist of the reforming and utilitarian group. But, though he was at times an acute dissector of confused thought, he was too ignorant of the English, the Roman, and every other system of law to make any considerable addition to the sum of knowledge; and when Savigny, the herald of evolution, was already in the field, the day for a "Nature-Right"—and Austin's projected "general jurisprudence" would have been a Nature-Right—was past beyond recall. The obsolescence of the map of law which Blackstone had inherited from Hale, and in which many outlines were drawn by mediæval formulas, left intelligent English lawyers without a guide, and they were willing to listen for a while to what in their insularity they thought to be the voice of cosmopolitan science. Little came of it all. The revived study of Germanic law in Germany, which was just beginning in Austin's day, seems to be showing that the scheme of Roman jurisprudence is not the scheme into which English law will run without distortion.

Bentham.

In the latter half of the 19th century some great and wise changes were made by the Legislature. Notably in 1875 the old courts were merged in a new Supreme Court of Judicature, and a concurrent administration of law and equity was introduced. Successful endeavours have been made also to reduce the bulk of old statute law, and to improve the form of Acts of Parliament; but the emergence of new forces whose nature may be suggested by some such names as "socialism" and "imperialism" has distracted the attention of the British Parliament from the commonplace law of the land, and the development of obstructive tactics has caused the issue of too many statutes whose brevity was purchased by disgraceful obscurity. By way of "partial codification" some branches of the common law (bills of exchange, sale of goods, partnership) have been skilfully stated in statutes; but a draft criminal code, upon which much expert labour was expended, lies pigeon-holed and almost forgotten. British India has been the scene of some large legislative exploits, and in America a few big experiments have been made in the way of code-making, but have given little satisfaction to the bulk of those who are competent to appreciate their results. In England there are large portions of the law which, in their present condition, no one would think of codifying: notably the law of real property, in which may still be found numerous hurtful relics of by-gone centuries. So omnipresent are statutes throughout the whole field of jurisprudence, that the opportunity of doing any great feat in the development of law can come but seldom to a modern court. More and more, therefore, the fate of English law depends on the will of Parliament, or rather of the ministry. The quality of legal text-books has steadily improved; some of them are models of clear statement and good arrangement; but no one has with any success aspired to be the Blackstone of a new age. In the matter of legal education it is to be feared that England has fallen behind America. The civil law that was taught in the two universities began to lose its interest in the 17th century. The domain which nominally belonged to its doctors, the old ecclesiastical domain, was being covered by English statutes and English precedents; the Chancery stole work from the ecclesiastical courts, and diplomatists of the modern type appropriated a field in which civilians had been active. On the other hand, the scholastic scheme which obtained in the Inns of Court quickly degenerated into a course of perfunctory exercises, and finally into a course of dinners supplemented by such instruction as a busy barrister might or might not give to his private pupils. Endeavours to remedy this state of things have been made, both by the Inns and by the Universities, but no plan of legal education that can be unreservedly commended has yet been established. Owing to the non existence of flourishing schools of law, England has hardly taken the share which should by rights have been hers in that systematic study of the history of law which was one of the main tasks of the 19th century. (F. W. M.)

English Literature (*since* 1879).—If we take up the history of English literature at the close of 1879 the first thing we notice is that the moment was one of a highly transitional character. In other words, it was remarkable not so much for what was being done as for what had lately been done, and for what was still suffusing through the country the warmth and colour of life. The aspect of literature in England when 1880 opened was brilliant; but we can see now what we could not see then, that the nature of its brilliance belonged to sunset and not to sunrise. The list of living men of letters at that moment was an extraordinarily splendid one. It ranked, in that matter, with the most shining instants that English literature has ever enjoyed. At that moment, on the 1st of January 1880, there were alive in Great Britain, Carlyle, Darwin, Tennyson, Browning, Ruskin, Matthew Arnold, Lord Beaconsfield, Stanley, Froude, Freeman, George Eliot, Huxley, Tyndall, Dante Gabriel and Christina Rossetti, Patmore, William Morris, R. L. Stevenson, Walter Pater, and Edward FitzGerald. Of men who in pure literature could at that time, or in the next decade, be for one moment named with these twenty, only four were still alive in 1902—Mr Herbert Spencer, Mr Swinburne, Mr George Meredith, Mr John Morley. Perhaps there are only two dates in English literary history—1600 and 1810—which could compete with 1880 in the magnificence of the living names producible on a bare list. But we see at once that to compare 1880 with either of the earlier dates would be to resign ourselves to a fallacy. The fact, just mentioned, of the deaths of so large a proportion of the illustrious persons would be enough to make us suspect a condition of things which a close examination of the circumstances shows to be the truth. Let it then be said at once, the concluding portion of the 19th century is remarkable, first and foremost, for the extinction of the great representative lights of that century. If we strain to the utmost our appreciation of what younger men have achieved, it is impossible to give it the importance of the passing away of the elder spirits. When we look broadly at the period we see above all else the quenching of the lights. It has been pre-eminently a period of great funerals. Death has followed death until we were tempted to believe that the stage would be left to us altogether darkened and empty. Nor, if again we look closer still, shall we find that a large proportion of the very eminent persons who adorned the opening of these later years contributed anything to the period. Most of them, or many, belonged to it merely by the accident of longevity. We must begin our history, then, by a record of these silenced voices.[1]

General survey.

The first to pass away was George Eliot (1819–1880), who had written no work of imagination for four years, and who, though probably unimpaired in power, gave signs of having finished saying what she had been born with the special gift to say. Charles Reade (1814–1884), although after his death a surprising number of unimportant volumes were extracted from his papers, had ceased for several years to be a contributor to current literature. Anthony Trollope (1815–1882), on the other hand, was in the full flow of active invention when he died, and must be considered as a living element in the very beginning of our period. But the main body of Charles Darwin's work (1809–1882) was done, although his lively and interesting monograph on *The Formation of Vegetable Mould* belongs to 1881. Beaconsfield (1804–1881) closed his long career as a novelist with *Endymion* just as our period was opening. Arthur Penrhyn Stanley (1815–1881) was writing to the last, but published nothing of more importance than the *Christian Institutions* of 1881. Of a still earlier generation, Carlyle (1795–1881), a portent of mysterious celebrity, in the melancholy isolation and decay of extreme old age, had long ceased to take the least part in the movement of letters. He survived, unseen, unheard, scarcely putting pen to paper during the last ten years of his existence. Nor though Newman (1801–1890) lived on so late, has he much more claim to count as an active factor in the literature of this period. One or two trifles, privately printed, alone reminded the circle of his disciples that he was thinking of them in his cell at Edgbaston. The literary life of Dante Gabriel Rossetti (1828–1882) had closed with the publication of his *Ballads and Sonnets*. Edward FitzGerald (1809–1883) had never been active; he had long been entirely indolent before his death. Of the greatest names, therefore, which we began by enumerating as the principal glory of 1880, we have already eliminated half as having no part whatever in the production of the subsequent years.

The presence and activity of Tennyson, Browning, Ruskin, Froude, and Mr Herbert Spencer, with the authority of certain writers a little younger than these, in particular Matthew Arnold, Huxley, Tyndall, and Mr George Meredith, formed a feature of literary life in the 'eighties which cannot be overlooked. It constituted, indeed, the principal fact of that particular decade. English literature was held, to a very remarkable, perhaps to an unprecedented, degree under the sway of a group of very old men of genius, who showed no tendency to disappear. These very old men were supported by those who were but slightly their juniors, and who might be expected to survive them and take their place. As a matter of fact, Tennyson, whose figure was the most dignified and most imposing of all, survived several of them, and continued intellectually active to the very last. The result of this governance by the aged was very curious. In some degree it may be held to have checked the productive enthusiasm of the newest men. Certainly the young writers occasionally groaned under what they took to be a gerontocracy, a tyranny by the aged. They—or some of them at least—were in a great hurry to come to the throne, neglectful of the fact that but one monarch is accustomed to hold it at a time. It may well be that a youthful poet could not hope, from 1880 to 1890, to publish a volume of verse which should interest even his friends so much as a new volume by Tennyson or Browning. But if this was a disadvantage to him, it is not certain that it was a disadvantage to the literary profession. It is a matter of immense importance in the practice of a living literature to have certain dignified figureheads to point to. It was a useful, because a steadying and sobering, thing to have even the silent Carlyle and Newman to look up to—great accepted masters of the art of writing, who had passed out of the dust of battle and become half-divine, who were recognized as giant figures challenged no longer. It was a far more inspiring and stimulating thing to have Browning, Ruskin, and Tennyson there, equally lifted out of mere vain discussion, and yet still actively engaged in composition. It gave just such a dignity to the mere art and tradition of authorship as is missing when no great

[1] In the present article it has been thought well to confine the attention of the reader strictly to the movement of English literature during the years 1879–1902, the article ENGLISH LITERATURE in the 9th edition of the *Ency. Brit.* having been published in 1879. In order, however, to cover the gap between the earlier and the later periods, reference should be made to the various biographies of prominent deceased authors, which will be found either in the 9th edition of the *Ency. Brit.*, as in the cases of Dickens, Macaulay, Thackeray, Kingsley, D. G. Rossetti, and many others, or in the course of the present Supplement, as in the cases of Newman, Tennyson, Carlyle, Browning, George Eliot, and Ruskin.

and unchallengeable reputation is before the public of a country. During the decade 1880–1890 the number and dignity of these figureheads was greater, perhaps, than it had ever been before; it was so great that it is with them—with the astonishing group of veterans—that the honours of the period lie. It was salutary that it should be so. Every one who loves the literature of his country will say with Jean Paul, "Gott, segne die Menschen mit grossen Menschen."

Poetry. In the history of the poetry of the period the earliest event which served as a landmark in the passage of time was the death of Dante Gabriel Rossetti (1828–1882). This was in itself of little importance, as the health of the poet had long been in a condition which could only point to the total obscuration of his genius. But the passing of Rossetti was the earliest public intimation of the fact that the so-called pre-Raphaelite school of English poetry, which had occupied so large a share of public attention for fifteen years, had now reached its height, and had even begun to decline. This school had been combative and full of audacity; it had shaken the coteries, and had made the recognized masters question the bases of their own authority. It had presented, pre-eminently, the aspect of militant youth, and thus the general public continued to regard it. After the death of the brilliant Rossetti, in physical and mental decay, it was impossible quite to regard it so any longer, and, indeed, as will presently be seen more in detail, its work as a school was over. But on this withdrawal of the rich pre-Raphaelite influences there followed a phenomenon of rare historical interest. This was the revival, the fresh outburst of sustained energy, of the two most celebrated poets of an earlier generation. In 1879 Tennyson (1809–1892) was in his seventy-first year; Browning three years younger. Each of these illustrious men had been before the public for half a century, had overcome misconception and detraction, had accustomed an ever-widening public to their mannerisms, and might well have been expected to withdraw into a dignified enjoyment of their fame. But this neither was content to do. In the face of advanced years, in the face of successive generations of more youthful rivals, they competed with the youngest and bore away, like the octogenarian Sophocles, prize after prize. Through the 'seventies Tennyson had mainly devoted his attention, since the completion of the *Idylls of the King*, to drama. Few were prepared, therefore, for the volume of *Ballads* in 1880 that enriched English poetry by such masterpieces as "Rizpah," "The Revenge," and "The Voyage of Maeldune." These may have been earlier in time of composition, but the same can hardly have been the case with the *Tiresias* volume of 1885, which contained "To Virgil" and "Frater ave atque vale." All doubt about the amazing and sustained fecundity of Tennyson's genius was set at rest by his publishing in the very next year a fresh volume of miscellanies, *Locksley Hall Sixty Years after.* At the age of eighty (1889) he put forth *Demeter*, a volume of narratives and lyrics in which there was, at last, a certain decline of energy, but in which such pieces as "Parnassus" and "Crossing the Bar" showed the old poet in the quintessence of his talent. Even this was not the latest of his appearances, for *The Foresters* appeared in the year of his death (1892) and *The Death of Œnone* a few weeks later than that event.

Robert Browning (1812–1889) showed a similar persistence, if it was, as must be confessed, combined with less charm. His works were extended by the publication of five considerable collections of short poems, from the second series of *Dramatic Idylls* (1880) to *Asolando*, published on the very day of his death. The intellectual element was stronger than the poetical in the bulk of these productions, which we may now look back upon as interesting and characteristic, but in the main not beautiful. To the essential work of Browning which posterity will read and value, these volumes (with the exception of *Asolando* in certain pages) added little, and in this respect he compared unfavourably with Tennyson, who preserved to the very last the key to the mystery of beauty. But the moral effect of Browning's punctual activity was not less marked than that of Tennyson. If what the former published was too hard and crabbed for unabated admiration, it showed no lessening of intellectual power. The giant was there, and still lusty and voluble. All through the decade 1879–1889, in spite of the heaped-up years, the interest of readers continued to centre in Tennyson and Browning.

At the death of Tennyson, Mr Algernon Charles Swinburne (*b.* 1837) was left without a rival as the principal living poet of England. He had originally been identified with the pre-Raphaelites, but he had long severed himself from them. He was moving on, upon his own planetary course, without any reference to any of his contemporaries. No poet has been less affected, since his early youth, by the example of other writers or by the presumable taste of the public. In isolation he has repeated his effects and dwelt upon such chords of life and literature as personally attracted him. His earliest publications in our period were *Mary Stuart* (1881), in which he completed his Scots trilogy, and *Tristram of Lyonesse* (1882), a short romantic epic, followed by a collection of lyrics. These are volumes so typical that if the other works of Mr Swinburne were unhappily to be lost they could almost be reconstructed on the pattern of these. Since that time eight or nine volumes of verse have testified to Mr Swinburne's untiring persistency; he will doubtless become, he is perhaps already, one of the most prolific of all the English poets. It is a matter of history that the position of Mr Swinburne greatly altered during the last twenty years of the century. In 1880 he was the most eminent of the younger writers, and seemed to the public more youthful still on account of his ebullience and literary courage. He carried high the flag of revolutionary ardour, although careful observers might even in 1880 have noted that it was no longer driven by so fierce a wind of feeling as it had been in 1870. Since then Mr Swinburne has not changed so much as his public has. New aspects of art and politics and conduct have attracted the minds of Englishmen, and Mr Swinburne, in his unflinching and unbending attitude, has been left more and more solitary. He no longer leads the army of impatient youth, but in a dignified isolation, never stooping for a moment to win the ear of a capricious public, he states the old formulas and insists upon the old ideals, a figure universally respected, but without a perceptible following.

The death of D. G. Rossetti, in 1882, has already been mentioned. The two authors who were particularly identified with him at the outset survived much longer, but did not add very largely to their poetical assets. During the last twenty years of the life of William Morris (1834–1896) he was mainly occupied with the socialist propaganda and with the practice of the decorative arts. The latest of his great poems, *Sigurd the Volsung*, does not come under our cognizance here, and in our period almost his only serious contributions to verse were contained in the collection of *Poems by the Way* (1891). But the abundance of Morris's fancy was bound to find some outlet, and he invented or adapted from the late mediæval romances a form of prose-poem, a wild and solemn narrative, out of place, out of time, which he cultivated without a rival or an imitator. The first of these was the *Tale of the House of the Wolfings* (1891), and the eighth and last, *The Water* *of the Wondrous Isles* (1897), was posthumous. Archaistic in language, closely parallel in mode of evolution to the old French romances, extremely artificial in their elaborate artlessness, these curious books form a little province of recent literature all by themselves. Christina G. Rossetti (1830–1894) never quitted the recognized methods of lyrical writing, and she continued to write and to publish until near the time of her death. Yet she also, as a poet, mainly belongs to the period prior to 1880. Her blossoming-time as a writer of secular verse had closed by 1875, and what is most remarkable and most beautiful in her later religious poetry (*Time Flies*, 1885; *Verses*, 1893) is mainly a variation on themes which she had invented in her earlier volumes. Her *Goblin Market*, nearly twenty years old when our period commenced, continued to contain the most perfect revelation of her genius. An interesting feature of the history of this time was the revival of the fame of Coventry Patmore (1823–1896). Exceedingly popular in his youth, Patmore had fallen into desuetude and ridicule, and his finest work, his irregular *Odes*, had passed almost entirely unnoticed. About 1880, however, a new generation rediscovered Patmore, not as the too domestic idyllist of *The Angel in the House*, but as the austere and mystic singer of *The Unknown Eros.* During the last sixteen years of his life he wrote no more verse, but he steadily increased in fame, and died leaving a little school of ardent disciples. A greater than any we have mentioned, except the two *dioscuri* themselves, was Matthew Arnold (1822–1888), whose career came abruptly to a close at the very moment when he seemed about to cross, in the fulness of health and energy, the threshold of a dignified old age. It was Arnold who, it was hoped and supposed, would step into the places ultimately left by Tennyson, Browning, and Ruskin, and would be the central ornament of the living world of thought for another generation. Had this been the case the advantage to literature from so dignified a figure-head might have proved inestimable. In point of fact, he died before all these his elders, even before the still more aged Newman. His additions to poetry, moreover, since 1879 had been extremely slight, and we meet with him again farther on. The most venerable of the British poets of this time, Mr Aubrey de Vere (1814–1902), survived all whom we have mentioned, and did not cease to publish poems until 1890. With him the latest of the pure Wordsworthians passed away.

The name of the "Parnassian School" has been given to a group of poets who belonged to the generation succeeding that of the Rossettis and William Morris, and who were more in sympathy, perhaps, with Arnold. In this title, which has no other recommendation, there seems to be a reference to the French poets who were the contemporaries of these particular writers, and who made their first appearance together in the *Parnasse Contemporain.* The poets of this group had not the ample flight of their predecessors, and attempted smaller effects. They were united, with all their individual distinctions, in a common effort after great technical precision and perfection of form. Whether in the lighter or the graver mood, they aimed at exactitude of verbal expression, the careful record of shades of emotion, delicate phenomena, avoidance of hackneyed or rhetorical phrases. In their different ways these poets were artists in miniature, and relied on the freshness and sharpness of their touch. Such writers rarely attain to a great prominence in the history of literature, for they never move the masses. But if they live, they live by the sincerity of their workmanship, and at certain epochs the meticulous production of such artists in verse is salutary for language as well as for literature. The group of later Victorian poets of which mention is here made possessed considerable influence between 1880 and 1890, but since then none of them have been so active in verse-writing.

The death of Tennyson (October 1892) was followed by a positive "crisis" in poetry. The field seemed almost empty, and it was freely predicted that it would remain uncultivated. Like most prophecies, this was not fulfilled. Within a few months of Tennyson's ceremonious public funeral a whole army of new poets made their appearance, and were greeted, in some cases, with extravagant approval. One or two writers who had struggled in vain to win attention to their poetry suddenly found it widely welcomed. The years from 1893 to 1895 saw the arrival of a surprising number of candidates for the laurel. Of these newest poets, two or three of whom possess unquestionable touches of genius, it may be said collectively that they aimed rather at suggesting an effect than at toilsomely producing it. In other words, the excessive attention to form, to technical perfection, which had been carried so far by the Parnassians, failed to please, and broader modes of expression were aimed at. Into this entered what has been called the "Celtic" spirit, by which music rather than painting, the ear rather than the eye, is appealed to. Here again, as so often in recent English poetical history, some distant analogy with French fashions was to be perceived, and several of the youngest and most promising British poets might be welcomed as brothers by the Symbolists across the Channel. Yet another movement, in extreme opposition to this, has been the Imperialist or Nationalist school of poetry, of which the fountain and origin has certainly been the much-discussed and disputed talent of Mr Rudyard Kipling (*b.* 1865), whose influence as a force in recent English literature the most adverse criticism could not dream of denying. This kind of poetry, about which it is not unfair to say that—for better or for worse—it abandons the slopes of Parnassus for the hustings and the music-hall, has attracted to its practice several writers of talent and a host that have no talent at all. On the whole, although poetry is still cultivated in England, the opening of the 20th century could not be said to find it in a very wholesome condition, and in its best forms it seems to be as remote as ever from the sympathies of the public.

The novel.

To turn from the consideration of the poetry of our period to that of its prose fiction is to enter upon a field of observation at once complicated and bewildering. In later Victorian poetry, despite its record of losses and of broken activities, we can at least trace certain definite movements, which, whatever their direction, have a share in the general development of literary art. Certain traditions are common to the craft; a thread of continuity combines the scattered groups. But the record of the novel during this period is tangled, confused, amorphous. So many interests other than those of pure literature have interfered in its development that it is difficult to trace any definite progress at all. At first sight the field presents the appearance of an overgrown, neglected garden,—not, indeed, devoid of flowers of beauty and rarity,—but so crowded with weeds and undergrowth that the paths and beds can scarcely be distinguished. The history of the novel since 1879 presents, however, one feature in common with that of poetry: its early record is one of depopulation. The leading figures of Victorian fiction do not, it is true, enter upon our period at all. Thackeray (1811–1863) had been dead seventeen years, and Dickens (1812–1870) ten, before our survey commences. Other losses of paramount importance to the novel followed during the 'seventies; Lytton's career closed in 1873, and the notes of gaiety and chivalry lost much of their resonance with the silencing of Lever (1806–1872) and of Kingsley (1819–1875). Then again, at the threshold of our inquiry, George Eliot (1819–1880) ceases to exercise her strenuously intellectual influence; and her death is followed in quick succession by those of Lord Beaconsfield (1881), Anthony Trollope (1882), and Charles Reade (1884). Thus many various and widely diverse schools of fiction were deprived of their legitimate leaders. The philosophical study of character, the political and social satire, the kindly but critical portraiture of British domesticity, and the intrepid crusade against current abuses—all those forms of fiction were suddenly left without a pilot. At such a crisis we might reasonably expect to find some paralysis, some sudden arrest of production. But this was far from being the case. The fecundity of fiction immediately increased with the magnitude of its losses, and from 1879 to 1901, when fewer novels of the highest order were published than during any equal period of the Victorian era, the positive number of novels issued was steadily advancing. Figures, we are often told, will prove any case; but in the present instance they are perhaps less fallacious than usual, since they rest upon the very accurate statistics of a central and authoritative bureau. In 1879, then, there were published 4294 new books in every class of literature, of which 607 only were works of fiction. Ten years later the number of new books was 4694 (no very great increase), but of this number no fewer than 1040 were novels. The proportion of fiction had therefore risen in ten years from less than one-seventh to very nearly one-fourth of the entire "literary output." By 1899 this proportion was actually increased. In that year 5971 new books were printed, and of these 1825 were novels. These figures take account only of first editions; but nowadays, when many novels are reprinted twenty or thirty times, it is hardly possible to overlook the claims of the reprint, especially as an indication of the kind of literature that the public welcomes most eagerly. If, then, we include the new editions in the statistics for 1899, we find that out of 7567 works issued from the press no fewer than 2561 were works of fiction, designed either for the old or young reader. The proportion has now become one-third, and the story-book is found to be riding roughshod over the entire field of literature.

When we proceed to examine this vast productivity rather more closely we are at once struck by one conspicuous characteristic. The recent history of the novel has no continuity; its succession is without method or development. It is true that the tendency of literature can only be observed with difficulty within the narrow limits of two decades; still, even within that period it ought to be possible to trace some significance in a phase of activity represented by considerably over 20,000 separate works. The curious analyst, however, will only be baffled if he seeks for a guiding thread running through the prose fiction that lies between the death of George Eliot and the opening of the 20th century. Not only is there no animating spirit in its production, but it is even shaken by every false wind of transient and passionate caprice. Fashion follows fashion without reason or excuse, for the gusts of taste and distaste that convulse the modern novel have scarcely any relation even to the passing fashions that affect society; they are manufactured for the moment in the offices of commercialism, and pass at once into exhaustion. We are thus confronted with the really regrettable fact that this form of representative and pictorial literature, which of all others ought to preserve the characteristics of the time, and hand on the natural lineaments of contemporary people to the remembrance of their children, has largely ceased to represent or depict anything of importance in British national life and character. Observation and consistency, its saving graces, are no longer preserved in any just proportion to the multiplicity of its energies. The novel of commerce has neither morality nor tendency: in the sifting fire of criticism it falls into ashes.

If we seek to find reasons for this, we can perhaps trace them in two principal defects of modern workmanship, the one subjective, the other affecting the author from without. The subjective defect is due to the extraordinary audacity with which the modern novelist plunges into the exercise of his craft. The great works of fiction had hitherto been produced by graduates in the university of life: men who had experienced and felt the various and poignant emotions of sorrow and aspiration; empirical judges fortified with culture. But nowadays a young man has no sooner concluded a desultory education, broken by every siren-charm of the river and cricket-field, than he is ready to attack the problems of life in the pages of a novel. Easy young spirits, with no leisure to look life in the face, scribbling against time in an atmosphere of sheltered ignorance,—what can these amateurs know of life or of their fellow-men? The result of their home-keeping energy is unfortunately harmful both to themselves and their "public"; for while the writer labours for his thirty or forty years in depicting conditions that never existed, the reader carries away from his yearly volumes an equally false ideal of life that clouds his own perception, and leaves him, at threescore years and ten, with the judgment of a child. Meanwhile from without there is the commercial temptation offered to young men of promise more lavishly every year. The man of business "sees money," as his phrase runs, in some imaginary aspect or problem; the book is suggested and commissioned: the warped and false philosophy maintained. Perhaps it is not so much to be wondered at that, under conditions so perilous to talent, so many bad novels should be produced, as that there should still be found men content to perfect themselves in their art by experience and observation, and to work upon the lines laid down for them by those unfailing allies, instead of succumbing to the easy persuasions of the market-place.

It will be interesting to look more closely at some of these fashions which have passed over the troubled field of fiction before we consider the small body of those who have risen above them. The most attractive, perhaps, is the romantic, adventurous story, clean-handed and clean-witted. In our own time there has been one master of this form of fiction, a master, too, of exquisite English, who, taking what was by descent the "boy's" story of Mayne Reid (1818–1883), moulded it to the noble uses of literature,—the fresh, humane, buoyant, humorous Robert Louis Stevenson (1850–1894). Few things should have been more helpful to literature than the fact that Stevenson chose this peculiarly popular form of novel for the exercise of his delightful genius; but unfortunately the full significance of his example has been but little felt. He has had one or two conscientious followers, and others have diverged from his wake into waters of a different but still pleasant romance; the majority, however, have missed his lessons of selection, elaboration, and style. In a spirit of more tremendously boyish vigour, roughly eloquent in a whirl of volcanic invention, Mr Rider Haggard (*b.* 1856) has dreamed dreams of inaccessible mountains, and lakes of molten gold. But too much of the purely popular romance of a later hour has lost the fervour of fancy altogether, and has wasted itself in purposeless pastiches and vague attempts to reconstruct Dumas for the use of the nursery-schoolroom. Invention, the quality most strained after by the mass of later English novelists, seems to be that most conspicuously lacking to them. It is not that realism, or more accurately naturalism, has found a congenial home in England; the English temperament will probably never be ready to accept a frankly naturalistic consideration of life,—it is certainly not ready yet. But there was, in the early 'nineties, a feverish attempt made, moribund at its birth, to combine the movement for Women's Rights with certain eternal but insoluble problems of sex. The attempt was made by women, and appealed chiefly to women. It produced much newspaper rhetoric, but no literature. Side by side with this movement, but unaffected by it, certain novelists have laboured with conscientious energy, but some lack of grace and persuasiveness, to establish, in the teeth of prejudice, a school of realism in British fiction; while in the very latest years of the 19th century one or two romance-writers succeeded in recovering the old flush and pulse of genuine imaginative invention, on semi-realistic lines.

The difficulty, however, of representing to the English novelist the true limits of realism and purpose in fiction is nowhere more apparent than in the strange, sensational, pseudo-religious form of fiction that has sprung up from a confusion of the methods of the two elements. These shapeless and gaudy productions, addressed often to the name of great causes and exquisite ideals, mar, by their entire lack of sensibility and reasonableness, the very loyalties which they profess, and render criticism of themselves impossible by their own violence. Their immense vogue only shows that there is still a vast English-speaking public untouched by appreciation of the literary spirit. No doubt, when over a thousand novels have to be produced every year to supply the demand of the circulating libraries, the difficulty of finding new subjects is responsible for many of these divagations. The same difficulty is probably the cause of the spread of the parochial novel, and more particularly of the Scottish parochial novel. Every corner of the United Kingdom has been ransacked in search of what the journalist calls "local colour," and Scottish village-life seems to have offered the most acceptable result. There was nothing new in this class of novel, which was originated by Sir Walter Scott, and worked out on the modern plan by Galt and Miss Ferrier, and which in the hands of Mr George MacDonald (*b.* 1824) was the delight of readers in the 'seventies. But it is a notable example of lack of judgment on the part of the public that while this Scottish movement produced at once some of the most exquisite and some of the most worthless literature of the decade 1890–1900, both classes, good and bad, were equally acclaimed, and blindly devoured. The public seemed to perceive no difference between the work of Stevenson or his delicate successor Mr J. M. Barrie (*b.* 1860) and the crudest vegetation of the kail-yard. Nor has the criticism of the press always helped the public to discernment.

Finally, among these shifting movements, we come to what is the most characteristic of the time, the literature of colonial imperialism, inspired by the extension of the British Empire, and its assumption of new interests and complexions. Here, at any rate, we have a movement which bears a definite relation to the history of the time. In the forefront of this moving army stands the figure of Mr Rudyard Kipling (*b.* 1865), whose literary appearance in England, in 1890, was so novel, so vigorous, so overwhelming in its sense of individuality and young life, as to raise him at once to a position in the public gaze brilliant enough almost to discountenance criticism. In India he had already published *Departmental Ditties* (1886) in verse, and the still more remarkable prose stories collected in 1887–89 under the general title of *Plain Tales from the Hills.* The reception of these Indian studies, so dazzling in their novelty, and that of the somewhat perverse romance, *The Light that Failed* (1890), led on to a still more brilliant success in the volume of poems which took its name from the *Barrack-Room Ballads* (1891). The youthful Anglo-Indian swept everything before him; no such world-wide notoriety had, perhaps, ever been obtained by an author so rapidly or so early in life. Since then Mr Kipling's work, from the *Many Inventions* of 1893 and *The Jungle Book* of 1894, down to the *Kim* of 1901, has been poured forth with great profusion, but has caused less critical amazement. It has naturally fallen into perspective, and taken its place in the general scheme. The picturesqueness of a new landscape, the persuasiveness of a new manner, have lost their first bewildering glitter, and criticism has not failed to note that these qualities are sometimes achieved at the cost of literary tone and moral distinction. He has had imitators, who have found some of his most effective tricks easy enough to catch. Still, among the new-comers Mr Kipling fills incomparably the most conspicuous place, and his influence upon the taste and thought of the mass of his countrymen is unparalleled among that of active men of letters at the opening of the 20th century.

In this brief survey we have considered many developments of the novel, but found in them little stability. But there are a few—unfortunately a very few—names that are found in none of these muster-rolls; for they are those of men who have been consistently faithful to an ideal of outlook and workmanship unaffected by passing fashions of taste. At the head of this little body of stalwarts stands Mr George Meredith (*b.* 1828), whose work was the unquestioned glory of English fiction during the last forty years of Queen Victoria's reign. Mr Meredith preserved the traditions of English fiction untarnished during one of its most prolific and most perilous periods. The preservation of the moral idea in fiction,—an idea standing as a backbone to the work, and itself sustained by the interaction of the characters displayed,—the preservation of this essential tradition is largely due to his loyal and unswerving devotion to the canons of literature. During the last years of the 19th century the abundance of his direct imitators among young men of ambition was curiously noticeable. With Mr Meredith is Mr Thomas Hardy (*b.* 1840), the master of modern English realism, in his stories of pastoral life in "Wessex." A third great figure was R. L. Stevenson, pure romanticist of an even purer style, the lineal descendant of Scott, touched with modernity and moved by more picturesque exotic interests than Scott ever knew. These three writers stand alone, towering above their fellows. In the prose fiction of the period there seems no fourth novelist quite on the same level. But Mr Joseph Henry Shorthouse (*b.* 1834) preserved the philosophical romance from extinction. Mrs Humphry Ward (*b.* 1851) sustained the tradition of George Eliot's later manner, and lent sincere intellectuality to the statement of hard and harassing problems of contemporary thought. Among earlier novelists Sir Walter Besant (1836–1901) and James Payn (1830–1899) worthily continued the humorous and humane tradition of Dickens. The moral and didactic side of fiction was supported by Charlotte Yonge (1823–1901). Wilkie Collins (1824–1889), Richard Doddridge Blackmore (1825–1900), and Margaret Oliphant (1828–1897) were eminent in their different fields. These have all passed away, but among their successors there are to be found, no doubt, a multiplicity of talent and many encouraging signs of the general vivacity of fiction. Yet it is not in the ranks of the triumphantly popular novel that these are found, and before recording the conquests of the few in this peculiarly deciduous class of contemporary literature the wise will probably prefer to wait and to see what the winnowing years will leave of genuine wheat in the mass of redundant vegetation.

To follow the achievement of a given period of modern history in pure criticism is rendered difficult by the prejudice which, in the minds of the vulgar, reduces this fine branch of literature to its basest expression, namely, to mere fault-finding, to the "picking of holes" in a particular product. Yet in the proper sense, criticism is not engaged with doling out blame or even praise, but with analysis, with the exact determination of the constituent parts of a work and their relation to one another. Applied to the past, it melts easily on one side into the history and on the other into the philosophy of literature or art. In recording, therefore, what was done well between 1879 and 1902, it will be found that there are many important factors which seem to have little connexion with one another, but which are so excellent as to deserve no less attention than is given to creative literature, being indeed at their best of the imaginative order, and that these have at last to be brought together under the general heading of criticism. Since 1880, although working against great difficulties, the leading English critics have shown, in their extreme and unfortunate diversity, one common tendency which is new. Their criticism, wherever and however directed, has tended to be subjective to a degree never acknowledged before. The two most famous English critics of the time were John Ruskin (1819–1900) and Matthew Arnold (1822–1888), alike in scarcely anything else than in their rejection of the objective vacuum. Each of them boldly essayed to recount, as M. Anatole France has put it, the adventures of a soul journeying among masterpieces. Neither of these great men belongs entirely or mainly to our period. But from 1880 to 1887 Ruskin was extremely active, and his work was remarkably characteristic of his genius. A sort of wild exuberance possessed him, and whether he wrote of the water-colour drawings of Turner and Prout, of the architecture of the Gothic cathedrals of Northern France, of English prosody, or of the principles of St George's Guild, his tone grew more and more unshackled, more and more violently personal. He measured his impressions less and less by tradition, even the tradition of his own earlier experience, and more and more by the eye and the mood of the moment. So that in *Fors Clavigera*, which did not cease to appear until 1884, we had at last one of the most stimulating, but at the same time one of the most reckless, contributions to autobiographical criticism which the world has ever seen. Immensely admired and closely studied by young people, although condemned to the last for his anarchical judgments by the organs of traditional opinion, the example of Ruskin in his fetterless old age was very widely felt. His tacit advice to every one was—Use your own eyes and ears; say how the object impresses you at such a moment, under such a light, in such a mood; and let the professors go hang. Ruskin never said this, of course, but this was the obvious effect of his system, and we have seen the result in much that is fresh and curious, as well as in much that is callow and pert.

Criticism.

Wholly distinct was the influence of Matthew Arnold. It is first to be remarked that although a younger man, he quitted the field of positive criticism sooner than Ruskin did. His *Irish Essays* of 1882 and his *Isaiah of Jerusalem* of 1883 indicated the direction which the mind of Matthew Arnold was taking at the end of his life. These, indeed, were criticisms of a sort, but not of that direct kind which influences literary workmanship. This latter had once been Arnold's peculiar province and glory; but neither his *Essays in Criticism*, nor *On Translating Homer*, nor *The Study of Celtic Literature* belongs to our period. These famous little books, indeed, were all published in the 'sixties. Arnold in his later years was drawn away from pure literature to speculations of a political, religious, and educational nature; into the treatment of these he brought his lucid temper and his elevated moral tone, but in such exercises he ceased to be a critic. The posthumous and valuable *Second Series of Essays in Criticism* is the only work of its class which mainly, though not entirely, belongs to dates subsequent to 1880, and as lately as 1886 Arnold was writing on Sainte Beuve. But the indifference of the English public to pure literature depressed and checked him more and more in the production of the kind of work in prose in which he was best fitted to stimulate and lead. The potency, however, of his early writings continued, and was never more an active force than between 1880 and 1890. During those years, it may be said that almost everything in the way of criticism which was really excellently done in English literature bore at least a faint relation to Arnold. Perhaps there was less than usual of Arnold and more of Ruskin, though surely most of all of the critic himself, in the criticism of Walter Pater (1839–1894)—so laborious, solid, and rich. His *Appreciations* (1889), his *Plato and Platonism* (1893), and two or three posthumous collections, have been read more and more widely since his death,—up to which time he was scarcely appreciated outside a narrow circle,—and have exercised an unquestionable force in contemporary writing. A critic of much acuteness and humour, prevented only, perhaps, by lack of concentrated effort from achieving the highest things, was Henry Duff Traill (1842–1900). Enthusiasm, wide knowledge, and a poetic habit of mind were combined with some laxity of judgment in the copious and illuminating, but not sufficiently concise, criticism of John Addington Symonds (1840–1893). Among veteran leaders of literary criticism in the elder generation in 1902 were Mr Leslie Stephen (*b.* 1832) and Mr Frederic Harrison (*b.* 1831). There has in general been no lack of acute, graceful, and personal criticism, but its influence has been weakened, and it has often been put out of sight altogether by the floods of what is called "reviewing" which darken the daily and weekly press, the incessant gabble of nobodies about the little books of other nobodies as ill-trained in judgment as themselves.

In history the work done has been solid and considerable, and it has had the advantage of moving on a more consistent plane than has been the case in other branches of literature. It is impossible to say that any particular school of poetry or fiction or criticism flourished pre-eminently in the period from 1880 onwards, but of an Oxford school of historians it is permissible to speak. These men were the direct successors and inheritors of the historians who, in the opening quarter of the 19th century, had determined that their first duty was to build the history of the country "upon unquestionable muniments." Of the leaders of this brilliant school, the eldest was James Anthony Froude (1818–1894), who was much exercised with the legacy of Carlyle's memoirs in the earlier part of our period, but who returned to his old investigations in his *Divorce of Catharine of Aragon* (1891), and his *Erasmus* (1894). He outlived his lifelong rival and opposite, Edward A. Freeman (1823–1892), whom, by a curious irony, Froude succeeded for a few months as regius professor at Oxford. Freeman was, on the whole, the most characteristically active historian of these years; during the first twelve of them he was ceaselessly at labour, and at his death he left a body of disciples engaged on important and prominent research according to his particular methods. Freeman's *William Rufus* belongs to 1882; his *History of Sicily* (1892–94) was unfinished at his death. During the interval he was incessantly working, and for eight years he was Professor at Oxford. Dr William Stubbs (1825–1901) had completed his *Constitutional History* before our period begins, and his later energies principally went out in the direction of diocesan work; in 1884 he was appointed bishop of Chester, and in 1889 translated to Oxford. His subsequent historical work was principally confined to the editing of one or two texts. The fourth of these great

History.

historians, Dr Samuel Rawson Gardiner (1829–1902), was engaged during the whole period with his patient delineation of the Commonwealth and the Protectorate. Two historians who derived their inspiration from the example of Stubbs and Freeman were John Richard Green (1837–1883) and Mandell Creighton (1843–1901), the former as much distinguished for the agreeable vivacity of his style as the latter for the austerity of his irreproachable search for truth. A historian who stood apart from the Oxford school was Sir John Robert Seeley (1834–1895), whose work on *The Expansion of England* (1883), and whose posthumously printed lectures on *The Growth of British Policy* (1895), had a very deep influence in inducing the development of imperialistic ideas in intelligent minds.

The essay.

The influences of the time have been very unfavourable to the essay as a branch of independent literature. This was, however, the field in which Robert Louis Stevenson (1850–1894) excelled before he was led away by the temptations of success to an almost exclusive cultivation of prose romance. The essay—from which criticism of books is here distinguished—tends more and more to disappear in journalism. It is very doubtful whether the successes of Sir Arthur Helps (1813–1875) or even of George Augustus Sala (1828–1895) could have been repeated in this generation. Perhaps the last of the specific essayists, who treated speculative themes in a dignified and yet popular manner, was Richard Holt Hutton (1826–1897), whose life, however, was almost entirely devoted to the best class of journalism. Several of the most distinguished critics of literature of the period, however, have divagated, in the composition of essays, to the criticism of life as well. The better kind of monthly reviews and magazines were open at the beginning of our epoch to the essay on abstract subjects, but the tendency of the monthly press has been to assimilate itself more and more with the newspaper. The brilliant writers of the present day, who might in other conditions have been essayists, give to the "leaders" of the daily journal what might have been matured and purified and made part of a book.

Biography.

A curious feature of English literary history during the last twenty years of the 19th century was the growth of the custom of biography. Almost entirely confined to England, this habit has struck Continental critics with amazement. During these years, and with an ever-increasing inevitability, few persons of any notoriety have died without the event being immediately followed by the publication of a "Life," very often—no matter how dull a correspondent the deceased had been—of a "Life and Letters." These books, in the vast majority entirely ephemeral, often enjoyed a momentary success of curiosity equalled only by that of the fashionable novel. Their "best stories" were quoted, and then they took their place with the lumber of the library. In no branch of literature was less skill shown, or the standard of merit kept so low, as it was in biography, and the best that can be said of most of these lives is that, where the subject happened to be one of any real note, the volumes remain as a storehouse of material available for the future critic. Several well-balanced and skilfully-built biographies were, in the period under discussion, produced by authors who had proved their distinction in other fields, but no biographer, pure and simple, was revealed to the world, and, as a rule, the last thing thought of in the preparation of these works was professional skill or a practised sense of proportion. In most cases, some one who had no experience of composition and no training in the art of portraiture was selected, merely because he (or she) was related to the subject of the book. In no branch of recent English literature is there less to boast of than in the conduct of biography.

Theology.

In theology the period has been remarkable for the extinction of a great many lives long surrounded by peace and respect, but around which in earlier years there raged the roar of battle. The High Church lost its intellectual protagonist in Edward Bouverie Pusey (1800–1882), and later luminaries in Bishop Joseph Barber Lightfoot (1828–1889), Dean R. W. Church (1815–1890), Canon Liddon (1829–1890), and Brooke Foss Westcott (1825–1901). The Church of Rome lost Newman (1801–1890) and Manning (1808–1892). The Broad Church had to mourn Mark Pattison (1813–1884) and Benjamin Jowett (1817–1893). Archbishop Edward White Benson (1829–1896) was one of the few English prelates who preserved an interest in general literature. The deaths of these venerable men changed the entire aspect of theology as a branch of current letters. As much in this province as in that of poetry, England was in 1880 under the rule of a body of old men who have passed away, removing with them the tradition of an eager and brilliant time of ardour and contest, but of those who took a prominent part in the Tractarian movement of 1835–1845, most of whom were still living in 1880, in 1902 not one was left. There has, however, been the beginning of a new treatment of certain old problems, auspiciously represented by *Lux Mundi* (1890), a collection of studies edited by Dr Charles Gore (*b.* 1853), now bishop of Worcester.

Modern tendencies.

The history of literature is, and always has been, diversified by inequalities of activity and merit. If a meteorological map of the subject could be devised it would be found to present, not straight lines, but great curves or undulations. It is difficult not to be persuaded that in 1880 English literature was near the height of one of its periodic waves, although perhaps the actual culmination should be placed a little farther back than that year. To pursue the image, the line was still high all through the 'eighties, although steadily descending. It has, if we can trust our observation, continued to descend, and whether there are as yet any signs of its recovery may be very gravely doubted. That pure literature of a very distinguished kind was, at the close of the 19th century, produced or encouraged to any signal degree—in comparison with the production and encouragement of it a quarter of a century earlier—is not to be maintained. But this is a very different thing from despairing of literature, from thinking that it is, as the phrase goes, "played out." At no time is the best kind of writing really welcome to the great mass of the population. It is kept alive by a minority; it appeals, in truth, to a small minority. But this minority is energetic, and at irregular periods its energy takes the form of forcing literature on the indifference of the public, of winning for it perforce an unwelcome warmth of consideration. The presence of men of genius—men, that is, of exceptional vitality, whose force of life is led along literary lines—greatly adds to this artificial predominance of letters, although that presence is not necessary to it, as the analogies of 1580 and 1790 may show us. But we are apt to forget how artificial it always is, how exaggerated—to put it plainly—are the fame and prominence of men of letters in comparison with the real part they bear in the experience of the millions. It would therefore be, perhaps, more true to say that 1875 was an exceptionally high-water mark of literary effort than to say that 1901 was a particularly low one. The latter was rather a return to the normal condition, an unbending of the bow, a relaxation of intellectual energy. We do not question for a moment that it will be followed, as every such period has been in history, by a fresh outbreak of effort, a fresh artificial insistence upon a kind of vitality interesting to, and indeed conceivable by, only a few persons. The authority of literature is mainly empirical, so far as the great world is concerned. The vast body of "men in the street" is not more capable of comprehending the difference between good writing and bad than it is of observing the difference between good painting or sculpture and bad. What is worse is that the cruder forms of education tend to encourage false judgment in these matters, so that bad books and bad pictures are deliberately preferred to good ones. This condition continues to extend, and to become more frequent and more threatening as the democracy becomes more and more confident. The absence of a recognized authority adds to the difficulty, and this is why, from time to time, the value of an Academy of Letters is maintained, in spite of its obvious defects and dangers. In the early months of 1902 several schemes of this nature were brought forward, with more definite purpose than ever before. It is now possible that an Academy, or better still, an Institute, embracing a cluster of academies, may yet be founded in England. That such institutions may be of very great value as a bulwark against the invasions of bad taste is not to be doubted, but we can hardly hope that a body with anything like the prestige of the French Academy will be seen in Great Britain, at least in our time. The great chance of such a foundation was lost when Charles II. hesitated in 1662. He created the Royal Society instead, and few would be found to deny that British science has benefited. But a Royal Society, founded now, would find it difficult to assert its authority; to be useful, such corporations must be venerable and must hand on a tradition. In the meantime, although the millions do not distinguish between a good book and a bad one, and although their tendency is to like the bad one best, there remains a distinction between good writing and bad. Experts disagree in detail about almost every contemporary product, but hitherto, and on large lines, they have agreed to a remarkable degree about what has been before the world for fifty years. As far as we can distinguish, no very worthless book—however successful in its own day—continues to collect suffrages half a century after its publication. It seems scarcely less certain that no remarkably fine book—however obscure when it was published—misses the meed of fame at last. If these conditions are to be repeated in the future, and there is every reason to suppose that they will, the winnowing of the wheat will remove even the remarkably abundant and flowering tares which are almost all that some despairing critics can see in the cornfield of to-day.

At the same time, it is not improbable that we may be on the edge of a much wider and more radical curve than any of those which have marked the course of English literature for one hundred years. Movements become exhausted, like men and races of men. It is unusual for one order of literary activity to last more than a century. After the course of a hundred years the varieties of expression are apt to become exhausted, the forms grow hard, all the obvious motives tend to express themselves no longer as thoughts but as clichés. The Romantic movement, in its different aspects, has entertained Europe for a century and more with little radical alteration. Between the various great poets of the Victorian age, for instance, no such difference is found as distinguished Herrick from Pope, or Goldsmith from Shelley. The distinctions have been matters of temperament, of execution, and of personal style. Wordsworth and Mr Swinburne, Byron and Browning, differ only as great poets must differ among themselves, as Ben Jonson, for example, does from Marlowe, or Corneille from Racine. Each and all belong to the modern English Romantic school, as it was founded in 1798. It is quite possible—one may go further and say it is not improbable—that the reduction of energy in literary creation of the first order, which we cannot prevent ourselves from recognizing as a feature of to-day, will be followed by a still more marked exhaustion and fatigue before the whole Romantic movement, having had its century, is swept away to make room for some wholly different mode of literary expression.

The years which followed 1880 were marked by a revival of the classical writers of English, and a persistency of investigation into their biography and text, which form a remarkable and creditable feature of the literary life of the time. Never before were the famous authors of past times, and of the second as well as of the first class, placed before readers with so exact a scholarship and in a form so attractive. The wide sale which these reprints have had should be taken into consideration as an important element in the culture of the time. In point of fact, while the abundance, beauty, and cheapness of reprints have added a very real disadvantage to the young author, who finds Milton and Fielding become his formidable rivals, yet at the same time, and from the point of view of the general education of taste, it cannot but be regarded as a very satisfactory thing that opportunities of studying what is best in the national literature should have been thus multiplied. To descend to particulars, the work of English scholars on Chaucer belongs, in its public results, almost wholly to this period. It culminated in the great edition of that poet by Professor Skeat (1896–97), in which for the first time Chaucer is presented to his own people in a really intelligent and intelligible form. In Shakespearean study, too, there has been an extraordinary revival of scholarship, conducted with discretion and good sense by Dr Aldis Wright, Mr Sidney Lee, Dr Furnivall, and many others. The work of editing the texts of the great Elizabethan poets has proceeded so actively that for the moment there seems little of importance left to do in this province, and for a few shillings each the reader might collect around him in 1901 the works of poets which hundreds of pounds would hardly have placed within his reach in 1880. The great *Dictionary of National Biography* (1882–1901) has been completed in time to be recorded here as a finished thing, and among the principal monuments raised to English scholarship in the period under consideration we can hardly hesitate to name this admirable dictionary. So much, indeed, has been achieved in historical and biographical work of this class, so exhaustively have the documents been examined, and so closely the existing records collated, that it is difficult to see what remains for future investigation to occupy itself upon. In elucidating the study of the early Scottish poets, of the Elizabethans, of Pope, of the writers of the centre of the 18th century, and finally, of the great poets of the beginning of the 19th century, so much has been done since 1880 that the main fields must, one is tempted to think, be permanently despoiled of their harvests. All this zeal for the writers of the past serves, no doubt, to counteract the frivolity and bad taste of uninstructed readers. The authority of the great dead is unimpeached, and every year it widens and deepens the bases on which it is built. It is of little moment what errors are popularly made as to the value of this or that contemporary author, if we all grow more and more sure of the degree and species of merit possessed by Dryden or Gibbon or Wordsworth. Sooner or later the products so wildly misjudged in contemporary popular esteem will have to be measured by this standard, and will inevitably take their right place in the harmony of literary history. It cannot be denied, however, that a great deal of talent and cleverness, and even weightier qualities, are wasted or are allowed to miss their fullest expression from neglect of the principles of literary art. Writing is pursued too rapidly, too perfunctorily, with too little previous study and present care. There is a want of unity of purpose in the literary products of the age which cannot but be deplored. When an author thinks that his chief business is to bow to the vague prejudice of crowds, the cause of pure literature is in a parlous state. It is not the large "returns," the reverberating and unprecedented "sales," which proclaim the author whose happiness it will be to live in the history of his country's literature. Good and careful writing is at this moment little approved of, and the conquering masses march gaily over it and leave it bleeding; but the true lover of letters and adept in style will disregard the gods of mere material success,—he will remember that *Victrix causa diis placuit, sed victa Catoni.* It is for the highest criticism to insist on playing the rôle of Cato.

A final reflection may be permitted. Through the history of English literature its vitality and health have been marked, in a manner curiously recurrent, by a curiosity to know what is being done in foreign literatures, and by a vigorous use of what can be adapted from them. In 1880 the reciprocity between England and the Continent in this matter was very close. There was a living curiosity to know what was being done by Russia in the novel, by Scandinavia in the drama, by France in criticism. This interest in foreign literature has steadily declined. The reasons may be perfectly intelligible; it remains that this is precisely one of the signs of a decline in native literary vitality which has never hitherto failed to be recognizable afterwards in history. (E. G.)

[As a supplement to the above survey, some others among the best-known writers of the period may be mentioned, excluding those to whom separate articles are devoted.

Poetry: Rev. H. C. Beeching (*b.* 1859. *In a Garden, &c.*, 1895). A. C. Benson (*b.* 1862. *Poems*, 1893). Wilfrid Scawen Blunt (*b.* 1840. *Love Sonnets of Proteus*, 1880). F. W. Bourdillon (*b.* 1852. *A Lost God*, 1891). Robert Bridges (*b.* 1844. *Shorter Poems*, 1890). W. J. Courthope (*b.* 1842. *The Paradise of Birds*, 1870). John Davidson (*b.* 1857. *Fleet Street Eclogues*, 1893, 1895). "Michael Field" (*The Tragic Mary*, 1885). Edmund Gosse (*b.* 1849. *Collected Poems*, 1896. In prose: *History of Modern English Literature*, 1897; *Gossip in a Library*, 1891; *Life of Donne*, 1899). A. P. Graves (*b.* 1846. *Songs of Killarney*, 1872). W. E. Henley (*b.* 1849. *Book of Verses*, 1888. In prose: *Views and Reviews*, 1890). Lionel Johnson (*b.* 1867. *Poems*, 1895. In prose: *The Art of Thomas Hardy*, 1894). Andrew Lang (*b.* 1844. *Ballads in Blue China*, 1880. In prose: *Custom and Myth*, 1884). Richard le Gallienne (*b.* 1866. *English Poems*, 1892. In prose: *George Meredith*, 1890; *Prose Fancies*, 1894, 1896). Sir Alfred C. Lyall (*b.* 1835. *Verses written in India*, 1889. In prose: *Asiatic Studies*, 1882). J. W. Mackail (*b.* 1859. Part author of *Love in Idleness*, 1883. In prose: *Life of William Morris*, 1899). Alice Meynell (*née* Thompson, 1850. *Preludes*, 1875; *Poems*, 1893. In prose: *The Rhythm of Life*, 1893). Henry Newbolt (*b.* 1862. *Admirals All*, 1897). Stephen Phillips (*b.* 1868. *Poems*, 1897). A. Mary F. Robinson (Madame Duclaux, previously Madame Darmesteter, *b.* 1857. *Collected Poems*, 1902. In prose: *The End of the Middle Ages*, 1888). Owen Seaman (*b.* 1861. *In Cap and Bells*, 1899). Arthur Symons (*b.* 1865. *Collected Poems*, 1901. In prose: *Studies in Two Literatures*, 1897). Francis Thompson (*b.* 1863. *Poems*, 1893). John Todhunter (*b.* 1839. *The Banshee*, 1888). William Watson (*b.* 1858. *Wordsworth's Grave*, 1890). Theodore Watts-Dunton (*b.* 1836. *The Coming of Love*, 1897. In prose: *Aylwin*, 1898). Margaret L. Woods (*née* Bradley, 1856. *Lyrics and Ballads*, 1889. In prose: *A Village Tragedy*, 1887). W. B. Yeats (*b.* 1865. *Poems*, 1895). "Violet Fane" (Lady Currie).

Prose Fiction: Grant Allen (*b.* 1848, *d.* 1899. *The Woman Who Did*, 1895. Also a popular writer on scientific subjects). "F. Anstey" (T. Anstey Guthrie, *b.* 1856. *Vice Versâ*, 1882). Rev. S. Baring-Gould (*b.* 1834. *Mehalah*, 1880) Rev. W. F. Barry (*b.* 1849. *The New Antigone*, 1887). E. F. Benson (*b.* 1867. *Dodo*, 1893). Miss Rhoda Broughton (*b.* 1840. *Belinda*, 1883). F. T. Bullen (*b.* 1857. *The Cruise of the Cachalot*, 1898). F. C. Burnand (*b.* 1836. *Happy Thoughts*, 1866). Mrs F. Hodgson Burnett (*b.* 1849. *Little Lord Fauntleroy*, 1886). Samuel Butler (*b.* 1835. *Erewhon*, 1872). T. H. Hall Caine (*b.* 1853. *The Christian*, 1897). Miss Marie Corelli (*A Romance of Two Worlds*, 1886). S. R. Crockett (*b.* 1860. *The Raiders*, 1894). A. Conan Doyle (*b.* 1859. *Adventures of Sherlock Holmes*, 1891). "George Egerton" (Mrs Clairmonte. *Keynotes*, 1893). Harold Frederic (*b.* 1856, *d.* 1898. *Illumination*, 1896). George Gissing (*b.* 1857. *Demos*, 1886). Sarah Grand (*The Heavenly Twins*, 1893). Anthony Hope Hawkins (*b.* 1863. *The Prisoner of Zenda*, 1894). Maurice H. Hewlett (*b.* 1861. *The Forest Lovers*, 1898). "John Oliver Hobbes" (Mrs Craigie, *b.* 1867. *Some Emotions and a Moral*, 1891). Jerome K. Jerome (*b.* 1859. *Idle Thoughts of an Idle Fellow*, 1889). "Vernon Lee" (Miss Violet Paget, *b.* 1859. *Baldwin*, 1886). "Edna Lyall" (Miss A. E. Bayly. *Donovan*, 1882). "Ian Maclaren" (Rev. J. Watson, *b.* 1850. *Beside the Bonnie Brier Bush*, 1894). "Lucas Malet" (Mrs Harrison. *The Wages of Sin*, 1891). W. H. Mallock (*b.* 1849. *The New Republic*, 1877. In sociology: *Aristocracy and Evolution*, 1898). H. Seton Merriman (*The Sowers*, 1896). George Moore (*Esther Waters*, 1894). Arthur Morrison (*b.* 1863. *Tales of Mean Streets*, 1894). W. E. Norris (*b.* 1846. *The Rogue*, 1888). Barry Pain (*b.* 1867. *Playthings and Parodies*, 1892). Gilbert Parker (*b.* 1862. *The Seats of the Mighty*, 1896). A. T. Quiller-Couch (*b.* 1863. *Dead Man's Rock*, 1887). W. Pett Ridge (*Mord Em'ly*, 1898). Mrs Richmond Thackeray Ritchie (*Miss Angel*, 1875). W. Clark Russell (*b.* 1844. *The Frozen Pirate*, 1877). "Mark Rutherford" (W. Hale White. *The Autobiography of Mark Rutherford*, 1885). Mrs F. A. Steel (*b.* 1847. *On the Face of the Waters*, 1896). G. R. Sims (*b.* 1847. *Rogues and Vagabonds*, 1885. Also *The Dagonet Ballads*). G. S. Street (*b.* 1867. *Autobiography of a Boy*, 1894). Frederick Wedmore (*b.* 1844. *Renunciations*, 1895). H. G. Wells (*b.* 1866. *The Time Machine*, 1895). Stanley J. Weyman (*b.* 1855. *Under the Red Robe*, 1894). Richard Whiteing (*b.* 1840. *No. 5, John Street*, 1899). "John Strange Winter" (Mrs Stannard, *b.* 1856. *Bootles' Baby*, 1874). Israel Zangwill (*b.* 1864. *Children of the Ghetto*, 1892). Others are: David Christie Murray (*b.* 1847), Silas Hocking (*b.* 1850), C. F. Keary, Robert Barr (*b.* 1850), R. H. Hichens (*b.* 1864), Egerton Castle (*b.* 1858), Frankfort Moore (*b.* 1855), Eden Philpotts (*b.* 1862), Percy White (*b.* 1852), J. A. Steuart (*b.* 1861), Morley Roberts (*b.* 1857), E. W. ENGRAVING.

Etching.

IN the article on Engraving in the 9th edition of this work Mr Hamerton devoted some paragraphs to that branch of engraving which is known as Etching; and the present writer was enabled to supplement those paragraphs by a later article on Méryon. In the interval much has passed—much remains to be said. To the greatest and almost the oldest living practitioner of etching a separate article is devoted (see WHISTLER): the writer's business in this place will chiefly be to discuss those etchers most or all of whose work has been accomplished since Mr Hamerton wrote; but opportunity shall first be taken to make good several omissions in Mr Hamerton's necessarily brief reference to comparatively recent etchers who may yet claim to be classics. The etchings of Andrew Geddes (1783–1844) and of Sir David Wilkie (1785–1841) somehow escaped him. Of these two men, Geddes was the finer artist with the needle; he it was whom Rembrandt best inspired; his work was in the grand manner. Of the rich and rare dry-points "At Peckham Rye" and "At Halliford-on-Thames," the deepest and most brilliant master of Landscape would have no need to be ashamed. David Wilkie's prints were, naturally, not less dramatic than his pictures, but the etcher's particular gift was possessed by him more intermittently: it is shown best in "The Receipt," a strong and vivid, dexterous sketch, quite full of character. Cotman's (1782–1842) etchings might have been mentioned, though they were "soft ground" for the most part. They show all his qualities of elegance and freedom as a draughtsman, and much of his large dignity in the distribution of light and shade. Turner too, who etched in outline the subjects for the *Liber Studiorum*, might have been mentioned as one who, while not seeking to rely upon etching for the completion of his effect, was yet singularly great in that selection of leading lines to which, as far as etching is concerned, he made it his business to confine himself. And Girtin (1775–1802), in the preparations for his views of Paris, was scarcely less happy.

Mr Hamerton had no space to devote to his own illustrious contemporaries, or he would have been amply eulogistic in his reference to Sir Seymour Haden (*b.* 1818), one of the most varied, prolific, and delightful of the etchers of Landscape. Between 1858 and 1879 Seymour Haden—the first president of the Royal Society of Painter Etchers—produced the vast majority of his plates, which have always good draughtsmanship, unity of effect, and a personal impression. They show a strong feeling for Nature. If, amongst nearly two hundred subjects, it were necessary to select one or two for peculiar praise, they might probably have to be the "Breaking up of the *Agamemnon*," the almost perfect "Water Meadow," the masterly presentment of "Erith Marshes," and the later dry-point of "Windmill Hill." Alphonse Legros—Frenchman by birth, but Englishman by long residence—has been etching admirably, at various periods, since 1860. Great in expression and suggestive draughtsmanship, austere and economical in line, Legros's work (see LEGROS) is the grave record of the observation and the fancy of an imaginative mind. In poetic Portraiture, nothing can well exceed his etched vision of G. F. Watts; "La Mort du Vagabond" is noticeable for terror and homely pathos; "Communion dans l'Église St Médard" is perhaps the best instance of the dignity, vigour, and grave sympathy with which he addresses himself to ecclesiastical themes. Something of these latter qualities, in dealing with similar themes, Legros has passed on to his pupil, Charles Holroyd (*b.* 1861)—an etcher in the true vein; whilst an earlier pupil, prolific as himself, as imaginative, and sometimes more deliberately uncouth—William Strang (*b.* 1859)—carries on in his own way the tradition of that part of Legros's practice, the preoccupation with the humble, for which Legros himself found certain warrant in a portion of the great *œuvre* of Rembrandt. Frank Short, who, as with the very touch of Turner, has carried to completion great designs that Turner left unfinished, and who has translated into perfect mezzotint something that is most characteristic in De Wint and in Constable, has found in the interpretation of other men's visions an obstacle to the encouragement of fertility in his own. Time—not skill—has been wanting to him; for the delicacy of "Sleeping till the Flood," the curiously suggestive realism of "Wrought Nails"—a scene in the Black Country—entitle him to a lasting place in the list of the fine wielders of the etching needle. Oliver Hall, a good free sketcher, bringing into his prints a quite unusual sense of wind and tree movement, has learnt something from Seymour Haden and is yet thoroughly himself. D. Y. Cameron betrays the influence of Rembrandt in a noble etching, "Border Towers," and the influence of Méryon in the firm elaboration—the finality, one may say—and the weirdness besides, of such a print as that of "The Palace, Stirling." His London Set is to be cherished even more. The individuality of C. J. Watson is less marked, but his skill, chiefly in architectural work, is noticeable. Admirers of the studiously accurate portraiture of a great monument may be able to set Watson's print of "St. Étienne du Mont" by the side of Méryon's august and mysterious and ever memorable vision; but to the lover of high imaginative art such a juxtaposition is impossible.

Minna Bolingbroke and Elizabeth Armstrong (Mrs Watson and Mrs Stanhope Forbes) have done observant, dexterous work, on quite a high level. A painter of the popularity and charm of Alfred East has several times trifled happily with the copper. Robert Macbeth has set down upon it sometimes his first thoughts and sometimes his elaborate interpretation of his own and other men's pictures. Walter Sickert is an artist of graceful and vivid impromptus. Robert Goff, in more than a hundred coppers, has shown the readiest perception of an attractive and a suitable theme, and has carried the work far enough to suggest the impression, and never so far as to confuse it. Mortimer Menpes, in his Japanese etchings, has found almost an individual touch, and has been alert in the dainty suggestion of artificial as well as of natural light and shade. Whistler has influenced Percy Thomas, and yet more notably an artist who has etched much less, but who has etched convincingly—Raven Hill. Herkomer is at his best in "Gwenydd." J. P. Heseltine and Holmes May carry on the best traditions of the amateur—the amateur who, had circumstances allowed it, might have been a considerable artist. Roussel, an artist of refined performance in many a medium, has devoted much time to the perfection of his decorative methods of printing plates in several colours. The coloured etchings of Raffaëlli must be mentioned with these, and Menpes, named already, claims here a fresh place. Little known, but full of an observation that is his own, and thoroughly characteristic, are the exercises in black and white, upon the copper, of that audacious and yet subtle colourist, Besnard. Another Frenchman, J. J. Tissot, before he turned to sacred subjects, was in Etching an adept at the effective presentation of mundane themes; and he it was who first led to thoughts of etching that genius of a sketcher, Paul Helleu, whose "snapshots at the grace of women" are among the freshest, truest, and most delightful things that the art of etching has witnessed in its later history. Helleu's dry-points—frank sketches, with elegance as their motive—are very numerous, but as the artist does not tolerate the slightest deterioration, and as dry-point deteriorates almost at once, the impressions of each are almost inconceivably few. If any further remark requires absolutely to be made about contemporary Etching, it is one to this effect—that the tendency, manifested about 1875, to use the medium very greatly for interpretation and reproduction of painted work, has now already long been on the wane; and it is probable that while the medium may still, and always, do some useful work in that direction, it will continue to be resorted to mainly as a convenient and delightful vehicle for the swift yet well-considered record of personal feeling and thought about the aspects of the world. (F. WE.)

Mezzotint.

During the 19th century two veritable revolutions occurred in the British art of Mezzotinto Engraving—"la Manière Anglaise." The original defect of the method was the incapacity of the mezzotint "burr" on copper to yield as many fine impressions as other forms of engraving. To this defect was attributable the introduction in 1823 of steel instead of the soft copper plates previously used, —a change which, in conjunction with the endeavour to avoid inherent technical difficulties, led to the "mixed style," or combination of mezzotint with etching, and a general departure from the traditional form of the art, "pure mezzotint" on copper. The affinity of the method to painting in black and white which differentiates it from other kinds of engraving, and was the distinguishing charm of the mezzotints of the 17th and 18th centuries, was for a time lost, but a revival of pure mezzotint on copper beginning in 1880—a return, in fact, to the mode in which the classics of the art were engraved in the time of Sir Joshua Reynolds—was made possible by the invention of steel-facing. By this process engraved copper plates are electroplated with a film of steel, renewable when worn in course of printing; and a mezzotint on copper, so protected, yields more of fine impressions than if it had been engraved on steel, whilst the painter-like quality remains unimpaired.

Method of work. In "pure mezzotint" the design is evolved from dark to light entirely by scraping away more or less of the previously laid "ground," the original "burr" of which is left untouched in the extreme darks, and no acid, etching, or line-work is used in it at all. The usual short descriptions of the method are misleading, because they fail to explain that it is the "ground," and not the "burr" of it only, which is scraped away in greater or smaller degree to produce the varying tones of the design. The necessity of realizing that there are two constituents of the "ground," the "burr," and the indentations out of which the "burr" is raised, will be appreciated later. The "burr" consists of innumerable particles of copper (resembling velvet pile in the finished "ground") raised above the surface of the plate out of the indentations made in it by the teeth of the rocking-tool in laying the ground before scraping the design.

Assuming that a mezzotint is to be scraped from a lady's portrait by Sir Joshua Reynolds in which a piece of black drapery crosses a white dress—the engraver begins to work on a previously laid "ground" which would print uniformly black before scraping commences. In the extreme darks of the black drapery the raised "burr" is left untouched by the "scraper,"—a two-edged steel instrument resembling an ancient Roman sword-blade in miniature, but having a longer point. Working from dark to light, the engraver produces the varying tones of the folds of the black drapery by scraping the raised "burr" down more or less, lowering it in fact so that it will not hold so much ink as where it is left untouched in the extreme darks. In the highest lights of the black drapery all the raised "burr" will have been removed and the original surface of the plate reached, but as yet the engraver has not produced any tone lighter than middle tint (although he has completely modelled up the black drapery), because the indentations out of which the "burr" was raised still remain in the plate and hold ink in printing. In order to produce the infinite gradation of delicate tones in the white dress, or in a sky, the scraping is continued, the indentations being thus made shallower in the passages scraped and therefore less capable of holding ink, whilst they are obliterated almost entirely in the highest lights. When the mezzotint is finished, the black drapery will stand higher than the surface of the plate modelled in a relief composed of the raised "burr," whilst all the tones of the white dress from middle tint to pure white will be so many actual depressions in the plate, the highest lights being the deepest. The speck of light in the eye, for instance, is a pit in the plate, surrounded by a tract of more or less raised "burr," which provides the intense black of the pupil and the half tints of the iris. The difference of surface levels is very appreciable where high-lights impinge on strong darks, but it exists in varying degree all over the plate, and the greatest technical difficulty in pure mezzotint is to obtain adequate "edge" and definition, because the tendency is to remove too much "ground" from the edges of adjacent darks in the course of the constant scrapings necessary to smooth and polish the depressed lights.

In printing a mezzotint a non-fluid ink is thoroughly worked into every part of the plate and the superfluities wiped off again, leaving as much ink as possible in the darks, the raised "burr." If the bottom of the small lights is not quite smooth, the ink sticks in the roughness and they print dark instead of light, or the printer has to wipe so hard to get the ink out of the depressed lights that he removes too much from the raised darks. In either case loss of definition and contrast of effect results. This inherent difficulty of scraping to a sharp edge caused the use of the "mixed" methods, in which the details were sharpened by outlining them with stipple or line-etching.

The scarcity of fine impressions of the pure mezzotints on copper of Sir Joshua's time was due to the "burr" which provides the extreme darks being raised above the surface of the plate, and thus exposed to all the wear and tear of printing processes, unlike the darks of an etching or line-engraving, which are protected by being sunk in the plate. The evanescence of the "burr" on copper led to the use of steel plates, and the temporary decay of the art.

Mezzotint is the best form of engraving for completeness of representation, but etching is better adapted for sketching from nature or for the expression of any fleeting idea. The two arts have distinct uses and limitations. The art function of true etching as practised by Rembrandt lies in economy of expressive line to suggest the artist's meaning, and that of mezzotint in completion of tonality to explain it. Artistic suggestion, which is not inherent in the solid tones of mezzotint, has to be imparted to the work entirely by the free play of the "scraper" on the "ground," much as the painter attains it on canvas with the brush. The best painter cannot, however, acquire the same facility with the "scraper" that he may possess in the use of the brush until he has had long practice in scraping and in "laying" grounds, even in texture, suitable to the subject to be engraved, and therefore offering the least possible resistance to his own idiosyncracies of execution with the "scraper."

History. The first reputed mezzotint was produced at Amsterdam in 1643 by Ludwig von Siegen, an officer in the service of the Landgrave of Hesse, and an amateur artist; but the work was rather a direct drawing on copper with an instrument of comparative precision resembling the roulette than a mezzotint, ground-laid with the rocking-tool and scraped from dark to light in the present manner of the art. Siegen's innovation was led up to by the previous stipple work of Giulio Campagnola and Janus Lutma; the roulette appears to have been used before his time; and though he shared in the evolution of the rocking-tool, he was not the sole inventor of it. The earliest works referable to the method at the Print Room of the British Museum afford evidence, though inconclusive, that Prince Rupert, to whom Siegen showed his mode of work in 1654, and possibly also their common friend Th. Caspar von Fürstenberger, and Rupert's assistant, Vallerant Vaillant, were more or less concerned in the gradual development of mezzotint engraving. The rocking-tool was apparently improved by Abraham Blooteling, a Dutch painter and engraver of fine portrait mezzotints, who worked in Holland and in England about the year 1680.

Rupert brought the new art over to England at the Restoration, and the portrait of Charles II., dated 1669, by William Sherwin, the first English mezzotinter, bears the engraver's acknowledgment of his indebtedness to Rupert for the secrets of the method. Mezzotint continued to be practised for a while on the Continent, but the successors of Sherwin in England so excelled in it that it early acquired abroad the title of "la manière anglaise," and has since become an exclusively British art. Though used for transcribing the subject-pictures of the great Italian masters, and of Rembrandt, Vandyck, and Rubens, almost every kind of subject being later engraved in it, the staple production in mezzotint has always been the portrait. Until the middle of the 18th century the tools continued somewhat archaic, causing in the prints an appearance of warp and woof, like that of ill-woven material, which detracted from reality of representation. The coarseness and unequal depth of the "grounds" offered so much resistance to freedom of execution with the "scraper" that, though the early engravers were quite as good artists as their successors, painter-like touch was not conspicuous in the work until M'Ardell and the interpreters of Sir Joshua Reynolds had improved the tools and technique.

Except for the collector, therefore, the chief attraction in the prints of F. Place and Luttrell, Beckett and Williams, and later those of John Simon, John Smith, and John Faber, jun., who were the principal exponents of mezzotint in the last years of the seventeenth and first half of the eighteenth centuries, lies in their long series of portraits after Vandyck, Lely, Kneller, and the Dutch painters then practising in England, representing such interesting personages as Charles II. and Nell Gwynn, Addison and Pope, Congreve and Wycherley, Locke, and the great Duke of Marlborough.

The classics of mezzotint engraving are to be found amongst the best plates after Sir Joshua Reynolds by James M'Ardell, J. R. Smith and Valentine Green, the Watsons, Dickinson, Fisher, Dixon, and some others, who worked during the last half of the 18th century. The brush-work of Reynolds was more in harmony with the mezzotint method than the slighter painting technique of Gainsborough and Romney, who were much less frequently engraved, perhaps because it is the highest technical difficulty in mezzotint to render the sharp edges of a sketch. For this reason a typical Gainsborough was never successfully engraved in the method. Though professional publishers and printers existed at this time and earlier, the word "excudit" on an old print implying "published," not "engraved," the authors of the "Sir Joshua" mezzotints in most cases printed, published, and sold their own works, and pure mezzotint, unmixed with etching, was almost exclusively the method they employed. Mezzotints were occasionally printed in colours, notably those engraved later after George Morland, the primary object being to conceal the worn-out condition of the plates.

The departure from pure mezzotint and temporary decay of the art began when, towards the end of the eighteenth century, Richard Earlom, otherwise a fine artist in the traditional method, notably in translations of Vandyck and Wright of Derby, began to outline the details of his plates with stipple etching in order to avoid the labour and difficulty of scraping them to a sharp edge, using the "ground" alone. Earlom, however, did not destroy the mystery of the rich velvety darks by etching into them. A demand then arose for larger editions than the soft copper plates would yield, and the engravers attempted to meet it by combining mezzotint with positive line-etching throughout the work, thus shortening the labour of scraping the details, and fortifying the darks with lines sunk below the surface of the plate. The harmony of line and tone in some of the prints in this style by S. W. Reynolds and Charles Turner, after Sir Joshua, Hoppner, and their contemporaries, was more convincing than the later "mixed style" of Samuel Cousins, because there was a certain artistic significance in the etched line itself apart from the mezzotint tone, but every touch of line in a mezzotint does something to destroy the painter-like quality, and a decadence was in progress.

The same mixed method on copper was used by J. W. M. Turner in his *Liber Studiorum* series of landscape plates, his object being to rival the pen-and-wash drawings of Claude's *Liber Veritatis.* Turner, however, was not so practised in etching or mezzotint as the engravers before mentioned, and the etched foundation of the *Liber* plates was too strong for the mezzotint tone, destroying the breadth of the light, the richness of the darks, and the artistic "keeping" of the whole effect. It is the grand design of Turner reflected in the plates, rather than any quality of mezzotint or etching in them, which appeals to the artist and the connoisseur. Perhaps the greatest success in harmonizing line and tone in one plate was achieved by David Lucas in his "English Landscape" series of mezzotint after John Constable, in which he sharpened his details with the roulette, or with a slight line put in with the point of the scraper as scraping proceeded, retaining the pure "burr" in his darks. Lucas, like Samuel Cousins and his contemporaries, was handicapped by being compelled to work on the steel plates introduced in 1823, and this was the cause of the chief defect of his plates, the excessive opposition of black and white. The warm general tone which assisted the picturesqueness of the 18th-century mezzotints was lost by the use of steel, because the ink did not cling to it as it does to the more porous copper. Steel being harder than copper, the rocking-tool penetrated less deeply, raising less "burr," and the consequent loss of force in the darks necessitated the scraping up of the lights to a higher key to force contrast of effect, which was also enhanced by the use of very white paper and a coarse black ink. It was soon found that the unfortified "burr," even on steel, would not yield the constantly increasing numbers of impressions demanded. The labour of scraping sharp lights was greatly enhanced, and though some pure mezzotints were engraved on steel, painter-like touch was practically unattainable on it, and the general effect was cold and uninteresting.

The early work of Samuel Cousins after Lawrence in the comparatively pure method, and the final development of the "mixed style" on steel in his later plates after Reynolds, Millais, and Landseer, are referred to in the article on Samuel Cousins.

For nearly forty years pure mezzotint ceased to be practised altogether, and the revival of it, which began in 1880, was led up to by the invention of steel-facing. The competition of photogravure, which steel-facing made a commercial possibility, for a time checked the new movement, but a photogravure, despite a mere surface resemblance to a mezzotint, is a photograph manipulated to imitate an engraving, and the qualities of artistic individuality are entirely wanting. In 1898 for the first time a Society of Mezzotint Engravers was formed to foster the art.

See also *British Mezzotinto Portraits*, by John Challoner Smith. London, 1878. This standard book of reference contains a long list of others at page xiv, part i. *Lectures on Etching and Mezzotint*, by Hubert von Herkomer, R.A. London, 1890. (The most useful work on the technique.) *Etching, Engraving, and other Methods of Printing Pictures*, by H. W. Singer and William Strang. London, 1897. *On the Making of Etchings*, by Frank Short. London, 1898. (Containing a slight reference to mezzotint technique.) *Art of Engraving*, by T. H. Fielding. London, 1854. *Masters of Mezzotint*, by Alfred Whitman. London, 1898. A little anonymous book, *A History of the Art of Engraving in Mezzotinto, from Its Origin to the Present Times* [by Dr James Chelsum], Winchester, 1786, is of considerable interest. Works on the technique are somewhat elementary, and no complete history of the art exists.

(G. P. R.)

Lithography.

In Great Britain the art of lithography, as distinct from its numerous commercial uses, was for all practical purposes killed by the competition of wood-engraving, which had been so largely developed in the years after 1860. (See Illustration.) In 1871 Thomas Way induced a number of artists to experiment with the process, the result being the publication of *Hogarth Sketches*, an interesting portfolio, which had, however, no immediate results. For some years no further attempt was made at a revival; the only art productions in any sense of the word being supplements, generally in colour,—those to various periodicals, such as *Vanity Fair*, *The Illustrated London News*, and *The Graphic* being the most noteworthy. There were also facsimile reproductions of popular pictures. But in both these categories the artist had little to do with the actual lithography, a notable exception, however, existing in the case of J. McNeill Whistler, whose contributions to *The Whirlwind* and other short-lived periodicals were entirely his personal work. In 1893 T. R. Way demonstrated the possibilities of the use of lithographic transfer paper to a meeting of the Art Workers' Guild in London; and the interest thus excited again encouraged many artists to try the method, both by this means and by working on the stone direct. It thus became possible for Great Britain to be represented at the Paris Centenary Exhibition of Lithography (1896) by a series of lithographic drawings which were at all events by artists of good position in other branches of the fine arts. Some have continued to practise lithography from time to time; those of most note being Alphonse Legros, Frank Short, Oliver Hall, Will Rothenstein, Charles H. Shannon, William Strang, Thomas R. Way, and Charles J. Watson, the last a representative of a small circle of lithographers centred at Norwich who had kept up the old tradition. Working in England or France, the American artists, J. McNeill Whistler and Joseph Pennell, must also be counted with the foregoing. The numerous productions of the former are of extreme delicacy and great excellence, within their own limits. In France the great traditions left by Raffet, E. Isabey, "Gavarni" (H. G. S. Chevalier), Daumier, and Decamps, had been maintained chiefly by H. Fantin-Latour, whose first lithograph was published in 1876. His work was hardly known or appreciated in England until recently, but the splendid series exhibited in the Centenary Exhibition at South Kensington Museum did not a little towards a proper realization of his true place as a lithographer. A great revival of lithography in France came in the 'eighties, influenced mainly by the development of the pictorial poster; and thus the use of colour, so markedly absent in the unsubstantial effort of the English artists, became a characteristic of the French school, and of the Germans who took their cue from it. Among the leaders of this school may be signalized A. Willette, H. de Toulouse-Lautrec, Steinlen, H. Rivière, and A. Lunois. In Germany the art was warmly adopted, and about the year 1891 began the appearance of a series of plates in colour, many of extreme daring, but all of at least experimental interest. These were mainly done by artists of Munich, Dresden, and Carlsruhe, and are noteworthy for the attention paid in many of them to landscape effects, as compared with the French tendency to deal mainly with the figure. The chief exponents of the modern German school—Menzel belonging essentially to the past—are H. R. von Volkmann, F. Unger, Hans Thoma, Cornelia Paczka, G. Kampmann, H. Daur, and Otto Greiner. Th. van Hoytema and Jan Veth represent the same phase of art in Holland. Technically, the art of lithography stands very much where Senefelder left it, the only improvements being in the fine adjustment of printing machinery, and the adoption of certain modern photographic printing processes in combination with the old use of the stone. Successful work, especially in colour, has also been produced lately by algraphy—a process in which aluminium takes the place of the stone. (E. F. S.)

Wood-Engraving.

Since 1877 the position of wood-engraving in England has wholly changed. At that time it was the chief means of book and newspaper illustration, and a frequent method of fine-art reproduction; but by the beginning of the 20th century it had been all but driven out of the field by "process" work of various kinds. It still flourishes in its commoner style for commercial and mechanical work; it is still occasionally maintained in its finest form by a sympathetic publisher here and there, who deplores and would arrest its decay. But the photograph and its facsimile reproduction have captivated the public, who want "illustration" and who do not want "art." The great body of the wood-engravers have therefore found their occupation entirely gone, while the minority have found themselves forced to devote their skill to "re-touching" the process-block—sometimes carrying their work so far that the print from the finished block is a close imitation of a wood-engraving. This system has been carried farthest in America.

It is not only to considerations of economy that the supersession of engraving by "process" is due. The apparent superiority of truthfulness claimed by the photograph over the artist's drawing is a factor in the case—the public forgetting that a photographic print shows us what a thing or a scene looks like to the lens, rather than what it looks like to the two eyes of the spectator. The rank and file of the engravers—even those who can "engrave" after a picture as well as "cut" a "special artist's" sketch—have succumbed not only to the public, but to the artists themselves, who frequently insist upon the process-block for the translation of their work. They seem to prefer the greater truth of outline (though not necessarily of tone) yielded by "process," to all the inherent charm of the beautiful (and expensive) art of xylography.

In England a few engravers of high rank and ability still followed in 1901 the art which was raised to so high a pitch by W. J. Linton (died 1898). Such were Mr Charles Roberts, Mr Biscombe Gardner, Mr Comfort, Mr Ulrich, and a few more—the first two the better engravers for being also practising artists. But there is every reason to fear that if wood-engraving as a craft, for ordinary purposes, ceases to exist, wood-engraving as a fine art must disappear as well; as there would be nothing to support the young craftsman during the years of apprenticeship and practice required to make an "artist" of him, and nothing to compensate him if he fail to attain at once the highest accomplishment.

Another circumstance which has contributed to the overthrow of wood-engraving in England is the rapture begotten of the extraordinary perfection to which the art had been brought in America. These engravings, published in magazines and books, having wide circulation in England, awakened not an intelligent but a foolish appreciation among the public. Just as Finden's over-refinement of engraving on steel killed his art by stripping it of all interest, so the unsurpassable perfection of the American wood-engraver, by the law of paradox, effectually stifled xylography in England. The reason is simple. With the object of "disindividualizing" himself, as he called it, the engraver sought to suppress his own recognizable manner of craftmanship when translating the work of the artist for the public; and the more he succeeded in effacing himself, and the more he refined and elaborated his technique and imitated textures, and the more he developed extreme minuteness and excessive dexterity (so as to secure faithfulness and smoothness), the more closely did the result approximate to a photograph. The result, in fact, became the *reductio ad absurdum* of the passion for the minute and the perfection of technique. The result was amazing in its completeness, but curiously grey and monotonous; and matter-of-fact publishers and public alike preferred the photograph, which in their eyes did not differ so very much (except in being a little greyer and more monotonous) from the half-tone block, while the cost of the latter was but a fraction of that of the former. The extreme elaboration, satisfying a craving of an acrobatic kind, defeated its own end. The public were pleased, and the result has been disastrous for the art.

In England, in spite of the International Society of Wood-Engravers, there are but slight signs of a general revival, and it seems as if the art must be born again, so long as the public interest in photographs continues. Mr C. Ricketts has gone back to a Düreresque, or perhaps Florentine, manner of the Early Renaissance wood-cut, while others are striving to begin engraving where Bewick began it. There is hope that the true art may be restored, but such revival will rather be based on a revolt against the greyness of the process-block, and the offensively shiny surface of the chalk-coated paper on which it is printed, than on any æsthetic delight in intelligent wood-engraving, its expressive line, its delicate, pearly tones, and its rich, fat blacks.

In America, where the power of resuscitation is great, the miraculous technical perfection brought about by Mr Timothy Cole and the late Frederick Juengling, as leaders of the school, has promptly given way to a greater feeling for art and a lesser worship of mechanical achievement, and wood-engraving is saved. Curiously enough, Mr Cole (himself, by the way, an Englishman by birth) was equally a leader in recognizing the danger which his own brilliant proficiency had helped to bring about. The "decadent" *de luxe* who had overwhelmed his art in the refinements which threatened to destroy it, and who had been seconded by the splendid printing-presses of America (which might without exaggeration be called instruments of precision), gave up what may be termed hyper-engraving, and, surrendering his wonderful power of imitating surfaces and textures, Mr Cole changed his manner. He became broader in handling; his example was followed by others, and wood-engraving in a few hands still prospers in the United States.

In France, where the art has reached the highest perfection and the most consummate and logical development, it flourishes on the true artistic instinct of the engraver, on the taste of an intelligent and appreciative public, and on official recognition and encouragement. Nevertheless, it has been found necessary to establish a "Society of Wood-Engravers" (with a magazine of its own) to protect it against the inroad of the process-block. The art doubtless produces more engravers of skill than it can provide work for; but that is evidence rather of vitality than of decay. M. Lepère, M. Baude, M. Jonnard, are among the leaders who, in different styles of wood-engraving, sustain the extraordinarily high level which has been attained in France, and which is likely to be maintained by virtue of the encouragement on which it flourishes. Florian, who died in 1900, was a man who successfully sought to obtain effects of tone rather than line, leaving masses of unengraved surface to enhance the delicate beauty of his pearly greys. But in rebelling against the mechanical style so much affected in Germany, of indicating roundness of form by curved lines carried at right angles to the convexity, and in substituting longitudinal lines of shading, he sacrificed a good deal of the logic of form-rendering, and started a method that has not been entirely successful.

In Germany the artistic standard is lower than in France. It is true that few outside Germany could model a head as finely as Herr M. Klinkicht in his own style of a judicious mingling of the black line and the white line; but, as a rule, German engraving is far more precise, more mechanical, more according to formula, and more old-fashioned than that of either France or America. The art has been injured by the great "studios" or factories which flourish on strictly business principles, and which, in the education of the craftsman, have to some extent annihilated the artist. A few there are, however, of great ability and taste. The attempt to print wood-engravings in colours has done little to improve the status of the art. In other countries, however, "original" work has done much to raise the standard. Thus the work of Mr Elbridge Kingsley, who would sit down in the woods and engrave the scene before him directly on to the block, exercised no little influence in America. The similar ability of M. Lepère to engrave directly from nature, whether from the trees of Fontainebleau Forest or the towers of Westminster, has been much appreciated in his own country and in England. The efforts at block-printing by M. Charpentier and others, not only with colour, but by reinforcing it with blocks that print neither lines nor colour but "blind" pattern, raised or depressed upon the paper, prove that there is a movement afoot to seek new methods to interest the public. The immediate results may not be very serious; yet the fact shows the existence of a vitality that gives hope for the future. But while the practice of dry-printing upon "surface paper" is maintained, it is hopeless to expect in the immediate future, in England at least, any permanently good results from orthodox wood-engraving.

LINE-ENGRAVING.

The record of the art of engraving in line upon copper or steel, since the 9th edition of this *Encyclopædia* was published, is one of continued decay. The impulse therein referred to has faded away. Technical improvements, it was hoped, might save the art; it was thought by some that the slight revival resultant on the turning back of the burin's cutting-point—whereby the operator pulled the tool towards him instead of pushing it from him—might affect much, in virtue of the time and labour saved by the device. At the beginning of the 20th century it is seen that pictorial line-engraving in England is practically non-existent, and that the spasmodic demand by publishers for engravers to cut new plates is unanswered. There are certainly a few men still working in line who are capable of touching-up old plates, and engraving new ones of a more or less mechanical kind. Mr C. W. Sherborn, the exquisite and facile designer and engraver of book-plates, has scarcely been surpassed in his own line, but his art is mainly heraldic, and he is himself a veteran. There are now no men capable of such work as that with which Doo, J. H. Robinson, and their fellows maintained the credit of the English School. Line-engraving has been killed by etching, mezzotint, and that bastard form of line-engraving known as the "mixed method"—a combination of etching, graving, and machine-ruling, such as is seen in Thomas Landseer's "Stag at Bay." The disappearance of the art is due not so much to the artistic objection that the personality of the line-engraver stands obtrusively between the painter and the public; it is rather that the public refuse to wait for several years for the proofs for which they have subscribed, when by another method they can obtain their plates more quickly. An important line plate may occupy a prodigious time in the engraving. Robinson's "Napoleon and the Pope" took about twelve years. The invention of steel-facing a copper plate would now enable the engraver to proceed more expeditiously; but even in this case he can no more compete with the etcher than the mezzotint-engraver can keep pace with the photogravure manufacturer. The Royal Academy has within recent years withdrawn from the list of school prizes the offer of a medal for line-engraving, for which for a long while previously there had been no competition; the late Mr Lumb Stocks, R.A., and the living Mr F. Stacpoole, (retired) A.R.A. (who is best known for his plates after Briton Riviere's "Circe," Lady Butler's "Roll-Call," and Holman Hunt's "Shadow of the Cross"), will have no successors on the list of Academicians; and the privilege of Academic recognition so fiercely won by Sir Robert Strange will lapse for lack of claimants. The Art Union of London has given what encouragement it could; but with the death of F. Bacon (1887) and J. Stephenson (1886) it was evident that all hope was gone. John Saddler came at last, in spite of his capacity to do original work, to spend most of his time in assisting Thomas Landseer to rule the skies on his plates, simply because there was not enough line-engraving to do. Since then there was some promise of a revival, and Mr Bourne engraved a few of the pictures by Gustave Doré. But little followed. It is not generally known that the last of the line-engravers of Turner's pictures died in the person of Sir Daniel Wilson, who, recognizing the hopelessness of his early profession, laid his graver aside, and in due time left Europe for Canada and eventually became President of the University of Toronto (died 1892).

If line-engraving still flourishes in France, it is due not a little to official encouragement and to intelligent fostering by collectors and connoisseurs. The prizes offered by the École des Beaux Arts would probably not suffice to give vitality to the art but for the employment afforded to the finished artist by the "Chalcographie du Musée du Louvre," in the name of which commissions are judiciously distributed. At the same time, it must be recognized that although French gravers are little less busy than they were in days when line-engraving was the only "important" method of picture-translation, they work for the most part for much smaller rewards. Moreover, the class of the work has entirely changed, partly through the reduction of prices paid for it, partly through the change of taste and fashion, and partly through the necessities of the situation. That is to say, that public impatience is but a partial factor in the abandonment of the fine broad sweeping trough cut deep into the copper which was characteristic of the earlier engraving, either simply cut or crossed diagonally so as to form the series of "lozenges" typical of engraving at about its finest and grandest period. That method was slow; but not less slow was the shallower work rendered possible by the steel plate or the steel-faced copper plate, by reason of the much greater degree of elaboration of which such plates were capable, and which the public was taught—mainly by Finden—to expect. The French engravers were therefore driven at last to simplify their work if they were to satisfy the public and live by the burin. To compensate for loss of colour, the art developed in the direction of elegance and refinement. Gaillard (died 1887), Blanchard, and Alphonse François (died 1888) were perhaps the earliest chiefs of the new school, the characteristics of which are the substitution of exquisite greys for the rich blacks of old, simplicity of method being often allied to extremely high elaboration. Yet the aim of the modern engraver has always been, while pushing the capability of his own art to the farthermost limit, to retain throughout the individual and personal qualities of the master whose work is translated on the plate. The height of perfection to which the art is reached is seen in the triptych of Mantegna by M. Achille Jacquet, to whom may perhaps be accorded the first place among several engravers of the front rank. This "Passion" (from the three pictures in the Louvre and at Tours, forming the predella of the San Zeno altarpiece in Verona) not only conveys the forms, sentiment, and colour of the master, but succeeds also in rendering the peculiar luminosity of the originals. M. Jacquet, who gained the *Prix de Rome* in 1870, has also translated the pictures of Sir Joshua Reynolds, and has engraved fine plates after Paul Dubois, Cabanel, Bouguereau, Meissonier, and Detaille. The freedom of much of his work suggests an affinity with etching and dry-point; indeed, it appears that he uses the etching-needle and acid to lay in some of his groundwork and outlines. M. Léopold Flameng's engraving after Jan van Eyck's "Virgin with the Donor," in the Louvre, is one of the most admirable works of its kind, retaining the quality and sentiment of the master, extreme minuteness and elaboration notwithstanding. M. Jules Jacquet is known for his work after Meissonier (especially the "Friedland") and after Bonnat; M. Adrien Didier for his plates after Holbein ("Anne of Cleves"), Raphael, and Paul Veronese, among the Old Masters, and Bonnat, Bouguereau, and Roybet among the new. M. Jazinski (Botticelli's "Primavera"), M. Sulpis (Mantegna and Gustave Moreau), M. Patricot (Gustave Moreau), M. Burney, and M. Champollion (died 1901), are among the leaders of the modern school. Their object is to secure the faithful transcript of the painter they reproduce, while readily sacrificing the power of the old method, which, whatever its force and its beauty, was easily acquired by mediocre artists of technical ability who were nevertheless unable to appreciate or reproduce anything beyond mechanical excellence.

The Belgian School of engraving is not without vitality. The veteran M. Gustave Biot is equally skilful in portraiture and subject (engraving after Gallait, Cabanel, Gustave Doré, among his best work); M. A. M. Danse has executed plates after leading painters, and has elaborated an effective "mixed method" of graver-work and dry-point; and M. de Meerman has engraved a number of good plates; but private patronage is hardly sufficient in Belgium to maintain the school in a high state of prosperous efficiency.

In Germany, as might be expected, line-engraving retains not a little of its popularity in its more orthodox form. The novel Stauffer-Bern method, in which freedom and lightness are obtained with such delicacy that the fine lines, employed in great numbers, run into tone, and yield a supposed advantage in modelling, has not been without appreciation. But the more usual virtue of the graver has been best supported, and many have worked in the old-fashioned manner. Friedrich Zimmermann (died 1887) began his career by engraving such prints as Guido Reni's "Ecce Homo" in Dresden, and then devoted himself to the translation of modern German painters. Rudolf Pfnor was an ornamentist representative of his class; and Joseph Kohlschein, of Düsseldorf, a typical exponent of the intelligent conservative manner. His "Marriage at Cana" after Paul Veronese, "The Sistine Madonna" after Raphael, and "St Cecilia" after the same master, are all plates of a high order.

In Italy the art is well-nigh as moribund as in England. When Signor Vittorio Pica (of Naples) and Signor Conconi (of Milan) have been named, it is difficult to mention other successors to the fine school of the 19th century which followed Piranesi and Volpato. A few of the pupils of Rosaspina and Paolo Toschi lived into the last quarter of the century, but to the present generation Asiolo, Jesi, C. Raimondi, L. Bigola, and Antonio Isac are remembered rather for their efforts than for their success in supporting their art against the combined opposition of etching, process, and public indifference.

Outside of Europe line-engraving can no longer be said to exist. Here and there a spasmodic attempt may be made to appeal to the artistic appreciation of a limited public; but no general attention is paid to such efforts, nor, it may be added, are these inherently worthy of much notice. There are still a few who can engrave a head from a photograph or drawing, or a small engraving for book-illustration; there are more who are highly proficient in mechanical engraving for decorative purposes; but the engraving-machine is fast superseding this class. In short, the art of worthily translating a fine painting, outside France, Belgium, Germany, and perhaps Italy, can scarcely be said to survive.

(M. H. S.)

Ennis (Gaelic, *Innis*, an island; Irish, *Ennis* and *Inish*), an inland town and urban sanitary district in the county of Clare, Ireland, on the river Fergus, 25 miles west-north-west of Limerick by rail. It ceased to be a parliamentary borough in 1885. Population, about 5460.

Enniskillen, a market-town and urban sanitary district in the county of Fermanagh, Ireland, on an island in the river connecting the upper and lower lakes of Lough Erne, 102 miles north-west of Dublin by rail. It ceased to be a parliamentary borough in 1885. Steamers now ply between Enniskillen and Belleek on the lower lake, and between Enniskillen and Knockninny on the upper lake. Population (1881), 5900; (1891), 5570; (1901), about 5339.

Enns, an ancient town in Upper Austria (the Roman *Laureacum*), on the Enns near its confluence with the Danube. It possesses the oldest charter (1212) of any town in the monarchy. The walls are said to have been built with the ransom paid by England for the release of Richard Cœur de Lion. It has an old Gothic church, a 15th-century castle, and a Rathhaus erected in 1565. There are numerous ironworks in the adjoining Enns valley. Population (1890), with suburbs, 4674; (1900), 4371.

Enschede, a town in the province of Overyssel, Netherlands, near the Prussian frontier, about 45 miles south-east of Zwolle. As a centre of the cotton-spinning and weaving industry it has flourished greatly, the population (24,253 in 1900) having quadrupled since 1875. The transport of coal has been much increased by the construction of a railway to the coal-fields of the Ruhr, and over 44,000 tons are now carried annually. A new park has been opened, more especially for the benefit of the working classes, and an industrial trade school has been established.

Entomostraca.—This term, as now restricted, includes the Branchiopoda, Ostracoda, and Copepoda. The Ostracoda have the body enclosed in a bivalve shell-covering, and normally unsegmented. The Branchiopoda have a very variable number of body-segments, with or without a shield, simple or bivalved, and some of the post-oral appendages normally branchial. The Copepoda have normally a segmented body, not enclosed in a bivalved shell-covering, the segments not exceeding eleven, the limbs not branchial.

Under the heading CRUSTACEA the Entomostraca have already been distinguished not only from the Thyrostraca or Cirripedes, but also from the Malacostraca, and an intermediate group of which the true position is still disputed. The choice is open to maintain the last as an independent subclass, and to follow Claus in calling it the Leptostraca, or to introduce it among the Malacostraca as the Nebaliacea, or with Packard and Sars to make it an entomostracan subdivision under the title Phyllocarida. At present it comprises the single family Nebaliidæ. The bivalved carapace has a jointed rostrum, and covers only the front part of the body, to which it is only attached quite in front, the valve-like sides being under control of an adductor muscle. The eyes are stalked and movable. The first antennæ have a lamellar appendage at the end of the peduncle, a decidedly non-entomostracan feature. The second antennæ, mandibles, and two pairs of maxillæ may also be claimed as of malacostracan type. To these succeed eight pairs of foliaceous branchial appendages on the front division of the body, followed on the hind division by four pairs of powerful bifurcate swimming feet and two rudimentary pairs, the number, though not the nature, of these appendages being malacostracan. On the other hand, the two limbless segments that precede the caudal furca are decidedly non-malacostracan. The family was long limited to the single genus *Nebalia* (Leach), and the single species *N. bipes* (O. Fabricius). Recently Sars has added a Norwegian species, *N. typhlops*, not blind but weak-eyed. There are also now two more genera, *Paranebalia* (Claus, 1880), in which the branchial feet are much longer than in *Nebalia*, and *Nebaliopsis* (Sars, 1887), in which they are much shorter. All the species are marine.

BRANCHIOPODA.—In this order, exclusion of the Phyllocarida will leave three suborders of very unequal extent, the Phyllopoda, Cladocera, Branchiura. The constituents of the last have often been classed as Copepoda, and among the Branchiopods must be regarded as aberrant, since the "branchial tail" implied in the name has no feet, and the actual feet are by no means obviously branchial.

Phyllopoda.—This "leaf-footed" suborder has the appendages which follow the second maxillæ variable in number, but all foliaceous and branchial. The development begins with a free nauplius stage. In the outward appearance of the adults there is great want of uniformity, one set having their limbs sheltered by no carapace, another having a broad shield over most of them, and a third having a bivalved shell-cover within which the whole body can be enclosed. In accord with these differences the sections may be named Gymnophylla, Notophylla, Conchophylla. The equivalent terms applied by Sars are Anostraca, Notostraca, Conchostraca, involving a termination already appropriated to higher divisions of the Crustacean class, for which it ought to be reserved.

1. *Gymnophylla.*—These singular crustaceans have long soft flexible bodies, the eyes stalked and movable, the first antennæ small and filiform, the second lamellar in the female, in the male prehensile; this last character gives rise to some very fanciful developments. There are three families, two of which form companies rather severely limited. Thus the Polyartemiidæ, which compensate themselves for their stumpy little tails by having nineteen instead of the normal eleven pairs of branchial feet, consist exclusively of *Polyartemia forcipata* (Fischer, 1851). This species from the high north of Europe and Asia carries green eggs, and above them a bright pattern in ultramarine (Sars, 1896, 1897). The Thamnocephalidæ have likewise but a single species, *Thamnocephalus platyurus* (Packard, 1877), which justifies its title "bushy-head of the broad tail" by a singularity at each end. Forward from the head extends a long ramified appendage described as the "frontal shrub," backward from the fourth abdominal segment of the male spreads a fin-like expansion which is unique. In the ravines of Kansas, pools supplied by torrential rains give birth to these and many other phyllopods, and in turn "millions of them perish by the drying up of the pools in July" (Packard). The remaining family, the Branchipodidæ, includes eight genera. In the long familiar *Branchipus*, *Chirocephalus*, and *Streptocephalus* the males have frontal appendages, but these are wanting in the "brine-shrimp" *Artemia*, and the same want helps to distinguish *Branchinecta* (Verrill, 1869) from the old genus *Branchipus*. Of *Branchiopsyllus* (Sars, 1897) the male is not yet known, but in his genera of the same date, the Siberian *Artemiopsis* and the South African *Branchipodopsis* (1898), there is no such appendage. Of the last genus the type species *B. hodgsoni* belongs to Cape Colony, but the specimens described were born and bred and observed in Norway. For the study of fresh-water Entomostraca large possibilities are now opened to the naturalist. A parcel of dried mud, coming for example from Palestine or Queensland, and after an indefinite interval of time put into water in England or elsewhere, may yield him living forms, both new and old, in the most agreeable variety. Some caution should be used against confounding accidentally introduced indigenous species with those reared from the imported eggs. Those, too, who send or bring the foreign soil should exercise a little thought in the choice of it, since dry earth that has never had any Entomostraca near it at home will not become fertile in them by the mere fact of exportation.

2. *Notophylla.*—In this division the body is partly covered by a broad shield, united in front with the head; the eyes are sessile, the first antennæ are small, the second rudimentary or wanting; of the numerous feet, sometimes sixty-three pairs, exceeding the number of segments to which they are attached, the first pair are more or less unlike the rest, and in the female the eleventh have the epipod and exopod (flabellum and sub-apical lobe of Lankester) modified to form an ovisac. Development begins with a nauplius stage. Males are very rare. The single family Apodidæ contains only two genera, *Apus* and its very near neighbour *Lepidurus*. *Apus australiensis* (Spencer and Hall, 1896) may rank as the largest of the Entomostraca, reaching in the male, from front of shield to end of telson, a length of 70 mm., in the female of 64 mm. In a few days, or at most a fortnight, after a rainfall numberless

specimens of these sizes were found swimming about, "and as not a single one was to be found in the water-pools prior to the rain, these must have been developed from the egg." Similarly, in Northern India *Apus himalayanus* was "collected from a stagnant pool in a jungle four days after a shower of rain had fallen," following a drought of four months (Packard).

3. *Conchophylla.*—Though concealed within the bivalved shell-cover, the mouth-parts are nearly as in the Gymnophylla, but the flexing of the caudal part is in contrast, and the biramous second antennæ correspond with what is only a larval character in the other phyllopods. In the male the first one or two pairs of feet are modified into grasping organs. The small ova are crowded beneath the dorsal part of the valves. The development usually begins with a nauplius stage (Sars, 1896, 1900). There are four families:—(*a*) The Limnadiidæ, with feet from 18 to 32 pairs, comprise four (or five) genera. Of these, *Limnadella* (Girard, 1855) has a single eye. It remains rather obscure, though the type species originally "was discovered in great abundance in a roadside puddle subject to desiccation." *Limnadia* (Brongniart, 1820) is supposed to consist of species exclusively parthenogenetic. But when asked to believe that males never occur among these amazons, one cannot but remember how hard it is to prove a negative. (*b*) The Lynceidæ, with not more than twelve pairs of feet. This family is limited to the species, widely distributed, of the single genus *Lynceus*, established by O. F. Müller in 1776 and 1781, and first restricted by Leach in 1816 in the *Encyclopædia Britannica* (art. ANNULOSA, of that edition). Leach there assigns to it the single species *L. brachyurus* (Müller), and as this is included in the genus *Limnetis* (Lovén, 1846), that genus must be a synonym of *Lynceus* as restricted. (*c*) Leptestheriidæ. *Estheria* (Rüppell, 1837) was instituted for the species *dahalacensis*, which Sars includes in his genus *Leptestheria* (1898); but *Estheria* was already appropriated, and of its synonyms *Cyzicus* (Audouin, 1837) is lost for vagueness, while *Isaura* (Joly, 1842) is also appropriated, so that *Leptestheria* becomes the name of the typical genus, and determines the name of the family. (*d*) Cyclestheriidæ. This family consists of the single species *Cyclestheria hislopi* (Baird), reported from India, Ceylon, Celebes, Australia, East Africa, and Brazil. Sars (1887) having had the opportunity of raising it from dried Australian mud, found that, unlike other phyllopods, but like the Cladocera, the parent keeps its brood within the shell until their full development.

Cladocera.—In this suborder the head is more or less distinct, the rest of the body being in general laterally compressed and covered by a bivalved test. The title "branching horns" alludes to the second antennæ, which are two-branched except in the females of *Holopedium*, with each branch setiferous, composed of only two to four joints. The mandibles are without palp. The pairs of feet are four to six. The eye is single, and in addition to the eye there is often an "eye-spot," *Monospilus* being unique in having the eye-spot alone and no eye, while *Leydigiopsis* (Sars, 1901) has an eye with an eye-spot equal to it, or larger. The heart has a pair of venous ostia, often blending into one, and an anterior arterial aorta. Respiration is conducted by the general surface, by the branchial lamina (external branch) of the feet, and the vesicular appendage (when present) at the base of this branch. The "abdomen," behind the limbs, is usually very short, occasionally very long. The "postabdomen," marked off by the two postabdominal setæ, usually has teeth or spines, and ends in two denticulate or ciliate claws, or it may be rudimentary, as in *Polyphemus*. Many species have a special glandular organ at the back of the head, which *Sida crystallina* uses for attaching itself to various objects. The Leydigian or nuchal organ is supposed to be auditory and to contain an otolith. The female lays two kinds of eggs—"summer-eggs," which develop without fertilization, and "winter-eggs" or resting eggs, which require to be fertilized. The latter in the Daphniidæ are enclosed in a modified part of the mother's shell, called the ephippium from its resemblance to a saddle in shape and position. In other families a less elaborate case has been observed, for which Mr Scourfield has proposed the term protoephippium. In *Leydigia* he has recently found a structure almost as complex as that of the Daphniidæ. In some families the resting eggs escape into the water without special covering. Only the embryos of *Leptodora* are known to hatch out in the nauplius stage. *Penilia* (Dana, 1849) is perhaps the only exclusively marine genus. The great majority of the Cladocera belong to fresh water, but their adaptability is large, since *Moina rectirostris* (O. F. Müller) can equally enjoy a pond at Blackheath, and near Odessa live in water twice as salt as that of the ocean. In point of size a Cladoceran of 5 mm. is spoken of as colossal.

Dr Jules Richard in his revision (1895) retains the sections, proposed by Sars in 1865, Calyptomera and Gymnomera. The former, with the feet for the most part concealed by the carapace, is subdivided into two tribes, the *Ctenopoda*, or "comb-feet," in which the six pairs of similar feet, all branchial and non-prehensile, are furnished with setæ arranged like the teeth of a comb, and the *Anomopoda*, or "variety-feet," in which the front feet differ from the rest by being more or less prehensile, without branchial laminæ.

The *Ctenopoda* comprise two families: (*a*) the Holopediidæ, with a solitary species, *Holopedium gibberum* (Zaddach), queerly clothed in a large gelatinous involucre, and found in mountain tarns all over Europe, in large lakes of N. America, and also in shallow ponds and waters at sea-level; (*b*) the Sididæ, with no such involucre, but with seven genera, and rather more than twice as many species. Of *Diaphanosoma modiglianii* Richard says that at different points of Lake Toba in Sumatra millions of specimens were obtained, among which he had not met with a single male.

The *Anomopoda* are arranged in four families, all but one very extensive. (*a*) Daphniidæ. Of the seven genera, the cosmopolitan *Daphnia* contains about 100 species and varieties, of which Mr Thomas Scott (1899) observes that "scarcely any of the several characters that have at one time or another been selected as affording a means for discriminating between the different forms can be relied on as satisfactory." Though this may dishearten the systematist, Mr Scourfield (1900) reminds us that "It was in a water-flea that Metschnikoff first saw the leucocytes (or phagocytes) trying to get rid of disease germs by swallowing them, and was so led to his epoch-making discovery of the part played by these minute amœboid corpuscles in the animal body." For *Scapholeberis mucronata* (O. F. Müller), Mr Scourfield has shown how it is adapted for movement back downwards in the water along the under side of the surface-film, which to many small crustaceans is a dangerously disabling trap. (*b*) Bosminidæ. To *Bosmina* (Baird, 1845) Richard adds *Bosminopsis*, in 1895. (*c*) Macrotrichidæ. In this family *Macrothrix* (Baird, 1843) is the earliest genus, among the latest being *Grimaldina* (Richard, 1892) and *Jheringula* (Sars, 1900). Dried mud and vegetable débris from S. Paulo in Brazil supplied Sars with representatives of all the three in his Norwegian aquaria, in some of which the little *Macrothrix elegans* "multiplied to such an extraordinary extent as at last to fill up the water with immense shoals of individuals." "The appearance of male specimens was always contemporary with the first ephippial formation in the females." For *Streblocerus pygmæus*, grown under the same conditions, Sars observes: "This is perhaps the smallest of the Cladocera known, and is hardly more than visible to the naked eye," the adult female scarcely exceeding 0·25 mm. Yet in the next family *Alonella nana* (Baird) disputes the palm and claims to be the smallest of all known Arthropoda. (*d*) Chydoridæ. This family, so commonly called Lynceidæ, contains a large number of genera, among which one may usually search in vain, and rightly so, for the genus *Lynceus*. The key to the riddle is to be found in the *Encyclopædia Britannica* for 1816. There, as above explained, Leach began the subdivision of Müller's too comprehensive genus, the result being that *Lynceus* belongs to the Phyllopoda, and *Chydorus* (Leach, 1816) properly gives its name to the present family, in which the doubly convoluted intestine is so remarkable. Of its many genera, *Leydigia*, *Leydigiopsis*, *Monospilus*, have been already mentioned. *Dadaya macrops* (Sars, 1901), from South America and Ceylon, has a very large eye and an eye-spot fully as large, but it is a very small creature, odd in its behaviour, moving by jumps at the very surface of the water. "To the naked eye it looked like a little black atom darting about in a most wonderful manner."

The Gymnomera, with a carapace too small to cover the feet, which are all prehensile, are divided also into two tribes, the Onychopoda, in which the four pairs of feet have a toothed maxillary process at the base, and the Haplopoda, in which there are six pairs of feet, without such a process. To the Polyphemidæ, the well-known family of the former tribe, Sars in 1897 added two remarkable genera, *Cercopagis*, meaning "tail with a sling," and *Apagis*, "without a sling," for seven species from the Sea of Azov. The Haplopoda likewise have but a single family, the Leptodoridæ, and this has but the single genus *Leptodora* (Lilljeborg, 1861). Dr Richard (1895, 1896) gives a Cladoceran bibliography of 601 references.

Branchiura.—This term was introduced by Thorell in 1864 for the Argulidæ, a family which had been transferred to the Branchiopoda by Zenker in 1854, though sometimes before and since united with the parasitic Copepoda. Though the animals have an oral siphon, they do not carry ovisacs like the siphonostomous copepods, but glue their eggs in rows to extraneous objects. Their lateral, compound, feebly movable eyes agree with those of the Phyllopoda. The family are described by Claus as "intermittent parasites," because when gorged they leave their hosts, fishes or frogs, and swim about in freedom for a considerable period. The long-known *Argulus* (O. F. Müller) has the second maxillæ transformed into suckers, but in *Dolops* (Audouin, 1837) (Fig. 1), the name of which supersedes the more familiar *Gyropeltis* (Heller, 1857), these effect attachment by ending in strong hooks (Bouvier, 1897). A third genus, *Chonopeltis* (Thiele, 1900), has suckers, but has lost its first antennæ, at least in the female.

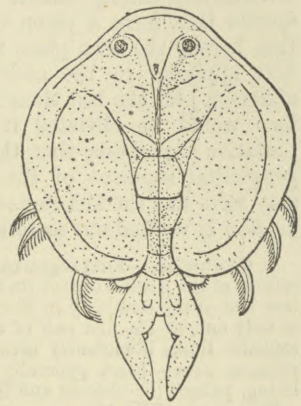

FIG. 1.—*Dolops ranarum* (Stuhlmann).

OSTRACODA.—The body, seldom in any way segmented, is wholly encased in a bivalved shell, the caudal part strongly inflexed, and almost always ending in a furca. The limbs, including antennæ and mouth organs, never exceed seven definite pairs. The first antennæ never have more than eight joints. The young usually pass through several stages of development after leaving the egg, and this commonly after, even long after, the egg has left the maternal shell. Parthenogenesis is frequent.

The four tribes instituted by Sars in 1865 were reduced to two by G. W. Müller in 1894, the Myodocopa, which almost always have a heart, and the Podocopa, which have none.

Myodocopa.—These have the furcal branches broad, lamellar, with at least three pairs of strong spines or ungues. Almost always the shell has a rostral sinus. Müller divides the tribe into three families, Cypridinidæ, Halocypridæ, and the heartless Polycopidæ, which constituted the tribe Cladocopa of Sars. From the first of these Brady and Norman distinguish the Asteropidæ (Fig. 3), remarkable for seven pairs of long branchial leaves which fold over the hinder extremity of the animal, and the Sarsiellidæ, still somewhat obscure, besides adding the Rutidermatidæ, knowledge of which is based on skilful maceration of minute and long-dried specimens. The Halocypridæ are destitute of compound lateral eyes, and have the sexual orifice unsymmetrically placed.

Podocopa.—In these the furcal branches are linear or rudimentary, the shell is without rostral sinus, and, besides distinguishing characters of the second antennæ, they have always a branchial plate well developed on the first maxillæ, which is inconstant in the other tribe. There are five families:—(*a*) Cyprididæ (? including Cypridopsidæ of Brady and Norman). In some of the genera parthenogenetic propagation is carried to such an extent that of the familiar *Cypris* it is said, "until quite lately males in this genus were unknown; and up to the present time no male has been found in the British Islands" (Brady and Norman, 1896). On the other hand, the ejaculatory duct with its verticillate sac in the male of *Cypris* and other genera is a feature scarcely less remarkable. (*b*) Bairdiidæ, which have the valves smooth, with the hinge untoothed. (*c*) Cytheridæ (? including Paradoxostomatidæ of Brady and Norman), in which the valves are usually sculptured, with toothed hinge. Of this family the members are almost exclusively marine, but *Limnicythere* is found in fresh water, and *Xestoleberis bromeliarum* (Fritz Müller) lives in the water that collects among the leaves of Bromelias, plants allied to the pine-apples. (*d*) Darwinulidæ, including the single species *Darwinula stevensoni*, Brady and Robertson, described as "perhaps the most characteristic Entomostracan of the East Anglian Fen District." (*e*) Cytherellidæ, which, unlike the Ostracoda in general, have the hinder part of the body segmented, at least ten segments being distinguishable in the female. They have the valves broad at both ends, and were placed by Sars in a separate tribe, called Platycopa.

The range in time of the Ostracoda is so extended that, in G. W. Müller's opinion, their separation into the families now living may have already taken place in the Cambrian period. Their range in space, including carriage by birds, may be coextensive with the distribution of water, but it is not known what height of temperature or how much chemical adulteration of the water they can sustain, how far they can penetrate underground, nor what are the limits of their activity between the floor and the surface of aquatic expanses, fresh or saline. In individual size they have never been important, and of living forms the largest is one of recent discovery, *Crossophorus africanus*, a Cypridinid about three-fifths of an inch, 15·5 mm. long; but a length of one or two millimetres is more common, and it may descend to the seventy-fifth of an inch. By multitude they have been, and still are, extremely important.

Though the exterior is more uniform than in most groups of crustacea, the bivalved shell or carapace may be strongly calcified and diversely sculptured (Fig. 2), or membranaceous and polished, hairy or smooth, oval or round or bean-shaped, or of some less simple pattern; the valves may fit neatly, or one overlap the other, their hinge may have teeth or be edentulous, and their front part may be excavated for the protrusion of the antennæ or have no such "rostral sinus." By various modifications of their valves and appendages the creatures have become adapted for swimming, creeping, burrowing, or climbing, some of them combining two or more of these activities, for which their structure seems at the first glance little adapted. Considering the imprisonment of the ostracod body within the valves, it is more surprising that the Asteropidæ and Cypridinidæ should have a pair of compound and sometimes large eyes, in addition to the median organ at the base of the "frontal tentacle," than that other members of the group should be limited to that median organ of sight, or have no eyes at all. The median eye when present may have or not have a lens, and its three pigment-cups may be close together or wide apart and the middle one rudimentary. As might be expected, in thickened and highly embossed valves thin spaces occur over the visual organ. The frontal organ varies in form and apparently in function, and is sometimes absent. The first antennæ, according to the family, may assist in walking, swimming, burrowing, climbing, grasping, and besides they carry sensory setæ, and sometimes they have suckers on their setæ (see Brady and Norman on *Cypridina norvegica*). The second antennæ are usually the chief motor-organs for swimming, walking, and climbing. The mandibles are normally five-jointed, with remnants of an outer branch on the second joint, the biting edge varying from strong development to evanescence, the terminal joints or "palp" giving the organ a leg-like appearance and function, which disappears in suctorial genera such as *Paracytherois*. The variable first maxillæ are seldom pediform, their function being concerned chiefly with nutrition, sensation, and respiration. The variability in form and function of the second maxillæ is sufficiently shown by the fact that G. W. Müller, our leading authority, adopts the confusing plan of calling them second maxillæ in the Cypridinidæ (including Asteropidæ), maxillipeds in the Halocypridæ and Cyprididæ, and first legs in the Bairdiidæ, Cytheridæ, Polycopidæ, and Cytherellidæ, so that in his fine monograph he uses the term first leg in two quite different senses. The first legs, meaning thereby the sixth pair of appendages, are generally pediform and locomotive, but sometimes unjointed, acting as a kind of brushes to cleanse the furca, while in the Polycopidæ they are entirely wanting. The second legs are sometimes wanting, sometimes pediform and locomotive, sometimes strangely metamorphosed into the "vermiform organ," generally long, many-jointed, and distally armed with retroverted spines, its function being that of an extremely mobile cleansing foot, which can insert itself among the eggs in the brood-space, between the branchial leaves of *Asterope* (Fig. 3), and even range over the external surface of the valves. The "brush-formed" organs of the Podocopa are medially placed, and, in spite of their sometimes forward situation, Müller believes

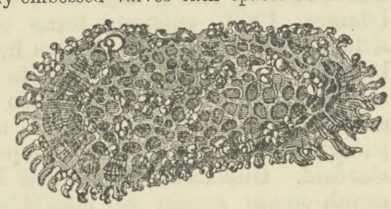

FIG. 2.—*Cythereis ornata* (G. W. Müller). One eye-space is shown above on the left.

among other possibilities, that they and the penis in the Cypridinidæ may be alike remnants of a third pair of legs, not homologous with the penis of other Ostracoda (Podocopa included). The furca is, as a rule, a powerful motor organ, and has its laminæ edged with strong teeth (ungues) or setæ, or both. The young, though born with valves, have at first a nauplian body, and pass through various stages to maturity.

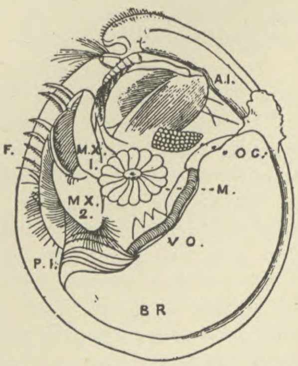

FIG. 3.—*Asterope arthuri*. Left valve removed. M, end of adductor muscle; OC, eye; AI, second antenna; MX. 1, first maxilla; MX. 2, second maxilla; P. 1, first foot; BR, seven branchial leaves; F, projecting ungues of the furca.

Brady and Norman, in their *Monograph of the Ostracoda of the North Atlantic and North-Western Europe*, 1889, give a bibliography of 125 titles, and in the second part, 1896, they give 55 more. The lists are not meant to be exhaustive, any more than G. W. Müller's literature-list of 125 titles in 1894. They do not refer to Latreille, 1802, with whom the term Ostracoda originates.

COPEPODA.—The body is not encased in a bivalved shell; its articulated segments are at most eleven, those behind the genital segment being without trace of limbs, but the last almost always carrying a furca. Sexes separate, fertilization by spermatophores. Ova in single or double or rarely several packets, attached as ovisacs or egg-strings to the genital openings, or enclosed in a dorsal marsupium, or deposited singly or occasionally in bundles. The youngest larvæ are typical nauplii. The next, the copepodid or cyclopid, stage is characterized by a cylindrical segmented body, with fore- and hind-body distinct, and by having at most six cephalic limbs and two pairs of swimming-feet.

The order thus defined (see Giesbrecht and Schmeil, *Das Tierreich*, 1898), with far over a thousand species (Hansen, 1900), embraces forms of extreme diversity, although, when species are known in all their phases and both sexes, they constantly tend to prove that there are no sharply dividing lines between the free-living, the semi-parasitic, and those which in adult life are wholly parasitic and then sometimes grotesquely unlike the normal standard. Giesbrecht and Hansen have shown that the mouth-organs consist of mandibles, first and second maxillæ, and maxillipeds; and Claus himself relinquished his long-maintained hypothesis that the last two pairs were the separated exopods and endopods of a single pair of appendages. Thorell's classification (1859) of Gnathostoma, Pœcilostoma, Siphonostoma, based on the mouth-organs, was long followed, though almost at the outset shown by Claus to depend on the erroneous supposition that the Pœcilostoma were devoid of mandibles. Brady added a new section, Choniostomata, in 1894, and another, Leptostomata, in 1900, each for a single species. Canu in 1892 proposed two groups, Monoporodelphya and Diporodelphya, the copulatory openings of the female being paired in the latter, unpaired in the former. It may be questioned whether this distinction, however important in itself, would lead to a satisfactory grouping of families. In the same year Giesbrecht proposed his division of the order into Gymnoplea and Podoplea.

In appearance an ordinary Copepod is divided into fore- and hind-body, of its eleven segments the composite first being the head, the next five constituting the thorax, and the last five the abdomen. The coalescence of segments, though frequent, does not after a little experience materially confuse the counting. But there is this peculiarity, that the middle segment is sometimes continuous with the broader fore-body, sometimes with the narrower hind-body. In the former case the hind-body, consisting only of the abdomen, forms a pleon or tail-part devoid of feet, and the species so constructed are Gymnoplea, those of the naked or footless pleon. In the latter case the middle segment almost always carries with it to the hind-body a pair of rudimentary limbs, whence the term Podoplea, meaning species that have a pleon with feet. It may be objected that hereby the term pleon is used in two different senses, first applying to the abdomen alone and then to the abdomen plus the last thoracic segment. Even this verbal flaw would be obviated if Giesbrecht could prove his tentative hypothesis, that the Gymnoplea may have lost a pre-genital segment of the abdomen, and the Podoplea may have lost the last segment of the thorax. The classification is worked out as follows:—

1. *Gymnoplea.*—First segment of hind-body footless, bearing the orifices of the genital organs (in the male unsymmetrically placed); last foot of the fore-body in the male a copulatory organ; neither, or only one, of the first pair of antennæ in the male geniculating; cephalic limbs abundantly articulated and provided with many plumose setæ; heart generally present. Animals usually free-living, pelagic (Giesbrecht and Schmeil).

This group, with 65 genera and four or five hundred species, is divided by Giesbrecht into tribes:—(*a*) Amphaskandria. In this tribe the males have both antennæ of the first pair as sensory organs. There is but one family, the Calanidæ, but this is a very large one, with 26 genera and more than 100 species. Among them is the cosmopolitan *Calanus finmarchicus*, the earliest described (by Bishop Gunner in 1770) of all the marine free-swimming Copepoda. Among them also is the peacock Calanid, *Calocalanus*

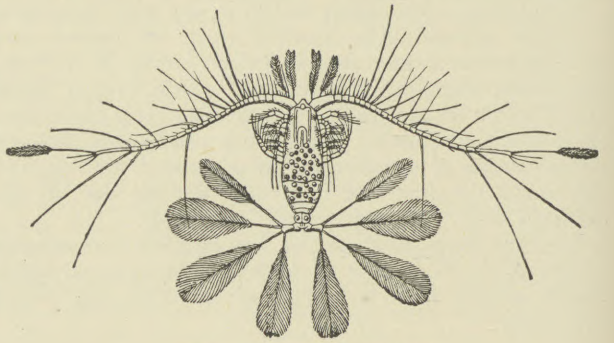

FIG. 4.—*Calocalanus pavo* (Dana).

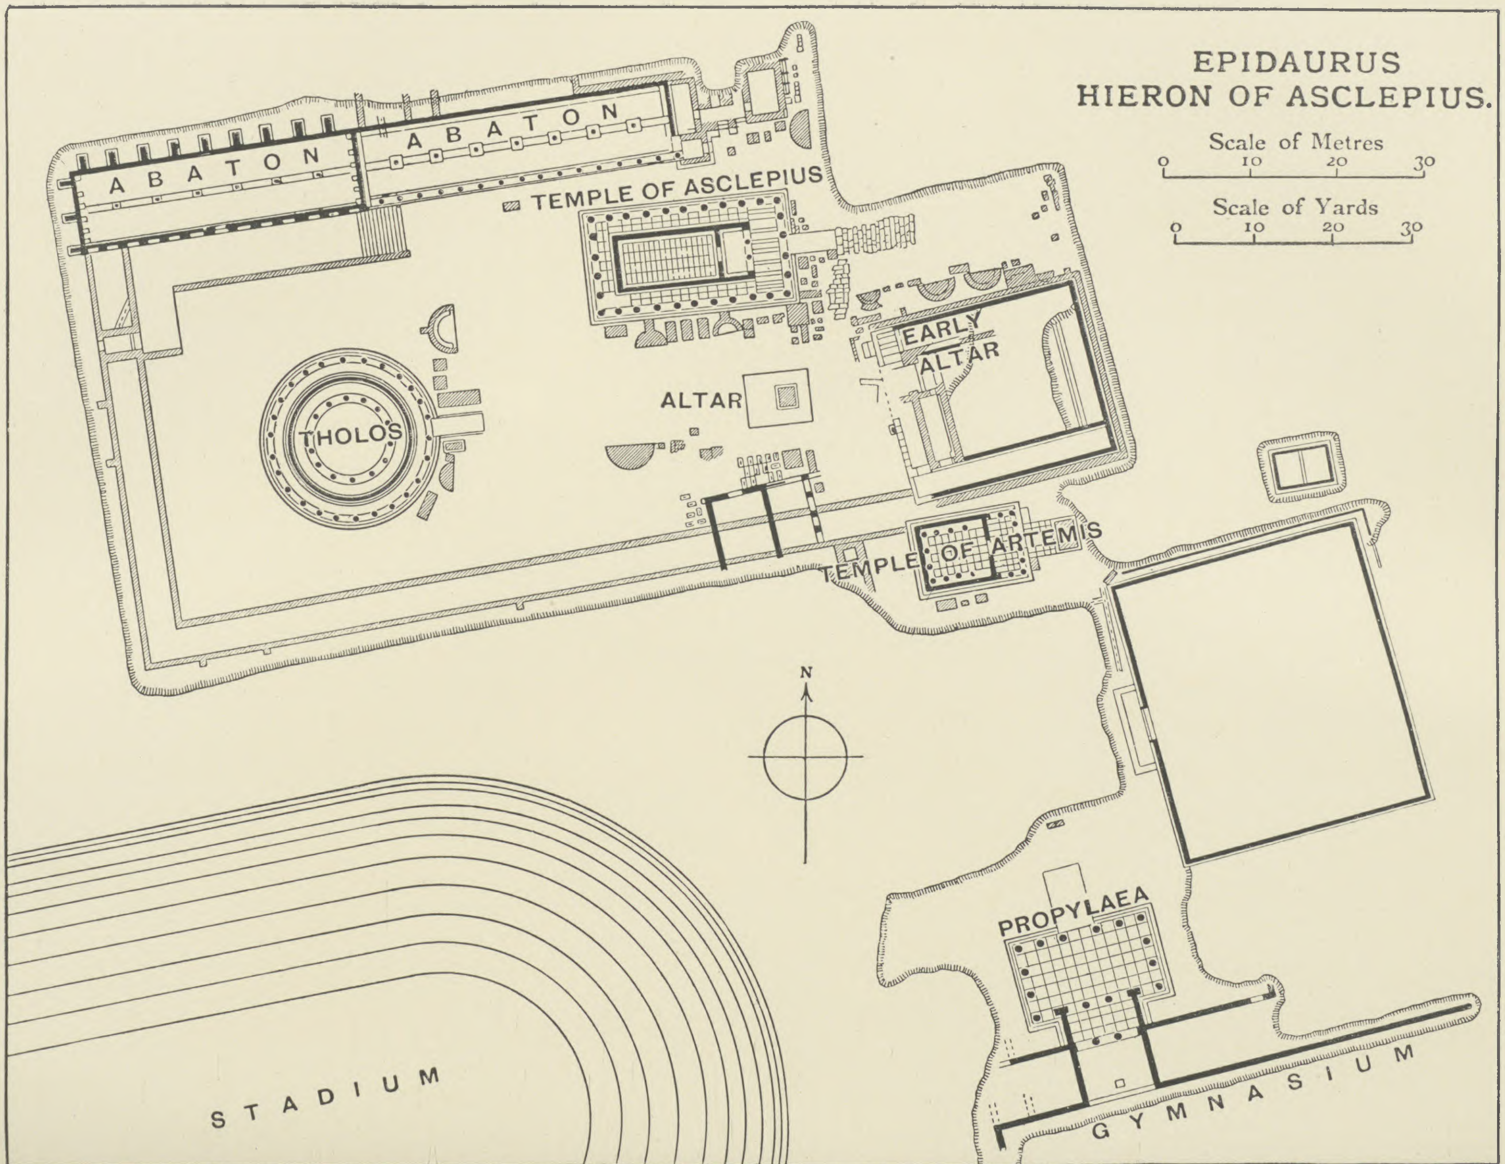
pavo (Dana), with its highly ornamented antennæ and gorgeous tail, the most beautiful species of the whole order (Fig. 4). (*b*) Heterarthrandria. Here the males have one or the other of the first pair of antennæ modified into a grasping organ for holding the female. There are four families, the Diaptomidæ with 27 genera, the Pontellidæ with 10, the Pseudocyclopidæ and Candaciidæ each with one genus. The first of these families is often called Centropagidæ, but, as Sars has pointed out, *Diaptomus* (Westwood, 1836) is the oldest genus in it. Of 177 species valid in the family Giesbrecht and Schmeil assign 67 to *Diaptomus*. In regard to one of its species Dr Brady says: "in one instance, at least (Talkin Tarn, Cumberland), I have seen the net come up from a depth of 6 or 8 feet below the surface with a dense mass consisting almost entirely of *D. gracilis*." The length of this net-filling species is about a twentieth of an inch.

2. *Podoplea.*—The first segment of the hind-body almost always with rudimentary pair of feet; orifices of the genital organs (symmetrically placed in both sexes) in the following segment; neither the last foot of the fore-body nor the rudimentary feet just mentioned acting as a copulatory organ in the male; both or neither of the first pair of antennæ in the male geniculating; cephalic limbs less abundantly articulated and with fewer plumose setæ or none, but with hooks and clasping setæ. Heart almost always wanting. Free-living (rarely pelagic) or parasitic (Giesbrecht and Schmeil).

This group is also divided by Giesbrecht into two tribes, Ampharthrandria and Isokerandria. In 1892 he distinguished the former as those in which the first antennæ of the male have both members modified for holding the female, and the genital openings of the female have a ventral position, sometimes in close proximity, sometimes strongly lateral; the latter as those in which the first antennæ of the male are similar to those of the female, the function of holding her being transferred to the male maxillipeds, while the genital openings of the female are dorsal,



Walker & Cockerell sc.

though at times strongly lateral. In 1899, with a view to the many modifications exhibited by parasitic and semi-parasitic species, the definitions, stripped of a too hampering precision, took a different form :—(*a*) Ampharthrandria. "Swimming Podoplea with geniculating first antennæ in the male sex, and descendants of such ; first antennæ in female and male almost always differently articulated." The families occupy fresh water as well as the sea. Naturally "descendants" which have lost the characteristic feature of the definition cannot be recognized without some further assistance than the definition supplies. Of the families comprised, the Mormonillidæ consist only of *Mormonilla* (Giesbrecht), and are not mentioned by Giesbrecht in 1899 in the grouping of this section. The Thaumatoessidæ include *Thaumatoessa* (Kröyer), established earlier than its synonym *Thaumaleus* (Kröyer), or than *Monstrilla* (Dana, 1849). The species are imperfectly known. The defect of mouth-organs probably does not apply to the period of youth, which some of them spend parasitically in the body-cavity of worms (Giard, 1896). To the Cyclopidæ six genera are allotted by Giesbrecht in 1900. *Cyclops* (O. F. Müller, 1776), though greatly restricted since Müller's time, still has several scores of species abundantly peopling inland waters of every kind and situation, without one that can be relied on as exclusively marine like the species of *Oithona* (Baird). The Misophriidæ are now limited to *Misophria* (Boeck). The presence of a heart in this genus helps to make it a link between the Podoplea and Gymnoplea, though in various other respects it approaches the next family. The Harpacticidæ owe their name to the genus *Arpacticus* (Milne-Edwards, 1840). Brady in 1880 assigns to this family 33 genera and 81 species. Canu (1892) distinguishes eight sub-families, Longipediinæ, Peltidiinæ, Tachidiinæ, Amymoninæ, Harpacticinæ, Idyinæ, Canthocamptinæ (for which Canthocampinæ should be read), and Nannopinæ, adding Stenheliinæ (Brady) without distinctive characters for it. The Ascidicolidæ have variable characters, showing a gradual adaptation to parasitic life in Tunicates. Giesbrecht (1900) considers Canu quite right in grouping together in this single family those parasites of ascidians, simple and compound, which had been previously distributed among families with the more or less significant names Notodelphyidæ, Doropygidæ, Buproridæ, Schizoproctidæ, Kossmechtridæ, Enterocolidæ, Enteropsidæ. Further, he includes in it his own *Enterognathus comatulæ*, not from an ascidian, but from the intestine of the beautiful starfish *Antedon rosaceus*. The Asterocheridæ, which have a good swimming capacity, except in the case of *Cancerilla tubulata* (Dalyell), lead a semi-parasitic life on echinoderms, sponges, &c., imbibing their food. Giesbrecht, displacing the older name Ascomyzontidæ, assigns to this family 21 genera in five subfamilies, and suggests that the long-known but still puzzling *Nicothoë* from the gills of the lobster might be placed in an additional subfamily, or be made the representative of a closely related family. The Dichelestiidæ, on account of their sometimes many-jointed first antennæ, are referred also to this tribe by Giesbrecht. (*b*) Isokerandria. "Swimming Podoplea without geniculating first antennæ in the male sex, and descendants of such. First antennæ of male and female almost always articulated alike." To this tribe Giesbrecht assigns the families Clausidiidæ, Corycæidæ, Oncæidæ, Lichomolgidæ, Ergasilidæ, Bomolochidæ, Clausiidæ, Nereicolidæ. Here also must for the time be placed the Caligidæ, Philichthyidæ (Philichthydæ of Vogt, Carus, Claus), Lernæidæ, Chondracanthidæ, Sphæronellidæ (better known as Choniostomatidæ, from H. J. Hansen's remarkable study of the group), Lernæopodidæ, Herpyllobiidæ, Entomolepidæ. For the distinguishing marks of all these, the number of their genera and species, their habits and transformations and dwellings, the reader must be referred to the writings of specialists. Sars (1901) proposed seven suborders—Calanoida, Harpacticoida, Cyclopoida, Notodelphoida, Monstrilloida, Caligoida, Lernæoida.

Epidaurus.—*Recent Archæological Discoveries.*—The Hieron of Asclepius, which lies inland about 8 miles from the town of Epidaurus, has been thoroughly excavated by the Greek Archæological Society since the year 1881, under the direction of M. Cavvadias. In addition to the sacred precinct, with its temples and other buildings, the theatre and stadium have been cleared; and several other extensive buildings, including baths, gymnasia, and a hospital for invalids, have also been found. The sacred road from Epidaurus, which is flanked by tombs, approaches the precinct through a gateway or propylæa. The chief buildings are grouped together, and include temples of Asclepius and Artemis, the Tholos, and the Abaton, or portico where the patients slept. In addition to remains of architecture and sculpture, some of them of high merit, there have been found many inscriptions, throwing light on the cures attributed to the god. The chief buildings outside the sacred precinct are the theatre and the stadium.

The temple of Asclepius, which contained the gold and ivory statue by Thrasymedes of Paros, had six columns at the ends and eleven at the sides; it was raised on stages and approached by a ramp at the eastern front. An inscription has been found recording the contracts for building this temple; it dates from about 460 B.C. The sculptor Timotheus—one of those who collaborated in the Mausoleum—is mentioned as undertaking to make the acroteria that stood on the ends of the pediments, and also models for the sculpture that filled one of them. Some of this sculpture has been found; the acroteria are Nereids mounted on sea-horses, and one pediment contained a battle of Greeks and Amazons. The great altar lay to the south of the temple, and a little to the east of it are what appear to be the remains of an earlier altar, built into the corner of a large square edifice of Roman date, perhaps a house of the priests. Just to the south of this are the foundations of a small temple of Artemis. The Tholos lay to the south-west of the temple of Asclepius; it must, when perfect, have been one of the most beautiful buildings in Greece; the exquisite carving of its mouldings is only equalled by that of the Erechtheum at Athens. It consisted of a circular chamber, surrounded on the outside by a Doric colonnade, and on the inside by a Corinthian one. The architect was Polyclitus, probably to be identified with the younger sculptor of that name. In the inscription recording the contracts for its building it is called the Thymele; and this name may give the clue to its purpose; it was probably the idealized architectural representative of a primitive pit of sacrifice, such as may still be seen in the Asclepianum at Athens. The foundations now visible present a very curious appearance, consisting of a series of concentric walls. Those in the middle are thin, having only the pavement of the cella to support, and are provided with doors and partitions that make a sort of subterranean labyrinth. There is no evidence for the statement sometimes made that there was a well or spring below the Tholos. North of the Tholos is the long portico described in inscriptions as the Abaton; it is on two different levels, and the lower or western portion of it had two storeys, of which the upper one was on a level with the ground in the eastern portion. Here the invalids used to sleep when consulting the god, and the inscriptions found here record not only the method of consulting the god, but the manner of his cures. Some of the inscriptions are contemporary dedications; but those which give us most information are long lists of cases, evidently compiled by the priests from the dedications in the sanctuary, or from tradition. There is no reason to doubt that most of the records have at least a basis of fact, for the cases are in accord with well-attested phenomena of a similar nature at the present day; but there are others, such as the miraculous mending of a broken vase, which suggest either invention or trickery.

In early times, though there is considerable variety in the cases treated and the methods of cure, there are certain characteristics common to the majority of the cases. The patient consulting the god sleeps in the Abaton, sees certain visions, and, as a result, comes forth cured the next morning. Sometimes there seem to be surgical cases, like that of a man who had a spear-head extracted from his jaw, and found it laid in his hands when he awoke in the morning, and there are many examples resembling those known at the present day at Lourdes or Tenos, where hysterical or other similar affections are cured by the influence of imagination or sudden emotion. It is, however, difficult to make any scientific use of the records, owing to the indiscriminate manner in which genuine and apocryphal cases are mingled, and circumstantial details are added. We learn the practice of later times from some dedicated inscriptions. Apparently the old faith-healing had lost its efficacy, and the priests substituted for it elaborate prescriptions as to diet, baths, and regimen which must have made Epidaurus and its visitors resemble their counterparts in a modern spa. At this time there were extensive buildings provided for the accommodation of invalids, some of which have been discovered and partially cleared; one was built by Antoninus Pius. They were in the form of great courtyards surrounded by colonnades and chambers.

Between the precinct and the theatre was a large gymnasium, which was in later times converted to other purposes, a small odeum being built in the middle of it. In a valley just to the south-west of the precinct is the stadium, of which the seats and goal are well preserved. There is a gutter round the level space of the stadium, with basins at intervals for the use of spectators or competitors, and a post at every hundred feet of the course, thus dividing it into six portions. The goal, which is well preserved at the upper end, is similar to that at Olympia; it consists of a sill of stone sunk level with the ground, with parallel grooves for the feet of the runners at starting, and sockets to hold the posts to which were fixed the strings that separated the tracks assigned to the various competitors. For these were submitted later a set of stone columns resembling those in the proscenium of a theatre. There was doubtless a similar sill at the lower end for the start of the stadium, this upper one being intended for the start of the diaulos and longer races.

The theatre still deserves the praise given it by Pausanias as the most beautiful in Greece. The auditorium is in remarkable preservation, almost every seat being still *in situ*, except a few where the supporting walls have given way on the wings. The whole plan is drawn from three centres, the outer portion of the curves being arcs of a larger circle than the one used for the central portion; the complete circle of the orchestra is marked by a sill of white limestone, and greatly enhances the effect of the whole. There are benches with backs not only in the bottom row, but also above and below the diazoma. The acoustic properties of the theatre are extraordinarily good, a speaker in the orchestra being heard throughout the auditorium without raising his voice. The stage buildings are not preserved much above their foundations, and show signs of later repairs; but their general character can be clearly seen. They consist of a long rectangular building, with a proscenium or column front which almost forms a tangent to the circle of the orchestra; at the middle and at either end of this proscenium are doors leading into the orchestra, those at the end set in projecting wings; the top of the proscenium is approached by a ramp, of which the lower part is still preserved, running parallel to the parodi, but sloping up as they slope down. The proscenium was originally about 14 feet high and 12 feet broad; so corresponding approximately to the Greek stage as described by Vitruvius. M. Cavvadias, who excavated the theatre, believes that the proscenium is contemporary with the rest of the theatre, which, like the Tholos, was built by Polyclitus (the younger); but Professor Dörpfeld maintains that it is a later addition. In any case, the theatre at Epidaurus ranks as the most typical of Greek theatres, both from the simplicity of its plan and the beauty of its proportions.

The excavations at Epidaurus have been recorded as they went on in the Πρακτικὰ of the Greek Archæological Society, especially for 1881–84 and 1889, and also in the Ἐφημερὶς Ἀρχαιολογική, especially for 1883 and 1885; see also Cavvadias, *Les fouilles d'Épidaure* and Τὸ Ἱερὸν τοῦ Ἀσκληπιοῦ ἐν Ἐπιδαύρῳ καὶ ἡ θεράπεια τῶν ἀσθενῶν; Defrasse and Lechat, *Épidaure*. (E. GR.)

Epsom, a market-town in the Epsom parliamentary division of Surrey, England, 15 miles south-west by south of London by rail. Recent erections are Christ Church (rebuilt), a town-hall, a cottage hospital, and a technical and art school. The Royal Medical Benevolent College has been enlarged. Area of urban district, 4424 acres. Population (1881), 6916; (1901), 10,915.

Erckmann-Chatrian, the joint names of two French writers whose collaboration made their work that of, so to speak, one personality. Émile Erckmann was born in 1822 at Phalsbourg, and Alexandre Chatrian in 1826 at Soldatenthal, Lorraine. In 1847 they began to write together, and continued doing so till 1889. Chatrian died in 1890 at Villemomble, and Erckmann at Lunéville in 1899. The list of their publications is a long one, ranging from *L'illustre docteur Mathéus* (1859), *L'ami Fritz* (1864), *Histoire d'un conscrit de 1813* (1864), *Waterloo* (1865), *Le blocus* (1867), *Histoire d'un Paysan* (1868), *L'histoire d'un plébiscite* (1872), to *Le grand-père Lebigre* (1880); besides dramas like *Le Juif Polonais* (1869), and *Les Rantzau* (1882). Without any special literary claim, their stories are distinguished by simplicity and genuine descriptive power, particularly in the battle scenes and in connexion with Alsatian peasant life, and also by their democratic spirit, to which was added, after the war of 1870, a markedly anti-German feeling.

Erdmann, Johann Eduard (1805–1892), German philosophical writer, was born at Wolmar in Livonia, 13th June 1805. He studied theology at Dorpat and afterwards at Berlin, where he fell under the influence of Hegel. From 1829 to 1832 he was a minister of religion in his native town; then finally resolved to devote himself to philosophy, and qualified in that subject at Berlin in 1834. In 1836 he was professor-extraordinary at Halle, became full professor in 1839, and died there 12th June 1892. He published many philosophical textbooks and treatises, and a number of sermons; but his chief claim to remembrance rests on his *Darstellung der Geschichte der Philosophie*, 3 vols. (1834–53), which has been translated into English, and is still the best work of the kind. Erdmann's special merit is that he does not rest content with being a mere summarizer of opinions, but tries to exhibit the history of human thought as a continuous and ever-developing effort to solve the great speculative problems with which man has been confronted in all ages. (H. ST.)

Erfurt, a town of Prussia, province of Saxony, 73 miles by rail south-west from Leipzig and 14 miles west from Weimar. On the west and south-west extensive new quarters have grown up within recent years—*e.g.*, Hirschbrühl. The town-hall (1869–75) has been adorned with legendary and historical pictures by Kämpffer and Janssen. Erfurt possesses also a picture gallery, library, antiquarian collection (in the hospital), musical academy, agricultural school, commercial school, and shoemaking school; also, a monument to Luther (1890). On the west side the old town is dominated by the two citadels of Petersberg and Cyriaxburg. The chief industry is still market-gardening and the production of vegetable and flower seeds. There is also a trade of some magnitude. Population (1885), 58,386; (1900), 85,828.

Erichsen, Sir John Eric, Bart. (1818–1896), British surgeon, born 19th July 1818, was the son of Eric Erichsen, a member of a well-known Danish family. He studied medicine at University College, London, and at Paris, devoting himself in the early years of his career to physiology, and lecturing on General Anatomy and Physiology at University College Hospital. In 1844 he was secretary to the Physiological Section of the British Association, and in 1845 he was awarded the Fothergillian Gold Medal of the Royal Humane Society for his essay on Asphyxia. In 1848 he was appointed Assistant Surgeon at University College Hospital, and in 1856 became full Surgeon, his lectures and clinical teaching being much admired; and in 1875 he joined the Consulting Staff. His *Science and Art of Surgery* (1853) went through many editions. He rose to be President of the College of Surgeons in 1880. From 1879 to 1881 he was President of the Royal Medical and Chirurgical Society. He was created a baronet in 1895, having been for some years Surgeon-Extraordinary to Queen Victoria. As a surgeon his reputation was world-wide, and he counts (says Sir W. MacCormac in his volume on the Centenary of the Royal College of Surgeons) "among the masters of modern surgery." He was a recognized authority on concussion of the spine, and was often called to give evidence in court on obscure cases caused by railway accidents, &c. He died 23rd September 1896.

Ericsson, John (1803–1889), naval engineer, was born at Langbanshyttan, Wermland, Sweden, on the 31st July 1803. He was the second son of Olaf Ericsson, an inspector of mines. Showing from his earliest years a strong mechanical bent, at the age of nine he was already skilled in the use of drawing instruments, and had made a very ingenious working model of a saw mill driven by water-power. At twelve he was employed as a draughtsman by the Swedish Canal Company, and at thirteen as an assistant leveller. The death of his father in 1818 left the family in very straitened circumstances; and though from 1820 to 1827 young Ericsson served in the army and attained the rank of captain, he was all the time working also as a draughtsman, and occupying his leisure with projects of invention. In 1826 he went to London, at first on leave of absence from his regiment, and in partnership with John Braithwaite constructed the "Novelty," a locomotive engine for the Liverpool and Manchester Railway competition at Rainhill in 1829, when the prize was won by Stephenson's "Rocket." In 1830 the firm constructed a steam fire-engine, which was proved at different fires to be effective, though prejudice for the time prevented it from coming into general use. The number of Ericsson's inventions at this period was very great. Among other things he worked out a plan for marine engines placed entirely below the water-line. Such engines were made for the *Victory*, for Captain Ross's voyage to the Arctic in 1829, but they did not prove satisfactory. In 1833 his caloric engine was made public. In 1836 he took out a patent for a screw-propeller, and though the priority of his invention could not be maintained, he was afterwards awarded a one-fifth share of the £20,000 given by the Admiralty for it. At this time he made the acquaintance of Captain Stockton, of the United States Navy, who gave an order for a small iron vessel to be built by Laird of Birkenhead, and to be fitted by Ericsson with engines and screw. This vessel reached New York in May 1839, thus giving a practical proof of the possibility of screw propulsion in the open sea. A few months later Ericsson followed his steamer to New York, and there he resided for the rest of his life, establishing himself as an engineer and a builder of iron ships. In 1848 he was naturalized as a citizen of the United States. He had many difficulties to contend with; he quarrelled with Stockton, for whom he had worked on an "understanding" without any definite agreement, and the Government denied his claims and left him a loser both in money and in credit. It was only by slow degrees that he established his fame and won his way to competence. Fortune, as it is understood in the United States, he never reached; at his death he seems to have been worth about £50,000. He was always busy over new ideas, attempting the solution of problems which were engaging the attention of many others. At one of these, the provision of defensive armour for ships of war, he had long worked, and had constructed plans and a model of a vessel lying low in the water, carrying one heavy gun in a circular turret mounted on a turn-table. His priority in this idea seems established. In 1854 he sent his design to the Emperor of the French, hoping that it might prove of use against the Russians, whom he regarded as the natural enemies of his native country. Louis Napoleon returned the plans with thanks, but declined to use them, being guided in this, we may suppose, by the skilled opinion of Dupuy de Lôme. They were then put on one side, till the American Civil War, and the report that the Confederates were converting the *Merrimac* into an ironclad, caused the Navy Department to invite proposals for the construction of armoured ships. Among others, Ericsson replied, and as it was thought that his design might be serviceable in inland waters, the first armoured turret ship, the *Monitor*, was ordered; she was launched on the 30th January 1862, and on the 9th March she fought the celebrated action with the Confederate ram *Merrimac*. The peculiar circumstances in which she was built, the tremendous importance of the battle, and the decisive nature of the result gave the *Monitor* an exaggerated reputation, which further experience did not confirm. Other turret ships were built and answered the immediate purpose; nine built for the United States proved of great service during the war, one crossed the Atlantic, and another rounded Cape Horn and reached San Francisco; but as seagoing vessels they were judged unsafe, and are now considered impracticable. Ericsson's work was marked by great ingenuity, but in no case does he seem to have attained an entirely satisfactory result, though his inventions served as finger-posts for others' guidance. In later years he devoted himself to the study of torpedoes and sun motors. He died at New York on 8th March 1889, and in the following year, on the request of the Swedish Government, his body was sent to Stockholm and thence into Wermland, where, at Filipstad, it was buried on the 15th September.

Ericsson's life has been written at length by William Conant Church, who had access to his letters and papers, and was personally acquainted both with him and his most intimate associates.

(J. K. L.)

Erie, capital of Erie county, Pennsylvania, U.S.A., in 42·07° N. lat. and 80·10° W. long., on the shore of Lake Erie, at an altitude of 684 feet. It is the only lake port of Pennsylvania, and has a large lake commerce, in grain, lumber, and iron ore as imports, and coal as an export. It is entered by four railways, the Lake Shore and Michigan Southern, the New York, Chicago, and St Louis, the Pennsylvania, and the Pittsburg, Bessemer, and Lake Erie, which give it great importance in inland traffic. It has an excellent water supply and sewerage system, and it is divided into six wards; the streets of the central part are paved with brick and asphalt. Its manufactures had in 1890 a capital of $12,800,000, employed 7029 hands, and had products valued at $12,765,768. One-third of these were foundry and machine-shop products, besides which flour and lumber were of great importance. The assessed valuation of property, real and personal, was, in 1900, $19,657,488; the net debt was but $765,040, and the rate of taxation was $24.00 per $1000. Population (1880), 27,737; (1900), 52,733. Death-rate (1900), 15·2.

Erith, a town in the Dartford parliamentary division of Kent, England, on the Thames, 14 miles east-south-east of London by rail. The churches are two Established, one ancient in Early English and later styles of architecture, containing ancient monuments and brasses, Roman Catholic, and various Nonconformist chapels. There is a public hall, a recreation ground (12 acres), and a sanatorium for infectious diseases. In the parish are the southern outfall works of the metropolitan main drainage system. The town has large engineering works and gun factories, and in the neighbourhood are powder works. Area of civil parish (an urban district), 3860 acres. Population (1881), 9812; (1901), 25,296.

Eritrea.—Under this name, which Italian taste for classical reminiscences resuscitated at the beginning of 1890, are designated the Italian possessions on the west coasts of the Red Sea and on the most northerly spurs of the Ethiopian high plateau. Originally the name covered both the territories really occupied and those over which a protectorate was claimed, but now Italy exercises suzerainty over all. It extends on the coast from Ras (Cape) Kasar (18° 2′ N. lat.), the limit fixed by the Anglo-Italian agreement of 1887, as far as Ras Dumeira (12° 42′ N. lat.), the southern boundary, settled by the Franco-Italian convention of January 1900, a coast-line of about 620 miles. In the vicinity of Ras Dumeira the territory extends inland for 38 miles, but to the north, towards Abyssinia, its boundary is marked by the torrents Muna and Belesa, and by the river Mareb as far west as the village of Mai Darò, whence it runs in a straight line to Tomat, a hut encampment situated at the confluence of the Setit and the Atbara. Towards the Sudan the frontier, as delimitated by the Anglo-Italian agreements of 1898–99, follows the watershed between the rivers Gash and Barka, and, on approaching the coast, crosses the northern slopes of the Haggar Nush plateau and follows the *Thalweg* of the torrent Carora to Ras Kasar. The Dahlak Archipelago and other groups of islands along the coast belong to Eritrea. The inhabitants of these islands live by fishing for mother-of-pearl, and the pearl-bearing oyster. The control of the fisheries is entrusted to a special company. The total area is about 88,500 square miles. The population is approximately 400,000, of which 1050 are whites, exclusive of soldiers. The inhabitants belong to many different tribes and races, much akin to those of Abyssinia (*q.v.*). Most of the tribes descend more or less directly from Ethiopian stock, and retain evident traces of their origin in their dialects.

Climate.—The climate is varied. The plateau, of which the average height is 6500 feet, but which at places rises to 10,000 feet (Sauria), the valleys of the Anseba and the Barka, and the lower course of the Mareb (or Gash) follow in their seasons the Ethiopian monsoon; some rain falls at the end of April, and abundant rain from June to September. The zone between the sea and 6500 feet has, on the other hand, abundant rain from November till March. At 6500 feet the temperature is mild, and grows cooler with increased altitude until, at 10,000 feet, it becomes almost cold. From the height of 3000 feet downwards the climate is torrid during the greater part of the year, and only becomes tolerable during the winter rains. In this zone malarial fevers prevail in winter. The heat is greatest at Massawa, where the mean temperature averages 88°, but where, in summer, the thermometer often rises to 120° in the shade. In the Barka Valley a like temperature is reached, but there it is rendered less trying by the breeze, the dry atmosphere, and the great difference between the temperatures of day and night.

Crops and Cultivation.—Almost all European cereals flourish on the high plateau, while the olive tree grows at more than 6500 feet, and covers the flanks of the plateau to within 3000 feet of sea-level. Lower down, *dhurra*, maize, and bultuc grow in profusion. Experiments in the cultivation of coffee, tobacco, and cotton have given good results in the intermediate zones. The fauna is similar to that of Abyssinia. Except for a short tract of land near the coast, and the locality of Sheb on the caravan route from Massawa and Monkullo to Keren, no part can be called a desert (atmur); but in the lower regions there are wide tracts, covered with mimosa and acacia trees, forming a kind of jungle which the natives term *khala*. The Danakil, Samhar, and Barka plains are broken by small chains of hills running in various directions; the torrents are covered by dense vegetation, and, especially in the Barka region, by the dum palm; in the dry season water is generally to be found in the torrent beds. The high plateau has a more fertile appearance. It is covered by rich, well-watered valleys, verdant plains and flat-topped hills with steep sides running in ranges or isolated.

Inhabitants.—The Mussulman inhabitants of the lower zone are for the most part semi-nomad shepherds, living on *dhurra* and milk; the inhabitants of the high zone are almost exclusively Coptic Christians with fixed abodes. They are agriculturists, living in round huts or in low, rectangular, flat-roofed houses. The nomad Mussulmans are, as a rule, docile, submissive, and pacific; the Christians, unruly and bellicose. Neither have succeeded in developing industry to any considerable extent, except mat-weaving, some little cotton-weaving, silver-working, and rudimentary iron and leather-working.

Centres of Population.—The principal places *on the coast* are Massawa, a city of more than 12,000 native and European inhabitants, built partly upon an island of the same name, partly on the island of Taudub, and partly on the small peninsula of Gherar and Abd-el-Kader. Formerly seat of the colonial government, it is now only the capital of the region between the sea and the lower slopes of the high plateau. It is well built in brick, is clean, and has considerable trade with the interior and with the other Red Sea ports. Assab, chief town of the Dankali region, is a small town to which converges the trade from Abyssinia across the Aussa country. The chief places *in the interior* are Asmarà, the present capital, formerly capital of the province of Hamasien, and favourite headquarters of Ras Alula. It is situated at nearly 6500 feet above the sea, and is beginning to assume the aspect of a European town. Several reefs of auriferous quartz of good promise have been found around it. Keren, centre of the tribal villages established to the north of the Anseba; Agordat, on the river Barka, a town on the road from Keren to Kassala, the centre of the Beni-Amer, Algheden and Sabdarat tribes; Mogolo, on the lower Mareb, rendezvous of the Barià and Bazà tribes. Towards Abyssinia the chief towns are Saganeiti (capital of the Okulé-Kusai province), Godofelassi and Adi-Ugri, the two latter situated in the fertile plain of the Seraè; Adiqualà, on the edge of the Mareb gorge; and Arrasà, the centre of the districts constituting the province of Deki-Tesfà. The whole territory is crossed by camel- and mule-paths between the sea and the high plateau and between various centres of population. Every valley that brings water to the Red Sea has a route leading to the high plateau. The great arteries, however, can be reasonably reduced to three, which, starting from Massawa by way of Asmarà, run, two to Abyssinia, and one to Kassala and Khartum. They are all more or less practicable for carts, and are flanked by a good telegraph line as long as they lie in Italian territory. The trade is indicated approximately by the Massawa harbour returns, which show an annual traffic (imports and exports) of £1,000,000. At Massawa there is a customs house, with branches at Assab, Edd, Meder, Mersa, Taclai, and Sabdarat.

Administration.—Eritrea is administered by a civil governor with a corps of colonial officers and clerks. It is divided into six provinces, each governed by a regional commissioner. Some tracts of frontier territory are detached from the various regions and entrusted to political residents, as, for instance, on the Abyssinian boundary, where strict surveillance is necessary to repress raiding incursions from Tigrè, and where the chief Intelligence Department is established. The six regions or principal provinces are:—Asmarà, which includes Hamasien and other small districts; Keren, which comprises the high territories to the north of the Anseba; Massawa, extending over all the tribes between the high plateau and the sea from the Habab to the Danakils; Assab, which extends from Edd to Raheita; Okulé-Kusai; Seraè, including Deki-Tesfà. The political residences are at present only three, namely, Shimenzana, which governs the district of the same name, and other small districts along the Belesà; Adiquala, having jurisdiction over the boundary from the Mareb-Belesà confluence to Mai Darò; the Barià, which governs that tribe as well as the Bazà, and watches over the lower course of the Mareb and over the frontier as far as Tomat. The regional commissioners and the political residents act either by means of the village headmen (*Shum* or *Chicca*); the chiefs of districts in the few localities where villages are still organized in districts; or by the headmen of tribes, and by the Councils of the Elders wherever these remain in vigour.

Justice.—Civil justice for natives is administered, in the first instance, by the headmen of villages, provinces, tribes, or Councils of Notables (*Shumagallè*); in Appeal, by the residents, regional commissioners, and regional tribunals, and, in the last instance, by the Colonial Court of Appeal. Europeans are under the jurisdiction of the commissioners, residents, regional tribunals, and Court of Appeal. Penal justice is administered by Italian judges only. An administrative tribunal settles, without appeal, questions of tribute, disputes concerning family, village, or tribal landmarks, as well as suits involving the colonial government. The civil laws for the natives are those established by local usage. Europeans are answerable to the Italian civil code. Penal laws are the same as in Italy, except where modified by local usages. Appeal to the Rome Court of Cassation is admitted against all penal and civil sentences. A company of Royal Carabineers, consisting partly of Italians and partly of natives, is entrusted with police service. The company is divided into the lieutenancies of Asmarà, Saganeiti, and Massawa, and subdivided into some twenty stations.

Defence.—Defence is entrusted to a corps of colonial troops, partly Italian and partly native; to a militia (*milizia mobile*) formed by natives who have already served in the colonial corps; and to the *chitet* or general levy which, in time of war, places all male able-bodied inhabitants under arms. The regional commissioners and political residents have at their disposal some hundreds of irregular, paid soldiers under native chiefs. In war time these irregulars form part of the colonial corps, but in time of peace serve as frontier police. The colonial corps is commanded by an Italian colonel. It is composed of (1) three companies of African light infantry (*Cacciatori d'Africa*), composed exclusively of Italians, and stationed at Asmarà, Keren, and Saganeiti, with a detachment at Massawa; (2) six battalions of native regulars, of which two battalions are stationed at Asmarà, one at Adi Cajeh, one at Saganeiti, one at Adi Ugri, one at Keren, with a company at Agordat; (3) a squadron of native cavalry stationed at Godofellassi; (4) two native batteries (six guns) of mountain artillery, one stationed at Keren and the other at Asmarà; (5) a native gunner company divided between Keren, Saganeiti, and Asmarà; (6) an engineer company with headquarters at Asmarà and detached sections at Keren and Saganeiti; (7) a train company with headquarters at Asmarà, and detachments at Ghinda and Saganeiti. All these troops have Italian cadres. They constitute a total force of about 6000 men. The irregular troops, on foot, or mounted on camels, at the disposal of the regional commissioners and political residents number about 1000 men. The militia, whose members are registered by name, consists of 3500 men of all arms, and is intended in time of war to reinforce the various divisions of the colonial corps, while any surplus constitutes a special division under Italian officers who are chosen for that command in time of peace. The *chitet* yields between 3000 and 4000 men, to be employed on the lines of communication or in caravan service. All these troops are intended to ward off a first attack, so as to allow time for the arrival of reinforcements from Italy. The customs and political surveillance along the coast is entrusted, afloat, to the Massawa naval station, and, ashore, to a coastguard company 400 strong stationed at Meder, with detachments at Assab, Massawa, Raheita, Edd, and Taclai.

Budget.—The administration and defence cost annually about £400,000, of which three-fourths are paid by the Italian Exchequer and one-fourth by the inhabitants. This expenditure has been much exceeded in the past, but may now and for the future be considered the normal *maximum*. Indeed, one-tenth of the £400,000 is available for useful public works. In the past the internal revenue has been small, on account of insecurity and of the wars against the Abyssinians and the Dervishes; but now, with the restoration of peace and tranquillity, tribute returns are constantly increasing, so that the contribution of the home exchequer will probably be progressively reduced. When all the resources have been explored and developed, and trade resumed with Northern Abyssinia—now suspended by the anarchy existing in Tigrè—its prosperity will reach a level corresponding to the fertility of its soil, the habits of its people, and the position of its ports on the Red Sea, and Eritrea will gradually cease to be a burden upon the home exchequer.

History.—Traces of the ancient Eritrean civilization are scarce. During the prosperous periods of ancient Egypt, Egyptian squadrons asserted their rule over the west Red Sea coast, and under the Ptolemies the port of Golden Berenice (Adulis ?) was an Egyptian fortress, afterwards abandoned. During the early years of the Roman Empire, Eritrea formed part of an important independent state—that of the Assamites. At the end of the reign of Nero, and perhaps even earlier, the King of the Assamites ruled over the Red Sea coast from Suakin to the strait of Bab el-Mandeb, and traded constantly with Egypt. This potentate called himself "King of Kings," commanded an army and a fleet, coined money, adopted Greek as the official language, and lived on good terms with the Roman Empire. The Assamites belonged originally to the Hamitic race, but the immigration of the Himyaritic tribes of Southern Arabia speedily imposed a new language and civilization. Therefore the ancient Abyssinian language, Gheez, and its living dialects, Amharic and Tigrin, are Semitic, although modified by the influence of the old Agau. Adulis (Adovlis), slightly to the north of Zula, was the chief Assamite port. Several traces remain of this emporium, which a Greek merchant of the time of Vespasian called a "well-arranged market"; namely, the ruins of a temple, fragments of columns and obelisks, and a Greek inscription of an Assamite king (Corpus Inscr. Gr. 51,276). From Adulis started the main road, which led across the high plateau to the capital Axomis (Axum). Along the road are still to be seen vestiges of cities and inscribed monuments, such as the Himyaritic inscriptions on the high plateau of Cohait, the six obelisks with a Saban inscription at Toeonda, and an obelisk with an inscription at Amba Sait. Other monuments exist elsewhere, as well as coins of the Assamite period with Greek and Ethiopian inscriptions. After the rise of the Ethiopian Empire the history of Eritrea is bound up with that of Ethiopia, but not so entirely as to be completely fused. The documents of the Portuguese expedition of the sixteenth century and other Ethiopian records show that all the country north of the Mareb enjoyed relative autonomy under a vassal of the Ethiopian emperor.

Michael, counsellor of Solomon, who was king of the country north of the Mareb, usurped the throne of Solomon during the reign of the Emperor Atziè Jasù II. (1729–1753), and, after proclaiming himself Ras of the Tigrè and "protector of the Empire," ceded the North Mareb country to an enemy of the rightful dynasty. Hence a long struggle between the dispossessed family and the occupants of the North Mareb throne. The Egyptians took advantage of the struggle to seize Keren and the Bogos country. Ras Uddenchiel, who had remained master of the North Mareb district, fought as ally of the Egyptians at Gura, but was betrayed to the Abyssinians and imprisoned upon an amba, or flat-topped mountain (1879), whence he only succeeded in escaping in 1890. In 1879 his territory was given by the Negus Johannes to Ras Alula, who retained it until, in August 1889, the Italians occupied Asmarà.

The purchase of Assab and the neighbouring territory from the Sultan Berehan of Raheita by the Italian Steamship Company Rubattino (1870) formed the nucleus of Italian possessions on the Red Sea. In 1882 the Italian Government took over the rights of the Rubattino Company. On 5th February 1885 an Italian expedition under Colonel Saletta landed at Massawa, which, in virtue of the treaty concluded between Admiral Hewett and the Negus Johannes (3rd June 1884), had been recognized as Egyptian territory. Besides Massawa, the Italians occupied Arafali (10th April) and Arkiko (12th April). Colonel Saletta's successor, General Gené, in order to protect caravans, occupied the wells of Wa (23rd November 1886) and Saati (14th January 1887). This was the signal for hostilities with Abyssinia. Ras Alula arrested an Italian mission bound for Ethiopia under Major Piano, and made an unsuccessful attack upon Saati (25th January). Next day, however, in the gorge of Dogali, he succeeded in destroying a detachment of Italian infantry under Colonel De Cristoforis. An expedition of 20,000 men under General di San Marzano was dispatched to avenge this disaster. In good relations with Menelek, king of Shoa, and after the failure of a British attempt at mediation made by Sir Gerald Portal (December 1887), hostilities were opened with Abyssinia. The Negus Johannes advanced towards the Italian lines at Saati, but finding them impregnable withdrew to the interior with the intention of chastening Menelek for his neutrality. The San Marzano expedition then returned to Italy, leaving General Baldissera, the first organizer of the colony, in command. A year later Johannes fell at Metemmeh fighting the Dervishes (March 10, 1889), and his succession was disputed between Mangashà, Ras of Tigrè, natural son of Johannes, and Menelek, who claimed descent from King Solomon and the Queen of Sheba. The Italians supported Menelek by threatening the chiefs of Tigrè and occupying Keren (June 2), Asmarà (August 3), and extending the Italian frontier to the Mareb, Belesa, and Muna. Menelek, having secured the imperial crown owing to Italian help, concluded with the Italian representative, Count Pietro Antonelli, a treaty at Ucciali (May 11, 1889), and sent to Rome a mission under one of his lieutenants, Makonnen, for the ratification of the treaty and the negotiation of a loan of £160,000. General Orero, who in the meantime had succeeded General Baldissera in the government of Eritrea, made a reconnaissance in force as far as Adowa towards the west and Makallè to the south. This move aroused the suspicions of both Menelek and Mangashà, who became reconciled at Ausien. Shortly afterwards Menelek disputed the Italian claim to the protectorate over Abyssinia, based on Article 17 of the treaty of Ucciali, and demanded for Ethiopia the Cis-Mareb provinces of Seraè and Okulé-Kusai. Almost simultaneously began a period of hostilities between Italy and the Dervishes. In June 1890 Dervish raiders plundered the Beni-Amer, an Arab tribe under Italian protection, but were defeated near Agordat by Captain Fara. The Italians then occupied and fortified Agordat. In consequence of this extension of territory an Anglo-Italian convention (March–April 1891) was concluded in order to delimitate the respective spheres of influence of the two countries. The convention also authorized Italy temporarily to occupy Kassala, if necessary. In June 1892 the Dervishes attacked the Italians, but were defeated at Sarobeiti (June 16) beyond Agordat. The Khalifa then ordered a holy war, but the Dervishes were routed with loss at Agordat (December 21, 1893). The Italians followed up their success by occupying Kassala on July 17, 1894, after surprising and defeating the Dervish garrison. Meanwhile Menelek and Mangashà prepared to attack the Italians, and fomented the rebellion of Batha-Agos, who had ruled the Okulé-Kusai, under Italian suzerainty. General Baratieri, however, with 3900 men defeated and killed Batha-Agos at Halai (December 18, 1894), marched upon Adowa, routed Mangashà at Coatit (January 13–14, 1895) and at Senafè (January 15), and prepared to conquer Tigrè. Meanwhile Menelek having collected a large army and secured the support of various chiefs, set out to reconquer Tigrè after the Feast of the Cross (September 27, 1895). A battalion under Major Toselli attempted, through a misunderstanding, to arrest the Abyssinian vanguard, 35,000 strong, and was annihilated at Amba Alagi (December 7). Pushing forwards, the Abyssinians, after taking the fort at Makallè (January 21, 1896), moved on to Adowa. Here their forces, numbering 90,000, armed with rifles, 8600 cavalry, and 42 guns, encountered the Italians. The Italian army, under General Baratieri, numbered less than 20,000 men, and was, moreover, molested by the rebellion of native bands. Nevertheless, the Italian commander decided to attack. A body of 12,500 men, of whom 10,450 were Italians, with 56 guns, divided into three columns under Generals Arimondi, Albertone, and Dabormida, and a reserve under General Ellena, moved against the Abyssinian camp at daybreak on March 1, 1896. The action developed into three separate and successive combats. Albertone was first defeated at Abba-Carima; Arimondi and Ellena later at Mounts Rajo and Rebbi-Arienni; and Dabormida at Mariam Shiavitù. The Italian losses were: killed, 6600, of whom 4600 were Italians; wounded, 1500, of whom 500 were Italians; prisoners, 1700, of whom 1500 were Italians. Among the dead were Generals Dabormida and Arimondi, Colonels Romero and Airaghi, and 264 other officers. The Abyssinian losses were: killed, 7000; wounded, 10,000. Among the dead were the Fitaurazi Jabeju, victor of Amba Alagi, and many other chieftains.

A few days later General Baldissera, reappointed Governor of Eritrea, reached Massawa with reinforcements. With a new army 16,000 strong he took the offensive and liberated the garrison of Adigrat. Menelek, discouraged by his heavy losses and lacking supplies, rapidly withdrew southwards. About the same time Colonel Stevani repelled a great Dervish invasion at Mount Mokram and at Tucruf, driving the invaders beyond the Atbara. Friendly relations between Abyssinia and Eritrea were re-established by the treaty of Addis Ababa (October 26, 1896), by which Italy revoked the treaty of Ucciali, and Abyssinia agreed to release the Italian prisoners on payment of an indemnity of 10,000,000 lire, and provisionally recognized the Mareb boundary. Kassala was handed over to Great Britain (December 25, 1897). The Government was placed upon a civil basis (October–November 1897); the frontiers were further regulated by a Franco-Italian Convention (January 24, 1900) fixing the limit between the French and Italian possessions at Ras Dumeira; and by agreements with Menelek, guaranteeing to Eritrea the possession in perpetuity of the Mareb-Belesa-Muna line.

Erivañ, a province of Russia, Transcaucasia, having Kars on the W., Tiflis on the N., Elisabethpol on the E., Persia and Turkey on the S. It lies entirely on the surface of a plateau (6000–8000 ft.), covered with volcanic formations. Regular chains of mountains are only met with on its borders and in its eastern portion, but the whole surface of the plateau is covered with short ridges and isolated mountains of volcanic origin, of which Alaghöz (13,436 ft.) and Ararat (17,212 ft.) are the main ones. Both are volcanoes which must have been active in Tertiary times. Lake Gokcha is surrounded by such volcanoes, and the neighbourhood of Alexandropol is a "volcanic amphitheatre," the surface of which is entirely covered with superficial volcanic deposits. The same is true of the slopes leading to the Arax, the valley of the upper Arax being consequently a stone desert, refreshed only by irrigation, which is conducted with considerable difficulty owing to the character of the soil. It is watered by the Arax, which forms the boundary with Persia, and flows with an extreme rapidity in its stony bed—the height of its fall being 22 and 17 ft. per mile in its upper part, and 9 ft. at Ordubat, and 23 ft. lower down. The chief lakes are Gokcha and Balykh-göl; many small lakes, filling up volcanic craters, are of great depth. Wood is very scarce. There is a variety of useful minerals, but only rock-salt is obtained at Nakhichevañ and Kulp. The climate is extremely varied, the following being the average temperatures and mean rainfall at Alexandropol (alt. 5078 ft.) and Aralykh (2732 ft.):—year 42°, January 12°, July 65°, mean rainfall, 16·2 in. in Alexandropol; and year 53°, January 20°·5, July 79°, rainfall, 6·3 in. in Aralykh.

The population numbers 830,000 (only 375,086 women), of whom 82,278 lived in towns. They are chiefly Armenians (375,700), Azerbaijan Tatars (407,949), Kurds (36,484), and 4150 Russians to whom some Aisors, Greeks, and Jews must be added. Most Armenians are Gregorians (only 5753 Catholics), and the Tatars are mostly Shiite Mussulmans (only 29,723 Sunnites). The percentage of births was (1897) 3·9, and of mortality only 1·9.

While barley only can be grown on the high parts of the plateau, the cotton tree, the mulberry tree, the vine, and all sorts of fruit trees are cultivated in the Arax valley. The total corn crop (mainly wheat and barley) attained 1,178,000 in 1897, and there were about 90,000 acres under cotton crop and 17,000 acres under vineyards. Cattle-breeding is extensive, and there were 35,650 horses, 26,200 donkeys, 336,000, horned cattle and 584,500 sheep. Industry is in infancy, but cottons, carpets, felt goods, and so on are fabricated in the villages. A considerable foreign trade is carried on with Persia, but trade with Asia Minor is on decline.

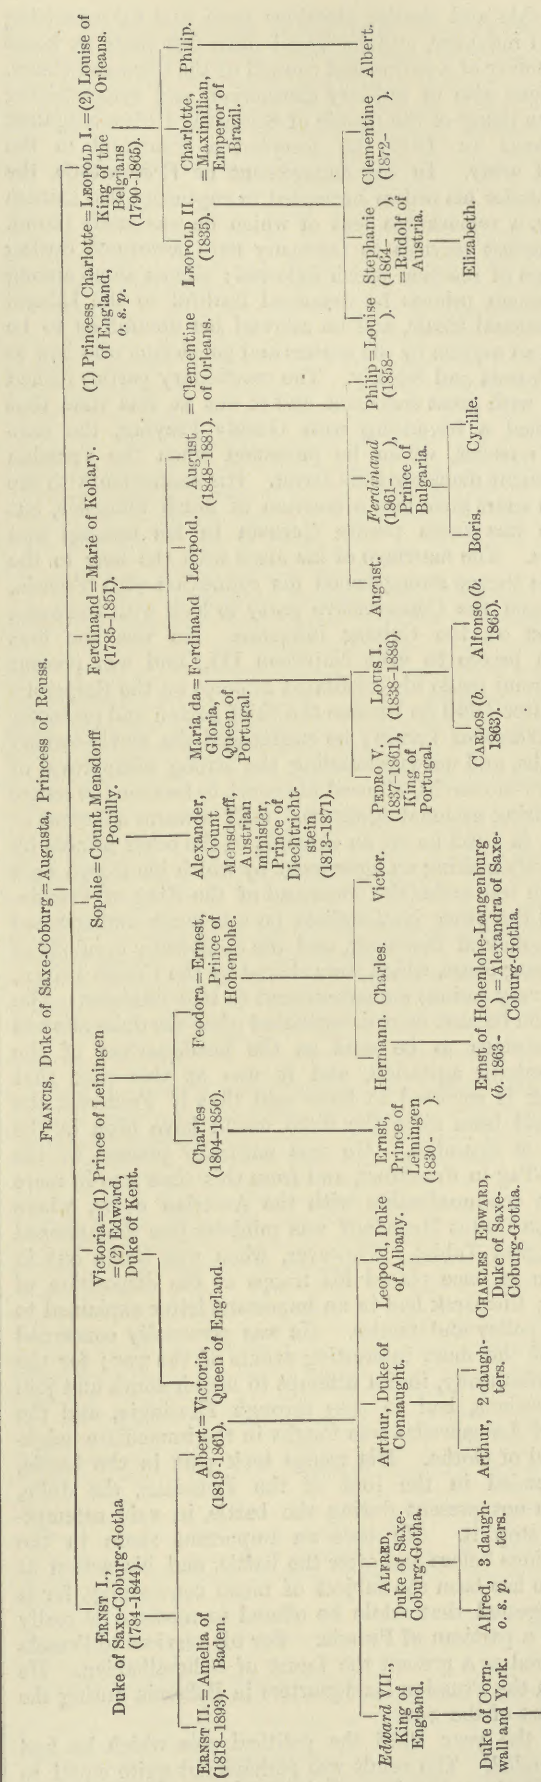
The government is divided into 7 districts:—Erivañ, Alexandropol, Echmiadzin (chief town, Vagarshapad), Nakhichevañ, Novobayazet, Surmalinsk (chief town, Igdyr), and Sharuro-Daralaghöz (chief town, Norashen). The main towns are: Erivañ, Alexandropol (32,018 inhabitants), Nakhichevañ (8845), Novobayazet (8507), and Vagarshapad (2910). (P. A. K.)

Erivañ, capital of the above government, is situated in 42° 14′ N., 44° 57′ E., 173 miles south-west of Tiflis, on Zanga river, from which a great number of irrigation canals are drawn. Altitude, 3087 ft. It has several remarkable relics of the Persian dominion in its old fortress. Population (1873), 11,938; (1897), 29,033.

Erlangen, a town of Bavaria, Germany, dist. Middle Franconia, on the river Regnitz, 15 miles by rail north from Nuremberg. Its chief importance centres in its university, which in 1900 was attended by 974 students, and had 69 professors. The principal buildings are those connected with the university, such as the library, which possesses 180,000 volumes, lecture halls (1889), and various scientific institutes and laboratories. Population (1885), 15,828; (1900), 22,953.

Erle, Sir William (1793–1880), English lawyer and judge, was born at Fifehead-Magdalen, Dorset, 1st October 1793, and was educated at Winchester and at New College, Oxford. Having been called to the Bar, he went the Western circuit, became counsel to the Bank of England, sat in Parliament from 1837 to 1841 for the city of Oxford, and, although of opposite politics to Lord Lyndhurst, was made by him a judge of the Common Pleas in 1845. He was transferred to the Queen's Bench in the following year, and in 1859 came back to the Common Pleas as Chief Justice upon the promotion of Sir Alexander Cockburn. He retired in 1866, receiving the highest eulogiums for the ability and impartiality with which he had discharged the judicial office. He died at his estate at Bramshott, Hampshire, on 28th January 1880; and a monument in his memory stands on the top of Hindhead.

Ernst II. [August Karl Johannes Leopold Alexander Eduard], duke of Saxe-Coburg-Gotha (1818–1893), was born at Coburg on the 21st of June 1818. He was the eldest son of Ernst I., duke of Saxe-Coburg-Saalfeld. In 1826, when the line of Saxe-Gotha became extinct, a rearrangement of the Saxon duchies took place. The duke of Coburg gave up the small territory of Saalfeld and acquired instead that of Gotha, and he changed his title to that of Ernst I. of Saxe-Coburg-Gotha. Ernst enjoyed a many-sided education; he studied at the University of Bonn with his brother Albert; his military training he received in the Saxon army. The widespread connexions of his family opened to him many courts of Europe; after he became of age he travelled much. The position of his uncle, who was King of the Belgians, and especially the marriage of his brother to the Queen of England, his cousin, gave him peculiar opportunities for becoming acquainted with the political problems of Europe. In 1840–41 he undertook a journey to Spain and Portugal; in the latter country another cousin was King-Consort. In 1844 he succeeded his father. His own character and the influence of the King of the Belgians, made him one of the most Liberal princes in Germany. He was able to bring to a satisfactory conclusion disputes with the Coburg estates. He passed through the ordeal of the Revolution with little trouble, for he anticipated the demands of the people of Gotha for a reform, and in 1852 introduced a new constitution by which the administration of his two duchies was assimilated in many points. The government of his small dominions did not afford sufficient scope for his restless and versatile ambition; his desire to play a great part in German affairs was probably increased by the feeling that, though he was the head of his house, he was to some extent overshadowed by the younger branches of the family which ruled in Belgium, England, and Portugal. He was one of the foremost supporters of every attempt made to reform the German constitution and bring about the unity of Germany. He took a warm interest in the proceedings of the Frankfort Parliament, and it was often said, probably without reason, that he hoped to be chosen Emperor himself. However that may be, he strongly urged the King of Prussia to accept that position when it was offered him in 1849; he took a very prominent part in the complicated negotiations of the following year, and it was at his suggestion that a congress of princes met at Berlin in 1850. He highly valued the opportunities



GENEALOGICAL TABLE OF SAXE-COBURG.

which this and similar meetings gave him for exercising political influence, and he would have felt most at home as a member of a permanent council of the German princes. Ambitious also of military distinction, and sympathizing with the rising of the people of Schleswig-Holstein against the Danes in 1849, he accepted a command in the Federal army. In the engagement of Eckernförde the troops under his orders succeeded in capturing two Danish frigates, a remarkable feat of which he was justly proud. His greatest services to Germany were performed during the years of reaction which followed; almost alone among the German princes he remained faithful to the Liberal and National ideals, and he allowed his dominions to be used as an asylum by the writers and politicians who had to leave Prussia and Saxony. The reactionary parties looked on him with great suspicion, and it was at this time that he formed a friendship with Gustav Freytag, the celebrated novelist, whom he protected when the Prussian Government demanded his arrest. His connexion with the English court gave him a position of much influence, but no one was more purely German in his feelings and opinions. The marriage of his niece with the heir to the Prussian throne strengthened his connexion with Prussia, but caused the Conservative party to look with increased suspicion on the Coburg influence. He was the first German prince to visit Napoleon III., and was present when Orsini made his celebrated attempt on the Emperor's life. After 1860 he became the chief patron and protector of the *National Verein*; he encouraged the newly-formed rifle clubs, and notwithstanding the strong disapproval of his fellow-monarchs, allowed his court to become the centre of the rising national agitation. Still a warm adherent of Prussia, in 1862 he set an example to the other princes by voluntarily making an agreement by which his troops were placed in war under the command of the King of Prussia. Like all the other Nationalists, he was much embarrassed by the policy of Bismarck, and the democratic opinions of the Coburg court, which were shared by the Crown Prince, were a very serious embarrassment to that minister. The opposition became more accentuated when the duke allowed his dominions to be used as the headquarters of the Augustenburg agitation, and it was at this time that Bismarck is reported to have said that if Frederick the Great had been alive the duke would have been in the fortress of Spandau. He was naturally present at the Fursten-Tag in Frankfort, and from this time was in more frequent communication with the Austrian court, where his cousin Count Mensdorff was minister (see the annexed Genealogical Table). However, when war broke out in 1866, he at once placed his troops at the disposition of Prussia; Bismarck had in an important letter explained to him his policy and tactics. He was personally concerned in one of the most interesting events of the war; for the Hanoverian army, in its attempt to march south and join the Bavarians, had to pass through Thuringia, and the battle of Langensalza was fought in the immediate neighbourhood of Gotha. His troops took part in the battle, which ended in the rout of the Prussians, the duke, who was not present during the battle, in vain attempting to stop it. He bore an important share in the negotiations before and after the battle, and his action at this time has been the subject of much controversy, for it was suggested that while he offered to mediate he really acted as a partisan of Prussia. For his services to Prussia he received as a present the forest of Schmalkalden. He was with the Prussian headquarters in Bohemia during the latter part of the war.

With the year 1866 the political rôle which he had played ended. The result was perhaps not quite equal to his expectations, but it must be remembered how difficult was the position of the minor German princes; and he quoted with great satisfaction the words used in 1870 by the Emperor William at Versailles, that "to him in no small degree was due the establishment of the empire." He was a man of varied tastes, a good musician—he composed several operas and songs,—and a keen sportsman, a quality in which he differed from his brother. Notwithstanding his Liberalism, he had a great regard for the dignity of his rank and family, and in his support of constitutional government would never have sacrificed the essential prerogatives of sovereignty. Several anonymous political pamphlets were attributed to him. He brought out, also, an account of travels in Egypt and Abyssinia, which he undertook in 1868; and in 1890 published his memoirs *Aus meinem Leben und meiner Zeit*, in three volumes, a work which contains much valuable information on the most critical period of German history; there is an English translation. See also *The Life of the Prince Consort*, by Sir THEODORE MARTIN; *The Early Years of the Prince Consort*, by Sir G. GREY; and for the war of 1866, HASSELL, *Geschichte Hannovers*, 1897–1901. He died on the 22nd of August 1893 at Reinhardsbrunn.

The Duke married, in the year 1842, Amelia, daughter of the Grand Duke of Baden. There was no issue to the marriage; the succession therefore passed on his death to the children of his younger brother. By the marriage contract of Prince Albert the duchy could not be held with the crown of England; it therefore passed to Prince Albert's second son, the Duke of Edinburgh. The latter's only son predeceased him, and therefore on his death it passed again to the Duke of Connaught; and he and his son passed on their claims to the Duke of Albany.

The genealogical table on p. 279 displays the widely-spread connexions of the family of Saxe-Coburg, and shows how large a part it has played in the recent history of Europe. (J. W. HE.)

Erode, a town of British India, in the Coimbatore district of Madras; situated in 11° 20′ N. lat. and 77° 46′ E. long., on the right bank of the river Cauvery, which is here crossed by an iron railway girder bridge of 22 spans. Population (1881), 9864; (1891), 12,238. Here the South Indian Railway joins the South-Western line of the Madras Railway, 243 miles from Madras. There are exports of cotton and saltpetre; and the town has a steam cotton press, a high school, and two printing-presses.

Error, Law of.—Error is defined in popular dictionaries as "deviation from truth"; and since truth commonly lies in a mean, while measurements are some too large and some too small, the term in scientific diction is extended to deviations of statistics from their average, even when that average—like the mean of human or barometric heights—does not stand for any real objective thing. A law of error is a relation between the extent of a deviation and the frequency with which it occurs: for instance, the proposition that if a digit is taken at random from mathematical tables, the difference between that figure and the mean of the whole series (indefinitely prolonged) of figures so obtained, namely, 4·5, will in the long run prove to be equally often ±0·5, ±1·5, ±2·5, ±3·5, ±4·5.[1] The more general term "law of frequency" is appropriate when there is no explicit reference to the mean, *e.g.*, the statement that one digit occurs as often as the other. The assignment of frequency to *discrete* values—as 0, 1, 2, &c., in the preceding example—is often replaced by a con-

Definition and division.

[1] See as to the fact and the evidence for it, Venn, *Logic of Chance*, 3rd ed., pp. 111, 114. Cp. *Ency. Brit.*, 8th ed., art. "Probability," p. 592.

tinuous curve with a corresponding equation. For example, it is found by Professor Pareto[1] that the number of incomes of different size (above a certain size) is approximately represented by the equation $y = A/x^a$, where x denotes the size of an income, y the number of incomes of that size, A and a are constants differing for different countries. Although this law is found to hold good for many countries, it is but *a* law of error or frequency; the right to be called *the* law of error is reserved for a function which is applicable not merely to one sort of statistics—such as digits or incomes—but to a great variety of miscellaneous groups generally at least, if not universally. What form is most deserving of this distinction is not decided by uniform usage: different authorities do not attach the same weight to the grounds on which the claim is based, the extent of cases to which the law may be applicable, the closeness of the application, and the presumption prior to specific experience in favour of the law. Three conceptions of the law of error, characterized by different degrees of these qualifications, will be considered here (sections 1 to 47, 48 to 51, 52 to 54); a fourth division (sections 55 to end) is required for certain derivative laws which may be expected to result from the law of error if prevalent in any of the three senses.

1. The simplest and best recognized statement of the law of error, often called the "normal law," is the equation

$$z = \frac{1}{\sqrt{\pi}c} e^{\frac{-(x-d)^2}{c^2}};$$

more conveniently written $(1/\sqrt{\pi}\,c)\exp-(x-d)^2/c^2$, where x is the magnitude of an observation or "statistic,"[2] *e.g.*, the stature of an individual man, z is the proportional frequency of observations measuring x, d is the arithmetic mean of the group (supposed indefinitely[3] multiplied) of similar statistics: c is a constant sometimes called the "modulus"[4] proper to the group; and the equation signifies that if any large number N of such a group is taken at random, the number of observations between x and $x + \triangle x$ is (approximately) equal to the right-hand side of the equation multiplied by $N\triangle x$.

Normal law of error: à priori proof.

2. An *à priori* proof of this law was given by Herschel[5] as follows: "The probability of an error depends solely on its magnitude and not on its direction"; positive and negative errors are equally probable. "Suppose a ball dropt from a given height with the intention that it should fall on a given mark," errors in all directions are equally probable, and errors in perpendicular directions are independent. Accordingly, the required law, "*which must necessarily be general and apply alike in all cases, since the causes of error are supposed alike unknown*,"[6] is for one dimension of the form $\phi(x^2)$, for two dimensions $\phi(x^2+y^2)$; and $\phi(x^2+y^2) \equiv \phi(x^2) \times \phi(y^2)$; a functional equation of which the solution is the function above written. A reason which satisfied Herschel is entitled to attention, especially if it is endorsed by Thomson and Tait.[7] But it must be confessed that the claim to universality is not, without some strain of interpretation,[8] to be reconciled with experience.

3. This objection is not equally applicable to a second form of *à priori* proof, which seems to have been first stated in all its generality by Dr Glaisher.[9] According to this view, the normal law of error is a first approximation to the frequency with which different values are apt to be assumed by a variable magnitude dependent on a great number of independent variables, each of which assumes different values in random fashion over a limited range, according to *a* law of error, not in general *the* law, nor in general the same for each variable. The normal law prevails in nature because it often happens—in the world of atoms, in organic and in social life—that things depend on a number of independent agencies. The validity of the explanation may best be tested by considering its application to the different classes of phenomena in which the normal law of error is approximately fulfilled.

4. (*a*) First in respect of simplicity, not practical importance, is the class of *games of chance*, or, more generally, *sortitions*, defined by the circumstance that we have a knowledge prior to specific[10] experience of the proportion of what Laplace calls favourable cases[11] to all cases—a category which includes, for instance, the distribution of digits obtained by random extracts from mathematical tables, as well as the distribution of the numbers of points on dominoes.

Games of chance.

The genesis of the law of error is most clearly illustrated by the simplest sort of "game," that in which the sortition is between two alternatives, Heads or Tails, Hearts or not-Hearts, or, generally, success or failure, the probability of a success being p and that of a failure q, where $p+q=1$. The number of such successes in the course of n trials may be considered as an aggregate made up of n independently varying elements, each of which assumes the values 0 or 1 with respective frequency q and p. The frequency of each value of the aggregate is given by a corresponding term in the expansion of $(q+p)^n$, and by a well-known theorem[12] this term is approximately equal to $\frac{1}{\sqrt{\pi 2npq}} e^{-\nu^2/2npq}$; where ν is the number of integers by which the term is distant from np (or an integer close to np); provided that ν is of (or below) the order $\sqrt{n}$. Graphically, let the sortition made for each element be represented by the taking or not taking with respective frequency p and q a step of length i. If a body starting from zero take successively n such steps, the point at which it will most probably come to a stop is at npi (measured from zero); the probability of its stopping at any neighbouring point within a range of $\pm\sqrt{n}i$ is given by the above-written law of frequency, νi being the distance of the stopping-point from npi. Put $\nu i = x$ and $2npqi^2 = c^2$; then the probability may be written $(1/\sqrt{\pi}\,c)\exp-x^2/c^2$.

5. It is a short step, but a difficult one, from this case, in which the element is *binomial*—Heads or Tails,—to the general case, in which the element has several values, according to any law of frequency—consists, for instance, of the number of points presented by a randomly-thrown die. According to the general theorem, if Q is the sum[13] of numerous elements, each of which assumes different magnitudes according to a law of frequency, $z = f_r(x)$, the function f being in general different for different elements, the number of

[1] *Cours d'Économie politique*, vol. ii. p. 306.

[2] The corresponding curve—often called the "probability-curve"—is represented in the art. on "Probability," *Ency. Brit.*, 9th ed., vol. xix.

[3] On this conception see below, § 15.

[4] *E.g.*, in the art. on "Probability" in the 9th ed. of the *Ency. Brit.*; also by Airy and other authorities. Bravais, in his article *Sur la probabilité des erreurs*. . . . "Mémoires présentés par divers savants," 1846, p. 257, takes as the "modulus or parameter" the inverse square of our c. Doubtless different parameters are suited to different purposes and contexts; c when we consult the common tables; $k(=\frac{1}{2}c^2)$ when we investigate the formation of the probability-curve out of independent elements (below, § 5); $h(=1/c^2)$ when we are concerned with weights or precisions (below, § 26). If one form of the coefficient must be uniformly adhered to, probably $\sigma(=c/\sqrt{2})$, for which Professor Pearson expresses a preference, appears the best. It is called by him the "standard deviation."

[13] The statement includes the case of a linear function, since an element multiplied by a constant is still an element. For a statement of some of the assumptions required by the theory see below, § 9.

times that Q assumes magnitudes between x and $x+\triangle x$ in the course of N trials is $\mathrm{N}z\triangle x$, if $z=(1/\sqrt{2\pi k})\ \exp-(x-a)^2/2k$; where a is the sum of the arithmetic means of all the elements, any one of which $a_r, =\left[\int x f_r(x)dx\right]$, the square brackets denoting that the integrations extend between the extreme limits of the element's range, if the frequency-locus for each element is continuous, it being understood that $\left[\int f_r(x)dx\right]=1$; and k is the sum[1] of the mean squares of error for each element,[2] $=\Sigma\left[\int \xi^2 f_r(a_r+\xi)d\xi\right]$, if the frequency-locus for each element is continuous, where a_r is the arithmetic mean of one of the elements, and ξ the deviation of any value assumed by that element from a_r, Σ denoting summation over all the elements. When the frequency-locus for the element is not continuous, the *integrations* which give the arithmetic-mean and mean-square of error for the element must be replaced by *summations*. For example, in the case of the dice above instanced, the law of frequency for each element is that it assumes equally often each of the values 1, 2, 3, 4, 5, 6. Thus the arithmetic mean for each element is 3·5, and the mean square of error $\{(3{\cdot}5-1)^2+(3{\cdot}5-2)^2+\text{etc.}\}/6=2{\cdot}91\dot{6}$. Accordingly, the sum of the points obtained by tossing a large number, n, of dice at random will assume a particular value x with a frequency which is approximately assigned by the equation

$$z=(1/\sqrt{\pi 5{\cdot}8\dot{3}n})\ \exp-(x-3{\cdot}5)^2/5{\cdot}8\dot{3}n.$$

The rule equally applies to the case in which the elements are not similar; one might be the number of points on a die, another the number of points on a domino, and so on. Graphically, each element is no longer represented by a step which is either null or i, but by a step which may be, with an assigned probability, one or other of several degrees between those limits, the law of frequency and the range i being different for the different elements.

6. The evidence for these statements can only be indicated here. The best-known proof that the sum of *multinomial* elements will vary according to the normal law of error approximately is that which was given by Laplace for elements with one and the same law of frequency of (almost) any kind; and was extended by Poisson to elements with different laws of frequency.[3] A simpler proof of the general theorem has been given by De Forest,[4] based on certain proportions respecting the multiplication of multinomials of the form $(a_0+a_1z+a_2z^2+\ .\ .\ .+a_nz^n)$. Another simple proof is based by Mr Morgan Crofton[5] on certain partial differential equations which must be satisfied in order that the taking in of a new element should not alter the form, but only the constants, of the resulting law of frequency.

7. The three proofs which have been mentioned have been extended to errors in two (or more) dimensions.[6] Let Q be the sum of a number of elements, each of which, being a function of two variables, x and y, assumes different pairs of values according to a law of frequency $z_r=f_r(x,y)$, the functions being in general different for different elements. The frequency with which Q assumes values of the variables between x and $x+\triangle x$ and between y and $y+\triangle y$ is $z\triangle x\triangle y$, if

$$z=\frac{1}{2\pi\sqrt{km-l^2}}\ \exp\ -\ \frac{m(x-a)^2-2l(x-a)(y-b)+k(y-b)^2}{2(km-l^2)};$$

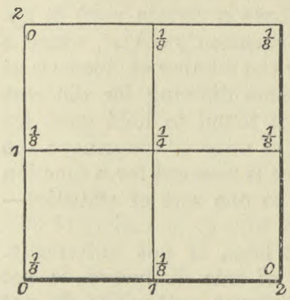
where, as in the simpler case, $a=\Sigma a_r$, a_r being the arithmetic mean of the values of x assumed in the long run by one of the elements, b is the corresponding sum for values of y, and

$$k=\Sigma\left[\iint(x-a_r)^2 f_r(x,y)dxdy\right]$$

$$m=\Sigma\left[\iint(y-b_r)^2 f_r(x,y)dxdy\right]$$

$$l=\Sigma\left[\iint(x-a_r)(y-b_r)f_r(x,y)dxdy\right];$$

the summation extending over all the elements, and the integration between the extreme limits of each; supposing that the law of frequency for each element is continuous, otherwise summation is to be substituted for integration. For example, let each element be constituted as follows. Three coins having been tossed, the number of Heads presented by the first and second coins together is put for x, the number of Heads presented by the second and third coins together is put for y. The law of frequency for the element is represented by the annexed diagrams, the integers outside denoting the values of x or y, the fractions inside probabilities of particular values of x and y concurring.



If i is the distance from 0 to 1 and from 1 to 2 on the abscissa, and i' the corresponding distance on the ordinate, the mean of the values of x for the element—$\triangle a$, as we may say,—is i, and the corresponding mean square of horizontal deviations is $\frac{1}{2}i^2$. Likewise $\triangle b=i'$; $\triangle m=\frac{1}{2}i'^2$; and $\triangle l=\frac{1}{8}(+i\times+i'-i\times-i')=\frac{1}{4}ii'$. Accordingly, if n such elements are put together (if n *steps* of the kind which the diagram represents are taken), the frequency with which a particular pair of aggregates x and y will concur, with which a particular point on the plane of xy, namely, $x=ri$ and $y=r'i'$, will be reached, is given by the equation

$$z=\frac{1}{2\pi}\sqrt{\frac{16}{3n}}\ \exp-\ \frac{8}{3n}\left[(r-n)^2i^2-(r-n)(r'-n)ii'+(r'-n)i'^2\right]^{7}.$$

8. A verification is afforded by a set of statistics obtained with dice by Professor Weldon, and here reproduced by his permission. A *success* is in this experiment defined, not by obtaining a Head when a coin is tossed, but by obtaining a face with more than three points on it when a die is tossed; the probabilities of the two events are the same, or rather would be if coins and dice were perfectly symmetrical.[8] Professor Weldon virtually took six *steps* of the sort above described when, six painted dice having been thrown, he added the number of successes in that painted batch to the number of successes in another batch of six to form his x, and to the number of successes in a *third* batch of six to form his y. The result is represented in the annexed diagram, where each

degree on the axis of x and y respectively corresponds to the i and i' of the preceding paragraphs, and $i=i'$. The observed frequencies being represented by numerals, a general correspondence between the facts and the formula is apparent. The maximum frequency is, as it ought to be, at the point $x=6i$, $y=6i'$. The density is particularly great along a line through that point, making 45° with the axis of x; particularly small in the complementary direction. This also is as it ought to be. For if the centre is made the origin by substituting x for $(x-a)$ and y for $(y-b)$, and then new co-ordinates X and Y are taken, making an

[1] Or rather what that sum would be if the series of observation could be indefinitely prolonged. Cp. below, § 15.

[2] In the case of binomial, $k=n(pq^2+qp^2)=npq$.

angle θ with x and y respectively, the curve which is traced on the plane of zX by its intersection with the surface is of the form

$$z = \mathrm{J}\ \exp - \mathrm{X}^2[\mathrm{k}\sin^2\theta - 2\,\mathrm{l}\cos\theta\sin\theta + \mathrm{m}\cos^2\theta]/2(\mathrm{km} - \mathrm{l}^2),$$

a probability-curve which will be more or less spread out according as the factor $\mathrm{k}\sin^2\theta - 2\,\mathrm{l}\cos\theta\sin\theta + \mathrm{m}\cos^2\theta$ is less or greater. Now this expression has a minimum or maximum when $(\mathrm{k}-\mathrm{m})\sin\theta - 2\,\mathrm{l}\cos 2\theta = 0$; a minimum when $(\mathrm{k}-\mathrm{m})\cos 2\theta + 2\,\mathrm{l}\sin 2\theta$ is positive, and a maximum when that criterion is negative; that is, in the present case, where $\mathrm{k}=\mathrm{m}$, a minimum when $\theta = \frac{1}{4}\pi$ and a maximum when $\theta = \frac{3}{4}\pi$.

9. The law which has been stated, that if numerous elements, each independently varying (in one or more dimensions) according to (almost) *any* law of frequency, are added together, the sum is apt to vary according to *the* (normal) law of error, may be called the *law of great numbers*.[1] As may be presumed from the examples just given, in order that there should be some approximation to the normal law the number of elements need not be very great. A very tolerable imitation of the probability-curve has been obtained by superposing *three* elements, each obeying a law of frequency quite different from the normal one,[2] that simple law according to which one value of a variable occurs as frequently as another between the limits within which the variation is confined ($y = \frac{1}{2\mathrm{a}}$, between limits $x = +\mathrm{a}$, $x = -\mathrm{a}$). If the component elements obey unsymmetrical laws of frequency, the compound will indeed be to some extent unsymmetrical, unlike the "normal" probability-curve. But, as the number of the elements is increased, the portion of the compound curve in the neighbourhood of its centre of gravity tends to be rounded off into the normal shape. The portion of the compound curve which is sensibly identical with a curve of the "normal" family becomes greater the greater the number of independent elements; *ceteris paribus*, and granted certain conditions as to the equality and the range of the elements. It will readily be granted that if one component predominates, it may unduly impress its own character on the compound. But it should be pointed out that the characteristic with which we are now concerned is not average magnitude, but deviation from the average. The component elements may be very unequal in their contributions to the average magnitude of the compound without prejudice to its "normal" character, provided that the fluctuation of all or many of the elements is of one and the same order. The proof of the law of great numbers (by way of partial differential equations) requires that the contribution made by each element to the mean square of deviation for the compound, k (see §§ 5–7), should be small, capable of being treated as differential with respect to k. It is not necessary that all these small quantities should be of the same order, but only that they should admit of being rearranged, by massing together those of a smaller order, as a numerous set of independent elements in which no two or three stand out as *sui generis* in respect of the magnitude of their fluctuation. For example, if one element consist of the number of points on a domino (the sum of two digits taken at random), and other elements, each of either 1 or 0 according as Heads or Tails turn up when a coin is cast, the first element, having a mean square of deviation 16·5, will not be of the same order as the others, each having 0·25 for its mean square of deviation. But *sixty-six* of the latter taken together would constitute an independent element of the same order as the first one, and accordingly if there are several times sixty-six elements of the latter sort, along with one or two of the former sort, the conditions for the generation of the normal distribution will be satisfied. These propositions would evidently be unaffected by altering the average magnitude, without altering the deviation from the average, for any element, that is, by adding a greater or less *fixed* magnitude to each element. The propositions are adapted to the case in which the elements fluctuate according to a law of frequency other than the normal. For if they are already normal, the aforesaid conditions are unnecessary. The normal law will be obeyed by the sum of elements which each obey it, even though they are not numerous and not independent and not of the same order in respect of the extent of fluctuation. A similar distinction is to be drawn with respect to some further conditions which the reasoning requires. A limitation as to the range of the elements is not necessary when they are already normal, or even have a certain affinity to the normal curve. Very large values of the element are not excluded, provided they are sufficiently rare. What has been said of curves with special reference to one dimension is of course to be extended to the case of surfaces and many dimensions. In all cases the theorem that under the conditions stated the normal law of error will be generated is to be distinguished from the hypothesis that the conditions are fairly well fulfilled in ordinary experience.

10. (β) The principles won by studying the sort of model which games of chance present are now to be applied to important concrete cases; among which errors-of-observation occupy a leading place. The *law of great numbers* is brought to bear on this case by the hypothesis that an error is the algebraic sum of numerous elements, each varying according to a law of frequency special to itself. This hypothesis involves two assumptions: (1) that an error is dependent on numerous independent causes; (2) that the function expressing that dependence can be treated as a linear function, by expanding in terms of ascending powers (of the elements) according to Taylor's theorem and neglecting higher powers,[3] or otherwise. The first assumption seems, in Dr Glaisher's words, "most natural and true. In any observation where great care is taken, so that no large error can occur, we can see that its accuracy is influenced by a great number of circumstances, which ultimately depend on independent causes: the state of the observer's eye and his physiological condition in general, the state of the atmosphere, of the different parts of the instrument, &c., evidently depend on a great number of causes, while each contributes to the actual error."[4] The second assumption seems to be frequently, but by no means universally, realized in nature. This rationale is applicable not only to the fallible perceptions of the senses, but also to impressions into which a large ingredient of inference enters, such as estimates of a man's height or weight from his appearance,[5] and even higher acts of judgment.[6] Aiming at an object is an act similar to measuring an object, misses are produced by much the same variety of causes as mistakes; and, accordingly, it is found that shots aimed at the same bull's eye are apt to be distributed according to the normal law, whether in two dimensions on a target or according to their horizontal deviations, as exhibited below (§ 47).

Errors proper.

11. (γ) A residual class comprises miscellaneous statistics, physical as well as social, in which the normal law of error makes its appearance, presumably in consequence of the action of numerous independent influences. Well-known instances are afforded by human heights and other bodily measurements, as tabulated by Quetelet[7] and others.[8] The tendency of social phenomena to conform to the normal law of frequency is well exemplified by Mr Bowley's grouping of the wages paid to different classes.[9]

Miscellaneous statistics.

12. Instances of the normal law might also be divided into two classes: observations which stand for a real objective thing, and such statistics as are not thus representative of something outside themselves, groups of which the mean is called "subjective"

Subdivisions.

[1] This definition is not identical with Poisson's use of the term "law of great numbers" in his *Recherches sur la Probabilité des jugements.*

[2] *Journ. Stat. Soc.*, March 1900, p. 73, referring to Dr Burton, *Phil. Mag.*, 1883, vol. xvi. p. 301.

[3] Let $\mathrm{F}(x'_1 + x_1,\ x'_2 + x_2 \cdots x'_{\mathrm{n}} + x_{\mathrm{n}})$ represent a variable quantity depending on n elements $x'_1 + x_1$ $x'_2 + x_2$, &c., each fluctuating according to its own law of frequency about its mean value, respectively x'_1, x'_2, ... Suppose that the range within which each element fluctuates is so small that F never differs sensibly from

$$\left[\frac{d\mathrm{F}}{dx_1}\right]_0 x_1 + \left[\frac{d\mathrm{F}}{dx_2}\right]_0 x_2 + \cdots \left[\frac{d\mathrm{F}}{dx_{\mathrm{n}}}\right]_0 x_{\mathrm{n}}, \text{ where } \left[\frac{d\mathrm{F}}{dx_1}\right]_0$$

denotes what the expression within the brackets becomes when 0 is substituted for each of the variables; this condition (together with those referred to in the preceding paragraph) would be sufficient for the generation of the normal law. The *necessary* condition is somewhat less stringent.

or "fictitious"; the first class nearly corresponding with our (α) and (β) put together, the second class with our (γ). But the division would be neither clear nor useful. On the one hand so-called real means are often only approximately equal to objective quantities. Thus the proportional frequency with which one face of a die—the *six* suppose—turns up is only approximately given by the objective fact that the *six* is one face of a nearly perfect cube. For a set of dice with which Professor Weldon experimented, the average frequency of a throw, presenting either five or six points, proved to be not ·3, but 0·3377.[1] The difference of this result from the regulation 0·3 is as unpredictable from objective data, prior to experiment, as any of the means called subjective or fictitious. So the mean of errors of observation often differs from the thing observed by a so-called "constant error." So shots may be constantly deflected from the bull's eye by a steady wind or "drift."

13. On the other hand, statistics, not purporting to represent a real object, have more or less close relations to magnitudes which cannot be described as fictitious. Where the items averaged are ratios, *e.g.*, the proportion of births or deaths to the total population in several districts or other sections, it sometimes happens that the distribution of the ratios exactly corresponds to that which is obtained in the simplest games of chance—"combinational" distribution in the phrase of Professor Lexis.[2] There is unmistakably suggested a *sortition* of the simplest type, with a real ascertainable relation between the number of "favourable cases" and the total number of cases. The most remarkable example of this property is presented by the proportion of male to female (or to total) births. Some other instances are given by Professor Lexis[3] and Professor Westergaard.[4] A similar correspondence between the actual and the "combinational" distribution has been found by Professor Bortkevitch[5] in the case of very small probabilities (in which case the law of error is no longer "normal"). And it is likely that some ratios—such as general death-rates—not presenting combinational distribution, might be broken up into subdivisions—such as death-rates for different occupations or age-periods—each distributed in that simple fashion.

14. Another sort of averages which it is difficult to class as subjective rather than objective occurs in some social statistics, under the designation of index-numbers. The percentage which represents the change in the value of money between two epochs is seldom regarded as the mere average change in the price of several articles taken at random, but rather as the measure of something, *e.g.*, the variation in the price of a given amount of commodities, or of a unit of commodity.[6] So something substantive appears to be designated by the *volume of trade*, or that of the *consumption of the working classes*, of which the growth is measured by appropriate *index-numbers*,[7] the former due to Mr Bourne and Sir Robert Giffen,[8] the latter to Mr George Wood.[9]

15. But apart from these peculiarities, any set of statistics may be related to a certain *quæsitum*, very much as measurements are related to the object measured. That *quæsitum* is the limiting or ultimate mean to which the series of statistics, if indefinitely prolonged, would converge, the mean of the complete group; this conception of a limit applying to any *frequency-constant*, to "c," for instance, as well as "a" in the case of the normal curve.[10] The given statistics may be treated as samples from which to reason up to the true constant by that principle of the Calculus which determines the comparative probability of different causes from which an observed event may have emanated.[11]

16. Thus it appears that there is a characteristic more essential to the statistician than the existence of an objective *quæsitum*, namely, the use of that method which is primarily, but not exclusively, proper to that sort of *quæsitum—inverse probability*. Without that delicate instrument the doctrine of error can seldom be fully utilized; but some of its uses may be indicated before the introduction of technical difficulties.

Direct applications of the normal law.

17. The mere presumption that wherever three or four independent causes co-operate, the law of error tends to be set up, has a certain speculative interest.[12] The assumption of the law as a hypothesis[13] is legitimate. When the presumption is confirmed by specific experience, this knowledge is apt to be turned to account. It is usefully applied to the practice of gunnery; a use which, so far as it involves inverse probabilities,[14] belongs, with the treatment of errors proper, or fallible observations, to a later section. In many kinds of examination it is found that the total marks given to different candidates for answers to the same set of questions range approximately in conformity with the law of error. It is understood that the Civil Service Commissioners have founded on this fact some practical directions to examiners. Apart from such direct applications, it is a useful addition to our knowledge of a class that the measurable attributes of its members range in conformity with this general law. Something is added to the truth that "the days of a man are threescore and ten," if we may regard that epoch, or more exactly for England 72, as "Nature's aim, the length of life for which she builds a man, the dispersion on each side of this point being . . . nearly normal."[15] So Herschel says: "An [a mere] average gives us no assurance that the future will be like the past. A [normal] mean may be reckoned on with the most complete confidence."[16] The existence of independent causes,[17] inferred from the fulfilment of the normal law, may be some guarantee of stability. In Natural History especially have the conceptions supplied by the law of error been fruitful. Investigators are already on the track of this inquiry: if those members of a species whose size or other measurable attributes are above (or below) the average are preferred —by "natural" or some other kind of selection—as parents, how will the law of frequency as regards that attribute be modified in the next generation?

18. The relations between different generations involve the law of error in two or more dimensions. It was found

by Galton that the heights and other measurable attributes of children of the same parents range about a mean which is not that of the parental heights, but nearer the average of the general population. The amount of this "regression" is simply proportional to the distance of the "mid-parent's" height from the general average. This is a case of a very general law which governs the relations not only between members of the same family, but also between members of the same organism, and generally between two (or more) coexistent or in any way co-ordinated observations, each belonging to a normal group. Let x and y be the measurements of a pair thus constituted. Then[1] it may be expected that the conjunction of particular values for x and y will approximately obey the two-dimensioned normal law which has been already exhibited (see § 7).

19. In the expression above given, put $1/\sqrt{km}=r$, and the equation for the frequency of pairs having values of the attribute under measurement becomes

$$z=\frac{1}{2\pi\sqrt{km}\sqrt{1-r^2}}\ \exp-\left[\frac{(x-d)^2}{k}-2r\frac{(x-d)(y-b)}{\sqrt{k}\ \sqrt{m}}+\frac{(y-b)^2}{m}\right]/2(1-r^2).$$

This formula is of very general application.[2] If two sets of measurements were made on the height, or other measurable feature, of the proverbial "Goodwin Sands" and "Tenterden Steeple," and the first measurement of one set was coupled with the first of the other set, the second with the second, and so on, the pairs of magnitudes thus presented would doubtless vary according to the above-written law, only in that case r would presumably be zero; the expression for z would reduce to the product of the two *independent* probabilities that particular values of x and y should concur. But slight interdependences between things supposed to be totally unconnected would often be discovered by this law of error in two or more dimensions.[3] It may be put in a more convenient form by substituting ξ for $(x-d)/\sqrt{k}$ and η for $(y-b)/\sqrt{m}$. The equation of the surface then becomes $z=(1/2\pi\sqrt{1-r^2})\ \exp-[\xi^2-2r\xi\eta+\eta^2]/2(1-r^2)$. If the frequency of observations in the vicinity of a point is represented by the number of dots in a small increment of area, when $r=0$ the dots will be distributed uniformly about the origin, the *curves of equal probability* will be circles. When r is different from zero the dots will be distributed so that the majority will be massed in two quadrants: in those for which ξ and η are both positive or both negative when r is positive, in those for which ξ and η have opposite signs when r is negative. In the limiting case, when $r=1$ the whole host will be massed along the line $\eta=\xi$, every deviation ξ being attended with an equal deviation η. In general, to any deviation of one of the variables ξ' there corresponds a set or "array" (Pearson) of values of the other variable; for which the frequency is given by substituting ξ' for ξ in the general equation. The section thus obtained proves to be a normal probability-curve with standard deviation $\sqrt{1-r^2}$. The most probable value of η corresponding to the assigned value of ξ is $r\xi'$. The equation $\eta=r\xi$, or rather what it becomes when translated back to our original co-ordinates $(d-b)/\sigma_2=r(x-d)\sigma_1$, where σ_1, σ_2 are our $\sqrt{k}$, $\sqrt{m}$ respectively,[4] is often called a *regression-equation.*[5] A verification is to hand in the above-cited statistics, which Professor Weldon obtained by casting batches of dice. If the dice were perfect, $r\ (=1/\sqrt{km})$ would equal $\frac{1}{2}$, and as the dice proved not to be very imperfect, the coefficient is doubtless approximately $=\frac{1}{2}$. Accordingly, we may expect that, if axes x and y are drawn through the point of maximum-frequency at the centre of the compartment containing 244 observations, corresponding to any value of x, say $2\nu i$ (where i is the side of each square compartment), the most probable value of y should be νi, and corresponding to $y=2\nu i$ the most probable value of x should be νi. And in fact these regression-equations are fairly well fulfilled for the *integer* values of ν (more than which could not be expected from *discrete* observations): *e.g.*, when $x=+4i$, the value of y, for which the frequency (25) is a maximum, is as it ought to be $+2i$; when $x=-2i$ the maximum (119) is at $y=-i$; when $x=-4i$ the maximum (16) is at $y=-2i$; when y is $+2i$ the maximum (138) is at $x=+i$; when y is $-2i$, the maximum (117) at $x=-i$, and in the two cases ($x=+2i$, and $y=+4i$), where the fulfilment is not exact, the failure is not very serious.

20. Analogous statements hold good for the case of three or more dimensions of error.[6] The normal law of error for any number of variables, $x_1\ x_2\ x_3$, may be put in the form $z=(1/(2\pi)^{\frac{n}{2}}\sqrt{\triangle})\ \exp-[R_{11}x_1^2+R_{22}x_2^2+\text{etc.}+2R_{12}x_1x_2+\text{etc}]/2\triangle$ where $\triangle$ is the determinant:—

$$\begin{matrix} 1 & r_{12} & r_{13} & \cdots \\ r_{21} & 1 & r_{23} & \cdots \\ r_{31} & r_{32} & 1 & \cdots \\ \vdots & \vdots & \vdots & \end{matrix}$$

each r, *e.g.*, $r_{23}\ (=r_{32})$, is the coefficient of correlation between two of the variables, *e.g.*, x_2, x_3; R_{11} is the first minor of the determinant formed by omitting the first row and first column; R_{22} is the first minor formed by omitting the second row and the second column, and so on; $R_{12}\ (=R_{21})$ is the first minor formed by omitting the first column and second row (or *vice versâ*). The principle of correlation plays an important *rôle* in Natural History. It has replaced the notion that there is a simple proportion between the size of organs by the appropriate conception that there are simple proportions existing between the *deviation* from the average of one organ and the *most probable* value for the coexistent deviation of the other organ from its average.[7] Attributes favoured by "natural" or other selection are found to be *correlated* with other attributes which are not directly selected. The extent to which the attributes of an individual depend upon those of his ancestors is measured by correlation.[8] The principle is instrumental to most of the important "mathematical contributions" which Professor Pearson has made to the theory of Evolution.[9] In social inquiries, also, the principle promises a rich harvest. Where numerous fluctuating causes go to produce a result like pauperism or immunity from small-pox, the ideal method of eliminating chance would be to construct "regression-equations" of the following type:—"Change per cent. in pauperism [in the decade 1871–81] in rural districts $= -27{\cdot}07$ per cent., $+0{\cdot}299$ (change per cent. out-relief ratio), $+0{\cdot}271$ (change per cent. on proportion of old), $+{\cdot}064$ (change per cent. in population)."[10]

21. In order to determine the best values of the coefficients involved in the law of error, and to test the worth of the results obtained by using any values, recourse must be had to *inverse probability*.

Inverse probability.

22. The simplest problem under this head is where the *quæsitum* is a single real object and the data consist of a large number of observations, $x_1, x_2, \ldots x_n$, such that if the number were indefinitely increased, the completed series would form a normal probability-curve with the true point as its centre, and having a given modulus c. It is as if we had observed the position of the dints made by the fragments of an exploding shell so far as to know the distance of each mark measured (from an origin) along a right line, say the line of an extended fortification, and it was known that the shell was fired perpendicular to the fortification from a distant ridge parallel to the fortification, and that the shell was of a kind of which the fragments are scattered according to a normal law[11] with a known coefficient of dispersion; the question is at what position on the distant ridge was the enemy's gun probably placed? By received principles the probability, say P, that the given set of observations should have resulted from measuring (or aiming at) an object of which the real position was between x and $x+\triangle x$ is

$$\triangle x\ J\ \exp-[(x-x_1)^2+(x-x_2)^2+\text{etc.}]/c^2;$$

where J is a constant obtained by equating to unity $\int_{-\infty}^{+\infty}P\,dx$

[1] Where plurality of independent causes is presumable.

[2] Herschel's *à priori* proposition concerning the law of error in two dimensions (above, § 2) might still be defended either as *generally* true, so many phenomena showing no trace of interdependence, or on the principle which justifies our putting $\frac{1}{2}$ for a probability that is unknown (below, § 24), or 5 for a decimal place that is neglected; correlation being equally likely to be positive or negative. The latter sort of explanation may be offered for the less serious contrast between the *à priori* and the empirical proof of the law of error in one dimension (below, § 44).

[11] If normally in any direction indifferently according to the two- or three-dimensioned law of error, then normally in one dimension when collected and distributed in *belts* perpendicular to a horizontal right line, as in the example cited below, § 47.

(since the given set of observations must have resulted from some position on the axis of x). The value of x, from which the given set of observations *most probably* resulted, is obtained by making P a *maximum*. Putting $\frac{dP}{dx}=0$, we have for the maximum $\left(\frac{d_2P}{dx_2}\right.$ being negative for this value), the arithmetic mean of the given observations. The accuracy of the determination is measured by a probability-curve with modulus $c/\sqrt{n}$. Thus in the course of a very long siege if every case in which the given group of shell-marks $x_1, x_2 \cdots x_n$ was presented could be investigated, it would be found that the enemy's cannon was fired from the position x', the (point right opposite to the) arithmetic mean of x_1, x_2, &c., x_n, with a frequency assigned by the equation

$$z=(\sqrt{n}/\sqrt{\pi}c)\ \exp.-n(x-x')^2/c^2.$$

23. Simple as this solution is, it is not the one which has most recommended itself to Laplace. He envisages the *quæsitum* not so much as that point which is *most probably* the real one, as that point which may *most advantageously* be put for the real one. In our illustration it is as if it were required to discover from a number of shot-marks not the point[1] which in the course of a long siege would be most frequently the position of the cannon which had scattered the observed fragments, but the point which it would be best to treat as that position—to fire at, say, with a view of silencing the enemy's gun—having regard not so much to the frequency with which the direction adopted is right, as to the extent to which it is wrong in the long run. As the measure of the detriment of error, Laplace[2] takes "la valeur moyenne de l'erreur à craindre," the mean first power of the errors taken positively on each side of the real point. The mean square of errors is proposed by Gauss as the criterion.[3] *Any* mean power indeed, the integral of any function which increases in absolute magnitude with the increase of its variable, taken as the measure of the detriment, will lead to the same conclusion, if the normal law prevails.[4]

24. Yet another speculative difficulty occurs in the simplest, and recurs in the more complicated, inverse problem. In putting P as the probability, deduced from the observations that the real point for which they stand is x (between x and $x+\triangle x$), it is tacitly assumed that prior to observation one value of x is as probable as another. In our illustration it must be assumed that the enemy's gun was as likely to be at one point as another of (a certain tract of) the ridge from which it was fired. If, apart from the evidence of the shell-marks, there was any reason for thinking that the gun was situated at one point rather than another, the formula would require to be modified. This *à priori* probability is sometimes grounded on our *ignorance*; according to another view, the procedure is justified by a rough general knowledge that over a tract of x for which P is sensible one value of x occurs about as often as another.[5]

25. Subject to similar speculative difficulties, the solution which has been obtained may be extended to the analogous problem in which the *quæsitum* is not the real value of an observed magnitude, but the mean to which a series of statistics indefinitely prolonged converges.[6]

26. Next, let the modulus, still supposed given, not be the same for all the observations, but c_1 for x_1, c_2 for x_2, &c. Then P becomes proportional to

$$\exp-[(x-x_1)^2/c_1^2+(x-x_2)^2/_2^2+\&c.].$$

Method of least squares. And the value of x which is both the most probable and the "most advantageous" is $(x_1/c_1^2+x_2/c_2^2+\text{etc.})/(1/c_1^2+1/c_2^2+\&c.)$; each observation being weighted with the inverse mean square of observations made under similar conditions.[7] This is the rule prescribed by the "Method of Least Squares"; but as the rule in this case has been deduced by genuine inverse probability, the problem does not exemplify what is most characteristic in that method, namely, that a rule deducible from the hypothesis that the errors of observations obey the normal law of error is employed in cases where the normal law is not known, or even is known not, to hold good. For example, let the law of error for each observation be of the form of

$$z=(1\sqrt{\pi}c)\ \times\ \exp[-x^2/c^2-2j(x/c-2x^3/3c^3)],$$

where j is a small fraction, so that z may equally well be equated to $(1/\sqrt{\pi}c)[1-2j(x/c-2x^3/3c^3)]\ \exp-x^2/c^2$, a law which is actually very prevalent.[8] Then, according to the genuine inverse method, the most probable value of x is given by the quadratic equation $\frac{d}{dx}\log P=0$, where $\log P=\text{Const.}-\Sigma(x-x_r)^2/c_r^2-\Sigma 2j[(x-x_r)/c_r-2(x-x_r)^3/3c_r^3]$, Σ denoting summation over all the observations. According to the Method of Least Squares, the solution is the weighted arithmetic mean of the observations, the weight of any observation being inversely proportional to the corresponding mean square, *i.e.* $c_r^2/2$ (the terms of the integral which involve j vanishing), which would be the solution if the j's are all zero. We put for the solution of the given case what is known to be the solution of an essentially different case. How can this paradox be justified? Many of the answers which have been given to this question seem to come to this. When the data are unmanageable, it is legitimate to attend to a part thereof, and to determine the most probable (or the "most advantageous") value of the *quæsitum*, and the degree of its accuracy, from the selected portion of the data as if it formed the whole. This throwing overboard of part of the data in order to utilize the remainder has often to be resorted to in the rough course of applied probabilities. Thus an Insurance Office only takes account of the age and some other simple attributes of its customers,[9] though a better bargain might be made in particular cases by taking into account all available details. The nature of the method is particularly clear in the case where the given set of observations consists of several batches, the observations in any batch ranging under the same law of frequency with mean x'_r and mean square of error k_r, the function and the constants different for different batches; then if we confine our attention to those parts of the data which are of the type x'_r and k_r—ignoring what else may be given as to the laws of error—we may treat the x'_r's as so many observations, each ranging under the normal law of error with its coefficient of dispersion; and apply the rules proper to the normal law. Those rules applied to the selected data give, as the most probable (and also the most advantageous) solution, that which is prescribed by the method of least squares, and for the law of error to which the relation is liable, the normal law with modulus $\sqrt{2\ \Sigma k/n}$.

27. This principle might be illustrated by the proposal to make the economy of datum a little less rigid: to utilize not indeed all, but a little more, of our materials—not only the mean square of error for each batch, but also the mean cube of error. To begin with the simple case of a single homogeneous batch; suppose that in our example the fragments of the shell are no longer scattered according to the normal law. By the Method of Least Squares it would still be proper to put the arithmetic mean of the given observations for the true point required, and to measure the accuracy of that determination by a probability-curve of which the modulus is $\sqrt{2k/n}$, where k is the mean square of deviation (of fragments from their mean). If it is thought desirable to utilize more of the data, there is available the proposition that the arithmetic mean of a numerous set of observations, say x_1, $x_2 \cdots x_n$, taken as a sample from an indefinitely large group obeying any the same law of frequency, varies from set to set according to the following law of error (to be established later[10])—

$$z=\sqrt{n/\pi}(1/c)\ \exp-[nx^2/c^2+2nj(x/c-2x^3/3c^3)/c^3]=f(x)\ \text{say};$$

where $\frac{1}{2}c^2=$ the mean square of deviation and $j=$ the mean cube of deviation and j/c^3, say j, is small. Then by abstraction analogous to that which has just been attributed to the Method of Least Squares, we may regard the datum as a single observation, the arithmetic mean subject to the law of error $z=f(x)$. The most probable value of the *quæsitum* is therefore[11] given by the equation $f'(x-x')=0$, where x' is the arithmetic mean of the given observations. From the resulting quadratic equation, putting $x=x'+\xi$, and recollecting that j is small, we have $\xi/c^2=j/c$, $\xi=jc$. That is the correction due to the utilization of the mean cube of error. The *most advantageous* solution cannot now be determined ($f(x)$ being unsymmetrical) without assuming a particular form for the function of detriment. The (additional) degree of accuracy is no longer measured by a normal probability-curve. This method of

least squares *plus* cubes may easily be extended[1] to the case of several batches, or even individual observations, having different laws of frequency.

28. This application of the rules of Inverse Probability not to the actual data but to a selected part thereof, this economy of probability, is widely practised in miscellaneous statistics in order to determine the worth of an average: whether the observed difference between two averages is accidental or significant of a real difference.[2] For instance, let the data be ages at death of individuals of two classes (*e.g.*, temperate or drunken, urban or rural, &c.) who have been under observation since the age of, say, 20. Granted that the ages of death conform to Gompertz's law,[3] the determination of the most probable mean of either class and of the probability that the observed means of say n individuals of one class, n' of another, should differ by so much, would most perfectly be effected by the genuine inverse method: dealing with Gompertz's law in the same manner as with the normal law of error in a case where the observations were known to obey the latter law. But it suffices by assumed inversion to proceed *as if* our data consisted of two observations x' and y', the average ages at death of the two classes, each average obeying the normal law of error, with respective moduli $c_1 = \sqrt{[(x'-x_1)^2 + (x'-x_2)^2 + \text{etc.}]2/n}$, $c_2 = \sqrt{[(y'-y_1)^2 + (y'-y_2)^2 + \text{etc.}]2/n}$, where x_1, x_2, &c., y_1 y_2, &c., are the respective sets of observed ages at death; as follows from the *law of great numbers*,[4] whatever the law of distribution of the given observations. According to a well-known property of the normal law, the difference between the averages of n and n' observations respectively will range under a probability-curve with modulus $\sqrt{c_1^2 + c_2^2}$, say c. Whence for the probability that a difference as great as the observed one, say e, should have occurred by chance we have $\frac{1}{2}[1-\theta(\tau)]$, where $\tau = e/c$, and $\theta(x)$ is the integral $(2/\sqrt{\pi}\int_0^x(\exp -x^2)dx$, given in many treatises.[5]

Abridged methods.

29. This principle may be applied to other kinds of means besides the arithmetic, in particular the *median* (that point which has as many of the given observations above as below it). By simple induction we know that the median of a large sample of observations is a probable value for the *true* median; how probable is determined as follows from a selection of our data. First suppose that all the observations are of the same weight. If x' were the true median, the probability that as many as $\frac{1}{2}n + r$ of the observations should fall on either side of that point is given by the normal law for which the exponent is $-2r^2/n$.[6] This probability that the observed median will differ from the true one by a certain number of observations is connected with the probability that they will differ by a certain extent of the abscissa, by the proposition that the number of observations contained between the true and apparent median is equal to the small difference between them multiplied by the density of observations at the median—in the case of normal and generally symmetrical curves the greatest ordinate. This is the second datum we require to select. In the case of the normal curve it may be calculated from the modulus itself, determined by induction from a selection of data. If the observations are not all of the same worth, weight may be assigned by counting one observation as if it occurred oftener than another. This is the essence of Laplace's Method of Situation.[7]

30. In its simplest form, where all the given observations are of equal weight, this method is of wide applicability. Compared with the genuine inverse method, it is always more convenient, seldom much less accurate, sometimes even more accurate. If the given observations obey the normal law, the precision of the median is less than the precision of the arithmetic mean by only some 25 per cent.—a discrepancy not very serious where only a rough estimate of the worth of an average (see § 28) is required. If the observations do not obey the normal law—especially if the extremities are abnormally divergent—the precision of the median may be greater than that of the arithmetic mean.[8]

31. Yet another instance of the contrast between genuine and abridged inversion is afforded by the problem to determine the modulus as well as the mean for a set of observations known to obey the normal law; what the first problem[9] becomes when the coefficient of dispersion is not given. By inverse probability we ought in that case, in addition to the equation $\frac{dP}{dx}=0$, to put $\frac{dP}{dc}=0$. Whence $c^2 = 2[x'-x_1)^{10}$ $+ (x'-x_2)^2 + \text{etc.} + (x'-x_n)^2]/n$, and $x' = (x_1 + x_2 + \text{etc.} + x^n)/n$. This solution differs from that which is often given in the text-books[2] in that there, in the expression for c^2, $(n-1)$ occurs in the denominator instead of n. The difference is explained by the fact that the authorities referred to determine c, not by genuine inversion, but by ordinary induction, by a condition which certainly would be fulfilled in the long run, but does not express the whole of our data; a condition in this respect like the equation of c to $\sqrt{\pi}(\Sigma e)/n$, where e is the difference (taken positively, without regard to its sign) between any observation and the arithmetic mean of all the observations.[11]

Determination of frequency-constants.

32. Of course the determination of the most probable value is subject to the speculative difficulties proper to *à priori* probability; which are particularly striking in this case, as it appears equally natural to take as that constant, of which the values are *à priori* equally probable, $k(=c^2/2)$, or even[12] $h(=1/c^2)$, the measure of weight, as in fact Laplace has done;[13] yet no two of these assumptions can be exactly true.[14]

33. A more convenient determination is obtained from simple induction by equating the modulus to some datum of the observed group to which it would be equal if the group were complete—in particular to the distance from the median of some percentile (or point which marks off a certain percentage, *e.g.*, 25 of the given observations) multiplied by a factor corresponding to the percentile obtainable from a familiar table. Mr Sheppard has given an interesting proof[15] that we cannot by way of percentiles obtain such good[16] results for the frequency-constants as by the use of "the average and average square" [the method prescribed by inverse probability].

34. The same philosophical subtleties, with greater mathematical complications, meet us when we pass on to the case of two or more *quæsita*. The problem under this head which mainly exercised the older writers was to determine a number of unknown quantities, given a larger number, n, of equations involving them.

Entangled measurements.

35. Supposing the true values approximately known, by substituting the approximate values in the given equations and expanding, according to Taylor's theorem, there will be obtained for the *corrections*, say x, y · · · ,n linear equations of the form

$$a_1x + b_1y \cdot\cdot = f_1$$
$$a_2x + b_2y \cdot\cdot = f_2,$$

where each a and b is a known coefficient, and each f is a fallible observation. Suppose that the error to which each is liable obeys the normal law, and that the modulus pertaining to each observation is the same—which latter condition can be secured by multiplying each equation by a proper factor—then if x' and y' are the true values of the *quæsita*, the frequency with which $(a_1x' + b_1y' - f_1)$ assumes different values is given by the equation $z = 1/(\sqrt{\pi}\,c_1)$ $\exp -[a_1x + b_1y - f_1]^2/c_1^2$, where c_1 is a constant which, if not known beforehand, may be inferred, as in the simpler case, from a set of observations. Similar statements holding for the other equations, the probability that the given set of observations f_1, f_2, &c., should have resulted from a particular system of values for $x, y \cdot\cdot$ is $J \exp -[(a_1x + b_1y - f_1)^2/c_1^2 + (a_2x + b_2y - f_2)^2/c_2^2 + \text{\&c.}]$, where J is a constant determined on the same principle as in the analogous simpler cases.[17] The condition that P should be a maximum gives as many linear equations for the determination of x' y' · · · as there are unknown quantities.

36. The solution proper to the case where the observations are

known to range according to the normal law may be extended to numerous observations ranging under any law, on the principles which justify the use of the Method of Least Squares in the case of a single *quæsitum*.

37. As in that simple case, the principle of economy will now justify the use of the *median, e.g.*, in the case of two *quæsita*, putting for the true values of x and y that point for which the sum of the perpendiculars let fall from it on each of a set of lines representing the given equations (properly weighted) is a minimum.[1]

Normal correlation.

38. The older writers have expressed the error in the determination of one of the variables without reference to the error in the other. But the error of one variable may be regarded as *correlated* with that of another; that is, if the system $x', y' \cdots$ forms the solution of the given equations, while $x'+\xi$, $y'+\eta \cdots$ is the real system, the (small) values of $\xi, \eta \cdots$ which will concur in the long run of systems from which the given set of observations result are normally correlated. From this point of view Bravais, in 1846, was led to several theorems which are applicable to the now more important case of correlation in which ξ and η are given (not in general small) deviations from the means of two or more correlated members (organs or attributes) forming a normal group.

39. To determine the frequency-constants of such a group it is proper to proceed on the analogy of the simple case of one-dimensioned error. In the case of two dimensions, for instance, the probability p_1 that a given pair of observations (x_1, y_1) should have resulted from a normal group of which the means are x' y' respectively, the standard deviations σ_1 and σ_2, and the coefficient of correlation r, may be written—

$$\triangle x \triangle y \triangle \sigma_1 \triangle \sigma_2 \triangle r \ (1/2\pi\sqrt{\sigma_1\sigma_2(1-r^2)} \exp - \tfrac{1}{2}E^2,$$

where $E^2 = (x'-x_1)^2/\sigma_1{}^2 - 2r(x'-x_1)(y'-y_1)/\sigma_1\sigma_2 + (y'-y_1)^2/\sigma_2{}^2$.

A similar statement holds for each other pair of observations (x_2y_2), $(x_3y_3)\cdots$; with analogous expressions for $p_2, p_3\cdots$. Whence, as in the simpler case, we have $p_1 \times p_2 \times$ &c. $\times p_n/J$ (a constant) for P, the *à posteriori* probability that the given observations should have resulted from an assigned system of the frequency-constants. The most probable system is determined by making P a maximum, and accordingly equating to zero each of the following expressions—

$$\frac{dP}{dx}, \quad \frac{dP}{dy}, \quad \frac{dP}{d\sigma_1}, \quad \frac{dP}{d\sigma_2}, \quad \frac{dP}{dr}.$$

The values of the arithmetic mean and of the standard deviation for each variable are what have been obtained in the simple case of one dimension. The value of r is $\Sigma(x'-x_r)(y'-y_r)/\sigma_1\sigma_2$.[2] The probable error of the determination is assigned on the assumption that the errors to which it is liable are small.[3] Such coefficients have already been calculated for a great number of interesting cases. For instance, the coefficient of correlation between the human stature and femur is 0·8, between the right and left femur is ·96, between the statures of husbands and wives is 0·28.[4]

40. This application of inverse probability to determine correlation-coefficients and the error to which the determination is liable was first made by Professor Pearson.[5] He has pointed out a circumstance which seems to be of great importance in the theory of evolution: that the errors incident to the determination of different frequency-coefficients are apt to be mutually correlated. Thus if a random selection be made from a certain population, the correlation-coefficient which fits the organs of that set is apt to differ from the coefficient proper to the complete group in the same sense as some other frequency-coefficients.

41. The last remark applies also to the determination of the coefficients, in particular those of correlation, by abridged methods, on principles explained with reference to the simple case; for instance, by the formula $r = \Sigma\eta/\Sigma\xi$, where $\Sigma\xi$ is the sum of (some or all) the positive (or the negative) deviations of the values for one organ or attribute measured by the modulus pertaining to that member, and $\Sigma\eta$ is the sum of the values of the other member, which are associated with the constituents of $\Sigma\xi$.[6] There is a variety of this method which is certainly much less troublesome, and is perhaps not much less accurate, than the method prescribed by genuine inversion.[7]

42. A method of rejecting data analogous to the use of percentiles in one dimension is practised when, given the frequency of observations for each increment of area, *e.g.*, each $\triangle x \triangle y$, we utilize only the frequency for *integral* areas. Mr Sheppard has given an elegant solution of the problem: to find the correlation between two attributes, given the medians L, and M, of a normal group for each attribute and the distribution of the total group, as thus[8]—

	Below L,	*Above L,*
Below M,	*P*	*R*
Above M,	*R*	*P*

If cos D is put for r, the coefficient of correlation, it is found that $D = \pi R/(P+R)$. For example, let the group of statistics relating to dice already[9] cited from Professor Weldon be arranged in four quadrants by a horizontal and a vertical line, each of which separates the total groups into two halves: lines of which the equations prove to be respectively $y = 6·11$ and $x = 6·156$. For R we have 1360·5, and for P 687·5 roughly. Whence $D = \pi \times 0·66$; $r = \cos 0·66 \times \pi = -\tfrac{1}{2}$ nearly, as it ought; the negative sign being required by the circumstance that the lower part of Mr Sheppard's diagram shown here corresponds to the upper part of Professor Weldon's diagram shown in § 8.

43. Necessity rather than convenience is sometimes the motive for resort to percentiles. Professor Pearson has applied the median method to determine the correlation between husbands and wives in respect of the darkness of eye-colour, a character which does not admit of exact graduation: "our numbers merely refer to certain groupings, arranged, it is true, in increasing darkness of colour, but in no way corresponding to equal increases in colour-intensity."[10] From data of this sort, having ascertained the number of husbands with eye-colour above the median tint who marry wives with eye-colour above the median tint, Professor Pearson finds for r the coefficient of correlation +0·1. A general method for determining the frequency-constants when the data are, or are taken to be, of the integral sort has been given by Professor Pearson.[11] Attention should also be called to Mr Yule's treatment of the problem by a sort of logical calculus on the lines of Boole and Jevons.[12]

Abnormal correlation.

44. In the cases of correlation which have been so far considered, it has been presupposed that the things correlated range according to the normal law of error. But now, suppose the law of distribution to be no longer normal: for instance, that the dots on the plane of xy,[13] representing each a pair of members, are no longer grouped in elliptic (or circular) rings of equal frequency, that the locus of the maximum y deviation, corresponding to an assigned x deviation, is no longer a right line. How is the interdependence of these deviations to be formulated? It is submitted that such data may be treated as if they were normal: by an extension of the *Method of Least Squares*, which is justified by the *law of great numbers*, in two or more dimensions.[14] Thus when the amount of pauperism together with the amount of outdoor relief is plotted in several unions, there is obtained a distribution far from normal. Nevertheless if the average pauperism and average outdoor relief are taken for *aggregates*—say quintettes or decades—of unions taken at random, it may be expected that these means will conform to the normal law, with coefficients obtained from the original data, according to the rule which is proper to the case of the normal law. By obtaining averages conforming to the normal law, as by the simple application of the method of least squares, we should not indeed have utilized the whole of our data, but we shall put a part of it in a very useful shape. Although the regression-equations obtained would not accurately fit the original material, yet they would have a certain correspondence thereto. What sort of correspondence may be illustrated by an example in games of chance, which

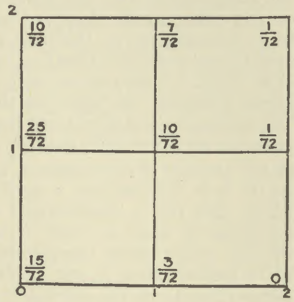
[13] Above, § 19.

[14] Above, § 9.

Professor Weldon has kindly supplied. Three half-dozen of dice having been thrown, the number of dice with more than three points in that dozen which is made up of the first and the second half-dozen, is taken for y, the number of sixes in the dozen made up of the first and the third half-dozen, is taken for x. Thus each twofold observation (xy) is the sum of six twofold elements, each of which is subject to a law of frequency represented by the annexed diagram; where[1] the figures outside denote the number of successes of each kind, for the ordinate the number of dice with more than three points (out of a cast of two dice), for the co-ordinate the number of sixes (out of a cast of two dice, one of which is common to the aforesaid cast); and the figures inside denote the comparative probabilities of each twofold value (*e.g.*, the probability of obtaining in the first cast two dice each with more than three points, and in the second cast two sixes, is 1/72). Treating this law of frequency according to the rule which is proper to the normal law, we have (for the element) if the sides of the compartments each $=i$



$$\sigma_1 = i\sqrt{5/18}\,;\ \sigma_2 = i/\sqrt{2}\,;\ \mathrm{r} = 1/\sqrt{20}.$$

Whence for the regression-equation which gives the value of the ordinate most probably associated with an assigned value of the abscissa we have $y = x \times \mathrm{r}\sigma_2/\sigma_1 = 0{\cdot}3x$; and for the other regression-equation, $x = y/6$. Accordingly, in Professor Weldon's statistics, which are reproduced in the annexed diagram, when

	0	1	2	3	4	5	6	7	8	9	10	11	12
12					1								
11		4	3	3	3	1							
10	3	17	15	13	10	4	3	1					
9	12	51	59	61	36	14	5	3					
8	36	135	154	150	64	21	5	2	1				
7	74	195	260	179	112	35	5	1					
6	90	248	254	170	75	26	3						
5	93	220	230	124	51	8	2						
4	86	162	127	75	19	4	1						
3	37	86	56	17	6	2							
2	14	23	23	4	3								
1	2	4											
0													

$x=3$ the most probable value of y ought to be 1. And in fact this expectation is verified, x and y being measured along lines drawn through the centre of the compartment, which *ought* to have the maximum of content, representing the concurrence of one dozen with *two* sixes and another dozen with *six* dice having each more than three points, the compartment which in fact contains 254 (*almost* the maximum content). In the absence of observations at $x = -3i$ or $y = \pm 6i$, the regression-equations cannot be further verified. At least they have begun to be verified by batches composed of six elements, whereas they are not verifiable at all for the simple elements. The normal formula describes the given statistics as they behave, not when by themselves, but when massed in crowds: the regression-equation does not tell us that, if x' is the magnitude of one member, the most probable magnitude of the other member associated therewith is rx', but that, if x' is the average of several samples of the first member, then rx' is the most probable average for the specimens of the other member associated with those samples. In the view of the present writer this is the rationale of Mr Yule's proposal to construct regression-equations according to the normal rule "without troubling to investigate the normality of the distribution."[2] Mr Yule's own view of the subject is, however, well worthy of attention.

[1] Cp. above, § 8.

[2] *Proc. Roy. Soc.* vol. lx. p. 477.

45. Professor Pearson has given a beautiful application of the theory of correlation to test the empirical evidence that a given group conforms to a proposed formula, *e.g.*, the normal law of error.[3]

Empirical verification.

46. Supposing the constants of the proposed function to be known,—in the case of the normal law the arithmetic mean and modulus—we could determine the position of any percentile, *e.g.*, the median, say a. Now the probability that if any sample numbering n were taken at random from the complete group, the median of the sample, a', would lie at such a distance from a that there should be r observations between a and a' is $\int_{\mathrm{r}}^{\infty} \sqrt{2/\pi n}\,\exp - 2\mathrm{r}^2/n$.[4]

If, then, any observed set has an excess which makes the above-written integral very small, the set has probably not been formed by a random selection from the supposed given complete group. To extend this method to the case of two, or generally n, percentiles, forming $(n+1)$ compartments, it must be observed that the excesses, say e and e′, are not independent but correlated. To measure the probability of obtaining a pair of excesses respectively as large as e and e′, we have now (corresponding to the extremity of the probability-curve in the simple case) the solid content of a certain probability-surface outside the curve of equal probability which passes through the points on the plane xy assigned by e, e′ (and the other data). This double, or in general multiple, integral, say P, is expressed by Professor Pearson with great elegance in terms of the quadratic factor, called by him χ^2, which forms the exponent of the expression for the probability that a particular system of the values of the correlated e, e′, &c., should concur—

$$\mathrm{P} = \sqrt{2/\pi}\int_{\chi}^{\infty} e^{-\frac{1}{2}\chi^2}\,d\chi + \sqrt{\frac{2}{\pi}}\,e^{-\frac{1}{2}\chi^2}\left[\frac{\chi}{1} + \frac{\chi^3}{1\cdot 3} + \cdots + \frac{\chi^{n-2}}{1\cdot 3\cdots(n-2)}\right]$$

when n is odd; with an expression different in form, but nearly coincident in result, when n is even. The practical rule derived from this general theorem may thus be stated. Find from the given observations the probable values of the coefficients pertaining to the formula which is supposed to represent the observations. Calculate from the coefficients a certain number, say n, of percentiles; thereby dividing the given set into $n+1$ sections, any of which, according to calculation, ought to contain say m of the observations, while in fact it contains m'. Put e for $m' - m$; then $\chi^2 = \Sigma e^2/m$. Professor Pearson has given in an appended table the values of P corresponding to values of $n+1$ up to 20, and values of χ^2 up to 70. He does not conceal that there is some laxity involved in the circumstance that the coefficients employed are not known exactly, only inferred with probability.[5]

47. One of Professor Pearson's illustrations is particularly relevant here. The annexed table gives the distribution of 1000 shots fired at a line in a target, the hits being arranged in belts drawn on the target parallel to the line:—

Belt.	Observed Frequency.	Normal Distribution.	e	e^2/m
1 . .	1	1	0	0
2 . .	4	6	−2	0·667
3 . .	10	27	−17	10·704
4 . .	89	67	+22	7·224
5 . .	190	162	+28	4·839
6 . .	212	242	−30	3·719
7 . .	204	240	−36	5·400
8 . .	193	157	+36	8·255
9 . .	79	70	+9	1·157
10 . .	16	26	−10	3·846
11 . .	2	2	0	0
	1000	1000	...	45·811

The "normal distribution" is obtained from a normal curve, of which the coefficients are determined from the observations. From the value of χ^2, viz. 45·8, and of $(n+1)$, viz. 11, we deduce, with sufficient accuracy from Professor Pearson's table, or more exactly from the formula on which the table is based, that P = ·000,001,5 · ·. "In other words, if shots are distributed on a target according to the normal law, then such a distribution as that cited could only be expected to occur on an average some 15 or 16 times in 10,000,000 times."

[3] *Phil. Mag.*, July 1900.

[4] As shown above, § 29.

[5] *Loc. cit.* p. 166.

48. That the normal law of error should not be exactly fulfilled is not disconcerting to those who ground the law upon the plurality of independent causes. On that view the normal law would only be exact when the numbers of elements from which it is generated is very great. In general, when that number is large, but not indefinitely great,[1] there is required a correction, formed by adding to the exponent of the normal function, namely, $-x^2/c^2$, a descending series of terms of the order $1/\sqrt{n}$, $1/n$, &c., respectively, where n is the number of the elements.[2]

Second and further approximations to the law of error.

49. The first term of this series may be written

$$-2(j/c^3)[x/c - 2\,x^3/3c^3];$$

where $c^2/2$ is the mean square of deviation for the compound and also the sum of the mean squares of deviations for the component elements, j is the mean cube of deviations for the compound and the sum of the mean cubes for the components; and the elements are supposed to be such and so numerous that j/c^3 is of the order $1/\sqrt{n}$. The order of the term being such, it is permissible to bring the term down from the exponent by expanding and neglecting higher powers.[3] This second approximation, first given by Poisson, was rediscovered by De Forest.[4] The present writer has obtained it[5] by extending the method of partial differential equations which Mr Morgan Crofton had applied to find the first approximation. By a further extension of this method a *third* and further approximations may be found. The corrected normal law is then of the form[6]

$$z = \frac{1}{\sqrt{\pi c}}\left(\exp - \frac{x^2}{c^2}\right)\left[1 - 2\mathrm{j}\left(\frac{x}{c} - \frac{2}{3}\frac{x^3}{c^3}\right) + \mathrm{j}^2\left(-\frac{5}{3} + 10\frac{x^2}{c^2} - \frac{20}{3}\frac{x^4}{c^4} + \frac{8}{9}\frac{x^6}{c^6}\right) + \mathrm{i}\left(\tfrac{1}{2} - 2\frac{x^2}{c^2} + \frac{2}{3}\frac{x^4}{c^4}\right)\right];$$

where $\mathrm{j} = j/c^3$, $\mathrm{i} = i/c^4$, j and c are defined as above, i is the sum of the respective differences for each element between its mean fourth power of error and thrice its mean square of error,[7] and also the corresponding difference for the compound. The formula may be verified by the case of the *binomial*, considered as a simple case of the law of great numbers. Here

$$c^2 = 2npq,\ j = npq\,(q-p),\ i = npq\,(1-6pq).^{8}$$

These values being substituted for the coefficients in the general formula, there results an expression which may be obtained directly by continuing[9] to expand the expression for a term of the binomial.

50. In virtue of the second approximation a set of observations is not to be excluded from the affinity to the normal curve because, like the curve of barometric heights,[10] it is slightly asymmetrical. In virtue of the third approximation it is not excluded because, like the group of shot-marks above examined, it is, though almost perfectly symmetrical, in other respects apparently somewhat abnormal. If the thus corrected *quasi-normal* curve be submitted to the same criterion as just now the normal curve, to test its capacity to represent a given group of shot-marks, the improbability is reduced from odds of millions to one to odds of hundreds to one.[11] The details of the calculation are given elsewhere,[12] but some points of general interest may be noticed here.

51. Regarding the contents of the *first* "belt" as spread out between 0·5 and 1·5, and so on, we have 6·482 for the arithmetic mean. For the mean square of deviation we have $(\Sigma\epsilon^2)/1000$, where ϵ is the distance of the centre of a belt from 6·482; upon the supposition that the contents of each belt are massed at its centre. But, as Mr Sheppard has pointed out,[13] in order to obtain from this sum, say μ_2, the proper *integral*, say (μ_2), the rough value ought to be corrected thus: $(\mu_2) = \mu_2 - h^2/12$, where h is the breadth of a "belt." Here h is unity, and accordingly, the rough value being 2·485676, we have for the corrected value of μ_2 2·402343. The correction is particularly important, when it is well above the probable error to which the determination of μ_2 is liable on account of the paucity of observations, namely, $\mu_2/\sqrt{n}$ nearly.[14] However, in all such calculations a good margin is to be left for the possibility that the n observations are not perfectly *independent*: the accidents of wind or nerve[15] which affected one shot may have affected other shots immediately before or after. Again, it is to be noticed that in our application of the criterion one or two compartments at the extremity have not been taken into account, since on the hypothesis under consideration it is not to be expected that there should be a close fit at the extremities.[16] The contents of the compartments, connected by the formula with the *integral* and the *ordinate* of the probability-curve, are readily determined from a table of that integral and its differences.[17]

52. A formula much more comprehensive than the corrected normal law is proposed by Professor Pearson under the designation of the "generalized probability-curve." The ground and scope of the new law cannot be better stated than in the words of the author:—

The "generalized probability-curve."

53. "The slope of the normal curve is given by a relation of the form

$$\frac{1}{y}\frac{dy}{dx} = -\frac{x}{c_1}.$$

The slope of the curve correlated to the skew binomial, as the normal curve to the symmetrical binomial, is given by a relation of the form

$$\frac{1}{y}\frac{dy}{dx} = -\frac{x}{c_1 + c_2 x}.$$

Finally, the slope of the curve correlated to the hypergeometrical series (which expresses a probability distribution in which the contributory causes are not independent, and not equally likely to give equal deviations in excess and defect), as the above curves to their respective binomials, is given by a relation of the form

$$\frac{1}{y}\frac{dy}{dx} = -\frac{x}{c_1 + c_2 x + c_3 x^2}.$$

This latter curve comprises the two others as special cases, and, so far as my investigations have yet gone, practically covers all *homogeneous* statistics that I have had to deal with. Something still more general may be conceivable, but I have found no necessity for it."[18]

54. The "hypergeometrical series," it should be explained, had appeared as representative of the distribution of black balls[19] in the following case. "Take n balls in a bag, of which pn are black and qn are white, and let r balls be drawn and the number of black be recorded. If $r > pn$, the range of black balls will lie between 0 and pn; the resulting frequency-polygon is given by a hypergeometrical series." The "generalized probability-curve" presents two forms[20]—

$$y = y_0(1 + x/a_1)^{\nu a_1}(1 - x/a_2)^{\nu a_2},$$

$$\text{and } y = y_0\,\frac{1}{(1 + x^2/a^2)^m}\,e^{-\nu\tan^{-1}x/a}.$$

[1] As probably in Natural History. Cp. Galton, *Phil. Mag.*, 1875.

[2] The elements being supposed independent and of the same order of magnitude; *mutatis mutandis* if there is a superior order. Cp. above, § 9.

[3] The form employed by Todhunter, *History of Probability*, Art. 993, and in the article on "Probability" in the 8th edition of *Ency. Brit.*, § 136.

[4] *The Analyst* (Iowa), vol. ix.

[5] *Phil. Mag.*, February 1896.

[6] The part of the third approximation affected with j^2 may be found by proceeding to another step in the method described (*Phil. Mag.*, 1896 vol., p. 96). The remaining part of the third approximation is found by the same method (or the variant on p. 97) from the new partial differential equation $\frac{dy}{di} = \frac{1}{24}\frac{d_4 y}{dx^4}$, where i is the difference between the actual mean fourth power of deviation and what it would be if the normal law held good. Further approximations may be obtained on the same principle.

[7] $\mu_4 - 3\mu_2^2$ in the notation which Professor Pearson has made familiar.

[8] Cp. Pearson, *Trans. Roy. Soc.*, 1895, vol. clxxxvi., A, p. 347.

[9] Above, § 4, referring to Todhunter, *History*, Art. 993. The third (or second additional term of) approximation for the binomial, given explicitly by Professor Pearson, *Trans. Roy. Soc.*, 1895, A, footnote of 347, will be found to agree with the general formula above given, when it is observed that the correction affecting the *absolute term*, his y_0, disappears in his formula by division.

[10] *Journ. Stat. Soc.*, 1899, p. 550, referring to Pearson, *Trans. Roy. Soc.*, 1898, A.

[11] That the improbability still remains so considerable is perhaps due to the fact that the statistics form a mixture of two types, as suggested by Professor Pearson, *Trans. Roy. Soc.*, 1894, vol. clxxxv., A, p. 91.

[12] *Journ. Stat. Soc.*, 1901.

[17] Such as Table III. appended to De Morgan's article on the "Calculus of Probabilities" in the *Ency.-Metropol.* Mr Burgess's tables in the *Transactions of the Edinburgh Royal Society for 1900*, giving the values of the *ordinate* as well the integral, are most convenient for the present purpose.

[18] *Trans. Roy. Soc.*, 1895, A, p. 381; *et ante.*

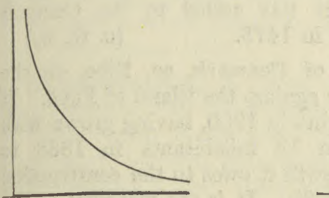
[19] *Ibid.* p. 360.

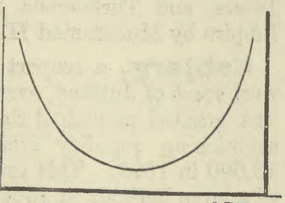
[20] *Ibid.* p. 367.

When a_1, a_2, ν are all finite and positive, the *first* form represents, in general, a skew curve, with limited range in both directions; in the particular case, when $a_1 = a_2$ a symmetrical curve, with range limited in both directions. If $a_2 = \infty$, the curve reduces to

$$y = y_0(1 + x/a_1)^{\nu a_1} e^{-\nu x};$$

representing an asymmetrical binomial with $\nu = 2\mu_2/\mu_3$, and $a_1 = 2\mu_2^2/\mu_3 - \mu_3/2\mu_2$, μ_2, and μ_3, being respectively the mean second and mean third power of deviation measured from the centre of gravity. In the particular case, when μ_3 is small, this form reduces to what is above called the "quasi-normal" curve; and when μ_3 is zero, a_1 becoming infinite, to the simple normal curve. The pregnant general form yields two less familiar shapes apt to represent curves of the character shown in the annexed diagrams—the





one occurring in a good number of instances, such as infant deaths, the values of houses, the number of petals in certain flowers; the other less familiarly illustrated by *Consumptivity* and *Cloudiness*.[1] The *second* solution represents a skew curve with unlimited range in both directions. Professor Pearson has successfully applied these formulæ to a number of beautiful specimens culled in the most diverse fields of statistics. The flexibility with which the generalized probability-curve adapts itself to every variety of existing groups no doubt gives it a great advantage over the normal curve, even in its extended form. It is only in respect of *à priori* evidence that the latter can claim precedence.[2]

55. Any law which has claims to be called *the* law of error may be expected in certain circumstances to give rise to some derivative laws which should be noticed here. First, statistics relating to two (or more) different types are apt to be mixed; for instance, the measurements of human heights in a country comprising two distinct races.[3]

56. If the measurements for each race are grouped according to a normal law of error, the *quæsita* are the constants in the curve

$$y = \alpha(1/\sqrt{\pi}c_1)\exp - (x-a)^2/c_1^2 + \beta(1/\sqrt{\pi}c_2)\exp - (x-b)^2/c_2^2,$$

where α and β are the proportionate sizes of the two groups $(\alpha + \beta = 1)$; a and b are the respective centres of gravity; and c_1 c_2 the respective moduli. The data are measurements each of which relates to *one or other* of these component curves. A splendid solution of this difficult problem has been given by Professor Pearson.[4] The five unknown quantities are connected by him with the centre of gravity of the given observations, and the mean second, third, fourth, and fifth powers of their deviations from that centre of gravity, by certain rational algebraic equations, which reduce to an equation in one variable of the *ninth* dimension. In an example worked by Professor Pearson, this fundamental equation had three possible roots, two of which gave very fair solutions of the problem, while the third suggested that there might be a *negative* solution, importing that the given system would be obtained by *subtracting* one of the normal groups from the other; but the coefficients for the negative solution proved to be imaginary. "In the case of crabs' foreheads, therefore, we cannot represent the frequency curve for their forehead length as the difference of two normal curves." In another case, which *primâ facie* seemed normal, Professor Pearson found that "all nine roots of the fundamental nonic lead to imaginary solutions of the problem. The best and most accurate representation is the normal curve."

57. Another modification may be introduced by an objection which has been made against the normal curve, and might be made, with as much or as little justice, against any other formula claiming to be *the* law. If there is any law applicable to things in general, it must be applicable to functions of things, which also are things. But if a group is transformed by substituting for the size of each member a certain function of that size, the resulting group will not conform to the same law of error as the original one, in general and except when the function is linear. If the diameters of oranges of the same species vary according to the normal, or any other law of error, then the volume of oranges, being proportioned to the cube of the diameter, will not vary according to that law. The answer to this difficulty is that, very generally, the variable part of an organ or attribute is so small relatively to the whole, that the cube or other ordinary function of the whole may be treated as a linear function of the variable part. Thus the cubes of a man's height may be written $M^3(1 + e/M^3)$, where M is the mean, say 67″, and e is the deviation of the individual's height from the mean. The modulus for human heights being about 3·7, it appears that the transformed measure is very nearly $M^3(1 + 3e/M)$, for five-sixths of the group differing by a proportion less than ·01 from the true cube. Occasionally, however, it may be expected that the deformation due to such transformations will be sensible. The case in which the compound magnitude is a function other than linear of a sum of elements is a species of the more general case in which the compound is a function, explicit or implicit, of the elements. If the function admits of expansion in ascending powers of the variables,[5] the second and further approximations to the law of error for the compound have the same form as that which has been given for the case in which the compound is a linear function of the elements (see § 49), the constants c j i, and have the same relation as before to the mean powers of the compound; but not the same relation to the mean powers of the elements. For instance, the mean cube of error for the compound (which, divided by the cube of the modulus, forms the constant j) is now affected not only by the asymmetry of the laws of frequency for the elements but also by the asymmetry of the structure, the function combining the elements. When the function involving the elements does not admit of expansion, being not even approximately linear, then the law of frequency for the compound will be not even approximately normal. For example, if the velocities (in any assigned direction) of molecules of equal, say unit, mass are distributed according to a normal law of which the centre is zero, then the squares of the velocities, the energies, will be distributed according to a quite different law[6] represented by a unilateral curve, in that respect like the statistics of infant mortality (above, § 54).

58. Other deformations of the law of error might be suggested. But the question recurs: How far does the fact that a certain function fits the facts tolerably establish that this, and not another, is the true formula? For instance, the hump in the curve representing the column headed d_x in a life-table, which has been regarded as a probability-curve of the "normal"[7] or of the "generalized"[8] variety, may really be due to those conditions of accelerated mortality which render the Gompertz–Makeham law appropriate to the facts; the expression for the decrement of l_x according to that law having a unique maximum when values of the constants suited to life-tables are substituted in the formula. The statistician must not forget that there are other laws besides the law of error.

An exhaustive list of writings on a nearly related subject, the "Method of Least Squares," was given by Merriman in *Connecticut Trans.* iv. Leading publications up to 1884 are noticed under PROBABILITY, *Ency. Brit.*, 9th edition. Czuber, the latest there mentioned, has referred to, criticized, and improved on many of his predecessors. Since that date a great advance has been made by Pearson in the mathematical papers frequently cited above. See also the references to Burbury, Galton, Lewis, Sheppard, and others. Bowley's *Elements of Statistics*, part ii., forms an introduction which leads the beginner easily, yet far. (F. Y. E.)

Erzerúm.—1. A viláyet of Asiatic Turkey, divided into three sanjaks—Erzerúm, Erzingan, and Bayezid; its area is about 29,600 square miles, and the population numbers 645,500 (Moslems, chiefly Kúrds, 500,500; Christians, 145,000, of whom 135,500 are Armenians). It includes the highest portion of the Armenian plateau (see ARMENIA), and in it the two arms of the Euphrates, the Araxes and the Acampsis, take their rise. It is an agricultural country with few industries. There are large forests; iron, salt, sulphur, and other mineral springs; and unworked salt and coal mines. 2. A fortified town,

capital of the viláyet and sanjak of the same name, residence of a Governor-General, situated at an altitude of 6250 ft., on the lower slopes of the Palentoken Dagh (10,300 ft.), at the south-east corner of a plain (5750 ft.), through which the Western Euphrates runs. North of the town there are large marshes, and to the east is the Deveboyún range (6950 ft.). It is an important military station, with a large garrison, military school, and hospital. It has an enceinte which encloses an area of 3 square miles, only partially covered by the town, and is protected against an attack from the east and south-east by a strong line of defences, 27 miles long. The houses are partly well built and partly underground. There are interesting remains of Seljúk buildings of the 12th century, including tombs and the beautiful Chifte Minareh. The chief Armenian quarter is on the north side. The streets are irregular, badly drained, and dirty, and the town, though well supplied with water, is said to be the most insanitary in Asia Minor. The climate is healthy, and the atmosphere clear and dry except in spring. The winter is very severe, with great cold (–20° to –22° F.), deep snow, and blizzards. The summer heat is moderate (59° to 77° F.). Roads lead to Trebizond and Riza on the Black Sea; westwards to Sivas, Kara-hissar, and Kelkit Chiftlik; southwards to Diarbekr, Músh, and Van; and eastwards to Olti and Kars. The industries, excepting blacksmith's and coppersmith's work and tanning, have died out. The fertile plain north of the town was well cultivated with wheat, barley, millet, and vegetables, but since the Armenian massacres of 1895 much of the land has lain fallow. The exports are wheat, linseed, furs, live-stock, &c. (value in 1896, £148,510; in 1900, £177,750). The imports are Manchester goods, sugar, copper, petroleum, &c. (value in 1896, £188,510; in 1900, £262,355). The Persian trade has almost disappeared since 1890; poverty has been increasing; and, with the Kúrds unsubdued and the Armenians impoverished, there seems little prospect of an early recovery of prosperity. The population is 40,000 (Moslems, 26,500; Armenians, 11,000; Greeks and Protestants, 1500; Persians, Jews, &c., 1000). There are British and other European consulates, and an American mission, with schools. The town was unsuccessfully attacked by the Russians, 9th November 1877; occupied by them, 7th February 1878, during the armistice; and restored to Turkey after the Treaty of Berlin. On the 30th and 31st October 1895 there was a massacre of Armenians, in which officers and men of the Turkish army took part. In November 1901 an earthquake caused serious damage to the town.

See Consular Reports in Parliamentary Papers, *Turkey*, 1878–99; Murray, *Handbook to Asia Minor*, 1895. (C. W. W.)

Erzingan, ERZINJAN, or ERIZA (Arsinga of Middle Ages), the chief town of a sanjak of the Erzerúm viláyet of Asiatic Turkey. It is the headquarters of the 6th Army Corps, and a place of great military importance, and is situated, at an altitude of 3900 feet, on the Sivas–Erzerúm road, near the western extremity of a rich well-watered plain, through which the Frát Su, or Western Euphrates, runs. It is surrounded by orchards and gardens, and stands on nearly level ground, about one mile from the right bank of the Frát, which here runs in two channels crossed by bridges. The main street, which forms part of the military road from west to east, is 30 feet wide; the other streets are narrow, unpaved, and dirty. In the town and its vicinity are large barracks, military stores, school, hospital, Government tanneries, and boot and clothing factories. There are also silk, cotton, and copper industries. The climate is hot in summer and moderate in winter. Roads lead to Sivas, Kerasund, Trebizond, Erzerúm, and Kharpút. The population numbers 23,000 (Moslems 15,500, Armenians 7500). The plain, which is almost surrounded by lofty mountains, is highly productive, and has many villages. Wheat, fruit, vines, &c., are grown, and cattle and sheep are bred. About 11 miles south-west of the town is the celebrated Armenian Monastery of St Gregory, "The Illuminator." It occupies the site of an early town in which there was a temple of Anaitis, and was an important place early in the 4th century, when St Gregory lived in it. The district passed from the Byzantines to the Seljúks after the defeat of Romanus, 1071, and from the latter to the Mongols, in 1243. After having been held by Mongols, Tatars, and Turkomans, it was added to the Osmanli Empire by Muhammad II. in 1473. (C. W. W.)

Esbjerg, a seaport of Denmark, co. Ribe, on the west coast of Jutland, over against the island of Fanö. It was granted municipal rights in 1900, having grown with astonishing rapidity from 13 inhabitants in 1868 to 13,000 in 1899. This growth it owes to the construction of a large harbour in 1868–88. It is the principal outlet westwards for S. Jutland; exports pork and meat, butter, eggs, fish, cattle and sheep, skins, lard, and agricultural seeds. The port was entered by 774 vessels of 257,418 tons in 1899 and cleared by 775 of 259,205 tons. There are very large slaughter-houses.

Escanaba, capital of Delta county, Michigan, U.S.A., on Little Bay de Noquette, an inlet of Green Bay, Lake Michigan, at an altitude of 608 feet. It is regularly laid out, with seven wards. The manufacture of lumber is its principal industry, and it has a large lake commerce in lumber and iron ore. Population (1880), 3026; (1890), 6808; (1900), 9549.

Esher, William Baliol Brett, 1ST VISCOUNT (1817–1899), English lawyer and Master of the Rolls, was a son of the Rev. Joseph G. Brett, of Chelsea, and was born on 13th August 1817. He was educated at Westminster and at Caius College, Cambridge. Called to the Bar in 1840, he went the Northern Circuit, and became a Q.C. in 1861. On the death of Richard Cobden he unsuccessfully contested Rochdale as a Conservative, but in 1866 was returned for Helston in unique circumstances. He and his opponent polled exactly the same number of votes, whereupon the Mayor, as returning officer, gave his casting vote for the Liberal candidate. As this vote was given after four o'clock, however, an appeal was lodged, and the House of Commons allowed both members to take their seats. Brett rapidly made his mark in the House, and in 1868 he was appointed Solicitor-General and received the honour of knighthood. On behalf of the Crown he prosecuted the Fenians charged with having caused the Clerkenwell explosion. In Parliament he took a leading part in the promotion of Bills connected with the administration of law and justice. He was shortly afterwards appointed a Justice in the Court of Common Pleas. Some of his sentences in this capacity excited much criticism, notably so in the case of the gas stokers' strike, when he sentenced the defendants to imprisonment for twelve months, with hard labour, which was afterwards reduced by the Home Secretary to four months. On the reconstitution of the Court of Appeal in 1876, Brett was elevated to the rank of a Lord Justice. After holding this position for seven years, he succeeded Sir George Jessel as Master of the Rolls in 1883. In 1885 he was raised to the House of Lords as Baron Esher. He opposed the Bill proposing that an accused person or his wife might give evidence in their own case, and supported the Bill which empowered Lords of Appeal to sit and vote after their retirement. The Solicitors Act of 1888, which increased the powers of the Incorporated

Law Society, owed much to his influence. In 1880 he delivered a remarkable speech in the House of Lords, deprecating the delay and expense of trials, which he regarded as having been increased by the Judicature Acts. Lord Esher suffered, perhaps, as Master of the Rolls from succeeding a lawyer of such eminence as Jessel. He had a caustic tongue, but also a fund of shrewd common sense, and one of his favourite considerations was whether a certain course was "business" or not. He retired from the Bench at the close of 1897, and a Viscounty was conferred upon him on his retirement, a dignity never given to any judge, Lord Chancellors excepted, "for mere legal conduct since the time of Lord Coke." He died 24th March 1899.

Eskilstuna, a town of Sweden, province of Södermanland, on the navigable river Eskilstuna, which connects Lakes Mälar and Hjelmar, 55 miles west from Stockholm, the chief seat in Sweden of the iron and steel industries, its cutlery being especially noted. There is a technical school for the metal industries. Population (1880), 8161; (1900), 13,663.

Eski-Shehr, a town in Asia Minor, in the Kutaya sanjak, of the Khudavendikiar (Brúsa) viláyet; a station on the Haidar Pasha–Angora Railway, 194½ miles from the former and 164 miles from Angora, and the junction for Konia; situated on the right bank of the Pursak Su (*Tembris*), a tributary of the Sakaría, at the foot of the hills that border the broad treeless valley. The town is divided by a small stream into a commercial quarter on low ground, in which are the bazárs, kháns, and the hot sulphur springs (122° F.); and a residential quarter on the higher ground. The population numbers 20,000 (Moslems 15,000, Christians 5000). The town is noted for its good climate, the Pursak Su for the abundance of its fish, and the plain for its fertility. The annual output of the celebrated meerschaum mines is valued at £272,000.

Eski-Zagra or **Stára-Zagóra,** chief town of a department in Eastern Rumelia, in the principality of Bulgaria, situated on the southern slope of the Balkans, 70 miles north-west of Adrianople. It is surrounded by vineyards, and has also cloth and carpet manufactures, copper foundries, and tanneries. The production of cocoons is also carried on in the district. The town having been almost wholly destroyed during the war of 1877, has been rebuilt on a regular plan, with wide and broad streets radiating from a fine central square, where are situated the principal public buildings. During the rebuilding of the town the foundations and remains of a very old town were discovered, with important Thracian, Roman, Byzantine, and Turkish antiquities. The old town, founded probably by the Macedonians, attained to such prosperity under the Romans that it was known as Augusta Traiana, but afterwards, to distinguish it from a Macedonian town of this name, it was named Beroe or Berrhoea. By the Turks the name was changed in the 17th century to Eski-Zagra or Eski-Zaara, but by the Bulgarians it is known as Stára-Zagóra. Population, 17,457, of whom about four-fifths are Bulgarians.

Esmarch, Johannes Friedrich August von (1823-——), German surgeon, was born at Tönning, in Schleswig-Holstein, on 9th January 1823. He studied at Kiel and Göttingen, and in 1846 became Langenbeck's assistant at the Kiel surgical hospital. He served in the Schleswig-Holstein War of 1848, first as officer and then as junior surgeon, and this directed his mind to the subject of military surgery. He was taken prisoner, but afterwards exchanged, and was then appointed as surgeon to a field hospital. During the truce of 1849 he settled at Kiel, but on the fresh outbreak of war he returned to the troops and was promoted to the rank of senior surgeon. In 1854 he became director of the surgical clinic at Kiel, and in 1857 head of the general hospital and professor at the university. During the Schleswig-Holstein War of 1864 Esmarch rendered good service to the field hospitals of Flensburg, Sundewitt, and Kiel. In 1866 he was called to Berlin as member of an Emergency Hospital Commission, and also to take the superintendence of the surgical work in the hospitals there. When the Franco-German War broke out in 1870 Esmarch was appointed surgeon-general and army consultant, and afterwards consulting surgeon at the great military hospital near Berlin. In 1872 he married Princess Henrietta von Schleswig-Holstein Sonderburg Augustenburg, aunt of the Empress Auguste Victoria. In 1887 a patent of nobility was conferred on him. Esmarch is one of the greatest authorities on hospital management and military surgery. His *Surgeon's Handbook on the Treatment of Wounded in War* was written for a prize offered by the Empress Augusta, on the occasion of the Vienna Exhibition of 1877, for the best handbook for the battlefield of surgical appliances and operations. This book is illustrated by admirable diagrams, showing the different methods of bandaging and dressing, as well as the surgical operations as they occur on the battlefield. Esmarch himself invented an apparatus, which bears his name, for squeezing the blood out of a limb before amputation. No part of Esmarch's work is more widely known than that which deals with "First Aid." *First Aid to the Wounded* and *First Aid to the Injured* are popular manuals on the subject. The latter is the substance of a course of lectures delivered by him in 1881 to a "Samaritan School," the first of the kind in Germany, founded by Esmarch in 1881, in imitation of the St John's Ambulance Classes which had been organized in England in 1878. These lectures were very generally adopted as a manual for First Aid Students, edition after edition has been called for, and they have been translated into twenty-three languages, the English version being the work of H.R.H. Princess Christian. No Ambulance course would be complete without a demonstration of the Esmarch bandage. It is a three-sided piece of linen or cotton, of which the base measures four feet and the sides two feet ten inches. It can be used folded or open, and applied in thirty-two different ways. It answers every purpose for temporary dressing and field-work, while its great recommendation is that the means for making it are always at hand.

Esperance, a town in West Australia, 275 miles north-east from Albany, with a large and safe natural harbour. It is a summer resort, and in the neighbourhood are interesting caves. Being on the high road between the Eastern states and the goldfields, it is likely to become an important seaport. It has a Government jetty 2000 feet long, with 18 feet depth of water alongside, and a new town jetty 600 feet long with 22 feet of water. Population, about 450.

Esperanza.—An old country town of Santa Clara Province, Cuba. It is noted for the quality and quantity of the guava jelly manufactured there. Population, 2177.

Espartero, Baldomero (1792–1879), Duke of Vitoria, Duke of Morella, Prince of Vergara, Count Luchana, Knight of the Toison d'Or, &c. &c., a famous Spanish soldier and statesman, was born at Granatula, a town of the province of Ciudad Real, on 27th February 1792. He was the ninth child of a carter, who wanted to make him a priest, but the lad at fifteen enlisted in a battalion of students to fight against the armies of Napoleon I. In 1811 Espartero was appointed a lieutenant of Engineers in Cadiz, but having failed to pass his examination, he entered a line regiment. In 1815 he went to America as a captain under General Morillo, who had been made commander-in-chief to quell the risings of the colonies on the Spanish Main. For eight years Espartero distinguished himself in the struggle against the colonists. He was several times wounded, and was made major and colonel on the battlefields of Cochabamba and Sapachni. He had to surrender to Sucre at the final battle of Ayacucho, which put an end to Castilian rule. He returned to Spain, and, like most of his companions in arms, remained under a cloud for some time. He was sent to the garrison town of Logroño, where he married the daughter of a rich landowner, Dona Jacinta Santa Cruz, who eventually survived him. Henceforth Logroño became the home of the most prominent of the Spanish political generals of the nineteenth century. Espartero became in 1832, on the death of King Ferdinand VII., one of the most ardent defenders of the rights of his daughter, Isabella II. The Government sent him to the front, directly the Carlist war broke out, as commandant of the province of Biscay, where he severely defeated the Carlists in many encounters. He was quickly promoted to a divisional command, and then made a lieutenant-general. At times he showed qualities as a *guerillero* quite equal to those of the Carlists, like Zumalacarregui and Cabrera, by his daring marches and surprises. When he had to move large forces he was greatly superior to them as an organizer and strategist, and he never disgraced his successes by cruelty or needless severity. Twice he obliged the Carlists to raise the siege of Bilbao before he was appointed commander-in-chief of the northern army on September 17, 1836, when the tide of war seemed to be setting in favour of the Pretender in the Basque provinces and Navarre, though Don Carlos had lost his ablest lieutenant, the Basque Zumalacarregui. His military duties at the head of the principal national army did not prevent Espartero from showing for the first time his political ambition. He displayed such radical and reforming inclinations that he laid the foundations of his popularity among the lower and middle classes, which lasted more than a quarter of a century, during which time the Progressists, Democrats, and advanced Liberals ever looked to him as a leader and adviser. In November 1836 he again forced the Carlists to raise the siege of Bilbao. His troops included the British Legion under Sir de Lacy Evans. This success turned the tide of war against Don Carlos, who vainly attempted a raid towards Madrid. Espartero was soon at his heels, and obliged him to hurry northwards, after several defeats. In 1839 Espartero carefully opened up negotiations with Maroto and the principal Carlist chiefs of the Basque provinces. These ended in their accepting his terms under the famous Convention of Vergara, which secured the recognition of their ranks and titles for nearly 1000 Carlist officers. Twenty thousand Carlist volunteers laid down their arms at Vergara; only the irreconcilables led by Cabrera held out for a while in the central provinces of Spain. Espartero soon, however, in 1840, stamped out the last embers of the rising, which had lasted seven years. He was styled "El pacificador de España," was made a grandee of the first class, and received two dukedoms.

During the last three years of the war Espartero, who had been elected a Deputy, exercised from his distant headquarters such influence over Madrid politics that he twice hastened the fall of the Cabinet, and obtained office for his own friends. At the close of the war the Queen Regent and her Ministers attempted to elbow out Espartero and his followers, but a *pronunciamiento* ensued in Madrid and other large towns which culminated in the Marshal's accepting the post of Prime Minister. He soon became virtually a dictator, as Queen Christina took offence at his popularity and resigned, leaving the kingdom very soon afterwards. Directly the Cortes met they elected Espartero Regent by 179 votes to 103 in favour of Arguelles, who was appointed guardian of the young Queen. For two years Espartero ruled Spain in accordance with his Radical and conciliatory dispositions, giving special attention to the reorganization of the administration, taxation, and finances, declaring all the estates of the church, congregations, and religious orders to be national property, and suppressing the *diezma*, or tenths. He suppressed the Republican risings with as much severity as he did the military *pronunciamientos* of Generals Concha and Diego de Leon. The latter was shot in Madrid. Espartero crushed with much energy a revolutionary rising in Barcelona, but on his return to Madrid was so coldly welcomed that he perceived that his prestige was on the wane. The advanced Progressists coalesced with the partisans of the ex-Regent Christina to promote *pronunciamientos* in Barcelona and many cities. The rebels declared Queen Isabelle of age, and, led by General Narvaez, marched upon Madrid. Espartero, deeming resistance useless, embarked at Cadiz on July 30, 1843, for England, and lived quietly apart from politics until 1848, when a Royal degree restored to him all his honours and his seat in the Senate. He retired to his house in Logroño, which he left six years later, in 1854, when called upon by the Queen to take the lead of the powerful Liberal and Progressist movement which prevailed for two years. The old Marshal vainly endeavoured to keep his own Progressists within bounds in the Cortes of 1854–56, and in the great towns, but their excessive demands for reforms and liberties played into the hands of a Clerical and reactionary Court, and of the equally retrograde governing classes. The growing ambition of General O'Donnell constantly clashed with the views of Espartero, until the latter, in sheer disgust, resigned his Premiership and left for Logroño, after warning the Queen that a conflict was imminent between O'Donnell and the Cortes, backed by the Progressist militia. O'Donnell's *pronunciamiento* in 1856 put an end to the Cortes, and the militia was disarmed, after a sharp struggle in the streets of the capital. After 1856 Espartero resolutely declined to identify himself with active politics, though at every stage in the onward march of Spain towards more liberal and democratic institutions he was asked to take a leading part. He refused to allow his name to be brought forward as a candidate when the Cortes of 1868, after the Revolution, sought for a ruler. Espartero, strangely enough, adopted a laconic phrase when successive Governments on their advent to power invariably addressed themselves to the venerable champion of liberal ideas. To all—to the Revolution of 1868, the Constituent Cortes of 1869, King Amadeus, the Federal Republic of 1873, the nameless Government of Marshal Serrano in 1874, the Bourbon restoration in 1875—he simply said: "Cumplase la voluntad nacional"—"Let the national will be accomplished." King Amadeus made him Prince of Vergara. The Restoration raised a statue to him near the gate of the Retiro Park in Madrid. Spaniards of all shades, except Carlists and Ultramontanes, paid homage to his memory when he passed away at his Logroño residence on January 8, 1879. His tastes were singularly modest, his manners rather reserved, but always kind and considerate for humble folk. He was a typical Spanish soldier-politician, though he had more of the better traits of the soldier born and bred than of the arts of the statesman. His military instincts did not always make it easy for him to accommodate himself to courtiers and professional politicians. (A. E. H.)

Espirito Santo, an Atlantic state of Brazil, between 18° 5′ and 21° 28′ S. lat., and 39° 48′ and 41° 30′ W. long., bounded on the N. by the state of Bahia, on the W. by that of Minas Geraes, on the S. by that of Rio de Janeiro, and on the E. by the Atlantic. Its area is 17,312 square miles, and it had a population in 1870 of 82,137, and in 1890 of 136,000. Its coast-line is about 250 miles long. The capital, Victoria, has 8000 inhabitants. Amongst other towns are Anchieta, S. Matheus, Serra, Guarapary Conceiçao da Barra, Porto do Cachoeiro, but of all of them the population is small. There are short railways at Cachoeiro do Ita, one along the Rio Castello, the other to Alegre.

Essen, a town of Prussia, in the Rhine province, 22 miles by rail north-east from Düsseldorf, the seat of the well-known iron and steel works of Krupp, employing (1900) some 25,150 persons. The buildings cover an area of 150 acres, and the area owned by the firm 870 acres. Here, too, are extensive coal-fields. Essen possesses a mining school and a deaf and dumb asylum. The very interesting minster church was restored in 1881–86. The Roman Catholics have a new church (St Joseph's) built in 1895, and the Evangelicals one (Holyrood) built in 1896. There are monuments to the Emperor William I. (1898), Alfred Krupp, and Bismarck. Population (1885), 65,064; (1895), 96,128; (1900) 118,863.

Essendon, a town in Victoria, Australia, in the county of Bourke, 5 miles north-west of Melbourne, with a station on the North-Eastern Railway. Meat-preserving and rope-making are the principal industries. Population, 15,200.

Essentuki, a watering town of Russia, North Caucasia, province of Terek, 10 miles by rail from Pyatigorsk; altitude, 1980 ft. Its alkaline and sulphur-alkaline mineral waters, similar to those of Ems, Selters, and Vichy, but superior in carbon dioxide and salts, are much visited in summer. The vegetation is poor, and the climate shows great variations in temperature. Population (1897), 9515.

Essex, one of the London home counties, situated on the south-east coast of England, and bounded on the E. and S.E. by the North Sea. On the S. it is separated from Kent by the river Thames, on the W. from Middlesex and Hertfordshire by the Lea and the Stort, and on the N.E. from Suffolk by the Stour, while on the N. it is conterminous with Cambridgeshire.

Area and Population.—The area of the ancient and geographical county is 987,028 acres, or 1542 square miles, with a population in 1881 of 576,434, and in 1891 of 785,445, of whom 390,515 were males and 394,930 females, the number of persons per square mile being 509, and of acres to a person 1·26. The population in 1901 was 1,085,576. Parts of Sudbury and Hawerhill Urban Sanitary Districts are in the administrative county of Suffolk, and must therefore be deducted from the administrative county of Essex, leaving an area of 985,545 acres. The area of the registration county is 904,642 acres, with a population in 1891 of 701,191; in 1901 of 1,062,452, of whom 524,634 were males and 537,818 females. Within this area the increase of population between 1891 and 1901 was 51·52 per cent. Between 1881 and 1891 the excess of births over deaths was 107,152, and the increase in resident population 208,894. The following table gives the number of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1899:—

Year	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880 .	3235	18,548	10,165	331	338
1890 .	4699	23,264	12,873	360	331
1899 .	7279	30,097	16,603	413	415

The following table shows the marriage-, birth-, and death-rates per 1000 of the population, with the percentage of illegitimate births, for a series of years:—

	1870–79.	1880.	1880–89.	1890.	1889–98.	1899.
Marriages . .	12·0	11·9	12·1	12·6	13·0	14·7
Births . . .	33·3	34·1	33·9	31·3	31·0	30·5
Deaths . . .	18·3	18·7	17·3	17·3	16·0	16·8
Percentage of Illegitimate Births .	4·1	3·6	3·3	3·0	2·9	2·8

The birth-rate is above the average and the death-rate is below the average. In 1891 there were in the county 8061 natives of Scotland, 7224 natives of Ireland, and 4012 foreigners.

Administration.—The ancient county is divided into eight parliamentary divisions, and it also includes the parliamentary boroughs of Colchester and West Ham, the latter consisting of two divisions. The administrative county includes six municipal boroughs, namely, Chelmsford (12,580), Colchester (38,351), Harwich (10,019), Maldon (5564), Saffron Walden (5896), Southend-on-Sea (28,857), and one county borough, West Ham (267,308). The following are urban districts:—Barking Town (21,547), Braintree (5330), Brentwood (4932), Brightlingsea (4501), Buckhurst Hill (4786), Burnham-on-Crouch (2918), Chingford (4372), Clacton (7453), East Ham (95,989), Epping (3789), Gray's Thurrock (13,831), Halstead (6072), Ilford (41,240), Leigh-on-the-Sea (3663), Leyton (98,899), Loughton (4730), Portslade-by-Sea (5217), Romford (13,656), Shoeburyness (4081), Waltham Holy Cross (6547), Walthamstow (95,125), Walton-on-the-Naze (2014), Wanstead (9179), Witham (3454), Wivenhoe (2560), Woodford (13,806). Essex is in the South-Eastern Circuit, and the assizes are held at Chelmsford. The boroughs of Harwich and West Ham have separate Commissions of the Peace, and the boroughs of Colchester, Maldon, and Saffron Walden have, in addition, separate courts of quarter sessions. The county is ecclesiastically within the diocese of St Albans, and is divided into two archdeaconries. There are 413 civil parishes and parts of three others.

Education.—The number of elementary schools on the 31st of August 1899 was 535, of which 175 were board and 360 were voluntary schools; the latter including 314 national Church of England schools, 5 Wesleyan, 14 Roman Catholic, and 27 "British and other." The average attendance at board schools was 67,026, and at voluntary schools 44,364. The total school board receipts for the year ended 29th September 1899 was over £612,516. The income under the Agricultural Rates Act was over £3604. There are five certified industrial schools in Essex, namely, Chelmsford, Essex Industrial School for Boys (150 boys); Grays, School Board for London Industrial School Ship *Shaftesbury* (350 boys); Halstead, Industrial School for Girls (70 girls); Little Ilford, St Nicholas Industrial School for Roman Catholic Boys (150 boys); Walthamstow, St John's Industrial School for Roman Catholic Boys (150 boys); also the Davenport Hill Industrial School (late of Brentwood, now in temporary premises at the Sanatorium, Margate), 100 boys; and Islington Home for Working Boys, closed for the present.

Agriculture.—About three-fourths of the total area is under cultivation, and of this area about one-third is under permanent pasture. Less than 2200 acres are in hill pasture, and nearly 31,000 acres are under woods. Wheat, barley, and oats are the principal corn crops (in this relative order), and their acreage has within recent years greatly diminished. Beans and peas are each nearly half the produce of oats. Turnips and Swedes and mangold occupy about half the area under green crops.

The following table gives the main divisions of the cultivated area at intervals of ten years from 1880:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	830,135	386,399	100,310	87,829	195,534	59,531
1890	834,151	353,918	98,677	94,807	236,314	49,630
1899	805,916	310,602	93,990	99,364	266,047	33,895

The following table gives particulars regarding the principal live stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880 .	43,385	77,332	23,886	356,536	83,245
1890 .	39,570	82,556	29,209	313,787	101,749
1899 .	39,040	90,377	35,766	295,051	88,743

Industries and Trade.—According to the annual report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 53,608, as compared with 50,494 in 1896. Textile factories employed 3288, of whom 1745 were employed in the manufacture of silk, and 757 in that of flax, hemp, jute, and China grass. In non-textile factories 43,912 persons were employed, of whom 6381 were employed in chemical industries and 5761 in the gas industry. Husbandry and stock-feeding are the chief industries of Essex. The manufacture of silk is carried on at Braintree and Halstead, and there is a silk mill at Chelmsford. Government powder works are situated at Waltham Abbey, and powder stores at Purfleet. The Royal Victoria and Albert Docks are in Plaistow Level; Tilbury docks were opened in 1886. The ports of the county are Barking, Bradwell, Brightlingsea, Burnham, Colchester, Grays, Harwich, Leigh, Maldon, Manningtree, Purfleet, Salcott, Southend, Wakering. There is steamer communication between London and Purfleet, Grays, Tilbury, Southend, Walton, Clacton, and Harwich. Steamers on the Orwell run from Harwich to Ipswich. There is a daily service of steamers between Harwich and Antwerp and the Hook of Holland. The oyster-beds of the Colne produce the famous Colchester native. The rivers Crouch, Roach, and Blackwater also produce native oysters.

Essex is supplied with railways by the Great Eastern Company—which has several distinct lines, with various branches.

There is a military station and depôt for recruits at Warley, and a garrison at Tilbury. At Shoeburyness there is an extensive ground for testing Government artillery of the largest calibre.

(H. B. W*.)

Essonnes, a town in the arrondissement of Corbeil, department of Seine-et-Oise, France, about 1 mile south-west of Corbeil, of which it may be regarded as a suburb. The church dates from the 13th century. The principal manufactures are machinery and paper, both conducted on a very extensive scale, the latter employing about 3000 men. Population (1881), 4999; (1896), 6844, (comm.) 8955; (1901), 9405.

Establishment AND **Disestablishment.**—Perhaps the best definition which can be given, and which will cover all cases, is that establishment implies the existence of some definite and distinctive relation between the State and a religious society (or conceivably more than one) other than that which is shared in by other societies of the same general character. Of course, a certain relationship must needs exist between the State and every society, religious or secular, by virtue of the sovereignty of the State over each and all of its members. Every society must possess certain principles or perform certain acts, and the State may make the profession of such principles unlawful, or impose a penalty upon the performance of such acts; and, moreover, every society is liable before the law as to the fulfilment of its obligations towards its members and the due administration of its property should it possess any. With all this establishment has nothing to do. It is not concerned with what pertains to the religious society *quâ* society, or with what is common to all religious societies, but with what is exceptional. It denotes any special connexion with the State, or privileges and responsibilities before the law, possessed by one religious society to the exclusion of others; in a word, establishment is of the nature of a monopoly. But it does not imply merely privilege. The State and the Church have mutual obligations towards one another: each is, to some extent, tied by the existence of this relationship, and each accepts the limitations for the sake of the advantages which accrue to itself. The State does so in view of what it believes to be the good of all its members; for "the true end for which religion is established is not to provide for the true faith, but for civil utility" (Warburton), even if the latter be held to be implied in the former. On the other hand, the Church accepts these relations for the facilities which they involve, *i.e.*, for its own benefit. It will be seen that this definition excludes, and rightly, many current presuppositions. Establishment affirms the *fact*, but does not determine the precise *nature*, of the connexion between the State and the religious society. It does not tell us, for example, when or how it began, whether it is the result of an unconscious growth (as with the Gallican Church previous to the French Revolution), or of a determinate legislative act (as with the same Church re-established by the Concordat of 1801). It does not tell us whether an endowment of the religious society by the State is included; what particular privileges are enjoyed by the religious society; and what limitations are placed upon the free exercise of its life. These things can only be ascertained by actual inquiry; for the conditions are precisely similar in no two cases.

Outside Britain.

To proceed to details. At the present day there is no established religion in the United States, the German Empire as a whole, Holland, Belgium, France (although France still exercises a certain influence in the East by virtue of its ancient relations with the Holy See, and certain provisions with regard to Roman Catholicism still exist by concordat), and Austria-Hungary (saving, indeed, "the rights of the sovereign arising from ecclesiastical dignity"); whereas there are religious establishments in Russia, Greece, Sweden, Norway, Denmark, Prussia, Spain, Portugal, and even in Italy, as well as in England and Scotland. These, however, differ greatly amongst themselves. In Russia the "Orthodox Catholic Eastern" is the State religion. The emperor is, by the fundamental laws of the empire, "the sovereign defender and protector of the dogmas of the dominant faith, who maintains orthodoxy and holy discipline within the Church," although, of course, he cannot modify either its dogmas or its outward order. Further, "the autocratic (*i.e.*, imperial) power acts in the ecclesiastical administration by means of the Most Holy Ruling Synod, created by it"; and all the officers of the Church are appointed by it. The enactments of the Synod do not become law till they have received the emperor's sanction, and are then published, not in its name but in his; and a large part of the revenues of the Church is derived from State subsidies. In Greece "the dominant religion (Ἡ ἐπικρατοῦσα θρησκεία) is that of the Eastern Orthodox Church of Christ"; and although toleration is otherwise complete, no proselytism from the Church of Greece is allowed. The king swears to protect it, but no powers pertain to him with regard to it such as those which the Tsar enjoys; the present king is not a member of it, but his successors must be. In Sweden, Lutheranism was adopted as the State religion by the Synod of Upsala (*Upsala möte*) in 1593, and the king must profess it. The "Lutheran Protestant Church" retains an episcopal order, and is supported out of its own revenues. Archbishops and bishops are chosen by the king out of those names submitted to him, and he also nominates to royal peculiars. The ecclesiastical law (*Kyrkolag*), first constituted in 1686, is part of the law of the State, but may not be modified or abrogated without the consent of a General Synod; and although *ad interim* interpretations of that law may be given by the king on the advice of the Supreme Court, since 1866 these have been subject to review and rejection by the next General Synod. In Norway the "Evangelical-Lutheran" is the "official religion," but the Church is supported by the State, its property having been secularized. It is also more subject to the king, who by the constitution is to "regulate all that concerns divine service and the clergy," and to see that the prescribed order is carried out. It is much the same in Denmark, where, however, the "Evangelical-Lutheran Church" has since 1849 been described as the National Church (*Folkekirche*) instead of the State Church (*Statskirche*) as formerly, and the constitution provides for a new fundamental law for its regulation, which has not yet been passed. For PRUSSIA, see *Ency. Brit.*, 9th edit., vol. xx. p. 17; it need only be added that self-government still tends to increase, but that the present emperor has exercised his office as *summus episcopus* more freely than most of his predecessors. In SPAIN the "Catholic, Apostolic, and Roman" religion is that of the State, "the nation binds itself to maintain its worship and its ministers," and the rites of any other religion are only permitted in private. The patriarch of the Indies and the archbishops are senators by right, and the king may nominate others from amongst the bishops; only laymen may sit in the chamber of deputies. Convents were suppressed, and their property confiscated, in 1835 and 1836; in 1859 the remaining ecclesiastical property was exchanged for untransferable Government securities, and the support of the clergy of the State Church is assured by an unrepealed law previous to the present constitution. In PORTUGAL it is much the same, but all the home bishops sit in the upper chamber as peers (*Pares do Reino*) by right, and there is no restriction on membership of the chamber of deputies. A more important point is that the king confers all ecclesiastical benefices and nominates the bishops, instead of their being chosen, as in Spain, by agreement between the civil power and the Papacy. In ITALY, in spite of the feud between the Papacy and the civil power, the fact remains that, by the *Statuto fondamentale*, "the Catholic, Apostolic, and Roman religion is the sole religion of the State," and the king may nominate "archbishops and bishops of the State" to be senators. The *Legge sulle prerogative del Summo Pontifice*, &c., or "Law of Guarantees," by which the papal prerogatives are secured, has been declared by the Council of State to be a fundamental law; and whilst many civil restrictions upon the activities of the Church are removed by it, outside Rome and the suburbicarian dioceses the royal *exequatur* is still required before a bishop is installed. Moreover, the bulk of Church property having been secularized, the Italian clergy receive a stipend from the State.

Church and State in Britain.

Establishment is, of course, a distinctively English term, but it implies precisely the same thing as "Staatsreligion" or "église dominante" does elsewhere, neither more nor less. It denotes the existence of a special relationship between Church and State without defining its precise nature. The statement that the Church of England or the Scottish Kirk is "established by law" denotes that it has a peculiar status before the law; but that is all. (*a*) There is no basis whatever for the once popular assumption that the word "established" as applied to the Church means "created," or the like; on the contrary, the modern use of the word in this sense is a misleading perversion. To *establish* is to make firm or stable; and a thing cannot be established unless it is already in existence. A few examples will make it clear that this is the true sense of the word, and that in which it is used here. "Stablish the thing, O God, that thou hast wrought in us" (Ps. lxviii. 28, P.B.; A.V. and R.V. "strengthen") implies that the thing is already wrought; it could not be "stablished" else. "Stablish your hearts" (Jas. v. 8) implies that the hearts are already in existence. "Until he had her settled in her raine With safe assuraunce and establishment" (*Faerie Queene*, v. xi. 35) would have been impossible unless the reign had already begun. This is the meaning of the words in many Tudor Acts of Parliament, "be it enacted, ordained, and established," or the like (21 Hen. VIII. c. 1; 27 Hen. VIII. c. 28, s. 9; 28 Hen. VIII. c. 13 [Ireland]; 28 Hen. VIII. c. 18 [Ireland], 33 Hen. VIII. c. 27; 1 Eliz. c. 1, ss. 15, 17; 1 Eliz. c. 4, s. 4); that which is then and there enacted is to be valid for the future. (*b*) Nor is it necessarily implied that establishment is a process completed once for all. Every law touching the Church slightly alters its conditions; everything that affects the relations of Church and State may be regarded as a measure of establishment or the reverse. When the two Houses of Parliament, in an address to William III. after his coronation, spoke of their proposed measures of toleration, the king said in his reply, "I do hope that the ease which you design to Dissenters will contribute very much to the establishment of the Church" (Cobbett, *Parl. Hist.* v. 218). And Defoe (in 1702) published an ironical tract with the title, *The Shortest Way with the Dissenters, or Proposals for the Establishment of the Church.* (*c*) Nor is it necessarily implied that there was any specific time at which establishment took place. Such may indeed be the case, as with the Kirk in Scotland; but it certainly cannot be said that the English Church was established at any particular time, or by any particular legislative act. There were, no doubt, periods when the existing relations between Church and State were modified or re-defined, notably in the 16th and 17th centuries; but the relations themselves are far older. In fact, they existed from the very first: the English Church and State grew up side by side, and from the beginning they were in close relations with one another. But although the state of thing which it represented was there from the first, the term "established" or "established by law" only came into use at a later date. Until there was some other religious society to be compared with it such a distinctive epithet would have had no point. As, however, there arose religious societies which had no status before the law, it became more natural; and yet more so when the formularies of the Church came to be "established" by civil sanctions (the Books of Common Prayer by 5 and 6 Edw. VI. c. 1, s. 4, &c.; the Articles by 13 Eliz. c. 12; the new Ordinal by 13 and 14 Car. II. c. 4, title). Accordingly, the Church itself came to be spoken of as established by law; first, it would seem, in the Canons of 1604, and subsequently in many statutes (12 and 13 Will. III. c. 2; 6 Anne, c. 8 and c. 11, &c.). In all such cases the Church is described as already established, not as being established by the particular canon or statute. In other words, the constitutional status of the Church is affirmed, but nothing is said as to how it arose.

The legislative changes of the 16th and 17th centuries brought "establishment" into greater prominence and greatly modified its conditions, but a moment's thought will show that it did not commence then. If, *e.g.*, all post-Reformation ecclesiastical statutes were non-existent, the relations between Church and State would be very different, but there would still be an "establishment." The bishops would sit in the House of Lords, the clergy would tax themselves in convocation, the Church courts would possess coercive jurisdiction, and so on. The present relations of Church and State in England may be briefly summed up as follows:—1. *The personal relation of the Crown to the Church*, including (*a*) restraints upon the action of convocation (formulated by 25 Hen. VIII. c. 19); (*b*) nomination of bishops, &c. (25 Hen. VIII. c. 20); (*c*) power of supervision as Visitor, long disused (26 Hen. VIII. c. 1; 1 Eliz. c. 1, s. 17); (*d*) power of receiving appeals as the fount of civil justice (25 Hen. VIII. c. 19, &c.). In connexion with these, it must be borne in mind that (*a*) the holder of the Crown receives coronation from the Church and takes an oath having reference to it (1 Will. III. c. 6), and (*b*) the Crown is held on the condition of communion with the Church of England (12 and 13 Will. III. c. 2, s. 3; the conditions of communion are laid down in the Prayer Book, which itself is sanctioned by law). 2. *The relation of the Church to the Crown in Parliament.* No change has been permitted in its doctrine or formularies without the sanction of an Act of Parliament. 3. *Privileges of the*

Church and clergy. Of these may be mentioned (*a*) the coercive jurisdiction of the Church courts; (*b*) the right of bishops to sit in the House of Lords. It need hardly be said that establishment in England does not include an endowment of the Church by the State. Nothing of the kind ever took place on any large scale, and the grants for Church purposes in the 18th century are comparable with the *regium donum* to Nonconformists.

The position of the Church of Ireland until its disestablishment (see below) was not dissimilar. With Scotland the case is different: it cannot with any accuracy be said that the legal status of the unreformed Church of Scotland survived the Reformation, even in a modified form. The establishment of the Kirk was an entirely new process, carried out by a more or less definite series of legislative and administrative Acts. For example, the Scottish Act of 1567, c. 6, declares it to be "the onely true and halie kirk of Jesus Christ within this realme." Again, by the Act of 1690, c. 5, the Crown and estates "ratifie and establish the Confession of Faith, . . . as also they do establish, ratifie, and confirm the Presbyterian government and discipline." The "Act of Security" of 1705, as incorporated in the Act of Union (5 Anne, c. 8, ss. 2–6), speaking of it "as now by law established," says that "Her Majesty . . . doth hereby establish and confirm" it, and finally declares this Act, "with the Establishment therein contained," to be "a fundamental and essential condition of the Union." Nevertheless, the conditions of establishment in the Scottish Kirk are much easier than those of the Church of England. It is bound by the statutes sanctioning its doctrine and order, but within these limits its legislative and judicial freedom is unimpaired. A Royal Commissioner is present at the meetings of the General Assembly, but he need not be a member of the Kirk; and there is no constitutional tie between the Crown and the Kirk such as there is in England. There is what may accurately be described as a State endowment, the bulk of the property of the old Church having been conferred upon the Scottish Kirk.

The Colonies.

Not unnaturally, the organization of Anglican Churches in the Colonies was followed in some cases by their establishment, which included endowment. It was so, for example, in the East and West Indies: and the disestablishment of the West Indian Church in 1868 was followed, in 1873, by a re-establishment of the Church in Barbadoes by the colonial legislature. India is the only other part of the empire (outside Great Britain) in which there is to-day a religious establishment.

Disestablishment.

Disestablishment is in theory the annulling of establishment; but since an established Church is usually rich, disestablishment generally includes disendowment, even where there is no State endowment of religion. It is, in a word, the abrogation of establishment, coupled with such a confiscation of Church property as the State thinks good in the interests of the community. The disestablishment of the West Indian Church in 1868 has already been referred to; in 1869 the Irish Church Disestablishment Bill was passed; and although nothing of the kind has yet taken place in England or Scotland, it is not for want of effort. Private bills relating to Scotland have more than once been brought forward; and in 1893 Mr Gladstone's Government made a determined attempt to disestablish and disendow the Church in Wales. A bill was passed through the House of Commons to suspend the creation of new interests in the four Welsh dioceses with a view to this; but it was thrown out by the House of Lords, and the subsequent general election showed that the feeling of the country was strongly against it.

The case of the Irish Church will illustrate the process of disestablishment, although, of course, the precise details would vary in other cases. The Irish Church Act (32 and 33 Vict. c. 42) was passed in 1869 by Mr Gladstone's first Government, after considerable opposition, and provided that from January 1, 1871, the union created by statute (39 and 40 Geo. III. c. 67) between the Churches of England and Ireland should be dissolved, and the Church of Ireland should "cease to be established by law." Existing ecclesiastical corporations were dissolved, and their rights ceased, compensation being given to all individuals and their personal precedence being secured for life. All rights of patronage, including those of the Crown, were abolished, with compensation in the case of private patrons; and the archbishops and bishops ceased to have the right of summons to the House of Lords. All laws restraining the freedom of action of the Church were repealed; the ecclesiastical law, however, to subsist by way of contract amongst the members of the Church (until altered by a representative body). Provision was made for the incorporation by charter of the representative body of the Church, should such a body be found, with power to hold landed property. All existing ecclesiastical property was vested in a Commission, which was to give compensation for life interests, to transfer to the new representative body the churches, glebe houses, and £500,000 in compensation for endowments by private persons since 1660, and to hold the rest for such purposes as Parliament might thereafter determine. For the subsequent fortunes of the disestablished Church, see IRELAND, CHURCH OF.

Estate Duty.—The Finance Act, 1894, imposed on all property passing by death after 1st August 1894 a duty called estate duty, in lieu of certain other duties previously payable. The objects of the Act were—(1) simplification of the death duties and equalization as between real and personal property, and (2) aggregation of all the property passing on a death, and taxation at rates graduated according to the value of the whole. Before the Act a duty (probate duty) was taken on the free personal property of deceased persons in the hands of the executor or administrator, without regard to the subsequent distribution. The legacy and succession duties were levied on distribution of the property passing on the death, from the persons taking any property under the will or intestacy of the deceased, or under settlement, or by devolution of title on his death. These two latter duties were mutually exclusive, and together covered practically all property passing by death. They were levied at rates graduated according to consanguinity. In 1888 an attempt was made to equalize the rates of the death duties as between property (mainly personalty in the United Kingdom not settled) which paid the probate and legacy duties, and property (mainly realty and settled personalty) which paid succession duty only. But the Finance Act, 1894, replaced the probate duty by a duty extending to all property real or personal passing on or by reference to death, whether by disposition of the deceased or not, without regard to its tenure or destination.

For this purpose all property passing on a death is aggregated to form one estate, on the capital value of which the duty is charged, at rates graduated from 1 to 8 per cent. according to the aggregate value. Besides the property of which the deceased was competent to dispose at his death, the aggregated estate includes property in which he had an interest ceasing on his death, from the cesser of which a benefit accrues, or which was disposed of by him within twelve months of death, or at any time, with reservation of an interest to himself. The extent to which property is deemed to pass on the cesser of a limited interest is measured by the proportion of the income to which the interest extended, without regard to the tenure of the deceased or his successor. Property may therefore be included in the aggregate estate at its capital value owing to the passing of a life-interest only, the property being settled so that the absolute ownership does not pass at all. But when the duty has once been paid on property passing under a settlement, the property does not again become chargeable until it passes on the death of a person who is or has been competent to dispose of it. To compensate for this advantage, when property passing under a settlement made after the Act pays the estate duty, a further duty of 1 per cent. (settlement estate duty) is taken, except where the only subsequent life-interest is that of the wife or husband of the deceased.

The rate of duty being fixed according to the aggregate capital value of the whole estate, the charge is distributed according to the different modes of disposition of the property comprised in the estate. The duty on the personalty which passes to the executor as such is paid by him, as the probate duty was, and comes out of the general estate. For the other property passing, trustees, or any person to whom it passes for a beneficial interest in possession, are made accountable, and are required to bring in an account of the property and pay the duty. The duty is a first charge on such property, and, when it is paid by a person having a life-interest only, he may charge the *corpus* of the property with it. The duty on real property included in an account is payable by eight yearly or sixteen half-yearly instalments, becoming due twelve months after the death, and bearing interest at 3 per cent. from that date. On other property, except in a few special cases, the duty bears interest at 3 per cent. from the date of the death. When the estate duty has been paid no further duty is chargeable on property comprised in the estate which passes to lineal relations of the deceased. But on property passing to collaterals or strangers legacy or succession duty, as the case may be, is payable by the devisees or successors, at a rate (which is the same whichever duty be payable) fixed according to consanguinity.

The total amount raised by death duties for the year 1893–94, the last complete year of the old system, was £9,941,855. For the year 1900–1901 the amount was £16,676,290, to which the estate duty contributed £12,685,211.

For a detailed account of the provisions of the Act of 1894 and subsequent amending Acts, and of the practical working of the new duty, reference is made to CARTMELL, *Finance Acts*, 1894–96—*Death Duties*, London, 1896; SOWARD, *Handbook to the Estate Duty*, 4th edit., London, 1900; and to the Reports of the Commissioners of Inland Revenue for 1894–95 and subsequent years. (P. D.)

United States.—The United States imposed a succession duty, by the War Revenue Act of 1898, on all legacies or distributive shares of personal property exceeding $10,000. It is a tax on the privilege of succession. Devises or distributions of land are not affected by it. The rate of duty runs from 75 cents on the $100 to $5 on the $100, if the legacy or share in question does not exceed $25,000. On those of over that value the rate is multiplied 1½ times on estates up to $100,000, twofold on those from $100,000 to $500,000, 2½ times on those from $500,000 to a million, and threefold for those exceeding a million. This statute has been supported as constitutional by the Supreme Court. Many of the States also impose succession duties, or transfer taxes; generally, however, on collateral and remote successions; sometimes progressive, according to the amount of the succession. The State duties generally touch real estate successions as well as those to personal property. If a citizen of State A. owns registered bonds of a corporation chartered by State B., which he has put for safe keeping in a deposit vault in State C., his estate may thus have to pay four succession taxes, one to State A., to which he belongs and which, by legal fiction, is the seat of all his personal property; one to State B., for permitting the transfer of the bonds to the legatees on the books of the corporation; one to State C., for allowing them to be removed from the deposit vault for that purpose; and one to the United States. (S. E. B.)

Este, a town of Italy (Venetia, prov. Padua), at the south end of the Euganean Hills, 21 miles by rail south-west from Padua. The town possesses a cathedral, an archæological museum, the Euganean Prehistoric Museum, and a technical school. Population, about 6800.

Esthonia (German, *Ehstland*; Esthonian, *Eesti-maa*), a Baltic province of Russia, on the south coast of the Gulf of Finland. An archipelago of islands, of which Dagö is the largest, belongs to it, while Oesel belongs to Livonia. Out of its area of 7818 square miles, 503 belong to the islands. Its surface consists of lowlands, having less than 100 ft. of altitude along the seacoast and in the environs of Lake Peipus, and in the interior of a table-land, having an average height of from 200 to 280 ft., saving a few points in the Wesenberg district, where 550 ft. is reached. It is entirely covered with the bottom moraine of the ice-sheet lying upon Silurian sandstones and limestones. Sands and clays cover in places the glacial deposits. It is watered by the navigable Narova, which flows from Lake Peipus into the Gulf of Finland, and countless small rivers and rivulets, and is dotted with small lakes and marshes. Although severe colds are experienced in winter, the climate is moderated by the moist west winds. The population, which consists chiefly of Ehstes, Germans (about 25,000), Russians (18,000), Swedes (5000), and some Jews, &c., is rapidly increasing: it was 323,960 in 1870, and 413,724 in 1897. Out of these, 210,199 are women, and 76,315 live in towns. In 1878 the nobility owned 52 per cent. of the land, 42 per cent. was farmed by the peasants, and only 3 per cent. was owned by persons not belonging to the nobility. Owing to the organization of credit, nearly 500,000 acres have since been bought by the peasants, one-fourth part of whom now own their farms. Agriculture is the chief occupation, and not only on the landlord's estates, but also on the wealthier peasants' farms, it is carried on more thoroughly than in any part of Russia. Every year more than 750,000 acres are under crops (71 to 75 per cent. of all arable land). The average crop is 787,400 quarters of cereals and 1,370,000 of potatoes, chiefly grown for the distilleries. Notwithstanding the density of population (55 per sq. mile), there is every year a surplus of cereals. Cattle-breeding is also in a good state. Meat and butter are yearly growing items of exports. Fine breeds of cattle and sheep are kept, and local wool is used in the woollen cloth factories of the province. Manufactures are chiefly distilleries (over 150), to which one large cotton mill (at Krenholm), one woollen cloth mill, flour mills, several iron and machinery works, paper mills, matches works, and saw mills must be added. Their aggregate production exceeds £4,000,000 per annum. The province is intersected by a railway running from St Petersburg to

Reval and the Baltic Port, with a branch from Taps to Dorpat. A considerable traffic is carried on along this line, Reval and Baltic Port being important towns, both for import and export. Hapsal and Kunda are next in importance, and Dagö for imports. Esthonia is divided into four districts, the chief towns of which are Reval, capital of the province (64,578 inhabitants in 1897); Hapsal, a lively watering-place (3238); Weissenstein (2509); and Wesenberg (5560). (P. A. K.)

Eston, a township and urban district, partly in the Cleveland parliamentary division of the North Riding of Yorkshire, England, 8 miles east from Stockton by rail. There are extensive blast-furnaces, iron foundries, and steam sawing mills in the district. Population of urban district (area, 2252 acres) (1881), 6297; (1891), 10,695.

Estremadura, a former province of Portugal, now divided into the administrative districts of Leiria, Lisbon, and Santarem (*qq.vv.*). Area, 6710 square miles. Population, 1,083,290; giving 161 inhabitants to the square mile. There are mineral waters and baths at Caldas da Rainha, Cucos (near Torres Vedras), Estoril (Cascaes), and Lisbon. Marble is quarried, and coal is mined at Porto de Moz. In 1892 the vineyards covered 88,560 acres, and their produce amounted to 17,941,850 gallons of wine, valued at £827,800. The fishing employs over 9600 men and 1600 boats, and the average value of the fish caught annually is £311,100. The ports of the province were entered in 1897 by 2615 vessels, of 3,569,589 tons.

Esztergom (Gran), a corporate town of Hungary, the capital of a county of the same name In 1898 it was united with its suburbs, and in 1900 had a population of 17,909.

Etah, a town and district of British India, in the Agra division of the North-West Provinces. The town is situated on the Grand Trunk Road, but with no railway station. Population, about 8000. The municipal income in 1897–98 was Rs.12,577.

The DISTRICT OF ETAH has an area of 1741 square miles. It had a population in 1881 of 756,523; and in 1891 of 702,063, giving an average density of 403 persons per square mile. In 1901 the population was 863,719, showing an increase of 23 per cent., due to the extension of canal irrigation. The land revenue and rates were Rs.13,16,370, the incidence of assessment being just over R.1 per acre; the cultivated area in 1896–97 was 570,194 acres, of which 340,424 were irrigated; the number of police was 2031; the number of vernacular schools in 1896–97 was 89, with 4158 pupils; the registered death-rate in 1897 was 24·25 per 1000. Part of the district is watered by the Ganges Canal. It is also now traversed by a branch of the Rajputana Railway from Agra to Cawnpore, with stations at Kasganj and Soron, which are the two largest towns. It has 5 printing presses; 141 indigo factories, employing 7743 persons, with an outturn valued at Rs.5,70,000; and one factory for pressing cotton.

Étampes, French town, in the department of Seine-et-Oise, 31 miles south of Versailles by rail. In addition to its great trade with Paris in food-stuffs, it supplies large quantities of sandstone for street-paving. Manufacturing industries are of little importance. Population (1881), 7465; (1896), 8094, (comm.) 8390; (1901) 8750.

Etawah, a town and district of British India, in the Agra division of the North-West Provinces. The town is situated on the left bank of the Jumna, and has a railway station, 206 miles from Allahabad. Population, about 38,000. The municipal income in 1897–98 was Rs.39,583; the registered death-rate in 1897 was 49·83 per 1000. Etawah is now only the civil headquarters of the district, the military cantonment having been abandoned in 1861. Considerable trade is carried on by rail and river. It makes specialities of cotton cloth, skin-bottles, combs and horn-ware, and sweetmeats.

The DISTRICT OF ETAWAH has an area of 1691 square miles. It had a population in 1881 of 722,371; and in 1891 of 727,629, giving an average density of 430 persons per square mile. In 1901 the population was 806,625, showing an increase of 11 per cent. The land revenue and rates were Rs.16,05,190, the incidence of assessment being R.1-3-8 per acre; the cultivated area in 1896–97 was 459,395 acres, of which 286,477 were irrigated; the number of police was 2094; the number of vernacular schools in 1896–97 was 84, with 3507 pupils; the registered death-rate in 1897 was 45·36 per 1000. It has six printing-presses, issuing two vernacular periodicals; 216 indigo factories, employing 11,128 persons, with an outturn valued at Rs.11,00,000; and three factories for cleaning and pressing cotton. The district is partly watered by branches of the Ganges Canal, and it is traversed throughout by the main line of the East Indian Railway from Cawnpore to Agra

ETHICS.

THE object of the following article is to describe and estimate the work done in Ethics since 1878, the date of Professor Sidgwick's article in the ninth edition of this *Encyclopædia*. The convenience of the reader will probably be best served if an outline is given of the general position in 1878, with some prefatory remarks on the 'Scope of Ethics,' which may help to indicate the point of view taken in regard to that position, and to the work by which it was modified during the last quarter of the 19th century. Following Professor Sidgwick's example, we practically confine our remarks to English Ethics, only mentioning a few foreign writers in the list of authorities given at the end.

The Scope of Ethics.

Ethics may be defined as the Theory of Conduct. It has two parts, which may be distinguished as the General and the Particular Theory of Conduct. The General Theory of Conduct seeks to embrace, within one architectonic survey, all the functions of human nature—all the modes of conduct by which man, as sentient animal, as moral agent, and as thinker, realizes his Type in an environment, which he 'conquers by obeying.' This Type—the end in relation to which alone all objects of human endeavour have 'reality' and 'value,' and are, and ought to be, desired—the General Theory of Conduct seeks to set forth, with the special view of furnishing principles by means of which the Particular Theory of Conduct may interpret that mode of 'conduct' which bulks most largely in man's life, and seems to be 'practical' in an eminent sense—moral conduct, which may be defined as conduct willed by members of the social system for the sake of that system. Moral conduct, as thus defined, is the central part of the subject-matter of Ethics, but must be exhibited in connexion with what is its necessary setting, conduct other than moral.

From 'Man in the State' our range of view must be extended till we can survey 'Man in the Cosmos.' As setting forth 'Man in the Cosmos,' the General Theory of Conduct will (1) describe him as he now is, and trace the history of the process from animal or even lower beginnings, by which he has become what he now is; and (2) will call attention to the significance of his being what he now is. Ethical schools differ chiefly as they take greater or, it may be, exclusive interest in one or the other of these two inquiries embraced within the scope of the General Theory of Conduct. Corresponding to these two ethical 'interests' or 'tendencies,' we find two ways of setting forth man's Type in relation to the Cosmos,—the positive way, and the way of imaginative representation. The way of imaginative representation recommends itself to—indeed, is forced upon—those whose reflection dwells on the significance of man's being what he is—a self-conscious subject. Man's Type for them is intuitively apprehended, being present in self-consciousness. It is "Eternal Consciousness present in my consciousness." This is the True Self, which constitutes the world—makes it the intelligible system that it is. Plato is the master of those who set forth the Type imaginatively. The reverence which the True Self inspires (it is what Aristotle would call τίμιον) finds, with Plato, expression in a solemn ritual, as it were, of mythic or prophetic representation. The history of the immortal soul (which in itself 'has no history') is unfolded in a vision, or miracle-play, before our eyes, from its 'creation' to the time when, purified by penance and philosophy, it is finally disembodied, and, returning to its own star, there participates in, and understands, the eternal motion of the Cosmos, being made 'like unto God.' This is not the place to discuss the reasons which justify Plato in thinking, as he certainly does, that such 'mythology' is part of 'philosophy.' We would only say that much of what has passed since his day under the name of 'metaphysic'—for example, the main part of the metaphysic which the 'Cambridge Platonists' and their present-day English successors supply as basis for morals—is best regarded as rationalized 'myth,' and owes its attractiveness and, we would add, its value to its 'mythological' character. The other way of setting forth man's Type we have called the positive way. While the way of imaginative representation is essentially 'protreptic,' making a personal appeal to the individual soul as such—'Reverence thyself, for thou art worthy,'—and relying largely on the 'prophetic' genius[1] and personal influence of him who employs it, the positive way merely aims at providing instruction for those who care to receive it. Those who employ this latter way, leaving it to others to say that 'we see all things in God,' and letting it go without saying that 'the world is intelligible by man's intelligence,' turn to the natural history of mankind for data out of which to construct a positive theory of man's Type. This 'theory' may either set forth the genetic process by which the Type has been evolved, or amount to nothing more than a descriptive account of the Type as it now appears; in either case the moral life—the life of conduct willed for the sake of the Public Good—being taken as central, the range of view is enlarged, and other than moral elements are included within the survey. In the difference between the descriptive and the genetic account lies the distinction between the old manner and the new of setting forth the Type positively. The positive method was employed in the descriptive manner by Plato (for he by no means confined himself to the method of imaginative representation) and by Aristotle when they took the civilization achieved by their own race—*the ensemble of all its activities*—as the Type to be described. Fortunately for Ethics, it was a many-sided, well-balanced Type; and the concrete presentation of it by Plato and Aristotle has been worth immeasurably more than any exposition starting from the abstract notion of human nature as such would have been. They present human nature as such in a fine rendering of their own particular Civilization—Ἑλληνὶς ἔσται, says Plato, speaking of his καλλίπολις. The result is a portrait which, like all great portraits, is an ideal, setting forth universal human *traits*, while rendering faithfully the features of an individual. The peculiar charm of the ethical portraiture which we have received from the great Greek masters depends, doubtless, on the circumstance that the Type portrayed was accepted without *arrière pensée* as final. The new biology has taught us that Type is never final—that there is no such thing as completed adjustment of organism to environment. Is portraiture, then, in the classical manner, a thing which Ethics, as General Theory of Conduct, cannot now hope to succeed in, and will not seriously attempt? We hold that Ethics must still attempt it. Provisional (or, if any one prefers the word, ideal) description of Type achieved is necessary to give aim to the genetic account. The only way in which the Type can be set forth positively (*i.e.*, for our guidance, as distinguished from our encouragement) is that which combines the genetic with the descriptive account. And the descriptive account will still take the form of the portraiture of some particular civilization. Some specific National Type must always sit as artist's model. Thus, if the moralist is an Englishman, he will do well to keep his eye on the civilization of England. But the new biology will make a great difference to his work. However tempted, as artist, he may be to follow his masters in setting forth the Type as if it were final, he is bound now to remember that it is not final, and, at the same time, that the relations involved are so complicated that calculation of what it will become even in the comparatively near future is not to be attempted. No biologist thinks of speculating about the form which a given organic type may assume in the future, or of interpreting present structure and function in the light of such hypothetical form. He knows that the calculation is too intricate. The scientific character of his 'teleology' is guaranteed by the definiteness of the already achieved organic whole or result, which is always taken as starting-point for the explanation of parts or stages clearly and distinctly perceived to be parts or stages. The scientific caution observed by the biologist in his employment of 'teleology' is likely to be imitated more and more by moralists in their attitude towards 'ideals.' When it is said that 'Ethics' is not really touched by the new biology, the remark must be taken as true only of 'Ethics' as setting forth the Type in the way of imaginative representation. As setting forth the Type in this way, Ethics is certainly not touched by the new biology, just as the *Divina Commedia* is not touched by it. But positive Ethics (whether its manner be principally that of the descriptive or that of the genetic account) is touched, and very nearly, by it, in the respects indicated.

We pass now to Ethics as Particular Theory of Conduct. It has for its subject-matter that branch of general conduct distinguished as 'moral conduct.' It is not necessary to describe 'moral conduct' here. It is enough to ask the reader to recall the subject-matter of any standard treatise on 'morals,' such as Reid's *Essays on the Active Powers* or Adam Smith's *Theory of Moral Sentiments.* But it is important to say, that, in our view, 'moral conduct' belongs to man not as individual, but only as member of society. Were there only one human being in the universe,

[1] Understood in the sense defined by Spinoza in his account of the nature and function of Prophecy: *Tractatus theologico-politicus*, chaps. 1, 2, 3.

there might conceivably be 'branches of knowledge,' and 'logic' or theory of the ways in which the endeavour after knowledge is made; but there could be no 'Ethics' in the narrower sense we are now considering; for the conduct which is its special subject-matter is the behaviour of persons to one another as members of a common concern in which they are fellow-workers. Aristotle recognizes this when he makes his solitary abstracted God a 'thinker,' but denies 'morality' to him. The distinction between 'politics,' *i.e.*, the science of man as πολιτικὸν ζῷον, and 'morals,' or 'private ethics,' is thus apt to be misleading as a distinction within the bounds of Ethics as Particular Theory of Conduct. 'Private morality' is an abstraction, like a caged bird. It may be convenient for observation to have it caged; but what is observed in the cage must always be interpreted with reference to the natural habitat of the prisoner. It may be convenient, for the moment, to look at moral virtue as simply the quality of an individual; but, after all, the quality is what it is because it puts its possessor in certain relations to others in society—ἡ ἕξις ταῖς ἐνεργείαις ὁρίζεται καὶ ὧν ἐστί. The distinction, however, between 'private ethics' and 'politics' where strongly pressed, has been urged not on the mere ground of its convenience for the methodical study of the individual as πολιτικὸν ζῷον, but because it is thought that, after all, the individual for 'Ethics' is not the πολιτικὸν ζῷον—that 'morality' consists essentially in a man's relations, not to fellow-men, but to himself as made in the image of God. The distinction between 'politics' and 'private ethics,' thus pressed, is really that between the Particular and the General Theory of Conduct, as the latter appears in the eschatological myths of Plato where the doctrine of Κάθαρσις is set forth, and in the metaphysical systems which have been more or less influenced by that doctrine. 'True Self to be realized by conscious participation in the intelligible forms which constitute the Eternal Wisdom and Goodness of God'—this is the main purport of these systems. What is characteristic of them is that they are devotional systems; their object is to make a personal appeal to the individual to be perfect even as God is perfect. This is expressly stated by John Norris, the Platonist, to be the object of his book *Reason and Religion* (1689), in which he sets forth the "Eternal and immutable morality" of his school. He explains in his Preface that devotional works exist in plenty for the use of the unlearned reader; but his design is to supply a devotional book for the learned reader. Like the other writers of his school, he sets forth the Divine Nature as the final object of contemplation and desire—as the Light of the World, the Good, the conscious subject of the eternal ideas in which it is man's prerogative to participate by 'Devotion.' Devotion is an act of the will directed to an object of contemplation,—*i.e.*, it is a rational act of the will. The critic of our present-day English 'idealism' has much to learn, we believe, as to the 'tendency' of the school, from its 17th century 'Platonist' representatives.

To understand the position which 'private ethics' ought to occupy within the Particular Theory of Conduct, we must turn to the work of such moralists as Shaftesbury, Hutcheson, and Adam Smith. The 'moral sentiments' so admirably described and analysed by these writers doubtless belong to the individual; but it is assumed throughout that they are 'designed' to operate for the 'Public Good.' The significance of the passage from Hobbes to the moralists of the 'sentimentalist' school is that the centre of interest is shifted from 'state' or 'sovereign' to 'private citizen.' Hobbes intrusts the 'Public Good' entirely to the sovereign, reducing the character of the subject, or private citizen, to the one quality of obedience. The sentimentalist moralists dwell on the initiative of the 'benevolent' private citizen, as reflectively pursuing the Public Good. The Public Good is thus placed in a new light. It is no longer regarded as identical with the stability of a centralized government armed against anarchy, but as gradually realizing itself in the progress of reforms suggested by the experience of enlightened and public-spirited private citizens. Starting from the principle that the private citizen can and ought to work *as private citizen* for the Public Good, the sentimentalist moralists analyse that character in the private citizen which makes him capable and desirous of working for the Public Good. Their psychology of the moral sentiments, though not very 'scientific,' indicates with sufficient clearness the lines on which the education of the private citizen must be conducted with a view to the establishment of the character in question. Their work may therefore be said appropriately to lie in the field of 'private ethics' or 'morals' as distinguished from 'politics' or 'legislation,' inasmuch as the private citizen, and not the sovereign or state, is the centre of interest. 'Private ethics' as cultivated by these moralists attempts to determine, always in relation to the Public Good, what is 'meritorious' in the private citizen, when acting in the ordinary everyday concerns of his life; not to estimate the 'value,' in relation to the same standard, of general rules proposed by a legislative body. It was fortunate for English Ethics that it passed through the hands of psychologists, who made it their business to furnish a theory of the 'merit' of the individual, before it reached the political and legal reformers, Bentham and his followers. It is the individual, as described in the 'private ethics' of the sentimentalist moralists, who ultimately inspires, and is willing to live under, the legislation outlined in the 'politics' of the later utilitarians. At the same time, it must be admitted that the sentimentalists go as far as it is possible to go safely in insisting on 'personal merit' or the 'moment of good' in the individual. They often come very near the substitution of the subjective standard of 'good intentions' for that of the Public Good. It was time that the centre of ethical interest should begin to be shifted back again to the state from the individual—that 'utilitarianism' should cease to be mainly a theory of 'morality,' and fulfil its end by becoming the theory of 'legislation.'

We have now said enough to explain our view of the nature and position of 'private ethics' as dealt with positively. It is the theory of the moral character of the individual; it is complementary to and, in turn, complemented by 'politics,' the theory of the state in which the individual inheres as citizen. There can properly be no 'private ethics' without 'politics,' or 'politics' without 'private ethics.' Both together make what we have called the Particular Theory of Conduct. This might well be called 'Politics'—πολιτική—in the generic sense; for it deals with man as πολιτικὸν ζῷον—is the theory of that kind of conduct by which individuals are brought and kept together as fellow-workers in and for the state. Regard for this common concern, restraining individualistic tendencies, is the living principle of moral conduct, and differentiates it from other forms of 'conduct.'

Position in 1878.

Ethical systems may be conveniently classified according as the interest which inspires them is political, religious, or scientific. English interest has been political and religious throughout, and only lately scientific. We do not mean, of course, that the 'political' moralists—Hobbes, Locke, Shaftesbury, Hutcheson, Adam Smith, Hume, Bentham, J. S. Mill—had no 'scientific' basis—they certainly had it ἐφ' ὅσον ἱκανῶς ἔχει πρὸς τὰ ζητούμενα; and the 'Cambridge Platonists' were most anxious to press 'modern science' into their service, in this respect resembling some of their present-day representatives. But it was not till the introduction of evolutionary theory into Ethics that the subject began to be studied as one of purely scientific interest—man's manner of life being investigated in the same spirit in which the habits of bees and ants are investigated. Where the chief interest is religious or scientific, the system is mainly a contribution to the General Theory of Conduct; where political, to the Particular Theory of Conduct. We shall best explain the position of Ethics in England when the last quarter of the 19th century opened by showing how the three interests—political, religious and, scientific—were then balanced. The prevailing interest of English Ethics was then no longer political, as it had been in Bentham's time. Bentham's preaching of the doctrine of the Public Good had borne fruit in the reforms, constitutional and legal, with which his name will always be associated: "I do not know," says Maine (*Early Hist. of Inst.* p. 397), "a single law reform effected since Bentham's day which cannot be traced to his influence." But when these reforms had been effected, utilitarianism entered on a long period of academic retirement, or even inactivity. As time went on it became more and more difficult for the young men, who made acquaintance with it at the universities, to appreciate the circumstances and temper of those to whom it had been a living gospel; more and more easy to cavil at the 'handy' psychology which had been good enough for Bentham's practical purpose, especially as that psychology was presented by J. S. Mill and Professor Bain. These later exponents of Bentham's system almost courted the charges (mistaken as they were) of 'hedonism,' and of converting a principle of 'legislation' into a principle of 'morals,' which began to be brought against utilitarianism in the 'sixties, and have been reiterated ever since. Here it is only necessary to say that they came chiefly from those whose paramount interest in Ethics was religious—who were dissatisfied with the merely secular aim of utilitarianism.

While Ethics had lost in the third quarter of the 19th century the inspiration of keen political interest, the other interests—the scientific and the religious—were both making themselves powerfully felt. It was during this period that, for the first time in the history of English Ethics, moral conduct was presented frankly as a subject of purely scientific interest—as part of the great *ensemble* covered by Biology, a science, or rather group of sciences, which had now found its Newton. Darwin had brought light into Biology, and made it a study of absorbing interest; Mr Spencer had definitely, without qualification, placed 'Ethics' within its borders. This he did even in writings published before the *Origin of Species*, although without anticipating the distinctive idea of that work.[1] If Darwin's was the greatest influence of the 19th century, it was chiefly through Mr Spencer's writings that it made itself felt among professional students of Ethics during the 'sixties and early 'seventies, although afterwards it reached them through other channels.

But the same period which saw Ethics thus claimed by the biologists for science, saw also a great awakening of the religious interest among the professional students of Ethics. The introduction of Darwinism into Ethics coincided with a notable revival of idealism in Ethics. Various causes contributed to this result. The spirit of the 'Cambridge Platonists,' which had always been cloistered in England, was powerfully appealed to by the so-called 'Oxford Movement.' Idealism became conscious of itself even in men who seemed to stand aloof from that movement. The newly awakened idealism found itself confronted by the utilitarianism of J. S. Mill, and the biological ethics of Mr Spencer, just as, two centuries before, it had been confronted by Hobbism and 'materialism.' At first it was merely with utilitarianism that idealism came into action. With arguments similar to those used by the Cambridge Platonists against 'materialism,' and in a similar spirit, their modern successors attacked the *end* of the popular utilitarianism. Utilitarianism seemed to them to acquiesce in the material welfare of masses, whereas the true end lies beyond in the perfection of persons. The good effected by utilitarian legislation in England was too great to be overlooked, and T. H. Green (whom we take in this article as representative of the idealist school) was not the man to underrate it—but the true end lies beyond in the perfection of persons. If the devotees of this ideal go forth from the cloister, as they often, in our day, feel it to be their duty to do, in order to take an active part in 'social work,' we must still distinguish them from the utilitarians. The ideal of the utilitarians, or political moralists, is a secular one—that of public prosperity. The ideal of the modern Platonist is a religious one—it is (to use a phrase which we hope will not be misunderstood as we use it) the ideal of 'souls to be saved'—of individuals to be made more perfect by personal care, in a social system which is the life of each one of them writ large. Another influence which contributed (though perhaps not so largely as might be supposed) to the revival of idealism in England was, of course, the study now beginning to be given to German philosophy. German philosophy, elaborated in universities, without the distraction of political interest, has always dwelt more on Self than on Citizen; and its influence, as felt by the English idealists twenty-five years ago, was entirely in favour of substituting the ideal of personal perfection, or self-realization, for the utilitarian standard. At the same time Hegel had insisted on the progressive realization of Self in Society. Here the English idealists readily followed Hegel's lead, for he seemed to indicate how they might, without sacrifice of philosophical principle, retain much with which they were in sympathy in the national utilitarianism. It is in social life, then, that personality must realize itself—in the Family, in the State, and, it is important to add, in the visible Church. The idea of 'visible church' had of late years become very vivid and attractive in England. A philosophical reason for its attractiveness seemed to many minds to be added by the teaching of the idealist school. The historian of religious opinion in England during the latter half of the 19th century will have to take serious account of the influence of that teaching within the Church.

The polemic of the new idealism was mainly, at first directed against utilitarianism—against J. S. Mill and his philosophical predecessors Locke and Hume. In time, however, it was turned against the biological ethics, with which it is now chiefly engaged. This conflict is more interesting to the critic than that with utilitarianism, inasmuch as it serves to show more clearly the 'tendency' of English idealism, by bringing out two connected doctrines as of cardinal importance to its whole teaching—(*a*) that man, as self-conscious, is absolutely distinct from the animals, and (*b*) that, in his self-consciousness the eternal self-consciousness is present. The position, it is contended, which biological ethics gives to man, is inconsistent with the ultimate fact that self-consciousness exists, presenting him to himself, in respect of his intelligence and moral freedom, not as product but as principle—as 'reproduction' of the eternal self-conscious principle which is the cause to all 'products' of their coming into existence and being intelligible. This epistemological Theism of the modern idealists, it is to be noted, is essentially that of Cudworth and the other 'Cambridge Platonists,' who argue that through the eternal and immutable truths of which reflection

[1] See the interesting note *Princ. of Biol.* ii. 500.

(Plato would say ἀνάμνησις) makes man aware as constitutive of his understanding and as conditioning his experience, he comes into communion with the Eternal Wisdom of God, Whose νοήματα they are, Who created the world after their pattern. To put this into the language of to-day:—in man's consciousness of self, the Eternal Consciousness is present. Judging from their recent writings, we take it that the modern representatives of Cudworth's school find Theistic Theory the most interesting part of their system; and we may expect that the chief developments of English idealism will be towards the elaboration of such theory.

Henry Sidgwick.

We must not close this general review of the position at the date of Professor Sidgwick's article without referring to his own *Methods of Ethics*, which appeared in 1874. The *Methods of Ethics* is important as being a critical restatement of utilitarianism by one who was intimately acquainted with the history of that doctrine, from Hobbes downwards, as a chapter in the History of the English People, and saw very clearly that that side of it, which received so much—perhaps too much—attention from the sentimentalist moralists, had been too little regarded by utilitarians since Bentham's time. It was, accordingly, to a re-examination of the problems of 'private ethics' (considered always as the other side of 'politics') that Professor Sidgwick mainly devoted his remarkable powers of insight and analysis. The *Methods of Ethics*, we believe, will stand as a landmark in the history of our national utilitarianism. It marks the shifting back of the centre of ethical interest from State or Government to private citizen. For Hobbes, as we have seen, the Public Good was secured entirely by the efficiency of the Government; for Shaftesbury and his school, mainly by the benevolent initiative of private citizens; for Bentham, again, mainly by the legislative action of the State; while the new utilitarianism represented by Professor Sidgwick comes back again to the importance of investigating the moral sentiments of the individual, in order to grasp the lines on which his education for citizenship may be conducted. The lead given by Professor Sidgwick has been followed by other adherents of utilitarianism. This development of utilitarianism in the direction of an exact positive psychology of the moral sentiments is likely to be an important one. The talent for such inquiry is native in England; and, aided by the scientific methods now employed in psychology, ought to produce valuable results. Political, as distinguished from scientific and religious, interest will doubtless again resume its normal influence in English Ethics. New social conditions have arisen which demand, and will undoubtedly create, a new utilitarianism, in which a theory of the moral and political education of the individual citizen based on an exact positive psychology of his moral sentiments will hold a prominent place.

Development since 1878.

Since the publication of Professor Sidgwick's article in the ninth edition of this *Encyclopædia*, important works have been published by English representatives of the evolutionary school—especially *Principles of Ethics* by Mr Spencer, *The Science of Ethics* by Mr Leslie Stephen, and *Moral Order and Progress* by Professor Alexander.

Spencer.

Mr Spencer defines Conduct as 'acts adjusted to ends,' and proceeds to lay down the principle that the part of conduct with which Ethics deals cannot be understood without the study of human conduct as a whole, or the latter without the study of conduct as belonging to animate beings in general. This means that Ethics must begin with the study of the 'evolution of conduct' out of that which cannot be called 'conduct.' The 'evolution of conduct' is marked by improvement in the adjustment of means to ends, so that life gains in 'length' and 'breadth'—life being at once that of the individual, and that of the species maintained by the rearing of offspring. Conduct subserving the life of the individual and conduct subserving the life of the species are mutually dependent. Each reaches its highest form simultaneously with the other; but not until the highest form of a third kind of conduct—social conduct—is reached. When this is reached, the ends of the two lower kinds of conduct are achieved without 'struggle for existence.' 'The limit of evolution can be reached by conduct only in permanently peaceful societies.' That conduct is best which simultaneously achieves the greatest totality of life in self, in offspring, and in fellow-men; the postulate involved in this judgment being that 'life is worth living'—which means that it brings a surplus of 'pleasure' or 'happiness.' Evolutionary theory enables us to substitute a scientific for an empirical utilitarianism, by exhibiting certain fundamental truths common to ethics with physics, biology, psychology, and sociology. In physics we see evolution always tending towards the better maintenance of a 'moving equilibrium.' This appears in biology as 'balance of functions'; the notion of 'balance of functions' yielding, on examination, the truth that "sentient existence can evolve only on condition that pleasure-giving acts are life-sustaining acts." Passing from the biological to the psychological view of ethics, we pass from presented pleasures and pains to represented pleasures and pains as constituting deliberate *motives*, and arrive at the conclusion that evolution is marked by the increasing subordination of simple presentative feelings to compound representative feelings. Thus the 'moral consciousness'—the 'feeling of obligation,' or 'sentiment of duty'—begins to emerge, as a balanced complex of representative feelings, an internal control gradually emancipating itself from three preparatory external controls, the political, religious, and social. Standing, as it does, for the experience of the individual and his progenitors, the 'moral consciousness' is a feeling "at once massive and vague." It is the "abstract consciousness" of the superior "authority" of the guidance supplied by the complex representative (and re-representative) feelings occupied with the future rather than the present. But "the sense of duty or moral obligation is transitory, and will diminish as fast as moralization increases." Passing to the sociological view of ethics, we find that what here corresponds to the 'equilibrium' of the physical view is realized under conditions which, formulated, make a 'code' that confers on Ethics the rank of a 'science': namely, The associated individuals shall (1) inflict no injury (*a*) directly or (*b*) indirectly on one another; and (2) shall help one another (*a*) under agreement and (*b*) beyond agreement. 'Happiness,' special and general, is the ultimately supreme end. Although 'Happiness' itself is not a thing that can be cut up and distributed at all; and although the concrete means to it cannot be distributed equally; yet each man may have like liberty to pursue 'happiness,' and like security in the possession of it. The 'greatest Happiness principle' is meaningless except as asserting the necessity of this. Although egoism, biologically considered, comes before altruism, yet "from the dawn of life altruism has been no less essential than egoism." "Self-sacrifice is no less primordial than self-preservation." Its primordial form is the "physical altruism" of reproduction by fissure. Scientific ethics has to recognize the fact (ignored by the "transformed utilitarianism" which assumes "pure altruism") that egoism *and* altruism coexist. Provisionally we must reconcile their respective claims by compromise. But the opposition between them tends to disappear. 'Sympathy' tends to become stronger; men tend more and more to make each others' pleasures, 'egoistic' and 'altruistic,' their own. This is the ideal of 'perfect conduct,' the subject-matter of 'absolute ethics,' which stands to 'relative ethics' (concerned with conduct which, as involving pain, is only relatively right, *i.e.*, partially wrong) as rational stands to experimental mechanics.

Leslie Stephen.

Mr Leslie Stephen summarizes his system in one sentence (*op. cit.* p. 454):—"Morality is a product of the social factor; the individual is moralized through his identification with the social organism; the conditions, therefore, of the security of morality are the conditions of the persistence of society; and if we ask from the scientific point of view what these conditions are, we can only reply by stating that the race is dependent upon the environment; by tracing so far as we are able the conditions under which it has been developed, and trying to foresee the future from the past." The ethical problem—to discover the general characteristic of the moral sentiments—Mr Stephen attacks from the position that human beings are the product of a long series of processes of adaptation acting either on the individual or the social organism in which he inheres as a member. The social organism (or better, 'social tissue') is a growth the laws of which can be studied apart from those of the individual atom. The 'social tissue' develops without a corresponding change of individual organism. We are born with brains very like those of remote progenitors; but we use them in an environment of laws, institutions, literature, tangible products of labour, scientific knowledge, logical and mathematical formulæ—a 'social tissue' very different from that in which these progenitors lived. It is on the social tissue, as primary unit, that the process of evolution impinges; and consequently it is in relation to the vitality of the social tissue that we speak of the individual's conduct as 'useful.' "That form of bee will flourish which forms the most efficient hives. The hive . . . will be the unit which must be taken into account in considering the general problem of survival." The social tissue—the all-pervading substance from which the various 'organs' or subordinate associations (governmental, religious, industrial, &c.) are constructed—is its own end. Society being an organic growth, certain instincts or customs are formed corresponding to a given state of the social tissue. What is the nature of those social instincts which give rise to 'morality'? Morality, gradually developed out of Law and Custom by natural process, is distinguished from them by substituting 'Be this' for 'Do this.' Rules of conduct are seen to be rules of character. "The individual must, so far as moral, be capable of aiming at the social welfare before his own." But is such 'self-sacrifice' possible? Yes. The reduction of altruism to egoism involves a confusion of thought. Altruistic does not differ from non-altruistic conduct in any sense which would imply that my conduct can spring from anything but my own feelings. Moreover, 'sympathy' is implied from the first in the very structure of knowledge (see pp. 230 ff.), and, as a matter of fact, is a stronger feeling than egoistic feeling. "The sympathetic being becomes, in virtue of his sympathies, a constituent part of a larger organization," apart from which he is unintelligible. "Altruism is the faculty essentially necessary to moral conduct." "The moral code is a statement of the conditions of social vitality." It is in relation to social vitality, as end, that we must explain merit, obligation, virtuous character, conscience, responsibility. Merit belongs only to voluntary actions, which are actions put forth by character in environment. Responsibility is the dependence of actions on character; conscience is not an instinct co-ordinate with other instincts, but "implies a judgment of the whole character." So far as I identify myself with the social organism I feel a sense of obligation to conform to the conditions of its welfare. While 'happiness' is the criterion of the old utilitarianism, the 'health of society' is that of evolutionary ethics. These two criteria are not really divergent, but the former is unscientific, the latter scientific. Can we modify the utilitarian sanction (that which supplies the motive to virtue) correspondingly with its criterion? Yes: we can show that the acquisition of virtuous character is conducive to 'happiness'—although we must admit that "there is no absolute coincidence between virtue and happiness."

In the first part of his work, dealing with 'moral statics,' Professor Alexander arrives at results similar to those reached by Mr Leslie Stephen. "Conduct and character are the same thing facing different ways." Biology has brought this truth to the front, and, with it, the conception (of course not a new one) of character and conduct as relative to society—'social organism,' or 'social tissue.' In respect of the individual, the goodness of an act depends upon its occupying a definite position in an equilibriated order of action. The good character in relation to which any act is judged good or bad is "an order or systematic arrangement of volitions"—an equilibrium of functions, and of structure. "The conception of a man's character is represented under the name of an *ideal*—a plan of conduct or way of life upon which he acts." "The good man's life is the good or moral ideal." In respect of society, a good act is one "by which the agent seeks to perform the function required of him by his position in society." 'Efficiency' is what is required by the moral judgment of every act. "Conduct is good, not because it leads to some further result, such as pleasure, or because it is determined by some inexplicable idea of good, but in virtue of the equilibrium it establishes between the various parts of conduct itself." "Good conduct (defined as a system or order), as it is the complete statement of the object of morality, is the complete form of the criterion or standard." There is no need to refer to the abstract standard of 'perfection' or of 'pleasure'; good conduct is 'perfect'; and 'pleasure' is part of the standard—for "without the pleasure the standard would be something divorced from our experience." The individual's good, then, "is *ipso facto* an element of the general welfare, and it is a common good because it binds him with others in the moral system." The common good is a medium of communication like language. Egoism and altruism are equally fundamental and original. Having dealt, as above, with 'moral statics,' Professor Alexander goes on to discuss 'moral dynamics,' of which there are two main problems: (1) to show how the moral equilibrium is produced and maintained, and (2) to examine the meaning and law of moral progress. Dealing with the first problem, he explains that the moral ideal, as a system or order, is "a species under which the various ideals as they exist in the minds of good men, are the different individuals"; and that "the course of morality represents the struggle between moral ideals, and the phenomena of the maintenance and growth of morality offer parallels to the history of natural forms." Professor Alexander claims great importance for this theory. It is a question, he thinks, "whether as much light may not be reflected on the natural problem by the ethical, as the reverse." Dealing with the problem of 'progress,' he explains that "the good is always ultimate, but, owing to the development of human nature, it is always in motion"; and that, therefore, there can be no contrast of a 'good' and a 'best,' but only of a 'good' and a 'better'—that adaptation, wherever, and so far as, it exists, is perfect adaptation. This amounts to saying that "goodness means progress," for "in changing from one form to another morality changes from what is right under one set of conditions to what is right under another set, and such change from good to good is what we mean by becoming better." The law of moral progress is stated as the 'law of comprehension'—*i.e.*, the tendency of evolution is towards one dominant ideal, such as that of Christian civilization.

Alexander.

What strikes one most on looking back over the last quarter of the 19th century is that evolutionary ethics in England becomes more and more Darwinian. To Mr Spencer is due the credit of having given vogue to the evolutionary point of view; but he has never shown himself, we venture to think, sufficiently alive to the importance of the distinctively Darwinian ideas of 'struggle for existence' and 'natural selection.' To the younger members of the school these ideas are all-important. The writings of Darwin himself and of the biologists who, on all sides, raise crop from the seed he gave them, have taught these younger moralists better to realize the meaning of 'correspondence of organism with environment'—indeed, to appreciate the complexity and delicacy of biological adaptation in a way which, once for all, gives a new aspect to the moral life. Some little variation which the complexity of the phenomena puts it beyond the power of science to explain, except as involved δυνάμει in an original germ, occurs and makes all the difference in the 'struggle for existence'; for not only does it enable the organism manifesting it to adjust itself to a pressing need in its present environment, but creates a new environment with fresh needs to be met, and so on indefinitely. The complexity and mobility of the relations between organism and environment, as understood by Darwinism, are such as to preclude entirely the idea of 'final correspondence.' Deeply impressed, then, with this, the younger moralists referred to decline to follow Mr Spencer in his doctrine of 'Absolute Ethics,' and 'perfect conduct.'[1] Ethics is only 'relative'; moral conduct, like all other conduct, is always realized in 'struggle.' Ἀεὶ πονεῖ τὸ ζῷον. This is the greatest lesson which Ethics, in our day, has taken home to itself from biology. Of course, 'moral struggle' has been recognized since the dawn of Ethics, but never before has the *necessity* of it been clearly seen. Again, the endless complexity of the relations between organism and environment, which makes perpetual struggle inevitable, also prescribes the method of that struggle as a little-by-little movement of adjustment to new circumstances as they arise. A 'leap in the dark,' or 'shot' aimed at the ideal as some far-off future condition, is out of the question. The balance of the innumerable forces involved is so precarious that any intervention other than slight would overturn it. Those who have learnt the lesson which the new biology teaches are content to think of a succession of 'ideals' which are always being realized—

Evolutionary Ethics criticized.

[1] That Mr Spencer himself has come to realize more fully than he once did the complexity of the relations which evolutionary theory obliges us to take account of, is shown by a noteworthy statement made in the Preface to vol. ii. of *Principles of Ethics* (1893):—"The Doctrine of Evolution has not furnished guidance to the extent I had hoped. . . . Some such result might have been foreseen. Right regulation of the actions of so complex a being as Man, living under conditions so complex as those presented by a society, evidently forms a subject-matter unlikely to admit of definite conclusions throughout its entire range." That Moral Science does not admit of τὸ ἀκριβές is indeed as true now as it was in Aristotle's day, and more evidently true. Whether recent attempts to introduce ἀκριβολογία μαθηματική into Biology (see K. Pearson, *The Grammar of Science*, chaps. x. and xi.) are likely to give results of appreciable value for Moral Science remains to be seen.

and *perfectly* realized—and then superseded—a succession of short views of betterment to be effected on customary lines, each one of these views being naturally suggested by the situation which the realization of its immediate predecessor has created.

It is because they favour the theory of one distant ideal (the aiming at which shall make the great difference between man and brute) that the English opponents of evolutionary ethics are not satisfied with the reasonable positive 'teleology' of the Darwinian moralists (identical with Aristotle's method in biology and ethics, which always has some definite organic whole before it in relation to which the parts are explained), and accuse them of 'explaining the higher by the lower.' This hackneyed phrase entirely misrepresents the method of the Darwinian moralists. They 'explain the higher by the lower' in explaining the lower by the higher. They know well, as biologists, that the parts or stages (the lower) cannot be understood in abstraction from the whole or result (the higher), any more than the whole or result can be understood in abstraction from the parts or stages. The fault which their critics have to find with them is really that they confine themselves to this sober Aristotelian or Darwinian teleology—that they take an achieved organic result, open to our observation (in this case 'Human Nature'), as a many-in-one to be positively set forth in the way of descriptive or genetic account, and do not allow themselves to interpret facts in the light of some theory of what *ought to be.* Thus it is objected that the 'historical method' cannot decide between various ethical ends and determine which *ought* to be followed—that an ethical theory from the standpoint of science is impossible—that it is the 'ideal' that explains the evolution, not *vice versâ* — that the Darwinian moralist does not tell us *why* we desire that society should be in equilibrium with itself—that it is necessary to show (which 'natural history' cannot do) that equilibrium is a *good*—conduces to the realization of the absolute good towards which, as *terminus ad quem*, 'the stream of development is leading.' The Darwinian moralist denies that such an objective is before us. It is always man's Type, as developed 'up to date,' that expresses itself in the successive ideals of slight betterment by which the moral life is maintained and transformed. This current Type must not be pushed forward into the unknown future, and set up there as an Absolute towards which 'the stream of development is leading.' The contention that this "Absolute" is ever present in my self-consciousness cannot be allowed to mean more than that, as a matter of fact, I am a being capable of knowledge and action in the world in which I find myself. From this truism no criterion of what ethical ends *ought* to be followed can be derived; for that we must go to the experience supplied by the 'natural history' which traces the actual development of my knowledge and action. Moreover, the idealist's admission that there is a history of the process by which the animal organism has become the 'vehicle' of consciousness concedes all that the Darwinian moralist contends for. What the idealist contends for, after this admission, is that consciousness *itself* 'has no history.' This is explained[1] to mean that "Existence, as a whole, contained within itself prior to its manifestation as consciousness, all that so manifested itself . . . What is posterior in time is prior in nature: the first is last, and the last first." 'Teleology' here falls back on an original δύναμις, which it rehabilitates as ἐνέργεια: arguing that, inasmuch as consciousness has actually manifested itself, the universe must always have contained the possibility of it—*that is*, the actuality of it. Here it is instructive to observe that 'mechanism,' in our day, seems inclined to take up with a similar employment of logical terms. Professor Weismann (*Romanes Lecture*, 1894) seems to argue that variations (some of which 'catch on' in the struggle for existence) are all *actually* provided for in the microcosm of the original germ-plasm, since that microcosm contains the *possibility* of all that manifests itself afterwards in the secular history of the species.

The polemic of the idealist against the evolutionist appears to us, then, to leave the position of the latter unaffected. The evolutionist never professed to do more than trace the process by which the animal nature has become 'organic' to knowledge and morality, and to supply reasons why, man's Type having a certain known constitution and history, certain actions *ought* to be preferred to others, if (as must be assumed) that Type is to be maintained. There is nothing beyond the competence of the evolutionary moralist in the determination of this *ought*, for the question is always about some immediate step to which he can see his way in the light of past experience. What the distant steps ought to be he cannot foresee; nor, indeed, does the idealist profess to tell him. The idealist merely supplies a 'protreptic.' He appeals to us in the language of 'prophecy,' and thereby helps to make more vivid and effectual in us that γλυκεῖα ἐλπίς[2] which is the very principle of life itself—the belief that 'life is worth living,' in the strength of which man struggles on and on, always seeking after a fuller and fuller 'comprehension of conditions' — a wider and wider 'correspondence with environment,' finding himself, after every successful act of adjustment to a given environment, confronted by a new environment, which does not appal him, but, as being of his own making, interests him and calls forth renewed efforts.

The social organism.

As evolutionary ethics in England becomes more and more Darwinian, greater prominence is given to the idea of 'social organism.' Mr Spencer's use of the idea—interesting as it undoubtedly is—is marred by his individualism and *laisser faire* theory of the functions of the State, inherited from the utilitarian politicians; but the younger evolutionist moralists, coming more directly under the influence of Darwin, use the idea in a way which promises results of great scientific and practical value. Some of them too, like some of their idealist rivals, owe much, in this connexion, to the political ethics of Plato and Aristotle, who still fortunately hold an important place in English philosophical study—perhaps a more important place than in the philosophical study of any foreign nation. When we say that our evolutionist moralists make great and increasing use of the idea of social organism, it must not be understood that they are constantly finding more and more points of close analogy between the body and the 'body politic'; on the contrary, it would seem that the more they know of each 'organism,' the less inclined they are to press into detail the analogy between them. What they do rather is to look at the social system in the light of the general conceptions of heredity, variability, struggle for existence, natural selection, and, above all, with a deep sense of the endless complexity and mobility of the relations involved. The result of this way of looking at society is that several truths of the first importance are brought home to us. It is made clear that moral and political reform is a slow process, and never can be 'radical'—that the general disturbance produced even by a little change may be a good reason for avoiding the latter, if possible; but, that since it is impossible to do so always, the most valuable quality a man or nation can have (always together with

[1] Watson, *An Outline of Philosophy*, p. 182.

[2] Plato, *Rep.* 331 A.

love of routine) is fortitude, wherewith to face the dangerous situations which may be produced by the most trifling constitutional interferences with the *status quo*; that, in any case, however, the unexpected is likely to happen—some quite inexplicable 'variation' will occur—a great man, for example, coinciding with his opportunity, will appear and alter the course of history; and, most important thing of all, it is made clear that 'War' can never cease, for, since development means the continuous differentiation of species, there will always be competing national types of life. Moralists who confine their view to *morals* strictly so called—whose Ethics is merely a Particular Theory of Conduct—are apt to lose sight of this, and to figure 'progress' as towards a cosmopolitan life of 'industrial prosperity' and civilized manners, under a *Pax Œcumenica*. Within each nation, as such, the art of political 'horticulture' may keep in abeyance the fierce physical struggle for existence characteristic of the 'cosmic process,' or 'state of nature'; but its place is taken by another struggle, as fierce—the ethical struggle between persons and parties representing 'ideals' of social life; while between different nations the struggle is always bound to be largely physical. It is easy to misread Huxley when he says (*Romanes Lecture*, 1893): "Let us understand, once for all, that the ethical progress of society depends not on imitating the cosmic process, still less in running away from it, but in combating it." The best commentary on the above is in his own words (*Collected Essays*, vol. ix. p. 11—*Prolegomena to Romanes Lecture*): "Man, physical, intellectual, and moral, is as much a part of nature, as purely a product of the cosmic process, as the humblest weed."

Idealistic Ethics.

Idealism in England received a great stimulus from the posthumous publication of Green's *Prolegomena to Ethics*, and *Works* (with R. L. Nettleship's *Memoir*), and from the comment which these books called forth.

Green.

Green's ethical doctrine is, briefly, that in the consciousness of a moral ideal—'the ideal of a best'—and the determination of human conduct thereby, a principle 'which is not natural' is involved. We are prepared for this result by a metaphysic of knowledge, the gist of which is contained in the following sentences. "The knowledge of nature is not itself a part or product of nature in the sense in which it is said to be an object of knowledge." "It is only because we are consciously objects to ourselves, that we can conceive the world as an object to a single mind, and thus as a connected whole. It is the irreducibility of this self-objectifying consciousness to anything else, the impossibility of accounting for it as an effect, that compels us to regard it as the presence in us of the mind for which the world exists." "The concrete whole which may be described indifferently as an eternal intelligence realized in the related facts of the world, or as a system of related facts rendered possible by such an intelligence, partially and gradually reproduces itself in us, communicating piece-meal, but in inseparable correlation, understanding and the facts understood, experience and the experienced world." "In the growth of our experience an animal organism, which has its history in time, gradually becomes the vehicle of an eternally complete consciousness." From the metaphysic of knowledge Green passes to the metaphysic of morality. "The transition from mere want to consciousness of wanted object, from impulse to satisfy the want to effort for the realization of the wanted objects, implies the presence of the want to a subject which distinguishes itself from it." Thus the want becomes a *motive*. Man is a 'free cause' in conduct, as in knowledge, because he is a 'reproduction' of the eternal self-conscious subject of the world, "carrying with it under all its limitations and qualifications the characteristic of being an object to itself." But how are we to distinguish between virtuous and vicious action? In either case the motive is the achievement of what the self-conscious subject presents to himself as his greatest good. Green's answer is that the true good is an end in which the effort of a moral agent "can really find rest"—"the Ideal of a Best." The distinction between the good and the bad man is that the former is 'conscientious,' wills what is in accordance with the system constituted by the eternal consciousness reproduced in him; while the latter is he whose "will does not answer to his reason," who habitually—knowing that he *should not*—acquiesces in 'self-satisfaction' inconsistent with man's betterment—his progressive ὁμοίωσις τῷ θεῷ in 'the Rational Life.' The ultimate standard of worth is an ideal of personal worth. The spiritual progress of mankind is "*of* personal character *to* personal character." As to man's future, the best conclusion we can draw is that "the end of human development is not one in which persons are extinguished." Meanwhile it is in society that, as a matter of fact, the human person realizes himself—his goodness appearing under the categories given in the Greek classification of the 'virtues.' The 'unconditional good' to which the 'good will' is directed—the 'ideal of humanity,' 'the perfection of man' (in principle identical with God), is thus a Common Good. This ideal of 'human perfection' is more definite, Green contends, than the 'pleasant life' of the utilitarians.

Modern idealism criticized.

We take Green as standing for the whole idealist school, with a few exceptions to be mentioned afterwards. He set his mark on English idealism; and its representatives are distinguished by a remarkable unanimity of opinion, the chief difference between them being, perhaps, with regard to the Theistic inference, in which the interest of the bulk of the school seems always to become stronger.

1. As regards the constructive part of the system, one asks why the primacy of self-consciousness is dwelt upon with such insistence. It seems unnecessary to say that without knower there can be no knowledge, without agent no action—that knowledge and action are relative to the nature and needs of the being that knows and acts. At any rate, this is just what the new biology teaches us—that organism and environment must not be abstracted from each other—that organism moulds environment no less than it is moulded by it. It is rather for the sake of the theistic inference that self-consciousness is made so prominent. The inference is (*a*) the fact that I know the world at all, involves the perfect knowability or rationality of the world; and (*b*) its perfect knowability involves an Eternal Knower, of whom I am an imperfect 'reproduction.' I know the world imperfectly, therefore there is One who knows it perfectly. If I were not conscious of knowing imperfectly, it would be unnecessary to represent me as 'reproduction' of a Perfect Knower. My imperfection must be sustained by a Perfect—an *actual* Perfect, not an ideal. Holding as we do that the ethical system to which this argument belongs is best regarded as 'prophetic' or 'protreptic,' we are not concerned to examine the logic of the argument; if it were fair (which it is not) to bring it to logical test, we should say that it neglects Kant's distinction of the Determinant and the Reflective Judgment, and concludes 'I cannot explain the world without the supposition of a God; therefore He exists.' We should also agree with Professor A. Seth (*Hegelianism and Personality*) and Mr Balfour (*Mind*, Oct. 1893) when they describe the God of this epistemological Theism as a *focus imaginarius*—a 'bare principle of unity,' without personality—or perhaps we should prefer to say that He has a personality which is inconsistent with human personality, putting Green's position thus:—On the one hand there is a 'personal' God, and on the other there is an indefinite number of human spirits, 'reproductions' of Him, the ideal of each one of which is to become indistinguishable from Him. This seems to us not to differ from the pantheistic ideal of the absorption of finite spirits in the Infinite Spirit. Such an ideal has never satisfied the 'religious consciousness'—at least, in the West—which demands 'personal relations' between man and God or gods, and 'personal immortality.' We venture to think that wherever the ground for an effectual Theism is to be sought, it is not in epistemology.[1]

[1] Bradley (*App. and Reality*, pp. 445 ff.) sets forth the difficulties under which theistic theory labours.

2. As regards the critical attitude taken up by the English idealists towards other ethical systems, we have already said enough about their attitude towards evolutionary ethics; but a few additional remarks on their criticism of English utilitarianism may be offered here. The English utilitarians from Hobbes to J. S. Mill are condemned for neglecting to recognize, in moral action, the agency of the self-conscious principle which presents to itself objects of desire—converts wants into motives, and is accordingly self-determined or free. Thus, speaking of Hobbes and Locke, Green says (*Hume*, *Treat.* vol. ii. p. 22): "Each started from the position that the ultimate motive to any action can only be the imagination of one's own pleasure or pain, and neither properly left room for the determination of desire by a conceived object, as distinct from remembered pleasure"; and again he says (*op. cit.* p. 11) that utilitarianism "excludes any test of pleasure but pleasure itself." We venture to think that the charge of 'hedonism'—whether 'ethical' or 'psychological"—brought against the English utilitarians is not reasonable. The English utilitarians were men of affairs in close touch with the actualities of English life. The national history is a testimony to the extraordinary influence which the conception of the 'Public Good' as 'Life of virtuous action sufficiently furnished with external good things' has had in England. The national character may be defined as 'Tendency to make organized social work, not ease and pleasure of separate individuals, the end.' It therefore seems to us to be paradoxical to say that English utilitarian moralists—men of affairs, in whose writings the national ἦθος is reflected with remarkable clearness—are 'hedonists' and 'individualists.' Indeed, one has only to reflect how largely the growth of the English Constitution and the progress of English legislation have been affected by the writings of those chiefly accused of 'hedonism'—Hobbes, Locke, and Bentham—to see how groundless the accusation really is. 'Hedonists' and 'individualists,' as described by the critics, could not have contributed anything effective towards the development of such embodiments of the 'Public Good.' *Laisser faire*, as it appears in Bentham's system, does not justify the charge of 'individualism.' It was forced upon Bentham and his associates by the political circumstances of which their utilitarianism took such careful account. Let us remember always that their utilitarianism was the theory which inspired the reforms of which 1832 is the central date. In order to break up the oligarchical régime, it was necessary to insist on the claim of obscure individuals to be left alone, under equal laws and a system of popular representation, to look after their own interests. The time had not yet come to think of *organizing* the life of these emancipated individuals on lines to be suggested by their own *communis sensus*. That 'individualism' is inseparable from utilitarianism it is quite incorrect to maintain. Benevolence, not self-interest, is its motto. The doctrine that society is an 'organism' (as we now say), of which the individual is conscious in 'Benevolence,' or 'Good Will' (see *Introd. to Princ. of Mor. and Leg.* ch. x., *Princ. of Pen. Code*, part iv. ch. xvi.), is essential to Bentham's system. It may, indeed, rank beside the doctrine of his critics that 'the end is realization as member of the community' (Bradley, *Eth. Stud.* p. 157). Bentham's social ideal is not that of a loose collection of individuals to be separately pleased, but of a body of fellow-workers to be organized under a system of equal laws—a prosperous industrial community the members of which are animated by the spirit of self-help and mutual help. The 'General Happiness' is not an 'abstraction' (Green, *Hume*, *Tr.* vol. ii. p. 7), but the most concrete 'object' which man, as rational being, sets before himself—a certain condition of social life, like the Greek εὐδαιμονία. In bringing the formal charge of 'hedonism' the critics seem to us to put too much into the language used by moralists who were writing for the large public, not for schoolmen. In the first place, it ought to be recognized that the utilitarians speak of pleasures in the plural, rather than of Pleasure; and, in the second place, that by 'pleasures' Bentham means *things* which men, constituted as they are, *like*—desire, and make their *ends or objects of pursuit*, it being often possible to measure the desirability of an object—described as 'mass or portion of happiness'—very accurately in terms of wealth (see *Principles of the Civil Code*, part i. ch. vi.). Among objects desired, the welfare of fellow-workmen, and the success of the common work, must be included. Bentham's view of the legislator's aim does not differ from that of Plato and Aristotle, who are not commonly accused of 'hedonism,' namely, that it is to get people χαίρειν τε καὶ λυπεῖσθαι οἷς δεῖ, the οἷς δεῖ being determined by the test of τὸ κοινῇ συμφέρον in his system as in their systems. By means of this test τὰ φύσει ἡδέα are distinguished from τὰ μὴ φύσει τοιαῦτα—pursuits which take their place in the harmonious rhythm of the public life are distinguished from those which jar. It is incorrect, then, to say that 'utilitarianism excludes any test of pleasure but pleasure itself'; and J. S. Mill is fully entitled, *as a utilitarian*, to recognize a qualitative difference between pleasures, and bring pleasure to a test which is not pleasure, namely, to the judgment of the connoisseur—the man who has been educated to correspond as accurately as may be with the best social conditions. His judgment is not based on mere 'feeling,' but on 'consciousness of adaptation.' It does not prefer certain 'feelings,' but certain 'objects' of pursuit suitable to human life as understood and valued by the good man. Of course, no system of morals can get out of the circle—'Those are good things which the good man likes.'

The charge, then, of 'ethical hedonism'—of holding that pleasure *ought* to be our end—is disposed of, we think, by a broad view of what utilitarianism is as a phase of the national life. But, it is said, utilitarianism is tainted by 'psychological hedonism,' defined by the critics as the theory that 'the ultimate motive of every action can only be the imagination of one's own pleasure or pain.' The utilitarians, it is admitted, are good men, and have done good, but they do not see how inconsistent their theory is with their practice. "The heart is in the right place, but the brain is wanting." It seems to us that what is stigmatized as 'psychological hedonism' is really nothing more than the Aristotelian theory of voluntary action. According to this theory (adopted without qualification by Hobbes and Locke), voluntary actions are those which proceed from, or are caused immediately by, a principle *within* the man. Just as a man can only see with his own eyes, or walk with his own legs, so he can only act from his own likes and dislikes. But this does not mean that his motives are always 'selfish,' or that even when they are he is seeking the abstraction 'Pleasure,' and not 'the pleasant thing.' We think, then, that the charge of 'psychological hedonism' is founded on a mistake, and that the charge of 'ethical hedonism' is misplaced as laid to the account of the English utilitarians. It is indeed to the English utilitarians, along with Plato and Aristotle, that the idealists are chiefly indebted for their conception of 'self-realization in society.' By this conception Green balances what, unbalanced, would be a more thoroughgoing individualism or 'solipsism' than that with which Bentham is charged. As we have said, the true objection of the idealists to utilitarianism is that it is a merely secular system. It must not be forgotten, however, that Green's writings, while they derive their interest from their religious character, have given a considerable impetus to utilitarianism—no longer that of *laisser faire*, but of social endeavour.

Besides the idealists who belong to the group of which Green is the central figure, there are others, more or less in sympathy with them, who stand somewhat apart; of whom we may mention the following:—The late Dr Martineau, whose *Types of Ethical Theory* has done much to popularize the idealist point of view; Professor Campbell Fraser, whose long sympathetic study of Berkeley, as man and philosopher, has helped him to the doctrine, which he sets forth in his *Gifford Lectures* (*Philosophy of Theism*), and elsewhere, that Faith underlies Knowledge; the late Professor Wallace, whose luminous *Lectures and Essays on Natural Theology and Ethics*,—notably the Essay on *Hedonism*,—neglecting the commonplaces of current controversy, reach conclusions which idealist and utilitarian might well agree to accept; and Professor Andrew Seth (A. S. Pringle-Pattison), whose criticism (*Hegelianism and Personality*) of Green's Theism has been alluded to. Mr Bradley's ethical position, so far as one may judge from *Appearance and Reality*, also seems to differ from Green's.

Utilitarianism.

While English Ethics has thus been chiefly represented, during the last twenty-five years, by idealists and evolutionists,—by moralists whose main interest is religious and scientific respectively, political interest (interest in the Public Good as served by legislation, and by education of the private citizen),—the animating principle of utilitarianism, has shown distinct signs of revival. We have already mentioned Sidgwick's *Methods of Ethics* as a landmark in the history of English utilitarianism. The utilitarian revival has since been marked by the appearance of two important works, *Progressive Morality* by Dr Fowler, and *The Principles of Morals* by the late J. M. Wilson and Dr Fowler—the latter having had by far the larger share in the work. These books are notable for the skill with which the moral experience of the individual is probed and analysed, always with the view of suggesting lines on which character may be educated for the duties of life. The world changes, and a re-examination of the 'moral sentiments' has to be undertaken periodically in the history of communities. The time for such re-examination has come, and the work begun afresh by Sidgwick and Dr Fowler is likely to occupy more and more the attention of *moralists* as distinguished from anthropologists and religious teachers. We must add here, to prevent possible misunderstanding, that Green incidentally makes some valuable contributions to a practical psychology of the 'moral sentiments' in his discussion of the Greek and Christian 'virtues.' It may be further added that economists, in taking, as they now do, greater account of moral and political considerations, are contributing to the revised 'utilitarianism' of the day. The vogue which the economic term 'value' has lately obtained in Ethics is chiefly interesting as showing that professed moralists are now feeling themselves in some sort of touch with economists. Of course, the idea of 'value' is no novelty in Ethics; and we do not think that the elaboration lately given to it has added anything to what was, though somewhat differently expressed, already familiar to all students. The reader, however, can form his own judgment on this point after perusing such a work as Meinong's *Psychologisch-ethische Untersuchungen zur Werththeorie*.

We have confined ourselves entirely to English Ethics; and will only say, in conclusion, that foreign influences have not been noticeable during the last twenty-five years. English utilitarianism rests on its own bottom; evolutionary ethics is the outcome of the work of Darwin and Mr Spencer, and of such anthropologists as Professor Tylor; and idealism, though Kant and Hegel stimulated it at first, has, since Green set his mark on it, become practically independent of outside influence—indeed, appears now as a product peculiar to ourselves. It does not seem to have influenced foreign thought except in America. On the other hand, the influence of Darwin and Mr Spencer, as well as of the English anthropologists, has been felt throughout the world.

In addition to the works referred to in the article, a few others, published since 1878, may be mentioned as bearing directly or indirectly on the subject of Ethics:—W. Wundt. *Ethik*, 1886 (Eng. trans. by Titchener, Gulliver, and Washburn, 1897).—F. Paulsen. *Ethik*, 1889, 1893 (Eng. trans. by Thilly, 1899).—H. Höffding. *Psychologie*, 1882, 1892 (Eng. trans. by Lowndes, 1892).—G. Simmel. *Einleitung in die Moralwissenschaft*, 1892, 1893.—A. Fouillée. *Le mouvement idéaliste et la réaction contre la science positive*, 1896; *La Liberté et le déterminisme*, 3rd ed., 1890; *L'enseignement au point de vue national* (Eng. trans. by Greenstreet, 1892).—J. M. Guyau. *La morale Anglaise contemporaine* (*morale de l'utilité et de l'évolution*), 1879; *Education et hérédité*, 1889 (Eng. trans. by Greenstreet, with introduction by Stout, 1891); *Esquisse d'une morale sans obligation ni sanction*, 1885 (Engl. trans. by Kapteyn, 1898).—Leslie Stephen. *The English Utilitarians*, 1900.—W. James. *Principles of Psychology*, 1891; *The Will to Believe*, 1897.—J. Martineau. *A Study of Religion*, 1887.—A. J. Balfour. *The Foundations of Belief*, 1895.—E. Caird. *Gifford Lectures* (*The Evolution of Religion*), 1893.—J. Ward. *Gifford Lectures* (*Naturalism and Agnosticism*), 1899.—J. Royce. *Gifford Lectures* (*The World and the Individual*), 1900.—T. B. Strong. *Bampton Lectures* (*Christian Ethics*), 1896.—H. Sidgwick. The "Philosophy of T. H. Green," *Mind*, Jan. 1901.—In Ueberweg's *Gesch. der Phil.* part iii. vol. ii. (*Nach-Kantische Systeme u. Phil. der Gegenwart*), edited by M. Heinze (1897), exhaustive lists of books and review articles up to date will be found. (J. A. St.)

Etna, a borough of Allegheny county, Pa., U.S.A., on the Allegheny river, opposite Pittsburg, and on the Pennsylvania and the Pittsburg and Western Railways. Population (1890), 3767; (1900), 5384.

Eton, a parish and town in the Wycombe parliamentary division of Buckinghamshire, England, on the Thames opposite Windsor. The town is under an Urban District Council, the public offices connected with which were erected in 1891. Area of town, 147 acres. Population, exclusive of Eton College (1901), 3293. Area of parish, 783 acres. Population, 2955. Two new boarding-houses have been erected by the governing body of Eton College, and the portion of land between Slough and Eton, known as Agar's Plough, has been converted into playing fields. The teaching staff has been greatly increased, and new laboratories have been built for the teaching of science. The average number of pupils at the college in 1900 was 1027.

Eugénie, Empress.—Marie-Eugénie-Ignace-Augustine, daughter of Don Cipriano Guzman y Porto Carrero, Count of Teba, subsequently Count of Montijo, and Grandee of Spain, was born at Grenada on 5th May 1826. Her mother was a daughter of William Kirkpatrick, United States Consul at Malaga, a Scotsman by birth and an American by nationality. Her childhood was spent in Madrid, but after 1834 she lived with her mother and sister chiefly in Paris, where she was educated, like so many French girls of good family, in the Convent of the Sacré Cœur. When Louis Napoleon became President of the Republic she appeared frequently with her mother at the balls given by the Prince President at the Elysée, and it was here that she made the acquaintance of her future husband. In November 1852 mother and daughter were invited to Fontainebleau, and in the picturesque hunting parties the beautiful young Spaniard, who showed herself an expert horsewoman, was greatly admired by all present, and by the host in particular. Three weeks later, on 2nd December, the Empire was formally proclaimed, and during a series of fêtes at Compiègne, which lasted eleven days (19th to 30th December) the Emperor became more and more fascinated. On New Year's Eve, at a ball at the Tuileries, Mdlle de Montijo, who had necessarily excited much jealousy and hostility in the female world, had reason to complain that she had been insulted by the wife of an official personage. On hearing of it the Emperor said to her, "*Je vous vengerai*"; and within three days he made a formal proposal of marriage. In a speech from the Throne on 22nd January he formally announced his engagement, and justified what some people considered a mésalliance. "I have preferred," he said, "a woman whom I love and respect to a woman unknown to me, with whom an alliance would have had advantages mixed with sacrifices." Of her whom he had chosen he ventured to make a prediction: "Endowed with all the qualities of the soul, she will be the ornament of the throne, and in the day of danger she will become one of its courageous supports." The marriage was celebrated with great pomp at Notre Dame on 30th January 1853, and on 16th March 1856 the Empress gave birth to a son, who received the title of Prince Imperial. The Emperor's prediction regarding her was not belied by events. By her beauty, elegance, and charm of manner she contributed largely to the brilliancy of the Imperial régime, and when the end came, she was, as the official *Enquête* made by her enemies proved, one of the very few who showed calmness and courage in face of the rising tide of revolution. The Empress acted three times as Regent during the absence of the Emperor,—in 1859, 1865, and 1870,—and she was generally consulted on important questions, but the materials for estimating her political influence are not yet available. What can be said with tolerable certainty is that when the Emperor vacillated between two lines of policy, she generally urged on him the bolder course, that she deprecated everything tending to diminish the temporal power of the Papacy, and that she disapproved of the Emperor's liberal policy at the close of his reign. On the collapse of the Empire she fled to England, and settled with the Emperor and her son at Chislehurst. After the Emperor's death she removed to Farnborough, where she built a mausoleum to his memory. In 1879 her son was killed in the Zulu War, and in the following year she visited the spot and brought back the body, to be interred beside that of his father at Farnborough. Here, and in a villa she built at Cap Martin on the Riviera, she continued to live in retirement, following closely the course of events, but abstaining from all interference in French politics.

Euphrates (Greek, Εὐφράτης, from the Old Persian, *Ufrátu*; Babylonian, *Purat*, from the Sumerian, *Pura*, "the water"; Hebrew, *Prath*; Arab, *Frát* or *Furát*), the largest and most notable river of Western Asia. It may be divided into the upper, middle, and lower Euphrates, each division being distinguished by special physical features. The Upper Euphrates consists of two arms, which, rising on the Armenian plateau, and flowing west in long shallow valleys parallel to Mount Taurus, eventually unite and force their way southwards through that range to the lower level of Mesopotamia. The northern, and shorter arm, Frát or Kara Su (Armenian, *Ephrát* or *Yephrát*; Arab, *Nahr el-Furát*), so well known as the Euphrates in the West, from its having been the boundary of the Roman Empire, is regarded by Orientals as the main stream. It rises in the Domlu Dagh, north-north-east of Erzerúm, in a large circular pool (altitude, 8625 ft.), which is venerated by Armenians and Moslems, and flows south-west to the plain of Erzerúm (5750 ft.). Thence it continues through a narrow valley west-south-west to Erzingan (3900 ft.), receiving on its way the Ovajik Su (right), the Tuzla Su (left), and the Merjan and Chanduklu (right). Below Erzingan, the Frát flows south-west through a rocky gorge to Kemakh (*Kamacha*; Armenian, *Gamukh*), where it is crossed by a bridge and receives the Kumur Su (right). At Avshin it enters a cañon, with walls over 1000 ft. high, which extends to the bridge at Pingan, and lower down it is joined from the west by the Chalta Irmak (*Lycus*; Arab, *Lúkíya*), on which stands Divrik (*Tephrike*). Then, entering a deep gorge, with lofty rock-walls and magnificent scenery, it runs south-east to its junction with the Murad Su. The Frát, separated by the easy pass of Deve-boyún from the valley of the Araxes, marks the natural line of communication between Northern Persia and the West,—a route followed by the nomad Turks, Mongols, and Tatars on their way to the rich lands of Asia Minor. It is a rapid river of considerable volume, and below Erzingan is navigable, down stream, for rafts. The southern and longer arm, Murad Su (*Arsanias Fl.*; Armenian, *Aradzani*; Arab, *Nahr Arsanás*), rises south-west of Diadin, in the northern flank of the Ala Dagh (11,500 ft.), and flows west to the Alashgerd plain. Here it is joined by the Sharian Su from the west, and the two valleys form a great trough through which the caravan road from Erzerúm to Persia runs. The united stream breaks through the mountains to the south, and, receiving on its way the Patnotz Su (left) and the Khinis Su (right), flows south-west, west, and south, through the rich plain of Bulanik, to the plain of Músh. Here it is joined by the Kara Su (*Teleboas*), which, rising near Lake Van, runs past Músh and waters the plain. The river now runs west-south-west through a deep rocky gorge, in which it receives the Gunig Su (right), to Palu (cuneiform inscriptions); and continues through more open country to its junction with the Frát Su. About 10 miles east-north-east of Kharpút the Murad is joined by its principal tributary, the Peri Su, which drains the wild mountain district, Dersim, that lies in the loop between the two arms. The Murad Su is of greater volume than the Frát, but its valley below Músh is contracted and followed by no great road. Below the junction of the two arms the Euphrates flows south-west past the lead mines of Keban Maden, where it is 120 yards wide, and is crossed by a ferry (altitude, 2425 ft.), on the Sivas-Kharpút road. It then runs west, south, and east round the rock-mass of Musher Dagh, and receives (right) the Kuru Chai, down which the Sivas-Malatia road runs, and the Tokhma Su, from Gurun (*Gauraina*) and Derendeh. At the ferry on the Malatia-Kharpút road (cuneiform inscription) it flows eastwards in a valley about a quarter of a mile wide, but soon afterwards enters a remarkable gorge, and forces its way through Mount Taurus in a succession of rapids and cataracts. After running south-east through the grandest scenery, and closely approaching the source of the western Tigris, it turns south-west, and leaves the mountains a few miles above Samsát (*Samosata*, altitude 1500 ft.). At Samosata, the capital of the Seleucid Kings of Commagene, the Persian Royal Road, from Sardis to Susa, probably crossed the river. The general direction of the great gorges of the Euphrates, Pyramus, and Sarus seems to indicate that their formation was primarily due to the same terrestrial movements that produced the Jordan-Âraba depression to the south. The length of the Frát is about 275 miles; of the Murad, 415 miles; and of the Euphrates from the junction to Samsát, 115 miles.

In the middle division, which extends from Samsát to Hit, the Euphrates runs through an open, treeless, and sparsely peopled country, in a valley a few miles wide, which it has eroded in the rocky surface. The valley bed is more or less covered with alluvial soil, and cultivated in places by artificial irrigation. Its rocky sides, which sometimes closely approach the river, as at Helebí-Jelebí, are composed of gypsum, sandstone, and conglomerates; and beyond them, on both banks, is the steppe-like desert, covered in spring with verdure. The right bank, or esh-Shám, is occupied by the ʿAnazeh Arabs, and the left, or el-Jezíre, by the great Shammar tribe. Below Samsát the river runs south-west to Rúm Kaleh (Armenian, *Hrhomgla*), and then south past Khalfat (ferry) to Birejik, where it is only 110 miles from the Mediterranean. From Birejik (*Apamea-Zeugma*, altitude 1170 ft.), where the high road from east to west crossed it, the river runs sluggishly southwards, over a sandy or pebbly bed, past Jerablús (*Europus, Carchemish*), and the confluence of the Sajúr (right), to Meskine, the highest point reached by steamers. At old Meskine, now some distance from the river, was Barbalissus (Arab, *Balis*), once the port of Syria on the Euphrates. Eight miles below Meskine, near Kalát Dibse, was Thapsacus (Tiphsah of 1 Kings iv. 24), the most important passage of the Middle *Euphrates*, and here the river turns east. Lower down is Rakka (*Nicephorium*), at the junction of the Belikh (*Bilechas*), which flows south through the Biblical Aram Naharaim from Urfa (*Edessa*) and Harrán (*Carrhae*). The direction is now south-east between banks green with willow and tamarisk, and before reaching Deir ez-Zor the river meets the first groves of date palms, lemons, and oranges, and encloses several islands. Below Deir the bed is rocky, and the river is joined near Kirkisíeh (*Circisium*; Assyrian, *Sirki*) by the Khabúr (*Chaboras*), which rises in the Karaja Dagh, and with its tributary the Jaghjagh (*Mygdonius*; Arab, *Hirmás*) flows south through the land of Gozan. In early Arab times a canal or river, eth-Tharthar, is said to have run from the Hirmás, through Jebel Sinjar, and past el-Hadhr (*Hatrae*), to the Tigris at Tekrít. Below the Khabúr the river has no affluents. From Werdi to Ana (*Anatho*) it runs east over a rocky bed, passing Deír el-Kaim (Gordian's Tomb (?) and the Perso-Roman boundary); and then south-east to Hit. Between Ana and Hit it is thickly studded with islands, on which are the ruins of several castles. The Middle Euphrates was important as a boundary in early times. It separated Assyria from the Khíta or Hittites; was the limit of the Jewish kingdom in its widest extent; divided the eastern from the western satrapies of Persia (Ezra iv. 17; Neh. ii. 7); and was at several periods the boundary of the Roman Empire. Until the advent of the nomads from Central Asia, there were many flourishing cities on its banks; but the riverain population is now sparse, and the only towns are Samsát, Birejik, Deir, Ana, and Hit. From Samsát to Hit the river is about 720 miles.

Hit (*Is* or *Ihi*), noted for its bitumen springs, stands at the head of the alluvial deposit, and marks the commencement of the Lower Euphrates. Thence the river flows south-east and south-south-east, to its junction with the Tigris at Korna, through an unbroken plain with no natural hill, and, except at el-Haswa, above Hillah, with no trace of rock. In the latitude of Baghdad the Euphrates and Tigris closely approach each other, and then, widening out, enclose the plain of Babylonia (Arab, *Sawád*). In early times great irrigating canals distributed the waters over the plain, and made it one of the richest countries of the East. The river then formed, as it does now, large salt marshes (*Paludes Chaldaici*; Arab, *el-Batiha*), before meeting the Tigris in the tidal estuary, Shatt el-Arab, which, in the time of the Khalifate, reached the open sea about 20 miles above the present shore-line. The distance from Hit to the Persian Gulf is about 550 miles. The ancient system of canalization described by Sir Henry Rawlinson in the 9th edition of this work (viii. 670) was inherited, from the Persians, by the Arabs, who long maintained it in working order (Ibn Serapion, translated by Guy le Strange in *Journal Royal Asiatic Society*, 1895, 1897). Its remote origin may be inferred from the excavations at Abu Habba, Tello, Niffer, &c., which have shown that those sites were occupied by towns 5000–4000 B.C. The astonishing fertility, and consequent prosperity, of the country watered by the Euphrates, its tributaries, and its canals is noticed by ancient writers. Its decline dates from the appearance of the Turkish nomads in the 11th century; its ruin was completed by the Shammar Arabs in the 17th century. If the ancient system of irrigation were restored, sufficient grain could be grown to alter the conditions of the wheat supply of the world.

The length of the Euphrates from its source near Diadin to the sea is about 1800 miles, and its fall during the last 1200 miles is about 10 inches per mile. The river begins to rise in the end of March, and attains its greatest height between the 21st and 28th May. It is lowest in November, and rocks, shallows, and the remains of old dams then render it unnavigable. During high water small steamers ascend to Meskine, but most of the navigation is by native rafts (*Kelek*). Boats, built in Syrian ports, were placed on the Euphrates by Sennacherib and Alexander; and the river was formerly a frequented route followed by merchants on their way from the Mediterranean to Babylon (*Herodotus* i. 185). In its present state it is unsuitable for continuous steam navigation, but the advantageous geographical position of its valley has originated schemes for connecting the Mediterranean and the Persian Gulf by railway as an alternative means of communication with India. All these schemes have fallen through, hitherto, on the money question, or on the unwillingness of the Turkish Government to sanction any line that was not connected directly with Constantinople. In 1872 and 1882 a line from Suedia, near the mouth of the Orontes, by Aleppo, to Meskine, and thence by the Euphrates to Basra, found favour with Committees of the House of Commons. Other schemes were for a line from Tripolis, on the Syrian coast, across the desert to Tekrít on the Tigris, and thence to Baghdad and Basra; from Alexandretta, by Aleppo, to Meskine; and an extension of the Mersina–Tarsus–Adana Railway to Aintab and Birejik. In 1898 Count Kapnist, a Russian subject, applied for a concession to construct a line from Tripolis to Hit, and thence along the Euphrates valley to Basra, and Koweit on the Persian Gulf, with branches to Baghdad and Kerbela. In the same year the scheme of a British syndicate to extend the Anatolian Railway from Konia, by Adana, Aleppo (with a branch to Alexandretta), and the valley of the Euphrates, to Hit, and thence by Baghdad and Basra to the Persian Gulf between Fao and Koweit, failed through the opposition of the Anatolian Railway Company, which is in German hands. This company has under consideration an extension of its Anatolian lines to Baghdad and Basra, either from Angora, by Kaisaríeh, Diarbekr, and Mosul, or from Konia by Marash, Aleppo, and Hit, but the preliminary surveys had not been completed in 1901.

(C. W. W.)

Eure, a department in Northern France, watered by the Seine and the Eure.

Area, 2331 square miles. The population had dropped to 358,829 in 1886, and in 1901 counted only 331,181. Births in 1899, 6598, of which 697 illegitimate; deaths, 8108; marriages, 2477. The schools in 1896 numbered 855, with 42,000 pupils, and the illiterate formed 7 per cent. of the population. Evreux, the capital, has 17,000 inhabitants. The area under cultivation in 1896 amounted to 1,383,840 acres, 872,313 acres of which were plough-land. The wheat crop of 1899 returned a value of £1,231,000; mangold-wurzel, £140,000; the grass lands, including the natural pastures, £780,000; cider-apples, £245,000. Of live-stock, Eure had, in 1899, 48,060 horses, 6450 asses, 133,250 cattle, 286,880 sheep, and 42,820 pigs. Though without either coal or iron, the industry in metals produced in 1898 nearly £45,000 in value. Louviers manufactures cloth of esteemed quality; Evreux and Gisors, yarn and cotton stuffs.

Eure-et-Loir, a department in Northern France, watered by the Eure.

Area, 2293 square miles. The population has decreased from 283,719 in 1886 to 274,862 in 1901. Births in 1899, 5742, of which 444 illegitimate; deaths, 6311; marriages, 2100. There were in 1896 731 primary schools, with 40,000 pupils; 2 per cent. of the population is illiterate. Out of 1,388,782 acres of cultivated land in 1896, 1,146,609 acres were arable, 69,190 acres were natural pastures, and 49,420 acres were woods and forests. The wheat crop of 1899 amounted to the value of £1,903,000; rye, £80,000; barley, £227,000; oats, £1,170,000; mangold-wurzel, £153,000; the natural pastures and grass lands, £650,000; beetroot, £275,000. The live-stock of 1899 included 44,330 horses, 102,990 cattle, 577,260 sheep, and 28,180 pigs. Agriculture is the only forward industry in this department, which forms one of the granaries of the basin of the Seine. The production of alcohol in 1898 exceeded 70,000 gallons. Chartres, the capital, counts 23,000 inhabitants.

Eureka, capital of Humboldt county, California, U.S.A., on the south shore of Humboldt Bay, and connected with San Francisco and Portland by steamship lines. Its site is level and the plan of its streets regular. It is in the celebrated coast redwood belt, and is the principal point for the manufacture and shipment of redwood lumber. Several short lumber railways run from this city and from Arcata, across the bay, into the forests, and bring lumber to the mills, most of which are in or near Eureka. The operations, both of lumbering and of milling the timber, are carried on here on a scale nowhere else to be seen. Population (1880), 2639; (1900), 7327.

Eureka Springs, capital of Carroll county, Arkansas, U.S.A., in the Ozark Hills, at an altitude of 1800 feet. It is chiefly noted for its medicinal springs, which attract a large summer population. Population (1880), 3984; (1900), 3572.

EUROPE.

I. Geography and Statistics.

On the subject of the boundaries of Europe there is still divergence of opinion. While some authorities take the line of the Caucasus as the boundary in the south-east, others take the line of the Manich depression, between the upper end of the Sea of Azov and the Caspian Sea, nearly parallel to the Caucasus. Various limits are assigned to the continent on the east. Officially the crest of the Caucasus and that of the Urals are regarded in Russia as the boundaries between Europe and Asia on the south-east and east respectively,[1] although in neither case does the boundary correspond with the great administrative divisions, and in the Urals it is impossible to mark out any continuous crest. Reclus, without attempting to assign any precise position to the boundary-line between the two continents, makes it run through the relatively low and partly depressed area north of the Caucasus and east of the Urals. The Manich depression, marking the lowest line of this area to the north of the Caucasus, has been taken as the boundary of Europe on the south-east by Wagner in his edition of Guthe's *Lehrbuch der Geographie*,[2] and the same limit is adopted in Kirchhoff's *Länderkunde des Erdteils Europa*[3] and Stanford's *Compendium of Geography and Travel*. In favour of this limit much weight ought, we think, to be given to the consideration put forward by Wagner, that from time immemorial the valleys on both sides of the Caucasus have formed a refuge for Asiatic peoples, especially when it is borne in mind that this contention is reinforced by the circumstance that the steppes to the north of the Caucasus must interpose a belt of almost unpeopled territory between the more condensed populations belonging undoubtedly to Asia and Europe respectively. Continuity of population would be an argument in favour of assigning the whole of the Urals to Europe, but here the absence of any break in such continuity on the east side makes it more difficult to fix any boundary-line outside of that system. Hence on this side it is perhaps reasonable to attach greater importance to the fact that the Urals form a boundary not only orographically, but to some extent also in respect of climate and vegetation,[4] and hence to take a line following the crest of the different sections of that system as the eastern limit between the two continents.[5] Obviously, however, any eventual agreement among geographers on this head must be more or less arbitrary and conventional, and provisionally it is advisable to give the area of the continent within different limits.

Boundaries.

The following calculations in English square miles (round numbers) of the area of Europe, within different limits, are given in Behm and Wagner's *Bevölkerung der Erde*, No. viii. (Gotha, Justus Perthes, 1891), p. 53:—

Extent.

Europe, within the narrowest physical limits (to the crest of the Urals and the Manich depression, and including the Sea of Azov, but excluding the Caspian Steppe, Iceland, Novaya Zemlya, Spitsbergen, and Bear Island, 3,570,000 square miles. The same, with the addition of the Caspian Steppe up to the Ural River and the Caspian Sea, 3,687,750 square miles. The same, with the addition of the area between the Manich depression and the Caucasus, 3,790,500 square miles. The same, with the addition of territories east of the Ural Mountains, the portion of the Caspian Steppe east of the Ural River as far as the Emba, and the southern slopes of the Caucasus, 3,988,500 square miles. The same, with Iceland, Novaya Zemlya, Spitsbergen, and Bear Island, 4,093,000 square miles.

In all these calculations the Marmora Islands, Canary Islands, Madeira, and even the Azores, are left out of account.

The estimate of the length of the coast-line in the 9th edition of the *Ency. Brit.*, 19,820 miles (Reuschle, 1869),

---

[1] At the summit of each of the Trans-Ural railways (Perm–Tyumen and Ufa–Chelyabinsk) and that of the road across the Caucasus from Vladikavkaz to Tiflis, sign-posts, with the name Europe on one side, Asia on the other, mark this boundary.

[2] Fifth edition, vol. ii. pp. 24–25.

[3] Pt. i. pp. 11–12.

[4] Griesbach, on the strength of Middendorff's observations, remarks that, in addition to European fruit trees, oak, maples, elms, ashes, and the black alder do not cross the Urals, while the lime tree is reduced to the size of a shrub (*La Végétation du Globe*, translated by Tchihatchef, i. p. 181).

[5] On the history of the boundary between Asia and Europe, see F. G. Hahn in the *Mitteilungen des Vereins für Erdkunde zu Leipzig*, 1881, pp. 83–104. Hahn, on the ground that true mountain systems must be regarded as forming geographical units, pronounces against the practice of making "natural boundaries" run along mountain crests, and assigns the whole of the Caucasus region to Europe as all belonging to such a system, but orographically quite different from the Armenian plateau (p. 103). But surely it is no less different from the European plain.

is one that does not take into account minor indentations. Reclus' estimate, including the more important indentations, brings the coast-line up to 26,700 miles, and that of Strelbitsky up to 47,790 miles (smaller islands not included), or 1 mile of coast for about 75 square miles of area. It may be pointed out, however, that the commercial value of this relation is diminished not merely by the absence in many parts of natural harbours, but in many other parts by the absence of natural facilities for communication between such harbours and a productive interior—in other words, by the absence of a hinterland.

Coast-line.

Several new estimates have been made of the mean elevation of the continent. The following list gives the results of all the estimates that have hitherto been made:—Humboldt, 675 ft.; Leipoldt,[1] 975 ft.; De Lapparent,[2] 960 ft.; Murray,[3] 939 ft.; Supan,[4] 950 ft.; v. Tillo,[5] 1040 ft.; Heiderich,[6] 1230 ft.; Penck,[7] 1085 ft. The exceptionally high estimate of Heiderich is due to the fact that by him Transcaucasia and the islands of Novaya Zemlya, Spitsbergen, and Iceland are reckoned as included in Europe.

Relief.

Since the publication of the ninth edition an estimate has been made by Strelbitsky of the length and of the area of the basins of all the principal rivers of Europe. In the following table all the estimates given without any special authority are based on Strelbitsky's figures, but it should be mentioned that the estimates of length made by him evidently do not take into account minor windings, and are therefore generally less than those given by others. The authorities are separately cited for the originals of all other figures given in the table.

* The equivalent of the figures given in *Superficie de l'Europe*. A later measurement by Strelbitsky yielded a result equal to 2215 English miles.

† General v. Tillo, in *Transactions* (*Izvestiya*) *Imp. Rus. Geog. Soc.* vol. xix. (1883), pp. 160-161.

‡ Dr Al. Bludau in *Petermanns Mitteilungen*, 1898, pp. 185-187, has given new calculations of the areas of the basins of certain European rivers, namely, the Tagus, 31,250 sq. m.; Ebro, 32,810 sq. m.; Guadalquivir, 21,620 sq. m.; Po, 28,800 sq. m.; Guadiana, 25,810 sq. m.; and Jucar, 8245 sq. m.

§ St Martin, *Dict. de Géog. Univ.*

The observations on the temperature of European rivers have been collected and discussed by Dr Adolf E. Forster.[8] He finds that the dominant factor in determining that temperature is the temperature of the air above, but that rivers are divisible into four groups with respect to the relation between these temperatures at different seasons of the year. These groups are rivers flowing from glaciers, in which the temperature is warmer than the air in winter, colder in summer; rivers flowing from lakes, characterized by peculiarly high winter temperatures, in consequence of which the mean temperature for the year is always above that of the air; rivers flowing from springs, which, at least near their source, are more rapidly cooled by low than warmed by high air temperatures; and rivers of the plains, which have a higher mean temperature than the air in all months of the year.

River temperatures.

Lakes.

Great attention has recently been given to limnology. For many European lakes, especially the smaller ones, estimates have been made of the mean depth and the volume. A list of all the European lakes for which the altitude, extent, and greatest depth could be ascertained, compiled by Dr K. Peucker, is published in the *Geog. Zeitschrift*, 1896, pp. 606–16, where estimates of the mean depth and the volume are also given where procurable. The following table, comprising only the larger lakes, is mainly based on this list, where the original authorities are mentioned. The figures entered in the following table not taken from this list are after Strelbitsky or the *Géog. Universelle* of V. de St Martin:—

* Including L. Pskov as well as the connecting arm known as Teploye.

Of engineering works carried out on European lakes since the publication of the article on Europe in the ninth edition, the most important are those for the draining of Lake Copais in Bœotia, completed in 1893, by means of which nearly 100 square miles have been added to the cultivable area of Greece; those by which Lake Fucino or Celano, in the Abruzzi, was completely drained in 1876, about 60 square miles having thus been reclaimed since the beginning of the operations in 1854; and those by which Lake Trasimeno, in Umbria, was reduced in size, and an area of about 8 square miles of land (including malarial swamp) reclaimed in 1898.

Geology.

The most important event in connexion with the geology of Europe as a whole in recent years has been the commencement of the publication of *The International Geological Map of Europe* on the scale of 1 : 1,500,000. It is to be completed in forty-nine sheets, of which eighteen had in October 1901 been published.

In the way of geological research and theoretical investigation an immense amount of detailed work has of course been done in every part of the continent, but the most extensive work has been in connexion with the Ice Age. It is enough to mention here that the chief questions now under discussion are the number of times that glacial phenomena were repeated in Europe, and the origin of the boulder-clay. While most glacialists appear to consider that there were three periods of ice expansion over parts of Europe, Professor Geikie believes that as many as six periods of glacial expansion and five inter-glacial periods can be distinguished.[1] With regard to boulder-clay, while the great majority of glacialists adhere to the belief that it was formed and transported under land-ice, there are still upholders of the theory that it is of subaqueous origin, and some adherents of the former view admit that in places it must have been finally deposited in a glacial lake.

Minerals.

With regard to the mineral production of Europe, the most notable fact to record is the relatively lower place taken by the United Kingdom in the production of the two minerals of the greatest industrial importance—coal and iron. Here it is enough to state the main results. In the production of coal the United Kingdom is indeed still far ahead of all other European countries, but notwithstanding the fact that the British export of coal has been increasing much more rapidly than the production, it has not been able to keep pace with Germany and Russia in the rate of increase of production. In 1878 the production of coal in the German Empire was only about 34 per cent. of that of the United Kingdom, but in 1900 it had grown to about 49 per cent. This, too, was exclusive of lignite, the production of which in Germany is increasing still more rapidly. It was equal to little more than one-fourth of the coal production in 1878, but more than one-third in 1900. The Russian coal production is still small, but it is increasing more rapidly than that of any other European country. While in 1878 it was little more than 2 per cent. of that of the United Kingdom, in 1900 the corresponding ratio was slightly above 7 per cent. In the production of iron ores the decline in the position of the United Kingdom is much more marked. The production reached a maximum in 1882 (18,032,000 tons), and since then it has sunk in one year (1893) as low as 11,200,000 tons, while, on the other hand, there has been a rapid increase in the production of such ores in the German Zollverein (including Luxemburg), Spain, Sweden, Russia, and Greece. In the total amount of production the United Kingdom now takes the second place. While in 1878 the production of iron ores in the German Zollverein was little more than a third of that in the United Kingdom, it has since 1892 regularly exceeded the British production.

The changes that have taken place in the production of the minor minerals may be seen by comparing the following table,[2] relating to the year 1898, with the corresponding table in the ninth edition:—

	Gold.	Silver.	Quicksilver Ore.	Tin Ore.
Austria	71 kilos.	40,305 kilos.	88,519 m. t.	13 m. t.
German Empire	2847 ,,	480,578 ,,	...	51
Hungary	2768 ,,	18,799 ,,	55 ,,	...
Norway (1897)	...	5,372 ,,	...	...
Portugal	6·8 ,,	119·5 ,,	...	102 ,
Spain	...	...	31,361 ,,	...
United Kingdom	395 oz.	211,403 oz.	...	7,498 ,,

Kilos. = kilograms. M. t. = metric tons.

M. t. = metric tons.

Climate.

The period since 1878 has been peculiarly rich in important papers on the subject of the climate of the continent. It must suffice to state here compendiously the nature of their subjects, and to refer the reader for their titles to the bibliography at the end of this article, where they are enumerated together. It may be added that the maps illustrating the more important of these papers are all either reproduced in the *Atlas of Meteorology* by Bartholomew and Herbertson (Westminster, 1899), or represented there by new maps based on a wider range of material. The temperature of the continent has been illustrated by Dr Supan in an interesting series of maps based on actual observations not reduced to sea-level, and showing the duration in months of the periods within which the mean daily temperature lies within certain ranges (at or below 32° F.; 50°–68° F.; above 68° F.).[1] Under this head may be mentioned also Mr Dickson's paper on the sea temperatures round the British Isles,[2] inasmuch as it is of wider interest than its immediate subject indicates, throwing new light on the nature of the influence of the Gulf Stream and the Gulf Stream Drift.

The map accompanying König's paper on the duration of sunshine[3] shows on the whole, outside of the Mediterranean peninsulas, an increase from north-west to south-east (Orkney Is., 1145 hours = 26 per cent. of the total possible; Sulina, 2411 h. = 55 per cent.). In the Mediterranean peninsulas the duration is everywhere great—greatest, so far as the records go, at Madrid, 2908 h. = 66 per cent. Dr P. Elfert's[4] map illustrating cloud-distribution in Central Europe embraces the region from Denmark to the basin of the Arno, and from the confluence of the Loire and Allier to the mouths of the Danube.

The seasonal distribution of rainfall in Europe has been illustrated by Dr Supan in four maps[5] showing the percentage of the total rainfall of the year occurring in spring, summer, autumn, and winter respectively.

Since 1893 M. Alf. Angot has been publishing in the *Annales du Bureau Central Météor. de France* a series of memoirs in which the rainfall observations of Europe for the thirty years 1861–90 are recorded and discussed. The first paper (1893, B, pp. 157–194) deals with the Iberian Peninsula, the second (1895, B, pp. 155–192) with Western Europe (from about 43° to 58° N. and as far east as about 19°–21° E.). Both papers are accompanied by maps showing by six tints the mean rainfall for each month as well as for the entire year; and that on Western Europe, by maps extending in the west as far south as Avila, the proportion of the rainfall occurring during the winter, spring, autumn, and summer months respectively.

Mention should here be made also of Brückner's remarkable treatise on the variations of climate in time. Though it deals with such variations over the entire land-surface of the globe, a large proportion of the data are derived from Europe, for which continent, accordingly, it furnishes a great number of particulars with regard to secular variations in temperature, rainfall, the date of the vintage, the frequency of cold winters, the level of rivers and lakes, the duration of the ice-free period of rivers (in this case all Russian), and other matters. Those relating to the date of the vintage are of peculiar interest. They apply to 29 stations in France, South-West Germany, and Switzerland, and for one station (Dijon) go back with few breaks to the year 1391; and as the variations of climate of which they give an indication correspond precisely to the indications derived from temperature and rainfall in those periods in which we have corresponding data for these meteorological elements, they may be taken as warranting conclusions with regard to these points even for periods for which direct data are wanting. A period of early vintages corresponds to one of comparatively scanty rains and high temperatures. It is accordingly interesting to note that the data referred to indicate, on the whole, for Dijon an earlier vintage for the average of all periods of five years down to 1435 than for the average of the periods of the same length from 1816–80; but that the figures generally show no regular retardation from period to period, but more or less regular oscillations, differing in their higher and lower limits in different periods of long duration. (See particularly pp. 261–267 and the chart at the end of the treatise cited.)

Races.

An enormous amount of investigation with regard to this subject has been carried on in recent years. These labours have chiefly consisted in the study of the physical type of different countries or districts, but it is not necessary to consider in detail the results arrived at. It should, however, be pointed out that the idea of an Aryan race may be regarded as definitely abandoned. One cannot even speak with assurance of the diffusion of an Aryan civilization. It is at least not certain that the civilization that was spread by the migration of peoples speaking Aryan tongues originated amongst and remained for a time peculiar to such peoples. The utmost that can be said is that the Aryan languages must in their earliest forms have spread from some geographical centre. That centre, however, is no longer sought for in Asia, but in some part of Europe, so that we can no longer speak of any detachment of Aryan-speaking peoples entering Europe.

The most important works, summarizing the labours of a host of specialists on the races of Europe, are those of Ripley[6] and Deniker.[6] Founding upon a great multitude of data that have been collected with regard to the form of the head, face, and nose, height, and colour of the hair and eyes, most of the leading anthropologists seem to have come to the conclusion that there are three great racial types variously and intricately intermingled in Europe. As described and named by Ripley, these are: (1) the Teutonic, characterized by long head and face and narrow aquiline nose, high stature, very light hair, and blue eyes; (2) the Alpine, characterized by round head, broad face, variable rather broad heavy nose, medium height and "stocky" frame, light chestnut hair, and hazel grey eyes; and (3) the Mediterranean, characterized by long head and face, rather broad nose, medium stature and slender build, dark brown or black hair, and dark eyes. The Teutonic race is entirely confined to North-Western Europe, and embraces some groups speaking Celtic languages. It is believed by Ripley to have been differentiated in this continent, and to have originally been one with the other

[6] See Bibliography at the end of the article.

long-headed race, sometimes known as the Iberian, and to the Italians as the Ligurian race, which "prevails everywhere south of the Pyrenees, along the southern coast of France, and in Southern Italy, including Sicily and Sardinia," and which extends beyond the confines of Europe into Africa. The Alpine race is geographically intermediate between these two, having its centre in the Alps, while in Western Europe it is spread most widely over the more elevated regions, and in Eastern Europe "becomes less pure in proportion as we go east from the Carpathians across the great plains of European Russia." This last race, which is most persistently characterized by the shape of the head, is regarded by Ripley as an intrusive Asiatic element which once advanced as a wedge amongst the earlier long-headed population as far as Brittany, where it still survives in relative purity, and even into Great Britain, though not Ireland, but afterwards retired and contracted its area before an advance of the long-headed races. Deniker, basing his classification on essentially the same data as Ripley and others, while agreeing with them almost entirely with regard to the distribution of the three main traits (cephalic index, colour of hair and eyes, and stature) on which anthropologists rely, yet proceeds further in the subdivision of the races of Europe. He recognizes six principal and four secondary races. The six principal races are the Nordic, answering approximately to the Teutonic of Ripley, the Littoral or Atlanto-Mediterranean, the Ibero-Insular, the Oriental, the Adriatic or Dinaric, and the Occidental or Cevenole.

Population. The following table shows the area of the countries of Europe, with their estimated or enumerated populations at different dates :—

* For explanation see top of next column.
† The contiguous parliamentary boroughs of Birmingham and Aston Manor.
‡ Part of Greater London.

It is estimated that to-day more than 10 per cent. of Europeans live in great cities.[1] In 1800 only those to which an asterisk is prefixed rose above 100,000. Thirty-four out of the 140 towns enumerated in the list above belong to the British Isles.

The following tables must be allowed to speak for themselves :—

*Land Forces.**

Countries.	Total Strength in Round Numbers.		Notes.
	Peace Footing.	War Footing.	
Austria-Hungary .	361,700	1,872,000	[1] Estimated total available force.

* Based mainly on *The Statesman's Year-Book*, 1900.

[1] Common revenue and expenditure.
[2] Gold debt, in addition to which there is a paper debt of about 174,000,000 drachmai.
[3] Exclusive of a debt of about £30,000,000 stated to be "partly in the hands of the Government."
[4] The actual revenue for 1900–01 was £130,385,000, and the expenditure £183,592,000.

Agricultural products and live-stock.

Though agricultural statistics are not obtainable for all European countries, and where obtainable not in every case for the same years, still the analysis of such as can be got brings out some very striking and interesting results. Since 1880 there has been a rise in the area under wheat in Hungary, the German Empire, Austria, and France, that in Hungary being the largest (more than 25 per cent.), while in the German Empire it has been about 8½ ; in Austria, about 7 per cent. ; and in France, slight. Between 1890 and 1899 there was a rise in the wheat area of Rumania of about 10 per cent., and in Italy one of 4 per cent. between 1890 and 1896. On the other hand, there has been a great decline in the wheat area in Denmark, Belgium, the Netherlands, and the United Kingdom ; that in the United Kingdom nearly reaching to, and in the other countries mentioned exceeding, 30 per cent. The area under rye has been extended in the Netherlands by more than 8 per cent. ; slightly also in Denmark ; while in Austria, Germany, and Hungary it has been practically stationary, and in France it has declined by nearly 20 per cent. Only two countries, Belgium and Ireland, show a decline in the area under potatoes ; that in Ireland amounting to more than 11 per cent. In Great Britain and Sweden the area under this crop has been practically stationary ; while Hungary, France, Austria, Denmark, the German Empire, and the Netherlands have added to the area under this crop by an amount varying from nearly 40 per cent. in Hungary to 8 per cent. in the Netherlands. All European countries for which statistics are available show a decline in the flax area, but these countries do not include Russia. In Ireland the decline between 1880 and 1899 amounted to nearly 80 per cent. Under maize, Hungary has increased its area by 25 per cent. since 1880, and Rumania in the same proportion since 1890. The area under the vine has declined in France since 1880 by more than 25, and in Hungary by more than 30 per cent. ; while in Italy there has been an extension of the vineyards since 1890, and in the German Empire their area has remained almost constant. In most European countries for which statistics are available the numbers of the main kinds of live-stock, except sheep, have been stationary or advancing (mostly advancing), but, except in Ireland and Poland, there has been a decline, generally a considerable decline, in the numbers of sheep and lambs. In Belgium, France, Ireland, the Netherlands, and Norway, the number of horses has remained nearly the same since 1880 ; but in Germany Russia, Great Britain, Austria, and Sweden there has been an increase in numbers, amounting in Germany to as much as 14 per cent. between 1883 and 1897 (since 1873 more than 20 per cent.). The number of cattle increased in all countries publishing statistics except Russia and Norway, the increase amounting to as much as 20 per cent. in Denmark (1881 to 1898), 17 per cent. in the German Empire (1885 to 1897), 16 per cent. in Great Britain, and 15 per cent. in Ireland (both from 1880 to 1899), and 14 per cent. in France and Sweden (both from 1880 to 1898). In Russia the decline amounted to 10 per cent. between 1877 and 1888. The increase was in a much higher ratio in the case of swine, Russia in this case being the only country showing a decline (amounting to 15 per cent. between 1877 and 1888). The increase varied from 20 per cent. in Norway (1875 to 1890) to nearly 100 per cent. in the Netherlands (1880 to 1895). In Belgium it was nearly 80 per cent. (1880 to 1895); in the German Empire, 55 per cent., between 1883 and 1897, and over 100 per cent. between 1873 and 1897; in Sweden, over 90 per cent. (1880 to 1898); in Ireland, over 60 per cent. (1880 to 1899); and in Great Britain, above 25 per cent. (same period). The decline in the number of sheep and lambs amounted in the German Empire to over 50 per cent. between 1873 and 1897, over 40 per cent. between 1883 and 1897; in Belgium, between 1880 and 1895, it was more than 35 per cent.; in Denmark and Italy it was nearly 20 per cent., in the first case between 1881 and 1893, in the second between 1881 and 1890. In most other countries it varied from 6½ to 16 per cent. In Great Britain it was as low as about 3 per cent. (1880 to 1899), and, on the other hand, there was a rise in the number of sheep in Ireland in the same period of nearly 23 per cent. In the United Kingdom, as a whole, the number was nearly the same at both dates. In Poland there was a rise of nearly 37 per cent. between 1890 and 1897.

Commerce, industries, and railways.

With regard to commerce, industries, and railways, as a whole, Europe may be said to be characterized by the rapid development of manufacturing at the expense of agricultural industry. With few exceptions the countries of Europe that export agricultural products are able to spare a diminishing proportion of the aggregate of such produce for export. Other countries are becoming more and more dependent on imported agricultural products. Most European countries, even if not able to export a large proportion of manufactured articles, are at least securing a greater and greater command of the home market for such products.[1] Inland centres of manufacturing industry are extending the range of their markets. All these changes have been largely, if not chiefly, promoted by the improvements in the means of communication, and the methods of transport by sea and land. Larger ships more economically propelled have brought grain at a cheaper and cheaper rate from all parts of the world, and since the date of the ninth edition improved methods of refrigeration have made fresh meat, butter, and other perishable commodities even from the southern hemisphere articles of rapidly growing importance in European markets. Improvements in shipping have likewise tended to cheapen British coal in many parts of the mainland of Europe. On the other hand, the extension of the railway network of the Continent has brought a wider area within the domain of the manufacturing regions associated with the coal-fields occurring at intervals in central Europe from the upper Oder to the basin of the Ruhr, as well as some of the more detached coal-fields of Russia. Among the more important railways that have been opened since the date of the ninth edition (mentioned roughly in the order from west to east in the trunk of Europe, and those in the peninsulas separately) are the line connecting Besançon with the watch-making region of the Swiss Jura; one from Zweibrücken by the valley of the Mosel to the Rhine, thus bringing the great iron-mining district on the borders of Luxemburg and Alsace-Lorraine into the most direct connexion with that river and its valley; three important trans-Alpine lines,—that through the St Gothard tunnel (opened in 1882), that connecting Venice with Vienna by way of Udine, Pontebba, and Klagenfurt, and that through the Arlberg tunnel (opened in 1884) connecting Zürich and the Rhine valley above the Lake of Constance with the valley of the Inn; lines connecting Breslau directly with Bohemia; the lines connecting Constantinople (since August 1888) and Salonica with Belgrade,

[1] Derived from the *Statesman's Year-Book*, 1900. Where the number of and attendance at infant schools are recorded, these particulars are included; but for the reasons stated in the ninth edition, it is impossible to draw up a table in which all the entries are strictly comparable with one another. For the most part returns relating to private schools are not included. No particulars under the head of this table are obtainable for the entire German Empire.
[2] Schools inspected and number of pupils on the register.
[3] Private infant and primary schools included.
[4] Number of urban schools as in 1891; of pupils as in 1895–96; particulars for rural schools as in 1896–97.
[5] Whole empire.

and thus with the general European system; that bringing Bucarest into connexion with the Black Sea port of Kustenji by means of a bridge across the Danube at Chernavoda (opened in Sept. 1895); a line across the Carpathians connecting Debrecsen with Lemberg, the continuation of the line eastwards from Lemberg to Kiev; a network bringing the coal-field of the Donets basin into connexion with ports on the Sea of Azov; a line in the south-east of Russia connecting Novocherkassk with Vladikavkaz, and branches running from the same point connecting that line with Novorossyisk on the Black Sea on the one hand, and with Tsaritsyn at the last angle of the Volga on the other hand; a line in Northern Russia bringing Archangel into connexion with the European system at Vologda (opened in 1898); a detached line in the north-east across the Urals from Perm by Ekaterinburg (completed in 1878) to Tyumeñ (completed in 1884); and a line in the east connecting the European system at Samara with the great mining centre of Zlatoust, already in 1890 continued across the Urals to Miyas, and since then carried farther east as the great Siberian Railway. All the railways in Greece have been opened since 1878; and since that date Madrid has first been brought into fairly direct connexion with Lisbon and with Oporto. The growth of telegraphic communication is shown on the table on p. 318.

In recent years two European canals of international interest have been excavated: the canal through the Isthmus of Corinth, opened in 1893 (August 6), and the Kaiser Wilhelm Canal between the Elbe and the Baltic Sea, opened in 1895 (June 20).

The table on p. 318 shows the condition of elementary education for the years named, and the following table that of religions:—

Religions.[1]

(G. G. C.)

II. HISTORY, 1870–1900.

By the Franco-German War of 1870–71 and the creation of the German Empire the political condition of Europe was profoundly changed. Germany became for a time the leading Power on the Continent, and German statesmanship had to devise means for preventing, until the new edifice was thoroughly consolidated, the formation of a hostile coalition of jealous rivals. The first thing to be done in this direction was to secure the support of Russia and Austria to the new order of things.

Russian policy towards Germany.

With regard to Russia there was little cause for apprehension. She had aided Bismarck to carry out his audacious schemes in the past, and there was no reason to suppose that she would change her policy in the immediate future. The *rapprochement* dated from the Polish Insurrection of 1863, when the Governments of France and England, yielding to popular excitement, made strong diplomatic representations to Russia in favour of the Poles, whereas Bismarck not only refused to join in the diplomatic campaign, but made a Convention with the Cabinet of St Petersburg by which the Russian and German military authorities on the frontiers should aid each other in suppressing the disturbances. From that time the friendship ripened steadily. The relations between the two Powers were not, it is true, always without a cloud. More than once the bold designs of Bismarck caused uneasiness and dissatisfaction in St Petersburg, especially during the Schleswig-Holstein complications of 1864 and the Austro-Prussian conflict of 1866; but the wily statesman of Berlin, partly by argument and partly by dexterously manipulating the mutual trust and affection between the two Sovereigns, always succeeded in having his own way without producing a rupture, so that during the Franco-German War Russia maintained an extremely benevolent neutrality, and prevented Austria and Italy from taking part in the struggle. So benevolent was the neutrality that the Emperor William at the end of the campaign felt constrained to write to the Tsar that he owed to His Majesty the happy issue of the war. Having thus helped to create the German Empire, Alexander II. was not likely to take an active part in destroying it, and Bismarck could look forward confidently to a long continuance of the cordial relations between the two Courts.

The second part of the German Chancellor's programme, the permanent conciliation of Austria, was not so easily carried out. Austria had been the great sufferer, more perhaps even than France, from Bismarck's aggressive policy. For generations she had resisted strenuously and successfully the efforts of the Hohenzollerns to play the leading part in Germany, and she had always considered her own influence in Germany as essential to the maintenance of her position as a first-class Power. By the disastrous campaign of 1866 and the consequent Treaty of Prague, Austria had been formally excluded from all direct influence in German affairs. With these events still fresh in his recollection, the Emperor Francis Joseph could hardly be expected to support the new Empire created by his rival at Austria's expense, and it was known that on the eve of the Franco-German War he had been negotiating with the French Government for a combined attack on Prussia. To an ordinary statesman the task of permanently conciliating such a Power might well have seemed hopeless, but Bismarck did not shrink from it, and even before the signature of the Treaty of Prague he had prepared the way for attaining his object. "With regard to Austria," he himself explained on one occasion, "I had two courses open to me after her defeat, either to destroy her entirely or to respect her integrity and prepare for our future reconciliation when the fire of revenge had died out. I chose the latter course, because the former would have been the greatest possible act of folly. Supposing that Austria had disappeared, consider the consequences." He then described very graphically those probable consequences, and drew the conclusion: "for the sake of our own life Austria must live. I had no hesitation, therefore, and ever since 1866 my constant effort has been to stitch up the great torn texture and to re-establish amicable relations with our ancient associate of the Confederation." For this purpose he tried to soothe Austrian susceptibilities, and suggested confidentially that compensation for the losses of territory, influence, and prestige in Italy and Germany might be found in South-Eastern Europe, especially by the acquisition of Bosnia and Herzegovina; but so long as his rival Count Beust was Minister for Foreign Affairs in Vienna, and Austria had the prospect of being able to recover her lost position by the assistance of Russia and France, these efforts had no success. It was only when Prince Gortchakoff had declined Count Beust's advances, which took the form of suggesting the abolition of the Black Sea clauses of the Treaty of Paris, and when France had been paralysed for some years by her war with Germany, that a *rapprochement* between the Cabinets of Vienna and Berlin became possible. Bismarck lost no time in making advances. From the German headquarters at Versailles he sent a despatch to Vienna suggesting the establishing of more cordial relations between the two countries, and Count Beust replied in an equally amicable tone. The Emperor Francis Joseph, finding himself isolated, had evidently accepted the inevitable with his customary resignation, and abandoned his dreams of again playing the leading part in Germany. As a further proof of the change in his disposition and aims he replaced Count Beust by Count Andrassy, who was a personal friend of Bismarck, and who wished, as a Hungarian, to see Austria liberated from her German entanglement, and he consented to pay a visit to Berlin for the purpose of drawing still closer the relations between the two Governments.

Austrian relations with Germany.

Bismarck was delighted at this turn of affairs, but he advanced with his usual caution. He gave it to be clearly understood that improvement in his relations with Vienna must not disturb the long-established friendship with St Petersburg. The Tsar, on hearing privately of the intended meeting, gave a hint to Prince Reuss, the German ambassador, that he expected an invitation, and was invited accordingly. The meeting of the three Sovereigns took place at Berlin at the end of August 1872. The three Ministers, Prince Bismarck, Prince Gortchakoff, and Count Andrassy, held daily conferences, on the basis that the chief aim in view should be the maintenance of peace in Europe, and that in all important international affairs the three Powers should consult with each other and act in concert. As a result of three days' consultation the Three Emperors' League was founded, without any formal treaty being signed. In this way the danger of a powerful coalition being formed against the young German Empire was averted, for in the event of a conflict with France, Germany could count on at least the benevolent neutrality of Russia and Austria, and from the other Powers she had nothing to fear. What ulterior designs Bismarck may have had in forming the League, or Alliance as it is often called, must be to some extent a matter of conjecture, but we shall probably not be far wrong in adopting the view of a competent Russian authority, who defines the policy of the German Chancellor thus: "To make Austria accept definitively her deposition as a Germanic Power, to put her in perpetual conflict with Russia in the Balkan Peninsula, and to found on that irreconcilable rivalry the hegemony of Germany."

The Dreikaiserbund.

For more than two years there was an outward appearance of extreme cordiality between the three Powers. They acted together diplomatically, and on all suitable occasions the three allied monarchs exchanged visits and sent each other congratulations and good wishes. There was, however, from the beginning very little genuine confidence between them. Before the breaking up of the Conferences at Berlin, Alexander II. and his Chancellor had conversations with the French Ambassador, in which they not only showed that they had suspicions of future aggressive designs on the part of Germany, but also gave an assurance that so long as France fulfilled her engagements to Germany she had nothing to fear. A few months later, when the Emperor William paid his return visit to the Tsar in St Petersburg, a defensive convention was concluded by the two monarchs behind the back of their Austrian ally. Without knowing anything about the existence of this convention, the Austrian ally did not feel comfortable in his new position. In Vienna the old anti-Prussian feeling was still strong. The so-called party of the Archdukes and the military resisted the policy of Andrassy, and sought to establish closer relations with Russia, so that German support might be unnecessary, but as Bismarck has himself testified, "Russia did not yet respond. The wound caused by the conduct of Austria during the Crimean War was not yet healed. Andrassy made himself very popular in the Court Society of St Petersburg during his visit there with his Imperial Master, but the traditional suspicion of Austrian policy remained." Altogether, the new League was not a happy family. So long as all the members of it were content to accept the *status quo*, the latent germs of dissension remained hidden from the outside world, but as soon as the temporary state of political quietude was replaced by a certain amount of activity and initiative, they forced their way to the surface. No one of the three Powers regarded the *status quo* as a satisfactory permanent arrangement. In Berlin much anxiety was caused by the rapid financial and military recovery of France, and voices were heard suggesting that a new campaign and a bigger war indemnity might be necessary before the recuperation was complete. In St Petersburg there was a determination to take advantage of any good opportunity for recovering the portion of Bessarabia ceded by the Treaty of Paris, and thereby removing the last tangible results of the Crimean War. In Vienna there was a desire to obtain in the Balkan Peninsula, in accordance with the suggestion of Bismarck, compensation for the losses in Italy and Germany. Thus each of the members of the League was hatching secretly a little aggressive scheme for its own benefit, and the danger for the rest of Europe lay in the possibility of their reconciling their schemes so far as to admit of an agreement for action in common. Fortunately for the onlookers there were important conflicting interests, and the task of reconciling them was extremely difficult, as the subsequent course of events proved.

The first of the three Powers to move was Germany. In February 1875 M. de Radowitz was despatched to St Petersburg on a secret mission in order to discover whether, in the event of hostilities between Germany and France, Russia would undertake to maintain a neutral attitude, as she had done in 1870–71; in that case Germany might be relied on to co-operate with her in her great designs in the East. Prince Gortchakoff did not take the bait with the alacrity that was expected. Having overcome in some measure his hatred of Austria, which had distorted for so many years his political vision, he had come to understand that it was not for the interests of his own country to have as neighbour a powerful united Germany instead of a weak confederation of small states, and he now perceived that it would be a grave error of policy to allow Germany to destroy still more to her own advantage the balance of power in Europe by permanently weakening France. No doubt he desired to recover the lost portion of Bessarabia and to raise Russian prestige in the East, but he did not wish to run the risk of exciting a great European war, and he believed that what he desired might be effected without war by the diplomatic skill which had warded off European intervention during the Polish troubles of 1863, and had recovered for Russia her freedom of action in the Black Sea during the Franco-Prussian War of 1870–71. In reply, therefore, to M. de Radowitz's inquiries and suggestions, he declared that the Russian Court fostered no ambitious designs in the East or in the West, and desired only peace and the maintenance of the *status quo*, with possibly an amelioration in the miserable condition of the Christian subjects of the Sultan. This rebuff did not suffice to dispel the gathering storm. The warlike agitation in the German inspired press continued, and the French Government became thoroughly alarmed. General Leflô, the French Ambassador in St Petersburg, was instructed to sound the Russian Government on the subject. Prince Gortchakoff willingly assured him that Russia would do all in her power to incline the Berlin Cabinet to moderation and peace, and that the Emperor would take advantage of his forthcoming visit to Berlin to influence the Emperor William in this sense. A few days later General Leflô received similar assurances from the Emperor himself, and about the same time the British Government volunteered to work likewise in the cause of peace. Representations were accordingly made by both Governments during the Tsar's visit to Berlin, and both the Emperor William and his Chancellor declared that there was no intention of attacking France. The danger of war, which the well-informed German press believed to be "in sight," was thus averted, but the incident sowed the seeds of future troubles, by awakening in Bismarck a bitter personal resentment against his Russian colleague. By certain incautious remarks to those around him, and still more by a circular to the representatives of Russia abroad, dated Berlin and beginning with the words *maintenant la paix est assurée*, Gortchakoff seemed to take to himself the credit of having checkmated Bismarck and saved Europe from a great war. Bismarck resented bitterly this conduct on the part of his old friend, and told him frankly that he would have reason to regret it. In the Russian official world it is generally believed that he took his revenge in the Russo-Turkish War and the Congress of Berlin. However this may be, he has himself explained that "the first cause of coldness" was the above incident, "when Gortchakoff, aided by Decazes, wanted to play at my expense the part of a saviour of France, to represent me as the enemy of European peace, and to procure for himself a triumphant *quos ego* to arrest by a word and shatter my dark designs!" In any case the incident marks the beginning of a new phase in the relations of the three Powers: henceforth Bismarck can no longer count on the unqualified support of Russia, and in controlling the Russo-Austrian rivalry in South-Eastern Europe, while professing to be impartial, he will lean to the side of Count Andrassy rather than to that of Prince Gortchakoff. He is careful, however, not to carry this tendency so far as to produce a *rapprochement* between Russsia and France. The danger of a Franco-Russian alliance hostile to Germany is already appearing on the political horizon, but it is only a little cloud no bigger than a man's hand.

The Storm-cloud of 1875.

Russia and Germany divided.

The next move in the aggressive game was made by Austria, with the connivance of Russia. During the summer of 1875 an insurrection of the Christian Slavs in Herzegovina, which received support from the neighbouring Principalities of Montenegro and Servia, was fostered by the Austrian authorities and encouraged by the Russian consuls on the Adriatic coast. A European Concert was formed for the purpose of settling the disturbance by means of local administrative reforms, but the efforts of the Powers failed, because the insurgents hoped to obtain complete liberation from Turkish rule; and in the beginning of July, with a view to promoting this solution, Servia and Montenegro declared war against the Porte. Thereupon Russia began to show her hand more openly. The Government allowed volunteers to be recruited in Moscow and St Petersburg, and the Russian General Tchernayef, who had distinguished himself in Central Asia, was appointed to the command of the Servian army. When the ball had thus been set rolling, the two Powers chiefly concerned considered that the time had come for embodying the result of their informal confidential pourparlers in a secret agreement, which is known as the agreement of Reichstadt, because it was concluded by the two Emperors in the little Bohemian town of that name. It bore the date of July 8, 1876,—exactly a week after Servia and Montenegro had declared war,—and it contained the following stipulations:—(1) That so long as the struggle which had just begun remained undecided, the two Sovereigns should refrain from interference, and that in the event of the Principalities being defeated, any modification of the territorial or political *status quo ante* to their detriment should be prevented; (2) That in the event of the Principalities proving victorious, and territorial changes taking place, Austria would claim compensation in Bosnia and Herzegovina, and Russia would demand the restitution of the portion of Bessarabia which she had lost by the Crimean War; (3) That in the event of the collapse of the Ottoman Empire, the two Powers should act together to create autonomous principalities in European Turkey, to unite Thessaly and Crete to Greece, and to proclaim Constantinople a free town. The contracting parties evidently expected that the two Principalities would be victorious in their struggle with the Porte, and that the compensations mentioned would be secured without a great European war. Their expectations were disappointed. Montenegro made a brave stand against superior forces, but before five months had passed Servia was at the mercy of the Turkish army, and Russia had to come to the assistance of her protégé. A Russian ultimatum stopped the advance of the Turks on Belgrade, and an armistice, subsequently transformed into a peace, was signed.

Austro-Russian agreement, 1876.

Russia and Austria had now to choose between abandoning their schemes and adopting some other course of action, and unforeseen incidents contributed towards making them select the latter alternative. In June an attempt at insurrection in Bulgaria had been repressed with savage brutality by the Turks, and the details, as they became known some weeks later, produced much indignation all over Europe. In England the excitement, fanned by the eloquence of Mr Gladstone, became intense, and compelled the Disraeli Cabinet to take part, very reluctantly, in a diplomatic campaign, with the object of imposing radical reforms on Turkey. In Russia the excitement and indignation were equally great, and the Tsar gradually formed the resolution that if the Powers would not act collectively and energetically, so as to compel the Porte to yield, he would undertake the work single-handed. This resolution he announced publicly in a speech delivered at Moscow on November 10. The Powers did not like the idea of separate Russian action, and in order to prevent it they agreed to hold a Conference in Constantinople for the purpose of inducing the Porte to introduce the requisite reforms. The Porte was at that moment under the influence of popular patriotic excitement which made it indisposed to accept orders, or even well-meant advice, from Governments more or less hostile to it, and the inconsiderate mode of procedure suggested by General Ignatief, and adopted by the other delegates, made it still more unconciliatory. At the first plenary sitting of the Conference the proceedings were disturbed by the sound of artillery, and the Turkish representative explained that the salvo was in honour of the new Ottoman Constitution, which was being promulgated by the Sultan. The inference suggested was that as soon as Turkey had spontaneously entered on the path of liberal and constitutional reform for all Ottoman subjects, it became superfluous and absurd to talk of small reforms for particular provinces, such as the Conference was about to propose. The deliberations continued, but finally the Porte refused to accept what the plenipotentiaries considered an irreducible minimum, and the Conference broke up without obtaining any practical result. The Tsar's Moscow declaration about employing single-handed the requisite coercive measures now came to be fulfilled.

Bulgarian Question.

In order to make a successful aggressive move on Turkey, Russia had first of all to secure her rear and flank by an arrangement with her two allies. In Berlin she encountered no difficulties. Bismarck had no objection to seeing Russia weaken herself in a struggle with Turkey, provided she did not upset the balance of Power in South-Eastern Europe, and he felt confident that he could prevent by diplomatic means any such catastrophe. He was inclined, therefore, to encourage rather than restrain the bellicose tendencies of St Petersburg. In Vienna the task of coming to a definite arrangement was much more difficult, and it was only after protracted and laborious negotiations that a Convention was concluded on January 15, 1877, and formally signed three months later. It was a development of the agreement of Reichstadt, modified according to the changes in the situation, but retaining the essential principle that in the event of the territorial *status quo* being altered, Russia should recover the lost portion of Bessarabia, and Austria should get Bosnia and a part of Herzegovina. Having made these preliminary arrangements, Russia began the campaign simultaneously in Europe and Asia Minor, and after many reverses and enormous sacrifices of blood and treasure, she succeeded in imposing on the Turks the "preliminary peace" of San Stefano. That peace was negotiated with very little consideration for the interests of the other Powers, and as soon as the terms of it became known in Vienna and London, there was an outburst of indignation. In negotiating the treaty General Ignatief had ignored the wishes of Austria, and had even, according to the contention of Andrassy, infringed the Convention signed at the beginning of the war. However this may be, the Peace of San Stefano brought to the surface the latent conflict of interests between the two Empires. Russia's aim was to create a big Bulgaria under the influence of St Petersburg, and to emancipate Servia and Montenegro as far as possible from Austrian influence, whereas Austria objected to the creation of any large Slav State in the Balkan Peninsula, and insisted on maintaining her influence in Servia and Montenegro. In vain Prince Gortchakoff endeavoured to conciliate Austria and to extract from Count Andrassy a clear statement of the terms he would accept. Count Andrassy was in no hurry to extricate Russia from her difficulties, and suggested that the whole question should be submitted to a European Congress. The suggestion was endorsed by Great Britain, which likewise objected to the San Stefano arrangements, and Bismarck declined to bring any pressure to bear on the Cabinet of Vienna.

San Stefano.

Deceived in her expectations of active support from her two allies, Russia found herself in an awkward position. From a military point of view it was absolutely necessary for her to come to an arrangement either with Austria or with England, because the communications of her army before Constantinople with its base could be cut by these two Powers acting in concert — the land route being dominated by Austria, and the Black Sea route by the British fleet, which was at that time anchored in the Sea of Marmora. As soon, therefore, as the efforts to obtain the support of her two allies against the demands of England had failed, negotiations were opened in London, and on May 30 a Secret Convention was signed by Lord Salisbury and Count Schuwaloff. By that agreement the obstacles to the assembling of the Congress were removed. The Congress met in Berlin on 13th June, and after many prolonged sittings and much secret negotiations, the Treaty of Berlin was signed on 13th July. By that treaty the Preliminary Peace of San Stefano was considerably modified. The big Bulgaria defined by General Ignatief was divided into three portions, the part between the Danube and the Balkans being transformed into a vassal Principality, the part between the Balkans and the Rhodope being made into an autonomous province, with a Christian governor named by the Sultan, with the assent of the Powers, and the remainder being placed again under the direct rule of the Porte. The independence of Montenegro, Servia, and Rumania was formally recognized, and each of these Principalities received a considerable accession of territory. Rumania, however, in return for the Dobrudja, which it professed not to desire, was obliged to give back to Russia the portion of Bessarabia ceded after the Crimean War. In Asia Minor Russia agreed to confine her annexations to the districts of Kars, Ardahan, and Batum, and to restore to Turkey the remainder of the occupied territory. As a set-off against the large acquisitions of the Slav races, the Powers recommended that the Sultan should cede to the kingdom of Greece the greater part of Thessaly and Epirus, under the form of a rectification of frontiers. At first the Sultan refused to act on this recommendation, but in March 1881 a compromise was effected by which Greece obtained Thessaly without Epirus. Bosnia and Herzegovina were to be occupied and administered by Austria-Hungary, and the Austrian authorities were to have the right of making

Berlin Congress.

roads and keeping garrisons in the district of Novi-Bazar, which lies between Servia and Montenegro. In all the provinces of European Turkey for which special arrangements were not made in the Treaty, the Porte undertook (Art. 23) to introduce organic statutes similar to that of Crete, adapted to the local conditions. This article, like many of the subordinate stipulations of the Treaty, has remained a dead letter. We may mention specially Art. 61, in which the Sublime Porte undertook to realize without delay the ameliorations and reforms required in the provinces inhabited by Armenians, and to guarantee their safety against the Circassians and Kurds. Equally unreliable proved the scheme of Lord Beaconsfield to secure good administration throughout the whole of Asia Minor by the introduction of reforms under British control, and to prevent the further expansion of Russia in that direction by a defensive alliance with the Porte. A Convention to that effect was duly signed at Constantinople a few days before the meeting of the Congress (4th June 1878), but the only part of it which was actually realized was the occupation and administration of Cyprus by the British Government. The new frontiers stipulated in the Treaty of San Stefano, and subsequently rectified by the Treaty of Berlin, are shown in the accompanying sketch-map.

Cyprus Convention.

B. V. Darbishire & O. J. R. Howarth. English Miles 0 50 100 200 Oxford, 1901.

The secret schemes of Russia and Austria, in so far as they were defined in the agreement of Reichstadt and the subsequent Austro-Russian Treaty of Vienna, had thus been realized. Russia had recovered the lost portion of Bessarabia, and Austria had practically annexed Bosnia and Herzegovina, though the nominal suzerainty of the Sultan over the two provinces was maintained. But Russia was far from satisfied with the results, which seemed to her not at all commensurate with the sacrifices imposed on her by the war, and her dissatisfaction led to a new grouping of the Powers. Before the opening of the Congress Bismarck had announced publicly that he would refrain from taking sides with any of the contending parties, and would confine himself to playing the part of an honest broker. The announcement was received by the Russians with astonishment and indignation. What they expected was not an impartial arbiter, but a cordial and useful friend in need. In 1871 the Emperor William, as we have seen, had spontaneously declared to the Tsar that Germany owed to His Majesty the happy issue of the war, and that she would never forget it, and we may add that on that occasion he signed himself "Your ever grateful Friend." Now, in 1878, when the moment had come for paying at least an instalment of this debt, and when Russia was being compelled to make concessions which she described as incompatible with her dignity, Bismarck had nothing better to offer than honest brokerage. The indignation in all classes was intense, and the views commonly held regarding Bismarck's "duplicity" and "treachery" were supposed to receive ample confirmation during the sittings of the Congress and the following six months. On February 4, 1879, Prince Gortchakoff wrote to the Ambassador in Vienna: "Needless to say, that in our eyes the Three Emperors' Alliance is practically torn in pieces by the conduct of our two allies. At present it remains for us merely to terminate the liquidation of the past, and to seek henceforth our support in ourselves alone." The same view of the situation was taken in Berlin and Vienna, though the result was attributed, of course, to different causes, and the danger of serious complications became so great that Bismarck concluded with Andrassy in the following October a formal defensive alliance, which was avowedly directed against Russia, and which subsequently developed into the Triple Alliance, directed against Russia and France.

Russian resentment against Bismarck.

The causes of the rupture are variously described by the different parties interested. According to Bismarck the Russian Government began a venomous campaign against Germany in the press, and collected, with apparently hostile intentions, enormous masses of troops near the German and Austrian frontiers, whilst the Tsar adopted in his correspondence with the Emperor William an arrogant and menacing tone which could not be tolerated. On the other hand, the Russians declare that the so-called Press-Campaign was merely the spontaneous public expression of the prevailing disappointment among all classes in Russia, that the military preparations had a purely defensive character, and that the Tsar's remarks, which roused Bismarck's ire, did not transgress the limits of friendly expostulation such as Sovereigns in close friendly relations might naturally employ. Subsequent revelations tend rather to confirm the Russian view. After an exhausting war and without a single powerful ally, Russia was not likely to provoke wantonly a great war with Germany and Austria. The press attacks were not more violent than those which frequently appear in newspapers which draw their inspiration from the German Foreign Office, and the accusations about the arrogant attitude and menacing tone of Alexander II. are not at all in harmony with his known character, and are refuted by the documents since published by Dr Busch. The truth seems to be that the self-willed Chancellor was actuated by nervous irritation and personal feeling more than by considerations of statecraft. His Imperial master was not convinced by his arguments, and showed great reluctance to permit the conclusion of a separate treaty with Austria. Finally, with much searching of heart, he yielded to the importunity of his Minister; but in thus committing an unfriendly act towards his old ally, he so softened the blow that the personal good relations between the two Sovereigns suffered merely a momentary interruption. Bismarck himself soon recognized that the permanent estrangement of Russia would be a grave mistake of policy, and the very next year (1880), negotiations for a treaty of defensive alliance between the two Cabinets were begun. Nor did the accession to the throne of Russia of Alexander III., who had long enjoyed the reputation of being systematically hostile to Germans, produce a rupture, as was expected. Six months after his father's death, the young Tsar met the old Kaiser at Danzig (Sept. 1881), and some progress was made towards a complete renewal of the traditional friendship. Immediately afterwards a further step was taken towards re-establishing the old state of things with regard also to Austria. On his return to St Petersburg, Alexander III. remembered that he had received some time previously a telegram of congratulation from the Emperor Francis Joseph, and he now replied to it very cordially, referring to the meeting at Danzig, and describing the Emperor William as "that venerable friend with whom we are united in the common bonds of a profound affection." The words foreshadowed a revival of the Three Emperors' League, which actually took place three years later.

Growth of the Triple Alliance.

The removal of all immediate danger of a Franco-Russian alliance did not prevent Bismarck from strengthening in other ways the diplomatic position of Germany, and the result of his efforts soon became apparent in the alliance of Italy with the two Central Powers. Ever since the Franco-German War of 1870–71, and more especially since the Congress of Berlin in 1878, the Italian Government had shown itself restless and undecided in its foreign policy. As it was to France that Italy owed her emancipation from Austrian rule, it seemed natural that the two countries should remain allies, but anything like cordial co-operation was prevented by conflicting interests and hostile feeling. The French did not consider the acquisition of Savoy and Nice as sufficient compensation for the assistance they had given to the cause of Italian unity, and they did not know, or did not care to remember, that their own Government was greatly to blame for the passive attitude of Italy in the hour of their great national misfortunes. On the other hand, a considerable amount of bitterness against France had been gradually accumulating in the hearts of the Italians. As far back as the end of the war of 1859, popular opinion had been freely expressed against Napoleon III., because he had failed to keep his promise of liberating Italy "from the Alps to the Adriatic." The feeling was revived and intensified when it became known that he was opposing the annexation of Central and Southern Italy, and that he obtained Savoy and Nice as the price of partly withdrawing his opposition. Subsequently, in the war of 1866, he was supposed to have insulted Italy by making her conclude peace with Austria, on the basis of the cession of Venetia, before she could wipe out the humiliation of her defeats at Custozza and Lissa. Then came the French protection of the Pope's temporal power as a constant source of irritation, producing occasional explosions of violent hostility, as when the new Chassepôt rifles were announced to have "worked wonders" among the Garibaldians at Mentana. When the Second Empire was replaced by the Republic, the relations did not improve. French statesmen of the Thiers school had always condemned the Imperial policy of permitting and even encouraging the creation of large, powerful states on the French frontiers, and Thiers himself publicly attributed to this policy the misfortunes of his country. With regard to Italy, he said openly that he regretted what had been done, though he had no intention of undoing it. The first part of this statement was carefully noted in Italy, and the latter part was accepted with scepticism. In any case his hand might perhaps be forced, for in the first Republican Chamber the Monarchical and Clerical element was very strong, and it persistently attempted to get something done in favour of the Temporal Power. Even when the party of the Left undertook the direction of affairs in 1876, the Government did not become anti-Clerical in its foreign policy, and Italian statesmen resigned themselves to a position of political isolation. The position had its advantages. Events in the Balkan Peninsula foreshadowed a great European war, and it seemed that in the event of Europe's being divided into two hostile camps, Italy might have the honour and the advantage of regulating the balance of power. By maintaining good relations with all her neighbours and carefully avoiding all inconvenient entanglements, she might come forward at the critical moment and dictate her own terms to either of the contending parties, or offer her services to the highest bidder. This Machiavellian policy did not give the expected results. Being friends with everybody in a general way may be the best course for an old, conservative country which desires merely the maintenance of the *status quo*, but it does not secure the energetic diplomatic support required by a young enterprising state which wishes to increase its territory and influence. At the Congress of Berlin, when several of the Powers got territorial acquisitions, Italy got nothing. The Italians, who were in the habit of assuming, almost as a matter of principle, that from all European complications they had a right to obtain some tangible advantage, were naturally disappointed, and they attributed their misfortune to their political isolation. The policy of the free hand consequently fell into disrepute, and the desire for a close, efficient alliance revived. But with what Power or Powers should an alliance be made? The remnants of the old party of action, who still carried the *Italia Irredente* banner, had an answer ready. They recommended that alliances should be concluded with a view to wresting from Austria the Trentino and Trieste, with Dalmatia, perhaps, into the bargain. On the other hand, the Conservatives and the Moderates considered that the question of the Trentino and Trieste was much less important than that of political influence in the Mediterranean. A strong Austria was required, it was said, to bar the way of Russia to the Adriatic, and France must not be allowed to pursue unchecked her policy of transforming the Mediterranean into a French lake. Considerations of this kind led naturally to the conclusion that Italy should draw closer to the Powers of Central Europe. So the question appeared from the standpoint of "la haute politique." From the less elevated standpoint of immediate political interests, it presented conflicting considerations. A *rapprochement* with the Central Powers might prevent the conclusion of a commercial treaty with France, and thereby increase the financial and economic difficulties with which the young kingdom was struggling, whereas a *rapprochement* with France would certainly excite the hostility of Bismarck, who was retiring from the *Culturkampf* and journeying towards Canossa, and who might possibly conciliate the Pope by helping him to recover his temporal sovereignty at the expense of Italy. Altogether the problem was a very complicated one. The conflicting currents so nearly balanced each other, that the question as to which way the ship would drift might be decided by a little squall of popular sentiment. A very big squall was brewing.

France and Tunis.

During the Congress of Berlin, the French Government was very indignant when it discovered that Lord Beaconsfield had recently made a secret convention with the Sultan for the British occupation of Cyprus, and in order to calm its resentment Lord Salisbury gave M. Waddington to understand that, so far as England was concerned, France would be allowed a free hand in the Regency of Tunis, which she had long coveted. Though the conversations on the subject and a subsequent exchange of notes were kept strictly secret, the Italian Government soon got wind of the affair, and it was at first much alarmed. It considered, in common with Italians generally, that Tunis, on the ground of historic right and of national interests, should be reserved for Italy, and that an extension of French territory in that direction would destroy, to the detriment of Italy, the balance of power in the Mediterranean. These apprehensions were calmed for a time by assurances given to the Italian Ambassador in Paris. M. Gambetta assured General Cialdini that he had no intention of making Italy an irreconcilable enemy of France, and M. Waddington declared, on his word of honour, that so long as he remained Minister of Foreign Affairs nothing of the sort would be done by France without a previous understanding with the Cabinet of Rome. M. Waddington honourably kept his word, but his successor did not consider himself bound by the assurance; and when it was found that the Italians were trying systematically to establish their influence in the Regency at the expense of France, the French authorities, on the ground that a Tunisian tribe called the Kroumirs had committed depredations in Algeria, sent an armed force into the Regency, and imposed on the Bey the Bardo treaty, which transformed Tunis into a French Protectorate.

The establishment of a French Protectorate over a country which the Italians had marked out for themselves as necessary for the defence and colonial expansion of the kingdom had the effect which Gambetta had foreseen—it made Italy, for a time at least, the irreconcilable enemy of France. Whilst the French were giving free expression to their patriotic exultation, and even Gambetta himself, in defiance of what he had said to Cialdini, was congratulating Jules Ferry on having restored France to her place among the nations, the Italians were trying to smother their indignation and to discover some means of retrieving what they had lost. The only remedy seemed to be to secure foreign alliances, and there was now no hesitation as to where they should be sought. Simple people in Italy imagined that if an alliance had been concluded sooner with Germany and Austria, these Powers would have prevented France from trampling on the sacred interests of Italy. This idea was entirely erroneous, because Austria had little or no interest in the Tunisian Question, and Bismarck was not at all sorry to see France embark on an enterprise which distracted her attention from Alsace-Lorraine and removed all danger of a Franco-Italian alliance. The illusion, however, had a powerful influence on Italian public opinion. The Government was now urged to conclude without further delay an alliance with the Central Powers, and the recommendation was not unwelcome to the King, because most of the Italian Gallophils had anti-dynastic and Republican tendencies, and he was naturally disposed to draw nearer to Governments which proclaimed themselves the defenders of Monarchical institutions and the opponents of revolutionary agitation. After protracted negotiations, in which Italy tried in vain to secure protection for her own separate interests in the Mediterranean, defensive treaties of alliance were concluded with the Cabinets of Vienna and Berlin in May 1882.

Triple Alliance signed 1882.

Though the Italian statesmen did not secure by these treaties all they wanted, they felt that the kingdom was protected against any aggressive designs which might be entertained by France or the Vatican, and when the treaties were renewed in 1887, they succeeded in getting somewhat more favourable conditions.

By the creation of this Triple Alliance, which still subsists, the diplomatic position of Germany was greatly strengthened, but Bismarck was still haunted by the apprehension of a Franco-Russian alliance, and he made repeated attempts to renew the old cordial relations with the Court of St Petersburg. He was bold enough to hope that, notwithstanding the Austro-German treaty of October 1879, avowedly directed against Russia, and the New Triple Alliance, by which the Austro-German Alliance was strengthened, he might resuscitate the Three Emperors' League in such a form as to ensure, even more effectually than he had done on the former occasion, the preponderance of Germany in the arrangement. With this object he threw out a hint to the Russian Ambassador, M. Sabourof, in the summer of 1883, that the evil results of the Congress of Berlin might be counteracted by a formal agreement between the three Emperors. The suggestion was transmitted privately by M. Sabourof to the Tsar, and was favourably received. Alexander III. was disquieted by the continuance of the Nihilist agitation, and was not averse to drawing closer to the Conservative Powers; and as he desired tranquillity for some time in the Balkan Peninsula, he was glad to have security that his rival would do nothing in that part of the world without a previous understanding. M. de Giers, who had now succeeded Prince Gortchakoff in the direction of Foreign Affairs, was accordingly despatched to Friedrichsruh to discuss the subject with Bismarck. The practical result of the meeting was that negotiations between the two Governments were begun, and on March 21, 1884, a formal document was signed in Berlin. About six months later, in the month of September, the three Emperors met at Skiernevice and ratified the agreement. Thus, without any modification of the Triple Alliance, which was directed against Russia, the old Three Emperors' League, which included Russia, was revived.

Dreikaiserbund revived 1884.

Germany and Austria, being members of both, were doubly protected, for in the event of being attacked they could count on at least the benevolent neutrality of both Russia and Italy. France was thereby completely isolated.

In drawing up the secret treaty of Skiernevice, which may be regarded as the *chef d'œuvre* of Bismarckian diplomacy, the German Chancellor's chief aims evidently were to paralyse Russia by yoking her to Germany and Austria, to isolate France, and to realize his old scheme of holding the balance between Russia and Austria in the Balkan Peninsula. With a view to attaining the first two objects it was stipulated that if any one of the three Powers were forced to make war on a fourth Power, the two other contracting parties should observe a benevolent neutrality towards their ally. If we may believe a well-informed Russian authority, Bismarck wished it to be understood that in the event of *two* of the Powers being at war with a fourth, the stipulation about benevolent neutrality should still hold good, but Alexander III. objected, on the ground that he could not remain a passive spectator of a duel in which France would be confronted by two antagonists. In his third object Bismarck was successful, for it was expressly laid down that in all cases of a disagreement between two of the parties in the affairs of the Balkan Peninsula, the third Power should decide between them. This meant, of course, that in all discussions between Russia and Austria, the two great rivals in the Eastern Question, Bismarck should always have a casting vote. In return for all this, Russia obtained two small concessions: firstly, that Germany and Austria should seek to restrain the Sultan from permitting the passage of the Dardanelles to an English fleet, as he had done in 1878, when the Russian army was before Constantinople; and, secondly, that they should not oppose the union of Bulgaria and Eastern Rumelia, if it was accomplished by the force of things and within the limits traced by the Congress of Berlin.

This new form of the Three Emperors' League had all the organic defects of its predecessor, and was destined to be still more shortlived. The claims of Russia and Austria might be reconcilable in theory, but in practice they were sure to conflict; and however much Bismarck might try to play the part of an honest broker, he was certain to be suspected of opposing Russia and favouring Austria. It was, therefore, only during a period of political stagnation in South-Eastern Europe that the arrangement could work smoothly. The political stagnation did not last long. Prince Alexander of Bulgaria had for some time been fretting under the high-handed interference of the Russian agents in the Principality, and had begun to oppose systematically what the Russians considered their legitimate influence. Relations between Sofia and St Petersburg had consequently become strained, when a crisis was suddenly brought about by the revolution of Philippopolis in September 1885. The conspirators arrested and expelled the Governor-General, who had been appointed by the Sultan with the assent of the Powers, and at the same time proclaimed the union of the autonomous province of Eastern Rumelia with the Principality of Bulgaria, in defiance of the stipulations of the Treaty of Berlin. The revolution had been effected with the connivance and approval of the regularly accredited Russian agents in Philippopolis, but it had not received the sanction of the Russian Government, and was resented as a new act of insubordination on the part of Prince Alexander. When he arrived in Philippopolis and accepted the declaration of union, the Cabinet of St Petersburg protested against any such infraction of the Berlin Treaty, and the Porte prepared to send an army into the province. It was restrained from taking this step by the Ambassadors in Constantinople, so that an armed conflict between Turks and Bulgarians was prevented; but no sooner had the Bulgarians been relieved from this danger on their eastern frontier than they were attacked from the west by the Servians, who were determined to get ample compensation for any advantage which the Bulgarians might obtain. The Bulgarian army defeated the Servians at Slivnitza (Nov. 19–20, 1885), and was marching on Belgrade when its advance was stopped and an armistice arranged by the energetic intervention of the Austrian Government. Following the example of the Servians, the Greeks were preparing to exact territorial compensation likewise; but as their mobilization was a slow process, the Powers had time to restrain them from entering on active hostilities, first by an ultimatum (April 26, 1886), and afterwards by a blockade of their ports (May 1886). By that time, thanks to the intervention of the Powers, a peace between Bulgaria and Servia had been signed at Bucarest (March 3); and with regard to Eastern Rumelia, a compromise had been effected by which the formal union with the Principality was rejected, and the Prince was appointed Governor-General of the province for a term of five years. This was in reality union in disguise.

Bulgarian crisis.

The diplomatic solution of the problem averted the danger of a European war, but it left a great deal of dissatisfaction, which soon produced new troubles. Not only had Prince Alexander escaped punishment for his insubordination to Russia, but he and the anti-Russian party among the Bulgarians had obtained a decided success. This could not well be tolerated. Before six months had passed (August 21, 1886), Prince Alexander was kidnapped by conspirators in his palace at Sofia and conveyed secretly to Russian Bessarabia. As soon as the incident was reported to the Tsar, the Prince was released, and he at once returned to Sofia, where a counter-revolution had been effected in his favour; but he considered his position untenable, and formally abdicated. A fortnight after his departure General Kaulbars arrived from St Petersburg with instructions from the Tsar to restore order in accordance with Russian interests. In St Petersburg it was supposed that the Bulgarian people were still devoted to Russia, and that they were ready to rise against and expel the politicians of the Nationalist party led by Stambolof. General Kaulbars accordingly made a tour in the country and delivered speeches to the assembled multitudes, but Stambolof's political organization counteracted all his efforts, and on November 20 he left Bulgaria and took the Russian consuls with him. Stambolof maintained his position, suppressed energetically several insurrectionary movements, and succeeded in getting Prince Ferdinand of Coburg elected Prince (July 7, 1887), in spite of the opposition of Russia, who put forward as candidate a Russian subject, Prince Nicholas of Mingrelia. Prince Ferdinand was not officially recognized by the Sultan and the Powers, but he continued to reign under the direction of Stambolof, and the Russian Government, passively accepting the accomplished facts, awaited patiently a more convenient moment for action.

These events in the Balkan Peninsula necessarily affected the mutual relations of the Powers composing the Three Emperors' League. Austria could not remain a passive and disinterested spectator of the action of Russia in Bulgaria. Her agents gave a certain amount of support to Prince Alexander in his efforts to emancipate himself from Russian domination; and when the Prince was kidnapped and induced to abdicate, Count Kalnoky did not conceal his intention of opposing further aggression. Bismarck resisted the pressure brought to bear on him from several quarters in favour of the anti-Russian party in Bulgaria, but he was suspected by the Russians of siding with Austria and secretly encouraging the opposition to Russian influence. This revived the hatred against him which had been created by his pro-Austrian leanings after the Russo-Turkish War. The feeling was assiduously fomented by the Russian press, especially by M. Katkoff, the editor of the *Moscow Gazette*, who exercised great influence on public opinion and had personal relations with Alexander III. On July 31, 1886, three weeks before the kidnapping of Prince Alexander, he began a regular journalistic campaign against Germany, and advocated strongly a new orientation of Russian policy. M. de Giers,

Russian hostility to Germany.

Minister of Foreign Affairs, was openly attacked as a partisan of the German alliance, and his "pilgrimages to Friedrichsruh and Berlin" were compared to the humiliating journeys of the old Russian Grand Princes to the Golden Horde in the time of the Tartar domination. The moment had come, it was said, for Russia to emancipate herself from German diplomatic thraldom, and for this purpose a *rapprochement* with France was suggested. The idea was well received by the public, and it seemed to be not unpalatable to the Tsar, for the *Moscow Gazette* was allowed to continue its attacks on M. de Giers's policy of maintaining the German alliance. In Berlin such significant facts could not fail to produce uneasiness, because one of the chief aims of Bismarck's policy had always been to prevent a Russo-French *entente cordiale.* The German press were instructed to refute the arguments of their Russian colleagues, and to prove that if Russia had really lost her influence in the Balkan Peninsula, the fact was due to the blunders of her own diplomacy. The controversy had no practical result, and caused no serious estrangement between the Cabinets of Berlin and St Petersburg. When the Treaty of Skiernevice was about to expire in 1887, the Russian Government positively declined to renew the Three Emperors' League, but the seductive eloquence of the German Chancellor induced the Tsar to make a new secret treaty of alliance with Germany for three years; and feeling his hands strengthened by this new instrument Bismarck thought he might use pressure to obtain greater advantages. An attack was made in the press and elsewhere on Russian credit, which was rapidly gaining a footing in the Paris Bourse. In the use of this kind of pressure the German Government generally remained in the background, and even expressed its regret, but on one occasion it showed its hand plainly by prohibiting the Reichsbank from accepting Russian securities as guarantees. From that moment the Tsar's attitude changed. All his dormant suspicions of German policy revived. When he passed through Berlin in November 1887, Bismarck had a long audience, in which he defended himself with his customary ability, but Alexander III. remained unmoved in his conviction that the German Government had systematically opposed Russian interests, and had paralysed Russian action in the Balkan Peninsula for the benefit of Austria; and he failed to understand the ingenious theory put forward by the German Chancellor, that two Powers might have a severe economic struggle without affecting their political relations. Bismarck had to recognize that, for the moment at least, the Three Emperors' League, which had served his purposes so well, could not be resuscitated, but he had still a certain security against the hostility of Russia in the secret Russo-German defensive treaty of 1887, which had been concluded without the knowledge of Austria. Soon, however, this link was also to be broken. When the secret treaty expired in 1890 it was not renewed. By that time Bismarck had been dismissed, and he subsequently reproached his successor, Count Caprivi, with not having renewed it, but in reality Count Caprivi was not to blame. Alexander III. was determined not to renew the alliance, and was already gravitating slowly towards an understanding with France.

Franco-Russian entente.

No treaty or formal defensive engagement of any kind existed between Russia and France, but it was already tolerably certain that in the event of a great war the two nations would be found fighting on the same side, and the military authorities in both countries felt that if no arrangements were made beforehand for concerted action,—such arrangements having been long ago completed by the Powers composing the Triple Alliance,—they would begin the campaign at a great disadvantage. This was perfectly understood by both Governments; and after some hesitation on both sides, Generals Vannotski and Obrutchef, on the one side, and Generals Saussier, Miribel, and Boisdeffre on the other, were permitted to discuss plans of co-operation. At the same time a large quantity of Lebel rifles were manufactured in France for the Russian army, and the secret of making smokeless powder was communicated to the Russian military authorities. The French Government wished to go further and conclude a defensive alliance, but the Tsar was reluctant to bind himself with a Government which had so little stability, and which might be induced to provoke a war with Germany by the prospect of Russian support. Even the military convention was not formally ratified until 1894. The enthusiastic partisans of the alliance flattered themselves that the Tsar's reluctance had been overcome, when he received very graciously Admiral Gervais and his officers during the visit of the French fleet to Cronstadt in the summer of 1891, but their joy was premature. The formal *rapprochement* between the two Governments was much slower than the unofficial *rapprochement* between the two nations. More than two years passed before the Cronstadt visit was returned by the Russian fleet, under Admiral Avelan. The enthusiastic ovations which the admiral and his subordinates received in Toulon and Paris (October 1893) showed how eager and anxious the French people were for an alliance with Russia, but the Russian Government was in no hurry to gratify their wishes. Of the official action all we know with certainty is, that immediately after the Cronstadt visit in 1891 a diplomatic protocol about a defensive alliance was signed; that during the special mission of General Boisdeffre to St Petersburg in 1892 negotiations took place about a military convention; that in 1894 the military convention was ratified; that in the summer of 1895 M. Ribot, when Prime Minister, first spoke publicly of an alliance; and that during the visit of the President of the French Republic to St Petersburg, in August 1897, France and Russia were referred to as allies in the complimentary speeches of the Tsar and of M. Felix Faure. Though we are still in the dark as to the precise terms of the arrangement, there is no doubt that close friendly relations exist between the two Powers, and that in all important international affairs they seek to act in accord with each other. It is equally certain that hitherto Russia has been the predominant partner, and that, in accordance with the pacific tendencies of the Tsar, she has systematically exercised a restraining influence on France. The great expectations excited among the French people by the *entente cordiale* have consequently not been realized, and there have already been premonitory symptoms of a reaction in public opinion. So long, however, as the Triple Alliance of Germany, Austria, and Italy exists, the Dual Alliance of Russia and France is likely to be maintained as a measure of self-defence. England has persistently refrained from joining either group, in accordance with her traditional policy of making no alliances except for specific purposes; but as her interests in the East and in the Mediterranean conflict with those of Russia and France rather than with these of Germany, Austria, and Italy, she has a tendency to lean towards the Triple, rather than towards the Dual, Alliance.

The grouping of the great Continental States into two opposite but not necessarily hostile camps has helped to preserve the balance of power and the peace of Europe. Since the two groups were formed, the causes of conflict which have arisen from time to time have been localized. Among these may be specially mentioned the Armenian Question, the Cretan Question, the partition of Africa, and the conflicts of interest in the Far East.

The Armenian Question was brought prominently before Europe by the Russo-Turkish War of 1877–78. In the Treaties of San Stefano and Berlin the Sublime Porte undertook "to carry out without delay the ameliorations and reforms required by local needs in the provinces inhabited by the Armenians, and to guarantee their security against the Circassians and the Kurds." This stipulation remained a dead letter, and the relations between the Armenians and the Mussulmans became worse than before, because the protection of the Powers encouraged in the oppressed nationality far-reaching political aspirations, and the Sultan regarded the political aspirations and the intervention of the Powers as dangerous for the integrity and independence of his Empire. For some fifteen years the Armenians continued to hope in the efficacious intervention of their protectors, but when their patience became exhausted and the question seemed in danger of being forgotten, they determined to bring it again to the front. Some of them confined themselves to agitating abroad, especially in England, in favour of the cause, whilst others made preparations for exciting an insurrectionary movement in Constantinople and Asia Minor. These latter knew very well that an insurrection could be suppressed by the Turkish Government without much difficulty, but they hoped that the savage measures of repression which the Turks were sure to employ might lead to the active intervention of Europe and ensure their liberation from Turkish rule, as the famous "atrocities" of 1876 had led to the political emancipation of Bulgaria. In due course—1895–96—the expected attrocities took place, in the form of wholesale massacres in Constantinople and various towns of Asia Minor. The Sultan was subjected to diplomatic pressure and threatened with more efficient means of coercion. In the diplomatic campaign England took the lead, and was warmly supported by Italy, but Germany, Austria, and France showed themselves lukewarm, not to say indifferent, and Russia, departing from her traditional policy of protecting the Christians of Turkey, vetoed the employment of force for extracting concessions from the Sultan. In these circumstances the Porte naturally confined itself to making a few reforms on paper, which were never carried out. Thus the last state of the Armenians was worse than the first, but the so-called European Concert was maintained, and the danger of a great European war was averted.

Armenia.

The next attempt to raise the Eastern Question was made by the Greeks. In 1896 a semi-secret society called the Ethniké Hetairia began a Panhellenic agitation, and took advantage of one of the periodical insurrections in Crete to further its projects. In February 1897 the Cretan revolutionary committee proclaimed the annexation of the island to the Hellenic Kindgom, and a contingent of Greek regular troops landed near Canea under the command of Colonel Vassos to take possession of the island in the name of King George. The Powers, objecting to this arbitrary proceeding, immediately occupied Canea with a mixed force from the ships of war which were there at the time, and summoned the Greek Government to withdraw its troops. The summons was disregarded, and the whole of the Greek army was mobilized on the frontier of Thessaly and Epirus. In consequence of a raid into Turkish territory the Porte declared war on 17th April, and the short campaign ended in the defeat of the Greeks. The Powers intervened to put an end to the hostilities, and after prolonged negotiations a peace was concluded by which Greece had to consent to a strategical rectification of frontier and to pay a war indemnity of £4,000,000. Thus a second time the European Concert acted effectually in the interests of peace, but it did not stand the strain of the subsequent efforts to solve the Cretan Question. Finding the Turks less conciliatory after their military success, and being anxious to remain in cordial relations with the Porte, Germany withdrew from further co-operation with the Powers, and Austria followed her example. They did not, however, offer any active opposition, and the question received a temporary solution by the appointment of Prince George, second son of the King of Greece, as High Commissioner and Governor-General of the island.

Crete.

During the period under review the friendly relations of the leading European Powers were frequently troubled by the conflicting desires of several of these Powers to obtain colonial possessions in various parts of the world, and to forestall their competitors in the act of taking possession. In the complications of this kind England, as the greatest of Colonial Powers, was generally involved; and as the unappropriated portions of the earth's surface at the beginning of the period in question were to be found chiefly in Africa, it was in the Dark Continent that the conflicts of interests mostly took place. England's chief competitors were France and Germany. Her traditional policy, except in the south of the continent, where the conditions of soil and climate were favourable to European colonists, has been purely commercial. She had refrained from annexation of territory, as involving too much expenditure and responsibility, and confined her protection to the trading stations on the coast. When France came into the field this policy had to be abandoned. The policy of France was also commercial in a certain sense, but the methods she adopted were very different. Feeling that she could not compete with England on equal terms, she endeavoured to bring under her authority, by annexation or the establishment of protectorates, the largest possible extent of territory, in order to increase her trade by a system of differential tariffs; and not content with holding long strips of coast, she systematically encroached on the hinterland of British settlements, and endeavoured to direct artificially the native inland trade towards her own ports. A glance at the map of the African West Coast will suffice to show the success with which this policy has been carried out. When the British Government awoke to the danger, it was too late to prevent the evil. All that could be done was to prevent further encroachments by likewise annexing territory and creating protectorates. The final result has been a series of delimitation treaties, which are dealt with in the article AFRICA, HISTORY. In her dealings with France about the partition of Africa, England was generally very conciliatory, but on one point she felt the necessity of being firm, namely, regarding the two entrances to the Mediterranean. France has long coveted the possession of Morocco, but she has powerful rivals in the field, and she is well aware that an attempt to gain possession of Tangier, or any other part of the south coast of the Straits of Gibraltar, would meet with determined opposition from England. In like manner the eastern entrance to the Mediterranean by the Suez Canal is carefully watched. When England in 1882 considered it necessary to suppress the Arabi insurrection, she invited France to co-operate, but the French Government declined, and left the work to be done by England alone. England had no intention of occupying the country permanently, but she had to take precautions against the danger of French occupation after her withdrawal, and these precautions were embodied in an Anglo-Turkish Convention signed at Constantinople in May 1887. France prevented the ratification of the Convention by the Sultan, with the result that the British occupation has been indefinitely prolonged. She still clung persistently, however, to the hope of obtaining a

Africa.

predominant position in the valley of the Nile, and she tried to effect her purpose by gaining a firm foothold on the upper course of the river. The effort which she made in 1898 to attain this end, by simultaneously despatching the Marchand Mission from her Congo possessions and inciting the Emperor Menelek of Abyssinia to send a force from the east to join hands with Major Marchand at Fashoda, was defeated by the overthrow of the Mahdi and the British occupation of Khartum. For a few days the two nations seemed on the brink of war, but the French Government, receiving no encouragement from St Petersburg, consented to withdraw the Marchand Mission, and a convention was signed defining the respective spheres of influence of the two countries.

With Germany likewise, from 1880 onwards, England had some diplomatic difficulties regarding the partition of Africa, but they never reached a very acute phase, and were ultimately settled by mutual concessions. By the arrangement of 1890, in which several of the outstanding questions were solved, Heligoland was ceded to Germany in return for concessions in East Africa. A conflict of interest in the Southern Pacific was amicably arranged by the Anglo-German Convention of April 1886, in which a line of demarcation was drawn between the respective spheres of influence in the islands to the north and east of the Australian continent, and by the Convention of 1899, in virtue of which Germany gained possession of Samoa and renounced in favour of England all pretensions to the Tonga Archipelago.

Asia.

In Asia the tendencies of the European Powers to territorial expansion, and their desire to secure new markets for their trade and industry, have affected from time to time their mutual relations. More than once England and Russia have had disputes about the limits of their respective spheres of influence in Central Asia, but the causes of friction have steadily diminished as the work of frontier delimitation has advanced. The important agreement of 1872–73 was supplemented by the Protocol of 22nd July 1887 and the Pamir delimitation of 1895, so that the Russo-Afghan frontier, which is the dividing line between the Russian and British spheres of influence, has now been carried right up to the frontier of the Chinese Empire. The delimitation of the English and French spheres of influence in Asia has also progressed. In 1885 France endeavoured to get a footing on the Upper Irrawaddy, the hinterland of British Burma, and England replied in the following year by annexing the dominions of King Thebaw, including the Shan States as far east as the Mekong. Thereupon France pushed her Indo-Chinese frontier westwards, and in 1893 made an attack on the Kingdom of Siam, which very nearly brought about a conflict with England. After prolonged negotiations an arrangement was reached and embodied in a formal treaty (Jan. 1896), which clearly foreshadows a future partition between the two Powers, but guarantees the independence of the central portion of the kingdom, the Valley of the Menam, as a buffer-state. Further north, in Eastern China, the aggressive tendencies and mutual rivalries of the European Powers have produced a problem of a much more complicated kind. Firstly Germany, then Russia, next England, and finally France took portions of Chinese territory, under the thin disguise of long leases. They thereby excited in the Chinese population and Government an intense anti-foreign feeling, which produced the Boxer movement and culminated in the attack on the foreign legations at Pekin in the summer of 1900. An account of these events will be found in the article on CHINA.

In 1899–1901 the relations of the European Powers were disturbed by the war in South Africa. In nearly every country of Europe popular feeling was much excited against England, and in certain influential quarters the idea was entertained of utilizing this feeling for the formation of a coalition against the British Empire; but in view of the decided attitude assumed by the British Government, and the loyal enthusiasm displayed by the Colonies, no foreign Government ventured to take the initiative of intervention, and it came gradually to be recognized that no European state had any tangible interest in prolonging the independence and maladministration of the Boer Republics. One permanent factor in the history of Europe during the last thirty years has been the constant increase of armaments by all the great Powers, and the proportionate increase of taxation. The fact made such an impression on the young Emperor of Russia, Nicholas II., that he invited the Powers to consider whether the further increase of the burdens thereby imposed on the nations might not be arrested by mutual agreement; and a Conference for this purpose was convened at The Hague (18th May–29th July 1899), but the desirable object in view was not attained. (See ARBITRATION, INTERNATIONAL.) (D. M. W.)

Eutaw Springs, a village of Berkeley county, South Carolina, U.S.A. The Atlantic Coast Railway connects it with Charleston and its fine harbour. One of the battles of the Revolutionary War was fought here, 8th September 1781; the Americans losing 554, the British, 1000.

Eutin, a town of Prussia, capital of the principality of Lübeck, belonging to the grand duchy of Oldenburg. It is situated as an enclave in the most picturesque part of Holstein, 20 miles north from the city of Lübeck by the railway to Kiel. It dates from the 12th century, and possesses a grand ducal castle, with a fine park, and a monument to Weber, the musician, who was born here in 1786. Towards the end of the 18th century Eutin acquired some fame as the residence of a group of contemporary poets and writers, of whom the best known were Voss, the two Stolbergs, and F. H. Jacobi. Population (1900), 5204.

Evangelical Alliance.—This alliance, which is not a religious "denomination" but an association of individual members of various Christian bodies, continues its effort to "enable Christians of different denominations and in all countries to realize in themselves, and to exhibit to others, that living and essential union which binds all true believers together in the fellowship of Christ," meanwhile endeavouring to counteract "Infidelity, Romanism, and Ritualism, and the desecration of the Lord's Day." General conferences of the whole Alliance were held at Basle 1879, Copenhagen 1884, Florence 1891, and London 1896; and the fifty-fourth annual conference of the British organization was held in October 1900. The objects of the Alliance are now sometimes stated as follows:—(*a*) *The world girdled by prayer*: a world-wide week of prayer is held annually, beginning on the first Sunday in the year. (*b*) *The maintenance of religious liberty throughout the world.* (*c*) *The relief of persecuted Christians in all parts*: the Alliance has agents in many countries to help the persecuted, distribute relief, &c., and in Russia there is a travelling agent who endeavours to help the Stundists. (*d*) *The manifestation of the unity of all believers and the upholding of the evangelical faith.* The following publications may be mentioned:—*The Evangelical Alliance Magazine*, *The Evangelical Alliance Quarterly*, both published in London, and *Jubilee of the Evangelical Alliance*, London, 1897.

Evans, Sir John (1823-——), English archæologist, son of the Rev. Dr. Evans, headmaster of

Market Bosworth Grammar School, was born at Britwell Court, 17th November 1823. He was for many years head of the extensive paper manufactory at Nash Mills, Hemel Hempstead, still carried on by his family, but is especially distinguished as an antiquary and numismatist. He is the author of three books, standard in their respective departments, *The Coins of the Ancient Britons*, 1864; *The Ancient Stone Implements, Weapons, and Ornaments of Great Britain*, 1872; and *The Ancient Bronze Implements, Weapons, and Ornaments of Great Britain and Ireland*, 1881. He has also written a number of separate papers on archæological subjects. He was President of the Society of Antiquaries from 1885 to 1892, and has been President of the Numismatic Society since 1875; he has also presided over the Geological Society and the Anthropological Institute, and is a trustee of the British Museum. He was made a K.C.B. in 1892. His eldest son, Arthur John, born in 1851, has been keeper of the Ashmolean Museum at Oxford since 1884, and has taken a prominent part in the recent archæological discoveries in Crete.

Evanston, a town of Cook county, Illinois, U.S.A., north of Chicago, of which it is a suburb, on the shore of Lake Michigan, and connected with Chicago by branches of the Chicago and North-Western and the Chicago, Milwaukee, and St Paul Railways. It is the seat of North-Western University, a flourishing Methodist Episcopal coeducational institution, founded in 1855, of which the schools of medicine, law, pharmacy, and dentistry are located at Chicago. In 1900 its corps of professors and instructors in all departments numbered 265, and the students in attendance 2246, about one-quarter of whom were women; 643 of the students were in the academic department and the remainder in the professional departments. Population (1880), 6703; (1900), 19,259.

Evansville, capital of Vanderburg county, Indiana, U.S.A., in 38°·00 N. lat. and 87°·30 W. long., on the north bank of Ohio river, at an altitude of 400 feet. The site of the city is the level valley of the Ohio; the street plan is regular, and the houses are numbered on the decimal plan; the city is supplied with water by the Holly pumping system, and is well sewered. The central part of the city is well paved with brick. It is the most important commercial and manufacturing city of Southern Indiana, and the second city in population in the State. It has eight railways, affording communication in all directions, and these, with the Ohio river, which is open and navigable at all times of the year, afford excellent avenues for trade. The invested manufacturing capital was, in 1890, $9,166,859; 7435 hands were employed; and the product was valued at $12,809,334. The principal products were clothing, flour, iron and steel goods, lumber and leather goods. The assessed valuation of real and personal property was, in 1900, $25,321,680, the net debt of the city was $2,144,937, and the rate of taxation $27.80 per $1000. Population (1880), 29,280; (1900), 59,007, of whom 7518 were negroes. The death-rate in 1900 was 17·7.

Evarts, William Maxwell (1818–1901), American lawyer, was born in Boston, 6th February 1818. He graduated at Yale in 1837, was admitted to the Bar in New York in 1841, and soon took high rank in his profession. In 1860 he was chairman of the New York delegation to the Republican national convention. In 1861 he was an unsuccessful candidate for the United States senatorship from New York. He was chief counsel for President Johnson during the impeachment trial, and from July 1868 until March 1869 he was Attorney-General of the United States. In 1872 he was counsel for the United States in the *Alabama* arbitration. During President Hayes's administration, 1877–81, he was Secretary of State; and from 1885 to 1891 he was one of the senators from New York. As an orator Senator Evarts stood in the foremost rank, and some of his best speeches were published. He died on 28th February 1901.

Everett, a city of Middlesex county, Massachusetts, U.S.A., a few miles north of Boston, and adjoining Malden, of which it formed a part until 1870, when it was incorporated as a town. It received a city charter in 1893. It has an undulating surface, and its street plan is irregular. It is on a branch of the Boston and Maine Railway. Its manufactures, according to the State census of 1895, employed a capital of $714,757, with 807 hands, and produced goods valued at $1,884,193. Population (1880), 4159; (1900), 24,336, of whom 6882 were foreign-born.

Everett, a city of Snohomish county, Washington, U.S.A., on Puget Sound. At this point the main transcontinental line of the Great Northern Railway reaches the western coast, whence it turns southwards to Seattle and northwards to Vancouver. Regular steamboat lines connect Everett with Seattle, Tacoma, and other Puget Sound ports. It has a good harbour and some commerce; in manufactures it has several large lumber and shingle mills, and a smelter, which is supplied with ores from the Cascade range. The city is of very recent growth. Population (1900), 7838, of whom 1677 were foreign-born.

Eversley, Charles Shaw Lefevre, Viscount (1794–1888), Speaker of the British House of Commons, only son of Mr Charles Shaw (who assumed his wife's name of Lefevre in addition to his own on his marriage), was born in London on 27th February 1794, and educated at Winchester and at Trinity College, Cambridge. He was called to the Bar in 1819, and though a diligent student was also a keen sportsman. Marrying a daughter of Mr Samuel Whitbread, whose wife was the sister of Earl Grey, afterwards Premier, he thus became connected with two influential political families, and in 1830 he entered the House of Commons as member for Downton, in the Liberal interest. In 1831 he was returned, after a severe contest, as one of the county members for Hampshire, in which he resided; and after the passing of the Reform Act of 1832 he was elected for the Northern Division of Hampshire. For some years Mr Shaw Lefevre was Chairman of a Committee on Petitions for Private Bills. In 1835 he was Chairman of a Committee on Agricultural Distress, but as his report was not accepted by the House, he published it as a pamphlet addressed to his constituents. He acquired a high reputation in the House of Commons for his judicial fairness, combined with singular tact and courtesy, and when Mr Speaker Abercromby suddenly retired in 1839, he was nominated as the Liberal candidate for the chair. The Conservatives put forward Mr Goulburn, but Mr Shaw Lefevre was elected by 317 to 299 votes. The period was one of fierce party conflict, and the debates were frequently very acrimonious; but the dignity, temper, and firmness of the new Speaker were never at fault. In 1857 he had served longer than any of his predecessors except the celebrated Arthur Onslow, and retired on a pension, being raised to the peerage as Viscount Eversley of Heckfield, in the county of Southampton. His appearances in the House of Lords were very infrequent, but in his own county he was active in the public service. From 1859 he was an Ecclesiastical Commissioner, and he was also appointed a Trustee of the British Museum. He died on 29th December 1888, the title becoming extinct. (G. B. S.)

Evesham, a municipal borough and market town in the Evesham parliamentary division (since 1885) of Worcestershire, England, on the Avon, 15 miles south-east by east of Worcester by rail. A cottage hospital, a sanatorium, and a Catholic church have been erected. The Evesham Institute Buildings have been acquired by the Corporation and opened as a free library and for classes of technical education; and the grammar school has been reorganized. Area, 2265 acres; population (1881), 5112; (1901), 7100.

EVIDENCE, LAW OF.

EVIDENCE may be described briefly as consisting of facts presented to the mind of a person for the purpose of enabling him to decide a disputed question of fact. Evidence in the widest sense includes all such facts. In a narrower sense it includes only such facts as are allowed by English law to be so presented in the course of judicial proceedings. Thus we say that a fact is not evidence, meaning thereby that it is not admissible as evidence in accordance with the rules of English law. The law of evidence is part of the law of procedure. It determines the kinds of evidence which may be produced in judicial proceedings, and regulates the mode in which, and the conditions under which, evidence may be produced and tested.

History. The English law of evidence is of comparatively modern growth. It enshrines certain maxims, some derived from Roman law, some invented by Coke, who, as Mr. Thayer says, "spawned Latin maxims freely." But for the most part it was built up by English judges in the course of the 18th century, and consists of this judge-made law, as modified by statutory enactments of the 19th century. Early Teutonic procedure knew nothing of evidence in the modern sense, just as it knew nothing of trials in the modern sense. What it knew was "proofs." There were two modes of proof, ordeals and oaths. Both were appeals to the supernatural. The judicial combat was a bilateral ordeal. Proof followed, instead of preceding, judgment. A judgment of the court, called by German writers the *Beweis-urtheil*, and by Mr Bigelow the "medial judgment," awarded that one of the two litigants must prove his case, by his body in battle, or by a one-sided ordeal, or by an oath with oath-helpers, or by the oaths of witnesses. The court had no desire to hear or weigh conflicting testimony. To do so would have been to exercise critical faculties, which the court did not possess, and the exercise of which would have been foreign to the whole spirit of the age. The litigant upon whom the burden of furnishing proof was imposed had a certain task to perform. If he performed it, he won; if he failed, he lost. The number of oath-helpers varied in different cases, and was determined by the law or by the court. They were probably, at the outset, kinsmen, who would have had to take up the blood-feud. At a later stage they became witnesses to character. In the cases, comparatively rare, where the oaths of witnesses were admitted as proof, their oaths differed materially from the sworn testimony of modern courts. As a rule no one could testify to a fact unless, when the fact happened, he was solemnly "taken to witness." Then, when the witness was adduced, he came merely to swear to a set formula. He did not make a promissory oath to answer questions truly. He merely made an assertory oath in a prescribed form.

In the course of the 12th and 13th centuries the old formal, accusatory procedure began to break down, and to be superseded by another form of procedure known as *inquisitio*, inquest, or *enquête*. Its decay was hastened by the decree of the fourth Lateran Council in 1215, which forbade ecclesiastics to take part in ordeals. The Norman administrative system introduced into England by the Conquest was familiar with a method of ascertaining and determining facts by means of a verdict, return, or finding made on oath by a body of men drawn from the locality. The system may be traced to Carolingian, and even earlier, sources. Henry II., by instituting the Grand Assize and the four petty assizes, placed at the disposal of litigants in certain actions the opportunity of giving proof by the verdict of a sworn inquest of neighbours, proof "by the country." The system was gradually extended to other cases, criminal as well as civil. The verdict given was that of persons having a general, but not necessarily a particular, acquaintance with the persons, places, and facts to which the inquiry related. It was, in fact, a finding by local popular opinion. Had the finding of such an inquest been treated as final and conclusive in criminal cases, English criminal procedure might, like the Continental inquisition, the French *enquête*, have taken the path which, in the forcible language of Fortescue (De Laudibus, &c.) "leads to hell" (*Semita ipsa est ad gehennam*). Fortunately English criminal procedure took a different course. The spirit of the old accusatory procedure was applied to the new procedure by inquest. In serious cases the words of the jurors, the accusing jurors, were treated not as testimony, but as accusation, the new indictment was treated as corresponding to the old appeal, and the preliminary finding by the accusing jury had to be supplemented by the verdict of another jury. In course of time the second jury were required to base their findings not on their own knowledge, but on evidence submitted to them. Thus the modern system of inquiry by grand jury and trial by petty jury was gradually developed.

A few words may here be said about the parallel development of criminal procedure on the Continent. The tendency in the 12th and 13th centuries to abolish the old formal methods of procedure, and to give the new procedure the name of inquisition or inquest, was not peculiar to England. Elsewhere the old procedure was breaking down at the same time, and for similar reasons. It was the great pope Innocent III., the pope of the fourth Lateran Council, who introduced the new inquisitorial procedure into the canon law. The procedure was applied to cases of heresy, and, as so applied, especially by the Dominicans, speedily assumed the features which made it infamous. "Every safeguard of innocence was abolished or disregarded; torture was freely used. Everything seems to have been done to secure a conviction." Yet, in spite of its monstrous defects, the inquisitorial procedure of the ecclesiastical courts, secret in its methods, unfair to the accused, having torture as an integral element, gradually forced its way into the temporal courts, and may almost be said to have been adopted by the common law of western Europe. In connexion with this inquisitorial procedure Continental jurists elaborated a theory of evidence, or judicial proofs, which formed the subject of an extensive literature. Under the rules thus evolved full proof (*plena probatio*) was essential for conviction, in the absence of confession, and the standard of full proof was fixed so high that it was in most cases unattainable. It therefore became material to obtain confession by some means or other. The most effective means was torture, and thus torture became an essential feature in criminal procedure. The rules of evidence attempted to graduate the weight to be attached to different kinds of testimony and almost to estimate that weight in numerical terms. "*Le parlement de Toulouse*," said Voltaire, "*a un usage très singulier dans les preuves par témoins. On admet ailleurs des demi-preuves, . . . mais à Toulouse on admet des quarts et des huitièmes de preuves.*" Modern Continental procedure, as embodied in the most recent codes, has removed the worst features of inquisitorial procedure, and has shaken itself free from the trammels imposed by the old theory and technical rules of proof. But in this, as in other branches of law, France seems to have paid the penalty for having been first in the field with codification by lagging behind in material reforms. The French Code of Criminal Procedure was largely based on Colbert's Ordonnance of 1670, and though embodying some reforms, and since amended on certain points, still retains some of the features of the unreformed procedure which was condemned in the 18th century by Voltaire and the *philosophes*. Military procedure is in the rear of civil procedure, and the trial of Dreyfus at Rennes presented some interesting archaisms. Among these were the weight attached to the rank and position of witnesses as compared with the intrinsic character of their evidence, and the extraordinary importance attributed to confession even when made under suspicious circumstances and supported by flimsy evidence.

The history of criminal procedure in England has been traced by Sir James Stephen. The modern rules and practice as to evidence and witnesses in the Common Law courts, both in civil and in criminal cases, appear to have taken shape in the course of the 18th century. The first systematic treatise on the English law of evidence appears to have been written by Chief Baron Gilbert, who died in 1726, but whose *Law of Evidence* was not published until 1761. In writing it he is said to have been much influenced by Locke.[1] It is highly praised by Black-

[1] Reference may be made to a well-known passage in the *Essay*

stone as "a work which it is impossible to abstract or abridge without losing some beauty and destroying the charm of the whole"; but Bentham, who rarely agrees with Blackstone, speaks of it as running throughout "in the same strain of anility, garrulity, narrow-mindedness, absurdity, perpetual misrepresentation, and indefatigable self-contradiction." In any case it remained the standard authority on the law of evidence throughout the remainder of the 18th century. Bentham wrote his *Rationale of Judicial Evidence, specially applied to English Practice,* at various times between the years 1802 and 1812. By this time he had lost the nervous and simple style of his youth, and required an editor to make him readable. His great interpreter, Dumont, condensed his views on evidence into the *Traité des Preuves Judiciaires,* which was published in 1823. The manuscript of the *Rationale* was edited for English reading, and to a great extent rewritten, by J. S. Mill, and was published in five volumes in 1827. The book had a great effect both in England and on the Continent. The English version, though crabbed and artificial in style, and unmeasured in its invective, is a storehouse of comments and criticisms on the principles of evidence and the practice of the courts, which are always shrewd and often profound. Bentham examined the practice of the courts by the light of practical utility. Starting from the principle that the object of judicial evidence is the discovery of truth, he condemned the rules which excluded some of the best sources of evidence. The most characteristic feature of the common-law rules of evidence, was, as Bentham pointed out, and, indeed, still is, their exclusionary character. They excluded and prohibited the use of certain kinds of evidence which would be used in ordinary inquiries. In particular, they disqualified certain classes of witnesses on the ground of interest in the subject-matter of the inquiry, instead of treating the interest of the witness as a matter affecting his credibility. It was against this confusion between competency and credibility that Bentham directed his principal attack. He also attacked the system of paper evidence, evidence by means of affidavits instead of by oral testimony in court, which prevailed in the Court of Chancery, and in ecclesiastical courts. Subsequent legislation has endorsed his criticisms. The Judicature Acts have reduced the use of affidavits in Chancery proceedings within reasonable limits. A series of Acts of Parliament have removed, step by step, almost all the disqualifications which formerly made certain witnesses incompetent to testify.

Before Bentham's work appeared, an Act of 1814 (54 Geo. III. c. 170, s. 9) had removed the incompetency of ratepayers as witnesses in certain cases relating to parishes. The Civil Procedure Act, 1833, enacted that a witness should not be objected to as incompetent solely on the ground that the verdict or judgment would be admissible in evidence for or against him. An Act of 1840 (3 and 4 Vict. c. 26) removed some doubts as to the competency of ratepayers to give evidence in matters relating to their parish. The Evidence Act, 1843, enacted broadly that witnesses should not be excluded from giving evidence by reason of incapacity from crime or interest. The Evidence Act, 1851, made parties to legal proceedings admissible witnesses subject to a proviso that "nothing herein contained shall render any person who in any criminal proceeding is charged with the commission of any indictable offence, or any offence punishable on summary conviction, competent or compellable to give evidence for or against himself or herself, or shall render any person compellable to answer any question tending to criminate himself or herself, or shall in any criminal proceeding render any husband competent or compellable to give evidence for or against his wife, or any wife competent or compellable to give evidence for or against her husband." The Evidence (Scotland) Act, 1853, made a similar provision for Scotland. The Evidence Amendment Act, 1853, made the husbands and wives of parties admissible witnesses, except that husbands and wives could not give evidence for or against each other in criminal proceedings or in proceedings for adultery, and could not be compelled to disclose communications made to each other during marriage. Under the Matrimonial Causes Act, 1857, the petitioner can be examined and cross-examined on oath at the hearing, but is not bound to answer any question tending to show that he or she has been guilty of adultery. Under the Matrimonial Causes Act, 1859, on a wife's petition for dissolution of marriage on the ground of adultery coupled with cruelty or desertion, husband and wife are competent and compellable to give evidence as to the cruelty or desertion. The Crown Suits &c. Act, 1865, declared that revenue proceedings were not to be treated as criminal proceedings for the purposes of the Acts of 1851 and 1853. The Evidence Further Amendment Act, 1869, declared that parties to actions for breach of promise of marriage were competent to give evidence in the action, subject to a proviso that the plaintiff should not recover unless his or her testimony was corroborated by some other material evidence. It also made the parties to proceedings instituted in consequence of adultery, and their husbands and wives, competent to give evidence, but a witness in any such proceeding, whether a party or not, is not to be liable to be asked or bound to answer any question tending to show that he or she has been guilty of adultery, unless the witness has already given evidence in the same proceeding in disproof of the alleged adultery. There are similar provisions applying to Scotland in the Conjugal Rights (Scotland) Amendment Act, 1861, and the Evidence Further Amendment (Scotland) Act, 1874. The Evidence Act, 1877, enacts that "on the trial of any indictment or other proceeding for the non-repair of any public highway or bridge, or for a nuisance to any public highway, river, or bridge, and of any other indictment or proceeding instituted for the purpose of trying or enforcing a civil right only, every defendant to such indictment or proceeding, and the wife or husband of any such defendant shall be admissible witnesses and compellable to give evidence." From 1872 onwards numerous enactments were passed making persons charged with particular offences, and their husbands and wives, competent witnesses. The language and effect of these enactments were not always the same, but the insertion of some provision to this effect in an Act creating a new offence, especially if it was punishable by summary proceedings, gradually became almost a common form in legislation. In the year 1874 a bill to generalize these particular provisions, and to make the evidence of persons charged with criminal offences admissible in all cases was introduced by Mr Gladstone's Government, and was passed by the Standing Committee of the House of Commons. During the next fourteen years bills for the same purpose were repeatedly introduced, either by the Government of the day, or by Lord Bramwell as an independent member of the House of Lords. Finally, the Criminal Evidence Act, 1898, introduced by Lord Halsbury, has enacted in general terms that "every person charged with an offence, and the wife or husband, as the case may be, of the person so charged, shall be a competent witness for the defence at every stage of the proceedings, whether the person so charged is charged solely or jointly with any other person." But this general enactment is qualified by some special restrictions, the nature of which will be noticed below. The Act applies to Scotland but not to Ireland. It was not to apply to proceedings in courts-martial unless so applied by general orders or rules made under statutory authority. The provisions of the Act have been applied by rules to military courts-martial, but have not yet been applied to naval courts-martial. The removal of disqualifications for want of religious belief is referred to below under the head of "Witnesses."

The Act of 1898 finishes for the present the history of legislation on evidence. For a view of the legal literature on the subject it is necessary to take a step backwards.

Literature.

Early in the 19th century Chief Baron Gilbert was superseded as an authority on the English law of evidence by the books of Phillips (1814) and Starkie (1824), who were followed by Roscoe (*Nisi Prius,* 1827; *Criminal Cases,* 1835), Greenleaf (American, 1842), Taylor (based on Greenleaf, 1848), and Best (1849). In 1876 Sir James FitzJames Stephen brought out his *Digest of the Law of Evidence,* based upon the Indian Evidence Act, 1872, which he had prepared and passed as law member of the Council of the Governor-General of India. This Digest obtained a rapid and well-deserved success, and has materially influenced the form of subsequent writings on the English law of evidence. It sifted out what Stephen conceived to be the main rules of evidence from the mass of extraneous matter in which they had been embedded. Roscoe's Digests told the lawyer what things must be proved in order to sustain particular actions or criminal charges, and related as much to pleadings and to substantive law as to evidence proper. Taylor's two large volumes were a vast storehouse of useful information, but his book was one to consult, not to master. Stephen eliminated much of this extraneous matter, and summed up his rules in a series of succinct propositions, supplemented by apt illustrations, and couched in such a form that they could be easily read and remembered. Hence the English Digest, like the Indian Act, has been of much educational value. Its most original feature, but unfortunately also its weakest point, is its theory of relevancy. Pondering the multitude of "exclusionary" rules which had been laid down by the English courts, Stephen thought that he had discovered the general principle on which those rules reposed, and could devise a formula by which the principle could be expressed. "My study of the subject," he says, "both practically and in books has convinced me that the doctrine that all facts in issue

---

concerning Human Understanding (Book iv. ch. xv.):—"The grounds of probability are—First, the conformity of anything with our own knowledge, observation, and experience. Second, the testimony of others touching their observation and experience. In the testimony of others is to be considered (1) the number. (2) The integrity. (3) The skill of the witnesses. (4) The design of the author, where it is a testimony out of a book cited. (5) The consistency of the parts and circumstances of the relation. (6) Contrary testimonies."

and relevant to the issue, and no others, may be proved, is the unexpressed principle which forms the centre of and gives unity to all the express negative rules which form the great mass of the law." The result was the chapter on the Relevancy of Facts in the Indian Evidence Act, and the definition of relevancy in s. 7 of that Act. This definition was based on the view that a distinction could be drawn between things which were and things which were not causally connected with each other, and that relevancy depended on causal connexion. Subsequent criticism convinced Stephen that his definition was in some respects too narrow and in others too wide, and eventually he adopted a definition out of which all reference to causality was dropped. But even in their amended form the provisions about relevancy are open to serious criticism. The doctrine of relevancy, *i.e.*, of the probative effect of facts, is a branch of logic, not of law, and is out of place both in an enactment of the Legislature and in a compendium of legal rules. The necessity under which Stephen found himself of extending the range of relevant facts by making it include facts "deemed to be relevant," and then narrowing it by enabling the judge to exclude evidence of facts which are relevant, illustrates the difference between the rules of logic and the rules of law. Relevancy is one thing; admissibility is another; and the confusion between them, which is much older than Stephen, is to be regretted. Rightly or wrongly English judges have, on practical grounds, declared inadmissible evidence of facts, which are relevant in the ordinary sense of the term, and which are so treated in non-judicial inquiries. Under these circumstances the attempt so to define relevancy as to make it conterminous with admissibility is misleading, and most readers of Stephen's Act and Digest would find them more intelligible and more useful if "admissible" were substituted for "relevant" throughout. Indeed it is hardly too much to say that Stephen's doctrine of relevancy is theoretically unsound and practically useless. The other parts of the work contain terse and vigorous statements of the law, but a Procrustean attempt to make legal rules square with a preconceived theory has often made the language and arrangement artificial, and the work, in spite of its compression, still contains rules which, under a more scientific treatment, would find their appropriate place in other branches of the law. These defects are characteristic of a strong and able man, who saw clearly, and expressed forcibly what he did see, but was apt to ignore or to deny the existence of what he did not see, whose mind was vigorous rather than subtle or accurate, and who, in spite of his learning, was somewhat deficient in the historical sense. But notwithstanding these defects, the conspicuous ability of the author, his learning, and his practical experience, especially in criminal cases, attach greater weight to FitzJames Stephen's statements than to those of any other English writer on the law of evidence.

Before proceeding to summarize the existing rules of the law of evidence, it may be useful to make some preliminary remarks.

Rules.

The object of every trial is, or may be, to determine two classes of questions or issues, which are usually distinguished as questions of law, and questions of fact, although the distinction between them is not so clear as might appear on a superficial view. In a trial by jury these two classes of questions are answered by different persons. The judge lays down the law. The jury, under the guidance of the judge, find the facts. It was with reference to trial by jury that the English rules of evidence were originally framed; it is by the peculiarities of this form of trial that many of them are to be explained; it is to this form of trial alone that some of the most important of them are exclusively applicable. The negative, exclusive, or exclusionary rules which form the characteristic features of the English law of evidence, are the rules in accordance with which the judge guides the jury. There is no difference of principle between the method of inquiry in judicial and in non-judicial proceedings. In either case a person who wishes to find out whether a particular event did or did not happen, tries, in the first place, to obtain information from persons who were present and saw what happened (direct evidence), and, failing this, to obtain information from persons who can tell him about facts from which he can draw an inference as to whether the event did or did not happen (indirect evidence). But in judicial inquiries the information given must be given on oath, and be liable to be tested by cross-examination. And there are rules of law which exclude from the consideration of the jury certain classes of facts which, in an ordinary inquiry, would, or might, be taken into consideration. Facts so excluded are said to be "not admissible as evidence," or "not evidence," according as the word is used in the wider or in the narrower sense. And the easiest way of determining whether a fact is or is not evidence in the narrower sense, is first to consider whether it has any bearing on the question to be tried, and, if it has, to consider whether it falls within any one or more of the rules of exclusion laid down by English law. These rules of exclusion are peculiar to English law and to systems derived from English law. They have been much criticized, and some of them have been repealed or materially modified by legislation. Most of them may be traced to directions given by a judge in the course of trying a particular case, given with special reference to the circumstances of that case, but expressed in general language, and, partly through the influence of text-writers, eventually hardened into general rules. In some cases their origin is only intelligible by reference to obsolete forms of pleading or practice. But in most cases they were originally rules of convenience laid down by the judge for the assistance of the jury. The judge is a man of trained experience, who has to arrive at a conclusion with the help of twelve untrained men, and who is naturally anxious to keep them straight, and give them every assistance in his power. The exclusion of certain forms of evidence assists the jury by concentrating their attention on the questions immediately before them, and by preventing them from being distracted or bewildered by facts which either have no bearing on the question before them, or have so remote a bearing on those questions as to be practically useless as guides to the truth. It also prevents a jury from being misled by statements the effect of which, through the prejudice they excite, is out of all proportion to their true weight. In this respect the rules of exclusion may be compared to blinkers, which keep a horse's eyes on the road before him. In criminal cases the rules of exclusion secure fair play to the accused, because he comes to the trial prepared to meet a specific charge, and ought not to be suddenly confronted by statements which he had no reason to expect would be made against him. They protect absent persons against statements affecting their character. And lastly they prevent the infinite waste of time which would ensue in the discussion of a question of fact if an inquiry were allowed to branch out into all the subjects with which that fact is more or less connected. The purely practical grounds on which the rules are based, according to the view of a great judge, may be illustrated by some remarks of the late Mr Justice Willes. In discussing the question whether evidence of the plaintiff's conduct on other occasions ought to be admitted, he said:—

> It is not easy in all cases to draw the line and to define with accuracy where probability ceases and speculation begins; but we are bound to lay down the rule to the best of our ability. No doubt the rule as to confining the evidence to that which is relevant and pertinent to the issue is one of great importance, not only as regards the particular case, but also with reference to saving the time of the court, and preventing the minds of the jury from being drawn away from the real point they have to decide. . . . Now it appears to me that the evidence proposed to be given in this case, if admitted, would not have shown that it was more probable that the contract was subject to the condition insisted upon by the defendant. The question may be put thus, Does the fact of a person having once or many times in his life done a particular act in a particular way make it more probable that he has done the same thing in the same way upon another and different occasion? To admit such speculative evidence would, I think, be fraught with great danger. . . . If such evidence were held admissible it would be difficult to say that the defendant might not in any case, where the question was whether

or not there had been a sale of goods on credit, call witnesses to prove that the plaintiff had dealt with other persons upon a certain credit; or, in an action for an assault, that the plaintiff might not give evidence of former assaults committed by the defendant upon other persons, or upon other persons of a particular class, for the purpose of showing that he was a quarrelsome individual, and therefore that it was highly probable that the particular charge of assault was well founded. The extent to which this sort of thing might be carried is inconceivable. . . . To obviate the prejudices, the injustice, and the waste of time to which the admission of such evidence would lead, and bearing in mind the extent to which it might be carried, and that litigants are mortal, it is necessary not only to adhere to the rule, but to lay it down strictly. I think, therefore, the fact that the plaintiff had entered into contracts of a particular kind with other persons on other occasions could not be properly admitted in evidence where no custom of trade to make such contracts, and no connexion between such and the one in question, was shown to exist (*Hollingham* v. *Head*, 1858, 4 C.B. N.S. 388).

There is no difference between the principles of evidence in civil and in criminal cases, although there are a few special rules, such as those relating to confessions and to dying declarations, which are only applicable to criminal proceedings. But in civil proceedings the issues are narrowed by mutual admissions of the parties, more use is made of evidence taken out of court, such as affidavits, and, generally, the rules of evidence are less strictly applied. It is often impolitic to object to the admission of evidence, even when the objection may be sustained by previous rulings. The general tendency of modern procedure is to place a more liberal and less technical construction on rules of evidence, especially in civil cases. In recent volumes of law reports cases turning on the admissibility of evidence are conspicuous by their rarity. Various causes have operated in this direction. One of them has been the change in the system of pleading, under which each party now knows before the actual trial the main facts on which his opponent relies. Another is the interaction of chancery and common-law practice and traditions since the Judicature Acts. In the Chancery Courts the rules of evidence were always less carefully observed, or, as Westminster would have said, less understood, than in the courts of common law. A judge trying questions of fact alone might naturally think that blinkers, though useful for a jury, are unnecessary for a judge. And the chancery judge was apt to read his affidavits first, and to determine their admissibility afterwards. In the meantime they had affected his mind.

The tendency of modern text-writers, among whom the late Professor Thayer, of Harvard, was perhaps the most independent, instructive, and suggestive, is to restrict materially the field occupied by the law of evidence, and to relegate to other branches of the law topics traditionally treated under the head of evidence. Thus in every way the law of evidence, though still embodying some principles of great importance, is of less comparative importance as a branch of English law than it was half a century ago. Legal rules, like dogmas, have their growth and decay. First comes the judge who gives a ruling in a particular case. Then comes the text-writer who collects the scattered rulings, throws them into the form of general propositions, connects them together by some theory, sound or unsound, and often ignores or obscures their historical origin. After him comes the legislator who crystallizes the propositions into enactments, not always to the advantage of mankind. So also with decay. Legal rules fall into the background, are explained away, are ignored, are denied, are overruled. Much of the English law of evidence is at present in a stage of decay.

The subject-matter of the law of evidence may be arranged differently according to the taste or point of view of the writer. It will be arranged here under the following heads:—I. Preliminary Matter; II. Classes of Evidence; III. Rules of Exclusion; IV. Documentary Evidence; V. Witnesses.

I. *Preliminary Matter.*

Under this head may be grouped certain principles and considerations which limit the range of matters to which evidence relates.

1. *Law and Fact.*—Evidence relates only to facts. It is therefore necessary to touch on the distinction between law and facts. *Ad quaestionem facti non respondent judices; ad quaestionem juris non respondent juratores.* Thus Coke, attributing, after his wont, to Bracton a maxim which may have been invented by himself. The maxim became the subject of political controversy, and the two rival views are represented by Pulteney's lines—

> For twelve honest men have decided the cause
> Who are judges alike of the facts and the laws,

and by Lord Mansfield's variant—

> Who are judges of facts, but not judges of laws.

The particular question raised with respect to the law of libel was settled by Fox's Libel Act. Coke's maxim describes in a broad general way the distinction between the functions of the judge and of the jury, but is only true subject to important qualifications. Judges in jury cases constantly decide what may be properly called questions of fact, though their action is often disguised by the language applied or the procedure employed. Juries, in giving a general verdict, often practically take the law into their own hands. The border line between the two classes of questions is indicated by the "mixed questions of law and fact," to use a common phrase, which arise in such cases as those relating to "necessaries," "due diligence," "negligence," "reasonableness," "reasonable and probable cause." In the treatment of these cases the line has been drawn differently at different times, and two conflicting tendencies are discernible. On the one hand, there is the natural tendency to generalize common inferences into legal rules, and to fix legal standards of duty. On the other hand, there is the sound instinct that it is a mistake to define and refine too much in these cases, and that the better course is to leave broadly to the jury, under the general guidance of the judge, the question what would be done by the "reasonable" or "prudent" man in particular cases. The latter tendency predominates in modern English law, and is reflected by the enactments in the recent Acts codifying the law on bills of exchange and sale of goods, that certain questions of reasonableness are to be treated as questions of fact. On the same ground rests the dislike to limit the right of a jury to give a general verdict in criminal cases. Questions of custom begin by being questions of fact, but as the custom obtains general recognition it becomes law. Many of the rules of the English mercantile law were "found" as customs by Lord Mansfield's special juries. Generally, it must be remembered that the jury act in subordinate co-operation with the judge, and that the extent to which the judge limits or encroaches on the province of the jury is apt to depend on the personal idiosyncrasy of the judge.

2. *Judicial Notice.*—It may be doubted whether the subject of judicial notice belongs properly to the law of evidence, and whether it does not belong rather to the general topic of legal or judicial reasoning. Matters which are the subject of judicial notice are part of the equipment of the judicial mind. It would be absurd to require evidence of every fact; many facts must be assumed to be known. The judge, like the juryman, is supposed to bring with him to the consideration of the question which he

has to try common sense, a general knowledge of human nature and the ways of the world, and also knowledge of things that "everybody is supposed to know." Of such matters judicial notice is said to be taken. But the range of general knowledge is indefinite, and the range of judicial notice has, for reasons of convenience, been fixed or extended, both by rulings of the judges and by numerous enactments of the Legislature. It would be impossible to enumerate here the matters of which judicial notice must or may be taken. These are to be found in the text-books. For present purposes it must suffice to say that they include not only matters of fact of common and certain knowledge, but the law and practice of the courts, and many matters connected with the government of the country.

3. *Presumptions.*—A presumption in the ordinary sense is an inference. It is an argument, based on observation, that what has happened in some cases will probably happen in others of the like nature. The subject of presumptions, so far as they are mere inferences or arguments, belongs, not to the law of evidence, or to law at all, but to rules of reasoning. But a legal presumption, or, as it is sometimes called, a presumption of law, as distinguished from a presumption of fact, is something more. It may be described, in Stephen's language, as "a rule of law that courts and judges shall draw a particular inference from a particular fact, or from particular evidence, unless and until the truth" (perhaps it would be better to say 'soundness') "of the inference is disproved." Courts and legislatures have laid down such rules on grounds of public policy or general convenience, and the rules have then to be observed as rules of positive law, not merely used as part of the ordinary process of reasoning or argument. Some so-called presumptions are rules of substantive law under a disguise. To this class appear to belong "conclusive presumptions of law," such as the common-law presumption that a child under seven years of age cannot commit a felony. So again the presumption that every one knows the law is merely an awkward way of saying that ignorance of the law is not a legal excuse for breaking it. Of true legal presumptions, the majority may be dealt with most appropriately under different branches of the substantive law, such as the law of crime, of property, or of contract, and accordingly Stephen has included in his *Digest of the Law of Evidence* only some which are common to more than one branch of the law. The effect of a presumption is to impute to certain facts or groups of facts a *primâ facie* significance or operation, and thus, in legal proceedings, to throw upon the party against whom it works the duty of bringing forward evidence to meet it. Accordingly the subject of presumptions is intimately connected with the subject of the burden of proof, and the same legal rule may be expressed in different forms, either as throwing the advantage of a presumption on one side, or as throwing the burden of proof on the other. Thus the rule in Stephen's Digest, which says that the burden of proving that any person has been guilty of a crime or wrongful act is on the person who asserts it, appears in the article entitled "Presumption of Innocence." Among the more ordinary and more important legal presumptions are the presumption of regularity in proceedings, described generally as a presumption *omnia esse rite acta*, and including the presumption that the holder of a public office has been duly appointed, and has duly performed his official duties, the presumption of the legitimacy of a child born during the mother's marriage, or within the period of gestation after her husband's death, and the presumptions as to life and death. "A person shown not to have been heard of for seven years by those (if any) who, if he had been alive, would naturally have heard of him, is presumed to be dead unless the circumstances of the case are such as to account for his not being heard of without assuming his death; but there is no presumption as to the time when he died, and the burden of proving his death at any particular time is upon the person who asserts it. There is no presumption" (*i.e.*, legal presumption) "as to the age at which a person died who is shown to have been alive at a given time, or as to the order in which two or more persons died who are shown to have died in the same accident, shipwreck, or battle" (Stephen, *Dig.*, art. 99). A document proved or purporting to be thirty years old is presumed to be genuine, and to have been properly executed and (if necessary) attested if produced from the proper custody. And the legal presumption of a "lost grant," *i.e.*, the presumption that a right or alleged right which has been long enjoyed without interruption had a legal origin, still survives in addition to the common law and statutory rules of prescription.

4. *Burden of Proof.*—The expression *onus probandi* has come down from the classical Roman law, and both it and the Roman maxims, *Agenti incumbit probatio*, *Necessitas probandi incumbit ei qui dicit non ei qui negat*, and *Reus excipiendo fit actor*, must be read with reference to the Roman system of actions, under which nothing was admitted, but the plaintiff's case was tried first; then, unless that failed, the defendant's on his *exceptio;* then, unless that failed, the plaintiff's on his *replicatio*, and so on. Under such a system the burden was always on the "actor." In modern law the phrase "burden of proof" may mean one of two things, which are often confused —the burden of establishing the proposition or issue on which the case depends, and the burden of producing evidence on any particular point either at the beginning or at a later stage of the case. The burden in the former sense ordinarily rests on the plaintiff or prosecutor. The burden in the latter sense, that of going forward with evidence on a particular point, may shift from side to side as the case proceeds. The general rule is that he who alleges a fact must prove it, whether the allegation is couched in affirmative or negative terms. But this rule is subject to the effect of presumptions in particular cases, to the principle that in considering the amount of evidence necessary to shift the burden of proof regard must be had to the opportunities of knowledge possessed by the parties respectively, and to the express provisions of statutes directing where the burden of proof is to lie in particular cases. Thus many statutes expressly direct that the proof of lawful excuse or authority, or the absence of fraudulent intent, is to lie on the person charged with an offence. And the Summary Jurisdiction Act, 1848, provides that if the information or complaint in summary proceedings negatives any exemption, exception, proviso, or condition in the statute on which it is founded, the prosecutor or complainant need not prove the negative, but the defendant may prove the affirmative in his defence.

II. *Classes of Evidence.*

Evidence is often described as being either oral or documentary. To these two classes should be added a third, called by Bentham real evidence, and consisting of things presented immediately to the senses of the judge or the jury. Thus the judge or jury may go to view any place the sight of which may help to an understanding of the evidence, and may inspect anything sufficiently identified and produced in court as material to the decision. Weapons, clothes, and things alleged to have been stolen or damaged are often brought into court for this purpose. Oral evidence consists of the statements of witnesses. Documentary evidence consists of documents submitted to the judge or jury by way of proof. The distinction between primary and secondary evidence relates only to documentary evidence, and will be noticed in the section under that head. A division of evidence from another point of view is that into direct and indirect, or as it is sometimes called, circumstantial evidence. By direct evidence is meant the statement of a person who saw, or otherwise observed with his senses, the fact in question. By indirect or circumstantial evidence is meant evidence of facts from which the fact in question may be inferred. The difference between direct and indirect evidence is a difference of kind, not of degree, and therefore the rule or maxim as to "best evidence" has no application to it. Juries naturally attach more weight to direct evidence, and in some legal systems it is only this class of evidence which is allowed to have full probative force. In some respects indirect evidence is superior to direct evidence, because, as Paley puts it, "facts cannot lie," whilst witnesses can and do. On the other hand facts often deceive; that is to say, the inferences drawn from them are often erroneous. The circumstances in which crimes are ordinarily committed are such that direct evidence of their commission is usually not obtainable, and when criminality depends on a state of mind, such as intention, that state must necessarily be inferred by means of indirect evidence.

III. *Rules of Exclusion.*

It seems desirable to state the leading rules of exclusion in their crude form instead of obscuring their historical origin by attempting to force them into the shape of precise technical propositions forming parts of a logically connected system. The judges who laid the foundations of our modern law of evidence, like those who first discoursed on the duties of trustees, little dreamt of the elaborate and artificial system which was to be based upon their remarks. The rules will be found, as might be expected, to be vague, to overlap each other, to require much explanation, and to be subject to many exceptions. They may be stated as follows:—(1) Facts not relevant to the issue cannot be admitted as evidence. (2) The evidence produced must be the best obtainable under the circumstances. (3) Hearsay is not evidence. (4) Opinion is not evidence.

1. *Rule of Relevancy.*—The so-called rule of relevancy is sometimes stated by text-writers in the form in which it was laid down by Baron Parke in 1837 (*Wright* v. *Doe and Tatham*, 7 A. and E. 384), when he described "one great principle" in the law of evidence as being that "all facts which are relevant to the issue may be proved." Stated in different forms, the rule has been made by FitzJames Stephen the central point of his theory of evidence. But relevancy, in the proper and natural sense, as we have said, is a matter not of law, but of logic. If Baron Parke's dictum relates to relevancy in its natural sense it is not true; if it relates to relevancy in a narrow and artificial sense, as equivalent to admissible, it is tautological. Such practical importance as the rule of relevancy possesses consists, not in what it includes, but in what it excludes, and for that reason it seems better to state the rule in a negative or exclusive form. But whether the rule is stated in a positive or in a negative form its vagueness is apparent. No precise line can be drawn between "relevant" and "irrelevant" facts. The two classes shade into each other by imperceptible degrees. The broad truth is that the courts have excluded from consideration certain matters which have some bearing on the question to be decided, and which, in that sense, are relevant, and that they have done so on grounds of policy and convenience. Among the matters so excluded are matters which are likely to mislead the jury, or to complicate the case unnecessarily, or which are of slight, remote, or merely conjectural importance. Instances of the classes of matters so excluded can be given, but it seems difficult to refer their exclusion to any more general principle than this. Rules as to evidence of character and conduct appear to fall under this principle. Evidence is not admissible to show that the person who is alleged to have done a thing was of a disposition or character which makes it probable that he would or would not have done it. This rule excludes the biographical accounts of the prisoner which are so familiar in French trials, and is an important principle in English trials. It is subject to three exceptions: first, that evidence of good character is admissible in favour of the prisoner in all criminal cases; secondly, that a prisoner indicted for rape is entitled to call evidence as to the immoral character of the prosecutrix; and thirdly, that a witness may be called to say that he would not believe a previous witness on his oath. The exception allowing the good character of a prisoner to influence the verdict, as distinguished from the sentence, is more humane than logical, and seems to have been at first admitted in capital cases only. The exception in rape cases does not allow evidence to be given of specific acts of immorality with persons other than the prisoner, doubtless on the ground that such evidence would affect the reputations of third parties. Where the character of a person is expressly in issue, as in actions of libel and slander, the rule of exclusion, as stated above, does not apply. Nor does it prevent evidence of bad character from being given in mitigation of damages, where the amount of damages virtually depends on character, as in cases of defamation and seduction. As to conduct there is a similar general rule, that evidence of the conduct of a person on other occasions is not to be used merely for the purpose of showing the likelihood of his having acted in a similar way on a particular occasion. Thus, on a charge of murder, the prosecutor cannot give evidence of the prisoner's conduct to other persons for the purpose of proving a bloodthirsty and murderous disposition. And in a civil case a defendant was not allowed to show that the plaintiff had sold goods on particular terms to other persons for the purpose of proving that he had sold similar goods on the same terms to the defendant. But this general rule must be carefully construed. Where several offences are so connected with each other as to form parts of an entire transaction, evidence of one is admissible as proof of another. Thus, where a prisoner is charged with stealing particular goods from a particular place, evidence may be given that other goods, taken from the same place at the same time, were found in his possession. And where it is proved or admitted that a person did a particular act, and the question is as to his state of mind, that is to say, whether he did the act knowingly, intentionally, fraudulently, or the like, evidence may be given of the commission by him of similar acts on other occasions for the purpose of proving his state of mind on the occasion. This principle is most commonly applied in charges for uttering false documents or base coin, and not uncommonly in charges for false pretences, embezzlement, or murder. In proceedings for the receipt or possession of stolen property, the Legislature has expressly authorized evidence to be given of the possession by the prisoner of other stolen property, or of his previous conviction of an offence involving fraud or dishonesty (Prevention of Crimes Act, 1871). Again, where there is a question whether a person committed an offence, evidence may be given of any fact supplying a motive or constituting preparation for the offence, of any subsequent conduct of the person accused, which is apparently influenced by the commission of the offence, and of any act done by him, or by his

authority, in consequence of the offence. Thus, evidence may be given that, after the commission of the alleged offence, the prisoner absconded, or was in possession of the property, or the proceeds of the property, acquired by the offence, or that he attempted to conceal things which were or might have been used in committing the offence, or as to the manner in which he conducted himself when statements were made in his presence and hearing. Statements made to or in the presence of a person charged with an offence are admitted as evidence, not of the facts stated, but of the conduct or demeanour of the person to whom or in whose presence they are made, or of the general character of the transaction of which they form part (under the *res gestæ* rule mentioned below).

2. *Best Evidence Rule.*—Statements to the effect of the best evidence rule were often made by Chief Justice Holt about the beginning of the 18th century, and became familiar in the courts. Chief Baron Gilbert, in his book on evidence, which must have been written before 1726, says that "the first and most signal rule in relation to evidence is this, that a man must have the utmost evidence the nature of the fact is capable of." And in the great case of *Omichund* v. *Barker* (1744), Lord Hardwicke went so far as to say, "The judges and sages of the law have laid down that there is but one general rule of evidence, the best that the nature of the case will admit" (1 Atkyns 49). It is no wonder that a rule thus solemnly stated should have found a prominent place in text-books on the law of evidence. But, apart from its application to documentary evidence, it does not seem to be more than a useful guiding principle which underlies, or may be used in support of, several rules.

It is to documentary evidence that the principle is usually applied, in the form of the narrower rule excluding, subject to exceptions, secondary evidence of the contents of a document where primary evidence is obtainable. In this form the rule is a rule of exclusion, but may be most conveniently dealt with in connexion with the special subject of documentary evidence. As noticed above, the general rule does not apply to the difference between direct and indirect evidence. And, doubtless on account of its vague character, it finds no place in Stephen's Digest.

3. *Hearsay.*—The term "hearsay" primarily applies to what a witness has heard another person say in respect to a fact in dispute. But it is extended to any statement, whether reduced to writing or not, which is brought before the court, not by the author of the statement, but by a person to whose knowledge the statement has been brought. Thus the hearsay rule excludes statements, oral or written, made in the first instance by a person who is not called as a witness in the case. Historically this rule may be traced to the time when the functions of the witnesses were first distinguished from the functions of the jury, and when the witnesses were required by their formula to testify *de visu suo et auditu*, to state what they knew about facts from the direct evidence of their senses, not from the information of others. The rule excludes statements the effect of which is liable to be altered by the narrator, and which purport to have been made by persons who did not necessarily speak under the sanction of an oath, and whose accuracy or veracity is not tested by cross-examination. It is therefore of practical utility in shutting out many loose statements and much irresponsible gossip. On the other hand, it excludes statements which are of some value as evidence, and may indeed be the only available evidence. Thus, a statement has been excluded as hearsay, even though it can be proved that the author of the statement made it on oath, or that it was against his interest when he made it, or that he is prevented by insanity or other illness from giving evidence himself, or that he has left the country and disappeared, or that he is dead.

Owing to the inconveniences which would be caused by a strict application of the rule, it has been so much eaten into by exceptions that some persons doubt whether the rule and the exceptions ought not to change places. Among the exceptions the following may be noticed:—(*a*) *Certain sworn Statements.*—In many cases statements made by a person whose evidence is material, but who cannot come before the court, or could not come before it without serious difficulty, delay, or expense, may be admitted as evidence under proper safeguards. Under the Indictable Offences Act, 1848, where a person has made a deposition before a justice at a preliminary inquiry into an offence, his deposition may be read in evidence on proof that the deponent is dead, or too ill to travel, that the deposition was taken in the presence of the accused person, and that the accused then had a full opportunity of cross-examining the deponent. The deposition must appear to be signed by the justice before whom it purports to have been taken. Depositions taken before a coroner are admissible under the same principle. And the principle probably extends to cases where the deponent is insane, or kept away by the person accused. There are other statutory provisions for the admission of depositions, as in the Criminal Law Amendment Act, 1867; the Foreign Jurisdiction Act, 1890; and the Prevention of Cruelty to Children Act, 1894. In civil cases the rule excluding statements not made in court at the trial is much less strictly applied. Frequent use is made of evidence taken before an examiner, or under a commission. Affidavits are freely used for subordinate issues or under an arrangement between the parties, and leave may be given to use evidence taken in other proceedings. The old chancery practice, under which evidence, both at the trial and at other stages of a proceeding, was normally taken by affidavit, irrespectively of consent, was altered by the Judicature Acts. Under the existing rules of the supreme court evidence may be given by affidavit upon any motion, petition, or summons, but the court or a judge may, on the application of either party, order the attendance for cross-examination of the person making the affidavit. (*b*) *Dying Declarations.*—In a trial for murder or manslaughter a declaration by the person killed as to the cause of his death, or as to any of the circumstances of the transaction which resulted in his death, is admissible as evidence. But this exception is very strictly construed. It must be proved that the declarant, at the time of making the declaration, was in actual danger of death, and had given up all hope of recovery. (*c*) *Statements in Pedigree Cases.*—On a question of pedigree the statement of a deceased person, whether based on his own personal knowledge or on family tradition, is admissible as evidence, if it is proved that the person who made the statement was related to the person about whose family relations the statement was made, and that the statement was made before the question with respect to which the evidence is required had arisen. (*d*) *Statements as to Matters of Public or General Interest.*—Statements by deceased persons are admissible as evidence of reputation or general belief in questions relating to the existence of any public or general right or custom, or matter of public and general interest. Statements of this kind are constantly admitted in questions relating to right of way, or rights of common, or manorial or other local customs. Maps, copies of court rolls, leases and other deeds, and verdicts, judgments, and orders of court fall within the exception in cases of this kind. (*e*) *Statements in course of Duty or Business.*—A statement with respect to a particular fact made by a deceased person in pursuance of his duty in connexion with any office, employment, or business, whether public or private, is admissible as evidence of that fact, if the statement appears to have been made from personal knowledge, and at or about the time when the fact occurred. This exception covers entries by clerks and other employees. (*f*) *Statements against Interest.*—A statement made by a deceased person against his pecuniary or proprietary interest is admissible as evidence, without reference to the time at which it was made. Where such a statement is admissible the whole of it becomes admissible, though it may contain matters not against the interest of the person who made it, and though the total effect may be in his favour. Thus, where there was a question whether a particular sum was a gift or a loan, entries in an account book of receipt of interest on the sum were admitted, and a statement in the book that the alleged debtor had on a particular date acknowledged the loan was also admitted. (*g*) *Public Documents.*—Under this head may be placed recitals in public Acts of Parliament, notices in the *London*, *Edinburgh*, or *Dublin Gazette* (which are made evidence by statute in a large number of cases), and entries made in the performance of duty in official registers or records, such as registers of births, deaths, or marriages, registers of companies, records in judicial proceedings, and the like. An entry in a public document may be treated as a statement made in the course of duty, but it is admissible whether the person who made the statement is alive or dead, and without any evidence as to personal knowledge, or the time at which the statement is made. (*h*) *Admissions.*—By the term "admission," as here used, is meant a statement made out of the witness-box by a party to the proceedings, whether civil or criminal, or by some person whose statements are binding on that party, against the interest of that party. The term includes admissions made in answer to interrogatories, or to a notice to admit facts, but not admissions made on the pleadings. Admissions, in this sense of the term, are admissible as evidence against the person by whom they are made, or on whom they are binding, without reference to the life or death of the person who made them. A person is bound by the statements of his agent, acting within the scope of his authority, and barristers and solicitors are agents for their clients in the conduct of legal proceedings. Conversely, a person suing or defending on behalf of another, *e.g.*, as agent or trustee, is bound by the statements of the person whom he represents. Statements respecting property made by a predecessor in title bind the successor. Where a statement is put in evidence as an admission by, or binding on, any person, that person is entitled to have the whole statement given in evidence. The principle of this rule is obviously sound, because it would be unfair to pick out from a man's statement what tells against him, and to suppress what is in his favour. But the application of the rule is sometimes attended with difficulty. An admission will not be allowed to be used as evidence if it was made under a stipulation, express or implied, that it should not be so used. Such admissions are said to be made "without prejudice." (*i*) *Confessions.*—A confession is an admission by a person accused of an offence that he has committed the offence of which he is accused. But the rules about admitting as evidence confessions in criminal proceedings are much more strict than the rules about admissions in civil proceedings. The general rule is, that a confession is not admissible as evidence against any person except the person who makes it. But a confession made by one accomplice in the presence of another is admissible against the latter to this extent, that, if it implicates him, his silence under the charge may be used against him, whilst on the other hand his prompt repudiation of the charge might tell in his favour. In other words, the confession may be used as evidence of the conduct of the person in whose presence it was made. A confession cannot be admitted as evidence unless proved to be voluntary. A confession is not treated as being voluntary if it appears to the court to have been caused by any inducement, threat, or promise which proceeded from a magistrate or other person in authority concerned in the charge, and which, in the opinion of the court, gave the accused person reasonable ground for supposing that by making a confession he would gain some advantage or avoid some evil in reference to the proceedings against him. This applies to any inducement, threat, or promise having reference to the charge, whether it is addressed directly to the accused person or is brought to his knowledge indirectly. But a confession is not involuntary merely because it appears to have been caused by the exhortations of a person in authority to make it as a matter of religious duty, or by an inducement collateral to the proceedings, or by an inducement held out by a person having nothing to do with the apprehension, prosecution, or examination of the prisoner. Thus, a confession made to a gaol chaplain in consequence of religious exhortation has been admitted as evidence. So also has a confession made by a prisoner to a gaoler in consequence of a promise by the gaoler, that if the prisoner confessed he should be allowed to see his wife. To make a confession involuntary, the inducement must have reference to the prisoner's escape from the charge against him, and must be made by some person having power to relieve him, wholly or partially, from the consequences of the charge. A confession is treated as voluntary if, in the opinion of the court, it was made after the complete removal of the impression produced by any inducement, threat, or promise which would have made it involuntary. Where a confession was made under an inducement which makes the confession involuntary, evidence may be given of facts discovered in consequence of the confession, and of so much of the confession as distinctly relates to those facts. Thus, A. under circumstances which make the confession involuntary, tells a policeman that he, A., had thrown a lantern into the pond. Evidence may be given that the lantern was found in the pond, and that A. said he had thrown it there. It is of course improper to try to extort a confession by fraud or under the promise of secrecy. But if a confession is otherwise admissible as evidence, it does not become inadmissible *merely* because it was made under a promise of secrecy, or in consequence of a deception practised on the accused person for the purpose of obtaining it, or when he was drunk, or because it was made in answer to questions, whether put by a magistrate or by a private person, or because he was not warned that he was not bound to make the confession, and that it might be used against him. If a confession is given in evidence, the whole of it must be given, and not merely the parts disadvantageous to the accused person. Evidence amounting to a confession may be used as such against the person who gave it, though it was given on oath, and though the proceeding in which it was given had reference to the same subject-matter as the proceeding in which it is to be used, and though the witness might have refused to answer the questions put to him. But if, after refusing to answer such questions, the witness is improperly compelled to answer, his answers are not a voluntary confession. The grave jealousy and suspicion with which the English law regards confessions offer a marked contrast to the importance attached to this form of evidence in other systems of procedure, such as the inquisitorial system which long prevailed, and still to some extent prevails, on the Continent. (*j*) *Res gestæ.*—Statements are often admitted as evidence on the ground that they form part of what is called the "transaction," or *res gestæ*, the occurrence or nature of which is in question. For instance, where an act may be proved, statements accompanying and explaining the act made by or to the person doing it, may be given in evidence. There is no difficulty in understanding the principle on which this exception from the hearsay rule rests, but there is often practical difficulty in applying it, and the practice has varied. How long is the "transaction" to be treated as lasting? What ought to be treated as "the immediate and natural effect of continuing action," and, for that reason, as part of the *res gestæ?* When an act of violence is committed, to what extent are the terms of the complaint made by the sufferer, as distinguished from the fact of a complaint having been made, admissible as evidence? These are some of the questions raised. The cases in which statements by a person as to his bodily or mental condition may be put in evidence may perhaps be treated as falling under the same principle. In the Rugeley poisoning case, statements by the deceased person before his illness as to his state of health, and as to his symptoms during illness, were admitted as evidence for the prosecution. Under the same principle may also be brought the rule as to statements in conspiracy cases. In charges of conspiracy, after evidence has been given of the existence of the plot, and of the connexion of the accused with it, the charge against one conspirator may be supported by evidence of anything done, written, or said, not only by him, but by any other of the conspirators, in furtherance of the common purpose. On the other hand, a statement made by one conspirator, not in execution of the common purpose, but in narration of some event forming part of the conspiracy, would be treated, not as part of the "transaction," but as a statement excluded by the hearsay rule. Thus the admissibility of writings in conspiracy cases may depend on the time when they can be shown to have been in the possession of a fellow-conspirator, whether before or after the prisoner's apprehension. (*k*) *Complaints in rape cases, &c.*—In trials for rape and similar offences, the fact that shortly after the commission of the alleged offence a complaint was made by the person against whom the offence was committed, and also the terms of the complaint, have been admitted as evidence, not of the facts complained of, but of the consistency of the complainant's conduct with the story told by her in the witness-box, and as negativing consent on her part.

4. *Opinion.*—The rule excluding expressions of opinion also dates from the first distinction between the functions of witnesses and jury. It was for the witnesses to state facts, for the jury to form conclusions. Of course every statement of fact involves inference, and implies a judgment on phenomena observed by the senses. And the inference is often erroneous, as in the answer to the question, "Was he drunk?" A prudent witness will often guard himself, and is allowed to guard himself, by answering to the best of his belief. But, for practical purposes, it is possible to draw a distinction between a statement of facts observed and an expression of opinion as to the inference to be drawn from these facts, and the rule telling witnesses to state facts and not express opinions is of great value in keeping their statements out of the region of argument and conjecture. The evidence of "experts," that is to say, of persons having a special knowledge of some particular subject, is generally described as constituting the chief exception to the rule. But perhaps it would be more accurate to say that experts are allowed a much wider range than ordinary witnesses in the expression of their opinions, and in the statement of facts on which their opinions are based. Thus, in a poisoning case, a doctor may be asked as an expert whether, in his opinion, a particular poison produces particular symptoms.

And, where lunacy is set up as a defence, an expert may be asked whether, in his opinion, the symptoms exhibited by the alleged lunatic commonly show unsoundness of mind, and whether such unsoundness of mind usually renders persons incapable of knowing the nature of their acts, or of knowing that what they do is either wrong or contrary to the law. Similar principles are applied to the evidence of engineers, and in numerous other cases. In cases of disputed handwriting the evidence of experts in handwriting is expressly recognized by statute (28 and 29 Vict. c. 18, s. 8).

IV. *Documentary Evidence.*

Charters and other writings were exhibited to the jury at a very early date, and it is to writings so exhibited that the term "evidence" or "evidences" seems to have been originally applied *par excellence.* The oral evidence of witnesses came later. Where a document is to be used as evidence the first question is how its contents are to be proved. To this question the principle of "best evidence" applies, in the form of the rule that primary evidence must be given except in the cases where secondary evidence is allowed. By primary evidence is meant the document itself produced for inspection. By secondary evidence is meant a copy of the document, or verbal accounts of its contents.

The rule as to the inadmissibility of a copy of a document is applied much more strictly to private than to public or official documents. Secondary evidence may be given of the contents of a private document in the following cases:—

(*a*) Where the original is shown or appears to be in the possession of the adverse party, and he, after having been served with reasonable notice to produce it, does not do so.

(*b*) Where the original is shown or appears to be in the possession or power of a stranger not legally bound to produce it, and he, after having been served with a writ of *subpœna duces tecum*, or after having been sworn as a witness and asked for the document, and having admitted that it is in court, refuses to produce it.

(*c*) Where it is shown that proper search has been made for the original, and there is reason for believing that it is destroyed or lost.

(*d*) Where the original is of such a nature as not to be easily movable, as in the case of a placard posted on a wall, or of a tombstone, or is in a country from which it is not permitted to be removed.

(*e*) Where the original is a document for the proof of which special provision is made by any Act of Parliament, or any law in force for the time being. Documents of that kind are practically treated on the same footing as private documents.

(*f*) Where the document is an entry in a banker's book, provable according to the special provisions of the Bankers' Books Evidence Act, 1879.

Secondary evidence of a private document is usually given either by producing a copy and calling a witness who can prove the copy to be correct, or, when there is no copy obtainable, by calling a witness who has seen the document, and can give an account of its contents. No general definition of public document is possible, but the rules of evidence applicable to public documents are expressly applied by statute to many classes of documents. Primary evidence of any public document may be given by producing the document from proper custody, and by a witness identifying it as being what it professes to be. Public documents may always be proved by secondary evidence, but the particular kind of secondary evidence required is in many cases defined by statute. Where a document is of such a public nature as to be admissible in evidence on its mere production from the proper custody, and no statute exists which renders its contents provable by means of a copy, any copy thereof or extract therefrom is admissible as proof of its contents, if it is proved to be an examined copy or extract, or purports to be signed or certified as a true copy or extract by the officer to whose custody the original is entrusted. Many statutes provide that various certificates, official and public documents, documents and proceedings of corporations and of joint stock and other companies, and certified copies of documents, bye-laws, entries in registers and other books, shall be receivable as evidence of certain particulars in courts of justice, if they are authenticated in the manner prescribed by the statutes. Whenever, by virtue of any such provision, any such certificate or certified copy is receivable as proof of any particular in any court of justice, it is admissible as evidence, if it purports to be authenticated in the manner prescribed by law, without calling any witness to prove any stamp, seal, or signature required for its authentication, or the official character of the person who appears to have signed it. The Documentary Evidence Acts, 1868, 1882, and 1895, provide modes of proving the contents of several classes of proclamations, orders, and regulations.

If a document is of a kind which is required by law to be attested, but not otherwise, an attesting witness must be called to prove its due execution. But this rule is subject to the following exceptions:—

(*a*) If it is proved that there is no attesting witness alive, and capable of giving evidence, then it is sufficient to prove that the attestation of at least one attesting witness is in his handwriting, and that the signature of the person executing the document is in the handwriting of that person.

(*b*) If the document is proved, or purports to be, more than thirty years old, and is produced from what the court considers to be its proper custody, an attesting witness need not be called, and it will be presumed without evidence that the instrument was duly executed and attested.

Where a document embodies a judgment, a contract, a grant, or disposition of property, or any other legal transaction or "act in the law," on which rights depend, the validity of the transaction may be impugned on the ground of fraud, incapacity, want of consideration, or other legal ground. But this seems outside the law of evidence. In this class of cases a question often arises whether extrinsic evidence can be produced to vary the nature of the transaction embodied in the document. The answer to this question seems to depend on whether the document was or was not intended to be a complete and final statement of the transaction which it embodies. If it was, you cannot go outside the document for the purpose of ascertaining the nature of the transaction. If it was not, you may. But the mere statement of this test shows the difficulty of formulating precise rules, and of applying them when formulated. FitzJames Stephen mentions, among the facts which may be proved in these cases, the existence of separate and consistent oral agreements as to matters on which the document is silent, if there is reason to believe that the document is not a complete and final statement of the transaction, and the existence of any usage or custom with reference to which a contract may be presumed to have been made. But he admits that the rules on the subject are "by no means easy to apply, inasmuch as from the nature of the case an enormous number of transactions fall close on one side or the other of most of them." The underlying principle appears to be a rule of substantive law rather than of evidence. When parties to an arrangement have reduced the terms of the arrangement to a definite, complete, and final written form, they should be bound exclusively by the terms embodied in that form. The question in each case is under what circumstances they ought to be treated as having done so.

The expression "parol evidence," which includes written as well as verbal evidence, has often been applied to the extrinsic evidence produced for the purpose of varying the nature of the transaction embodied in a document. It is also applied to extrinsic evidence used for another purpose, namely, that of explaining the meaning of the terms used in a document. The two questions, What is the real nature of the transaction referred to in a document? and, What is the meaning of a document? are often confused, but are really distinct from each other. The rules bearing on the latter question are rules of construction or interpretation rather than of evidence, but are ordinarily treated as part of the law of evidence, and are for that reason included by FitzJames Stephen in his Digest. In stating these rules he adopts, with verbal modifications, the six propositions laid down by Vice-Chancellor Wigram in his

Examinations of the Rules of Law respecting the admission of Extrinsic Evidence in Aid of the Interpretation of Wills. The substance of these propositions appears to be this, that wherever the meaning of a document cannot be satisfactorily ascertained from the document itself, use may be made of any other evidence for the purpose of elucidating the meaning, subject to one restriction, that, except in cases of equivocation, *i.e.*, where a person or thing is described in terms applicable equally to more than one, resort cannot be had to extrinsic expressions of the author's intention.

V. *Witnesses.*

1. *Attendance.*—If a witness does not attend voluntarily he can be required to attend by a writ of *subpœna*.

2. *Competency.*—As a general rule every person is a competent witness. Formerly persons were disqualified by crime or interest, or by being parties to the proceedings, but these disqualifications have now been removed by statute, and the circumstances which formerly created them do not affect the competency, though they may often affect the credibility, of a witness.

Under the general law as it stood before the Criminal Evidence Act, 1898, came into force, a person charged with an offence was not competent to give evidence on his own behalf. But many exceptions had been made to this rule by legislation, and the rule itself was finally abolished by the Act of 1898. Under the new law a person charged is a competent witness, but he can only give evidence for the defence, and can only give evidence if he himself applies to do so. Under the law as it stood before 1898, persons jointly charged and being tried together were not competent to give evidence either for or against each other. Under the new law a person charged jointly with another is a competent witness, but only for the defence, and not for the prosecution. If, therefore, one of the persons charged applies to give evidence his cross-examination must not be conducted with a view to establish the guilt of the other. Consequently, if it is thought desirable to use against one prisoner the evidence of another who is being tried with him, the latter should be released, or a separate verdict of not guilty taken against him. A prisoner so giving evidence is popularly said to turn King's evidence. It follows that, subject to what has been said above as to persons tried together, the evidence of an accomplice is admissible against his principal, and *vice versâ*. The evidence of an accomplice is, however, always received with great jealousy and caution. A conviction on the unsupported testimony of an accomplice may, in some cases, be strictly legal, but the practice is to require it to be confirmed by unimpeachable testimony in some material part, and more especially as to his identification of the person or persons against whom his evidence may be received. The wife of a person charged is now a competent witness, but, except in certain special cases, she can only give evidence for the defence, and can only give evidence if her husband applies that she should do so. The special cases in which a wife can be called as a witness either for the prosecution or for the defence, and without the consent of the person charged, are cases arising under particular enactments scheduled to the Act of 1898, and relating mainly to offences against wives and children, and cases in which the wife is by common law a competent witness against her husband, *i.e.*, where the proceeding is against the husband for bodily injury or violence inflicted on his wife. The rule of exclusion extends only to a lawful wife. There is no ground for supposing that the wife of a prosecutor is an incompetent witness. A witness is incompetent if, in the opinion of the court, he is prevented by extreme youth, disease affecting his mind, or any other cause of the same kind, from recollecting the matter on which he is to testify, from understanding the questions put to him, from giving rational answers to those questions, or from knowing that he ought to speak the truth. A witness unable to speak or hear is not incompetent, but may give his evidence by writing or by signs, or in any other manner in which he can make it intelligible. The particular form of the religious belief of a witness, or his want of religious belief, does not affect his competency. This ground of incompetency has now been finally removed by the Oaths Act, 1888 (see below). It will be seen that the effect of the successive enactments which have gradually removed the disqualifications attaching to various classes of witnesses has been to draw a distinction between the *competency* of a witness and his *credibility*. No person is disqualified on moral or religious grounds, but his character may be such as to throw grave doubts on the value of his evidence. No relationship, except to a limited extent that of husband and wife, excludes from giving evidence. The parent may be examined on the trial of the child, the child on that of the parent, master for or against servant, and servant for or against master. The relationship of the witness to the prosecutor or the prisoner in such cases may affect the credibility of the witness, but does not exclude his evidence.

3. *Privilege.*—It does not follow that, because a person is *competent* to give evidence, he can therefore be compelled to do so.

No one, except a person charged with an offence when giving evidence on his own application, and as to the offence wherewith he is charged, is bound to answer a question if the answer would, in the opinion of the court, have a tendency to expose the witness, or the wife or husband of the witness, to any criminal charge, penalty, or forfeiture, which the court regards as reasonably likely to be preferred or sued for. Accordingly, an accomplice cannot be examined without his consent, but if an accomplice who has come forward to give evidence on a promise of pardon, or favourable consideration, refuses to give full and fair information, he renders himself liable to be convicted on his own confession. However, even accomplices in such circumstances are not required to answer on their cross-examination as to other offences. Where, under the new law, a person charged with an offence offers himself as a witness, he may be asked any question in cross-examination, notwithstanding that it would tend to criminate him as to the offence charged. But he may not be asked, and if he is asked must not be required to answer, any question tending to show that he has committed, or been convicted of, or been charged with, any other offence, or is of bad character, unless:—

(i.) The proof that he has committed, or been convicted of, the other offence is admissible evidence to show that he is guilty of the offence with which he is then charged; or,

(ii.) He has personally, or by his advocate, asked questions of the witnesses for the prosecution, with a view to establish his own good character, or has given evidence of his good character, or the nature or conduct of the defence is such as to involve imputations on the character of the prosecutor or the witnesses for the prosecution; or,

(iii.) He has given evidence against any other person charged with the same offence.

He may not be asked questions tending to criminate his wife.

The privilege as to criminating answers does not cover answers merely tending to establish a civil liability. No one is excused from answering a question or producing a document only because the answer or document may establish or tend to establish that he owes a debt, or is otherwise liable to any civil proceeding. It is a privilege for the protection of the witness, and therefore may be waived by him. But there are other privileges which cannot be so waived. Thus, on grounds of public policy, no one can be compelled, or is allowed, to give evidence relating to any affairs of state, or as to official communications between public officers upon public affairs, except with the consent of the head of the department concerned, and this consent is refused if the production of the information asked for is considered detrimental to the public service.

Again, in cases in which the Government is immediately concerned, no witness can be compelled to answer any question the answer to which would tend to discover the names of persons by or to whom information was given as to the commission of offences. It is, as a rule, for the court to decide whether the permission of any such question would or would not, under the circumstances of the particular case, be injurious to the administration of justice.

A husband is not compellable to disclose any communication made to him by his wife during the marriage; and a wife is not compellable to disclose any communication made to her by her husband during the marriage.

A legal adviser is not permitted, whether during or after the termination of his employment as such, unless with his client's express consent, to disclose any communication, oral or documentary, made to him *as such legal adviser*, by or on behalf of his client, during, in the course of, and for the purpose of his employment, or to disclose any advice given by him to his client during, in the course of, and for the purpose of such employment. But this protection does not extend to—

(*a*) any such communication if made in furtherance of any criminal purpose; nor

(*b*) any fact observed by a legal adviser in the course of his employment as such, showing that any crime or fraud has been committed since the commencement of his employment, whether his attention was directed to such fact by or on behalf of his client or not; nor

(*c*) any fact with which the legal adviser became acquainted otherwise than in his character as such.

Medical men and clergymen are not privileged from the disclosure of communications made to them in professional confidence, but it is not usual to press for the disclosures of communications made to clergymen.

4. *Oaths.*—A witness must give his evidence under the sanction of an oath, or of what is equivalent to an oath, that is to say, of a solemn promise to speak the truth. The ordinary form of oath is adapted to Christians, but a person belonging to a non-Christian religion may be sworn in any form prescribed or recognized by the custom of his religion.

Special provisions have been made by statute for two classes of persons: (1) Christians who object on conscientious grounds to the taking of an oath; and (2) persons who refuse to admit the binding force of an oath. Special provision was first made for Quakers and Moravians (9 Geo. IV. c. 32; 3 and 4 Will. IV. c. 49; 1 and 2 Vict. c. 77) and for Separatists. Then came general enactments relating to civil (Common Law Procedure Act, 1854, s. 20) and criminal (24 and 25 Vict. c. 66, s. 1) proceedings respectively, and allowing a witness who alleged conscientious objections to being sworn to make a solemn affirmation. The Evidence Further Amendment Act, 1869, s. 4, enabled any person who objected to take an oath, or was objected to as incompetent to take an oath (*i.e.*, on the ground that he did not recognize its binding force) to make a solemn promise and declaration in a prescribed form. The law is now embodied in the Oaths Act, 1888, under which any person, on objecting to being sworn, and stating as the ground of his objection, either that he has no religious belief, or that the taking of an oath is contrary to his religious belief, may make a solemn affirmation, which is to have the same effect, and involve the same penalties for false statement, as an oath. Under s. 5 of the same Act a person may swear in the Scottish form, with uplifted hand, and if he desires to do so "the oath shall be administered to him in such form and manner without further question"—in other words, he must not be asked as to his religious belief.

5. *Publicity.*—The evidence of a witness at a trial must, as a general rule, be given in open court in the course of the trial. The secrecy which was such a characteristic feature of the "inquisition" procedure is abhorrent to English law, and, even where publicity conflicts with decency, English courts are very reluctant to dispense with or relax the safeguards for justice which publicity involves.

6. *Examination.*—The normal course of procedure is this. The party who begins, *i.e.*, ordinarily the plaintiff or prosecutor, calls his witnesses in order. Each witness is first examined on behalf of the party for whom he is called. This is called the examination in chief. Then he is liable to be cross-examined on behalf of the other side. And, finally, he may be re-examined on behalf of his own side. After the case for the other side has been opened, the same procedure is adopted with the witnesses for that side. In some cases the party who began is allowed to adduce further evidence in reply to his opponent's evidence. The examination is conducted, not by the court, but by or on behalf of the contending parties. It will be seen that the principle underlying this procedure is that of the duel, or conflict between two contending parties, each relying on and using his own evidence, and trying to break down the evidence of his opponent. It differs from the principle of the "inquisition" procedure, in which the court takes a more active part, and in which the cases for the two sides are not so sharply distinguished. In a Continental trial it is often difficult to determine whether the case for the prosecution or the case for the defence is proceeding. Conflicting witnesses stand up together and are "confronted" with each other. In the examination in chief questions must be confined to matters bearing on the main question at issue, and a witness must not be asked leading questions, *i.e.*, questions suggesting the answer which the person putting the question wishes or expects to receive, or suggesting disputed facts about which the witness is to testify. But the rule about leading questions is not applied where the questions asked are simply introductory, and form no part of the real substance of the inquiry, or where they relate to matters which, though material, are not disputed. And if the witness called by a person appears to be directly hostile to him, or interested on the other side, or unwilling to reply, the reason for the rules applying to examination in chief breaks down, and the witness may be asked leading questions and cross-examined, and treated in every respect as though he was a witness called on the other side, except that a party producing a witness must not impeach his credit by general evidence of bad character (28 and 29 Vict. c. 18, s. 3). In cross-examination questions not bearing on the main issue and leading questions may be put and (subject to the rules as to privilege) must be answered, as the cross-examiner is entitled to test the examination in chief by every means in his power. Questions not bearing on the main issue are often asked in cross-examination merely for the purpose of putting off his guard a witness who is supposed to have learnt up his story. In cross-examination questions may also be asked which tend either to test the accuracy or credibility of the witness, or to shake his credit by impeaching his motives or injuring his character. The license allowed in cross-examination has often been seriously abused, and the power of the court to check it is recognized by one of the rules of the supreme court (R.S.C. xxxvi. 39, added in 1883). It is

considered wrong to put questions which assume that facts have been proved which have not been proved, or that answers have been given contrary to the fact. A witness ought not to be pressed in cross-examination as to any facts which, if admitted, would not affect the question at issue or the credibility of the witness. If the cross-examiner intends to adduce evidence contrary to the evidence given by the witness, he ought to put to the witness in cross-examination the substance of the evidence which he proposes to adduce, in order to give the witness an opportunity of retracting or explaining. Where a witness has answered a question which only tends to affect his credibility by injuring his character, it is only in a limited number of cases that evidence can be given to contradict his answer. Where he is asked whether he has ever been convicted of any felony or misdemeanour, and denies or refuses to answer, proof may be given of the truth of the facts suggested (28 and 29 Vict. c. 15, s. 6). The same rule is observed where he is asked a question tending to show that he is not impartial. Where a witness has previously made a statement inconsistent with his evidence, proof may be given that he did in fact make it. But before such proof is given the circumstances of the alleged statement, sufficient to designate the particular occasion, must be mentioned to the witness, and he must be asked whether he did or did not make the statement. And if the statement was made in, or has been reduced to writing, the attention of the witness must, before the writing is used against him, be called to those parts of the writing which are to be used for the purpose of contradicting him (28 and 29 Vict. c. 18, ss. 4, 5). The credibility of a witness may be impeached by the evidence of persons who swear that they, from their knowledge of the witness, believe him to be unworthy of credit on his oath. These persons may not on their examination in chief give reasons for their belief, but they may be asked their reasons in cross-examination, and their answers cannot be contradicted. When the credit of a witness is so impeached, the party who called the witness may give evidence in reply to show that the witness is worthy of credit. Re-examination must be directed exclusively to the explanation of matters referred to in cross-examination, and if new matter is, by the permission of the court, introduced in re-examination, the other side may further cross-examine upon it. A witness under examination may refresh his memory by referring to any writing made by himself at or about the time of the occurrence to which the writing relates, or made by any other person, and read and found accurate by the witness at or about the time. An expert may refresh his memory by reference to professional treatises.

For the history of the English law of evidence, see BRUNNER, *Entstehung der Schwurgerichte* ; BIGELOW, *History of Procedure in England* ; STEPHEN (Sir J. F.), *History of the Criminal Law of England* ; POLLOCK and MAITLAND, *History of English Law*, bk. ii. ch. ix. ; THAYER, *Preliminary Treatise on Evidence at the Common Law*. The principal text-books now in use are—ROSCOE, *Digest of the Law of Evidence on the Trial of Actions at Nisi Prius*, 16th ed., 1891 ; ROSCOE, *Digest of the Law of Evidence in Criminal Cases*, 12th ed., 1898 ; TAYLOR, *Treatise on the Law of Evidence*, 9th ed., 1895 ; BEST, *Principles of the Law of Evidence*, 8th ed., 1893 ; POWELL, *Principles and Practice of the Law of Evidence*, 7th ed., 1898 ; STEPHEN, *Digest of the Law of Evidence*, 5th ed., 1899 ; WILLS, *Theory and Practice of the Law of Evidence*, 1894. For history of the law of criminal evidence in France, see ESMEIN, *Hist. de la procédure criminelle en France*. For Germany, see HOLTZENDORFF, *Encyclopädie der Rechtswissenschaft* (passages indexed under head "Beweis") ; HOLTZENDORFF, *Rechtslexikon*, ("Beweis"). (C. P. I.)

Evolution.—Since Professors Huxley and Sully wrote their masterly essays in the ninth edition of this Encyclopædia, the doctrine of evolution has outgrown the trammels of controversy and has been accepted as a fundamental principle. Writers on biological subjects no longer have to waste space in weighing evolution against this or that philosophical theory or religious tradition ; philosophical writers have frankly accepted it, and the supporters of religious tradition have made broad their phylacteries to write on them the new words. A closer scrutiny of the writers of all ages who preceded Charles Darwin, and, in particular, the light thrown back from Darwin on the earlier writings of Herbert Spencer, have made plain that without Darwin the world by this time might have come to a general acceptance of evolution ; but it seems established as a historical fact that the world has come to accept evolution, first, because of Darwin's theory of natural selection, and second, because of Darwin's exposition of the evidence for the actual occurrence of organic evolution. The evidence as set out by Darwin has been added to enormously ; new knowledge has in many cases altered our conceptions of the mode of the actual process of evolution, and from time to time a varying stress has been laid on what are known as the purely Darwinian factors in the theory. The balance of these tendencies has been against the attachment of great importance to sexual selection, and in favour of attaching a great importance to natural selection ; but the dominant feature in the history of the theory since 1875 has been its universal acceptance and the recognition that this general acceptance has come from the stimulus given by Darwin.

Ontogeny.

A change has taken place in the use of the word evolution. Huxley, following historical custom, devoted one section of his article to the "Evolution of the Individual." The facts and theories respecting this are now discussed under such headings as EMBRYOLOGY, HEREDITY, and VARIATION ; under these headings must be sought information on the important recent modifications with regard to the theory of the relation between the development of the individual and the development of the race, the part played by the environment on the individual, and the modern developments of the old quarrel between evolution and epigenesis. The most striking general change has been against seeing in the facts of ontogeny any direct evidence as to phylogeny. The general proposition as to a parallelism between individual and ancestral development is no doubt indisputable, but extended knowledge of the very different ontogenetic histories of closely allied forms has led us to a much fuller conception of the mode in which stages in embryonic and larval history have been modified in relation to their surroundings, and to a consequent reluctance to attach detailed importance to the embryological argument for evolution.

Phylogeny.

The vast bulk of botanical and zoological work on living and extinct forms published during the last quarter of the 19th century increased almost beyond all expectation the evidence for the fact of evolution. The discovery of a single fossil creature in a geological stratum of a wrong period, the detection of a single anatomical or physiological fact irreconcilable with origin by descent with modification, would have been destructive of the theory and would have made the reputation of the observer. But in the prodigious number of supporting discoveries that have been made no single negative factor has appeared, and the evolution from their predecessors of the forms of life existing now or at any other period must be taken as proved. It is necessary to notice, however, that although the general course of the stream of life is certain, there is not the same certainty as to the actual individual pedigrees of the existing forms. In the attempts to place existing creatures in approximately phylogenetic order, a striking change, due to a more logical consideration of the process of evolution, has become established and is already resolving many of the earlier difficulties and banishing from the more recent tables the numerous hypothetical intermediate forms so familiar in the older phylogenetic trees. The older method was to attempt the comparison between the highest member of a lower group and the lowest member of a higher group—to suppose, for example, that the gorilla and the chimpanzee, the highest members of the apes, were the existing representatives of the ancestors of man, and to compare these forms with the lowest members of the human race. Such a comparison is necessarily illogical, as the existing apes are separated from the common ancestor by at least as large a number of generations as separate it from any of the forms of existing man. In the natural process of growth, the gap must necessarily be wider between the summits of the twigs than lower down, and, instead of imagining "missing links," it is necessary to trace each separate branch as low down as possible, and to institute the comparisons between the lowest points that can be reached. The method is simply the logical result of the fact that every existing form of life stands at the summit of a long branch of the whole tree of life. A due consideration of it leads to the curious paradox that if any two animals be compared, the zoologically lower will be separated from the common ancestor by a larger number of generations, since, on the average, sexual maturity is reached more quickly by the lower form. Naturally very many other factors have to be considered, but this alone is a sufficient reason to restrain attempts to place existing forms in linear phylogenetic series. In embryology the method finds its expression in the limitation of comparisons to the corresponding stages of low and high forms and the exclusion of the comparisons between the adult stages of low forms and the embryonic stages of higher forms. Another expression of the same method, due to Cope, and specially valuable to the taxonomist, is that when the relationship between Orders is being considered, characters of sub-ordinal rank must be neglected. It must not be supposed that earlier writers all neglected this method, or still less that all writers now employ it, but merely that formerly it was frequently overlooked by the best writers, and now is neglected only by the worst. The result is, on the one hand, a clearing away of much fantastic phylogeny, on the other, an enormous reduction of the supposed gaps between groups.

Comparative anatomy.

There has been a renewed activity in the study of existing forms from the point of view of obtaining evidence as to the nature and origin of species. Comparative anatomists have been learning to refrain from basing the diagnosis of a species, or the description of the condition of an organ, on the evidence of a single specimen. Naturalists who deal specially with museum collections have been compelled, it is true, for other reasons to attach an increasing importance to what is called the type specimen, but they find that this insistence on the individual, although convenient as a guard against rash or imperfect diagnosis, is unsatisfactory from the point of view of scientific zoology; and propositions for the amelioration of this condition of affairs range from a refusal of Linnæan nomenclature in such cases, to the institution of a division between *master species* for such species as have been properly revised by the comparative morphologist, and *provisional species* for such species as have been provisionally registered by those working at collections. Those who work with living forms of which it is possible to obtain a large number of specimens, and those who make revisions of the provisional species of palæontologists, are slowly coming to some such conception as that a species is the abstract central point around which a group of variations oscillate, and that the peripheral oscillations of one species may even overlap those of an allied species. It is plain that we have moved far from the connotation and denotation of the word *species* at the time when Darwin began to discuss the origin of species, and that the movement, on the one hand, tends to simplify the problem philosophically, and, on the other, to make it difficult for the amateur theorist.

The conception of evolution is being applied more rigidly to the comparative anatomy of organs and systems of organs. When a series of the modifications of an anatomical structure has been sufficiently examined, it is frequently possible to decide that one particular condition is primitive, ancestral, or central, and that the other conditions have been derived from it. Such a condition has been termed, with regard to the group of animals or plants the organs of which are being studied, *archecentric*. The possession of the character in the archecentric condition in (say) two of the members of the group does not indicate that these two members are more nearly related to one another than they are to other members of the group; the archecentric condition is part of the common heritage of all the members of the group, and may be retained by any. On the other hand, when the ancestral condition is modified, it may be regarded as having moved outwards along some radius from the archecentric condition. Such modified conditions have been termed *apocentric*. It is obvious that the mere apocentricity of a character can be no guide to the affinities of its possessor. It is necessary to determine if the modification be a simple change that might have occurred in independent cases, in fact if it be a multiradial apocentricity, or if it involved intricate and precisely combined anatomical changes that we could not expect to occur twice independently; that is to say, if it be a uniradial apocentricity. Multiradial apocentricities lie at the root of many of the phenomena that have been grouped under the designation *Convergence*. Especially in the case of manifest adaptations, organs possessed by creatures far apart genealogically may be moulded into conditions that are extremely alike. Ray Lankester's term, *homoplasy*, has passed into currency as designating such cases where different genetic material has been pressed by similar conditions into similar moulds. These may be called heterogenous homoplasies, but it is necessary to recognize the existence of homogeneous homoplasies, here called multiradial apocentricities. A complex apocentric modification of a kind which we cannot imagine to have been repeated independently, and which is to be designated as uniradial, frequently forms a new centre around which new diverging modifications are produced. With reference to any particular group of forms such a new centre of modification may be termed a *metacentre*, and it is plain that the archecentre of the whole group is a metacentre of the larger group of which the group under consideration is a branch. Thus, for instance, the archecentric condition of any Avian structure is a metacentre of the Sauropsidan stem. A form of apocentricity extremely common and often perplexing may be termed *pseudocentric*; in such a condition there is an apparent simplicity that reveals its secondary nature by some small and apparently meaningless complexity.

Bionomics

Another group of investigations that seems to play an important part in the future development of the theory of evolution relates to the study of what is known as organic symmetry. The differentiations of structure that characterize animals and plants are being shown to be orderly and definite in many respects; the relations of the various parts to one another and to the whole, the modes of repetition of parts, and the series of changes that occur in groups of repeated parts appear to be to a certain extent inevitable, to depend on the nature of the living material itself and on the necessary conditions of its growth. Closely allied to the study of symmetry is the study of the direct effect of the circumambient media on embryonic young and adult stages of living beings (see EMBRYOLOGY, PHYSIOLOGY OF; HEREDITY; and VARIATION), and a still larger number of observers have added to our knowledge of these. It is impossible here to give even a list of the names of the many observers who in recent times have made empirical study of the effects of growth-forces and of the symmetrical limitations and definitions of growth. It is to be noticed, however, that, even after such phenomena have been properly grouped and designated under Greek names as laws of organic growth, they have not become explanations of the series of facts they correlate. Their importance in the theory of evolution is none the less very great. In the first place, they lessen the number of separate facts to be explained; in the second, they limit the field within which explanation must be sought, since, for instance, if a particular mode of repetition of parts occur in mosses, in flowering-plants, in beetles, and in elephants, the seeker of ultimate explanations may exclude from the field of his inquiry all the conditions individual to these different organic forms, and confine himself only to what is common to all of them; that is to say, practically only the living material and its environment. The prosecution of such inquiries is beginning to make unnecessary much ingenious speculation of a kind that was prominent from 1880 to 1900; much futile effort has been wasted in the endeavour to find on Darwinian principles special "selection-values" for phenomena the universality of which places them outside the possibility of having relations with the particular conditions of particular organisms. On the other hand, many of those who have been specially successful in grouping diverse phenomena under empirical generalizations have erred logically in posing their generalizations against such a *vera causa* as the preservation of favoured individuals and races. The period between the publication of the *Origin of Species* and the writing of the article EVOLUTION in the ninth edition of this Encyclopædia was characterized chiefly by anatomical and embryological work; the period to which this supplementary article refers has been marked by no diminution in anatomical and embryological enthusiasm, but by the fact that a large number of the continually increasing body of investigators have turned again to bionomical work. Inasmuch as Lamarck attempted to frame a theory of evolution in which the principle of natural selection had no part, the interpretation placed on their work by many bionomical investigators recalls the theories of Lamarck, and the name *Neo-Lamarckism* has been used of such a school of biologists, particularly active in America. The weakness of the Neo-Lamarckian view lies in its interpretation of heredity; its strength lies in its zealous study of the living world and the detection therein of proximate empirical laws, a strength shared by very many bionomical investigations, the authors of which would prefer to call themselves Darwinians, or to leave themselves without sectarian designation.

Biometrics. Statistical inquiry into the facts of life has long been employed, and in particular Galton, within the Darwinian period, has advocated its employment and developed its methods. Within quite recent years, however, a special school has arisen with the main object of treating the processes of evolution quantitatively. It has been the habit of biologists to use the terms variation, selection, elimination, correlation, and so forth, vaguely; the new school, which has been strongly reinforced from the side of physical science, insists on quantitative measurements of the terms. When the anatomist says that one race is characterized by long heads, another by round heads, the biometricist demands numbers and percentages. When an organ is stated to be variable, the biometricist demands statistics to show the range of the variations and the mode of their distribution. When a character is said to be favoured by natural selection, the biometricist demands investigation of the death-rate of individuals with or without the character. When a character is said to be transmitted, or to be correlated with another character, the biometricist declares the statement valueless without numerical estimations of the inheritance or correlation. The subject is still so new, and its technical methods (see VARIATION) have as yet spread so little beyond the group which is formulating and defining them, that it is difficult to do more than guess at the importance of the results likely to be gained. Enough, however, has already been done to show the vast importance of the method in grouping and codifying the empirical facts of life, and in so preparing the way for the investigation of ultimate "causes." The chief pitfall appears to be the tendency to attach more meaning to the results than from their nature they can bear. The ultimate value of numerical inquiries must depend on the equivalence of the units on which they are based. Many of the characters that up to the present have been dealt with by biometrical inquiry are obviously composite. The height or length of arm of a human being, for instance, is the result of many factors, some inherent, some due to environment, and until these have been sifted out, numerical laws of inheritance or of correlation can have no more than an empirical value. The analysis of composite characters into their indivisible units and statistical inquiry into the behaviour of the units would seem to be a necessary part of biometric investigation, and one to which much further attention will have to be paid.

Segregation. It is well known that Darwin was deeply impressed by differences in flora and fauna, which seemed to be functions of locality, and not the result of obvious dissimilarities of environment. Wallace's studies of island life, and the work of many different observers on local races of animals and plants, marine, fluviatile, and terrestrial, have brought about a conception of segregation as apart from differences of environment as being one of the factors in the differentiation of living forms. The segregation may be geographical, or may be the result of preferential mating, or of seasonal mating, and its effects plainly can be made no more of than proximate or empirical laws of differentiation, of great importance in codifying and simplifying the facts to be explained.

Bathmism. Consideration of phylogenetic series, especially from the palæontological side, has led many writers to the conception that there is something of the nature of a growth-force inherent in organisms and tending inevitably towards divergent evolution. It is suggested that even in the absence of modification produced by any possible Darwinian or Lamarckian factors, that even in a neutral environment, divergent evolution of some kind would have occurred. The conception is necessarily somewhat hazy, but the words *Bathmism* and *Bathmic Evolution* have been employed by a number of writers for some such conception. Closely connected with it, and probably underlying many of the facts which have led to it, is a more definite group of ideas that may be brought together under the phrase "phylogenetic limitation of variation." In its simplest form, this phrase implies such an obvious fact as that whatever be the future development of, say, existing cockroaches, it will be on lines determined by the present structure of these creatures. In a more general way, the phrase implies that at each successive branching of the tree of life, the branches become more specialized, more defined, and, in a sense, more limited. The full implications of the group of ideas require, and are likely to receive, much attention in the immediate future of biological investigation, but it is enough at present to point out that until the more obvious lines of inquiry have been opened out much more fully, we cannot be in a position to guess at the existence of a residuum, for which such a metaphysical conception as Bathmism would serve even as a convenient disguise for ignorance.

Contributions to the theory of evolution have been extremely numerous since 1879. It has been a feature of great promise that such contributions have received attention almost directly in proportion to the new methods of observation and the new series of facts with which they have come. Those have found little favour who brought to the debate only formal criticisms or amplifications of the Darwinian arguments, or re-marshallings of the Darwinian facts, however ably conducted. The time has not yet come for the attempt to synthesize the results of the many different and often apparently antagonistic groups of workers, however plainly it may appear that they are pressing towards similar conclusions under different banners. The great work that is going on is the simplification of the facts to be explained by grouping them under empirical laws; and the most general statement relating to these that can yet be made is that no single one of these laws has as yet shown signs of taking rank as a *vera causa* comparable with the Darwinian principle of natural selection.

Evora, a city and archiepiscopal see of Portugal, capital of district Evora, about 60 miles east by south from Lisbon, at an altitude of 909 feet. Here is held, in June, one of the largest fairs in the country. The "Temple of Diana" is now used as a library. Good marble is quarried. Population, 15,134. The district of Evora has an area of 2736 square miles, and population 118,408, giving 43 inhabitants to the square mile. A great part of its surface is uncultivated. The district is famous for its mules, and abounds in cork-woods; there are mines of iron, copper, and asbestos, and marble quarries.

Evreux, chief town of department Eure, France, 67 miles west-north-west of Paris by rail. The cathedral has been entirely restored (finished 1896). The Hôtel de Ville is a handsome edifice, completed 1895; in front of it is a sculptured fountain with allegorical figures. The manufacture of ticking is the principal textile industry, and there are important iron and copper works. Population (1881), 9286; (1891), 10,825; (1901), 18,322.

Ewell, Richard Stoddert (1817–1872), American soldier, was born in Georgetown, D.C., 8th February 1817, and graduated at the U.S. Military Academy in 1840. He resigned his captain's commission in 1861, and entering the Confederate army, rose by successive grades (1861–65) from lieutenant-colonel to lieutenant-general. He lost a leg during the second Bull Run engagement in August 1862. General "Stonewall" Jackson trusted him greatly, and when fatally wounded nominated him as his successor. At the head of Jackson's veterans he fought at Winchester, Gettysburg, and the Wilderness, but was captured with his entire force by Sheridan on 6th April 1865. He died in Springfield, Tenn., on 25th January 1872.

Ewing, Juliana Horatia Orr (1842–1885), English writer of books for children, daughter of the Rev. Alfred Scott Gatty and of Margaret Gatty (see *Ency. Brit.* 9th ed. vol. x. p. 109), was born at Ecclesfield, Yorkshire, in 1842. One of a large family, she was accustomed to act as nursery story-teller to her brothers and sisters, and her brother Alfred Scott Gatty provided music to accompany her plays. She was well educated in classics and modern languages, and at an early age began to publish verses, being a contributor to *Aunt Judy's Magazine*, which her mother started in 1866. In 1867 she married Major Alexander Ewing, himself an author, and the composer of the well-known hymn "Jerusalem the Golden." From this time until her death (13th May 1885), previously to which she had been a constant invalid, Mrs Ewing produced a number of charming children's stories. The best of these are: *The Brownies* (1870), *A Flat-Iron for a Farthing* (1873), *Lob-lie-by the Fire* (1874), and *Jackanapes* (1884), the last-named, in particular, obtaining a great success; among others may be mentioned *Mrs Over-the-Way's Remembrances* (1869), *Six to Sixteen*, *Jan of the Windmill* (1876), *A Great Emergency* (1877), *We and the World* (1881), *Old-Fashioned Fairy Tales*, *Brothers of Pity* (1882), *The Doll's Wash*, *Master Fritz*, *Our Garden*, *A Soldier's Children*, *Three Little Nest-Birds*, *A Week Spent in a Glass-House*, *A Sweet Little Dear*, and *Blue-Red* (1883). Many of these were published by the S.P.C.K. Simple and unaffected in style, and sound and wholesome in matter, with quiet touches of humour and bright sketches of scenery and character, Mrs Ewing's stories have never been surpassed in the style of literature to which they belong.

Exchequer.—The ancient term "Exchequer" has survived mainly as the official title of the national banking account of the United Kingdom. For the conduct of the complicated business of a modern state many subsidiary accounts are necessary; but it is an essential part of the financial system of Great Britain that there should be one central account into which all sources of revenue flow, out of which all expenditure is provided, and on the operations of which the principal statements of national finance are based. This central account is commonly called the Exchequer, and its statutory title is "His Majesty's Exchequer." It may also be described with statutory authority as "The Account of the Consolidated Fund of Great Britain and Ireland." This account is, in fact, divided between the Banks of England and Ireland. At the head office of each of these institutions receipts are accepted and payments made on account of the Exchequer; but in published documents the two accounts are consolidated into one, the balances only at the two banks being shown separately.

Operations affecting the Exchequer are regulated by the Exchequer and Audit Departments Act, 1866. Section 10 prescribes that the gross revenue of the United Kingdom (less drawbacks and repayments, which are not really revenue) is payable, and must sooner or later be paid into the Exchequer. Section 11 directs that payments should be made from the fund so formed to meet the current requirements of spending departments. Sections 13, 14, 15 lay down the conditions under which money can be drawn from the Exchequer. Drafts on the Exchequer require the approval of an officer independent of the executive Government, the Comptroller and Auditor-General. But the description of the formal procedure required by statute cannot adequately express the actual working of the system, or the part it plays in the national finance. The simplicity of the system laid down by the Act of 1866 has been disturbed by the diversion of certain branches or portions of revenue from the Exchequer to "Local Taxation Accounts," under a system initiated by the Local Government Act, 1888, and much extended since.

While the Exchequer is, as already stated, the central account, it is not directly in contact with the details of either revenue or expenditure. As regards revenue, the produce of taxes and other sources of income passes, in the first instance, into the separate accounts of the respective receiving departments—mainly, of course, those of the Customs, Inland Revenue, and Post Office. A not inconsiderable portion is received in the provinces, and remitted to London or Dublin by bills or otherwise, and the ultimate transfers to the Exchequer are made (in round sums) from the accounts of the receiving departments in London or in Dublin. Thus, there are always considerable sums due to the Exchequer by the revenue departments; on the other hand, as floating balances are (for the sake of economy) used temporarily for current expenses, there are generally amounts due by the Exchequer to the receiving departments; such cross claims are adjusted periodically, generally once a month. Pages 16 and 17 of the "Finance Accounts of the United Kingdom for 1898–99" (House of Commons paper No. 258 of 1899), or the corresponding pages of the volume for any other year, show the gross amounts due to the Exchequer from the departments, and likewise the amounts payable out of the gross revenue in priority to the claim of the Exchequer. On the expenditure side a similar system prevails. No detailed payments are made direct from the Exchequer, but round sums are issued from it to subsidiary accounts, from which the actual drafts for the public services are met. For instance, the interest on the national debt is paid by the Bank of England from a separate account fed by transfers of round sums from the Exchequer as required. Similarly, payments for army, navy, and most civil services are met by the Paymaster-General out of an account of his own, fed by daily transfers from the Exchequer.

This system has two noticeable effects. Firstly, it secures the simplicity and finality of the Exchequer accounts, and therefore of all ordinary statements of national finance. Every evening the Chancellor of the Exchequer can tell his position so far as the Exchequer is concerned; on the first day of every quarter the Press is able to comment on the national income and expenditure up to the evening before. The annual account is closed on the evening of 31st March, and there can be no reopening of the budget of a past year such as may occur under other financial systems. The second effect of the system is to introduce a certain artificiality into the financial statements. Actual facts cannot be reduced to the simplicity of Exchequer figures; there is always (as already explained) revenue received by Government which has not yet reached the Exchequer; and there must always be a considerable outstanding liability in the form of cheques issued but not yet cashed. The suggested criticism is, however, met if it can be shown that, on the whole, the differences between the true revenue and the Exchequer receipts, or between the true (or audited) expenditure and the Exchequer issues, are not, taking one year with another, relatively considerable. The following figures illustrate this point:—

Expenditure (000s omitted)

	Exchequer Issues.	Audited Expenditure.	Difference.
	£	£	£
1888–89	85,674	86,070	+396
1889–90	86,083	86,033	− 50
1890–91	87,732	87,638	− 94
1891–92	89,928	90,125	+197
1892–93	90,375	90,164	−211
1893–94	91,303	91,530	+227
1894–95	93,919	93,818	−101
1895–96	97,764	97,667	− 97
1896–97	101,477	101,543	+ 66
1897–98	102,936	103,010	+ 74
Total for 10 years	927,191	927,598	+407

Revenue (000s omitted)

	Exchequer Receipts.	Actual Revenue.	Difference.
	£	£	£
1888–89	88,473	88,038	−435
1889–90	89,304	89,416	+112
1890–91	89,489	89,282	−207
1891–92	90,995	91,428	+433
1892–93	90,395	90,181	−214
1893–94	91,133	91,265	+132
1894–95	94,684	94,873	+189
1895–96	101,974	102,031	+ 57
1896–97	103,960	104,089	+129
1897–98	106,614	106,691	+ 77
Total for 10 years	947,011	947,294	+273

Surplus (000s omitted)

	Exchequer Accounts.	Diff. between Actual Rev. and Aud. Exp.	Difference.
	£	£	£
1888–89	2799	1968	−831
1889–90	3221	3383	+162
1890–91	1757	1644	−113
1891–92	1067	1303	+236
1892–93	20	17	− 3
1893–94	*−170*	*−265*	− 95
1894–95	765	1055	+290
1895–96	4210	4364	+154
1896–97	2473	2546	+ 73
1897–98	3678	3681	+ 3
Total for 10 years	19,820	19,696	−124

The third column in the above shows the price which has to be paid (in the form of discrepancies between facts and figures) for the simplicity secured to statements and records of the national finance by the present system embodied in the term Exchequer. Probably few will think the price too high in consideration of the advantages secured.

The principal official who derives a title from the Exchequer in its living sense is, of course, the Chancellor of the Exchequer. He is the person named second in the patent appointing commissions for executing the office of Lord High Treasurer of Great Britain and Ireland; but he is appointed Chancellor of the Exchequer for Great Britain and Chancellor of the Exchequer for Ireland by two additional patents. Although, in fact, the finance minister of the United Kingdom, he has no *statutory* power over the Exchequer apart from his position as second commissioner of the Treasury; but in virtue of his office he is by statute master of the Mint, senior commissioner for the reduction of the national debt, a trustee of the British Museum, an ecclesiastical commissioner, a member of the Board of Agriculture, a commissioner of Public Works and Buildings, Local Government, and Education, a commissioner for regulating the offices of the House of Commons, and has certain functions connected with the office of the Secretary of State for India. The only other Exchequer officer requiring mention is the Comptroller and Auditor-General, whose functions as Comptroller-General of the Exchequer have been already described.

The ancient name of the national banking account is still attached to one (until recently two) of the forms of unfunded national debt. Exchequer bills, which date from the reign of William and Mary, became extinct in 1897, and are not likely to be revived, but Exchequer bonds still possess a practical importance. An Exchequer bond is a promise by Government to pay a specified sum after a specified period, generally three or five years, and meanwhile to pay interest half-yearly at a specified rate on that sum. Government possesses no general power to issue Exchequer bonds; such power is only conferred by a special Act, and for specified purposes; but when the power has been created, Exchequer bonds issued in pursuance of it are governed by general statutory provisions contained in the Exchequer Bills and Bonds Act, 1866, and amending Acts. These Acts create machinery for the issue of Exchequer bonds and for the payment of interest thereon, and protect them against forgery.

Some traces may be mentioned of the ancient uses of the name Exchequer which still remain. The Chancellor of the Exchequer still presides at the ceremony of "pricking the list of sheriffs," which is a quasi-judicial function; and on that occasion he wears a robe of black silk with gold embroidery, which suggests a judicial costume. In England the last judge who was styled Baron of the Exchequer (Baron Pollock) died in 1897. In Scotland the jurisdiction of the Barons of the Exchequer was transferred to the Court of Session in 1856, but the same Act requires the appointment of one of the judges as "Lord Ordinary in Exchequer causes," which office still exists. In Ireland there remains a Lord Chief Baron of the Exchequer (Palles) who, however, is now a member of the King's Bench Division, and will be replaced by an ordinary judge of the division. A street near Dublin Castle is called Exchequer Street, recalling the separate Irish Exchequer, which ceased in 1817. The old term also survives in the full title of the Treasury representative in Scotland, which is "The King's and the Lord Treasurer's Remembrancer in Exchequer," while his office in the historic Parliament Square is styled "Exchequer Chambers." (S. E. S.-R.)

Excise Revenue.—The duties of excise in the United Kingdom are under the control of the Commissioners of Inland Revenue; the amount raised, apart from changes in the rate, shows a fairly constant tendency to increase, and is usually regarded as one of the best tests of the prosperity of the working classes. In the year 1900–1 the amount raised under the several heads of duty was as follows:—Spirit duty, £20,124,003; beer duty, £13,940,536; excise licences, £4,136,526; railway passenger duty, £331,214; miscellaneous, £7808; total, £38,540,087. Of this total about £33,200,000 was paid into the Exchequer, and about £5,200,000 to the Local Taxation Account in aid of the expenditure of local authorities. More than 88 per cent. of the whole revenue was derived from the taxation of two articles—spirits and beer.

The *spirit duty* is levied according to the quantity of "proof spirit" contained in the product of distillation, and the charge is taken at three different points in the process of manufacture, the trader being liable for the result of the highest of the three calculations. What is known as "proof spirit" is obtained by mixing nearly equal weights of pure alcohol and water, the quantity of pure alcohol being in bulk about 57 per cent. of the whole. The rate of duty in the year 1900 was 11s. per proof gallon, of which 6d. per gallon was paid to the Local Taxation Account. Owing to the high rate of duty as compared with the volume and intrinsic value of the spirits, the whole process of manufacture is carried on under the close supervision of revenue officials. All the vessels used are measured by them and are secured with revenue locks; the premises are under constant survey; and notice has to be given by the distiller of the materials used and of the several stages of his operations. Though the charge for duty is raised at the time when the process of distillation is completed, the duty is not actually paid until the spirits are required for consumption. In the meanwhile they may be retained in an approved "warehouse," which is also subject to close supervision.

The *beer duty* dates from 1880, in which year it was substituted for the duty on malt. In the first complete year after its imposition it produced £8,500,000. The rate of duty in 1900 was 7s. 9d. for every 36 gallons of worts at the standard gravity of 1055°. Out of this sum 3d. was paid to the Local Taxation Account and the remainder to the Exchequer. The specific gravity of the worts depends chiefly on the amount of sugar which they contain, and is ascertained by the saccharometer.

Excise *licences* may be divided into—(*a*) licences for the sale or manufacture of excisable liquors (about £2,180,000), (*b*) licences for other trades, such as tobacco dealers or manufacturers, auctioneers, pawnbrokers, &c. (about £330,000), (*c*) licences for male servants, carriages, and armorial bearings (about £749,000), and (*d*) gun, game, and dog licences (about £868,000). Nearly the whole of the licence duties (with the exception of about £250,000) is paid over to the Local Taxation Account.

The *railway passenger duty*, which was made an excise duty by 10 and 11 Vict. cap. 42, applies only to Great Britain. It is levied on all passenger fares exceeding 1d. per mile, the rate being 2 per cent. on urban, and 5 per cent. on other traffic.

The other items which go to make up the excise revenue are the charges on deliveries from bonded warehouses (£5168), and the duties on coffee mixture labels (£1573), and on chicory (£1067). For more detailed information reference should be made to Highmore's *Excise Laws*, and the annual reports of the Commissioners of Inland Revenue, especially those issued in 1870 and 1885. (G. H. M.)

Execution, Civil.—Execution may be defined as the process by which the judgments or orders of courts of law are made effectual. The English law of execution is very complicated, and only a statement of the principal forms can here be attempted. To begin with the High Court of Justice: A judgment for the recovery of money or costs is enforced, as a rule, by a writ of *fieri facias* addressed to the sheriff, and directing him to cause to be made (*fieri facias*) of the goods and chattels of the debtor a levy of a sufficient sum to satisfy the judgment. The wearing apparel, bedding, tools, &c., of the debtor to the value of £5 are protected. Competing claims are brought before the courts by the procedure of "interpleader." Where it is necessary to have recourse to the debtor's land for the purpose of getting payment of a judgment debt, a writ of *elegit* is issued to the sheriff, and the value of the land is assessed by an inquisition before a jury. Where a judgment directing the payment of money into court, or the performance by the defendant of any act within a limited time, has not been complied with, or where a corporation has wilfully disobeyed a judgment, a writ of sequestration is issued, to not less than four sequestrators, ordering them to enter upon the real estate of the party in default, and "sequester" the rents and profits until the judgment has been obeyed. Judgments for the recovery or for the delivery of the possession of land are enforceable by writ of possession. The recovery of specific chattels is obtained by writ of delivery. A judgment creditor may "attach" debts due by third parties to his debtor by what are known as garnishee proceedings. Stock and shares belonging to a judgment debtor may be charged by a charging order, so as, in the first instance, to prevent transfer of the stock or payment of the dividends, and ultimately to enable the judgment creditor to realise his charge. Under the Judgments Act, 1864, a debtor's interest in land may be sold. Where a judgment creditor is otherwise unable to reach the property of his debtor he may obtain equitable execution, usually by the appointment of a receiver, who collects the rents and profits of the debtor's land for the benefit of the creditor. A writ of attachment of the person of a defaulting debtor or party may be obtained in a variety of cases akin to contempt (*e.g.*, against a person failing to comply with an order to answer interrogatories, or against a solicitor not entering an appearance in an action, in spite of his written undertaking to do so), and in the cases where imprisonment for debt is still preserved by the Debtors Act, 1869. Contempt of court (*q.v.*) in its ordinary forms is also punishable by summary committal. In the county courts the chief modes of execution are "warrant of execution in the nature of a writ of *fieri facias*"; garnishee proceedings; equitable execution; warrants of possession and delivery, corresponding to the writs of possession and delivery above mentioned; committal, where a judgment debtor has, or, since the date of the judgment has had, means to pay his debt; and attachment of the person for contempt.

The principal modes of execution or "diligence" in Scots law are (i.) Arrestment and furthcoming, which corresponds to the English garnishee proceedings; (ii.) Arrestment *jurisdictionis fundandæ causâ*, *i.e.*, the seizure of movables within the jurisdiction to found jurisdiction against their owner, being a foreigner; this procedure, which is not, however, strictly a "diligence," as it does not bind the goods, is analogous to the French *saisie-arrêt*, and to the obsolete practice in the Mayor's Court of London known as "foreign attachment" (see Glyn and Jackson, *Mayor's Court Practice*, 2nd ed., vii. 260); (iii.) Arrestment under *meditatione fugæ* warrant, corresponding to the old English writ of *ne exeat regno*, and applicable in the case of a debtor who intends to leave Scotland to evade an action; (iv.) Arrestment on dependence, *i.e.*, of funds in security; (v.) Poinding, *i.e.*, valuation and sale of the debtor's goods; (vi.) Sequestration, *e.g.*, of tenant's effects under a landlord's hypothec for rent; (vii.) Action of adjudication, by which a debtor's "heritable" (*i.e.*, real) estate is transferred to his judgment creditor in satisfaction of his debt or security therefor. In Scots law "multiplepoinding" is the equivalent of "interpleader."

Execution in the *United States* is founded upon English law, which it closely resembles. See Bouvier, *Law. Dict.* (ed. Rawle, 1897, *s.v.* "Execution"). The "homestead laws" of various states exempt a certain amount or value of real estate occupied by a debtor as his homestead from a forced sale for the payment of his debts. This homestead legislation has been copied in some British Colonies (see *Journn. Soc. Comp. Leg.* N.S. No. III. pp. 441–48).

(A. W. R.)

Exeter, a city and county of itself, municipal, county (1888), and parliamentary borough, port and county town of Devonshire, England, on the Exe, 194 miles by rail west-south-west of London. In 1885 the parliamentary representation was reduced to one. In 1877 the grammar school was reorganized, the present buildings being erected on a new site in 1886. There are also a technical university extension college, an industrial, and a reformatory school. Among recent erections are four Established churches, a Roman Catholic church, a public hall, a volunteer drill hall, and an additional wing to the Technical and University Extension College. Belmont Pleasure Ground and the city asylum, costing £80,000, were both opened in 1886. There are four daily newspapers. Exeter has several large foundries. The imports of foreign and colonial merchandise in 1898 amounted to the value of £117,665, against £173,069 in 1888. In 1898, 24 vessels of 1514 tons were registered at the port. Showing a slight increase on 1888 were: entrances, 981 vessels of 79,333 tons; clearances, 979 of 78,193. Area of municipal and county borough and city prior to extension in 1900, 1883 acres. Population (1881), 37,447; (1891), 37,404. Extended area, 3158 acres. Population (1891), 45,588; (1901), 47,180.

Exhibitions.—The first exhibition of which there is any account, in either sacred or profane history, was that held by King Ahasuerus, who, according to the Book of Esther, showed in the third year of his reign "the riches of his glorious kingdom, and the honour of his excellent majesty, many days, even a hundred and fourscore days." The locale of this function was Shushan, the palace and the exhibits consisted of "white, green, and blue hangings, fastened with cords of fine linen and purple to silver rings and pillars of marble: the beds were of gold and silver, upon a pavement of red, and blue, and white, and black marble. And they gave them drink in vessels of gold, the vessels being diverse one from another." The first exhibition since the Christian era was at Venice during the dogeship of Lorenzo Tiepolo, in 1268. On that occasion there was a grand display, consisting of a water fête, a procession of the trades, and an industrial exhibition. The various guilds of the Queen City of the Seas marched through the narrow streets to the great square of St Mark, and their leaders asked the Dogaressa to inspect the products of their industry. Other mediæval exhibitions were the fairs held at Leipzig and Nijni-Novgorod in Europe, at Tantah in Egypt, and in 1689 that by the Dutch at Leyden.

The first modern exhibition was held at London in 1756 by the Society of Arts, which offered prizes for improvements in the manufacture of tapestry, carpets, and porcelain, the exhibits being placed side by side. Five years afterwards, in 1761, the same society gave an exhibition of agricultural machinery. In 1797 a collective display of the art factories of France, including those of Sèvres, the Gobelins, and the Savonnerie, was made in the Palace of St Cloud, and the exhibition was repeated during the following year in the Rue de Varennes, Paris. This experiment was so successful that in the last three days of the same year an exhibition under official auspices, at which private exhibitors were allowed to compete, was held in the Champ de Mars. Four years later, in 1801, there was a second official exhibition in the Grand Court of the Louvre. Upon that occasion juries of practical men examined the objects shown, and the winners of a gold medal were invited to dine with Napoleon, who was at that time First Consul. In the report of the jury the following remarkable sentence appeared:—"There is not an artist or inventor who, once obtaining thus a public recognition of his ability, has not found his reputation and his business largely increased." The third Paris Exhibition, held in 1802, was the first to publish an official catalogue. There were 540 exhibitors, including Montgolfier, the first aëronaut, and Jacquard, the inventor of the loom which bears his name. The fourth exhibition was held in 1806 in the esplanade in front of the Hotel des Invalides, and attracted 1422 exhibitors. There were no more exhibitions till after the fall of the empire, but in 1819 the fifth was held during the reign of Louis XVIII., with 1622 exhibitors. Others were held at Paris at various intervals, that in 1849 having 4500 exhibitors.

Other exhibitions, though on a smaller scale, were held in Dublin, London, and in various parts of Germany and Austria during the first half of the 19th century—that in 1844, held at Berlin, having 3040 exhibitors. Switzerland, Holland, Belgium, Sweden, Russia, Poland, Italy, Spain, and Portugal all held exhibitions, and there was a Free Trade Bazaar of British Manufactures at Covent Garden Theatre in 1845, which at the time created a great deal of interest. But all these exhibitions were confined to the products of the country in which they took place, and the first great International Exhibition was held in London in 1851 by the Society of Arts, under the Presidency of the Prince Consort All nations were invited to compete; a site was obtained in Hyde Park, and a building 20 acres in extent was erected, after the design of Sir Joseph Paxton, at a cost of £193,168. The exhibition was open for five months and fifteen days. The receipts amounted to £506,100, and the surplus was £186,000. The number of visitors was 6,039,195, and the money taken at the doors was £423,792. The total number of exhibitors was 13,937, of which Great Britain contributed 6861, the British Colonies 520, and foreign countries 6556. The International Exhibition of 1851 was followed by those of New York and Dublin in 1853, Melbourne and Munich in 1854, and Paris in 1855,—this latter was held in the Palais d'Industrie, which remained in existence until pulled down to make room for the two Palais des Beaux Arts, which formed one of the attractions of the 1900 exhibition. The exhibitors numbered 20,839, and the visitors 5,162,330. There were national exhibitions during the following years in several European countries, but the next great world's fair was held at London in 1862. The total space roofed in amounted to 988,000 square feet, 22·65 acres, the number of visitors was 6,211,103, and the amount received at the doors £408,530. The death of the Prince Consort had a depressing effect upon the enterprise. In 1865 an exhibition was held at Dublin, the greater proportion of the funds being supplied by Sir Benjamin Lee Guinness. The number of attendances during six months was 900,000, and the exhibition was opened at night. An Italian exhibition was held at Rome in 1862.

The Paris Exhibition of 1867 was upon a far larger scale than that of 1855. It was held, like those that preceded and succeeded it, at the Champ de Mars, and covered 41 acres. The building resembled an exaggerated gasometer. The external ring was devoted to machinery, the internal to the gradual development of civilisation, commencing with the stone age and continuing to the present era. A great feature of the exhibition was the park, which was studded with specimens of every style of modern architecture—Turkish mosques, Swedish cottages, English lighthouses, Egyptian palaces, and Swiss châlets. The number of attendances was 6,805,969. The exhibitors numbered 43,217, and the total amount received for entrances, concessions, &c., was £420,735. This was the first exhibition at which there were international restaurants. The cost of the exhibition was defrayed partly by the State and partly by private subscriptions.

Small exhibitions were held in various parts of Europe between 1867 and 1870, and in the latter year a series of international exhibitions, confined to one or two special descriptions of produce or manufactures, was inaugurated in London at South Kensington. These continued till 1874, but they failed to attract any very large attendance of the public, and were abandoned. A medal was given to each exhibitor, and reports on the various exhibits were published, but there was no examination of the exhibits by jurors. In 1873 there was an International Exhibition at Vienna. The main building, a rotunda, was erected in the beautiful park of the Austrian capital. There were halls for machinery and agricultural products, and hundreds of buildings, erected by different nations, were scattered amongst the woodlands of the Prater. Unfortunately, an outbreak of cholera diminished the attendance of visitors, and the receipts were only £206,477, although the visitors were said to have reached 6,740,500, and the number of exhibitors was 25,760.

None of the International Exhibitions held between 1857 and 1873 had attracted as many as 7,000,000 visitors, but the gradual extension of education amongst the masses, and the greater facilities for locomotion, brought about by the growth of the railway system in all portions of the civilized world, largely increased the attendances at subsequent World's Fairs. The Centennial Exhibition of 1876, to celebrate the one-hundredth anniversary of American Independence, was held at Fairmount Park, Philadelphia. The funds were raised partly by private subscriptions, and partly by donations from the city of Philadelphia, from Pennsylvania, and some of the neighbouring states. The Central Government at Washington made a large loan, which was subsequently repaid. The principal buildings, five in number, occupied an area of 48½ acres, and there were several smaller structures, which in the aggregate must have filled half as much space more, the largest being that devoted to the exhibits of the various departments of the United States Government, which covered 7 acres. Several novelties in exhibition management were introduced at Philadelphia. Instead of gold, silver, and bronze medals, only one description, bronze, was issued, the difference between the merits of the different exhibits being shown by the reports. Season tickets were not issued, and the price of admission, the same on all occasions, was half a dollar, or about 2s. 1d. The exhibition was not open at night or on Sundays, thus following the British, and not the continental, precedent. The number of visitors was 9,892,625, of whom 8,004,214 paid for admission, the balance being exhibitors, officials, and attendants. The total receipts amounted to £763,899. Upon one occasion, the Pennsylvania day, 274,919 persons—the largest number that had visited any exhibition up to that date—passed through the turnstiles. The display of machinery was the finest ever made, that of the United States occupying 480,000 square feet. The motive-power was obtained from a Corliss engine of 1600 horse-power. At this exhibition the United Kingdom and the British Colonies of Canada, Victoria, New South Wales, New Zealand, Cape Colony, and Tasmania made a very fine display, which was only excelled by that of the United States.

The Paris Exhibition of 1878 was upon a far larger scale in every respect than any which had been previously held in any part of the world. The total area covered not less than 66 acres, the main building in the

Champ de Mars occupying 54 acres. The French exhibits filled one-half the entire space, the remaining moiety being occupied by the other nations of the world. The United Kingdom, British India, Canada, Victoria, New South Wales, Queensland, South Australia, Cape Colony, and some of the British Crown Colonies occupied nearly one-third of the space set aside for nations outside France. Germany was the only great country which was not represented, but there were a few German paintings. The display of fine arts and machinery was upon a very large and comprehensive scale, and the Avenue des Nations, a street 2400 feet in length, was devoted to specimens of the domestic architecture of nearly every country in Europe, and to several in Asia, Africa, and America. The palace of the Trocadero, on the northern bank of the Seine, was erected for the exhibition. It was a handsome structure, with towers 250 feet in height, and flanked by two galleries. The rules for admission were the same as those at Philadelphia, and every person—exhibitor, journalist, or official—who had the right of entrance was compelled to forward two copies of his or her photograph, one of which was attached to the card of entry. The ordinary tickets were not sold at the doors, but were obtainable at various Government offices and shops, and from numerous pedlars in all parts of the city and suburbs. The buildings were somewhat unfinished upon the opening day, political complications having prevented the French Government and the French people from paying much attention to the exhibition till about six months before it was opened; but the efforts made in April were prodigious, and by June 1st, a month after the opening, the exhibition was complete, and afforded an object-lesson of the recovery of France from the calamities of 1870–71. The decisions arrived at by the international juries were accompanied by medals of gold, silver, and bronze. The expenditure by the United Kingdom was defrayed out of the consolidated revenue, each British colony defraying its own expenses. The display of the United Kingdom was under the control of a Royal Commission, of which the Prince of Wales was President. The number of paying visitors to the exhibition was 13,000,000, and the cost of the enterprise to the French Government, which supplied all the funds, was a little less than a million sterling, after allowing for the value of the permanent buildings and the Trocadero Palace, which were sold to the city of Paris. The total number of persons who visited Paris during the time the exhibition was open was 571,792, or 308,974 more than came to the French metropolis during the year 1877, and 46,021 in excess of the visitors during the previous exhibition of 1867. It was stated at the time that, in addition to the impetus given to the trade of France, the revenue of the Republic and of the city of Paris from customs and octroi duties was increased by nearly three millions sterling as compared with the previous year.

Exhibitions on a scale of considerable magnitude were held at Sydney and Melbourne in 1879 and 1880, and many Continental and American manufacturers took advantage of them in order to bring the products of their industry directly under the notice of Australian consumers, who had previously purchased their supplies through the instrumentality of British merchants. The United Kingdom and India made an excellent display at both cities, but the effect of the two great Australian exhibitions was to give a decided impetus to German, American, French, and Belgian trade. One of the immediate results was that lines of steamers to Melbourne and Sydney commenced to run from Marseilles and Bremen; another, that for the first time in the history of the Australian Colonies, branches of French banks were opened in the two principal cities. The whole cost of these exhibitions was defrayed by the local Governments.

Exhibitions were held at Turin and Brussels during 1880, and smaller ones at Newcastle, Milan, Lahore, Adelaide, Perth, Moscow, Ghent, and Lille during 1881 and 1882, and at Zurich, Bordeaux, and Caraccas in Venezuela during 1883. The next of any importance was held at Amsterdam in the latter year. On that occasion a new departure in Exhibition management was made. The Government of the Netherlands was to a certain extent responsible for the administration of the exhibition, but the funds were obtained from private sources, and a charge was made to each nation represented for the space it occupied. The United Kingdom, India, Victoria, and New South Wales took part in the exhibition, but there was no official representation of the mother country. Exhibitions on somewhat similar lines were held at Nice and Calcutta in the winter of 1883 and 1884, and at Antwerp in 1895.

A series of exhibitions, under the Presidency of the Prince of Wales, and managed by the late Sir Cunliffe Owen, was commenced at South Kensington in 1883. The first was devoted to a display of the various industries connected with Fishing; the second, in 1884, to objects connected with Hygiene; the third, in 1885, to Inventions; and the fourth, in 1886, to the British Colonies and India. These exhibitions attracted a large number of visitors, and realized a substantial profit. They might have been continued indefinitely if it had not been that the buildings in which they were held had become very dilapidated, and that the ground covered by them was required for other purposes. There was no examination of the exhibits by juries, but a tolerably liberal supply of instrumental music was supplied by military and civil bands. The Crystal Palace held a successful International Exhibition in 1884, and there was an Italian Exhibition at Turin, and a Forestry Exhibition at Edinburgh, during the same year. A World's Industrial Fair was held at New Orleans in 1884–85, and there were Universal Exhibitions at Montenegro and Antwerp in 1885, at Edinburgh in 1886, Liverpool, Adelaide, Newcastle, and Manchester in 1887, and at Glasgow, Barcelona, and Brussels in 1888. Melbourne held an International Exhibition in 1888–89 to celebrate the Centenary of Australia. Great Britain, Germany, France, Austria, and the United States were officially represented, and an expenditure of £237,784 was incurred by the local Government.

The Paris Exhibition of 1889 marked an important change in the policy which had previously characterized the management of these gatherings. The funds were contributed partly by the State, which voted 17,000,000 francs, and by the municipality of Paris, which gave 8,000,000. A guarantee fund amounting to 23,124,000 francs was raised, and on this security a sum of 18,000,000 francs was obtained and paid into the coffers of the administration. The bankers who advanced this sum recouped themselves by the issue of 1,200,000 "bons," each of 25 francs. Every bon contained 25 admissions, valued at 1 franc, and certain privileges in the shape of participation in a lottery, the grand prix being £20,000. The calculations of the promoters were tolerably accurate. The attendances reached the then unprecedented number of 32,350,297, of whom 25,398,609 paid in entrance tickets, and 2,723,366 entered by season tickets. A sum of 2,307,999 francs was obtained by concessions for restaurants and "side-shows," upon which the administration relied for much of the attractiveness of the exhibition. The total expenditure was 44,000,000 francs, and there was a small surplus. The space covered in the Champ de Mars, the Trocadero, the Palais d'Industrie, the Invalides, and the Quai d'Orsay was 72 acres, as compared with 66 acres in 1878, and 41 acres in 1867. Amongst the novelties was the Eiffel Tower, 1000 feet in height, and a faithful reproduction of a street in Cairo. The system of international juries was continued, but instead of gold, silver, and copper medals, diplomas of various merits were granted, each entitling the holder to a uniform medal of bronze. Some of the "side-shows" did not add to the dignity, although perhaps to the pecuniary success, of the exhibition. The date at which it was held, the Centenary of the French Revolution, did not commend it to several European Governments. Austria, Hungary, Belgium, China, Egypt, Spain, Great Britain, Italy, Luxembourg, Holland, Peru, Portugal, Rumania, and Russia took part, but not officially, while Germany, Sweden, Turkey, and Montenegro were conspicuous by their absence. On the other hand, Argentina, Bolivia, Chili, the United States, Greece, Guatamala, Morocco, Mexico, Nicaragua, Norway, Paraguay, Salvador, the South African Republic, Switzerland, Uruguay, and Venezuela sent Commissioners, who were accredited to the Government of the French Republic. The total number of exhibitors was 61,722, of which France contributed 33,937, and the rest of the world 27,785. The British and Colonial section was under the management of the Society of Arts, which obtained a guarantee fund of £16,800, and, in order to recoup itself for its expenditure, made a charge to exhibitors of 5s. per square foot for the space occupied. There were altogether 1149 British exhibitors, of whom 429 were in the Fine Arts section. One of the features of the exhibition was the number of congresses and conferences held in connexion with it.

During the year 1890 there was a Mining Exhibition at the Crystal Palace, and a Military Exhibition in the grounds of Chelsea Hospital; in 1891, a Naval Exhibition at Chelsea, and an International at Jamaica. In 1891–92 there were exhibitions at Palermo and at Launceston in Tasmania; in 1892, a Naval Exhibition at Liverpool, and one of Electrical Appliances at the Crystal Palace. A series of small national exhibitions under private management were held at Earl's Court between 1887 and 1891. The first of the series was that of the United States—Italy followed in 1888, Spain in 1889, France in 1890, and Germany in 1891.

The next Exhibition of the first order of magnitude was at Chicago in 1893, and was held in celebration of the 400th anniversary of the discovery of America by Columbus. The financial arrangements were undertaken by a company, with a capital of £2,000,000. The Central Government at Washington allotted £20,000 for the purposes of foreign exhibits, and £300,000 for the erection and administration of a building to contain exhibits from the various Departments of State. The exhibition was held at Jackson Park, a place for public recreation, 580 acres in extent, situated on the shore of Lake Michigan, on the southern side of the city, with which it was connected by railways and tramways. Special provision was made for locomotion in the grounds themselves by a continuous travelling platform and an elevated electric railway. The proximity of the lake, and of some artificial canals which had been constructed, rendered possible the service of electric and steam launches. The exhibition remained open from May 1st to October 30th, and was visited by 21,477,212 persons, each of whom paid half a dollar (about 2s. 1d.) for admission. The largest number of visitors on any one day was 716,881. In addition to its direct vote of £320,000, Congress granted £500,000 to the Exhibition in a special coinage, which sold at an enhanced price. The receipts from admissions were £2,120,000; from concessions, £750,000; and the miscellaneous receipts, £159,000: total, £3,029,000. The total expenses were £5,222,000. Of the sums raised by the Company, £400,000 was returned to the subscribers. Speaking roughly, it may be said that the total outlay on the Chicago Exhibition was six millions sterling, of which three millions were earned by the Fair, two millions subscribed by Chicago, and a million provided by the United States Government. The sums expended by the participating foreign Governments was estimated at £1,440,000. The total area occupied by buildings at Chicago was as nearly as possible 200 acres, the largest building, that devoted to Manufactures, being 1687 feet by 787, and 30·5 acres. The funds for the British Commission, which was under the control of the Society of Arts, were provided by the Imperial Government, which granted £60,000. The number of British exhibitors was 2236, of whom 597 were Industrial, 501 Fine Arts, and 1138 Women's work. In this total was included 18 Indian exhibitors. The space occupied by Great Britain was 306,285 square feet; and, in addition, separate buildings were erected in the grounds. These were Victoria House, the headquarters of the British Commission; the Indian Pavilion, erected by the Indian Tea Association; the Kiosk of the White Star Steamship Company; and the structure set up by the Maxim-Nordenfelt Company. Canada and New South Wales had separate buildings, which covered 100,140 and 50,951 square feet respectively; and Cape Colony occupied 5250, Ceylon 27,574, British Guiana 3367, Jamaica 4250, Trinidad 3400, and India 3584 square feet in the several buildings. The total space occupied by the British Colonies was therefore 193,660 square feet. The system of awards was considered extremely unsatisfactory. Instead of international juries, a single judge was appointed for each class, and the recompenses were all of one grade, a bronze medal and a diploma, on which was stated the reasons which induced the judge to make his decision. Some judges took a high standard, and refused to make awards except to a small proportion of selected exhibits; others took a low one, and gave awards indiscriminately. About 1183 awards were made to British exhibitors. The French refused to accept any awards. The value of the British goods exhibited was estimated, exclusive of Fine Arts, at £430,000, and the expenses of showing them at £200,000. A large expenditure was incurred in the erection of buildings, which were more remarkable for their beauty and grandeur than for their suitableness to the purposes for which they were intended. Considerable areas were devoted to "side-shows," and the midway Plaisaunce, as it was termed, resembled a gigantic fair. Every country in the world contributed something. There were sights and shows of every sort from everywhere. The foreign countries represented were Argentina, Austria, Belgium, Bolivia, Brazil, Bulgaria, Chili, Columbia, Costa Rica, Cuba, Curaçoa, Denmark, Danish West Indies, Ecuador, France, Germany, Greece, Guatamala, Honduras, Hayti, Japan, Johore, Korea, Liberia, Mexico, Monaco, Netherlands, Norway, Orange Free State, Paraguay, Persia, Portugal, Russia, Siam, Spain, Sweden, Turkey, United Kingdom and Colonies, Uruguay, and Venezuela.

Exhibitions were held at Antwerp, Madrid, and Bucharest in 1894; Hobart in 1894–95; Bordeaux, 1895; Niji Novgorod, Berlin, and Buda-Pest in 1896; Brussels and Brisbane in 1897. A series of exhibitions, under the management of the London Exhibitions Company, commenced at Earls Court in 1895 with that of India. India and Ceylon followed in 1896, the Victorian Era in 1897, the Universal in 1898, the Greater Britain (at which Victoria, Queensland, West Australia, Rhodesia, West

Africa, and the West Indies were represented) in 1899, Woman's Work in 1900, and a Military Exhibition in 1901.

The Paris Exhibition of 1900 was larger than any which had been previously held in Europe. The buildings did not cover so much ground as those at Chicago, but many of those at Paris had two or more floors. In addition to the localities occupied in 1889, additional space was obtained at the Champs Elysées, the Park of Vincennes, on the north bank of the Seine between the Place de la Concorde, and at the Trocadero. The total superficial area occupied was as follows:—Champs de Mars, 124 acres; Esplanade des Invalides, 30 acres; Trocadero Gardens, 40 acres; Champs Elysées, 37 acres; quays on left bank of Seine, 23 acres; quays on right bank of Seine, 23 acres; Park at Vincennes, 270 acres: total, 549 acres. The space occupied by buildings and covered in amounted to 4,865,328 square feet, $111\frac{1}{2}$ acres. The French section covered 2,691,000 square feet, the Foreign 1,829,880, and those at the Park of Vincennes 344,448 square feet. About one hundred French and seventy-five Foreign pavilions and detached buildings were erected in the grounds in addition to the thirty-six official pavilions, which were for the most part along the Quai d'Orsay. Funds were raised upon the same system as was adopted in 1889. The French Government granted £800,000, and a similar sum was contributed by the municipality of Paris. £2,400,000 was raised by the issue of 3,250,000 "bons," each of the value of 20 francs, and containing 20 tickets of admission to the Exhibition of the face value of one franc each, and a document which gave its holder a right either to a reduced rate for admission to the different "side-shows" or else to a diminution in the railway fare to and from Paris, together with a participation in the prizes, amounting to six million francs, drawn at a series of lotteries. Permission to erect restaurants, and to open places of amusement in buildings erected for that purpose, were sold at high prices, and for these privileges, which only realised 2,307,999 francs in 1889, the concessionaires agreed to pay 8,864,442 francs in 1900. The results did not justify the expectations which had been formed, and the administration finally consented to receive a much smaller sum. The administration calculated that they would have 65,000,000 paying visitors, though there were only 13,000,000 in 1878 and 25,398,609 in 1889. A very few weeks after the opening day, April 15th, it became evident that the estimated figures would not be reached, and as a large number of holders of "bons" threw them on the market, and the selling price of an admission ticket declined from the par value of one franc to less than half that amount, or from 30 to 50 centimes. The proprietors of the restaurants and "side-shows" discovered that they had paid too much for their concessions, that the buildings they had erected were far too handsome and costly to be profitable, and that the public preferred the Exhibition itself to the so-called attractions. The Exhibition was largely visited by foreigners, but various causes kept away many persons of wealth and position. Although many speculators were ruined, the Exhibition itself was successful. The attendance was unprecedentedly large, and during the seven months the Exhibition was open, 39,000,000 persons paid for admission with 47,000,000 tickets, since from two to five tickets were demanded at certain times of the day and on certain occasions. The entries of exhibitors, attendants, and officials totalled 9,000,000. The receipts were 114,456,213 francs (£4,578,249), and the expenditure 116,500,000 (£4,660,000), leaving a deficiency of rather more than two millions of francs (£80,000). It was calculated that the expenditure of the foreign nations which took part in the Exhibition was six millions sterling, and of the French exhibitors and concessionaires three millions sterling.

A new plan of classifying exhibits was adopted at Paris, all being displayed according to their nature, and not according to their country of origin, as had been the system at previous Exhibitions. One-half the space in each group was allotted to France, so that the exhibitors of that nation were enabled to overwhelm their rivals by the number and magnitude of the objects displayed by them. All the agricultural implements, whatever their nationality, were in one place, all the ceramics in another, so that there was no exclusively British and no exclusively German court. The only exceptions to this rule was in the Trocadero, where the French, British, Dutch, and Portuguese Colonies, Algeria, Tunis, Siberia, the South African Republic, China, and Japan were allowed to erect at their own cost separate pavilions. The greater number of the nationalities represented had palaces of their own in the Rue des Nations along the Quai d'Orsay, in which thoroughfare were to be seen the buildings erected by Italy, Turkey, the United States, Denmark, Portugal, Austria, Bosnia, Herzegovina, Peru, Hungary, the United Kingdom, Persia, Belgium, Norway, Luxemburg, Finland, Germany, Spain, Bulgaria, Monaco, Sweden, Rumania, Greece, Servia, and Mexico. Scattered about the grounds, in addition to those in the Trocadero, were the buildings of San Marino, Morocco, Ecuador, and Corea. Nearly every civilized country in the world was represented at the Exhibition, the most conspicuous absentees being Argentina, Brazil, Chili, and some other South and Central American Republics, and a number of the British Colonies. The most noteworthy attractions of the Exhibition were the magnificent effects produced by electricity in the Palace devoted to it in the Chateau d'Eau and in the Hall of Illusions, the two Palaces of the Fine Arts in the Champs Elysées, and the Bridge over the Seine dedicated to the memory of Alexander II. These permanent Fine Art palaces were devoted, the one to modern painting and sculpture, the other to the works of French artists and art workmen who flourished from the dawn of French art up to the end of the 18th century.

The United Kingdom was well but not largely represented both in Fine Arts and Manufactures, the administration of the section being in the hands of a Royal Commission, presided over by the Prince of Wales. The British Pavilion contained an important collection of paintings of the British school, chiefly by Reynolds, Gainsborough, and their contemporaries, and by Turner and Burne-Jones. Special buildings had been erected by the British Colonies and by British India. Canada, West Australia, and Mauritius occupied the former, India and Ceylon the latter. For the first time since the war of 1870 Germany took part in a French International Exhibition, and the exhibits showed the great industrial progress which had been made since the foundation of the empire in 1870. The United States made a fine display, and fairly divided the honours with Germany. Remarkable progress was manifested in the exhibits of Canada and Hungary. France maintained her superiority in all the objects in which good taste was the first consideration, but the more utilitarian exhibits were more remarkable for their number than their quality, except those connected with electrical work and display, automobiles, and iron-work. The number of exhibitors in the Industrial Section from the British Empire, including India and the Colonies, was 1250, who obtained 1647 awards, as many persons exhibited in several classes. There were, in addition, 465 awards for "collaborateurs," that is, assistants, engineers, foremen, craftsmen, and workmen who have co-operated in the production of the exhibits. In the British Fine Arts section there were 429 exhibits by 282 exhibitors, and 175 awards.

Important International Exhibitions were held at Glasgow, and at Buffalo, New York, during 1901. (G. C. L.)

Exmouth, a market-town, seaport, and watering-place in the Honiton parliamentary division of Devonshire, England, 10 miles south-east by south of Exeter by rail. The scenery of the neighbourhood is unrivalled, and the drives over Black Hill and Woodbury Common are very beautiful. Recent erections are two district churches, a mission church, a Catholic chapel, a Reformed Church of England, a Congregational chapel, a Wesleyan chapel, a public hall, yacht clubhouse, and the Maud Hospital. A pleasure ground and public garden has been opened. A new system of sewerage is nearly completed, at a cost of £35,000. There is an excellent supply of pure water. Two commodious excursion steamers run to different places on the coast daily during the summer. A new dispensary has lately been built, and it is proposed to erect a new hospital to take the place of the Maud Hospital. Area of urban district (two parishes), 4800 acres. Population (1881), 7265; (1901), 10,442.

Experiments on Animals.—The purpose of this article is to give some account of the present method of experiments on animals in the United Kingdom, and to set forth the chief discoveries that have been made by the help of such experiments.

I. Methods Employed.—The Act relating to experiments on animals was passed in 1876. At that time the majority of these experiments were physiological. There was, it may be fairly said, no such thing as bacteriology, and the doctrine of spontaneous generation was still held by one, at least, among men eminent in science. A few experiments were made in pathology, for instance in tubercle; and a few in surgery, in pharmacology, and in the action of poisons, especially snake-venom. But the chief use of experiments on animals was for the advancement of physiology. The evidence given before the Royal Commission (1875) was, almost entirely, on physiological matters, on the discoveries of Harvey, Bell, Magendie, and Claude Bernard, on the *Handbook for the Physiological Laboratory*, and so forth. The Act, therefore, was drafted with a view to physiology, without much concern for pathology, and without foreknowledge of bacteriology. At the present time, about 80 per cent. of the experiments are inoculations.

The chief conditions of the Act must be mentioned here, though they are also referred to under Vivisection. Every experiment must be made in a registered place open to Government inspection. As the Home Secretary said in 1898, "The only experiments performed elsewhere than at registered places are inoculation operations in connexion with the diseases of cattle; and inspection in such cases is deemed unnecessary and does not take place." Every experiment must be made under a licence; and every application for a licence must be recommended by the signatures of two out of a small body of authorities specified in the Act—presidents of certain learned societies, and professors of certain universities and colleges. The word "experiment" is not allowed to cover the use of more than one animal.

Most experiments are made not under a licence alone, but under a licence *plus* one or more certificates, and the wording and working of these certificates must be clearly understood, because it is over them that the question arises as to the amount of pain inflicted by these experiments. Under the licence alone the animal must be kept under an anæsthetic during the whole of the experiment; and "if the pain is likely to continue after the effect of the anæsthetic has ceased, or if any serious injury has been inflicted on the animal," it must be killed forthwith under the anæsthetic. Thus, under the licence alone, it is impossible to make an inoculation; for the experiment consists not in the introduction of the needle under the skin, but in the observation of the results of the inoculation. A guinea-pig inoculated with tubercle cannot be kept under an anæsthetic till it dies of the disease. The disease is the experiment, and it is therefore an experiment made without an anæsthetic, and not authorized by the licence alone. Again, under the licence alone it would have been impossible to work out the thyroid treatment of myxœdema, or the facts of cerebral localization. For to remove the thyroid gland, or to remove a portion of the surface of the brain, is to inflict a serious injury on the animal. The operation is done under profound anæsthesia—it would be impracticable otherwise: the wound is treated and dressed by the antiseptic method—suppuration would invalidate the result. But a serious injury has been inflicted. Nevertheless, the animal must not be killed forthwith: the result must be watched. These and the like experiments cannot therefore be made under the licence alone. For the removal of such disabilities as these, the Act empowers the Home Secretary to grant certain certificates, to be held with the licence. They must be recommended by two signatures, and various restrictions are put upon them by the Home Secretary. On July 11, 1898, the Home Secretary was asked, in the House of Commons, what were the conditions and regulations attached by the Home Office to licences and certificates; and he answered—

"The conditions are not always the same, but may vary according to the nature of the investigation. It is hardly possible, therefore, for me to state all the conditions attached to licences and certificates. The most important conditions, however (besides the limitations as to place, time, and number of experiments), and the conditions most frequently imposed, are those as to reporting and the use of antiseptics. The latter condition is that the animals are to be treated with strict antiseptic precautions, and if these fail and pain results, they are to be killed immediately under anæsthetics. The reporting conditions are, in brief, that a written record, in a prescribed form, is to be kept of every experiment, and is to be open for examination by the inspector; that a report of all experiments is to be forwarded to the inspector; and that any published account of an experiment is to be transmitted to the Secretary of State. Another condition requires the immediate destruction under anæsthetics of an animal in which severe pain has been induced, after the main result of the experiment has been attained."

The certificates are distinguished as A, B, C, E, EE, and F. Certificate D, which permitted the testing, by experiments, of "former discoveries alleged to have been made," has fallen into disuse. Certificate C permits experiments to be made by way of illustration of lectures. They must be made under the provisions contained in the Act as to the use of anæsthetics. Certificates E, EE, and F permit experiments to be made on the dog, cat, horse, ass, or mule. These certificates are linked with Certificate A or Certificate B. It is round these two certificates, A and B, that the controversy as to the pain caused by experiments on animals is centred.

Certificate A permits experiments to be made without anæsthesia. It is worded as follows:—"Whereas A. B. of [*here insert address and profession*] has represented to us (*i.e.*, two authorities) that he proposes, if duly authorized under the above-mentioned Act, to perform on living animals certain experiments described below: We hereby certify that, in our opinion, insensibility in the animal on which any such experiment may be performed cannot be produced by anæsthetics without necessarily frustrating the object of such experiment." All inoculations under the skin, all feeding experiments, and the like, are scheduled under this certificate. They must be scheduled somehow: they cannot legally be made under a licence alone. Though the only instrument used is a hypodermic needle, yet every inoculation is officially returned as an experiment, calculated to give pain, performed without an anæsthetic. It is for inoculations and the like experiments, and for them alone, and for nothing else, that Certificate A is allowed (or A linked with E or F). This want of a special certificate for inoculations, and this wresting of Certificate A for the purpose, have led to an erroneous belief that "cutting operations" are permitted by the Act without an anæsthetic. But, as the Home Secretary said in Parliament, in March 1897, "Certificate A is never allowed except for inoculations and similar trivial operations, and in every case a condition is attached to prevent unnecessary pain." And again he wrote in 1898, "Such special certificates (dispensing with anæsthetics) are granted only for inoculations, feeding, and similar procedures involving no cutting. The animal has to be killed under anæsthetics if it be in pain, so soon as the result of the experiment is ascertained."

Certificate B permits the keeping alive of the animal after the initial operation of an experiment. It is worded as follows:—"Whereas A. B. of [*here insert address and profession*] has represented to us (*i.e.*, two authorities) that he proposes, if duly authorized under the above-mentioned Act, to perform on living animals certain experiments described below, such animals being, during the whole of the initial operation of such experiments, under the influence of some anæsthetic of sufficient power to prevent their feeling pain: We hereby certify that, in our opinion, the killing of the animal on which any such experiment is performed before it recovers from the influence of the anæsthetic administered to it would necessarily frustrate the object of such experiment." Certificate B (or B linked with EE or F) is used for those experiments which consist in an operation *plus* subsequent observation of the animal. The section of a nerve, the removal of a secretory organ, the establishment of a fistula, the plastic surgery of the intestine, the transplantation of particles of a tumour, the sub-dural method of inoculation—these and the like experiments are made under this certificate. We may take, to illustrate the use of Certificate B, Mr. Horsley's observations on the thyroid gland. The removal of the gland was the initial operation; and this was performed under an anæsthetic, and with the antiseptic method. Then the animal was kept under observation. The experiment is neither the operation alone nor the observation alone, but the two together.

It has been said that Certificate B allows a licensee to make an incision under an anæsthetic, and then, when the anæsthetic has passed off, to keep the animal under curare, and make painful experiments on it through the incision. Curare, however, is not an anæsthetic under the Act; and Certificate B is granted "on condition that antiseptic precautions are used; and if these fail and pain continues after the anæsthetics have ceased to operate, the animal is immediately killed painlessly" (Letter from the Home Secretary, 1898). The purpose of this certificate is set forth in the Inspector's report for 1899:—"In experiments performed under Certificate B (or EE or F linked with B) the animal is anæsthetized during the operation, but is allowed to recover. These operations, in order to ensure success, are necessarily done with as much care as are similar operations upon the human subject, and the operations being performed aseptically, the process of healing takes place without pain."

From this brief account of the chief provisions of the Act, we come to consider the general method of experiments on animals in the United Kingdom, and the question of the infliction of pain on them. The total number of licensees in Great Britain and Ireland in 1899 was 259, of whom 74 (or 30 per cent.) performed no experiments. The total number of experiments was 8696. Of these, only 227 were made in Ireland; and since the report of the Inspector for Ireland is separate from that of the Chief Inspector for England and Scotland, we may take separately the experiments made in Great Britain. These are 8469 in number. They are tabulated in two divisions, called iii. A and iii. B:—

Table iii. is divided into two parts, A and B, for the purpose of separating experiments which are performed without anæsthetics from experiments in which anæsthetics are used. The only experiments performed without anæsthetics are inoculations, hypodermic injections, vaccinations, and similar proceedings, in which the pain inflicted is not greater than the prick of a needle. *No experiments requiring anything of the nature of a surgical operation, or that would cause the infliction of an appreciable amount of pain, are allowed to be performed without an anæsthetic.*

The total number of experiments included in Table iii. (A) is 1656. Of these there were performed—

Under licence alone	820
,, Certificate C	182
,, Certificate B	449
,, Certificate B and EE	205

In experiments performed under the licence alone, or under Certificate C, the animal suffers no pain, because it is kept under the influence of an anæsthetic from the beginning of the experiment until it is killed.

In experiments performed under Certificate B (or EE or F linked with B) the animal is anæsthetized during the operation, but is allowed to recover. These operations, in order to ensure success, are necessarily done with as much care as are similar operations upon the human subject, and the operations being performed aseptically, the process of healing takes place without pain. Inoculations made (upon rodents) with the object of diagnosing rabies in dogs have been placed, together with other inoculations requiring a preliminary incision in order to expose the part into which the injection is made, in Table iii. (A). In all these cases the whole operation is performed under an anæsthetic.

Table iii. (B) is devoted entirely to inoculations, hypodermic injections, and some few other proceedings, performed without anæsthetics. It includes 6813 experiments, whereof there were performed—

Under Certificate A	6689
,, Certificate A and E	83
,, Certificate A and F	41

A large number of these experiments were performed as a matter of professional duty for the diagnosis and prevention of disease, for the standardization of remedies, and for the testing of articles of food, such as water, milk, and butter, many of them on behalf of Government Departments, County Councils, and Municipal Corporations. The demand for antitoxins continues to increase, and during the past year 54,569 doses of diphtheria antitoxin have been sent out from two institutions.

It may be well to consider first the 6813 experiments included in Table iii. B. All, except 124, were performed on animals not especially protected by the Act. The animals most used for inoculations are mice, rats, guinea-pigs, and rabbits. The act of inoculation is not in itself painful. A small area of the skin is carefully shaved and cleansed, that it may be aseptic, the hypodermic needle is sterilized, and the method of hypodermic injection or of vaccination is the same as it is in medical practice. "A guinea-pig that will rest quietly in your hands before you commence to inject it, will remain perfectly quiet during the introduction of the needle under the skin; and the moment it is returned to the cage it resumes its interrupted feeding. Arteries, veins, and most of the parts of the viscera are without the sense of touch. We have actual proof of this in what takes place when a horse is bled for the purpose of obtaining curative serum. With a sharp lance a cut may be made in the skin so quickly and easily that the animal does nothing more than twitch the skin-muscle of the neck, or give his head a shake, while of the further proceeding of introducing a hollow needle into the vein, the animal takes not the slightest notice. Some horses, indeed, will stand perfectly quiet during the whole operation, munching a carrot, nibbling at a wisp of hay, or playing with a button on the vest of the groom standing at its head." These sentences, written in the *Medical Magazine* (June 1898) by Dr Woodhead, Professor of Pathology at Cambridge, are sufficient evidence that inoculations and the like experiments are not painful in the act. In a few instances cultures of micro-organisms have been made in the anterior chamber of the eye, by the introduction of a needle behind the cornea. This might be thought painful, but cocain renders the surface of the eye wholly insensitive. Many operations of ophthalmic surgery are done under cocain alone, and the anterior chamber of the eye is so far insensitive that a man may have blood or pus (*hypopyon*) in it, and hardly be conscious of the fact. The results of inoculation are in some cases negative, in others positive: the positive results are, in the great majority of cases, not a local change, but a general infection which may end in recovery, or in death. The diseases thus induced may, in many cases, fairly be called painless — such are septicæmia in a mouse, snake-venom in a rat, and malaria in a sparrow. Rabbits affected with rabies do not suffer in the same way as dogs and some other animals, but become subject to a painless kind of paralysis. It is probable that animals kept for inoculation have, on the whole, less pain than falls to the lot of a like number of animals in a state of nature or in the service of man: they are well fed and sheltered, and escape the rapacity of larger animals, the inevitable cruelties of sport, and the drudgery and sexual mutilation that man inflicts on the higher domestic animals.

The Inspector's report for 1899 says:—"The animals being experimented on under Certificates A and B have been carefully examined, and among the large number that I have seen there have been none showing any signs of pain. The guinea-pigs and rabbits, for example, which have been inoculated under Certificate A for the testing of antitoxins, for the diagnosis of disease, and so forth, are generally indistinguishable from the untouched animals in stock; and in most cases that have come under my notice of animals operated on under Certificate B, it would be quite impossible, apart from the scar or healing wound, to recognize that anything had been done to them."

We have now to consider Table iii. A, which includes all experiments other than inoculations and the like. In all of them (1656) anæsthetics were used. Those that were made under the licence alone, or under Certificate C, may be excluded, so far as the question of pain is concerned; for the animals were killed under the anæsthetic. There remain 654 experiments, made under Certificate B, or B linked with EE, in which the animal was anæsthetized during the operation, but was allowed to recover.

If it were lawful, under Certificate B, to make an incision under an anæsthetic, to call this the "initial operation," and then, without an anæsthetic, to make painful experiments through the incision on the deeper structures, doubtless much pain might be inflicted under this certificate. But experiments of this kind can be, and are, made under the licence alone, the animal being kept under an anæsthetic all the time, and killed under it. "No experiments requiring anything of the nature of a surgical operation, or that would cause the infliction of an appreciable amount of pain, are allowed to be performed without an anæsthetic" (Inspector's Report for 1899). "These certificates (B) are granted on condition that antiseptic precautions are used; and if these fail and pain continues after the anæsthetics have ceased to operate, the animal is immediately killed painlessly" (Letter from the Home Secretary, 1898). Of the 654 experiments made in 1899 under Certificate B, more than a fourth part were of the nature of inoculations only; but an anæsthetic was given, because the inoculation was made not under the skin, but by incision into the deeper structures.

Of other experiments such as are made under this certificate (which must be linked with Certificate EE for any experiment on a dog or a cat), three instances may be given here: an operation on the brain, a removal of part or the whole of a secreting gland, and the establishment of a fistula. It is to be noted that, for these and the like operations, profound anæsthesia and the strict observance of the aseptic method are matters of absolute necessity for the success of the experiment: the operation could not be performed without anæsthesia; and the experiment would come to nothing if the wound suppurated. It is to be noted, also, that these operations are such as are performed in surgery for the saving of life or for the relief of pain.

As to operations on the brain, it must be remembered that the surface of the brain is not sensitive. Therefore the removal or destruction of a portion of the surface of the brain, or the division of some tract of central nervous tissue, though it might entail some loss of power or of control, do not cause pain: a wound of the brain is painless. Tension within the cranial cavity, as in cases of cerebral tumour or cerebral abscess, may indeed cause great pain; and if the aseptic method failed in an experiment, inflammation and tension would ensue: in that case the animal must be killed.

The removal of part or the whole of a secreting gland (*e.g.*, the thyroid, the spleen, the kidney) is performed by the same methods, and with the same precautions, as in human surgery. Profound anæsthesia, and the use of a strict antiseptic or aseptic procedure, are of absolute necessity. The skin over the part to be removed must be shaved and carefully cleansed for the operation; the instruments, sponges, and ligatures must be sterile, not capable of infecting the wound; and when the operation is over, the wound must be carefully closed with sutures, and left to heal under a proper surgical dressing.

The establishment of a fistula, again, is an operation practised, as a matter of course, in large numbers of surgical cases. The stomach, the gall-bladder, the large intestine, are opened for the relief of obstruction, and kept open either for a time or permanently, according to the nature of the case. Under anæsthesia, the organ that is to be opened is exposed through an incision made through the structures overlying it, and is secured in the wound by means of fine sutures. Then, when it has become adherent there, it is opened by an incision made into it; no anæsthetic is needed for this purpose, because these internal organs are so unlike the skin in sensitiveness that an incision is hardly felt: the patient may say that he "felt a prick," or he may be wholly unconscious that anything has been done. A fistula thus established is not afterward painful, though there may be some discomfort now and again.

The classical instance is the case of Alexis St Martin, who was shot in the stomach in 1822, and recovered, but with a fistula. He let Dr Beaumont make experiments on him for nine years:—"During the whole of these periods, from the spring of 1824 to the present time (1833), he has enjoyed general good health . . . active, athletic, and vigorous; exercising, eating, and drinking like other healthy and active people. For the last four months he has been unusually plethoric and robust, though constantly subjected to a continuous series of experiments on the interior of the stomach; allowing to be introduced or taken out at the aperture different kinds of food, drinks, elastic catheters, thermometer tubes, gastric juice, chyme, &c., almost daily, and sometimes hourly. Such have been this man's condition and circumstances for several years past; and he now enjoys the most perfect health and constitutional soundness, with every function of the system in full force and vigour" (Beaumont, *Experiments and Observations on the Gastric Juice*, 1838).

We come now to the question, What anæsthetics are used in these experiments, and are they properly administered? In almost every case the anæsthetic used is chloroform or ether, sometimes combined with and followed by morphia or chloral. The anæsthetic given in each case must be stated in the returns sent to the Home Office. Animals take ether well, and there is no difficulty in rendering them unconscious with it. With some animals, chloroform is equally good; with others, it is dangerous to life; but Professor Hobday, of the Royal Veterinary College, published in 1898 an account of five hundred administrations of chloroform to dogs, in veterinary surgery, with only one death (*Lancet*, September 1898). Still, for dogs and cats ether is generally used. Morphia is seldom used alone, but in some cases it is used after chloroform or ether. It is certain that an animal, so far under the influence of morphia that it lies still, cannot be suffering, for the drug does not act directly on the muscles, but on the higher nervous centres. It happens now and again that a dog is excited, not narcotized, by morphia (see Professor Lugaro's paper, *Brit. Med. Journ.*, January 14, 1899). But this is altogether exceptional; an animal in such a condition could not be used for experiment; and the physiologist has other anæsthetics. Except in these rare cases, animals take morphia well, and are profoundly influenced by it. Curare is not an anæsthetic under the Act. Its use was thus defined in 1899 by the Home Secretary: "It is illegal to use curare as an anæsthetic. It is often used in addition to anæsthetics, for very good reasons; and as it does not render an anæsthetized animal sensitive, it would be absurd to forbid its use."

The following accounts of the action of curare are by Professor Rüffer, some time Hon. Secretary of the Institute of Preventive Medicine, and by a writer in the *Edinburgh Review*, who seems to speak from experience:—

1. "It is quite true that curare in small doses has the effect of paralyzing the motor nerves without affecting the nerves of sense; but in such doses as are used in the laboratory it paralyzes both sets of nerves, and this has actually been proved on man, as there have been cases of accidental curare poisoning in men who recovered, and in whom sensation has been totally abolished, while the action of the drug was apparent. Moreover, curare is nowadays not used alone, but is always used in combination with morphia, ether, chloroform, or other anæsthetics" (Professor Rüffer, *Liberty Review*, October 1893).

2. "It is pretty certainly known now that Claude Bernard was wrong, and that though curare acts first upon the motor nerves, it also, though less rapidly, paralyzes the sensory nerves, always supposing that by artificial respiration the animal is kept alive long enough for the less rapid effect to be produced. It would be out of place here to give the experimental evidence which satisfies physiologists upon this point. . . . Probably the truth is that, like all other nerve-poisons, the effect of curare varies with the dose. The muscular nerves are the first affected, then the sensory, and finally the central nervous system. As a matter of fact, however, morphia or some other narcotic is always given in addition to curare when it is used in laboratory work in England" (*Edinburgh Review*, July 1899).

The administration of chloroform or ether is performed by the ordinary methods of surgery; and the drug is given freely, if only for the reason that the absolute unconsciousness of the animal makes the accuracy and success of the experiment more certain. Lately, in an account of some experiments, it was stated that in two or three cases the anæsthesia was "incomplete." Such use of chloroform or ether may be made sometimes in surgery because of the general condition of the patient, or the special circumstances of the operation. But alike in surgery and in experiments on animals it is altogether exceptional, or something more than exceptional. The administration of morphia or of chloral is pushed beyond the point at which these drugs are "sedatives," almost to the point at which they become fatal.

It may be interesting to compare the pain or death or discomfort of these 8469 animals, used for experiment in Great Britain in 1899, with the fate of an equal number of the same kinds of animals, either wild, or preserved as game, or kept for the service or the amusement of man. Of the 8469 animals, the vast majority, no less than 6813, were used for inoculation only; and these were, most of them, mice, rats, guinea-pigs, or rabbits. Those which died may fairly be said to have suffered neither more nor less than the like number of domestic animals dying in the ordinary course of nature. Of the remaining 1656, the majority, 1002, were put under an anæsthetic, and kept in a condition of profound anæsthesia, and killed under the anæsthetic, there and then. The minority, 654, were subjected under profound anæsthesia to a surgical operation, and were allowed (provided their wounds healed well and they were not in pain) to recover. These 654 may fairly be put against the like number of animals wounded in the course of sport, or mutilated as live stock.

In 1900, in England and Scotland, the total number of licensees was 247, of whom 63 performed no experiments; and the inspector, Mr Thane, reported that licences and certificates had been granted and allowed only upon the recommendation of persons of high scientific standing; that the licensees were persons who, by their training and education, were fitted to undertake experimental work and to profit by it; and that all experimental work had been conducted in suitable places. The total number of experiments was 10,839, being 2370 more than in 1899. This increase is accounted for by 229 under Table III. (A): "experiments other than those of the nature of simple inoculations, hypodermic injections, or similar proceedings"; and 2141 under Table III. (B): "inoculations, hypodermic injections, and some few other proceedings performed without anæsthetics." Few of these experiments had been in any serious degree painful. Taking first those recorded in Table III. (A), 1885 in number, the experiments performed under licence alone or under Certificate C, "permitting experiments in illustration to lectures," together amounting to 1299, were unattended by pain, because the animal was kept under an anæsthetic during the whole of the experiment, and, if the pain was likely to continue after the effect of the anæsthetic had ceased, or if any serious injury had been inflicted on the animal, was killed before it recovered. In the remaining 586 experiments the operations were performed under anæsthetics, from the influence of which the animals were allowed to recover. The operations were performed aseptically, and the healing of the wounds as a rule took place without pain. If the antiseptic precautions failed and suppuration occurred, the animal was required to be killed. Mr. Thane reported that he had seen numerous animals on which serious operations had been performed—removal of organs and the like—and which were clearly not in pain; indeed, they were often to all appearance in perfect health. The experiments included in Table III. (B), 8954 in number, were all performed without anæsthetics. They were mostly inoculations, but a few were feeding experiments or the administration of various substances by the mouth. In no case had a certificate dispensing with the use of anæsthetics been presented for an experiment involving a serious operation.

In a large proportion of the inoculations included in Table III. (B) the result was negative—the animal did not exhibit any ill effects, and therefore did not suffer any pain. This was especially the case with many inoculations for purposes of diagnosis, with the great majority of the inoculations performed for the testing of articles of food, and with many of the inoculations made for the purpose of standardizing antitoxic serum, namely, those cases in which the antitoxin was sufficiently powerful to neutralize the amount of toxin injected, so that the latter had no action. It was only a small proportion of the inoculations practised that were followed by disease or poisoning. In some of these cases, such as the injection of certain drugs or of tetanus toxin, the effect produced was without doubt painful; but in the two most frequently employed proceedings of this kind—namely, inoculation for the diagnosis of tuberculosis and for the standardization of diphtheria antitoxin—there was some difference of opinion, amongst those who had had most experience, as to whether the effects produced were attended by pain or not. There was, however, strong reason for holding that the gradual development of tuberculosis, and the poisoning by diphtheria-toxin, resulting from such inoculations, although they might not be accompanied by acute suffering, were conditions which brought those proceedings within the category of "experiments calculated to give pain." In the event of pain ensuing as the result of an inoculation, a condition attached to the licence required that the animal should be killed under anæsthetics as soon as the main result of the experiment had been attained. Therefore in a very large number of instances, especially in the case of experiments performed without the use of anæsthetics, the experiments were entirely painless. The large increase in the number of inoculation experiments included in Table III. (B) was mainly due to the growing appreciation of their great value as a means of detecting, curing, and preventing disease. Inoculations for the purpose of diagnosis were now part of the routine of medical practice. During the year 1900, 2230 inoculations were made by three licensees for the purpose of standardizing antitoxins, and over 1500 inoculations were made by two licensees for the testing of milk. These experiments were performed in large numbers on behalf of the authorities responsible for the care of the public health. The appearance of the bubonic plague in England had afforded an illustration of the value of the experimental method in diagnosis. "It is," Mr Thane says, "of the greatest importance that this disease should be recognized as early as possible. This can only be done with certainty with the aid of inoculations into animals. Two fresh places were registered and two new licences were granted during 1900 expressly to allow of the necessary experiments being performed in localities where infection was apprehended."

Six licences were in existence in Ireland during 1900. The experiments performed were 135. They had been of a useful character, and were attended by little or no pain. The experiments were chiefly in connexion with the identification of canine rabies and tuberculosis, or the investigation of tetanus and epidemic cerebro-spinal meningitis.

II. Scientific Results.—The advantages that have been obtained by the help of experiments on animals may be arranged under two heads—(A) Physiology, (B) Pathology, Bacteriology, and Therapeutics.

A. Physiology.

1. *The Blood.*—Galen (A.D. 131) confuted the doctrine of Erasistratus, that the arteries contained πνεῦμα, the breath of life, proving by experiment that they contain blood. "Ourselves, having tied the exposed arteries above and below, opened them, and showed that they were indeed full of blood." Realdus Columbus (1559), though he did not discover the general or "systemic" circulation of the blood, yet seems to have discovered, by experiment, the pulmonary circulation. "The blood is carried through the pulmonary artery to the lung, and there is attenuated; thence, mixed with air, it is carried through the pulmonary vein to the left side of the heart. Which thing no man hitherto has noted or left on record, though it is most worthy of the observance of all men. . . . And this is as true as truth itself; for if you will look not only in the dead body but also in the living animal, you will always find this pulmonary vein full of blood, which assuredly it would not be if it were designed only for air and vapours. . . . Verily I pray you, O candid reader, studious of authority, but more studious of truth, to make experiment on animals. You will find the pulmonary vein full of blood, not air or *fuligo*, as these men call it, God help them." Harvey's treatise *De Motu Cordis et Sanguinis in Animalibus* was published at Frankfort in 1621. It begins thus: "When by many dissections of living animals, as they came to hand—*Cum multis vivorum dissectionibus, uti ad manum dabantur*—I first gave myself to observing how I might discover, with my own eyes, and not from books and the writings of other men, the use and purpose of the movement of the heart in animals, forthwith I found the matter hard indeed and full of difficulty; so that I began to think, with Frascatorius, that the movement of the heart was known to God alone. . . . At last, having daily used greater disquisition and diligence, by frequent examination of many and various living animals—*multa frequenter et varia animalia viva introspiciendo*—I came to believe that I had succeeded, and had escaped and got out of this labyrinth, and therewith had discovered what I desired, the movement and use of the heart and the arteries. And from that time, not only to my friends but also in public in my anatomical lectures, after the manner of the Academy, I did not fear to set forth my opinion in this matter." Here, and again at the end of the Preface, and again in the eighth chapter of the *De Motu*, he puts his experiments in the very foreground of the argument. Take the headings of his first four chapters:—1. *Causæ, quibus ad scribendum auctor permotus fuerit.* 2. *Ex vivorum dissectione, qualis fit cordis motus.* 3. *Arteriarum motus qualis, ex vivorum dissectione.* 4. *Motus cordis et auricularum qualis, ex vivorum dissectione.* He had, of course, help from other sources—from anatomy, and from physics; but it is certain, from his own words, that he attributed his discovery, in a very great measure, to experiments on animals. Malpighi (1661), professor of medicine at Bologna, by examining with a microscope the lung and the mesentery of the live frog, made out the capillary vessels. He writes to Borelli, professor of mathematics at Pisa, that he has failed in every attempt to discover them by injecting fluids into the larger vessels, but has succeeded by examining the tissues with the microscope: "Such is the divarication of these little vessels, coming off from the vein and the artery, that the order in which a vessel ramifies is no longer preserved, but it looks like a network woven from the offshoots of both vessels" (*De Pulmonibus*, 1661). Stephen Hales (1733), rector of Farringdon and minister of Teddington, and a Fellow of the Royal Society, made the first exact estimates of the blood-pressure, the real force of the blood, by inserting one end of a vertical glass tube into the crural artery of a mare, and noting the rise of the blood in the tube (*Statical Essays, containing Hæmostaticks, &c., 1733*). John Hunter, born 1738, made many observations on the nature and processes of the blood; and, above all, he discovered the facts of collateral circulation. These facts were fresh in his mind when he first ventured, in December 1785, to tie the femoral artery in "Hunter's canal" for the cure of aneurism in the popliteal space. The experiment that gave him his knowledge of the collateral circulation was made on one of the deer in Richmond Park: he tied its external carotid artery, to see what effect would be produced on the shedding of the antler. Some days later he found that the circulation had returned in the antler. He had the buck killed, and found that the artery had been completely closed by the ligature; but the small branches coming from it, between the heart and the ligature, were enlarged, and were in communication with others of its branches beyond the ligature; and by this collateral circulation the flow of blood to the antler had been restored. Among later observations on the circulation must be mentioned the use of the mercurial manometer by Poiseuille (1828) and Ludwig (1849), the study of the blood-pressure within the heart by Hering (1849), and the permanent tracing of the pressure-curves by Chauveau and Marey (1863). Finally, the study of those more abstruse problems of the circulation that the older physiologists had left alone—the influences of the central nervous system, the relations between blood-pressure and secretion, the automatism of the heart-beat, and the influence of gravitation.

2. *The Lacteals.*—Asellius (1622) by a single experiment demonstrated the flow of chyle along the lacteals. The existence of these minute vessels had been known even to Galen and Erastistratus, but they had made nothing of their knowledge. Asellius says: "I observed that the nerves of the intestines were quite distinct from these white threads, and ran a different course. Struck with this new fact, I was silent for a time, thinking of the bitter warfare of words among anatomists as to the mesenteric veins and their purposes. When I came to myself, to satisfy myself by an experiment I pierced one of the largest cords with a scalpel. I hit the right point, and at once observed a white liquid like milk flowing from the divided vessel." Jehan Pecquet (1647), in the course of an experiment on the heart, observed the flow of chyle into the subclavian vein, and its identity with the chyle in the lacteals; and by further experiment found the thoracic duct, and the chyle flowing up it: "I perceived a white substance, like milk, flowing from the vena cava ascendens into the pericardium, at the place where the right auricle had been. . . . I found these vessels (the thoracic duct) all along the dorsal vertebræ, lying on the spine, beneath the aorta. They swelled below a ligature; and when I relaxed it, I saw the milk carried to the orifices that I had observed in the subclavian vein." The existence of this duct, which is empty and collapsed after death, had been overlooked by Vesalius and all the great anatomists of his time.

3. *The Gastric Juice.*—Our knowledge about digestion dates back to the end of the 17th century, when Valisnieri first observed that the stomach of a dead animal contained a fluid which acted on certain bodies immersed in it—"a kind of *aqua fortis*." In 1752 Réaumur began his observations on this fluid: making birds swallow fine fenestrated tubes containing grain or meat, or sponges with threads attached; and observed that digestion consists in the dissolution of food, not in any sort of mechanical action or trituration. His observations were extended and perfected by Spallanzani (1777). Then came a period of uncertainty, without further advance; until in 1823 the French Academy offered a prize for the best work on the subject, and Tiedemann and Gmelin submitted their observations to them: "The work of Tiedemann and Gmelin is of especial interest to us on account of the great number of their experiments, from which came not only the absolute proof of the existence of the gastric juice, but also the study of the transformation of starch into glucose. Thus the theory of digestion entered a new phase: it was finally recognized, at least for certain substances, that digestion is not simply dissolution, but a true chemical transformation" (Claude Bernard, *Physiologie Opératoire*, 1879.) Beaumont's experiments on Alexis St Martin (*vide supra*) were published in 1838. They were, of course, based on the work of the physiologists: "I make no claim to originality in my opinions as it respects the existence and operation of the gastric juice. My experiments confirm the doctrines (with some modifications) taught by Spallanzani and many of the most enlightened physiological writers" (Preface to Dr Beaumont's book). Eberlé, in 1834, showed how this knowledge of the gastric juice might be turned to a practical use, by extracting it from the mucous membrane of the stomachs of animals after death: hence came the invention of the various preparations of pepsin. Later, Blondlot of Nancy, in 1842, studied the gastric juice by the method of a fistula, like that of St Martin. More recent observations have been made on the movements of the stomach during digestion, and on the influences of the nervous system on the process.

4. *Glycogen.*—The importance of Claude Bernard's discovery of glycogen is not annulled either by the fact that there is still work to be done on the finer issues of this part of physiology, or by the fact that many cases of diabetes are still past cure. It must be measured by the ignorance about the liver, which his work dispelled, and by the far-reaching influence of his discovery. His first experiments on the assimilation and destruction of sugar in the body were made in 1843. His discovery of the glycogenic action of the liver was made by keeping two dogs on different diets, one with sugar, the other without it, then killing them during digestion, and testing the blood in the veins coming from the liver: "What was my surprise when I found a considerable quantity of sugar in the hepatic veins of the dog that had been fed on meat only, and had been kept for eight days without sugar! . . . Finally, after many attempts—*après beaucoup d'essais et plusieurs illusions que je fus obligé de rectifier par des tâtonnements*—I succeeded in showing, that in dogs fed on meat the blood passing through the portal vein (from the stomach) does not contain sugar before it reaches the liver; but when it leaves the liver and comes by the hepatic veins into the inferior vena cava, this same blood contains a considerable quantity of a sugary substance (glucose)" (*Nouvelle Fonction du Foie*, Paris, 1853).

5. *The Pancreas.*—The 17th century was a time of very fanciful theories about the pancreas (Lindanus, Wharton,

Bartholini), which need not be recalled here. But Sylvius (François de Bois) had the wisdom to see that the pancreas must be estimated, not according to its position, but according to its structure, as of the nature of the salivary glands. He urged his pupil, Regnier de Graaf, to study it by experiment, and de Graaf says: "I put my hand to the work; and though many times I despaired of success, yet at last, by the blessing of God on my work and prayers, in the year 1662 I discovered a way of collecting the pancreatic juice." By the method of a fistula he collected and studied the secretion of the pancreas; and by further experiment he refuted Bartholini's theory that the pancreas was a sort of appanage or "biliary vesicle" of the spleen. But he got no help from the chemistry of his time; and could no more discover the amylolytic action of the pancreatic secretion than Galvani could discover wireless telegraphy. Still, he did good work; and Claude Bernard, 180 years later, went back to de Graaf's method of the fistula. His observations, begun in 1846, received a prize from the French Academy in 1850. Sir Michael Foster says of them: "Valentin, it is true, had in 1844 not only inferred that the pancreatic juice had an action on starch, but confirmed his view by actual experiment with the juice expressed from the gland; and Eberlé had suggested that the juice had some action on fat; but Bernard at one stroke made clear its threefold action. He showed that it on the one hand emulsified, and on the other hand split up into fatty acids and glycerine, the neutral fats; he clearly proved that it had a powerful action on starch, converting it into sugar; and lastly, he laid bare its remarkable action on proteid matters." Of late years it has been discovered that the pancreas, beside its work in digestion, has an "internal secretion": that it, like the thyroid gland and the suprarenal capsules, helps to keep the balance of the general chemistry of the whole body. Professor Schäfer, writing in 1894, says on this subject: "It was discovered a few years ago by von Mering and Minkowski that if, instead of merely diverting its secretion, the pancreas is bodily removed, the metabolic processes of the organism, and especially the metabolism of carbo-hydrates, are entirely deranged, the result being the production of permanent diabetes. But if even a very small part of the gland is left within the body, the carbo-hydrate metabolism remains unaltered, and there is no diabetes. The small portion of the organ which has been allowed to remain (and which need not even be left in its proper place, but may be transplanted under the skin or elsewhere) is sufficient, by the exchanges which go on between it and the blood generally, to prevent those serious consequences to the composition of the blood, and the general constitution of the body, which result from the complete removal of this organ." These later facts, not contradicting Bernard's work but adding to it, are of the very highest importance, alike in physiology and in pathology.

6. *The Growth of Bone.*—The experiments made by du Hamel (1739–1843) on the growth of bone by deposit from the periosteum (the thin membrane ensheathing each bone) rose out of Belchier's observation (1735) that the bones take up the stain of madder mixed with their food. Du Hamel studied the whole subject very carefully, and discovered this bone-producing power of the periosteum, that is an important fact in all operations on the bones. As he puts it, in the title of one of his own memoirs, *Les os croissent en grosseur par l'addition de couches osseuses qui tirent leur origine du périoste, comme le corps ligneux des Arbres augmente en grosseur par l'addition de couches ligneuses qui se forment dans l'écorce.* By feeding pigs at one time with dyed food, at another with undyed food, he obtained their bones in concentric layers alternately stained and unstained. His facts were confirmed by Bazan (1746) and Boehmer (1751); but his conclusions, unfortunately, were opposed by Haller. Still, he brought men to study the whole subject of the growth of bones, in length as well as in thickness, and the whole modelling of the bones, in adult life, by deposit and absorption. Bichat, John Hunter, Troja, and Cruveilhier took up his work in physiology and in surgery. Later, from the point of view of surgery, Syme (1837) and Stanley (1849) made experiments on the growth of bone, and on the exfoliation of dead bone; and, after them, Ollier, whose influence on this part of surgical practice has been of the very highest value.

7. *The Nervous System.*—*A.* The Nerve-Roots. Through all the centuries between Galen, who lived in the time of Commodus, and Sir Charles Bell, who lived in the time of George III., no great advance was made in our knowledge of the nervous system. The way of experiment, which had led Galen far ahead of his age, was neglected, and everything was overwhelmed by theories. Bell in London and Magendie in Paris took up the experimental study of the nervous system about where Galen had left it. The question of priority of discovery does not concern us here: we may take Sir Michael Foster's judgment, that Magendie brought exact and full proof of the truth which Bell had divined rather than demonstrated, that the anterior and posterior roots of spinal nerves have essentially different functions—"a truth which is the very foundation of the physiology of the nervous system." The date of Bell's work is 1811, *An Idea of a New Anatomy of the Brain, submitted for the Observation of the Author's Friends.* In it he says: "Considering that the spinal nerves have a double root, and being of opinion that the properties of the nerves are derived from their connexions with the parts of the brain, I thought that I had an opportunity of putting my opinion to the test of experiment, and of proving at the same time that nerves of different endowments were in the same cord (the same nerve-trunk) and held together by the same sheath. On laying bare the roots of the spinal nerves I found that I could cut across the posterior fasciculus of nerves, which took its origin from the spinal marrow, without convulsing the muscles of the back; but that on touching the anterior fasciculus with the point of the knife, the muscles of the back were immediately convulsed. Such were my reasons for concluding that the cerebrum and cerebellum were parts distinct in function, and that every nerve possessing a double function obtained that by having a double root. I now saw the meaning of the double connexion of the nerves with the spinal marrow; and also the cause of that seeming intricacy in the connexions of nerves throughout their course, which were not double at their origins." His other work, on the cranial nerves, which are "not double at their origins," bore fruit at once in surgery. Sir John Erichsen says of it: "Up to the time that Sir Charles Bell made his experiments on the nerves of the face, it was the common custom of surgeons to divide the facial nerve for the relief of neuralgia, *tic douleureux*; whereas it exercises, and was proved by Sir Charles Bell to exercise, no influence over sensation, and its division consequently for the relief of pain was a useless operation." *B.* Reflex Action.—The observations made by Sir Robert Boyle, Redi, Le Gallois, and others on the reflex movements of decapitated vipers, frogs, eels, and butterflies were of no great use from the point of view of physiology; but they led toward the discovery that nerve-power is stored in the spinal cord, and is liberated thence in action independent of the higher cerebral centres. Marshall Hall (1832–1837) discovered, by his experiments, that reflex actions are the work of definite groups of cells, set at certain points or levels in the cord; he proved the segmental structure of the cord, the existence of nerve-centres in it; and thus foreshadowed the discovery of the like centres in the brain. In his earlier writings (1832–1833) he extended the principles of the doctrines of reflex action to the larynx, the pharynx, and the sphincter muscles; later, in 1837, he demonstrated the course of nerve-impulses within the cord, from one level to another, and the effects of direct stimulation of the cord. Also he noted the effects of opium and of strychnine on reflex action; and the reflex character of the convulsions that occur in certain diseases. *C.* The Medulla Oblongata and the Cerebellum.—Flourens, who was among the earliest students of the use of chloroform, is best known for his experiments on the respiratory centre and the cerebellum. He localized the cells in the medulla that govern the reflex movement of respiration. Afterward came the discovery of cardiac and other centres in the neighbourhood of the respiratory centre. He showed also that the cerebellum is concerned with the equilibration and co-ordination of the muscles: that an animal, a few days old, deprived of sensation and consciousness by removal of the cerebral hemispheres, was yet able to stand and to move forward, but when the cerebellum also was removed, lost all power of co-ordination (*Recherches Expérimentales*, Paris, 1842). And from the observations made by him and by others, it was found that the semicircular canals of the internal ears are the terminal organs of this sense of equilibration. *D.* The Vaso-Motor Nerves.—Claude Bernard, studying the sympathetic nervous system, discovered the vaso-motor nerves, that control the calibre of the arteries. The question of priority between him and Brown Séquard need not be considered here. His first account of his work was communicated to the Société de Biologie in December 1851. The following account of it is from his *Leçons de Physiologie Opératoire* (1879):—

"Let me remind you how I was led to discover the vaso-motor nerves. Starting from the clinical observation, made long ago, that in paralyzed limbs you find at one time an increase of cold and at another an increase of heat, I thought that this contradiction might be explained by supposing that, side by side with the general action of the nervous system, the sympathetic nerve might have the function of presiding over the production of heat; that is to say, that in the case where the paralyzed limb was chilled, I supposed the sympathetic nerve to be paralyzed, as well as the motor nerves; while in the paralyzed limbs that were not chilled the sympathetic nerve had retained its function, the systematic nerves alone having been attacked. This was a theory, that is to say, an idea, leading me to make experiments; and for these experiments I must find a sympathetic nerve-trunk of sufficient size, going to some organ that was easy to observe: and must divide the trunk to see what would happen to the heat-supply of the organ. You know that the rabbit's ear, and the cervical sympathetic of this animal, offered us the required conditions. So I divided this nerve; and, at once, the experiment gave the lie direct to my theory—*Je coupai donc ce filet et aussitôt l'expéri-*

ence donna à mon hypothèse le plus éclatant démenti. I had thought that the section of the nerve would suppress the function of nutrition, of calorification, over which the sympathetic system had been supposed to preside, and would cause the hollow of the ear to become chilled; and here was just the opposite, a very warm ear, with great dilatation of its vessels." The experiments of Budge and Waller (1853) and of Schiff (1856) threw light on the action of these vaso-motor nerves, and on the place of the vaso-motor centre in the cord; and in 1858 Claude Bernard, by his experiments on the chorda tympani and the submaxillary gland, demonstrated their twofold influence, either to dilate or to constrict the vessels. "It is almost impossible to exaggerate the importance of these labours of Bernard on the vaso-motor nerves, since it is almost impossible to exaggerate the influence which our knowledge of the vaso-motor system, springing as it does from Bernard's researches as from its fount and origin, has exerted, is exerting, and in widening measure will continue to exert, on all our physiological and pathological conceptions, on medical practice, and on the conduct of human life. There is hardly a physiological discussion of any width in which we do not sooner or later come on vaso-motor questions" (Foster). *E.* Cerebral Localization.—The study of the motor and sensory centres of the cerebral hemispheres began in clinical observation. Observation of cases, and examination of the brain after death (Bouillard, 1825, Dax, 1836, Broca, 1861), led men to believe that a particular area of the left frontal lobe of the brain did indeed govern and permit the use of speech. Physiological experiments had nothing to do with the discovery of the speech centres. "Bouillard in 1825 collected a series of cases to show that the faculty of speech resided in the frontal lobes. In 1861 his views were brought by Aubertin before the notice of the Anthropological Society of Paris. Broca, who was present at the meeting, had a patient under his care who had been aphasic for twenty-one years, and who was in an almost moribund state. The autopsy proved of great interest, as it was found that the lesion was confined to the left side of the brain, and to what we now call the third frontal convolution. . . . In a subsequent series of fifteen typical cases examined, it was found that the lesion had destroyed, among other parts, the posterior part of the third frontal in fourteen" (Hamilton, *Text-Book of Pathology*). From this clinical fact, that the movements of speech depend on the integrity of a special area of the brain's surface, and from the facts of "Jacksonian epilepsy," and similar observations in medicine and surgery, began the experimental work of cerebral localization, by Hitzig, Goltz, Schiff, Ferrier, Yeo, Horsley, Beevor, and many more. It would be hard to find a more striking instance of the familiar truth that science and practice work hand in hand.

[These notes cover a part only of the results that have been obtained in physiology by the help of experiments on animals. The work of Boyle, Hunter, Lavoisier, Despretz, Regnault, and Haldane, on animal heat and on respiration; of Petit, Dupuy, Breschet, and Reid, on the sympathetic system; of Galvani, Volta, Hallex, du Bois-Reymond, and Pflüger, on muscular contraction—all these subjects have been left out, and many more. In his evidence before the Royal Commission (1875), Mr Darwin said: "I am fully convinced that physiology can progress only by the aid of experiments on living animals. I cannot think of any one step which has been made in physiology without that aid."]

B. Pathology, Bacteriology, and Therapeutics.

1. *Inflammation.*—Pathology is so intimately associated with the work of the microscope that it is a new study, in comparison with physiology. Fifty years ago the microscope was not in general use as it is now; nor did men have the lenses, microtomes, and staining-fluids that are essential to modern histology. Bacteriology, again, is even younger than pathology. Five and twenty years ago it had hardly begun to exist. For example, in the evidence before the Royal Commission (1875) one of the witnesses said that they "believed they were beginning to get an idea of the nature of tubercle." Anthrax was the first disease studied by the methods of bacteriology; and in his evidence concerning this disease, Sir John Simon speaks of bacteriology as of a discovery wholly new and unexplored: "We are going through a progressive work that has many stages, and are now getting more precise knowledge of the contagium. By these experiments on sheep it has been made quite clear that the contagium of sheep-pox is *something of which the habits can be studied, as the habits of a fern or a moss can be studied*; and we look forward to opportunities of thus *studying the contagium outside the body which it infects.* This is not a thing to be done in a day, or perhaps in ten years, but must extend over a long period of time." A few years later (1881) came Koch's discovery of the bacillus of tubercle. But a great advance was made in days before 1875 by the more general use of the microscope. Every change in the tissues during inflammation—the slowing of the blood-stream in the capillary vessels, the escape of the leucocytes through their walls into the surrounding tissues, the stagnation of the blood in the affected part—all these were observed in such transparent structures as the web or the mesentery of the frog, the bat's wing, or the tadpole's tail, irritated by a drop of acid, or a crystal of salt, or a scratch with a needle. It was in the course of observations of this kind that Wharton Jones observed the rhythmical contraction of veins, and Waller and Cohnheim observed the escape of the leucocytes, *diapedesis,* through the walls of the capillaries. From these simple experiments under the microscope arose all our present knowledge of the minute processes of inflammation. Later, came the work of Metchnikoff and others, showing the importance of *diapedesis* in relation to the presence of bacteria in the tissues.

2. *Suppuration and Wound-Infection.*—Suppuration may, in exceptional conditions, occur without micro-organisms, but practically every case of suppuration, wound-infection, or "blood-poisoning," all abscesses, boils, carbuncles, and all cases of puerperal fever, septicæmia, or pyæmia, are due to infection, either from without or from within the body, by various forms of *micrococcus.* The same is true of every case of erysipelas, or cellulitis, or acute gangrene—in short, of the whole multitude of "septic" diseases. The work done on these micrococci, and on other pathogenic micro-organisms, involved the study of the phases, antagonisms, and preferences of each kind, their range of variation and of virulence, and their products, and the influences on them of air, light, heat, and chemical agents. To establish a micro-organism as the cause of a disease, Koch postulated that it should be found in the diseased tissues, should be cultivated outside the body *in vitro,* should reproduce the same disease by inoculation in animals, and should be found again in the animals inoculated; and these postulates are but a single instance of the strict methods of bacteriology.

From the study of these organisms of suppuration arose Lister's work on the antiseptic method, as well as the serum-treatment for cases of micrococcic infection.

3. *Anthrax.*—The bacillus of anthrax (charbon, malignant pustule, wool-sorter's disease) was the first specific micro-organism discovered. Rayer and Davaine (1850) observed the *petits bâtonnets* in the blood of sheep dead of the disease; and in 1863, when Pasteur's observations on lactic-acid fermentation were published, Davaine recognized that the *bâtonnets* were not blood-crystals but living organisms. Koch afterward succeeded in cultivating the bacillus, and in reproducing the disease in animals by inoculation from these cultures. Pasteur's discovery of preventive inoculation of animals against the disease was communicated to the Académie des Sciences in February 1881; and in May of that year he gave his public demonstration at Pouilly-le-Fort. Two months later, at the International Medical Congress in London, he spoke as follows of this discovery:—". . . La méthode que je viens de vous exposer pour obtenir des vaccins du charbon était à peine connue qu'elle passait dans la grande pratique pour prévenir l'affection charbonneuse. La France perd chaque année pour une valeur de plus de vingt millions d'animaux frappés du charbon, plus de 30 millions, m'a dit une des personnes autorisées de notre Ministère de l'Agriculture; mais des statistiques exactes font encore défaut. On me demanda de mettre à l'épreuve les résultats qui précèdent par une grande expérience publique, à Pouilly-le-Fort, près de Melun. . . . Je la résume en quelques mots; 50 moutons furent mis à ma disposition, nous en vaccinâmes 25, les 25 autres ne subirent aucun traitement. Quinze jours après environ, les 50 moutons furent inoculés par le microbe charbonneux le plus virulent. Les 25 vaccinés résistèrent; les 25 non-vaccinés moururent, tous charbonneux, en cinquante heures. Depuis lors, dans mon laboratoire, on ne peut plus suffire à préparer assez de vaccin pour les demandes des fermiers. En quinze jours, nous avons vacciné dans les départements voisins de Paris près de 20,000 moutons et un grand nombre de bœufs, de vaches et de chevaux." The extent of this preventive vaccination may be judged from the fact that a single institute, the Sero-Therapeutic Institute of Milan, in a single year (1897–1898) sent out 165,000 tubes of anti-charbon vaccine, enough to inoculate 33,734 cattle and 98,792 sheep. In France, during the years 1882–1893, more than three million sheep and nearly half a million cattle were inoculated. In the *Annales de l'Institut Pasteur,* March 1894, M. Chamberland published the results of these twelve years in a paper entitled *Résultats Pratiques des Vaccinations contre le Charbon et le Rouget en France.* The mortality from charbon, before vaccination, was 10 per cent. among sheep and 5 per cent. among cattle, according to estimates made by veterinary surgeons all over the country. With vaccination, the whole loss of sheep was about 1 per cent.; the average for the twelve years was 0·94. The loss of vaccinated cattle was still less; for the twelve years it was 0·34, or about one-third per cent. The annual reports sent to M. Chamberland by the veterinary surgeons represent not more than half of the work. "A certain number of

veterinary surgeons neglect to send their reports at the end of the year. The number of reports that come to us even tends to become less each year. The fact is, that many veterinary surgeons who perform vaccinations every year content themselves with writing, 'The results are always very good; it is useless to send you reports that are always the same.' We have every reason to believe, as a matter of fact, that those who send no reports are satisfied; for if anything goes wrong with the herds, they do not fail to let us know it at once by special letters."

The following tables, from M. Chamberland's paper, give the results of Pasteur's treatment against *charbon* during 1882–1893, and against *rouget* (swine-measles) during 1886–1892. It is to be noted that the mortality from *rouget* among swine, in years before vaccination, was much higher than that from *charbon* among sheep and cattle: "it was about 20 per cent.; a certain number of reports speak of losses of 60 and even 80 per cent.; so that almost all the veterinary surgeons are loud in their praises of the new vaccination."

4. *Tubercle.*—Laennec, who in 1816 invented the stethoscope, recognized the fact that tubercle is a specific disease, not a simple degeneration of the affected tissues. Villemin, in 1865, communicated to the Académie des Sciences the fact that he had produced the disease in rabbits, by inoculating them with tuberculous matter; and he appealed to these inoculations—*en voici les preuves*—to show that *La tuberculose est une affection spécifique: Sa cause réside dans un agent inoculable: L'inoculation se fait très-bien de l'homme au lapin: La tuberculose appartient donc à la classe des maladies virulentes.* In 1868 Chauveau produced the disease not by inoculation but by admixture of tuberculous matter with the animals' food. In 1880, after a period of some uncertainty and confusion of doctrines, Cohnheim reaffirmed the infectivity of the disease, and even made the proof of tubercle depend on inoculation alone: "everything is tuberculous that can produce tuberculous disease by inoculation in animals that are susceptible to the disease; and nothing is tuberculous that cannot do this." In 1881 Koch discovered the tubercle-bacillus, and, in spite of the tragic failure of his *tuberculin* in 1890–91, a vast amount of practical advantage has already issued out of Koch's discovery, if not by way of cure, yet by way of prevention. It has been proved, by experiment on animals, that the sputa of phthisical patients are infective; and this and the like facts have profoundly influenced the nursing and general care of such cases. Bacteriology has brought about (under the safeguard of modern methods of surgery) a thorough and early surgical treatment of all primary tuberculous sores or deposits—the excision of tuberculous ulcers, the removal of tuberculous glands, and the like. It has helped us to make an early diagnosis, in obscure cases, by finding tubercle-bacilli in the sputa, or in the discharges, or in a particle of the tissues. It has proved, past all reasonable doubt, that *tabes mesenterica*, a disease that kills every year in England alone seven or eight thousand children, may arise from infection of the bowels by the milk of tuberculous cows. It has helped to bring about the present rigorous control of the milk-trade and the meat-trade. Moreover, *tuberculin* is used, because of the reaction that it causes in tuberculous animals, as a test for the detection of latent tuberculosis in cattle. An injection of one to two cubic centimetres under the skin of the neck is followed by a high temperature, if the animal be tuberculous. If it be not, there is no rise of temperature, or only a very slight rise. For example, in 1899 this test was applied to 270 cows on farms in Lancashire: 180 reacted to the test, 85 did not, 5 were "doubtful." Tuberculous disease was actually found in 175 out of the 180. Eber of Dresden used the test on 174 animals, of whom 136 reacted, 32 did not react, and 6 were doubtful. Of the 136, 22 were slaughtered, and were all found to have tubercle; of the 32, 3 were slaughtered, and were found free. The opinion of Professor M'Fadyean, one of the highest authorities on the subject, is as follows:—"I have most implicit faith in tuberculin as a test for tuberculosis when it is used on animals standing in their own premises and undisturbed. It is not reliable when used on animals in a market or slaughter-house. A considerable number of errors at first were found when I examined animals in slaughter-houses after they had been conveyed there by rail, &c. Since that, using it on animals in their own premises, I have found that it is practically infallible. I have notes of one particular case where 25 animals in one dairy were tested, and afterwards all were killed. There was only one animal which did not react, and it was the only animal not found to be tuberculous when killed."

5. *Diphtheria.*—The *Bacillus diphtheriæ* (Klebs-Loeffler bacillus) was described by Klebs in 1875, and obtained in pure cultures by Loeffler in 1884. Behring and Kitasato, in 1890, succeeded in immunizing animals against the disease. The first cases treated with diphtheria-antitoxin were published in 1893, by Behring, Kossel, and Huebner. In England the antitoxin treatment was begun in the latter part of 1894. Beside its curative use, the antitoxin has also been used as a preventive, to stop an outbreak of diphtheria in a school or institute or hospital or village, and with admirable success. (See DIPHTHERIA.)

6. *Tetanus* (Lock-jaw).—Experiments on animals have taught us the true nature of this disease, and have led to the discovery of an antitoxin which has given fairly good results. We possess, moreover, a preventive treatment against the disease; though, unfortunately, the time of latency, when the antitoxin is most needed, cannot be recognized. The old, mischievous doctrine that tetanus was due to acute inflammation of a nerve, tracking up from a wound to the central nervous system, was abolished once and for ever by Sternberg (1880), Carle and Rattone (1884), and Nicolaier (1884), who proved that the disease is due to infection by a specific flagellate organism in superficial soil. "It is said to be present in almost all rich garden-soils, and that the presence of horse-dung favours its occurrence. There seems to be no doubt as to the ubiquity of the tetanus germ" (Poore, *Milroy Lectures*, 1899). The work of discovering and isolating the bacillus was full of difficulty. Nicolaier, starting from the familiar fact that the disease mostly comes from wounds or scratches contaminated with earth, studied the various microbes of the soil, and inoculated rabbits with garden-mould: he produced the

disease, and succeeded in finding and cultivating the bacillus, but failed to obtain a pure culture. Kitasato, in 1899, obtained a pure culture. Others have studied the chemical products of the bacillus, and have been able to produce the symptoms of the disease by injection of these chemical products obtained from cultures, or from the tissues in cases of tetanus. It has been proved that the infection tends to remain local; that the bacilli in and near the wound pour thence into the blood their chemical products, and that these have a selective action, like strychnine, on the cells of the central nervous system. Therefore the rule, that the wounded tissues should be at once excised, in all cases where this can possibly be done, has received confirmation. Before Nicolaier, while men were still free to believe that tetanus was the result of an acute ascending neuritis, this rule was neither enforced nor explained.

The antitoxin-treatment has given the following results. The *Journal of the American Medical Association*, November 13, 1897, gives 26 cases, with 12 recoveries. The *Münchener Med. Wochenschrift*, November 16, 1897, gives 98, with 57. The *Brit. Med. Journ.*, July 23, 1898, gives 36, with 25. Erdheim, in September 1898, published 22, with 11. Engelmann, in 1898, 51, with 36. But some of these cases may have been published more than once. Tavel of Berne lately published 10 cases, with 7 recoveries, against 13 cases treated without antitoxin, of whom 11 died. On the other hand, Baccelli (*Brit. Med. Journ.*, 1899) reported better results than these, without antitoxin. The figures are all of them too small, and the disease too variable in intensity, for a final judgment at present. At all events, the use of the antitetanic serum does not exclude the use of other drugs also. The mortality of tetanus in this country, before the serum-treatment, may be estimated at 75 or 80 per cent.

The preventive use of the serum, in veterinary practice, has yielded admirable results. In some parts of the world tetanus is terribly common among horses. Nocard of Paris has reported as follows:—"The use of antitetanus serum as a preventive has been in force for some years in veterinary practice in cases of wounds or surgical procedures. To this end the Pasteur Institute has supplied 7000 doses of antitetanus serum, a dose being 10 cubic centimetres; a quantity which has sufficed to treat preventively 3100 horses in those parts of the country where tetanus is endemic. Among these there has been no death from tetanus. In the case of one horse, injected five days after receiving a wound, tetanus developed, but the attack was slight. During the same time that these animals were injected, the same veterinary surgeon observed, among animals not treated by injection, 259 cases of tetanus" (*Lancet*, August 7, 1897).

7. *Rabies.*—The date of the first case treated by Pasteur's preventive method—Joseph Meister, an Alsatian shepherd-boy—is July 1885. The existence of a specific micro-organism of rabies was a matter of inference. The incubation period of the disease is so variable that no preventive treatment was possible unless this incubation period could be regulated. Inoculations of the saliva of a rabid animal, introduced under the skin of animals, sometimes failed; and if they succeeded, the incubation period of the disease thus induced was hopelessly variable. Next, Pasteur used not saliva, but an emulsion of the brain or the spinal cord; because the central nervous system is the chief seat of the poison. But this emulsion, introduced under the skin, was also uncertain in action, and gave no fixed incubation period.

Therefore, he argued, as the poison has a selective action on the nerve-cells of the central nervous system, and a sort of natural affinity with them, it must be introduced directly into them, where it will have its proper environment: the emulsion must be put not under the skin, but under the *dura mater* (the membrane enveloping the brain). These subdural inoculations were the turning-point of his work. By transmitting the poison through a series of rabbits, by subdural inoculation of each rabbit with a minute quantity of nerve-tissue from the rabbit that had died before it, he was able to intensify the poison, to shorten its period of incubation, and to fix this period at six days. Thus he obtained a poison of exact strength, a definite standard of virulence, *virus fixe*: the next rabbit inoculated would have the disease in six days, neither more nor less. By gradual drying, after death, of the cords of rabid animals, he was able to attenuate the poison contained in them. The spinal cord of a rabbit that has died of rabies slowly loses virulence by simple drying. A cord dried for four days is less virulent than a cord dried for three, and more virulent than a cord dried for five. A cord dried for a fortnight has lost all virulence; even a large dose of it will not produce the disease. By this method of drying, Pasteur was able to keep going one or more series of cords, of known and exactly graduated strengths, according to the length of time they had been dried, ranging from absolute non-virulence through every shade of virulence.

As with fowl-cholera and anthrax, so with rabies: the poison, attenuated till it is innocuous, can yet confer immunity against a stronger dose of the same poison. A man, bitten by a rabid animal, has at least some weeks of respite before the disease can break out; and during that time of respite he can be immunized against the disease, while it is still dormant: he begins with a dose of poison attenuated past all power of doing harm, and advances day by day to more active doses, guarded each day by the dose of the day before, till he has manufactured within himself enough antitoxin to make him proof against any outbreak of the disease. (See HYDROPHOBIA.)

7. *Cholera.*—The specific organism of Asiatic cholera, the "comma-bacillus," was discovered by Koch in 1883; but such a multitude of difficulties arose over it, that it was not universally recognized as the real cause of the disease before 1892, the year of the epidemic at Hamburg. The discovery of preventive inoculation was the work of many men, but especially of Haffkine, one of Pasteur's pupils. Ferran's earlier inoculations in Spain (1885) were a failure. Haffkine's first inoculations were made in 1893. At Agra, in April 1893, he vaccinated over 900 persons; and from Agra went to many other cities of India. Altogether, in twenty-eight months (April 1893–July 1895) no less than 42,179 persons were vaccinated (many of them twice) in towns, cantonments, jails, tea-estates, villages, schools, &c., "without having to record a single instance of mishap or accident of any kind produced by our vaccines." (See CHOLERA.)

9. *Bubonic Plague.*—The *Bacillus pestis* was discovered in 1894 by Kitasato and Yersin, working independently. The preventive treatment was worked out by Haffkine in 1896:—"Twenty healthy rabbits were put in cages. Ten of them were inoculated with Haffkine's plague vaccine. Then both the vaccinated rabbits and the other ten rabbits that had not been vaccinated were infected with plague. The unprotected rabbits all died of the disease, and in their bodies innumerable quantities of the microbes were found. But the vaccinated rabbits remained in good health. Professor Haffkine then vaccinated himself and his friends. This produced some fever, from which, after a day or two, they recovered. Plague broke out in Byculla Jail, in Bombay, in January 1897. About half the prisoners volunteered to be inoculated. Of these, 3 developed plague on the day of inoculation, and it is probable that they had already plague before the treatment was carried out. Of the remaining 148 who were inoculated, only 2 were afterwards attacked with plague, and both of them recovered. At the same time, of the 173 who had not been vaccinated, 12 of them were attacked; and out of these, 6 died." (See PLAGUE.)

10. *Typhoid Fever.*—The *Bacillus typhosus* was discovered by Klebs, Eberth, and Koch in 1880–81. The first protective inoculations in England were made at Netley Hospital in 1896 by Professor Wright and Surgeon-Major Semple: sixteen medical men and two others offered themselves as subjects. The first use of the vaccine during an actual outbreak of typhoid was in October 1897 at the Kent County Asylum:—"All the medical staff and a number of attendants accepted the offer. Not one of those vaccinated—84 in number—contracted typhoid fever; while of those unvaccinated, and living under similar conditions, 16 were attacked. This is a significant fact, though it should in fairness be stated that the water was boiled after a certain date, and other precautions were taken, so that the vaccination cannot be said to be altogether responsible for the immunity. Still, the figures are striking" (*Lancet*, March 1898).

In 1899 Professor Wright vaccinated against typhoid more than 3000 of the Indian army, at Bangalore, Rawal Pindi, and Lucknow. Typhoid, among the soldiers in India, is on the increase; and Government has now sanctioned voluntary inoculation against typhoid, at the public expense, among the British troops.

Beside the preventive treatment, bacteriology has given us "Widal's reaction" for the early diagnosis of the disease—a matter of the very highest practical importance. A drop of blood, from the finger of a patient suspected to be suffering from typhoid fever, is diluted fifty or more times, that the perfect delicacy of the test may be ensured; a drop of this dilution is mixed with a nutrient fluid containing living bacilli of typhoid, and a drop of this mixture is observed under the microscope. The motility of the bacilli is instantaneously or very quickly arrested, and in a few minutes the bacilli begin to aggregate together into clumps. This "clumping" is also made visible to the naked eye by the subsidence of the agglutinated bacilli to the bottom of the containing vessel. The amazing delicacy of "Widal's test" is but a part of the wonder. Long after recovery, a fiftieth part of a drop of the blood will still cause clumping: it has even been obtained from an infant whose mother had typhoid shortly before the child was born. A drop of blood from a case suspected to be typhoid can now be sent by post to be tested, a hundred miles away, and the answer telegraphed back.

11. *Malta Fever* (Mediterranean Fever).—The *Bacillus Melitensis* was discovered in 1887 by Surgeon-Major Bruce. The work of discovering and preparing an immunizing serum was done at Netley Hospital. In this fever, as in typhoid and some others, Widal's test is of great value: "the diagnosis of Malta fever from typhoid is, of course, a highly important practical matter. It is exceedingly difficult in the early stages" (Manson). Even in a

dilution of 1 in 1000, the blood of Malta fever can give the typical reaction with the *Bacillus Melitensis*; and this occurred in a case at Netley of accidental inoculation with Malta fever: one of three cases that have happened there. The case is reported in the *British Medical Journal*, October 16, 1897:—"It appears that he had scratched his hand with a hypodermic needle on September 17, when immunizing a horse for the preparation of serum-protective against Malta fever; and his blood, when examined, had a typical reaction with the micrococcus of Malta fever in 1000-fold dilution. The horse, which has been immunized for Malta fever for the last eight months, was immediately bled, and we are informed that the patient has now had two injections, each of 30 cub. cm. of the serum. He is doing well, and it is hoped that the attack has been cut short." About fifty cases of the fever, by April 1899, had been treated at Netley. The *Lancet*, April 15, 1899, says that the treatment was "with marked benefit: whereas they found that all drug-treatment failed, the antitoxin treatment had been generally successful."

12. *Yellow Fever.*—The *Bacillus icteroides* was discovered by Sanarelli in 1896 during his study of yellow fever in the lazaretto of Flores. By 1897 he had prepared an immunizing serum, which gave excellent results on animals:—"This serum was tried on guinea-pigs against a mortal dose of virulent cultures. Half a cubic centimetre of this serum, injected twenty-four hours before the dose of virulent cultures, gave immunity. Two centimetres of it succeeded in saving guinea-pigs already ill, even if it were injected forty-eight hours afterward. . . . The preventive and curative power of the serum of the guinea-pig, the dog, and the horse, vaccinated against the *Bacillus icteroides*, should be held as absolutely demonstrated in the case of animals." At Rio de Janeiro Sanarelli treated 8 cases of yellow fever, with 4 recoveries: at San Carlos do Pinhal, in January 1898, 22 cases, with 16 recoveries; and of the 6 who died, 4 appeared hopeless from the first. The case of two children at the isolation hospital at San Carlos is worth quoting:—"La plupart des gens préféraient rester chez eux pour mourir; les seuls malades à ce moment à l'hôpital étaient deux enfants, ramassés dans la maison où leur père était déjà mort de fièvre jaune. Ces deux petits malades présentaient les symptômes caractéristiques de la maladie, y compris le *vomito negro*. Ils furent soumis de suite au traitement, dont les résultats furent presque immédiats; la fièvre et l'albuminurie disparurent, les symptômes généraux s'atténuèrent, et les deux enfants entrèrent en franche convalescence." Sanarelli was careful to select severe cases; and his work was done in a part of the country where the fever was most fatal:—"Chaque cas était choisi de commun accord entre nous, dans le but de mettre bien en évidence l'action thérapeutique du sérum, mettant toujours de côté tous les cas qui se présentaient avec des symptômes vagues ou atténués ou en forme légère ou fruste." In February 1898 the fever broke out in the jail at San Carlos, with 4 cases and 3 deaths. Preventive treatment was given to all the prisoners, except one who had already had the fever; and at once the outbreak stopped; no more cases occurred, though only a weak serum was used, and though the fever, two months later, was still active in the town.

13. *Malaria.*—Laveran, in 1880, discovered the *Plasmodium malariæ*, an amœboid organism, in the blood of malarial patients. In 1894 Manson took, as a working theory of malaria, the old belief that the mosquito is the intermediate host of the parasite. In 1895 came MacCullum's observations on an allied organism, *Halteridium*. In 1897, after two years' work, Ross found bodies, pigmented like the *Plasmodium*, in the outer coat of the stomach of the grey or "dapple-winged" mosquito, after it had been fed on malarial blood. In February 1898 he started work in Calcutta:—"Arriving there at a non-fever season, he took up the study of what may be called 'bird malaria.' In birds, two parasites have become well known—(1) the *Halteridium*, (2) the *Proteosoma* of Labbé. Both have flagellate forms, and both are closely allied to the *Plasmodium malariæ*. Using grey mosquitoes and proteosoma-infected birds, Ross showed by a large number of observations that it was only from blood containing the proteosoma that pigmented cells in the grey mosquito could be got; therefore that this cell is derived from the proteosoma, and is an evolutionary stage of that parasite" (Manson, 1898). These pigmented cells give issue to innumerable swarms of spindle-shaped bodies, "germinal rods"; and in infected mosquitoes Ross found these rods in the glands of the proboscis. Finally, he completed the circle of development, by infecting healthy sparrows by causing mosquitoes to bite them. Other workers in this field of science have also infected themselves, from mosquito-bites, with the disease. It would be hard to surpass Ross's work, and that done in Italy by Grassi and others, for fineness and carefulness. He says, for instance, "out of 245 grey mosquitoes fed on birds with proteosoma, 178, or 72 per cent., contained pigmented cells; out of 249 fed on blood containing halteridium, immature proteosoma, &c., not one contained a single pigmented cell. . . . Ten mosquitoes fed on the sparrow with numerous proteosoma contained 1009 pigmented cells, or an aveage of 101 each. Ten mosquitoes fed on the sparrow with moderate proteosoma contained 292 pigmented cells, or an average of 29 each. Ten mosquitoes fed on the sparrow with no proteosoma contained no pigmented cells." The destruction of the breeding-puddles of the special mosquito of malaria is therefore the chief thing to be done: and the habits and habitations of *Anopheles claviger* have become a matter of world-wide importance. A mass of evidence has also been accumulated which shows that mosquitoes also convey the parasitic organisms that are the cause of *filariasis*.

The list of diseases studied by the help of bacteriology is not yet complete: nothing has been said of glanders, rinderpest, Texas fever, and other infective diseases. Nothing, again, has been said of the grosser parasites, tape-worms, hydatids, trichina, and the like: whose whole history and life-changes have been worked out by the help of feeding-experiments on animals. Only three more examples need be given of discoveries made by the help of experiments on animals; and these are the nature and treatment of myxœdema, the actions of certain important drugs, and the serum-treatment of cases of snake-bite.

14. *Myxœdema.*—Our knowledge of myxœdema, like our knowledge of cerebral localization, began not in experimental science but in clinical observation (Gull, 1873; Ord, 1877). In 1882–1883 Reverdin and Kocher published cases where removal of the thyroid gland for disease (goître) had been followed by symptoms such as Gull and Ord had described. In 1884 Horsley, by removal of the thyroid gland of monkeys, produced in them a chronic myxœdema, a cretinoid state, the exact image of the disease in man: the same symptoms, course, tissue-changes, mental and physical hebetude, the same alterations of the excretions, the temperature, and the voice. In 1888 the Clinical Society of London published an exhaustive report, of 215 pages, on 119 cases of the disease, giving all historical, clinical, pathological, chemical, and experimental facts; but out of 215 pages there is but half a page about treatment, of the useless old-fashioned sort. In 1890 Horsley published the suggestion that a graft of thyroid gland from a newly-killed animal should be transplanted beneath the skin in cases of myxœdema:—"The justification of this procedure rested on the remarkable experiments of Schiff and von Eisselsberg. I only became aware in April 1890 that this proposal had been in fact forestalled in 1889 by Dr Bircher in Aarau. Kocher had tried to do the same thing in 1883, but the graft was soon absorbed; but early in 1889 he tried it again in five cases, and one greatly improved." In 1891 George Murray published his *Note on the Treatment of Myxœdema by Hypodermic Injections of an Extract of the Thyroid Gland of a Sheep*. Later, the gland was administered in food. At the present time tabloids of thyroid extract are given. We could not have a better example how experiments on animals are necessary for the advancement of medicine. Now, with little bottles of tabloids, men and women are restored to health who had become degenerate in body and mind, disfigured and debased. The same treatment has given back mental and bodily growth to countless cases of sporadic cretinism. Moreover, the action of the thyroid gland has been made known, and the facts of "internal secretions" have been in part elucidated. (Claude Bernard, speaking of the thyroid, the thymus, and the suprarenal capsules, said: "We know absolutely nothing about the functions of these organs; we have not so much as an idea what use and importance they may possess, because experiments have told us nothing about them, and anatomy, left to itself, is absolutely silent on the subject.")

15. *The Action of Drugs.*—Even in the 18th century medicine was still tainted with magic and with gross superstition: the 1721 Pharmacopœia contains substances that were the regular stock-in-trade of witchcraft. Long after 1721 neither clinical observation, nor anatomy, nor pathology brought about a reasonable understanding of the action of drugs: it was the physiologists, more than the physicians, who worked the thing out—Bichat, Magendie, Claude Bernard. Magendie's study of upas and strychnine, Bernard's study of curare and digitalis, revealed the *selective* action of drugs: the direct influence of strychnine on the central nerve-cells, of curare on the terminal filaments of motor nerves.

Two instances may be given how experiments on animals have elucidated the action of drugs. A long list might be made—aconite, belladonna, chloride of calcium, cocain, chloral, ergot, morphia, salicylic acid, strophanthus, the chief diuretics, the chief diaphoretics—all these and many more have been studied to good purpose by this method; but it must suffice to quote here Professor Fraser's account of digitalis, and Sir Thomas Lauder Brunton's account of nitrite of amyl:—

"1. Digitalis was introduced as a remedy for dropsy; and on the applications which were made of it for the treatment of that disease, a slowing action upon the cardiac movements was observed, which led to its acquiring the reputation of a cardiac sedative. . . . It was not until the experimental method was applied in its investigation, in the first instance by Claude Bernard, and subsequently by Dybkowsky, Pelikan, Meyer, Boehm, and Schmiedeberg, that the true action of digitalis upon the circulation was discovered. It was shown that the effects upon the circulation were not in any exact sense sedative, but, on the contrary, stimulant and tonic, rendering the action of the heart more powerful, and increasing the tension of the blood-vessels. The indications for its use in disease were thereby revolutionized, and at the same time rendered more exact; and the striking benefits which are now afforded by the use of this substance in most (cardiac) diseases were made available to humanity."

"2. In the spring of 1867 I had opportunities of constantly observing a patient who suffered from angina pectoris, and of obtaining from him numerous sphygmographic tracings, both during the attack and during the interval. These showed that during the attack the pulse became quicker, the blood-pressure rose, and the arterioles contracted. . . . It occurred to me that if it was possible to diminish the tension by drugs instead of by bleeding, the pain would be removed. I knew from unpublished experiments on animals by Dr. A. Gamgee that nitrite of amyl had this power, and therefore tried it on the patient. My expectations were perfectly answered."

15. *Snake-Venom.*—Sewall (1887) showed that animals could be immunized, by repeated injection of small doses of rattlesnake's venom, against a sevenfold fatal dose. Kanthack (1891) immunized animals against cobra-venom: afterward Fraser, Calmette, and many others, worked at the subject. Fraser's work on the antidotal properties of the bile of serpents is of the very highest interest and value, both in physiology and in sero-therapy. Calmette's work is an admirable instance of the delicacy and accuracy of the experimental method. The different venoms were measured in decimal milligrammes, and their action was estimated by the body-weights of the animals inoculated; but of course this estimate of virulence was checked according to the susceptibility of the animals; guinea-pigs, rabbits, and especially rats, being more susceptible than dogs:—

"The following table gives the relative toxicity, for 1 kilogramme of rabbit, of the different venoms that I have tested":—

1. Venom of *Naja* . . . . 0·25 milligramme per kilogramme of rabbit. One gramme of this venom kills 4000 kilogrammes of rabbit: activity = 4,000,000.
2. Venom of *Hoplocephalus* . . . . 0·29 . . 3,450,000.
3. Venom of *Pseudechis* . . . . . 1·25 . . 800,000.
4. Venom of *Pelias berus* . . . . 4·00 . . 250,000.

By experiments *in vitro* Calmette studied the influence of heat and chemical agents on these venoms; and, working by various methods, was able to immunize animals:—

"I have got to immunizing rabbits against doses of venom that are truly colossal. I have several, vaccinated more than a year ago, that take without the least discomfort so much as forty milligrammes of venom of *Naja tripudians* at once. Five drops of serum from these rabbits wholly neutralize *in vitro* the toxicity of one milligramme of *Naja* venom. . . . It is not even necessary that the serum should come from an animal vaccinated against the same sort of venom as that in the mixture. The serum of a rabbit immunized against the venom of the cobra or the viper acts indifferently on all the venoms that I have tested."

In 1895 he had prepared a curative serum: "If you first inoculate a rabbit with such a dose of venom as kills the control-animals in three hours; and then, an hour after injecting the venom, inject under the skin of the abdomen four to five cubic centimetres of serum, recovery is the rule. When you interfere later than this, the results are uncertain; and out of all my experiments the delay of an hour and a half is the most that I have been able to reach."

In 1896 four successful cases were reported in the *British Medical Journal*. In 1898 Calmette reports:—

"It is now nearly two years since the use of my antivenomous serum was introduced in India, in Algeria, in Egypt, on the West Coast of Africa, in America, in the West Indies, Antilles, &c. It has been very often used for men and domestic animals (dogs, horses, oxen), and up to now none of those that have received an injection of serum have succumbed. A great number of observations have been communicated to me, and not one of them refers to a case of failure" (*Brit. Med. Journ.*, May 14, 1898; see also *Boston Medical and Surgical Journal*, April 7, 1898).

It is of course impossible that "antivenene" should be always at hand, or that it should bring about any great decrease in the number of deaths from snake-bite, which in India alone are 30,000 annually; but at least something has been accomplished with it.

The account given above of the chief discoveries that have been made by the help of experiments on animals, in physiology, pathology, bacteriology, and therapeutics, might easily have been lengthened if we added to it other methods of treatment that owe less, but yet owe something, to these experiments: for example, transfusion of saline fluid, hypodermic medication, torsion of arteries, grafting of skin, transplantation of bone, the absorbable ligature, the diagnostic and therapeutic uses of electricity. Nevertheless, the facts quoted in this article are sufficient to indicate the great debt that medicine owes to the experimental method. (S. P.)

Explosives.—Explosives are substances capable of producing, under certain circumstances, a more or less violent action. This action may be very local or may extend to some distance around the place where it happens. It is generally accompanied by an aërial disturbance or noise. Sometimes this action results in the propulsion of solids, or liquids, to some distance, or in a local disruption of matters in the immediate vicinity. Where the second action is very pronounced and projection is at a minimum, the term *detonation* is applied to the action, to distinguish it from *explosion*, and *detonator* or "disruptor" explosive to the substance. Explosives may be classified under these two headings. An explosive of the projecting, or propulsive, class generally acts by burning in a more or less rapid and regular manner, and producing from a comparatively small volume of solid (liquid or gas) a much larger volume of gases, and at the same time much heat may be evolved, which further expands the gases. Time is an important factor. Many ordinary combustion actions can be so accelerated as to become explosive, and this effect can be determined by increasing the area of contact between combustible and oxygen or oxygen-producers. Quantity of heat-energy alone does not necessarily give an explosive action. Some metals burn with extreme vigour, as indicated by the temperatures produced, but unless the products be gaseous, no real explosive action results.

Explosives may be mixtures of combustible matters with oxygen or suppliers of oxygen, or chemical compounds. All chemical compounds may be classified under one of two headings, being either "endothermic" or "exothermic." The former term means that in the construction or building up of the compound some amount of energy becomes latent or potential. This is the case where any two elementary substances unite only under the compulsion of a high temperature, an electric current, or while some other reactions are proceeding. For example, oxygen and nitrogen unite only under the influence of an electric spark; similarly with carbon and nitrogen and carbon and hydrogen. In some complex chemical reactions what are known as secondary products appear. In some of these the main reaction is one of running down of energy, and the secondary one a piling up of energy in the form of a complex and relatively unstable compound. The formation of chlorates is a good example of this, five-sixths of the reaction representing the running down of energy, and only one-sixth the formation of an "endothermic" compound. A further meaning of endothermic will be apparent from facts about acetylene, a compound of carbon and hydrogen. When 26 parts, by weight, of acetylene are burnt, the heat produced will warm up 310,450 parts of water one degree centigrade. Twenty-four of the 26 parts are carbon, and when this quantity in the form of pure charcoal is burnt, only 192,000 of these heat-units are produced, and from two parts of hydrogen 68,000 units, in all 256,000 units. Therefore 50,450 units of heat are given by the compound over the heat given by its constituents burning to the same end products. This excess of heat-energy is supposed to be due to a form of latent or potential, perhaps chemical, energy in the compound, which becomes actual energy in some form[1] or other when the compound is broken up or resolved.

The *manner* in which a substance is endothermic is of importance as regards the practical employment of explosives. Some particular endothermic state or form evidently

[1] Not necessarily heat. Silver acetylide, nitrogen chloride or iodide, and other compounds decompose with great violence, but very little heat is evolved.

results from the mode of formation, and the consequent internal structure as a chemical or physical molecule. Physical structure alone is certainly answerable for a decidedly endothermic condition in some materials, as, for instance, the chilled glass bulbs or drops known as Bologna phials and Ruperts drops. They are made by suddenly cooling glass from a melted state. They explode on scratching or cutting to a certain depth. The cause is probably that the glass is occupying at the ordinary temperature the same, or nearly the same, volume it occupied when in a melted state, so that all the particles are in a state of strain, tending to revert to an easier relative position. "Superfused" substances are probably in a similar physical state of potential. Acetate of soda melts when heated a little above 56° C., and if kept melted for some time and then cooled in a clean atmosphere, can be kept for any length of time in a fluid condition. On contact with a crystal of the same substance the whole will rapidly solidify, at the same time becoming heated to about 56° C. again. Among endothermic substances may be included almost all carbon compounds, with the exception of carbon dioxide; and many, if not all, compounds of nitrogen. As substances can be endothermic in more than one way, it is not at present possible to arrange the known examples in a strict order. Most explosives contain nitrogen in some form. It may be stated, generally, that all explosive compounds, whatever be the manner of their explosion, are endothermic, and all endothermic substances *should* be explosible under some circumstance.

The *detonating* explosives may be termed "disruptors" in distinction to propellants, because their effect is to break up immediately surrounding matter into very small particles—to pulverize them in fact—rather than to throw them any distance. Some few substances are so nearly purely "disruptors" that their action on explosion is always of this nature: for instance, silver acetylide, silver fulminate, chloride of nitrogen, some diazo compounds, &c. They cannot be used as propellants under any known conditions. Some substances can behave in both ways under certain circumstances and within limits. Gun-cotton, for instance, can be really detonated and also burnt quietly. Nitro-glycerine burns quietly as a constituent of cordite, but, as dynamite, detonates and "disrupts" in a typical manner.

Exothermic compounds are in a certain sense the reverse of endothermic. They are *relatively* dead or exhausted, and will do but little except when energy is expended upon them from the outside. Water and the ordinary minerals of the earth's crust belong to this class; they are the end products of the running down of energy.

Gunpowders are mechanical mixtures of a nitrate[1] with compounds of carbon (charcoal) and sulphur. The mechanical operations of manufacture are all to the end of producing an intimate mixture. The action on explosion is combustion only, and it is doubtful if gunpowders can be detonated by ordinary friction or percussion. Black powder contains 75 per cent. potassium nitrate, 10 per cent. sulphur, and 15 per cent. charcoal, which again may contain about 10 per cent. oxygen and nearly 3 per cent. hydrogen. As these proportions are not in any simple chemical relation, it is not easy to express the explosion by an equation. Debus thinks that at least two actions occur—first, $16KNO_3 + 13C + 5S = 3K_2CO_3 + 5K_2SO_4 + 9CO_2 + CO + 8N_2$. These products again interact; thus with carbon, $4K_2SO_4 + 7C = 2K_2CO_3 + 2K_2S_2 + 5CO_2$, and with sulphur $4K_2SO_4 + 7S = K_2SO_4 + 3K_2S_2 + 4CO_2$. The main products are carbon dioxide, nitrogen, a little carbon monoxide and steam as gases, and potassium carbonate, sulphate, and sulphide as solids.

[1] Potassium nitrate only can be employed; all others are either deliquescent, decompose too easily, or have other objectionable qualities.

The difference between black and brown powders lies in the nature of the carbonaceous material and in the amount of sulphur. In formulæ it may be represented

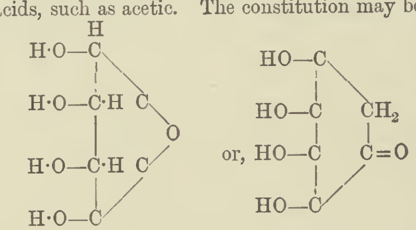
$$\text{as } 16KNO_3 \left\{ \begin{array}{l} 17{\cdot}39 \text{ carbon} \\ 12{\cdot}62 \text{ hydrogen} \\ 12{\cdot}0 \text{ oxygen} \end{array} \right\} \text{charcoal, } 1{\cdot}52 \text{ sulphur.}$$

The combustion products are carbon dioxide, nitrogen, much steam, and a very little carbon monoxide as gases; potassium carbonate, sulphate, and a little nitrite as solids. Brown powders burn slower than black, and, even under great pressures, the rate of burning is not appreciably quicker than when under moderate pressures. Black powder when burnt in large charges gives a sharp pressure curve somewhat approaching the character of a detonation. The reason for the slow burning of brown powder is that the cellulosic material (brown charcoal) requires to be further decomposed before it actually burns, as in the case of the wax of a candle, which only burns as vapour, not as wax.

Chlorates cannot be used in mixtures containing sulphur, being far too sensitive to friction. With organic materials, as sugar, it is possible to use them, but even such compounds are unsafe against percussion, and the way in which they develop pressure on explosion renders them dangerous for artillery purposes; in fact, they are only suitable for blasting-powders.

Gun-cotton was the earliest-discovered explosive compound, from a practical point of view. It is produced by the action of nitric acid on cotton, paper, or wood-fibre (Pelouze, 1838). Starch yields a similar substance. The product from cotton-wool was investigated in 1845 by Schönbein, who proposed its use as a substitute for gunpowder. Gun-cotton contains the elements of nitric acid combined in the whole cellulose molecule, no doubt in the form of an ester or nitrate. The precise constitution of this substance is still a matter of some controversy.

The smallest formula for cellulose is $C_6H_{10}O_5$, but the substance is probably more complex. Four of the oxygen atoms are supposed to be present in the hydroxylic form ($-OH$), as they are replaceable by some acids, such as acetic. The constitution may be therefore



On contact with strong nitric acid at the ordinary temperature a reaction—probably $C_6H_{10}O_5 + 2HNO_3 = 2H_2O + C_6H_8O_3(NO_3)_2$—takes place. Analyses of the product do not quite bear out this equation, but it is probably what would happen if the correct condition of temperature and strength of acid could be found and maintained. The product, after washing and drying, ignites at about 150° C. It is very soluble in a mixture of alcohol and ether, and is the main constituent of collodion. A mixture of nitric and sulphuric acids produces, under the same conditions, a more highly nitrated product, the sulphuric acid for the most part acting only as a dehydrating agent in taking up the water eliminated by the action of the nitric acid on the cellulose.

$$C_6H_{10}O_5 + 3HNO_3 = 3H_2O + C_6H_7O_2(NO_3)_3$$

$$\downarrow$$

$$+ \; {}^*3H_2SO_4$$

$$\|$$

$$3(H_2SO_4H_2O).$$

* The sulphuric acid does not appear in the final product, and may be omitted from the equation, but it is doubtful whether its action is confined to dehydration only.

As with nitric acid alone, this action takes some time at the ordinary temperature, depending on the fineness of the cotton employed. The product is unchanged in appearance, but shows a difference from cotton when examined by polarized light. It has gained in weight, but not up to the extent required by the equation. It is insoluble in alcohol and ether, singly or mixed, and its igniting point is about 180° C. It is very doubtful whether the formula $C_6H_7O_2(NO_3)_3$ is not much too simple, but serious difficulties occur in the investigation of this substance (and cellulose compounds generally) owing to its insoluble nature. Gun-cotton is certainly a nitrate. Alkalies and alkaline sulphides act somewhat readily upon it, tending to reproduce cellulose. The artificial silk process depends upon this circumstance. Ammonia is particularly active in decomposing it. Dilute acids have little or no action. Several substances, as acetone and acetic ether, dissolve or gelatinize gun-cotton, and on the solvent evaporating away, the gun-cotton is left in what is known as a colloidal state. The employment of gun-cotton as the basis or main ingredient of smokeless gunpowder depends entirely on this gelatinizing action, and all attempts to employ gun-cotton before this was discovered were failures. Fibrous gun-cotton may burn or explode at any rate, and under a little pressure detonation almost always takes place. In the colloid form burning can only take place at the outer surface, as gases are quite unable to penetrate a colloidal substance. Assuming gun-cotton to be a cellulose trinitrate, there is enough contained oxygen for a partial combustion without external air. The products of burning are steam, carbon monoxide, and dioxide (CO and CO_2), nitrogen, nitric oxide (NO), and sometimes methane (CH_4). The relative amounts of these vary considerably with the conditions of firing. There is some dispute and controversy about the matter, but probably nitric oxide is always one product. Dry gun-cotton can be detonated by a charge of fulminate or by a smart blow on an anvil, though the explosion seldom spreads from the piece struck. Wet gun-cotton can be detonated by the shock of the dry substance detonating. Starches, sugars, and many similar substances can be converted into nitrates of a similar type to gun-cotton, but some are soluble in water, and all have some objectionable properties which unfit them for practical use as explosives.

Nitro-glycerine, or glycerine nitrate, is the product of the action of a mixture of nitric and sulphuric acids on glycerine at temperatures below 20° C.

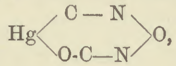
Its chemical constitution may be said to be accurately known. Glycerine has the composition and constitution shown by $\begin{matrix} CH_2OH \\ CHOH, \\ CH_2OH \end{matrix}$ as proved by synthetic methods. The action of the mixed acids is to replace the three hydroxyl groups (OH) by NO_3, so that nitro-glycerine is represented as $C_3H_5-(NO_3)_3$, or a trinitrate of the glycerine radical C_3H_5. Nitric acid alone does not form this compound. Sulphuric is, in addition, necessary, and probably exerts the same function here as in the case of gun-cotton formation. In making nitro-glycerine the glycerine is carefully added to the cooled acid mixture, a great excess of acids being employed. The reaction is completed within about one minute of contact, a slight rise in temperature taking place. The product is separated from the acids and washed repeatedly by water, and finally with an alkaline solution. Nitro-glycerine is an oily liquid heavier than water, and almost insoluble therein. It boils at about 120° C., and begins to decompose at the same time, generally detonating very violently at about this temperature, though when rapidly heated in very small quantity it may simply flash off quietly. Soaked into a porous substance, as blotting-paper, a little may be burnt quietly, as also when incorporated into a jelly of gun-cotton, as in cordite. Its combustion is more complete than is the case with gun-cotton, since it contains relatively more oxygen. Under atmospheric pressure the products are the same as with gun-cotton, but the quantity of carbon dioxide is greater in proportion. A probable equation is—

$$2(C_3H_5(NO_3)_3) = 5H_2O + 5CO_2 + CO + 2N_2 + 2NO.$$

Detonation may be brought about by a sharp blow on a hard surface, more completely when the nitro-glycerine is soaked into some porous material, as kieselguhr, or even sawdust, when almost any form of "detonator," as fulminate of mercury, will bring about a complete detonation. This is the essential condition in the various forms of *dynamite*. Nascent hydrogen, from almost any source, or alkaline sulphides will reduce nitro-glycerine to glycerine, and convert the NO_3 portion of the substance into ammonia; hence alkaline sulphides are well adapted for the quiet destruction of nitro-glycerine or dynamite. Glycerine belongs to a class of compounds known as alcohols. All these substances contain one or more groups of $-OH$, and in consequence of this react with nitric acid under certain circumstances, to produce nitrates with properties more or less resembling nitro-glycerine as to their explosiveness. Ordinary alcohol (C_2H_5OH), for instance, will form a nitrate $C_2H_5NO_3$, the vapour of which explodes with considerable violence. The volatile nature of this and several similar compounds preclude any practical employment as explosives.

Fulminates.—The first of the fulminates was discovered by Howard in 1800, as a product of the action of alcohol on a solution of mercury in nitric acid.

The only fulminate of practical importance is the mercury compound $HgC_2N_2O_2$. The essential condition for formation is that the nitrate of mercury solution shall contain some nitrous acid. The probable constitution of mercury fulminate may be



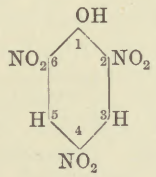
but several other formulæ have been proposed. Its explosiveness no doubt depends for the most part on its structure. It is a white crystalline solid, only slightly soluble in water. Small quantities, when heated in air, burn very rapidly. Slight friction or percussion will cause violent detonation. Its rate of burning is too high to allow it time to ignite common powder. In igniting and firing compositions, therefore, for which it is mostly employed, it is mixed with certain quantities of inert substances, as glass-powder, &c., which reduce the rate of burning or explosion. The products of its burning are: mercury, carbon, and carbon dioxide and nitrogen. Other metallic fulminates are known, but they are either too sensitive when in a dry state,—as silver fulminate, which when dry will explode if shaken on paper,—or decompose in solution. Alkaline sulphides act very rapidly on fulminate of mercury, decomposing it into quite non-explosive compounds. Fulminate of mercury is largely employed both as an igniting and detonating material for other explosives.

Nitro Explosives from Benzene.—Benzene, C_6H_6, is a hydrocarbon extracted from coal-tar. Nitric acid forms with it a number of derivatives called nitro compounds, most, if not all, of which are explosives under certain conditions.

The simplest is nitro-benzene, $C_6H_5NO_2$, a liquid; then comes dinitro-benzene, $C_6H_4(NO_2)_2$, known in three modifications, all of which are solids; then trinitro and tetra-nitro compounds, of which little is known. Dinitro-benzene can actually be employed as a constituent of blasting explosives, and to a small extent is also used in some sporting-powders. All these compounds are difficult to explode as compared with gun-cotton or nitro-glycerine.

Picric Acid.—Coal-tar contains some benzene compounds in addition to benzene itself. One of these is phenol or carbolic acid, C_6H_5OH, a hydrate of benzene. When this substance is brought in contact with nitric acid several products are formed, depending on strength of acid and temperature, the final stage being a trinitro derivative known as picric acid or trinitro-phenol, $C_6H_2(NO_2)_3OH$. The action is too violent to allow of this direct process of manufacture being employed on a large scale. As a matter of fact several physical modifications of trinitro-phenol are formed by the direct action of nitric acid on phenol, and some of these are very easily decomposed.

The usual method of manufacture is to act on phenol with hot sulphuric acid, which forms a phenol sulphonic acid of a particular kind, $C_6H_5OH + H_2SO_4 = C_6H_4{}^{OH}_{SO_3}H + H_2O$. This sulphonic acid, when heated with dilute nitric acid, gives a very perfect yield of the particular variety of trinitro-phenol known as picric acid. This is pictured in structural formula as



The other trinitro-phenols alluded to have a different structure, and in consequence differ in properties. Picric acid is a yellow crystalline solid, soluble in hot, but very slightly in cold, water. Metallic oxides combine with it to form picrates, as $C_6H_2(NO_2)_3OK$, the potassium salt. All its metallic compounds are very sensitive to heat or friction, and detonate very vigorously. When burnt in a vacuum vessel, the products from picric acid agree very closely with the equation: $2(C_6H_2(NO_2)_3OH) = 3H_2O + 3N_2 + 5CO_2 + CO + 6C$, but pressure exerts much influence on the relative amounts of these products. Many substances belonging to the class phenols will similarly form explosive nitro compounds.

Picric Acid melts at 122·5 C. to a pale yellow liquid, at which temperature a little vapour is formed, which can be ignited, and the substance then burns quietly, with a very smoky flame. When rapidly heated above its melting-point it may undergo internal decomposition and, depending on the quantity and pressure developed, either burn rapidly or detonate violently.

After melting and again solidifying, picric acid becomes somewhat denser, although still crystalline.

Lyddite is picric acid that has been melted. Owing to its more compact state, resulting from fusion, it is much easier to detonate by means of exploders of the fulminate class or, better, with some metallic compounds of picric acid itself (picrates) or even by rapidly heating in a confined space. Compared with gun-cotton or nitro-glycerine, and many other explosives, picric acid is difficult to detonate.

Melinite may consist of picric acid alone or mixtures of that substance with certain picrates or nitrates, as ammonium nitrate, which increase its sensibility to percussion or heat, and may add to the violence of explosion.

Diazo Compounds.—From the nitro-benzene compounds substances known as amino compounds, of which aniline, $C_6H_5 - NH_2$, is an example, may be obtained. Many of these react in a certain way with nitrous acid, producing diazo compounds, of which diazo-benzene, $C_6H_5 - NN{-}OH$, is an example. In a dry state these substances are generally not only very explosive but very sensitive to either heat or friction. They are scarcely practical explosives at present.

Amino explosives are becoming a large class. Amino acetic acid, CH_2NH_2COOH, combines with nitric acid and is known as glycocoll nitrate. It burns rapidly and quietly when ignited, or will detonate under pressure.

Hydrazoic acid, N_3H, is possibly the most powerful explosive known. It was discovered by Curtius. It is a gaseous substance which forms salts with metals,—as silver and sodium,—which explode with extreme violence on heating to a little above the boiling-point of water. The ammonia compound N_3NH_4 gives, according to Berthelot, 1148 cubic centimetres of gases for 1 gram weight of substance,—a greater change of volume than in any other known case.

See also PROPELLANTS, ORDNANCE (*Ammunition*), and MINING. (W. R. E. H.)

Exterritoriality is a term of international law, used to denominate certain immunities from the application of the rule that every person is subject for all acts done within the boundaries of a state to its local laws. It is also employed to describe the quasi-extraterritorial position, to borrow the phrase of Grotius, of the dwelling-place of an accredited diplomatic agent, and of the public ships of of one state while in the waters of another. Latterly its sense has been extended to all cases in which states refrain from enforcing their laws within their territorial jurisdiction. The cases recognized by the law of nations relate to: (1) the persons and belongings of foreign sovereigns, whether incognito or not; (2) the persons and belongings of Ambassadors, Ministers Plenipotentiary, and other accredited diplomatic agents and their suites (but not Consuls, except in some non-Christian countries, in which they sometimes have a diplomatic character); (3) public ships in foreign waters. Exterritoriality has also been granted by treaty to the subjects and citizens of contracting Christian states resident within the territory of certain non-Christian states. Lastly, it is held that when armies or regiments are allowed by a foreign state to cross its territory, they necessarily have exterritorial rights. "The ground upon which the immunity of sovereign rulers from process in our courts," said Mr Justice Wills in the case of Mighell *v.* Sultan of Johore, 1894, "is recognized by our law, is that it would be absolutely inconsistent with the status of an independent sovereign that he should be subject to the process of a foreign tribunal, unless he deliberately submits to its jurisdiction." It has, however, been held where the foreign sovereign was also a British subject (Duke of Brunswick *v.* King of Hanover, 1844), that he is amenable to the jurisdiction of the English Courts in respect of transactions done by him in his capacity as a subject. A "foreign sovereign" may be taken to include the President of a Republic, and even a potentate whose independence is not complete. Thus in the case, cited above, of Mighell *v.* the Sultan of Johore, the Sultan was ascertained to have abandoned all right to contract with foreign states, and to have placed his territory under British protection. The Court held that he was, nevertheless, a foreign sovereign in so far as immunity from British jurisdiction was concerned. The immunity of a foreign diplomatic agent, as the direct representative of a foreign sovereign (or state), is based on the same grounds as that of the sovereign authority itself. The international practice in the case of Great Britain was confirmed by an Act of Parliament of the reign of Queen Anne, which is still in force. The preamble to this Act states that "turbulent and disorderly persons in a most outrageous manner" had insulted the person of the then Ambassador of his Czarish Majesty, Emperor of Great Russia," by arresting and detaining him in custody for several hours, "in contempt to the protection granted by Her Majesty, contrary to the law of nations, and in prejudice of the rights and privileges which Ambassadors and other public Ministers, authorized and received as such, have at all times been thereby possessed of, and ought to be kept sacred and inviolable." This preamble has been repeatedly held by our Courts to be declaratory of the English common law. The Act provides that all suits, writs, processes, against any accredited Ambassador or public Minister or his domestic servant, and all proceedings and judgments had thereupon, are "utterly null and void," and that any person violating these provisions shall be punished for a breach of the public peace. Thus a foreign diplomatic agent cannot, like the sovereign he represents, waive his immunity by submitting to the British jurisdiction. The diplomatic immunity necessarily covers the residence of the diplomatic agent, which some writers describe as assimilated to territory of the state represented by the agent; but there is no consideration which can justify any extension of the immunity beyond the needs of the diplomatic mission resident within it. It is different with public ships in foreign waters. In their case the exterritoriality attaches to the vessel. Beyond its bulwarks captain and crew are subject to the ordinary jurisdiction of the state upon whose territory they happen to be. By a foreign public ship is now understood any ship in the service of a foreign state. It was even held in the case of the *Parlement Belge* (1880), a packet belonging to the Belgian Government, that the character of the vessel as a public ship was not affected by its carrying passengers and merchandise for hire.

Writers frequently describe the exterritoriality of both embassies and ships as absolute. There is, however, this difference, that the exterritoriality of the latter not being, like that of embassies, a derived one, there seems to be no ground for limitation of it. It was, nevertheless, laid down by the arbitrators in the *Alabama* case (Cockburn dissenting), that the privilege of exterritoriality accorded to vessels had not been admitted into the law of nations as an absolute right, but solely as a proceeding founded on the principle of courtesy and mutual deference between different nations, and that it could therefore "never be appealed to for the protection of acts done in violation of neutrality."

The exterritorial settlements in the Far East, the privileges of Christians under the arrangements made with the Ottoman Porte, and other exceptions from local jurisdictions, are subject to the conditions laid down in the treaties by which they have been created. There are also cases in which British communities have grown up in barbarous countries without the consent of any local authority. All these are regulated by Orders in Council, issued now in virtue of the Foreign Jurisdiction Act, 1890, an Act enabling the Crown to exercise any jurisdiction it may have "within a foreign country" in as ample a manner as if it had been acquired "by cession or conquest of territory." A very exceptional case of exterritoriality is that granted to the Pope under a special Italian enactment. (T. BA.)

Extradition.—(1) UNITED KINGDOM. The Extradition Acts, 1870–73 (33 and 34 Vict. cc. 62 and 36, and 37 Vict. c. 60), and the Fugitive Offenders Act, 1881 (44 and 45 Vict. c. 69), deal with different branches of the same subject, the recovery and surrender of fugitive criminals. The Extradition Acts apply in the case of countries with which Great Britain has extradition treaties. The Fugitive Offenders Act applies—(1) as between the United Kingdom and any British possession, (2) as between any two British possessions, and (3) as between the United Kingdom or a British possession and certain foreign countries, such as Turkey and China, in which the Crown exercises foreign jurisdiction. Most of the extradition treaties and the Fugitive Offenders Act are of later date than the article on EXTRADITION in the ninth edition of this work; and it appears desirable to present a general view of the law governing the recovery and surrender of fugitive criminals, including, for the sake of completeness, the case of fugitives from one part of the United Kingdom to another.

Conditions of Surrender.—In spite of some earlier authorities it has long been settled that in English law there is no power to surrender fugitive criminals to a foreign country without express statutory authority. Such authority is now given by the Extradition Acts, 1870–73, but only in the case of the offences therein specified, and with regard to countries with which an arrangement has been entered into, and to which the Acts have been applied by Order in Council. The Acts are further to be applied, subject to such "conditions, exceptions, and qualifications as may be deemed expedient" (s. 2); and these conditions, &c., are invariably to be found in the extradition treaty which is set out in the Order in Council applying the Extradition Acts to a particular country. To support a demand for extradition from Great Britain it is therefore necessary to show that the offence is one of those enumerated in the Extradition Acts, and also in the particular treaty, and that the acts charged amount to the offence according to the laws both of Great Britain and of the state demanding the surrender.

Surrender of Subjects.—A further question arises where a state is called on to surrender one of its own subjects. Some of the treaties, such as those with France and Germany, stipulate that neither contracting party shall surrender its own subjects, and in such cases a British subject cannot be surrendered by his own country. The treaties with Spain, Switzerland, and Luxembourg provide for the surrender by Great Britain of her own subjects, but there is no reciprocity. Other treaties, such as those with Austria, Belgium, Russia, and the Netherlands, give each party the option of surrendering or refusing to surrender its own subjects in each particular case. Under such treaties British subjects are surrendered unless the Secretary of State intervenes to forbid it. Lastly, some treaties, such as that with the United States, contain no restriction of this kind, and the subjects of each Power are freely surrendered to the other. Surrender by Great Britain is also subject to the following restrictions contained in s. 3 of the Extradition Act, 1870:—(1) that the offence is not of a political character, and the requisition has not been made with a view to try and punish for an offence of a political character; (2) that the prisoner shall not be liable to be tried for any but the specified extradition offences; (3) that he shall not be surrendered until he has been tried and served his sentence for offences committed in Great Britain; and (4) that he shall not be actually given up until fifteen days after his committal for extradition, so as to allow of an application to the courts.

Political offences.

The question as to what constitutes a political offence is one of some nicety. It was discussed in *In re* Castioni (1890, 1 Q.B. 149), where it was held, following the opinion of Mr Justice Stephen in his *History of the Criminal Law*, that to give an offence a political character it must be "incidental to and form part of political disturbances." Extradition was accordingly refused for homicide committed in the course of an armed rising against the constituted authorities. In the more recent case of *In re* Meunier (1894, 2 Q.B. 415), an Anarchist was charged with causing two explosions in Paris —one at the Café Véry resulting in the death of two persons, and the other at certain barracks. It was not contended that the outrage at the Café was a political crime, but it was argued that the explosion at the barracks came within the description. The Court, however, held that to constitute a political offence there must be two or more parties in the state, each seeking to impose a government of its own choice on the other, which was not the case with regard to Anarchist crimes. The party of anarchy was the enemy of all governments, and its effects were directed primarily against the general body of citizens. The test applied in the earlier case is perhaps the more satisfactory of the two.

With regard to the provision that surrender shall not be granted if the requisition has in fact been made with a view to try and punish for an offence of a political character, it was decided in the recent case of Arton (1896, 1 Q.B. 108) that a mere suggestion, that after his surrender for a non-political crime, the prisoner would be interrogated on political matters (his alleged complicity in the Panama scandal), and punished for his refusal to answer, was not enough to bring him within the provision. The Court also held that it had no jurisdiction to entertain a suggestion that the request of the French Government for his extradition was not made in good faith and in the interests of justice.

Extradition Offences.—The following is a list of crimes in respect of which extradition may be provided for under the Extradition Acts, 1870–73, and the Slave Trade Act, 1873. *Extradition Act*, 1870:—(1) Murder; (2) Attempt to murder; (3) Conspiracy to murder; (4) Manslaughter; (5) Counterfeiting and altering money, uttering counterfeit or altered money; (6) Forgery, counterfeiting, and altering and uttering what is forged or counterfeited or altered; (7) Embezzlement and larceny; (8) Obtaining money or goods by false pretences; (9) Crimes by bankrupts against bankruptcy law; (10) Fraud by a bailee, banker, agent, factor, trustee, or director, or member or public officer of any company made criminal by any law for the time being in force; (11) Rape; (12) Abduction; (13) Child-stealing; (14) Burglary and housebreaking; (15) Arson; (16) Robbery with violence; (17) Threats by letter or otherwise with intent to extort; (18) Crimes committed at sea, (*a*) Piracy by the law of nations, (*b*) Sinking or destroying a vessel at sea, or attempting or conspiring to do so, (*c*) Assault on board a ship on the high seas, with intent to destroy life or to do grievous bodily harm, (*d*) Revolt, or conspiring to revolt, by two or more persons on board a ship on the high seas against the authority of the master. *Extradition Act*, 1873:—(19) Kidnapping and false imprisonment; (20) Perjury and subornation of perjury. This Act also extends to indictable offences under 24 and 25 Vict. cc. 96, 97, 98, 99, 100, and amending and substituted Acts. Among such offences included in various extradition treaties are the following:—(21) Obtaining valuable securities by false pretences; (22) Receiving any money, valuable security, or other property, knowing the same to have been stolen or unlawfully obtained; (23) Falsification of accounts (see *In re* Arton, 1896, 1 Q.B. 509); (24) Malicious injury to property, if such offence be indictable; (25) Knowingly making, without lawful authority, any instrument, tool, or engine adapted and intended for the counterfeiting of coin of the realm; (26) Abandoning children; exposing or unlawfully detaining them; (27) Any malicious act done with intent to endanger the safety of any person in a railway train; (28) Wounding or inflicting grievous bodily harm; (29) Assault occasioning actual bodily harm; (30) Assaulting a magistrate or peace or public officer; (31) Indecent assault; (32) Unlawful carnal knowledge, or any attempt to have unlawful carnal knowledge, of a girl under age; (33) Bigamy; (34) Administering drugs or using instruments with intent to procure the miscarriage of women; (35) Any indictable offence under the laws for the time being in force in relation to bankruptcy. *Slave Trade Act*, 1873 (36 and 37 Vict. c. 88, s. 27):—(36) Dealing in slaves in such manner as to constitute a criminal offence against the laws of both states.

The Act of 1873 provides for the surrender of accessories before and after the fact to extradition crimes, and most of the treaties contain a clause by which extradition is to be granted for participation in any of the crimes specified in the treaty, provided that such participation is punishable by the laws of both countries. Several of the treaties also contain clauses providing for optional surrender in respect of any crime not expressly mentioned for which extradition can be granted by the laws of both countries.

Extradition Treaties.—The extradition treaties now in force, with their dates, and the dates of the Orders in Council applying them, are shown in the table below. The Orders in Council setting out the treaties will be found in the London *Gazette*. Extradition between Cape Colony and the Orange Free State and South African Republic was till the outbreak of war in 1899 regulated by the Cape Act, No. 22, of 1882.

It is not practicable to state which of the statutory extradition crimes are included in each of the treaties. It appears, however, from an examination kindly permitted of tables prepared for official use that the later treaties include nearly all the crimes in the above list. Rumania, however, reserves the right to refuse surrender for a crime punishable with death, and Portugal will not surrender in such a case. Of the earlier treaties, that with the United States, even as amended by the Convention of 1889, is much the most restricted, omitting crimes 8, 9, 17, 21, 24, 29, 30, 31, 32, 33, 34, 35 in the above list. It may be said generally that crimes 1 to 17 inclusive are covered by all the other treaties.

It is further to be noted that the restrictions on

surrender in the Extradition Acts apply only to surrenders by Great Britain. Foreign countries may surrender fugitives to Great Britain without any treaty, if they are willing to do so and their law allows of it, and such surrenders have not infrequently been made. But when surrendered for an extradition crime, the prisoner cannot be tried in England for any other crime committed before such surrender, until he has been restored, or has had an opportunity of returning, to the foreign state from which he was extradited.

Procedure.

To obtain from a foreign country the extradition of a fugitive from the United Kingdom, it is necessary to procure a warrant for his arrest, and to send it, or a certified copy, to the Home Secretary together with such further evidence as is required by the treaty with the country in question. In most cases an information or deposition containing evidence which would justify a committal for trial in Great Britain will be required. The Home Secretary will then communicate through the Foreign Secretary and the proper diplomatic channels with the foreign authorities, and in case of urgency will ask them by telegraph for a provisional arrest. For the arrest in the United Kingdom of fugitive criminals, whose extradition is requested by a foreign state, two procedures are provided in ss. 7 and 8 of the Act of 1870:—(1) On a diplomatic requisition supported by the warrant of arrest and documentary evidence, the Home Secretary, if he thinks the crime is not of a political character, will order the chief magistrate at Bow Street to proceed; and such magistrate will then issue a warrant of arrest on such evidence as would be required if the offence had been committed in the United Kingdom. (2) More summarily, any magistrate or justice of the peace may issue a provisional warrant of arrest on evidence which would support such a warrant if the crime had been committed within his jurisdiction. In practice a sworn information is required, but this may be based on a telegram from the foreign authorities. The magistrate or justice must then report the issue of the warrant to the Home Secretary, who may cancel it and discharge the prisoner. When arrested on the provisional warrant, the prisoner will be brought up before a magistrate and remanded to Bow Street, and will then be further remanded until the magistrate at Bow Street is notified that a formal requisition for surrender has been made; and unless such requisition is made in reasonable time the prisoner is entitled to be discharged. The examination of the prisoner prior to his committal for extradition ordinarily takes place at Bow Street. The magistrate is required to hear evidence that the alleged offence is of a political character, or is not an extradition crime. If satisfied in these respects, and if the foreign warrant of arrest is duly authenticated, and evidence is given which according to English law would justify a committal for trial, if the prisoner has not yet been tried, or would prove a conviction if he has already been convicted, the magistrate will commit him for extradition. Under the Extradition Act, 1895, the Home Secretary, if of opinion that removal to Bow Street would be dangerous to the prisoner's life, or prejudicial to his health, may order the case to be taken by a magistrate at the place where the prisoner was apprehended, or then is, and the magistrate may order the prisoner to be detained in such place. After committal for extradition, every prisoner has fifteen days in which to apply for *habeas corpus*, and after such period, or at the close of the *habeas corpus* proceedings if they are unsuccessful, the Home Secretary issues his warrant for surrender, and the prisoner is handed over to the officers of the foreign government.

The Extradition Acts apply to the British colonies, the Governor being substituted for the Secretary of State. Their operation may, however, be suspended by Order in Council, as in the case of Canada, where the colony has passed an Extradition Act of its own (see Statutory Rules and Orders).

Fugitive Offenders Act.—There are no extradition treaties with certain countries in which the Crown exercises foreign jurisdiction, such as Cyprus, Turkey, Egypt, China, Japan, Corea, Zanzibar, Morocco, Siam, Persia, Somali, &c. In these countries the Fugitive Offenders Act, 1881 (44 and 45 Vict. c. 69), has been applied, pursuant to s. 36 of that statute, and the measures for obtaining surrender of a fugitive criminal are the same as in a British colony. The Act, however, only applies to persons over whom the Crown has jurisdiction in these territories, and generally is expressly restricted to British subjects.

Under this Act a fugitive from one part of the King's dominions to another, or to a country where the Crown exercises foreign jurisdiction, may be brought back by a procedure analogous to extradition, but applicable only to treason, piracy, and offences punishable with twelve months' imprisonment with hard labour, or more. The original warrant of arrest must be endorsed by one of several authorities where the offenders happen to be,—in practice by the Home Secretary in the United Kingdom, and by the Governor in a colony. Pending the arrival of the original warrant a provisional arrest may be made, as under the Extradition Acts. The fugitive must then be brought up for examination before a local magistrate, who, if the endorsed warrant is duly authenticated, and evidence is produced "which, according to the law administered by the magistrate, raises a strong or probable presumption that the offender committed the offence, and that the Act applies to it," may commit him for return. An interval of fifteen days is allowed for *habeas corpus* proceedings, and (s. 10) the court has a large discretion to discharge the prisoner, or impose terms, if it thinks the case frivolous, or that the return would be unjust or oppressive, or too severe a punishment. The next step is for the Home Secretary in the United Kingdom, and the Governor in a colony, to issue a warrant for the return of the prisoner. He must be removed within a month, in the absence of reasonable cause to the contrary. If not prosecuted within six months after arrival, or if acquitted, he is entitled to be sent back free of cost.

In the case of fugitive offenders from one part of the United Kingdom to another, it is enough to get the warrant of arrest backed by a magistrate having jurisdiction in that part of the United Kingdom where the offender happens to be. A warrant issued by a metropolitan police magistrate may be executed, without backing, by a metropolitan police officer anywhere, and there are certain other exceptions, but as a rule a warrant cannot be executed without being backed by a local magistrate. (J. E. P. W.)

(2) United States. Foreign extradition is purely an affair of the United States, and not for the individual states themselves. Upon a demand upon the United States for extradition, there is a preliminary examination before a commissioner or judge before there can be a surrender to the foreign government (Revised Statutes, Title LXVI.; 22 Statutes at Large, 215). It is enough to show probable guilt (*Ornelas* v. *Ruiz*, 161 United States Reports, 502). An extradition treaty covers crimes previously committed. If a Power, with which the United States have such a treaty, surrenders a fugitive charged with a crime not included in the treaty, he may be tried in the United States for such crime. Inter-state extradition is regulated by Act of Congress under the Constitution of the United States (Article LV. s. 2; United States Revised Statutes, s. 5278). A surrender may be demanded of one properly charged with an act which constitutes a crime under the laws of the demanding state, although it be no crime in the other state. A party improperly surrendered may be released by writ of *habeas corpus*, either from a state or United States court (*Robb* v. *Conolly*, 111 United States Reports, 624). On his return to the state from which he fled, he is subject to prosecution for any crime, though on a foreign extradition the law is otherwise (*Lascelles* v. *Georgia*, 148 United States Reports, 537). (S. E. B.)

Eye. See Physiology (*Special Senses*), and Pathology (*Eye*).

Eyemouth, a police burgh and fishing town of Berwickshire, Scotland, situated at the mouth of the river Eye, 5½ miles north-north-west of Berwick-on-Tweed by rail. The bay is easily accessible and affords good anchorage. The harbour was increased in 1887. It is the centre of one of the Scottish fishery districts. The fish landed in 1898 was valued at £24,365. (See Berwickshire for statistics of district.) There are a town hall and a library, and Established, two United Free, Congregational, and Primitive Methodist churches. The public school had an average attendance of 457 in 1898–99. The population in 1881 was 2825, and in 1901, 2377.

Eyre, Edward John (1815–1901), colonial governor, the son of a Yorkshire clergyman, was born on 5th August 1815. He was intended for the army, but delays having arisen in procuring a commission, went out to New South Wales, where he engaged in the difficult but very necessary undertaking of transporting stock westward to the new colony of South Australia, then in great distress, and where he became magistrate and protector of the aborigines, whose interests he warmly advocated. Already experienced as an Australian traveller, he undertook the most extensive and difficult journeys in the desert country north and west of Adelaide, and after encountering the greatest hardships proved the possibility of land communication between South and West Australia. In 1845 he returned to England, and published the narrative of his travels. In 1846 he was appointed lieutenant-governor of New Zealand, where he served under Sir George Grey. After successively governing St Vincent and Antigua he was in 1862 appointed acting-governor of Jamaica, and in 1864 governor. In October 1865 a negro insurrection broke out, and was repressed with laudable vigour, but the unquestionable severity and alleged illegality of Eyre's subsequent proceedings raised a storm at home which induced the Government to suspend him and to despatch a special commission of investigation, the effect of whose inquiries, declared by his successor, Sir John Peter Grant, to have been "admirably conducted," was that he should not be reinstated in his office. The Government, nevertheless, saw nothing in Eyre's conduct to justify legal proceedings; indictments preferred by amateur prosecutors at home against him, and military officers who had acted under his direction, resulted in failure, and he retired upon the pension of a colonial governor. As an explorer Eyre must be classed in the highest rank, but opinions are always likely to differ as to his action in the Jamaica rebellion. He died 30th November 1901.

Fabre, Ferdinand (1830–1898), French novelist, was born at Bédarieux, in Hérault, a very picturesque division of the south of France, which he made completely his own in literature. He was the son of a local architect, who failed in business, and Ferdinand was brought up by his uncle, the Abbé Fulcran Fabre, at Camplong among the mulberry woods. Of his childhood and early youth he has given a charming account in *Ma Vocation*. He was destined to the priesthood, and was sent for that purpose to the seminary of St Pons de Thomières, where, in 1848, he had, as he believed, an ecstatic vision of Christ, who warned him "It is not the will of God that thou shouldst be a priest." He had now to look about for a profession, and, after attempting medicine at Montpellier, was articled as a lawyer's clerk in Paris. In 1853 he published a volume of verses, broke down in health, and crept back, humble and apparently without ambition, to his old home at Bédarieux. After some eight or nine years of country life he reappeared in Paris, with the MS. of his earliest novel, *Les Courbezon* (1862), in which he treated the subject which was to recur in almost all his books, the daily business of country priests in the Cevennes. This story enjoyed an immediate success with the literary class of readers; George Sand praised it, Sainte-Beuve hailed in its author "the strongest of the disciples of Balzac," and it was crowned by the French Academy. From this time forth Fabre settled down to the production of novels, of which at the time of his death he had published about twenty. Among these the most important were *Le Chevrier* (1867), unique among his works as written in an experimental mixture of Cevenol *patois* and French of the 16th century; *L'Abbé Tigrane* (1873), by common consent the best of all Fabre's novels, a very powerful picture of unscrupulous priestly ambition; *Mon Oncle Célestin* (1881), a study of the entirely single and tender-hearted country abbé; and *Lucifer* (1884), a marvellous gallery of serious clerical portraits. In 1883 Fabre was appointed curator of the Mazarine Library, with rooms in the Institute, where, on 11th February 1898, he died after a brief attack of pneumonia. Ferdinand Fabre occupies in French literature a position somewhat analogous to that of Mr Thomas Hardy amongst English writers of fiction. He deals almost exclusively with the population of the mountain villages of Hérault, and particularly with its priests. He loved most of all to treat of the celibate virtues, the strictly ecclesiastical passions, the enduring tension of the young soul drawn between the spiritual vocation and the physical demands of nature. Although never a priest, he preserved a comprehension of and a sympathy with the clerical character, and he always indignantly denied that he was hostile to the Church, although he stood just outside her borders. Fabre possessed a limited and a monotonous talent, but within his own field he was as original as he was wholesome and charming. (E. G.)

Fabrizi, Nicola (1804–1885), Italian patriot, was born at Modena, 4th April 1804. He took part in the Modena insurrection of 1831, and attempted to succour Ancona, but was arrested at sea and taken to Toulon, whence he proceeded to Marseilles. Afterwards he organized with Mazzini the ill-fated Savoy expedition. Taking refuge in Spain, he fought against the Carlists, and was decorated for valour on the battlefield (18th July 1837). At the end of the Carlist war he established a centre of conspiracy at Malta, endeavoured to dissuade Mazzini from the Bandiera enterprise, but aided Crispi in organizing the Sicilian revolution of 1848. With a company of volunteers he distinguished himself in the defence of Venice, afterwards proceeding to Rome, where he took part in the defence of San Pancrazio. Upon the fall of Rome he returned to Malta, accumulating arms and stores, which he conveyed to Sicily, after having, in 1859, worked with Crispi to prepare the Sicilian revolution of 1860. While Garibaldi was sailing from Genoa towards Marsala Fabrizi landed at Pizzolo, and, after severe fighting, joined Garibaldi at Palermo. Under the Garibaldian Dictatorship he was appointed Governor of Messina and Minister of War. Returning to Malta after the Neapolitan plebiscite, which he had vainly endeavoured to postpone, he was recalled to aid Cialdini in suppressing brigandage. While on his way to Sicily in 1862, to induce Garibaldi to give up the Aspromonte enterprise, he was arrested at Naples by Lamarmora. During the war of 1866 he became Garibaldi's chief of staff, and in 1867 fought at Mentana. In parliament he endeavoured to promote agreement between the chiefs of the Left, and from 1878 onwards worked to secure the return of Crispi to power, but died on 31st March 1885, two years before the realization of his object. His whole life was characterized by ardent patriotism and unimpeachable integrity. (H. W. S.)

Factors.—A *factor* is a mercantile agent (of the class known as "general" agents) employed to sell for a compensation, commonly called factorage or commission; but he differs from a broker (*q.v.*) in two respects—firstly, he has possession of the goods or the documents of title to them, and secondly, he may sell in his own name. A factor may also be employed to buy goods.

The main source of the law on the subject is now to be found in the Factors Act, 1889, where all previous enactments were repealed and their provisions consolidated and amended. But before discussing the Act it will be necessary to describe briefly what a factor is, and what are his duties and his authority.

I. Factor and Principal.

A factor is appointed or dismissed in the same way as any other agent. He may be employed for a single transaction or to transact all his principal's business of a certain class during a limited period or till such time as his authority may be determined. A factor's duty is to sell or buy as directed; to carry out any instructions he may receive with care, skill, and good faith; to receive or make payment; to keep accounts, and to hand over to his principal the balance standing to his principal's credit, without any deduction save for commission and expenses. All express instructions he must carry out to the full; and on any point not covered by his express instructions he must follow the usual practice of his particular business if not inconsistent with his instructions or his position as factor. Many usages of businesses in which factors are employed have been proved in court, and may now be regarded as legally established. For instance, he may, unless otherwise directed, sell in his own name, give warranties as to goods sold by him, sell by sample (in most businesses), give such credit as is usual in his business, receive payment in cash or as customary, and give receipts in full discharge, sell by indorsement of bills of lading, and insure the goods. It is his duty to clear the goods at the customs, take charge of them and keep them safely, give such notices to his principal and others as may be required, and if necessary take legal proceedings for the protection of the goods. On the other hand, he has not authority to delegate his employment, or to barter; and it was decided long ago that to pledge the goods is not within his authority. It is, moreover, inconsistent with his employment as agent that he should buy or sell on his own account from or to his principal. A factor has no right to follow any usage which is inconsistent with the ordinary duties and authority of a factor unless his principal has expressly or impliedly given his consent.

On the due performance of his duties the factor is entitled to his commission, which is usually a percentage on the value of the goods sold or bought by him on account of his principal, regulated in amount by the usages of each business. Sometimes the factor makes himself personally responsible for the solvency of the persons with whom he deals, in order that his principal may avoid the risk entailed by the usual trade credit. In such a case the factor is said to be employed on *del credere* terms, and is entitled to a higher rate of commission, usually 2½ per cent. extra. Such an arrangement is not a contract of guarantee within the Statute of Frauds, and therefore need not be in writing. Besides his remuneration, the factor is entitled to be reimbursed by his principal for any expenses, and to be indemnified against any liabilities which he may have properly incurred in the execution of his principal's instructions. For the purpose of enforcing his rights a factor has, without legal proceedings, two remedies. Firstly, by virtue of his general *lien* (*q.v.*) he may hold any of his principal's goods which come to his hands as security for the payment to him of any commission, out of pocket expenses, or even general balance of account in his favour. Although he cannot sell the goods, he may refuse to give them up until he is paid. Secondly, where he has consigned goods to his principal but not been paid, he may "*stop in transit*" subject to the same rules of law as an ordinary vendor; that is to say, he must exercise his right before the transit ends; and his right may be defeated by his principal transferring the document of title to the goods to some third person, who takes it in good faith and for valuable consideration (Factors Act 1889, section 10). If the factor does not carry out his principal's instructions, or carries them out so negligently or unskilfully that his principal gets no benefit thereby, the factor loses his commission and his right to reimbursement and indemnity. If by such failure or negligence the principal suffers any loss, the latter may recover it as damages. So too if the factor fails to render proper accounts his principal may by proper legal proceedings obtain an account and payment of what is found due; and threatened breaches of duty may be summarily stopped by an injunction. Criminal acts by the factor in relation to his principal's goods are dealt with by section 78 of the Larceny Act 1860.

II. Principal and Third Party.

(*a*) *At Common Law.*—The actual authority of a factor is defined by the same limits as his duty, the nature of which has been just described; *i.e.*, firstly, by his principal's express instructions; secondly, by the rules of law and usages of trade, in view of which those instructions were expressed. But his power to bind his principal as regards third parties is often wider than his actual authority; for it would not be reasonable that third parties should be prejudiced by secret instructions, given in derogation of the authority ordinarily conferred by the custom of trade; and, as regards them, the factor is said to have "*apparent*" or "*ostensible*" authority, or to be *held out* as having authority to do what is customary, even though he may in fact have been expressly forbidden so to do by his principal. But this rule is subject to the proviso that if the third party have actual notice of the factor's instructions, the "apparent" authority will not be greater than the actual. "The general principle of law," said Lord Blackburn in the case of Cole *v.* North-Western Bank (L. R. 10 C. P. at p. 363), "is that when the true owner has clothed any one with apparent authority to act as his agent, he is bound to those who deal with the agent on the assumption that he really is an agent with that authority, to the same extent as if the apparent authority were real." Under such circumstances the principal is for reasons of common fairness precluded, or, in legal phraseology, *estopped*, from denying his agent's authority. On the same principle of estoppel, but not by reason of any trade usages, a course of dealing which has been followed between a factor and a third party with the assent of the principal will give the factor apparent authority to continue dealing on the same terms even after the principal's assent has been withdrawn; provided that the third party has no notice of the withdrawal.

Such apparent authority binds the principal both as to acts done in excess of the actual authority and also when the actual authority has entirely ceased. For instance, A. B. receives goods from C. D. with instructions not to sell below 1s. per ℔; A. B. sells at 10½d., the market price; the buyer is entitled to the goods at 10½d., because A. B. had apparent authority, although he exceeded his actual authority. On the same principle the buyer would get a good title by buying from A. B. goods entrusted to him by C. D., even though at the time of the sale C. D. had revoked A. B.'s authority and instructed him not to sell at all. In either case the factor is held out as having authority to sell, and the principal cannot afterwards turn round and say that his factor had no such authority. As in the course of his business the factor must necessarily make representations preliminary to the contracts into which he enters, so the principal will be bound by any such representations as may be within the factor's actual or apparent authority to the same degree as by the factor's contracts.

(*b*) *Under the Factors Act* 1889.—The object of the Factors Acts (which deal with other persons as well as factors) has been to add to the number of cases in which third parties honestly buying or lending money on the security of goods may get a good title from persons in whose possession the goods are with the consent, actual or apparent, of the real owners, thus calling in aid the principle of French law that "*possession vaut titre*" as against the doctrine of the English common law that "*nemo dat quod non habet.*" The chief change in the law relating specially to factors has been to put pledges by factors on the same footing as sales, so as to bind a principal to third parties by his factor's pledge as by his factor's sale. The Factors Act 1889 in part re-enacts and in part extends the provisions of the earlier Acts of 1823, 1825, 1842, and 1877; and is, so far as it relates to sales by factors, in large measure merely declaratory of the law as it previously existed. Its most important provisions concerning factors are as follows:—

Section I., s.s. 1. The expression mercantile agent shall mean a mercantile agent having in the customary course of his business as such agent authority either to sell goods, or to consign goods for the purpose of sale, or to buy goods, or to raise money on the security of goods;

(2) A person shall be deemed to be in possession of goods or of the documents or title to goods when the goods or documents are in his actual custody or are held by any other person subject to his control or for him or on his behalf.

(4) The expression "document of title" shall include any bill of lading, dock warrant, warehouse keeper's certificate, and warrant or order for the delivery of goods, and any other document used in the ordinary course of business as proof of the possession or control of goods, or authorizing or purporting to authorize, either by endorsement or by delivery, the possessor of the document to transfer or receive goods thereby represented.

Section II., s.s. 1. Where a mercantile agent is, with the consent of the owner, in possession of goods or of the documents or title to goods, any sale, pledge, or other disposition of the goods made by him when acting in the ordinary course of business of a mercantile agent, shall, subject to the provisions of this Act, be as valid as if he were expressly authorized by the owner of the goods to make the same: provided that the person taking under the disposition acts in good faith, and has not at the time of the disposition notice that the person making the disposition has not authority to make the same.

(2) Where a mercantile agent has, with the consent of the owner, been in possession of goods or of the documents of title to goods, any sale, pledge, or other disposition, which would have been valid if the consent had continued, shall be valid notwithstanding the determination of the consent: provided that the person taking under the disposition has not at the time thereof notice that the consent has been determined.

(3) Where a mercantile agent has obtained possession of any documents of title to goods by reason of his being or having been, with the consent of the owner, in possession of the goods represented thereby, or of any other documents of title to the goods, his possession of the first-mentioned documents shall, for the purposes of the Act, be deemed to be with the consent of the owner.

III. Enforcement of Contracts.

(1) Where a factor makes a contract in the name of his principal and himself signs as agent only he drops out as soon as the contract is made, and the principal and third party alone can sue or be sued upon it. As factors usually contract in their own name this is not a common case.

(2) Where a factor makes a contract for the principal without disclosing his principal's name, the third party may, on discovering the principal, elect whether he will sue the factor or his principal; provided that if the factor contract expressly as factor, so as to exclude the idea that he is personally responsible, he will not be liable. The principal may sue upon the contract, so also may the factor, unless the principal first intervene.

(3) Where a factor makes a contract in his own name without disclosing the existence of his principal the third party may, on discovering the existence of the principal, elect whether he will sue the factor or the principal. Either principal or factor may sue the third party upon the contract. But if the factor has been permitted by the principal to hold himself out as the principal, and the person dealing with the factor has believed that the factor was the principal and has acted on that belief before ascertaining his mistake, then in an action by the principal the third party may set up any defences he would have had against the factor if the factor had brought the action on his own account as principal.

(4) Where a factor has a lien upon the goods and their proceeds for advances made to the principal it will be no defence to an action by him for the third party to plead that he has paid the principal, unless the factor by his conduct led the third party to believe that he agreed to a settlement being made with his principal.

(5) The factor who acts for a foreign principal will always be personally liable unless it is clear that the third party has agreed to look only to the principal.

(6) If a factor contract by deed under seal he alone can sue or be sued upon the contract; but mercantile practice makes contracts by deed uncommon.

Factory Acts. See Labour Legislation.

Faenza, a town and episcopal see of Italy (Emilia, prov. Ravenna), 31 miles S.E. from Bologna by rail. The picture gallery, the technical school, the school of design (1879), and the fountain (1621) deserve mention. The *fayence* industry is still carried on. Population about 18,500.

Faidherbe, Louis Léon César (1818–1889), French general, born on 3rd June 1818 at Lille, was educated at the Polytechnic schools at Paris and Metz, and entered the Engineer Corps in 1840. From 1844 to 1847 he served in Algeria, then two years in the West Indies, and again in Algeria, taking part in many expeditions against the Arabs. In 1852 he was transferred to Senegambia as sub-director of engineers, and in 1854 was promoted major and appointed governor of the colony. His eleven years' administration was notable for a number of successful expeditions and several large annexations (major-general, commander Legion of Honour). From 1867 to the early part of 1870 he commanded the subdivision of Bona in Algeria, when he became general of division, and was commanding the Constantine division at the commencement of the Franco-German war. Appointed by the Government of National Defence on 23rd November 1870 to be commander-in-chief of the Army of the North, he succeeded Bourbaki early in December, and proved himself an able general, although unable to relieve Paris. He fought several hotly contested but indecisive battles, such as Pont Noyelles and Bapaume against Manteuffel, but having been seriously defeated by Göben on the 19th January 1871 at St Quentin, he retired on Cambrai and Lille, where he remained until the armistice stopped operations. Elected to the National Assembly for the department of the North, he resigned his seat in consequence of its reactionary proceedings. For his services he was decorated with the Grand Cross, and made chancellor of the order, of the Legion of Honour. In 1872 he was sent on a scientific mission to Upper Egypt, where he studied the monuments and inscriptions. An enthusiastic geographer and archæologist, he wrote numerous works on his favourite subject, among which may be mentioned *Collection des Inscriptions Numidiques* (1870) and *Epigraphie Phénicienne* (1873). He also wrote on the Senegal and the Sahara, and *La Campagne de l'Armée du Nord* (1871). He was elected a senator in 1879. He died on 29th September 1889, and his remains received a public funeral. (R. H. V.)

Failsworth, a suburban township of Manchester, 4 miles to the N.E. by rail, in the Prestwich parliamentary division of Lancashire, England, on the Manchester and Leeds canal. The industries are mainly cotton-spinning, silk-weaving, and the manufacture of hats. Area of township (an urban district), 1073 acres. Population (1881), 7912; (1891), 10,425; (1901), 14,152.

Fairhaven, a city of Whatcom County, Washington, U.S.A., on Bellingham Bay, on the east coast of Puget Sound, 3 miles south of New Whatcom, and on a line of the Great Northern railroad. Like most of the smaller places on Puget Sound, its chief industry is the manufacture of lumber, and it contains several saw and shingle mills. Population (1890), 4076; (1900), 4228.

Fairmont, capital of Marion County, West Virginia, U.S.A., on the Monongahela river, at the intersection of two railways. Population (1890), 1023; (1900), 5655.

Fair Oaks, a station on a branch of the Southern railroad, 6 miles east of Richmond, Virginia, U.S.A. It is noted as the site of one of the great battles of the Civil War, fought 31st May and 1st June 1862, between McClellan and Johnston, in command of the Union and Confederate forces respectively. The result was indecisive, the Union troops having, however, rather the best of it. The Union losses were 5031 in killed, wounded, and missing; those of the Confederates were 6134. The battle is sometimes known as the Battle of Seven Pines.

Fajardo, a small city and port of entry at the north-east end of Porto Rico, in the province of Humacao. Population (1899), 3414.

Falk, Paul Ludwig Adalbert (1827–1900), German politician, was born at Matschkau, Silesia, 10th August 1827. In 1847 he entered the Prussian State service, and in 1853 became public prosecutor at Lyck. In 1858 he was elected a deputy, joining the Old Liberal party. In 1868 he became a privy-councillor in the ministry of justice. In 1872 he was made minister of education, and in connexion with Bismarck's policy of the Kultur-kampf he was responsible for the famous May Laws against the Catholics (see GERMANY, *May Laws*, and VATICANISM). In 1879 his position became untenable, owing to the death of Pius IX. and the change of German policy with regard to the Vatican, and he resigned his office, but retained his seat in the Reichstag till 1882. He was then made president of the supreme court of justice at Hamm, where he died in 1900.

Falkirk, a parliamentary burgh (Falkirk group) of Stirlingshire, Scotland, is 25½ miles W. by N. of Edinburgh by rail. In recent years the iron trade has greatly increased, and the town is the chief seat of the light-casting trade in Scotland. There now are in the burgh and immediate neighbourhood 23 foundries; and brewing, distilling, and the manufacture of dynamite and chemicals are all carried on. The cattle "trysts," or open markets, though still among the largest in the kingdom, have greatly diminished in importance, owing to the common preference for auction marts. There are county buildings, burgh buildings, a town hall, a free library and institute, parish council chambers, and a new post office. Waterworks have been opened, and the parish church has been renovated and a hall added to it. There are two United Free churches. A high school and a science and art school are under the School Board. Population of parliamentary burgh (1881), 13,170; (1901), 20,503; of burgh and suburbs (1881), 15,599; (1891), 19,769; (1901), 29,271.

Falkland Islands, a group of islands in the South Atlantic, belonging to Great Britain, lie about 250 miles east of the nearest point in the mainland of South America. The area of the islands is about 6500 square miles, of which the two main islands, East and West Falkland, take up 5300. The soil is well adapted for sheep-farming, which is the main industry. "Practically the entire acreage of the colony is sold or leased to some thirty-six farmers for pastoral purposes, the leased lands giving a total rental to the crown of about £5000." The revenue and expenditure were (1880), £5519 and £5607; (1890), £9492 and £9456; (1899), £13,219 and £13,314. There is no public debt. The imports and exports were (1880), £33,503 and £88,564; (1890), £67,182 and £115,845; (1899), £73,978 and £139,203. The main export is naturally wool. The population was (1881), 1414; (1897), 2050. The large majority are found in the East island, and the predominating element is Scotch—Scotch shepherds having superseded the South American Guachos. Education has been made compulsory, "with the best results." The climate is healthy. The temperature is normally low, always cold, without either the extreme frosts or summer heats of England. The prevailing winds, from west, south-west, and south, which blow continuously, make the cold more penetrating. "At the same time they contribute largely to the healthy condition which prevails in the absence of organized sanitation." The rainfall is not great, about 20 inches in the year, but slight rain is very frequent, and November is the only dry month. The mails are delivered by a German line of steamers once in every three weeks. The average length of the journey to England is about five weeks.

The Falkland Islands are a crown colony, with a governor and executive and legislative councils. The legislative council consists of the governor and two official and two unofficial nominated members.

Historical Geography of the British Colonies, vol. ii., "The West Indies," Lucas, 1890, and *Colonial Reports Annual*. (H. E. EG.)

Fall River, a city of Bristol County, Massachusetts, U.S.A., situated in 41° 30′ N. and 71° 09′ W. on Hope Bay, at the mouth of the Taunton river, and at the terminus of a branch of the New York, New Haven, and Hartford railway. Its plan is irregular; it has an excellent water supply, pumped from Watuppa Lake, east of the city; it is well sewered; the streets are macadamized or gravelled, and there are nine wards. Its public library contains 55,000 volumes. Fall River is a port of entry, with a good harbour and considerable commerce, and is the eastern terminus of the Fall River Line of Sound steamers to New York. But it is as a manufacturing city that Fall River is pre-eminent. In 1895 there were 571 establishments, with an aggregate capital of $43,850,952, employing 28,703 hands. The value of the product was $38,934,678. Of this, $26,403,043, or more than two-thirds, consisted of cotton goods; several of the other industries, such as dyeing and finishing establishments, are accessory to this. Formerly the water power of Taunton river was largely used, but at present steam power is in general use. The assessed valuation of property, real and personal, was, in 1899, $71,601,670, the net debt of the city was $3,688,434, and the rate of taxation was $17·80 per $1000. Population (1880), 48,961;

(1890), 74,398; (1900), 104,863. Of the total population in 1890, 50,042 were foreign-born, and 324 negroes. There were 35,532 persons of school age (5 to 20 years inclusive). Of 26,842 males of voting age, 4158 were illiterate (unable to write). The death-rate was 22·4.

Falmouth, a municipal and contributory parliamentary borough (returning with Penryn one member), seaport, and market-town of Cornwall, England, on Falmouth Bay, 306 miles S.W. of London by rail. Recent erections are an Established church, new buildings of the Meteorological and Magnetic Observatory, a submarine mining establishment, a Seamen's Bethel and Institute, a hospital, a cottage hospital, and a free library. The defences of Pendennis and St Mawes Castle have been reconstructed. Engineering and shipbuilding are carried on. There are also oyster and trawl fisheries. The registered shipping at the end of 1898 consisted of 134 vessels of 18,531 tons. In 1888, 1707 vessels of 209,938 tons entered, and 1760 of 212,468 tons cleared. In 1898, 1825 vessels of 347,434 tons entered, and 1749 of 353,750 tons cleared. Population (on the unextended area of 617 acres), (1881), 5973; (1891), 4737; (on the area extended in 1892 to include the whole of Falmouth parish, 643 acres, and part of an adjoining parish), (1891), 12,791; (1901), 11,773.

False Bay. See SIMONS TOWN.

Falticeni, chief town of the district of Suceava, Rumania, 265 miles from Bucarest. It is a place of some commercial standing. An important fair is annually held there, commencing on the 20th of July and lasting for five weeks, the chief trade being in cattle, horses, and carriages. The population, about one-half Jews, is 9643.

Falun, a town of Sweden, capital of the province of Kopparberg (or Dalecarlia), 57 miles by rail W. from Gefle, famous for its copper mines. In 1896 the yield was 15,985 tons of ore, from which were extracted 1506 tons of sulphate of copper and 112 tons of iron pyrites; other products, 2400 oz. gold, 9684 oz. silver, 66 tons of sulphur, 2267 tons of sulphuric acid, and 796 tons of red ochre. The mines belong to the Kopparberg Mining Company, the largest joint stock concern in Sweden, many of the shares, since the reorganization of the company in 1888, being held by the crown, by philanthropic institutions, and by other public bodies. The company also owns iron mines, limestone quarries, and quartz quarries, some 3600 acres of forests, two large ironworks, steam and water-driven sawmills; and, besides the output of the copper mine, they produce manufactured iron and steel, bricks, timber, wood-pulp, and charcoal. Besides the mining establishments there are railway engine and waggon works. Population (1880), 7305; (1898), 9115.

Famagusta (Greek, AMMOCHOSTOS), a town and harbour on the east coast of Cyprus, about 2½ miles south of the ruins of Salamis. About 800 Moslems live within the walls of the fortress; the Christian population has migrated to a suburb called Varosia. The foundation of Salamis was ascribed to Teucer: it was probably the most important town in early Cyprus. St Barnabas, it is said, was born and buried there. The revolt of the Jews under Trajan, and earthquakes under Constantius and Constantine the Great, helped in turn to destroy it. It was restored by Fl. Constantius II. (A.D. 337–361) as Constantia. The ruins were partially explored in 1890. The sites of two temples, the *agora*, and a remarkable reservoir (*loutron*, *castellum*, or *piscina*) were disclosed, and a fine bull's head capital of Ptolemaic date secured for the British Museum (*Journal of Hell. Studies*, vol. xii., 1891). More valuable antiquities were unearthed by Dr A. S. Murray in 1896 from a Mycenean necropolis at Encomi. Another town a little to the south, built by Ptolemy Philadelphus in 274 B.C., and called Arsinoe in honour of his sister, received the refugees driven from Constantia by the Arabs under Muʿawiyah, became the seat of the orthodox archbishopric, and was eventually known as Famagusta. This received a large accession of population at the fall of Acre in 1291; was coveted and annexed by the Genoese in 1373; reunited to the throne of Cyprus in 1464; and surrendered, after an investment of more than a year, to the Turks in 1571. The fortifications, remodelled by the Venetians after 1489, the castle, the grand cathedral church of St Nicolas, and the remains of the palace and many other churches make Famagusta a place of unique interest. Acts ii. and v. of *Othello* pass there. It is melancholy to add that its charm is threatened under a scheme to spend part of a sum of £314,000, advanced by the Colonial Loans Act 1899, on railway and harbour works, which would destroy a great part of the sea front.

Fano, a town and episcopal see of Italy (the Marches, prov. Pesaro and Urbino), on the Adriatic coast, 8 miles S.E. from Pesaro by rail. It has important silk industries, and makes bricks. There is also a technical school. In 1899 several Roman statues and other remains of a large building were discovered in the former convent of St Philip. Population about 11,250.

Fanö, an island of Denmark, off the west coast of Jutland, 2 miles south from Esbjerg, the northernmost of the North Frisian Islands, is in great part (75 per cent.) covered with drift-sand, dunes, and barren heath. Area, 20 square miles. Population, 3202. Chief town, Nordby (population 2600), on the east coast, which has recently acquired repute as a summer seaside resort, and possesses a school of navigation. There is another village, Sönderho, near the south extremity, which also attracts visitors for the sea-bathing. The inhabitants, who are Frisians, support themselves by seafaring and fishing. In 1897 they owned a fleet of 109 vessels of 40,450 tons.

Fargo, capital of Cass County, North Dakota, U.S.A., on the west bank of the Red river, which is here not navigable, at an altitude of 902 feet. It lies in the rich wheat region of the Red river valley, and is a very important market for wheat, farm implements, and machinery. It is entered by the Northern Pacific, the Great Northern, and the Chicago, Milwaukee, and St Paul railways. Fargo College is a Congregational institution, founded in 1887. In 1893 a large part of the town was destroyed by fire, at an estimated loss of $3,000,000. Population (1880), 2693; (1890), 5664; (1900), 9589, of whom 2564 were foreign-born.

Faribault, capital of Rice County, Minnesota, U.S.A., on the Cannon river, and the Chicago, Milwaukee, and St Paul, and the Chicago Great Western railways, at an altitude of 1000 feet. It contains the State schools for the blind, deaf, and feeble-minded. Its manufactures consist largely of flour and furniture. Population (1880), 5415; (1890), 6520; (1900), 7868, of whom 1586 were foreign-born.

Faridkot, a native state of India within the Punjab. It ranks as one of the Cis-Sutlej states which came under British influence in 1809. Its area is 643 square miles. In 1881 the population was 97,034, and in 1891 it was 115,040, giving an average density of 178 persons per square mile. In 1901 the population was 124,912, showing an increase of 9 per cent. The estimated gross revenue is Rs. 3,56,000; the military force numbers 571 men; there is no tribute. The territory is traversed by the Rewari-Ferozepore railway, and also crossed by the Fazilka line, which starts from Kotkapura, the old capital. It is irrigated by a branch of the Sirhind canal. In 1896–97 there were seven schools attended by 262 pupils; the proportion of boys at school was as low as one in 243 of the total male population. The town of FARIDKOT has a railway station, 84 miles from Lahore.

Faridpur, or **Furreedpore,** a town and district of British India, in the Dacca division of Bengal. The town, which has a railway station, stands on an old channel of the Ganges. Population about 10,500. There are a Baptist mission, a Government high school, attended in 1896–97 by 277 pupils, and three printing presses, with two vernacular newspapers. The DISTRICT comprises an area of 3267 square miles. Population (1881), 1,636,785; (1891), 1,797,320, showing an average density of 792 persons per square mile. Classified according to religion, Hindus numbered 699,307; Mahommedans, 1,120,612; Christians, 3539, of whom 99 were Europeans; "others," 85. In 1901 the population was 1,937,922, showing an increase of 6 per cent. The land revenue and rates were Rs.6,47,392; the number of police was 433; there were 37,980 boys at school in 1896–97, being 27·9 per cent. of the male population of school-going age; the registered death-rate in 1897 was 39·45 per thousand, a high mortality attributed to the contamination of drinking-water by the steeping of jute. The north of the district is crossed by the line of the Eastern Bengal railway to Goalundo, the port of the Brahmaputra steamers, and a branch runs to Faridpur town. But most of the trade is conducted by river.

Faringdon, Great, a market-town and railway station in the Abingdon parliamentary division of Berkshire, England, 17 miles S.W. by W. of Oxford. Edward the Elder died in a royal palace there in 925. All Saints' church has an Early English tower, and contains memorials; there are an ancient town-hall, a corn exchange, with a library and reading-room, a cottage hospital, and Faringdon House, built by Henry James Pye, poet laureate from 1790 to 1813. About 6½ miles to the S.E. is the White Horse, a figure dug in the slope of a chalk hill. Area of civil parish, 5897 acres; population (1881), 3141; (1901), 2900.

Farnborough, a parish in the Basingstoke parliamentary division of Hampshire, England, 2½ miles N. of Aldershot by rail. The parish church is ancient; St Michael's Catholic memorial church, erected in 1887 by the ex-Empress Eugénie, contains the remains of Napoleon III. and the Prince Imperial. An adjoining priory is occupied by Benedictine fathers; the convent is a ladies' boarding school. Aldershot north camp is within the parish. Area of civil parish (an urban district), 2331 acres; population (1881), 6266 (including 2840 military); (1901), 11,499 (including 5070 military).

Farnborough, Thomas Erskine May, 1ST BARON (1815–1886), was born in 1815, and educated at Bedford Grammar School under Dr Brereton. In 1831 he was nominated by Mr Manners Sutton, speaker of the House of Commons, to the post of assistant librarian, so that his long connexion with parliament began in his youth. He studied for the bar, and was called at the Middle Temple in 1838. In 1844 he published the first edition of his *Treatise on the Law, Privilege, Proceedings, and Usage of Parliament.* This work, which has passed through many editions, is not only an invaluable mine of information for the historical student, but it is known as the text-book of the law by which parliament governs its proceedings. It has been observed that "since its first publication the framers of constitutions have found in it the groundwork of their various systems; and while colonial legislatures have been modelled on the lines laid down in it, its translation into more than one foreign language has extended its influence beyond the English-speaking race." In 1846 Mr Erskine May was appointed examiner of petitions for private bills, and the following year taxing-master of the House of Commons. He published his *Remarks to Facilitate Public Business in Parliament* in 1849; a work *On the Consolidation of Election Laws* in 1850; and his *Rules, Orders, and Forms of the House of Commons* was printed by command of the House in 1854. In 1856 he was appointed clerk assistant at the table of the House of Commons. He received the Companionship of the Bath in 1860 for his parliamentary services, and became a Knight Commander in 1866. His important work, *The Constitutional History of England since the Accession of George III.* (1760–1860), was published in 1861–63, and it received frequent additions in subsequent editions. In 1871 Sir Erskine May was appointed clerk of the House of Commons. His *Democracy in Europe: a History,* appeared in 1877, but it failed to take the same rank in critical esteem as his *Constitutional History.* He retired from the post of clerk to the House of Commons in April 1886, having for fifteen years discharged the onerous duties of the office with as much knowledge and energy as unfailing tact and courtesy. Shortly after his retirement from office he was raised to the peerage under the title of Baron Farnborough of Farnborough, in the county of Southampton, but he only survived to enjoy the dignity for a few days. He died 10th May 1886, and as he left no issue the title became extinct. (G. B. S.)

Farnworth, a town in the Radcliff-cum-Farnworth parliamentary division of Lancashire, England, on the Irwell, 3 miles S.E. of Bolton by rail. The churches and chapels are four parish, a chapel of ease, Roman Catholic, Baptist, four Congregational, three Wesleyan, Catholic-Apostolic, &c. There are a grammar-school, market-place, public baths, recreation ground, a fever hospital, and a theatre. A public park of 16 acres was opened in 1864. Cotton mills, iron foundries, brick and tile works, and collieries supply industries. Area of urban district, 1502 acres; population (1881), 20,708; (1901), 25,927.

Faroe Islands, in Danish FÆRÖERNE—that is, "the Sheep Islands,"—belonging to Denmark, between Iceland (250 miles to the N.W.) and the Shetland Islands (180 miles to the S.E.), on the submarine ridge which separates the Atlantic from the Norwegian Sea. Strömö has an area of 144 sq. miles. Total population (1880), 11,220; (1900), 15,230. Chief town, Thorshavn; population, 1656. The loftiest elevations are Slattaretinde (2894 ft.) in Österö, and Kopende (2592 ft.) and Skellingfjeld (2520 ft.) in Strömö. The cultivation of the soil (which belongs for the most part to the Danish state) is extremely primitive, and the cultivated area only about 6 per cent. Hay is the principal crop. Coal is mined. In 1897 the islanders owned a fleet of 87 vessels of a total of 6150 tons.

V. U. Hammershaimb has published a collection of folk-songs and popular legends (*Færöisk Anthologi,* 2 vols., Copenhagen, 1886–91). Engl. version of the *Fœreyinga Saga,* by F. York Powell (Lond. 1896). The islands are being surveyed by the Danish General Staff. See *Geog. Tidskrift,* Copenhagen, 1895 (vol. xiii.) and 1897 (vol. xiv.).

Farr, William (1807–1883), English statistician, was born at Kenley, in Shropshire, on 30th November 1807. When nineteen he became the pupil of a doctor in Shrewsbury, also acting as dresser in the infirmary there. He then went to Paris to study medicine, but after two years returned to London, where, in 1832, he qualified as L.S.A. Next year he began to practise, but without very brilliant results, for five years later he definitely abandoned the exercise of his profession on accepting the post of compiler of abstracts in the registrar-general's office. The commissioners for the 1841 census consulted him on several points, but did not in every case follow his advice. For the next two decennial censuses he acted as assistant-commissioner; for that of 1871 he was a commissioner, and he wrote the greater part of the reports of all. He had an ambition to become registrar-general; and when that post became vacant in 1879, he was so disappointed at the selection of Sir Brydges Henniker instead of himself, that he refused to stay any longer in the registrar's office. He died of paralysis of the brain a year or two later, on 14th April 1883. A great part of Farr's literary production is to be found in the papers which, from 1839 to 1880, he wrote for each annual report of the registrar-general on the cause of the year's deaths in England. He was also the author of many papers on general statistics and on life-tables for insurance, some read before the Royal Statistical Society, of which he was president in 1871 and 1872, some contributed to the *Lancet* and other periodicals. A selection from his statistical writings was published in 1885 under the editorship of Mr Noël Humphreys.

Farrar, Frederic William (1831——), English divine, was born 7th August 1831, in the Fort of Bombay, his father, afterwards rector of Sidcup, Kent, being then a missionary of the Church Missionary Society. While very young he was sent to England, and placed in King William's College, Castletown, Isle of Man, a school whose external surroundings are reproduced in his popular schoolboy tale, *Eric; or, Little by Little.* In 1847 he entered King's College, London. Through the influence of Maurice he was led to the study of Coleridge, whose writings had a profound influence upon his faith and opinions. He proceeded to Trinity College, Cambridge, in October 1851, but while studying here returned to take his degree of B.A. at the university of London. He became a foundation scholar at Cambridge in 1852, and two years later he took his degree as fourth junior optime, and fourth in the first class of the classical tripos. In addition to other college prizes he gained the chancellor's medal for the English prize poem on the search for Sir John Franklin in 1852, the Le Bas prize, and the Norrisian prize. He was elected fellow of Trinity College in 1856. On leaving the university, Mr Farrar became an assistant master under Dr Cotton at Marlborough College. In November 1855 he was appointed an assistant-master at Harrow; here he remained for fifteen years. He was elected a fellow of the Royal Society in 1864, university preacher in 1868, honorary chaplain to the queen in 1869, and Hulsean lecturer in 1870. Mr Farrar was appointed headmaster of Marlborough College in 1871, and in the following year became chaplain-in-ordinary to the queen. In 1876 he was appointed canon of Westminster and rector of St Margaret's, Westminster. He took his D.D. degree in 1874, being the first to take theological degrees in accordance with the new regulations at Cambridge. Dr Farrar began his literary labours with the publication of *Eric* in 1858, succeeded in the following year by *Julian Home* and *Lyrics of Life*, and in 1862 by *St Winifred's; or the World of School.* He had already published a work on *The Origin of Language;* and now for a number of years philology took the place of fiction. His series of works on grammar and scholastic philology included *Chapters on Language*, 1865; *Greek Grammar Rules*, 1865; *Greek Syntax*, 1866; and *Families of Speech*, 1869. He edited *Essays on a Liberal Education* in 1868; and published *Seekers after God* in the Sunday Library, 1869. It was by his theological works, however, that Dr Farrar attained his greatest popularity. His Hulsean lectures were published in 1870 under the title of *The Witness of History to Christ.* *The Life of Christ*, which was published in 1874, speedily passed through a great number of editions, and ultimately became one of the most widely-read theological works of the 19th century. It reveals considerable powers of imagination and eloquence, and was partly inspired by a personal knowledge of the sacred localities depicted. In 1877 appeared *In the Days of My Youth*, sermons preached in the chapel of Marlborough College; and during the same year his volume of sermons on *Eternal Hope*—in which he called in question the doctrine of eternal punishment—caused much controversy in religious circles. In 1879 appeared *The Life and Works of St Paul*, and this was succeeded in 1882 by *The Early Days of Christianity.* Then came in order of publication the following works: *Every-day Christian Life; or, Sermons by the Way*, 1887; *Lives of the Fathers*, 1888; *Sketches of Church History*, 1889; *Darkness and Dawn*, 1891; *The Voice from Sinai*, 1892; *The Life of Christ as Represented in Art*, 1894; a work on Daniel, 1895; *Gathering Clouds*, a tale of the days of Chrysostom, 1896; and *The Bible, its Meaning and Supremacy*, 1896. In addition to his separate works, Dr Farrar has been a copious contributor of articles to various magazines, encyclopædias, and theological commentaries. In 1883 he was made archdeacon of Westminster and rural dean; and in 1885 he was appointed Bampton lecturer at Oxford, taking for his subject "The History of Interpretation." Dr Farrar was appointed dean of Canterbury in 1895. From 1890 to 1895 he was chaplain to the speaker of the House of Commons, and in 1894 he was appointed deputy-clerk of the closet to Queen Victoria. As a theologian Dean Farrar occupies a position midway between the Evangelical party and the Broad Church; while as a rather rhetorical preacher and writer he exerts a commanding influence over wide circles of readers. He is an ardent temperance and social reformer, and was one of the founders of the institution known as the Anglican Brotherhood, a religious band with modern aims and objects.

Farrer, Thomas Henry Farrer (1819–1899), 1st Baron, English civil servant and statistician, was the son of Thomas Farrer, a solicitor in Lincoln's Inn Fields. Born 24th June 1819, he was educated at Eton and Balliol College, Oxford, where he graduated in the second class in classics in 1840. He was called to the bar at Lincoln's Inn in 1844, but retired from practice in the course of a few years. In 1857 he was appointed assistant-secretary in the marine department of the Board of Trade, and permanent secretary to the Board of Trade in 1862. His tenure of this office, which he held for upwards of twenty years, was marked by many reforms and an energetic administration. Not only was he an advanced Liberal in politics, but he was a thorough Free-trader of the strictest school. He was created a baronet for his services at the Board of Trade in 1883, and in 1886 he retired from office. During the same year he published a work entitled *Free Trade versus Fair Trade*, in which he dealt with an economic controversy then greatly agitating the public mind. He had already written for the Citizen Series a volume on *The State in its Relation to Trade.* In 1889 he was co-opted by the Progressives an alderman of the London County Council, of which he became vice-chairman in 1890. His efficiency and ability in this capacity were warmly recognized; but in the course of time divergencies arose between his personal views and many of those of his colleagues. The tendency towards socialistic legislation which became apparent was quite at variance with his principles of individual enterprize and responsibility. He consequently resigned his position. In 1893 he was raised to the peerage. From this time forward he devoted much of his energy and leisure to advocating his views at the Cobden Club, the Political Economy Club, on the platform, and in the public press. Especially were his efforts directed against the opinions of the Fair Trade League, and upon this and other controversies on economic questions he wrote able, clear, and uncompromising letters, which left no doubt that he still adhered to the doctrines of free trade as advocated by its earliest exponents. In 1898 he published his *Studies in Currency*. He died at Abinger Hall, Dorking, 11th October 1899.

Fars (the name FARSISTAN is seldom used), one of the five great provinces of Persia. It has a population of about 750,000, and pays a yearly revenue of about £140,000. The subdivision of the province in districts, the chief places of the districts and their population, and the number of inhabited villages in each, as they appear in the latest available lists (dated 1884), are shown in the following table:—

	Name of District.	Chief Place or Seat of Government.		Number of Inhabited Villages in District.
		Name.	Population.	
1	Abádeh Iklid	Abádeh	4,000	33
2	Abádeh Tashk	Tashk		8
3	Abarj	Dashtek	2,000	6
4	*Abbássi*—			
	1. Bender Abbássi and Villages	Bender Abbássi	10,000	14
	2. Issín and Tázián	Issín		6
	3. Shamíl	Shamíl	1,000	18
	4. Móghistán	Ziárat		10
	5. Mínáb	Mínáb	4,000	23
5	Abrkúh	Abrkúh	10,000	22
6	Afzar	Nímdeh		12
7	'Alamrúd	Sabzpushán	1,000	16
8	*Arb'ah* (the four)—			
	1. Deh Rúd 2. Deh Ram 3. Hengám 4. Rúdbál	Deh Ram	1,500	19
9	Ardakán	Ardakán	5,000	10
10	Arsinján	Arsinján	5,000	25
11	Asír	Asír	500	10
12	Baizá	Baizá	2,000	55
13	Bashákerd	Angúrán		5
14	Bídshehr and Juvim	Bídshehr	3,000	23
15	Bovanát	Súrián	500	23
16	Daráb	Daráb	5,000	62
17	*Dashti*—			
	1. Bardistán	Bender Dair	1,000	28
	2. Bulúk	Bushgán		18
	3. Mándistán	Kákí	1,500	40
	4. Tassúj	Tang Bágh	500	11
	5. Shumbeh	Shumbeh		15
18	*Dashtistán*—			
	1. Angáli	Haftjúsh		10
	2. Ahrom	Ahrom	1,500	5
	3. Borazján	Borazján	4,000	19
	4. Bushire	Bushire	25,000	20
	5. Dálikí	Dálikí	1,500	7
	6. Gonávah	Gonávah	1,000	12
	7. Hayát Daúd	Bender Ríg	1,000	6
	8. Khurmúj	Khurmúj	1,000	5
	9. Rúd Hillah	Kelát Sukhteh		10
	10. Shabánkáreh	Deh Kohneh		27
	11. Tangistán	Tangistán	1,000	31
	12. Zengeneh	Samal	750	4
	13. Zíráh	Zíráh		6
19	Dizgird	Cherkes	500	6
20	Famúr	Págáh	300	3
21	Farráshband	Farráshband	1,000	14
22	Fasá	Fasá	5,000	40
23	Fírúzábád	Fírúzábád	4,000	29
24	Gillehdár	Gillehdár	1,000	43
25	Húmeh (immed. environs) Shiráz	Zerkán	1,000	89
26	Istahbonát	Istahbonát	10,000	12
27	Jahrom	Jahrom	10,000	33
28	Jireh	Ishfáyikán		23
29	Kámfírúz	Palangerí		34
30	Kamin	Kalílek		11
31	Kázerún	Kázerún	8,000	46
32	Kavár	Kavár		26
33	Kír and Karzín	Kír	1,000	23
34	Khafr	Khafr	1,000	41
35	Khájeh	Zanjírán	500	15
36	Khisht	Khisht	2,500	25
37	Khunj	Khunj	1,500	27
38	Kongán	Bender Kongán		12
39	Kúh Gílúyeh	Behbahan	10,000	182
40	Kurbál	Gávkán	600	67
41	*Láristán*—			
	1. Lár	Lár	8,000	34
	2. Panjeh Ihshám	Bairam		11
	3. Panjeh Fál	Ishkenán		10
	4. Jehángíriyeh	Bastak	4,000	30
	5. Shíb Kúh	Bender Chárek		36
	6. Fúmistán, or Gávbandi	Gávbandi		13
	7. Kauristán	Kauristán		4
	8. Lingah	Bender Lingah	10,000	11
	9. Mazáyiján	Mazáyiján		6
42	Maimand	Maimand	5,000	14
43	Maliki	Bender Assalú	1,000	25
44	*Mamasenni* (old Shúlistán)—			
	1. Bekesh	Kalát Safíd		8
	2. Javídí, or Jáví			6
	3. Dushmanziári			16
	4. Rustami			26
	5. Fahlián			7
	6. Kákán			5
45	Marvast and Herát	Marvast		14
46	*Marvdasht*—			
	1. Upper Khafrek	Fathábád	1,250	14
	2. Lower Khafrek			16
	3. Marvdasht			22
47	Mashhad Mádar Sulimán	Murgháb	800	6
48	Máyin	Máyin		8
49	Nairíz	Nairíz	9,000	24
50	Ramjird	Jashíán		36
51	Rúdán and Ahmedí	Dehbáriz		21
52	*Sab'ah* (the seven)—			
	1. Bívunj	Durz		14
	2. Hassanábád	Hassanábád		7
	3. Tarom	Tarom	2,000	15
	4. Fáraghán	Fáraghán	1,500	13
	5. Forg	Forg	3,000	18
	6. Fín and Gulreh	Fín		13
	7. Gilch Gáh (abandoned)			—
53	Sarchahán	Ziáret	1,000	11
54	*Sarhad Chahár Dungeh*—			
	1. Dasht Uján 2. Dasht Khosro va Shirín 3. Dasht Khúngasht 4. Dasht Kúshk Zard	Kúshk Zard		31
55	*Sarhad Shesh Nahíyeh*—

	5. Vardasht	Garmabad		
	6. Vank	Vank		
56	Sarvistán	Sarvistán	4,500	23
57	Shíráz (town)		53,607[1]	—
58	Síyákh	Darinján		13
59	Simkán	Dúzeh		38

[1] Persian census (1884): 6327 houses; 25,284 males, 28,323 females; total population, 53,607.

The above fifty-nine districts are grouped into eighteen sub-provinces, under governors appointed by the Governor-general of Fars, but the towns of Bushire, Lingah, and Bender Abbássi, together with the villages in their immediate neighbourhood, form a separate government known as that of the "Persian Gulf ports" (Benáder i Khalíj i Fárs), under a governor appointed from Teherán. Many districts are fertile, but some, particularly those in the south-eastern part of the province, do not produce sufficient grain for the requirements of the population. In consequence of droughts, ravages of locusts, and misgovernment by local governors, the province has been much impoverished, and hundreds of villages are in ruins and deserted. Turbulent and lawless nomad tribes, when on the march from summer to winter, or from winter to summer camping grounds, frequently render the roads insecure, and occasionally plunder whole districts, leaving the inhabitants without means of subsistence.

The province produces much wheat, barley, rice, and cotton, but the authorities every now and then prohibiting the exportation of cereals, the people only sow just as much as they think will suffice for their own wants. Much tobacco, principally for home consumption, is also grown (specially in Fasa and Daráb), and a considerable quantity of opium, much of it for export to China, is produced. Salt, lime, and gypsum are abundant. There are some oil wells at Dálikí, near Bushire, but attempts to tap the oil have been unsuccessful. There are no valuable oyster banks in Persian waters, and all the Persian Gulf pearls are obtained from banks on the coast of Arabia and near Bahrain. (A. H.-S.)

Farukhabad, a city and district of British India, in the Agra division of the North-West Provinces. The city is near the right bank of the Ganges, 87 miles by rail from Cawnpore. It forms a joint municipality with Fatehgarh, the civil headquarters of the district, with a military cantonment. Population (1881), 62,437; (1891), 78,032; (1901), 62,878. The municipal income in 1897–98 was Rs. 53,427; the registered death-rate in 1897 was 42 per thousand. At Fatehgarh is the government gun-carriage factory; also an American Presbyterian mission, with high school, and a tent factory. The district of FARUKHABAD has an area of 1720 square miles, and had a population in 1881 of 907,608, and in 1891 of 856,687, giving an average density of 499 persons per square mile. In 1901 the population was 924,660, showing an increase of 8 per cent. The land revenue and rates were Rs. 13,24,696, the incidence of assessment being R. 1-1-8 per acre; the cultivated area in 1896–97 was 504,976 acres, of which 278,480 were irrigated; the number of police was 2912; the number of vernacular schools in 1896–97 was 104, with 3880 pupils; the registered death-rate in 1897 was 43·42 per thousand. There are eight printing-presses, issuing four vernacular periodicals, and 87 indigo factories, employing 3927 persons, with an out-turn valued at Rs. 2,07,000. Part of the district is watered by distributaries of the Ganges canal, and it is now traversed throughout its length by the Agra-Cawnpore line of the Rajputana railway.

Fashoda. See EGYPT (*History*), and NILE.

Fatehpur (*Fathepur*), a town and district of British India, in the Allahabad division of the North-West Provinces. The town is 73 miles by rail north-west of Allahabad. In 1881 the population was 21,328, in 1891 it was 20,179; the municipal income in 1897–98 was Rs. 12,191. The district of FATEHPUR has an area of 1633 square miles. It had a population in 1881 of 683,745, and in 1891 of 699,157, giving an average density of 428 persons per square mile. In 1901 the population was 686,411, showing a decrease of 2 per cent. The land revenue and rates were Rs. 11,79,482, the incidence of assessment being R. 1-14-1 per acre; the cultivated area was 307,439 acres, of which 127,703 were irrigated from wells, &c.; the number of police was 2370; the number of vernacular schools in 1896–97 was 95, with 2952 pupils; the registered death-rate in 1897 was 54·35 per thousand. There are three printing-presses, issuing three vernacular periodicals. The district is traversed by the main line of the East Indian railway from Allahabad to Cawnpore, 55 miles in length.

Faure, François Félix (1841–1899), President of the French Republic, was born in Paris, 30th January 1841, being the son of a small furniture maker. Having started as a tanner and merchant at Havre, he acquired considerable wealth, was elected to the National Assembly in August 1881, and took his seat as a member of the Left, interesting himself chiefly in matters concerning economics, railways, and the Navy. In November 1882 he became under-secretary for the colonies in M. Ferry's Ministry, and retained the post till 1885. He held the same post in M. Tirard's Ministry in 1888, and in 1893 was made vice-president of the Chamber. In 1894 he obtained cabinet rank as minister of marine in the administration of M. Dupuy. In the January following he was unexpectedly elected President of the Republic upon the resignation of M. Casimir-Périer. The principal cause of his elevation was the determination of the various sections of the moderate republican party to exclude M. Brisson, who had had a majority of votes on the first ballot, but had failed to obtain an absolute majority. To accomplish this end it was necessary to unite among themselves, and union could only be secured by the nomination of some one who offended nobody. M. Faure answered perfectly to this description. His fine presence and his tact on ceremonial occasions rendered the state some service when in 1896 he received the Tsar of Russia at Paris, and in 1897 returned his visit, after which meeting the momentous Franco-Russian alliance was publicly announced. The latter days of M. Faure's presidency were embittered by the Dreyfus affair, which he was determined to regard as *chose jugée*. But at a critical moment in the proceedings his death occurred suddenly, from apoplexy, on 16th February 1899. With all his faults, and in spite of no slight amount of personal vanity, President Faure was a shrewd political observer and a good man of business. After his death, some alleged extracts from his private journals, dealing with French policy, were published in the Paris press.

Fauré, Gabriel (1845 ——), French musical composer, was born at Pamiers on 13th May 1845. He studied at the school of sacred music directed by Niedermeyer, first under Dietsch, and subsequently under Saint-Saëns. He became "maître de chapelle" at the church of the Madeleine in 1877, and organist in 1896. His works include a symphony in D minor (Op. 40), two quartets for piano and strings (Opp. 15 and 45), a suite for orchestra (Op. 12), sonata for violin and piano (Op. 13), concerto for violin (Op. 14), berceuse for violin, elegie for violoncello, pavane for orchestra, incidental music for Alexandre Dumas' *Caligula* and De Haraucourt's *Shylock*, a requiem, a cantata, *The Birth of Venus*, produced at the Leeds Festival in 1898. He has also written a quantity of piano music and a large number of songs. Fauré occupies a place to himself among modern French composers. He delights in the *imprévu*, and loves to wander through labyrinthine harmonies. There can be no denying the intense fascination and remarkable originality of his music. He is a composer whose works are more likely to appeal to those of delicate and refined tastes than to the masses. His muse is essentially aristocratic, and suggests the surroundings of the boudoir and the perfume of the hothouse.

Faversham, a municipal borough, port, and market-town, in the Faversham parliamentary division of Kent, England, on a creek of the Swale, 9 miles W.N.W. of Canterbury by rail. Recent erections are an Established church, a cottage hospital, and an isolation hospital. Area, 693 acres; population (1881), 9374; (1901), 11,234.

Favre, Jules (1809–1880), French advocate and statesman, was born at Lyons on 31st March 1809. After a brilliant career as a barrister, especially as counsel for defendants in political prosecutions, he achieved political importance by his defence of Felice Orsini in 1858, and in 1860 was returned to the Legislative Assembly as one of the miniature but formidable party of five opposed to the Empire. Unlike most of his colleagues, he consistently maintained this hostile attitude, and it was upon his proposition that the deposition of Napoleon III. was proclaimed after the disaster of Sedan. He naturally obtained a leading position in the new Government, but the post of Minister of Foreign Affairs was unsuited to him; his famous declaration, "Not an inch of our territory, not a stone of our fortresses," had to be taken back, and his neglect of Prince Bismarck's advice to disarm the National Guard brought about the horrors of the Commune. After this, though still practising with distinction as a pleader, he took little part in political affairs. He died at Versailles on 20th January 1880.

Fawcett, Henry (1833–1884), English politician and economist, was born at Salisbury on 26th August 1833. His father, William Fawcett, a native of Kirkby Lonsdale, in Westmorland, started life as a draper's assistant at Salisbury, opened a draper's shop on his own account in the market-place there in 1825, married a solicitor's daughter of the city, became a prominent local man, took a farm, developed his north-country sporting instincts, and displayed his shrewdness by successful speculations in Cornish mining. His second son, Henry, inherited a full measure of his shrewdness, along with his masculine energy, his straightforwardness, his perseverance, and his fondness for fishing. The father was active in electioneering matters, and his wife was an ardent reformer. Henry Fawcett was educated locally and at King's College school (1848–51), and proceeded to Peterhouse, Cambridge, in October 1852, migrating in 1853 to Trinity Hall. He was seventh wrangler in 1856, and was elected to a fellowship at his college. He had already attained some prominence as an orator at the Cambridge Union. Before he left school he had formed the ambition of entering parliament, and, being a poor man, he resolved to approach the House of Commons through a career at the bar. He had already entered Lincoln's Inn. His prospects, however, were shattered by a calamity which befell him in September 1858, when two stray pellets from his father's fowling-piece passed through the glasses he was wearing and blinded him for life. Within ten minutes after his accident he had made up his mind "to stick to his old pursuits as much as possible." He kept up all recreations contributing to the enjoyment of life; he fished, rowed, skated, took abundant walking and horse exercise, and learnt to play cards with marked packs. Soon after his accident he established his headquarters at Trinity Hall, Cambridge, entered cordially into the social life of the college, and came to be regarded by many as a typical Cambridge man. He gave up mathematics (for which he had little aptitude), and specialized in political economy. He paid comparatively little attention to economic history, but he was in the main a devout believer in economic theory, as represented by Ricardo and his school. The later philosophy of the subject he believed to be summed up in one book, Mill's *Principles of Political Economy*, which he regarded as the indispensable "vade mecum" of every politician. He was not a great reader, and Mill probably never had a serious rival in his regard, though he was much impressed by Buckle's *History of Civilization* and Darwin's *Origin of Species* when they severally appeared. He made a great impression in 1859 with a paper at the British Association, and he soon became a familiar figure there and at various lecture halls in the north as an exponent of orthodox economic theory. Of the sincerity of his faith he gave the strongest evidence by his desire at all times to give a practical application to his views and submit them to the test of experiment. Among Mill's disciples he was, no doubt, far inferior as an economic thinker to Cairnes, but as a popularizer of the system and a demonstrator of its principles by concrete examples he had no rival. His power of exposition was illustrated in his *Manual of Political Economy* (1863), of which in twenty years as many as 20,000 copies were sold. Alexander Macmillan had suggested the book, and it appeared just in time to serve as a credential, when, in the autumn of 1863, Fawcett stood and was elected for the Chair of Political Economy at Cambridge. The appointment attached him permanently to Cambridge, gave him an income, and showed that he was competent to discharge duties from which a blind man is often considered to be debarred. He was already a member of the Political Economy Club, and was becoming well known in political circles as an advanced Radical. In January 1863, after a spirited though abortive attempt in Southwark, he was only narrowly beaten for the borough of Cambridge. Early in 1864 he was adopted as one of the Liberal candidates at Brighton, and at the general election of 1865 he was elected by a large majority. Shortly after his election he became engaged to Millicent, daughter of Mr Newson Garrett of Aldeburgh, Suffolk, and in 1867 he was married.

Fawcett entered parliament just in time to see the close of Palmerston's career and to hail the adoption by Gladstone of a programme of reform to which most of the *laissez-faire* economists gave assent. He was soon known as a forcible speaker, and quickly overcame the imputation that he was academic and doctrinaire, though it is true that a certain monotony in delivery often gave a slightly too didactic tone to his discourses. But it was as the uncompromising critic of the political shifts and expedients of his leaders that he attracted most attention. He constantly insisted upon the right of exercising private judgment, and he especially devoted himself to the defence of causes which, as he thought, were neglected both by his official leaders and by his Radical comrades. Reelected for Brighton to the parliament of 1868–74, he greatly hampered the Government by his persistence in urging the abolition of clerical fellowships and the payment of election expenses out of the rates, and by opposing the "permissive compulsion" clauses of the Elementary Education Bill, and the exclusion of agricultural children from the scope of the Act. His hatred of weak concessions made him the terror of parliamentary wirepullers, and in 1871 he was not undeservedly spoken of in the

Times as the most "thorough Radical now in the House." His liberal ideals were further shocked by the methods by which Gladstone achieved the abolition of Army Purchase. His disgust at the supineness of the Cabinet in dealing with the problems of Indian finance and the growing evil of Commons' Enclosures were added to the catalogue of grievances which Fawcett drew up in a powerful article, "On the Present Position of the Government," in the *Fortnightly Review* for November 1871. In 1867 he had opposed the expenses of a ball given to the Sultan at the India Office being charged upon the Indian budget. In 1870 he similarly opposed the taxation of the Indian revenue with the cost of presents distributed by the duke of Edinburgh in India. In 1871 he went alone into the lobby to vote against the dowry granted to the Princess Louise. The soundness of his principles was not impeached, but his leaders looked askance at him, and from 1871 he was severely shunned by the Government whips. Their suspicion was justified when in 1873 Fawcett took a leading share in opposing Gladstone's scheme for university education in Ireland as too denominational, and so contributed largely to a conclusive defeat of the Gladstone Ministry.

From 1869 to 1880 Fawcett concentrated his energies upon two important subjects which had not hitherto been deemed worthy of serious parliamentary attention. The first of these was the preservation of commons, especially those near large towns; and the second was the responsibility of the British Government for the amendment of Indian finance. In both cases the success which he obtained exhibited the sterling sense and shrewdness which made up such a great part of Fawcett's character. In the first case Fawcett's great triumph was the enforcement of the general principle that each annual Enclosure Act must be scrutinized by parliament and judged in the light of its conformity to the interests of the community at large. Probably no one did more than he did to prevent the disafforestation of Epping Forest and of the New Forest. From 1869 he regularly attended the meetings of the Commons Preservation Society, and he remained to the end one of its staunchest supporters. His intervention in the matter of Indian finance, which gained him the sobriquet of the "member for India," led to no definite legislative achievements, but it called forth the best energies of his mind and helped to rouse an apathetic and ignorant public to its duties and responsibilities. Fawcett was defeated at Brighton in February 1874. Two months later, however, he was elected for Hackney, and retained the seat during his life. He was promptly replaced on the Indian Finance Committee, and continued his searching inquiries with a view to promote a stricter economy in the Indian budget, and a more effective responsibility in the management of Indian accounts.

As an opponent of the Disraeli Government (1874–80) Fawcett came more into line with the Liberal leaders. In foreign politics he gave a general adhesion to Gladstone's views, but he continued to devote much attention to Indian matters, and it was during this period that he produced two of his best publications. His *Free Trade and Protection* (1878) illustrated his continued loyalty to Cobdenite ideas. At the same time, his admiration for Palmerston and his repugnance to schemes of Home Rule show that he was not by any means a peace-at-any-price man. He thought that the Cobdenites had deserved well of their country, but he always maintained that their foreign politics were biassed to excess by purely commercial considerations. As befitted a writer whose linguistic gifts were of the slenderest, Fawcett's English was a sound homespun, clear and unpretentious. In a vigorous employment of the vernacular he approached Cobbett, whose writing he justly admired. The second publication was his *Indian Finance* (1880), three essays reprinted from the *Nineteenth Century*, with an introduction and appendix. When the Liberal party returned to power in 1880 Gladstone offered Fawcett a place in the new Government as Postmaster-General (without a seat in the Cabinet). On Egyptian and other questions of foreign policy Fawcett was often far from being in full harmony with his leaders, but his position in the Government naturally enforced reserve. He was, moreover, fully absorbed by his new administrative functions. He gained the sympathy of a class which he had hitherto done little to conciliate, that of public officials, and he showed himself a most capable head of a public department. To his readiness in adopting suggestions, and his determination to push business through instead of allowing it to remain permanently in the stage of preparation and circumlocution, the public is mainly indebted for five substantial postal reforms:—(1) The parcels post, (2) postal orders, (3) sixpenny telegrams, (4) the banking of small savings by means of stamps, (5) increased facilities for life-insurance and annuities. In connexion with these last two improvements Fawcett, in 1880, with the assistance of Mr James Cardin, took great pains in drawing up a small pamphlet called *Aids to Thrift*, of which over a million copies were circulated gratis. A very useful minor innovation of his provided for the announcement on every pillar-box of the time of the "next collection." In the post office, as elsewhere, he was a strong advocate of the employment of women. Proportional representation and the extension of franchise to women were both political doctrines which he adopted very early in his career, and never abandoned. Honours were showered upon him during his later years. He was made an honorary D.C.L. of Oxford, a Fellow of the Royal Society, and was in 1883 elected Lord Rector of Glasgow University. But the stress of departmental work soon began to tell upon his health. In the autumn of 1882 he had a sharp attack of diphtheria complicated by typhoid, from which he never properly recovered. He resumed his activities, but on the 6th November 1884 he succumbed at Cambridge to an attack of congestion of the lungs. He was buried in Trumpington churchyard, near Cambridge, and to his memory were erected a monument in Westminster Abbey, a statue in Salisbury market-place, and a drinking fountain on the Thames embankment.

In economic matters Fawcett's position can best be described as transitional. He believed in co-operation almost as a panacea. In other matters he clung to the old *laissez-faire* theorists, and was a strong anti-socialist, with serious doubts about free education, though he supported the Factory Acts and wished their extension to agriculture. Apparent inconsistencies were harmonized to a great extent by his dominating anxiety to increase the well-being of the poor. One of his noblest traits was his kindliness and genuine affection for the humble and oppressed, country labourers and the like, for whom his sympathies seemed always on the increase. Another was his disposition to interest himself in and to befriend younger men. In the great affliction of his youth Fawcett bore himself with a fortitude which it would be difficult to parallel. The effect of his blindness was, as the event proved, the reverse of calamitous. It brought the great aim and purpose of his life to maturity at an earlier date than would otherwise have been possible, and it had a mellowing influence upon his character of an exceptional and beneficent kind. As a youth he was rough and canny, with a suspicion of harshness. The kindness evoked by his misfortune, a strongly reciprocated family affection, a growing capacity for making and keeping friends—these and other causes tended to ripen all that was best, and apparently that only, in a strong but somewhat stern character. His acerbity passed away, and in later life was reserved exclusively for official witnesses before parliamentary committees. Frank, helpful, conscientious to a fault, a shrewd gossip, and a staunch friend, he was a man whom no one could help liking. Several of his letters to his father and mother at different periods of his career are preserved in Mr Stephen's admirable *Life* (1885), and show a goodness of heart, together with a homely simplicity of nature, which is most touching. In appearance Fawcett was gaunt and tall, over 6 feet 3 inches in height, large of bone, and massive in limb. (T. SE.)

Fayrer, Sir Joseph, BART. (1824– ——), English physician, was born at Plymouth, 6th December 1824. Beginning his medical career in the navy, he was present as a surgeon at the sieges of Palermo and Rome, and then, after a short time in the army, entered the Bengal medical service in 1850. During the next few years he was again actively engaged in the field, for he went through the Burmese campaign of 1852 and was political assistant and Residency surgeon at Lucknow during the Mutiny. From 1859 to 1874 he was professor of surgery at the Medical College of Bombay, and when the Prince of Wales made his tour in India he was appointed to accompany him as physician. Returning from India he acted as president of the Medical Board of the India Office from 1874 to 1895, and in 1896 he was created a baronet. Sir Joseph Fayrer, who became a fellow of the Royal Society in 1877, has written much on subjects connected with the practice of medicine in India; but he is especially known for his studies on the poisonous snakes of that country and on the physiological effects produced by their virus.

Fazokl, or **Fazogl,** a town of the Anglo-Egyptian Sudan, on the left bank of the Blue Nile, close to the Tumat confluence, and opposite FAMAKA, near the Abyssinian frontier, formerly the residence of a powerful native king. During the Egyptian rule it was capital of the upper province of the Blue Nile of the same name, but was soon replaced by Famaka, where Mahomet Ali built a palace in 1839. Then Fazokl dwindled to a mere hamlet, and both places were abandoned at the outbreak of the Mahdi's revolt. It was reoccupied in 1899, and is now a chief station in the reconstituted Equatorial province under Anglo-Egyptian rule. It is important both as a frontier post towards Abyssinia, and as the nearest station to the auriferous district of the Tumat basin. The chief gold-washings lie on the west slope of the hills draining to the White Nile. Here is the steep Jebel-Dul, which appears to contain rich gold-bearing reefs, as the precious metal occurs in all the ravines on its flanks.

Fécamp, a town in the arrondissement of Havre, department of Seine Inférieure, 27 miles N.N.E. of Havre by rail. It has a library and museum of painting and objects of art, a hydrographical school, and an establishment for pisciculture. In 1900 1,681,237 bottles of liqueurs were produced. The total value of the imports, in 1900, was £185,600, and of the exports £39,934; 120 vessels of 49,516 tons entered and cleared, and 59 ships were engaged in the Newfoundland cod-fisheries. Amongst minor improvements, it may be said that a length of 165 yards of new quay wall was completed in 1900; that the north pier has been lengthened, and that a new lighthouse with powerful light has been erected on the extremity to replace that on the cliff. Population (1881), 11,831; (1896), 13,679; (comm.) 14,448.

Fechner, Gustav Theodor (1801–1887), the founder of German experimental psychology, was born on 19th April 1801 at Gross-Särchen, near Muskau, in Lower Lusatia, where his father was pastor. He was educated at Sorau and Dresden and the university of Leipzig. In this city he spent the rest of his life. In 1834 he was appointed professor of Physics, but in 1839 contracted a disease of the eyes while studying the phenomena of colour and subjective light, and, after much suffering, resigned. He now turned to the study of mind and the relations between body and mind, giving public lectures on the subjects of which his books treat. He died on 16th November 1887. Among his works may be mentioned: *Das Büchlein vom Leben nach dem Tode* (1836), which has been translated into English; *Nanna, oder über das Seelenleben der Pflanzen* (1848); *Zendavesta, oder über die Dinge des Himmels und des Jenseits* (1851); *Ueber die physikalische und philosophische Atomenlehre* (1855); *Elemente der Psychophysik* (1860); *Vorschule der Aesthetik* (1876); *Die Tagesansicht gegenüber der Nachtansicht* (1876). He also published chemical and physical papers, and translated chemical works by Biot and Thénard from the French. A different but essential side of his character is seen in his poems and humorous pieces, such as the *Vergleichende Anatomie der Engel* (1825), written under the pseudonym of Dr Mises. Fechner's epoch-making work was his *Elemente der Psychophysik*. He starts from the Spinozistic thought that bodily facts and conscious facts, though not reducible one to the other, are different sides of one reality. His originality lies in trying to discover an exact mathematical relation between them. The most famous outcome of his inquiries is the law known as Weber's or Fechner's law which may be expressed as follows:—In order that the intensity of a sensation may increase in arithmetical progression, the stimulus must increase in geometrical progression. Though holding good within certain limits only, the law has been found immensely useful. Unfortunately, from the tenable theory that the intensity of a sensation increases by definite additions of stimulus, Fechner was led on to postulate a unit of sensation, so that any sensation S might be regarded as composed of n units. Sensations, he argued, thus being representable by numbers, psychology may become an "exact" science, susceptible of mathematical treatment. His general formula for getting at the number of units in any sensation is $S = C \log R$; where S stands for the sensation, R for the stimulus numerically estimated, and C for a constant that must be separately determined by experiment in each particular order of sensibility. This reasoning of Fechner's has given rise to a great mass of controversy, but the fundamental mistake in it is simple. Though stimuli are composite, sensations are not. "Every sensation," says Professor James, "presents itself as an indivisible unit; and it is quite impossible to read any clear meaning into the notion that they are masses of units combined." Still, the idea of the exact measurement of sensation has been a fruitful one, and mainly through his influence on Wundt, Fechner is the father of that "new" psychology of laboratories which investigates human faculties with the aid of exact scientific apparatus. Though Fechner has had a vast influence in this special department, the disciples of his general philosophy are few. His world-conception is highly animistic. He feels the thrill of life everywhere, in plants, earth, stars, the total universe. Man stands midway between the souls of plants and the souls of stars, who are angels. God, the soul of the universe, must be conceived as having an existence analogous to men. Natural laws are just the modes of the unfolding of God's perfection. In his last work Fechner, aged but full of hope, contrasts this joyous "daylight view" of the world with the dead, dreary "night view" of materialism. Fechner's work in æsthetics is also important. He conducted experiments to show that certain abstract forms and proportions are naturally pleasing to our senses, and gave some new illustrations of the working of æsthetic association. Fechner's position in reference to predecessors and contemporaries is not very sharply defined. He was remotely a disciple of Schelling, learnt much from Herbart and Weisse, and decidedly rejected Hegel and the monadism of Lotze. (H. St.)

Fechter, Charles Albert (1824–1879), actor, was born in London, of French parents, 23rd October 1824. While he was still a child his parents returned to France. He inherited considerable artistic ability from his father (who was a sculptor), and would probably have at once devoted himself to a sculptor's life but for the accident of a striking success made in some private theatricals. The result of this was an engagement early in 1841 to play in a travelling company that was going to Italy. The tour was a failure, and the company broken up; whereupon Fechter returned home and worked assiduously at sculpture. At the same time he attended classes at the Conservatoire with the view of gaining admission to the Comédie Française. Late in 1844 he enjoyed the double success of winning the grand medal of the Académie des Beaux Arts with a piece of sculpture and of being admitted to make his *début* at the Comédie Française. He acquitted himself at the latter with considerable credit; but, tired of the small parts he found himself condemned to play, returned again to his sculptor's studio in 1846. In that year he accepted an engagement to play with a French company in Berlin, where he made his first decisive success as an actor. He there became acquainted with Eléonore Rabut, an actress, whom he married on his return to Paris in the following year. Previously to this he appeared for some months in London, in a season of French classical plays given at the St James's Theatre. In Paris for the next ten years he fulfilled a series of engagements at the Ambigu-Comique, Théâtre Historique, Porte St Martin, and Vaudeville theatres, his chief successes being his performance of Armand Duval in *La Dame aux Camélias*. From March 1857 to December 1858 he was manager of the Odéon, where he produced *Tartufe* and other pieces from the classical repertory. Having received tempting offers to play in English at the Princess's Theatre, London, he made a diligent study of the language, and appeared there in October 1860 in a version of *Ruy Blas*. This was followed by *The Corsican Brothers* and *Don Cæsar de Bazan;* and in March 1861 he first attempted *Hamlet*. The result was an extraordinary triumph, the play running for 115 nights. This was followed by *Othello*, in which he played at first the character of the Moor, and afterwards that of Iago. In January 1863 he became lessee of the Lyceum Theatre, which he opened with *The Duke's Motto;* this was followed by *The King's Butterfly*, *The Mountebank* (in which his son Paul, a boy of seven, appeared), *The Roadside Inn*, *The Master of Ravenswood*, and *The Lady of Lyons*. After this he appeared at the Adelphi (in 1868) in *No Thoroughfare*, *Monte Cristo*, and *Black and White;* and after a tour through the English provinces in 1869, he set sail in 1870 for the United States, where (with the exception of a visit to London in 1872) he remained till his death. He played in the United States between 1870 and 1876 in most of the parts in which he had won his chief triumphs in England, making at various times attempts at management. As manager, however, he was rarely successful, owing to his ungovernable temper. The downfall of his career began after an accident upon the ice in 1876, which rendered him physically infirm. Ill-health speedily overtook him, and the last three years of his life were spent in practical seclusion on a farm which he had bought at Rockland Centre, near Quakertown, in Pennsylvania. He died there, of a painful internal malady, on 5th August 1879, and was buried in Mount Vernon cemetery, Philadelphia. (R. F. S.)

Felanitx, or Felaniche, a town of Spain, in the south-east of the island of Majorca, stands 11 miles from the sea, surrounded by hills. Population, 11,442. It has well-built streets, a good town hall, and a fine parish church. Near at hand are the ruins of a Moorish castle. There is trade in wine, fruit, wheat, cattle, brandy, chalk, and soap.

Felixstowe, a seaside resort of England, straggling about 3 miles along the coast of Suffolk, just outside the estuary of the Orwell, 12 miles south-east from Ipswich. It has good golf-links, and is much frequented by visitors in the summer for its excellent sea-bathing. Population of Felixstowe and Walton (1901), 5805.

Fens, a district in the east of England, possessing a distinctive history and peculiar characteristics. It lies west and south of the Wash, and extends over more than 70 miles in length (Lincoln to Cambridge) and some 35 miles in maximum breadth (Stamford to Brandon in Suffolk), its area being considerably over half a million acres. Although low and flat, and seamed by innumerable watercourses, the entire region is not, as the Roman name of *Metaris Æstuarium* would imply, a river estuary, but is a silted up bay of the North Sea, of which the Wash is the last surviving portion. Hydrographically, the Fens embrace the lower parts of the drainage-basins of the rivers Witham, Welland, Nene, and Great Ouse; and against these streams, as also against the ocean, they are protected by earthen embankments, 10 to 15 feet high. As a rule the drainage water is lifted off the Fens into the rivers by means of steam-pumps, formerly by windmills.

General History.—According to fairly credible tradition, the first systematic attempt to drain the Fens was made by the Romans. They dug a catchwater drain (as the artificial fenland watercourses are called), the Caer or Car Dyke, from Lincoln to Ramsey (or, according to Stukeley, as far as Cambridge), along the western edge of the Fens, to carry off the precipitation of the higher districts which border the fenland, and constructed alongside the Welland and on the seashore earthen embankments,[1] of which some 150 miles still survive. After the departure of the Romans from Britain in the first half of the 5th century the Fens fell into neglect; and despite the preservation of the woodlands for the purposes of the chase by the Norman and early Plantagenet kings, and the unsuccessful attempt which Richard de Rulos, chamberlain of William the Conqueror, made to drain Deeping Fen, the fenland region became almost everywhere waterlogged, and relapsed to a great extent into a state of nature. In addition to this it was ravaged by serious inundations of the sea, for example, in the years 1178, 1248 (or 1250), 1288,[2] 1322, 1335, 1467, 1571. Yet the fenland was not altogether a howling wilderness of reed-grown marsh and watery swamp. At various spots, more particularly in the north and in the south, there existed islands of firmer and higher ground, resting generally on the boulder clays of the Glacial epochs and on the inter-Glacial gravels of the Palæolithic Age.[3]

---

[1] See, for a full discussion, S. H. Miller and S. B. J. Skertchly, *The Fenland*, p. 144 *et seq.* (Wisbech and London, 1878). Mr Miller is disposed to credit the native British inhabitants of the Fens with having executed certain of these works.

[2] W. Chapman, *Facts and Remarks relative to the Witham and the Welland* (Boston, 1800), pp. 21–23.

[3] Miller and Skertchly, *op. cit.*, pp. 513–551. In Chap. xv. (pp. 492–583) of the same work will be found an exhaustive discussion of the geology of the entire region.

On these isolated localities members of the monastic orders (especially at a later date the Cistercians) began to settle after about the middle of the 7th century. At Medeshampstead (*i.e.*, Peterborough), Ely, Crowland, Ramsey, Thorney, Spalding, Peakirk, Swineshead, Tattershall, Kirkstead, Bardney, Sempringham, Bourne, and numerous other places, they made settlements, built churches and monasteries, founded abbeys, and even reared magnificent cathedrals.[1] And, in spite of the appalling incursions of the predatory Northmen and Danes in the 9th and 10th centuries, and of the disturbances consequent upon the establishment of the Camp of Refuge by Hereward the Wake in the fens of the Isle of Ely in the 11th century, these scattered outposts continued to shed rays of civilization across the lonely Fenland down to the dissolution of the monasteries in the reign of Henry VIII. Then they, too, were partly overtaken by the fate which befell the rest of the Fens; and it was only in the end of the 18th century and the beginning of the 19th century that the complete drainage and reclamation of the Fen region was finally effected. Attempts, and on a considerable scale, were indeed made to reclaim them in the 17th century—notably the Witham Fens by Sir Anthony Thomas, the Earl of Lindsey, Sir William Killigrew, King Charles I., and others in 1631 and succeeding years; the Deeping or Welland Fens in 1638 by Sir W. Ayloff, Sir Anthony Thomas, and other "adventurers," after one Thomas Lovell had ruined himself in a similar attempt in the reign of Queen Elizabeth; and the Fens of the Nene and Great Ouse, known generally as the Bedford Level, by the Dutch engineer Cornelius Vermuyden and the Earls of Bedford, in the first half of the century; although Lord Chief-Justice Popham and a Company of Londoners had begun the work in 1605.[2] But all these attempts equally failed, owing to the determined opposition[3] of the native fenmen, whom the drainage and appropriation of the unenclosed fenlands would deprive of valuable and long-enjoyed rights of commonage, turbary (turf-cutting), fishing, fowling, &c. Holland and other Fens on the west side of the Witham were finally drained in 1767, although not without much rioting and lawlessness;[4] and a striking account of the wonderful improvements effected by a generation later is recorded in Arthur Young's *General View of the Agriculture of the County of Lincoln* (London, 1799). The East, West, and Wildmore Fens on the east side of the Witham were drained in 1801–7 by John Rennie, who carried off the precipitation which fell on the higher grounds by catchwater drains, on the principle of the Roman Car Dyke, and improved the outfall of the river, so that it might the more easily discharge the Fen water which flowed or was pumped into it.[5] The Welland or Deeping Fens were drained in 1794, 1801, 1824, 1837, and other years.[6] The drainage of the Great Bedford Level between the year 1630 and the end of the 17th century has been treated of in the ninth edition (see BEDFORD LEVEL, iii. 482).[7] Almost the only portion of the original wild Fens now remaining is Wicken Fen, which lies east of the river Cam, and south-east of the Isle of Ely.

Map of the Fens.

The Fen Rivers.—The preservation of the Fens depends in an intimate and essential manner upon the preservation of the rivers, and especially upon the preservation of their banks. The Witham, known originally as the Grant Avon, also called the Lindis,[8] some 70 miles long, and draining an area of 1070 square miles, owes its present condition to engineering works carried out in the years 1762–64, 1865, 1881, and especially in 1880–84. In 1500 the river was dammed immediately above Boston by a large sluice, the effect of which was, not only to hinder free navigation up to Lincoln (to which city sea-going vessels used to penetrate in the 14th and 15th centuries), but also to choke the channel below Boston with sedimentary matter. The sluice, or rather a new structure made in 1764–66, still remains; but the river below Boston has been very materially improved (1880–84), first by the construction of a new outfall, 3 miles in length, whereby the channel was not only straightened, but its current carried directly into deep water, without having to battle against the sandbanks, often shifting, of the Wash; and secondly, by the deepening and regulation of the river-bed up to Boston, so

8 By Leland (*Itinerary*, vol. vii. p. 41), and in Jean Ingelow's *High Tide on the Lincolnshire Coast.*

that vessels drawing nearly 3000 feet can now steam up to the docks of the town.[1] The Welland, which is about 40 miles long, and drains an area of 760 square miles, was made to assume its present shape and direction in 1620, 1638, 1650, 1794, and 1835 and following years.[2] The most radical alteration took place in 1794, when a new outfall was made from the confluence of the Glen (30 miles long) to the Wash, a distance of nearly 3 miles. The Nene, 100 miles long, and draining an area of some 1005 square miles, was first regulated by Bishop Morton (of Peterborough) between the years 1478 and 1490, and it was further improved in 1631, 1721, and especially, under plans by Rennie and Telford, in 1827–30 and 1832.[3] The work done in the years last quoted (1721 onwards) consisted in straightening the lower reaches of the stream and in directing and deepening the outfall. The Great Ouse, which has a length of over 140 miles, and drains an area of 2605 square miles, seems to have been deflected, at some unknown period, from a former channel connecting *viâ* the Old Croft river with the Nene, into the Little Ouse[4] below Littleport; and the courses of the two streams are now linked together by an elaborate network of artificial drains, the results of the great engineering works carried out in the Bedford Level in the 17th century. The salient features of the plan executed by Vermuyden[5] for the Earl of Bedford in the years 1632–53 were as follows:—Taking the division of the area made in 1697–98 into (i) the North Level, between the river Welland and the river Nene; (ii) the Middle Level, between the Nene and the Old Bedford river (which was made at this time, *i.e.*, 1630); and (iii) the South Level, from the Old Bedford river to the south-eastern border of the fenland. In the North Level the Welland was embanked, the New South Eau, Peakirk Drain, and Shire Drain made, and the existing main drains deepened and regulated. In the Middle Level the Nene was embanked from Peterborough to Guyhirn, also the Ouse from Earith to Over, both places at the south-west edge of the fenland; the New Bedford river was made from Earith to Denver, and the north side of the Old Bedford river and the south side of the New Bedford river were embanked, a long narrow "wash," or overflow basin, being left between them; several large feeding-drains were dug, including the Forty Foot or Vermuyden's Drain, the Sixteen Foot river, Bevill's river, and the Twenty Foot river; and a new outfall was made for the Nene, and Denver sluice (to dam the old circuitous Ouse) constructed. In the South Level Sam's Cut was dug and the rivers were embanked.[6] Since that period the mouth of the Ouse has been straightened above and below King's Lynn (1795 to 1821), a new straight cut made between Ely and Littleport, the North Level Main Drain and the Middle Level Drain constructed, and the meres of Ramsey, Whittlesea (1851–52), &c., drained and brought under cultivation.[7] The effect of all these drainage schemes has been to lower the level of the fenlands generally by some 18 inches, owing to the shrinkage of the peat consequent upon the extraction of so much of its contained water; and this again has tended, on the one hand, to diminish the speed and erosive power of the fenland rivers, and, on the other, to choke up their respective outfalls with the sedimentary matters which they themselves sluggishly roll seawards.

The Wash.—From this it will be plain that the Wash, although 24 miles long by 12 miles wide, is being slowly but gradually overtaken by the fate which has already come upon the rest of the once considerably greater bay; namely, it is being silted up by riverine detritus. Its floor is already thickly beset with sandbanks, many of them fixed and permanent, and showing 8 to 15 feet above low water, but several of them constantly shifting, and so diverting the interlacing and often antagonistic currents of the rivers. Through these sandbanks there are two main channels into deep water; one, Boston Deeps, is kept open by the conjoint waters of the Witham and the Welland; the other, Lynn Deeps, gives passage to the waters of the Nene and the Great Ouse. The formation of new dry land, known at first as "marsh," goes on however but slowly. During the sixteen or seventeen hundred years which have elapsed since the Romans are believed to have constructed the sea-banks which shut out the ocean, it is computed that an area of not more than 60,000 to 70,000 acres has been won from the Wash, embanked, drained, and brought more or less under cultivation. The greatest gain has been at the direct head of the bay, between the Welland and the Great Ouse, where the average annual accretion is estimated at 10 to 11 lineal feet. On the Lincolnshire coast, farther north, the average annual gain has been not quite 2 feet; whilst on the opposite, Norfolk coast, it has been little more than 6 inches annually. On the whole some 35,000 acres were inclosed in the 17th century, about 19,000 acres during the 18th, and about 10,000 acres during the 19th century.[8]

The first comprehensive scheme for regulating the outfall channels and controlling the currents of the Fen rivers seems to be that proposed by Nathaniel Kinderley in 1751. His idea[9] was to link the Nene with the Ouse by means of a new cut to be made through the marshland, and guide the united stream through a further new cut "under Wotten and Wolverton through the Marshes till over against Inglesthorp or Snetsham, and there discharge itself immediately into the Deeps of Lyn Channel." In a similar way the Witham, "when it has received the Welland from Spalding," was to be carried "to some convenient place over against Wrangle or Friskney, where it may be discharged into Boston Deeps." This scheme was still further improved upon by Sir John Rennie, who, in a report which he drew up in 1839, recommended that the outfalls of all four rivers should be directed by means of fascined channels into one common outfall, and that the land lying between them should be inclosed as rapidly as it consolidated. By this means he estimated that 150,000 acres would be won to cultivation. But beyond one or two abortive or half-hearted attempts, *e.g.*, by the Lincolnshire Estuary Company in 1851, and in 1876 and subsequent years by the Norfolk Estuary Company, no serious effort has ever been made to execute either of these schemes.

Climate.—The annual mean temperature, as observed at Boston, in the period 1864–85, is 48·7° F.; January, 36·5°; July, 62·8°; and as observed at Wisbech, for the period 1861–75, 49·1°. The average mean rainfall for the seventy-one years 1830–1900, at Boston, was 22·9 inches;[10] at Wisbech for the fifteen years 1860–75, 24·2 inches,[11] and for the fifteen years 1866–80, 26·7 inches; and at Maxey near Peterborough, 21·7 for the nineteen years 1882–1900.[12] Previous to the drainage of the Fens, ague, rheumatism, and other ailments incidental to a damp climate were widely prevalent, but at the present day the Fen country is as healthy as the rest of England; indeed, there is reason to believe that it is conducive to longevity.[13]

Historical Notes.—The earliest inhabitants of this region of whom we have record were the British tribes of the Iceni confederation; the Romans, who subdued them, called them Coriceni or Coritani. In Saxon times the inhabitants of the Fens were known (*e.g.*, to Bede) as Gyrvii, and are described as traversing the country on stilts. Macaulay, writing of the year 1689, gives to them the name of Breedlings, and describes them as "a half-savage population . . . who led an amphibious life, sometimes wading, sometimes rowing, from one islet of firm ground to another." In the end of the 18th century those who dwelt in the remoter parts were scarcely more civilized, being known to their neighbours by the expressive term of "Slodgers." And yet these rude fen-dwellers have in all ages been animated by a tenacious love of liberty. Boadicea, queen of the Iceni, the worthy foe of the Romans; Hereward the Saxon, who defied William the Conqueror; Cromwell and his Ironsides, are representative of the fenman's spirit at its best. And the Fen peasantry showed a stubborn defence of their rights, not only when they resisted the encroachments and selfish appropriations of the "adventurers" in the 17th century, in the Bedford Level, in Deeping Fen, and in the Witham Fens, and again in the 18th century, when Holland Fen was finally inclosed, but also in the Peasants' Rising of 1381, and in the Pilgrimage of Grace in the reign of Henry VIII. So long as the Fens were uninclosed and thickly studded with immense "forests" of reeds, and innumerable marshy pools and "rows" (channels connecting the pools), they were a very paradise of wild fowl, being regularly frequented by various species of wild duck and geese, garganies, polchards, shovelers, teals, widgeons, peewits, terns, grebes, coots, water-hens, water-rails, red-shanks, lapwings, godwits, whimbrels, cranes, bitterns, herons, swans, ruffs and reeves.[14]

Vast numbers of these were taken in decoys,[1] and sent to the London markets. At the same time equally vast quantities of tame geese were reared in the Fens, and driven by road[2] to London to be killed at Michaelmas. Their down, feathers, and quills (for pens) were also a considerable source of profit. The Fen waters, too, abounded in fresh-water fish, especially pike, perch, bream, tench, rud, dace, roach, eels, and sticklebacks. The Witham, on whose banks so many monasteries stood, was particularly famous for its pike; as were certain of the monastic waters in the southern part of the Fens for their eels.[3] The soil of the reclaimed Fens is of exceptional fertility, being almost everywhere rich in humus, which is capable not only of producing very heavy crops of wheat and other corn, but also of fattening live-stock with peculiar ease. Lincolnshire oxen were famous in Elizabeth's time,[4] and are specially singled out by Arthur Young,[5] the breed being the shorthorn. Of the crops peculiar to the region it must suffice to mention the old British dye-plant woad, which is still grown on a small scale in two or three parishes immediately south of Boston; hemp, which was extensively grown in the 18th century,[6] but is not now planted; and peppermint, which is occasionally grown, *e.g.*, at Deeping and Wisbech. In the second half of the 19th century the Fen country acquired a certain celebrity in the world of sport from the encouragement it gave to speed skating. Whenever practicable, championship and other racing meetings are held, chiefly at Littleport and Spalding. The little village of Welney, between Ely and Wisbech, has produced some of the most notable of the typical Fen skaters, *e.g.*, "Turkey" Smart and "Fish" Smart.[7]

Apart from fragmentary ruins of the former monastic buildings of Crowland, Kirkstead, and other places, the Fen country of Lincolnshire (division of Holland) is especially remarkable for the size and beauty of its parish churches, which, in many cases, are crowned by lofty and graceful spires. Amongst the finest of these churches, mostly built of Barnack rag from Northamptonshire, may be mentioned Boston, Kirton, Donington, Swineshead, Gosberton, Pinchbeck, Spalding, Moulton, Holbeach, Gedney, Whaplode, and Long Sutton.[8] Using these fine opportunities, the Fen folk have long cultivated the science of campanology.

Dialect.—Owing to the comparative remoteness of their geographical situation, and the relatively late period at which the Fens were definitely inclosed, the Fenmen have preserved several dialectal features of a distinctive character, not the least interesting being their close kinship with the classical English of the present day.[9] It was the late Professor E. Freeman[10] who reminded modern Englishmen that it was a native of the Fens, "a Bourne man, who gave the English language its present shape." This was Robert Manning, or Robert of Brunne, who in or about 1303 wrote *The Handlynge Synne.* Tennyson's dialect poems, *The Northern Farmer*, &c., do not reproduce the pure Fen dialect, but rather the dialect of the Wold district of Mid Lincolnshire.

Authorities.—In addition to the works already quoted, see the bibliographies printed as an appendix to *Lincs. N. and Q.*, vol. ii. pp. 27–31 (1890–91); W. H. Wheeler, *Fens of South Lincolnshire*, Appendix ii.; and in *Fenland N. and Q.*, vol. iii. pp. 28–29 (1895). For a discussion of the general principles of draining low-lying lands like the Fens, see River Engineering. Various phases of Fen life, mostly of the past, are described in Charles Kingsley's *Hereward the Wake* (Cambridge, 1866), Baring Gould's *Cheap-Jack Zita* (London, 1893), Manville Fenn's *Dick o' the Fens* (London, 1887), and J. T. Bealby's *A Daughter of the Fen* (London, 1896).

(J. T. Be.)

Fenton, a township adjoining the east side of Stoke-upon-Trent (in which parliamentary division it is included), Staffordshire, England, on the North Staffordshire railway. There is a town hall (1889). The principal industry is the manufacture of earthenware. Area of urban district, 1748 acres. Population (1881), 13,830; (1901), 22,742. The area of the civil parish is 1726 acres; population (1881), 14,136; (1891), 17,323.

Ferdinand, Maximilian Karl Leopold Maria, Prince of Bulgaria (1861——), fifth and youngest son of Prince Augustus of Saxe-Coburg and Gotha, was born 26th February 1861. Great care was exercised in his education, and every encouragement given to the taste for natural history which he exhibited at an early age. In 1879 he travelled with his brother Augustus to Brazil, and the results of their botanical observations were published at Vienna, 1883–88, under the title of *Itinera Principum S. Coburgi.* Having been appointed to a lieutenancy in the 2nd regiment of Austrian hussars, he was holding this rank when, by unanimous vote of the National Assembly, he was elected prince of Bulgaria, 7th July 1887, in succession to Prince Alexander, who had abdicated on the 7th of September preceding. He assumed the government 14th August 1887, but Russia for a long time refused to acknowledge the election, and he was accordingly exposed to frequent military conspiracies, due to the influence or attitude of that Power. The firmness and vigour with which he met all attempts at revolution were at length rewarded, and his election was confirmed in March 1896 by the Porte and the great Powers. On 20th April 1893 he married Marie Louise de Bourbon, eldest daughter of Duke Robert of Parma, and in May following the Grand Sobranjé confirmed the title of Royal Highness to the prince and his heir. The prince adheres to the Roman Catholic faith, but his son and heir, the young Prince Boris, was received into the Orthodox Greek Church, 14th February 1896. The latter, who is the godson of Tsar Nicholas III., accompanied his father to Russia in 1898, when Prince Ferdinand visited St Petersburg and Moscow, and still further strengthened the bond already existing between Russia and Bulgaria. The prince is a widower, having lost his consort 31st January 1899. (See also Bulgaria.)

Fergana, a province of Russian Turkestan, formed in 1876 out of the former khanate of Kokand. It is bounded by the Russian provinces of Syr-daria on the N. and N.W., and Semiryechensk on the N.E., China (Kashgaria) on the E., and the Bokhara and Afghanistan bekdoms of Vakhan, Shugnan, Darvaz, and Karateghin, and the Russian province of Samarkand on the S. Its southern limits, on the Pamirs, were established by an international commission, from Lake Zor-kul (Victoria) to the Chinese frontier, while the Shugnan, the Roshan, and the Vakhan were given, in consequence of an agreement between Great Britain and Russia, to Bokhara, in exchange for part of Darvaz (on the left bank of the Panj), which was assigned to Afghanistan. The area is about 57,000 square miles, of which about 17,600 square miles are on the Pamirs. It occupies the rich and fertile valley of the upper Syr and Naryn, which opens towards the south-west, and it extends northwards over the mountains of the Tian Shan system, while in the south it spreads over

[10] In *Longman's Magazine*, 1875.

the Alai and Transalai Mountains, including also a portion of the Pamirs. The valley is thus surrounded by a ring of high mountains, reaching their highest altitude in Peak Kaufmann (23,000 feet).

Two rivers, rising in the mountains, water the valley—the Naryn and the Kara-daria, which, by their confluence near Namangan, form the Syr. This latter, by the numerous irrigation canals drawn from it, gives life to the valley; but it receives also many small affluents, which bring down great masses of sand, which is deposited along its banks, especially where it pierces the Khojent-Ajar ridge (Karakchi-kums). Here nearly 750 square miles are covered with moving sands, which invade under the influence of the prevailing south-west winds the agricultural districts.

The climate of the valley is dry and warm. In March the temperature reaches 68° F., rapidly rising to 95° in June, July, and August. For five months, from May, there is no rain, which begins to fall in October. Snow and frosts occur in December and January and occasionally in February. All the fertility of the valley is thus dependent on irrigation.

The population in 1897 was 1,560,411, of whom 707,132 were women, and 286,369 lived in towns. Two-thirds of the people are Sarts (of Turkish origin), who mostly live in the valley, while Kirghiz, partly nomad and partly agricultural, occupy the slopes of the mountains. Tajiks are not numerous, and are scattered everywhere. There are, besides, some Dungans, Kipchaks, Jews, and Tsiganes. On the Pamirs the population was only 2348. The Russians belong to the ruling, merchant, and artizan class, and have only one agricultural settlement. The mass of the population (1,039,115) are Musulmans, and only 3985 belong to the Russian Church.

Of the 2,563,100 acres of cultivated land, 1,936,700 acres are under constant and the remainder under partial irrigation. The land is admirably cultivated, and the crops in 1896 were: wheat, 3,223,000 cwts.; rice, 1,277,000; *jugara*, 2,395,000; millet, 388,000; various, 1,606,000. Lucerne, tobacco, root plants, and all sorts of vegetables are grown in large quantities. Tobacco is exported. Gardening reaches a high degree of perfection. The number of cattle kept by the agricultural population is very great (198,530 horses, 266,700 cattle, 402,200 sheep, 7145 camels). Moreover, the nomads, who graze their cattle on the alpine meadows, keep 113,600 horses, 122,200 cattle, 626,500 sheep, and 16,000 camels. No less than 17,300 acres are under vineyards (yielding 460,000 cwts. of grapes) and 347,500 acres under cotton, the crop of which in 1896 attained to 2,203,000 cwts. Nearly the whole of this (2,006,200 cwts.) was American cotton, which was mostly cleaned within the province, representing an income of £1,300,000. The remainder was transformed into about 660,000 cwts. of cotton wool, worth about £200,000. Nearly 150,000 acres are under forests belonging to the Crown. The state keeps at Marghilan a forestry farm, from which from 120,000 to 200,000 young trees are given free every year to the population. The silkworm culture, formerly prosperous, has decayed, notwithstanding the efforts of a state farm at Novo-Marghilan. The total income from this source was estimated at about £48,000 in 1896. Naphtha, coal, sulphur, gypsum, rock-salt and lake-salt are known to exist, but only the latter is extracted. The aggregate production of all factories, chiefly sixty-nine cotton-cleaning works, reached £112,500 in 1896, and the small factories and workshops (9000 in number) showed a return of £150,000. A considerable trade is carried on with Russia for the export of raw cotton, raw silk, hides, sheepskins, and some cotton and leather goods, and the import of various manufactured goods, which are exported to Kashgaria and Bokhara.

The Transcaspian railway has given a fresh impetus to trade. As to the routes leading to the Pamirs and Kashgaria they are mere bridle paths crossing the mountains. Two passes, Karakazyk (14,400 feet) and Tenghiz-bai (11,200 feet), which are open all the year, lead from Marghilan to Karateghin and the Pamirs, while Kashgar is reached from Osh to Gulcha, and then across the passes Terek-davan (13,000 feet; open all the year), Taldyk (11,600), Archat (11,600), and Shart-davan (about 14,000 feet).

Only 347 boys and girls received education in Russian schools in 1896, and 14,072 in the native and Russian-native schools.

A railway now enters the province from Kokand, reaching Andijan, while a branch runs south to New Marghilan and Kuva.

The province is divided into five districts, of which the chief towns are: New Marghilan, capital of the province (8977 inhabitants), Andijan (46,680), Kokand (82,054), Namangan (61,906), and Osh (36,474). To these Old Marghilan (36,592) and Chust (13,686) must be added. (P. A. K.)

Fergus Falls, capital of Ottertail County, Minnesota, U.S.A., on the Red river and on two railways. It has fine water power, which is utilised for flour mills. Population (1890), 3772; (1900), 6072, of whom 2131 were foreign-born.

Ferguson, Sir Samuel (1810–1886), Irish antiquarian and poet, was born at Belfast, 10th March 1810. He went to the bar, and was made Q.C. in 1859, but in 1867 retired from practice upon his appointment as deputy-keeper of the Irish records, then in a much neglected condition. All causes of complaint were removed during his administration. His spare time was given to general literature, and in particular to poetry. He had long been a leading contributor to the *Dublin University Magazine* and to *Blackwood*, where he had published his two literary masterpieces, "The Forging of the Anchor," one of the finest of modern ballads, and the humorous extravaganza of "Father Tom and the Pope." He published volumes of miscellaneous poems in 1865 and 1880, and in 1872 "Congal," a metrical narrative of the heroic age of Ireland, and, though far from ideal perfection, perhaps the most successful attempt yet made by a modern Irish poet to revivify the spirit of the past in a poem of epical proportions. Lyrics have succeeded better in other hands; many of Ferguson's pieces on modern themes are, nevertheless, excellent. He was an extensive contributor on antiquarian subjects to the *Transactions of the Royal Irish Academy*, and was elected its president in 1882. His manners were delightful, and his hospitality was boundless. He died at Howth on 9th August 1886. (R. G.)

Fergusson, James (1808–1886), an eminent Scottish writer on architecture, was born at Ayr on the 22nd of January 1808. His father was an army surgeon with advanced views (for his day) on the hygiene and construction of hospitals, and thus the son may have inherited a capacity for the study of plan and construction. But the bent of his life was probably decided when he went to Calcutta as partner in a mercantile house. Here he was attracted by the remains of the ancient architecture of India, little known or understood at that time. This he studied, illustrating and classifying it in his book on *The Rock-cut Temples of India*, published in 1845. The task of analysing the historic and æsthetic relations of this type of ancient buildings led him to undertake a historical and critical comparative survey of the whole subject of architecture, a work which first appeared in 1855 under the title of *The Handbook of Architecture*. Although this was in itself a remarkable survey of so wide and complex a subject, it did not satisfy him, and the work was reissued ten years later in a much more extended form under the title of *The History of Architecture*. The chapters on Indian architecture, which had been considered at rather disproportionate length in the *Handbook*, were removed from the general *History*, and the whole of this subject treated more fully in a separate volume, *The History of Indian and Eastern Architecture*, which appeared in 1876, and formed a kind of appendix to the *History of Architecture*, although complete in itself. Previously to this, in 1862, he issued his *History of Modern Architecture*, in which the subject was continued from the Renaissance to the present day, "modern architecture" being distinguished as the period of revivals and imitations of ancient styles, which began with the Renaissance. The essential difference between this and the spontaneously evolved architecture of preceding ages Fergusson was the first clearly to point out and characterize. His treatise on *The True Principles of Beauty in Art*, an early publication which attracted little notice at the time, is nevertheless one of the best and most thoughtful of the class of metaphysical studies to which it belongs. Some of his essays on special points in archæology, such as the treatise on *The Mode in which Light was introduced into Greek Temples*, and his *Notes on the Site of the Holy Sepulchre*, included theories which have not received general acceptance. His real monument is his *History of Architecture*, which, for grasp of the whole subject, comprehensiveness of plan, and thoughtful critical analysis, stands quite alone in architectural literature; nor has any other country produced a book comparable with it. His breadth and impartiality of view are especially remarkable. A French or German treatise on architecture, historical or æsthetic, always represents the subject from a French or German point of view; but Fergusson is absolutely cosmopolitan in his standpoint. He received the gold medal of the Royal Institute of British Architects in 1871. Among his works, besides those already mentioned, are: *A Proposed New System of Fortification* (1849), *Palaces of Nineveh and Persepolis restored* (1851), *Mausoleum at Halicarnassus restored* (1862), *Tree and Serpent Worship* (1868), *Rude Stone Monuments in all Countries* (1872), and *Temples of the Jews and other Buildings in the Haram Area at Jerusalem* (1878). The sessional papers of the Institute of British Architects include papers by him on *The History of the Pointed Arch*, *Architecture of Southern India*, *Architectural Splendour of the City of Beejapore*, *On the Erechtheum* (an exceedingly interesting paper), and on the *Temple of Diana at Ephesus*.

Although Fergusson never practised, he took a keen interest in all the professional work of his time. He was adviser with Mr (afterwards Sir) Austen Layard in the scheme of decoration for the Assyrian Court at the Crystal Palace, and indeed assumed in 1856 the duties of General Manager to the Palace Company, a post which he held for two years. Moreover, he was largely instrumental in establishing the Palestine Exploration Fund. His manifold activities continued till his death, which took place in London on 8th January 1886. (H. H. S.)

Fermanagh, an inland county of Ireland, province of Ulster, bounded on the N. by Donegal and Tyrone; on the E. by Tyrone and Monaghan; on the W. by Cavan and Leitrim; and on the S. by Cavan. The area of the administrative county in 1900 was 417,665 acres, of which 98,287 were tillage; 249,574, pasture; 83, fallow; 5777, plantation; 18,680, turf bog; 1774, marsh; 21,196, barren mountain; and 22,294, water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, is identical with the old judicial county. The population in 1881 was 84,879; and in 1891, 74,170, of whom 37,344 were males, and 36,826 females, divided as follows among the different religions: Roman Catholics, 41,102; Protestant Episcopalians, 26,869; Presbyterians, 1312; Methodists, 4779; and other denominations, 108. The decrease of population between 1881 and 1891 was 12·62. The average number of persons to an acre was ·16. Of the total, 68,600 inhabited the rural districts, being an average of 127 persons to each square mile under crops and pasture. In 1901 the population was 65,243 (Roman Catholics, 36,066; Protestant Episcopalians, 23,109; Presbyterians, 1269; Methodists, 4702; others, 97), being a decrease of 12·0 per cent.

The following table gives the number of births, deaths, and marriages in various years:—

Year.	Births.	Deaths.	Marriages.
1881	1569	1203	287
1891	1392	1245	294
1899	1306	1095	270

In 1899 the birth-rate per 1000 was 17·6, and the death-rate 14·8; the rate of illegitimacy was 2·9 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1899 was 53,895, of whom 27,642 were males and 26,253 females. Enniskillen (5570 in 1891) is the only town with a population of over 1000.

Education.—The following table gives the degree of education in 1891:—

	Males.	Females.	Total.	Percentage.			
				R. C.	Pr.Ep.	Presb.	Meth.
Read and write	24,723	22,980	47,703	62·9	72·2	88·1	89·2
Read only .	4,035	5,394	9,429	16·6	11·5	6·9	7·3
Illiterate .	5,164	5,214	10,378	20·5	10·3	5·0	3·5

The percentage of illiterates among Roman Catholics in 1881 was 28·2. In 1891 there was one superior school with 102 pupils (all Protestants except one), and there were 190 primary schools, with 9486 pupils (Roman Catholics 5077, and Protestants 4409). The number of pupils on the rolls of the national schools on 30th September 1899 was 11,352, of whom 6329 were Roman Catholics and 5023 Protestants.

Administration.—The county is divided into two parliamentary divisions, north and south, the number of registered electors in 1900 being respectively 5242 and 5622. The rateable value in 1900 was £241,360. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury and (to a less extent) of other bodies were transferred to a county council; urban and rural district councils were established; and under that Act the county now comprises one urban and five rural sanitary districts.

Agriculture.—The following tables give the acreage under crops, including meadow and clover, and the amount of live stock, in 1881, 1891, 1895 and 1900.

Year.	Wheat.	Oats.	Barley, Beans, &c.	Potatoes.	Turnips.	Other Green Crops.	Flax.	Meadow and Clover.	Total.
1881	579	23,252	295	16,353	3097	1788	3323	57,752	106,439
1891	872	19,676	400	15,401	3081	1985	1455	65,083	107,953
1895	491	19,149	226	14,434	3127	1647	1610	64,251	104,935
1900	789	16,120	216	13,056	2713	1594	268	63,531	98,287

In 1899 the total value of the cereal and other crops was estimated by the Registrar-General at £652,280. The number of acres under pasture in 1881 was 235,423; in 1891, 239,003; and in 1900, 249,574.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	7075	4088	91,780	6,691	16,851	4411	390,969
1891	8283	4547	102,731	18,742	24,843	5450	439,611
1895	8611	4837	98,398	11,116	23,981	4746	480,555
1900	7609	4854	98,639	11,942	20,150	4702	517,813

The number of milch cows in 1891 was 41,125, and in 1900, 39,572. It is estimated that the total value of cattle, sheep, and pigs in 1899 was £1,290,668. In 1900 the number of holdings not exceeding 1 acre was 767; between 1 and 5, 1047; between 5 and 15, 3414; between 15 and 30, 4204; between 30 and 50, 2328; between 50 and 100, 1273; between 100 and 200, 355; between 200 and 500, 82; and above 500, 12;—total, 13,482. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1900, was 1785, amounting to £531,351. The number of loans for agricultural improvements, sanctioned under section 31 of the Land Act, 1881, between 1882 and 1900 was 181, and the amount issued was £9815. The total amount issued on loan for all classes of works, under the Land Improvement Acts, from the commencement of operations in 1847 to 31st March 1900, was £87,158. (W. H. Po.)

Fernando Po, a Spanish island off the west coast of Africa, about 20 miles from the mainland, facing the Kamerun coast. About 44 miles from N. to S., and 20 miles broad, it has an area of 760 square miles; the population in 1887 was 30,000. The capital, Santa Isabel, was said to have 1284 inhabitants in 1885: 170 whites, 31 half-breeds, and 1082 negroes. The island is now administered by a governor, generally an officer of rank in the Spanish navy, who is at the same time commandant of the naval station in the Gulf of Guinea, as which part of his duty is to superintend the sub-governor of the island of Elobey Chico, and the Spanish agents in Annobon, Elobey Grande, and the mainland between the Campo and Muni rivers. The Spanish claim to rule on the mainland from the Campo to the Gabun has often caused considerable friction between the Spanish and French Governments. After very protracted negotiations on the matter, a mixed delimitation commission was appointed, and the respective territorial rights were partly defined by a treaty in 1885. The French again began encroaching, despite Spanish protests; but at last the limits of the Spanish sphere of influence were definitely fixed in June 1900, when, in return for concessions in the Adrar country, France acknowledged Spain's right to the country from the Campo river and the Cameroon frontier as far south as the Muni river—some 75 miles. Inland, Spanish authority is to extend about 110 miles, the eastern boundary being fixed along, roughly, 11° 30′ E. long.

Spain keeps an old and badly-equipped war vessel and a few companies of marines to assert her rights in Fernando Po and its mainland dependencies and other isles. The cost of maintaining her rule is £20,500 a year, of which three-quarters are assigned to army, navy, and civil services, barely a quarter going to public works and other useful expenditure. The governor rules the island with a council of officials. Public education is in the hands of the Father of the Immaculate Heart of Mary order. Long neglected by its Spanish rulers, Fernando Po has excited more interest in the peninsula since the Spaniards awoke to the fact that other European nations were casting longing eyes at a colony of strategical, naval, and commercial importance, the latter through an increasing trade in the hands of foreigners. The exports of Fernando Po exceeded £200,000 in 1899, and the area of cultivation in the island increased from 4190 acres in the seventies to 15,000 acres in 1899. Negro labourers drawn from Lagos and other British West African colonies chiefly contributed to the development of the resources of the island.

Ferozepore, or **Firozpur,** a city and district of British India, in the Jullundur division of the Punjab. The city is a railway junction connecting the North-Western and Rajputana railways, and is situated about 4 miles from the present south bank of the Sutlej. The population in 1881 was 39,570, in 1891 it was 50,437; the municipal income in 1897–98 was Rs. 44,681. The arsenal is the largest in India. The District comprises an area of 4302 square miles. It had a population in 1881 of 747,329, and in 1891 of 886,676, giving an average density of 206 persons per square mile. In 1901 the population was 958,218, showing an increase of 8 per cent. The land revenue and rates were Rs. 11,34,911, the incidence of assessment being a little over 8 annas per acre; the cultivated area in 1896–97 was 1,009,006 acres, of which 756,401 were irrigated, including 536,808 from government canals; the number of police was 670; the number of schools in 1896–97 was 210, with 6337 pupils, the proportion of boys at school to the male population of school-going age being 7·6 per cent.; the registered death-rate in 1897 was 31·73 per thousand. There are four printing-presses, issuing one vernacular periodical. The district has 117 miles of railway, and the length of metalled roads is 97 miles. Distributaries of the Sirhind canal water the whole.

Ferrara, a fortified city and archiepiscopal see of Italy (Emilia), capital of the province of Ferrara, on a low, marshy site, $7\frac{3}{4}$ feet above sea-level, but 3 feet *below* the level of the Po, 3 miles distant, the town itself being on the Po di Volano, a southern arm of the Po delta. Under modern conditions of warfare the fortifications would count for little. There are fine law-courts (Palazzo della Ragione), a brick building in the Gothic style, dating from the 14th cent., but renewed in the 16th, and again in 1838. There are further statues to Savonarola (1875), who was born here, to Ariosto (1833), also a native, and to Victor Emmanuel (1890). The free university, with courses in law, medicine, and natural science, was attended in 1898 by 77 students, the number of professors being 22. Amongst the other educational institutions may be mentioned an engineering college, a musical academy, and a school of design (1882). The principal industry is the manufacture of clothing. Population of commune (1881), 75,553; (1901), 87,697; of province, (1881), 230,807; (1901), 271,467.

Ferrol, a seaport of Spain, 12 miles north-east of Corunna. Population in 1897, 24,957. Both the arsenal and dockyards have been much improved, and the defences seawards increased and mounted with heavy modern guns. A new dock was constructed in 1879, since when good quays have been constructed for the merchant vessels, and, in the new part of the town called Esteiro, for the coasting and smaller vessels. Private building yards have been recently established near the town, which has, indeed, been generally improved, notably in its public buildings—the town hall, palace of the naval captain-general for Ferrol, Cartagena, and Cadiz; prison, foundling hospital, theatres, casinos, bull-ring, and excellent schools of primary and secondary instruction. In 1898, 299 vessels of 140,638 tons entered, and the same number cleared. The principal exports were pit-wood, old iron and copper, cotton textiles, salt fish, and pyrites. The principal imports were coal (chiefly from England), cereals, cotton, flour, iron, olive oil, textiles, timber, and wines. The total exports in 1898 were valued at £48,946, imports at £273,553, as compared with £19,240 and £317,950 respectively in 1897.

An excellent relief plan of the fortifications of Ferrol, ancient and modern, exists in the Madrid Royal Engineers' Museum.

Ferry, Jules François Camille (1832–1893), French statesman, was born at Saint Dié, Vosges, 5th April 1832. In 1851 he went to the bar, and both as advocate and in the press he took an active part in opposition to the Second Empire. In 1869 he was elected for the Seine to the *Corps législatif*, and fought energetically against Ollivier. He was a member of the Government of National Defence after the revolution of 1870, and was entrusted by it with the administration of the Seine department; but, for all his energy, he was powerless against the Communards; he was even taken prisoner by them, but rescued. In 1872 he was sent by Thiers as minister to Athens, but returned in 1873. He joined the Republican Left, opposed the *Seize Mai*, and was a prominent and bitter fighter against clericalism. In 1879, after MacMahon's retirement, he became minister of education in M. Waddington's cabinet; and besides successfully reorganizing the Paris University, he brought forward the measure of March 1880, aimed at dissolving the "Jesuits' unauthorized religious associations." In September 1880 he became prime minister, and undertook an active colonial programme, including the extension of French influence over Tunis; but his ministry broke up in November 1881. In 1883, however, he again formed a cabinet, and, pursuing his colonial programme, authorized campaigns in Madagascar and Tongking, the latter of which, owing to the disaster at Langson in 1885, not only brought about his downfall, but ruined his popularity. In future he was to Frenchmen *le*

Tonkinois, and his influence was permanently damaged. In 1887 he was proposed for the Presidency on Grevy's retirement, but though assisted by the Monarchists, was beaten through M. Clemenceau's tactics in supporting an "outsider" rather than that he should succeed. It was not till 1891 that he recovered his position to some extent, being then elected senator for the Vosges, and two years later became president of the Senate. He died in Paris on 17th March 1893. Jules Ferry was a man of great administrative ability, but his name will inevitably be associated chiefly with his anti-clerical campaign and with the Tongking failure.

Fertö, an extensive lake in the western part of Hungary, between the counties of Moson and Sopron. The Romans knew it under the name of *Teiso*, and the Germans call it *Neusiedler-See*. Its surface (335 square kilomètres) frequently varies, and the lake is so shallow that it sometimes dries up in parts. Eastwards it is united with a marsh, called the *Hanság*. It has only a few tributaries. Its water has a taste of salt and alkali, and is much recommended for bathing. Among the reeds on its banks waterfowl congregate in vast numbers, and the fishing is also considerable. In several places of the dry bed traces of prehistoric lake-dwellings (pile-dwellings) have been discovered. Plans for drying up the lake have been proposed.

Festiniog, a town and parish of Merionethshire, Wales, at the head of Festiniog valley, standing at a height of over 600 feet above the sea, near the river Dwyryd, 19 miles W.N.W. of Bala by rail. There are many and large slate quarries in this extensive parish. The extension of the railway from Bettws-y-coed to Blaenau Festiniog in 1879 has given a great accession of life to the latter place, which, the centre of the slate quarries and the nucleus of three railways, is a modern town compared with Festiniog "the original village." The "toy" railway, as it is called, has a length of 13 miles from Portmadoc to Blaenau, with a rise of about 700 feet. Area of urban district, 16,323 acres; population (1881), 11,274; (1891), 11,073; (1901), 11,435.

Feuillet, Octave (1821–1890), French novelist and dramatist, was born at Saint-Lô, Manche, on the 11th of August 1821. He was the son of a Norman gentleman of learning and distinction, who would have played a great part in politics "sans ses diables de nerfs," as Guizot said. This nervous excitability was inherited, though not to the same excess, by Octave, whose mother died in his infancy and left him to the care of the hypersensitive invalid. The boy was sent to the Collège de Louis-le-Grand, in Paris, where he achieved high distinction, and was destined for the diplomatic service. In 1840 he appeared before his father at Saint-Lô, and announced that he had determined to adopt the profession of literature. There was a stormy scene, and the elder Feuillet cut off his son, who returned to Paris and lived as best he could by a scanty journalism. In company with Paul Bocage he began to write for the stage, and not without success; at all events, he continued to exist until, three years after the quarrel, his father consented to forgive him. Enjoying a liberal allowance, he now lived in Paris in comfort and independence, and he published his early novels, none of which are quite of sufficient value to retain the modern reader. The health and spirits of the elder M. Feuillet, however, having still further declined, he summoned his son to leave Paris and bury himself as his constant attendant in the melancholy château at Saint-Lô. This was to demand a great sacrifice, but Octave Feuillet cheerfully obeyed the summons in 1850, after printing his novel called *Bellah*. In 1851 he married his cousin, Mlle. Valérie Feuillet, who helped him to endure the mournful captivity to which his filial duty bound him. Strangely enough, in this exile—rendered still more irksome by his father's mania for solitude and by his tyrannical temper—the genius of Octave Feuillet developed. He wrote books which have held their place for half a century, *La Petite Comtesse*, *Dalila*, and in particular that universal favourite, *Le Roman d'un jeune Homme pauvre*. He himself fell into a nervous state in his "prison," but he was sustained by the devotion and intelligence of his wife and her mother. In 1857, having been persuaded to make a play of the novel of *Dalila*, he brought out this piece at the Vaudeville, and enjoyed a brilliant success; on this occasion he positively broke through the *consigne* and went up to Paris to see his play rehearsed. His father bore the shock of his temporary absence, and the following year Octave ventured to make the same experiment on occasion of the performance of *Un jeune Homme pauvre*. To his infinite chagrin, during this brief absence his father died. Octave was now, however, free, and the family immediately moved to Paris, where they took part in the splendid social existence of the Second Empire. The elegant and distinguished young novelist became a favourite at court; his pieces were performed at Compiègne before they were given to the public, and on one occasion the Empress Eugénie deigned to play the part of Mme. de Pons in *Les Portraits de la Marquise*. Feuillet did not abandon the novel, and in 1862 he achieved a great success with *Sibylle*. His health, however, had by this time begun to decline, affected by the sad death of his eldest son. He determined to quit Paris, where the life was far too exciting for his nerves, and to regain the quietude of Normandy. The old château of the family had been sold, but he bought a house called "Les Paillers" in the suburbs of Saint-Lô, and there he lived, buried in his roses, for fifteen years. He was elected to the French Academy in 1862, and in 1868 he was made librarian of Fontainebleau Palace, where he had to reside for a month or two in each year. In 1867 he produced his masterpiece of *Monsieur de Camors*, and in 1872 he wrote *Julia de Trécœur*, which is hardly less admirable. His last years, after the sale of "Les Paillers," were passed in a ceaseless wandering, the result of the agitation of his nerves. He was broken by sorrow and by ill-health, and when he passed away in Paris on December 29, 1890, his death was a release. His last book was *Honneur d'Artiste* (1890). Among the too-numerous writings of Feuillet, the novels have lasted longer than the dramas; of the former three or four seem destined to retain their charm as classics. He holds a place midway between the romanticists and the realists, with a distinguished and lucid portraiture of life which is entirely his own. He drew the women of the world whom he saw around him with dignity, with indulgence, with extraordinary penetration and clairvoyance. There is little description in his novels, which sometimes seem to move on an almost bare and colourless stage, but, on the other hand, the analysis of motives, of emotions, and of "the fine shades" has rarely been carried further. Few have written French with greater purity than Feuillet, and his style, reserved in form and never excessive in ornament, but full of wit and delicate animation, is in admirable uniformity with his subjects and his treatment. It is probably in *Sibylle* and in *Julia de Trécœur* that he can now be studied to most advantage, though *Monsieur de Camors* gives a greater sense of power, and though *Le Roman d'un jeune Homme pauvre* still preserves its popularity.

Fez (*Fás*), the most important city of Morocco, is situated about 150 miles, or six days by caravan, south of Tangier, and contains probably 150,000 inhabitants, including several thousand Jews. Progress has shown itself there by the establishment in 1888 of English lady missionaries, previous to which no foreigners resided in this capital, and subsequently of British and French vice-consulates. European visitors are now more frequent.

Fichte, Immanuel Hermann von (1797–1879), German philosopher, son of the famous J. G. Fichte, was born at Jena on the 18th of July 1796 or 1797 (authorities differ), and began life as a schoolmaster at Saarbrücken and at Düsseldorf. In 1836, having published some philosophical writings, he became extra-professor of Philosophy at Bonn, and in 1839 full professor. In 1842 he received a call to Tübingen; retired in 1863, when he was ennobled, and died at Stuttgart on the 8th of August 1879. Fichte's writings cover the whole field of philosophy. The titles of the most noteworthy are: *System der Ethik*, 2 vols. (1850–53), *Anthropologie* (1856), *Psychologie* (1864), *Die theistische Weltansicht* (1873). In 1837 he had founded the still-existing *Zeitschrift für Philosophie* as an organ of his views, more especially on the subject of philosophy of religion, where he was in alliance with Weisse. The difference between Weisse and Fichte is, that whereas Weisse thought that the Hegelian structure was sound in the main, and that its imperfections might be mended, Fichte held it to be incurably defective, and spoke of it as a "masterpiece of erroneous consistency or consistent error." Fichte's general views on philosophy seem to have changed considerably as he advanced in years, and his influence has been impaired by these inconsistencies and an appearance of eclecticism; an appearance strengthened by his predominantly historical treatment of problems, his desire to include divergent systems within his own, and the conciliatory tone of his writing. He is best remembered as an opponent of Hegel in the interests of religion and ethics. He attacks Hegelism for its pantheism, its lowering of human personality, and imperfect recognition of the demands of the moral consciousness. God, he says, is to be regarded not as an Absolute but as an Infinite Person, whose nature it is that He should realize himself in finite persons. These persons are objects of God's love, and He arranges the world for their good. Fichte, in short, advocates an ethical theism, and his arguments might easily be turned to account by the apologist of Christianity. In his conception of finite personality Fichte recurs to something like the monadism of Leibnitz. His insistence on moral experience is connected with his insistence on personality. One of the tests by which Fichte discriminates the value of previous systems is the adequateness with which they interpret moral experience. The same reason that made him depreciate Hegel made him praise Krause and Schleiermacher, and speak respectfully of English philosophy. It is characteristic of Fichte's almost excessive receptiveness that in his latest published work, *Der neuere Spiritualismus* (1878), he supports his position by arguments of a somewhat occult or theosophical cast, not unlike those adopted by F. W. H. Myers in his writings for the Psychical Research Society. (H. St.)

Field, Cyrus West (1819–1892), American capitalist, founder of the first Atlantic cable, was born at Stockbridge, Mass., on the 30th of November 1819. At the age of fifteen he became a clerk in the store of Alexander T. Stewart & Co. of New York. Five years later he began to manufacture paper, and by 1853 had accumulated a sufficient fortune to retire from the business. The following year, in connexion with Peter Cooper and other capitalists, he organized the New York, Newfoundland, and London Telegraph Company. A submarine cable to Ireland was laid by this company in 1856, but it failed to work. The same year he organized the Atlantic Telegraph Company, and in 1858 this company laid a cable which transmitted messages successfully, but for only about a fortnight. In 1865 an attempt was made with the *Great Eastern* to lay another cable, but the cable parted in mid-ocean. Still another attempt was made in the following year, with the same vessel, and this time his long-continued efforts were crowned with complete success. Mr Field received many honours as a result of his achievement, among others a gold medal and a vote of thanks from the U.S. Congress. Among his other enterprises Mr Field took an important part in the development of the elevated railway system in New York City. He died at New York on 12th July 1892.

Field, Eugene (1850–1895), American poet, was born at St Louis, Missouri, 2nd September 1850. He spent his boyhood in Vermont and Massachusetts; studied for short periods at Williams and Knox Colleges and the University of Missouri, but without taking a degree; and worked as a journalist on various papers, finally becoming connected with the Chicago *News*. *A Little Book of Profitable Tales* appeared in Chicago in 1889 and in New York the next year; but Field's place in later American literature chiefly depends upon his poems of Christmas-time and childhood (of which *Little Boy Blue* and *A Dutch Lullaby* are most widely known), because of their union of obvious sentiment with fluent lyrical form. His principal collections of poems are: *A Little Book of Western Verse* (Chicago, 1889; New York, 1890); *A Second Book of Verse* (Chicago, 1892; New York, 1893); and *With Trumpet and Drum* (1892). Field died at Chicago, 4th November 1895.

Field, William Ventris, Baron (1813–——), English judge, son of Mr Thomas Flint Field of Fielden, Bedfordshire, was born on the 21st of August 1813. He was educated at Burton Grammar School in Somersetshire, and entered the legal profession as articled clerk to Messrs Terrell, Barton, & Smale, a firm of solicitors at Exeter. He was afterwards in a London office (that of Messrs Price & Bolton in Lincoln's Inn), and from 1840 to 1843 was junior partner in the firm of Thompson, Debenham, & Field, of Salter's Hill Court. In 1843, however, he ceased to practise as a solicitor, and entered at the Inner Temple, reading for the bar in the chambers of Mr T. K. Kingdon of the Western circuit. After having practised for a short time as a special pleader, Mr Field was called to the bar in 1850, and joined the Western circuit, but soon exchanged it for the Midland. He obtained a large business as a junior, and became a Queen's counsel and bencher of his inn in 1864. As a Q.C. he had a very extensive common-law practice, and had for some time been the leader of the Midland circuit, when in February 1875, on the retirement of Mr Justice Keating, he was raised to the bench as a justice of the Queen's Bench, and was knighted. Mr Justice Field was an excellent puisne judge of the type that attracts but little public attention. He was a first-rate lawyer, had a good knowledge of commercial matters, great shrewdness, and a quick intellect, while he was also painstaking and scrupulously fair. When the rules of the Supreme Court 1883 came into force in the autumn of that year, Mr Justice Field was so well recognized an authority upon all questions of practice that the Lord Chancellor selected him to sit continuously at Judges' Chambers, in order that a consistent practice under the new rules might as far as possible be established. This he did for nearly a year, and his name will always, to a large extent, be associated with the settling of the details of the new procedure, which finally did away with the former elaborate system of "special pleading." When in 1890 Mr Justice Field accepted a life peerage and retired, becoming at the same time a member of the Privy Council, his title and retirement were recognized as well earned by the work that he had done. In the House of Lords he at first took part, not unfrequently, in the hearing of appeals to that chamber, and notably delivered a carefully-reasoned judgment in the case of the Bank of England *v.* Vagliano Brothers (5th March 1891), in which, with Lord Bramwell, he differed from the majority of his brother peers. Before long, however, deafness and advancing years rendered his attendances less frequent. Lord Field married Louisa, daughter of Mr J. Smith, but his wife died in 1880.

Fields, James Thomas (1817–1881), American publisher and author, was born in Portsmouth, New Hampshire, 31st December 1817, and at the age of fourteen went to Boston as clerk in a bookseller's. Afterwards he wrote for the newspapers, and in 1835 he read a poem before the Boston Mercantile Library Association. In 1838 he became junior partner in the publishing and bookselling firm afterwards known as Ticknor & Fields. The first collected edition of De Quincey was due to his efforts. In 1862 he became editor of the *Atlantic Monthly*, which had been edited by James Russell Lowell since its commencement in 1857. In 1871 Fields retired from business and from his editorial duties, and devoted himself to literary work. Of his books the chief were the collection of sketches and essays entitled *Underbrush* (1877) and the chapters of reminiscence composing *Yesterdays with Authors* (1871), in which he recorded his personal acquaintanceship with Wordsworth, Thackeray, Dickens, Hawthorne, and others. He died in Boston, 24th April 1881.

Fife, a peninsular county of Scotland, bounded N. by the Firth of Tay, separating it from Perthshire and Forfar, S. by the Firth of Forth, separating it from the Lothians, E. by the German Ocean, and W. by parts of Kinross, Perth, and Clackmannan.

Area and Population.—The area of the county is 314,952 acres, or 492·1 square miles, with a population in 1881 of 171,931, and in 1891 of 187,346, of whom 89,135 were males and 98,211 females, the number of persons per square mile being 381, and of acres to a person 1·7. In 1881 the town population amounted to 85,973, the village to 46,576, and the rural to 39,382; and in 1891 the town population to 98,508, the village to 49,923, and the rural to 38,915. Between 1881 and 1891 the increase in population was 8·96 per cent. In 1901, the population was 218,843, of whom 105,096 were males, and 113,747 females. The following table gives the numbers of marriages, births, and deaths, with the number and percentage of illegitimate births for 1880, 1890, and 1899:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				No.	Percentage.
1880	987	5307	3099	361	6·8
1890	1181	5346	3477	291	5·4
1899	1524	5895	3334	277	4·7

The percentage of illegitimacy is considerably below the average for Scotland. In 1891 there were in the county 3453 English, 61 Welsh, 1732 Irish, and 103 foreigners.

The following are the most important towns in Fife, from the point of view of population: Kirkcaldy, Dunfermline, St Andrews, Cowdenbeath, and Leven.

Administration.—For parliamentary purposes Fife is divided into an eastern and a western division. It also includes the Kirkcaldy district of parliamentary burghs (comprising Burntisland, Dysart, Kinghorn, and Kirkcaldy) and the St Andrews district of parliamentary burghs (comprising Anstruther Eastern, Anstruther Western, Crail, Cupar, Kilrenny, Pittenweem, and St Andrews), in addition to which Dunfermline and Inverkeithing are included in the Stirling district of parliamentary burghs. The county town is Cupar.

Education.—St Andrews, the seat of the oldest university of Scotland, contains also many private boarding schools for boys and girls. There are in the county five higher class schools in receipt of government grants, and offering various facilities for education: Bell Baxter School, Cupar; High School, Dunfermline; High School, Kirkcaldy; Madras College, St Andrews; and Waid Academy, Anstruther. The grant for higher class schools for the year ending 31st March 1900 was £2446. The total accommodation in elementary schools on 31st September 1899 was 44,797, the average attendance was 31,990, and the average cost per scholar was £2 : 6 : 9¼. The amount of school rates received in 1895–96 was £31,280, in 1896–97 £32,993, and in 1898–99 £36,199, the average rate per £ on rateable value for these years being 8·10d., 8·38d., and 8·48d. respectively.

Communications.—Within recent years the railway communication has been greatly improved, especially in the eastern portion of the county, the whole of the coast towns being now connected by rail from St Andrews to Burntisland; and while the Forth Bridge has facilitated traffic both with Edinburgh and Glasgow, the Tay Bridge gives easy access to Dundee and the north. In 1898 a line for goods traffic only was opened, bisecting the eastern portion of the county from Cameron Bridge to Lochty.

Agriculture.—About four-fifths of the total area of the county is under cultivation, and of this about three-sevenths is in permanent pasture. In addition about 9000 acres are in hill pasturage, and over 24,000 acres under wood. Within the last twenty years the acreage under corn crops has considerably diminished, the decrease being mainly in the acreage under barley, which is now about a third less than in 1880; there has also been a decrease of about 2000 acres in the wheat area, but almost no decrease in that of oats, which occupy more than half of the corn crop acreage. Turnips occupy nearly three-fourths of the acreage under green crops, and potatoes about a third, while over 1000 acres are under other varieties of green crops. More attention has lately been given to dairy farming, but cattle are still kept mainly for feeding purposes. The following table gives the main divisions of the cultivated area at intervals of five years from 1880:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	246,480	86,584	47,179	62,033	48,849	1835
1885	250,918	88,752	43,716	67,636	55,524	1267
1890	253,756	76,994	42,782	68,342	64,131	1409
1895	256,060	74,028	42,536	63,125	75,594	614
1900	255,398	73,282	41,118	64,341	75,878	593

The following table gives particulars regarding the principal live stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	10,202	39,674	9.038	72,783	5229
1885	9,717	44,360	10 347	88,346	6713
1890	9,481	48,004	10,628	105,093	6669
1895	10,535	49,912	11,285	94,578	6532
1899	9,791	47,673	12,186	109,780	5511

Industries and Trade.—According to the report for 1898 of the Chief Inspector of Factories (1900) the total number of persons employed in factories and workshops in 1897 was 26,052, as compared with 25,871 in 1896. Of these 12,580 were employed in textile factories, 12,481 being employed in the flax, hemp, and jute industries, and nine-tenths of these in the flax or linen industry, which besides having its chief seats in Kirkcaldy and Dunfermline is prosecuted at many of the inland villages, specially those in the neighbourhood of the Eden and Leven. Non-textile factories employed 10,859 persons, of whom 2069 were employed in the manufacture of machines and 1516 in the manufacture of paper, &c. Workshops employed 2613 persons, 1514 of whom were employed in clothing industries. The total number of persons employed in connexion with mines and quarries in 1899 was 14,870. The same year 103,479 tons of sandstone were raised, 83,716 tons of limestone, and 97,355 tons of igneous rocks. The coalfield is one of the largest and richest in Scotland, and while coal mining is being prosecuted with increasing enterprise and success, there are ample possibilities of much greater development of the industry. The following table gives the tonnage and value of fireclay, coal, and iron ore in 1890 and 1899:—

Year.	Fireclay.		Coal.		Iron.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.
1890	23,618	£4137	3,121,646	£1,131,597	4,100	£1845
1899	35,662	5349	4,927,489	1,847,808	25,269	9476

On account of the great extent of its sea coast and its situation between two large firths, both the salmon and deep-sea fisheries of Fife are of great importance. All the deep-sea fishing stations east of Wemyss and round by the north coast to Newburgh are included in the Anstruther district, and Wemyss and the small stations in the western portion of the south coast—which together land fish of a total value of less than a twelfth of that of the fish landed in the Anstruther district—in the Leith district. The following table gives particulars regarding the Anstruther district at intervals from 1885:—

Year.	Fishermen.	Total Persons employed.	Value of Boat Lines and Nets.	Value of Fish landed.
1890	3325	5354	£151,555	£44,671
1899	1937	2493	£156,763	£47,272

AUTHORITIES.—Chief among later works is A. H. MILLAR's *Fife, Pictorial and Historical* (2 vols. Cupar-Fife, 1895)—a very minute history of the different parishes with notices of the principal families. Other books are:—BABINGTON. *Records of the Fife Foxhounds.* Edinburgh, 1883.—G. G. *Our Old Neighbours: Folklore of Fife.* Anstruther, 1887.—SHERIFF ÆNEAS MACKAY. *Sketch of the History of Fife.* Edinburgh, 1890. *History of Fife and Kinross* (Scottish County History Series). Edinburgh, 1896.—THOMSON. *History of the Fife Light Horse.* Edinburgh, 1892.—GEDDIE. *Fringes of Fife.* Edinburgh, 1894.—PRYDE. *The Queer Folk of Fife.* Glasgow, 1897.

Figueira da Foz, a town of Portugal, at the mouth of the Mondego, in the district of Coimbra, 25 miles west from Coimbra. It is a summer seaside resort, a new villa quarter, Bairro Novo, having grown up to the north-west of the old town. It is connected with Cape Mondego by tramway. Coal is mined, and glass is manufactured. The port is a fishing station. In 1899 it was entered by a total of 322 vessels of 22,995 tons. The custom-house returns in 1899 showed a total of £67,244. The products are corn, fruit, wine, olive oil, and cork. Population, 5676.

Fiji Islands.—The Fiji archipelago comprises about 250 islands and islets, lying between 177° E. and 178° W. long., and between 15° 40′ and 22° S. lat., about 1700 miles north-east of Sydney and 1200 miles north of New Zealand. The colony includes the island of Rotuma (or Rotumah), which lies 300 miles due north, and supports a population of 2219, its people being apparently a cross between the Polynesians and Micronesians. The peculiar formation of Vitilevu, the largest of the group, gives rise to three rivers, the Rewa, Singatoka, and Ba, which are disproportionately large for an island scarcely half the size of Wales. The land is of recent geological formation, the principal ranges being composed of igneous rock, and showing traces of much volcanic disturbance. There are boiling springs in Vanualevu and Ngau, and slight shocks of earthquake are occasionally felt. With few exceptions the islands are surrounded by barriers of coral, broken by openings opposite the mouths of streams. The mean temperature of the group is 80°, but in the hill sanatorium at Nandarivatu (2000 feet) the thermometer occasionally falls below 50°. Some part of the group is usually visited by a cyclone at intervals of four or five years.

Recent Commercial History.—Fiji became a British colony in 1874. At that date the islands were suffering from commercial depression, following a fall in the price of cotton after the American civil war. Coffee, tea, cinchona, and sugar were tried in turn, with limited success. The coffee was attacked by the leaf disease; the tea could not compete with that grown by the cheap labour of the East; the sugar machinery was too antiquated to withstand the fall in prices consequent on the European sugar bounties. In 1878 the first coolies were imported from India, and the cultivation of sugar began to pass into the hands of large companies working with the most modern machinery. With the introduction of coolies the Fijians began to fall behind in the development of their country. Many of the coolies chose to remain in the colony after the termination of their indentures, and these are rapidly displacing the European country traders. The recruiting of *kanaka* labourers has, with a regular and plentiful supply of Indian coolies, practically ceased. The settlement of European land claims, and the measures taken for the protection of native institutions, caused lively dissatisfaction among the colonists, who laid the blame of the commercial depression at the door of the Government; but with returning prosperity this feeling has almost disappeared. Out of 4,953,920 acres in the colony the natives own over 4,500,000, or 45 acres a head. They are not permitted to sell their lands, but large tracts are leased to European planters at a low rental. In 1882 the capital was transferred from Levuka to Suva, on the south-east coast of Vitilevu, where there is a better harbour, and where a larger area of land was at the disposal of the Government.

Vital Statistics.—There has been a steady, if not a very rapid, decrease in the native population since 1875. The terrible epidemic of measles in that year swept away 40,000, or about one-third of the Fijians, and although measles again revisited the group in 1898, out of the 200 cases there were no deaths. There has, however, been a steady leakage, principally among young children, owing to whooping-cough, tuberculosis, and croup. Every Fijian child seems to contract *yaws* at some time in its life, through the mistaken notion on the part of the parents that it strengthens the child's physique. One per cent. of the natives is a leper. A commission appointed in 1891 to inquire into the causes of the native decrease collected much interesting anthropological information regarding native customs, and provincial inspectors and medical officers have been specially appointed to compel the natives to carry out the sanitary reforms recommended by the commission. A considerable sum has also been spent in laying on good water to the native villages. The Fijians have shown no disposition to intermarry with the Indian coolies. The European half-castes, who numbered in 1900 1258, are not prolific *inter se*, and they are subject to a scrofulous taint. The most robust cross in the islands is the offspring of the African negro and the Fijian. Probably the only hope of saving the native population lies in miscegenation with the Micronesians, the only race in the Pacific which is rapidly increasing, but the immigration of the Gilbert and Ellice islanders would have to be undertaken by the Government.

The following table shows the population by census 5th April 1891, and by vital statistics 31st December 1899:—

Class.	Census 1891.			Vital Statistics 1899.		
	Male.	Female.	Total.	Male.	Female.	Total.
Europeans	1,273	763	2,036	2,759	1,614	4,373
Half-castes .	529	547	1,076	624	634	1,258
Asiatics . .	4,998	2,470	7,468	8,875	4,407	13,282
Polynesians .	1,923	344	2,267	1,672	289	1,961
Rotumans .	1,056	1,163	2,219	1,033	1,138	2,171
Fijians . .	56,445	49,355	105,800	52,354	46,124	98,478
Others . .	143	171	314	471	679	1,150
Grand total	...	...	121,180	...	...	122,673

Constitution and Government.—There has been no change in the government since annexation. The legislative council consists of six official and six non-official members nominated by the crown, and the governor has a casting vote. The New Zealand Government made overtures in 1900 to absorb Fiji. The Aborigines Society sent a protest to the Colonial Office on 3rd April 1901, and the Imperial Government declined to sanction the proposal. As the power of the chiefs has declined, the *roko tui*, or native lieutenant-governor, has been occasionally replaced by a European resident commissioner. The native chiefs have shown considerable ability both as administrators and magistrates, but, with some exceptions, they seem unable to withstand the temptation of converting public money to their own uses.

Religion and Instruction.—The majority of the natives are Wesleyan Methodists. The Roman Catholic missionaries have about 3000 adherents; the Church of England is confined to the Europeans and *kanakas* in the towns; the Indian coolies are divided between Mahommedans and Hindus. There are public schools for Europeans and half-castes in the towns, but there is, as yet, no provision for the education of the children of settlers in the out-districts. The missions have established schools in every native village, and most natives are able to read and write their own language. The Government has besides established a native technical school for the teaching of useful handicrafts. The natives have shown themselves very slow in adopting European habits in food, clothing, and house-building. The law of custom has so far decayed as to deprive them of many safeguards to health, and the law of competition not having yet taken its place, the Fijian is left, as it were, stranded between two tides. Until the custom of *kerekere*, under which he who has is obliged to give to him who has not, is broken down, the lazy will continue to live upon the industrious, and there will be no inducement to accumulate property.

Finance.—The revenue is derived from customs, native taxation, and stamp duties. The customs tariff, formerly about 12½ per cent. *ad valorem*, was in 1897 largely increased by specific duties. The native taxes, paid in produce cultivated under European supervision, are assessed annually at about £18,000, any excess being sold to the contractor, and returned to the native in cash. In 1899 some £12,000 was thus returned, and so elaborate is the system of book-keeping, that every individual native receives his share before the close of the year in which the produce was grown. Owing to the freedom from hurricanes for the last five years there has been a steady increase in the revenue, and a surplus varying from £5000 to £7000. The actual revenue for 1898 was £94,165, the expenditure £85,741. There is a debt of £109,500 in 4½ per cent. debentures, which is being gradually paid off by a sinking fund, and a debt of £95,476 advanced by the imperial treasury without interest, which is also being paid off. A reserve of £25,000 is being formed to meet any temporary loss of revenue by hurricanes. A branch of the Bank of New Zealand is the only banking establishment in the colony. The currency and weights and measures are English.

Defence.—The armed native constabulary numbers 100 men, and there is a volunteer and cadet corps in Suva and Levuka.

Agriculture and Industries.—The principal exports are sugar and copra and bananas. The production of sugar has passed almost exclusively into the hands of one powerful company, whose plant is one of the largest in the world. As fresh areas of cocoanuts have come into bearing the export of copra has much increased. The cultivation of tea and coffee is now almost abandoned, but sufficient tobacco is grown to supply the local consumption of cigars. Soap made from cocoanut oil also supplies the local market.

Year.	Imports.	Exports.		
		Sugar.	Copra.	Total.
1890	£206,757	£244,655	£31,013	£364,532
1895	241,759	208,889	94,084	332,209
1899	263,044	340,602	77,330	481,856

Internal Communications.—Good bridle tracks now exist in all the larger islands, and macadamized roads are being pushed forward from Suva. There is a bi-weekly overland mail service by native runners, and a telephone line connects Suva with Ba and Nandi.

Filey, a seaside resort and fishing village of England, stands on the north side of a bay on the Yorkshire coast, between Scarborough and Bridlington, 9 miles south-east from the former. It has firm sands, a golf-course, and mineral springs, now however neglected. Population (1901), 3004.

Finance.—The complete alteration of the English financial system involved in the thorough application of a free-trade policy was substantially accomplished in 1860. Since then the history of English finance has been one of normal growth, influenced indeed by new conditions and marked by considerable readjustments, but altogether free from revolutionary change. The repeal of the 1s. duty on corn (1869), and the abolition of the sugar duty (1874), were in fact the removal of a last trace of Protection, and a continuation of the work of simplifying the taxation of commodities, and reducing the charge on the poorer consumers, which was characteristic of the reforms of Peel and Gladstone. In tracing the financial history of the thirty years, 1870–1900, the first noticeable point is the almost continuous growth of expenditure. From being under 70 millions in 1870, it rose to nearly 87 millions in 1890; it passed the 100 million point in 1897, until in 1901, under the pressure of war, it exceeded 183 millions. The principal element in this movement was obviously the increased demands of both the army and navy. The outlay on the former, which was 15 millions in 1870, came in time of peace to exceed 20 millions. In the case of the navy the increase was from less than 10 millions to 30 millions, or over 200 per cent. The revival of international ill-feeling, the immense development in implements of war, and the higher rates of pay required, owing to the improvement in the standard of life, were, though in unequal degree, the underlying causes. Civil administration has also become more costly. The State has undertaken new tasks, and has discharged its older duties with greater vigour. Especially remarkable is the advance of expenditure on education, which was less than 2 millions in 1870, but came to 12½ millions in 1900. One item of increase is, however, rather apparent than real, viz., the post-office expenditure, for it is the necessary condition of the more than proportional increase in postal receipts. Up to 1899 a reduction is also found under the head of interest and management of debt, which only amounted to £16,200,000 in that year, as against 22½ millions in 1869—a result due in part to the repayment of principal, in part to the conversion measure of 1888. The war loans of 1900 and 1901 seriously increased this item.

Expenditure, 1870-1900.

This great increase in national expenditure has been met by a corresponding growth of revenue, which has enabled the various claims of the State to be satisfied without undue pressure on the enjoyments or the industries of the people. The great division of *taxes on commodities* (or indirect taxation) has been strictly confined to a few productive articles—spirits, beer, wines, tobacco, and tea (with its substitutes). The rates of imposition have not seriously altered—the lowering of the tea duty from 6d. to 4d. per lb, small increases on spirits and beer, with some adjustment of the tobacco duty, being the chief changes—and yet there has been an advance in receipts. The customs, indeed, have not shown much change from the average of 20 millions attained between 1865 and 1900 (their yield in 1901 was 26¾ millions). But this steady return has been secured in spite of the surrender of the sugar duty (1874), and one-third of the tea duty (1890). The South African War led to the raising of the tea duty to its old level, the reimposition of the sugar duty, and to an export duty on coal. The excise has proved more elastic. From 23½ millions in 1871–72, its return advanced to over 33 millions in 1900-1, together with 5 millions set aside for the purposes of local finance. Thus it appears that nearly 60 millions is the sum obtained by the State from taxation of commodities. From being regarded as a temporary and unsatisfactory resource, the *income tax* has gained the place of a well-established and important element in the tax system. Placed at the very low rate of 2d. in the £ in 1874, it was gradually advanced, until in 1894 what since seemed the normal peace rate of 8d. was established. The necessary result has been a great increase in yield. In 1876 the returns were just over 4 millions; for 1893 they were 13½ millions; in 1899–1900 they reached 18¾ millions. These figures show clearly that a considerable part of the burden of growing expenditure has fallen directly on the payers of income tax as such. But there has been also a rearrangement, which has affected the relations of different classes of payers. In 1870 the limit for exemption from the tax was only £100, and incomes of £200 paid the full tax without abatement. By a series of changes the exemption point has been raised to £160, while all incomes of £700 and under are allowed abatements. The practical effect is to throw by far the greater part of the burden on the possessors of incomes over £700, leaving moderate incomes unaffected by the increase. The fact that, in spite of so extensive a relief, the yield per penny now amounts to £2,300,000 is a good illustration of the growth of wealth in the United Kingdom. The war rates of 1s. (1900) and 1s. 2d. (1901) proved productive, as the yield for 1900–1 was almost 27 millions.

Revenue.

A still more remarkable feature of modern English finance is the increased rigour of the duties on succession to property—the *death duties.* Instead of the system in force in 1870, under which real property escaped the general or probate duty, which only amounted to 3 per cent., there has been since 1894 a comprehensive "estate" duty applicable to all property, and so graduated as to levy 8 per cent. on estates of 1 million. By this agency the death duties, which supplied less than 5 millions in 1870, and had not reached 10 millions in 1890, came in 1900–1 to 13 millions (besides over 4 millions for local finance). This group of taxes operates as the complement of the income tax, and taking the two together, it is evident that between 1876 and 1901 the taxation on income and property increased more than fourfold, or from 10 millions to 40 millions. Other items of the tax revenue so-called need only cursory mention. The land tax and house duty have both been recently reduced, and the more productive "stamps" have been somewhat enlarged in order to include commercial transactions, until in 1899–1900 they produced 8½ millions. The industrial departments of the post-office have yielded more than 80 per cent. of the non-tax revenue (over 16½ millions in 1899–1900), subject, however, to a heavy deduction for expenses, which reduces the net revenue to the moderate amount of 4 millions, or 1 million more than in 1872.

The avoidance of deficits or undue surpluses has been a cardinal principle of modern English finance; but the great war period, ending in 1815, bequeathed a heritage of debt, involving heavy interest payments. This charge has (as already mentioned) been reduced by (1) the substitution of terminable annuities for funded debt, (2) the establishment of a fixed annual sum for the debt service—the "new sinking fund" (1875)—which in 1899 was reduced to 23 millions, and (3) the "old sinking fund," *i.e.*, the application of actual surplus to redemption of debt—this last a resource which has in recent years been restricted by the continual introduction of late supplementary estimates. The process of reduction has varied in its rate. In 1869 the debt principal was 750 millions, in 1885 it was 740 millions, a trivial diminution of 10 millions. By 1899 more progress had been made, as the total debt was only 635 millions, or 105 millions less than in 1885. The work of redemption, which was aided by the conversion of the 3 per cent. stock into 2¾ per cent. in 1888, was, broadly speaking, nullified by the war loans of 1900 and 1901, as they added over 100 millions to the capital charge.

The chief changes in the complementary system of *local finance* since 1870 have been (1) even greater increase in expenditure than that of the State; (2) a considerable development of "non-tax" revenue derived from municipal industries; (3) a great increase in indebtedness, mainly the consequence of the preceding process; (4) the automatic growth of the share of tax-revenue assigned to local purposes. As a whole, the English financial system appears to be based on simple and intelligible principles, and to be extremely productive of revenue without great sacrifice on the part of the tax-payers. Through the movable income tax and the reserve of untaxed articles it has ample resources for emergencies, while the distribution of burdens is not seriously unjust. Its weakest points are probably the treatment of the classes of (1) the very poor, who consume taxed articles, and (2) the possessors of moderate incomes, and also the want of relation between central and local finance. (See also TAXATION.)

(For the finance generally of other countries than Great Britain, see the articles on those countries.)

Findlay, capital of Hancock County, Ohio, U.S.A., on the Blanchard river, at an altitude of 778 feet. It is a railway centre of much importance, being at the intersection of five lines—the Cincinnati, Hamilton, and Dayton; the Cleveland, Cincinnati, Chicago, and St Louis; the Findlay, Fort Wayne, and Western; the Lake Erie and Western; and the Ohio Central. About 1885 the development of a natural gas field in the neighbourhood induced a rapid growth of population and manufactures, especially of iron, steel, and glass. Population (1880), 4633; (1890), 18,553; (1900), 17,613, of whom 1051 were foreign-born, and 294 negroes.

Findlay, Sir George (1829–1893), English railway manager, was of pure Scottish descent, and was born at Rainhill, in Lancashire, on 18th May 1829. For some time he attended Halifax Grammar School, but left at the age of fourteen, and began to learn practical masonry on the Halifax railway, upon which his father was then employed. Two years later he obtained a situation on the Trent Valley railway works, and when that line was finished in 1847 went up to London. There he was for a short time among the men employed in building locomotive sheds for the London & North-Western Railway at Camden Town, and years afterwards, when he had become general manager of that railway, he was able to point out stones which he had dressed with his own hands. For the next two or three years he was engaged in a higher capacity as supervisor of the mining and brickwork of the Harecastle tunnel on the North Staffordshire line, and of the Walton tunnel on the Birkenhead, Lancashire, and Cheshire Junction Railway. In 1850 the charge of the construction of a section of the Shrewsbury and Hereford line was entrusted to him, and when the line was opened for traffic Mr Brassey, the contractor, having determined to work it himself, installed him as manager. In the course of his duties he was brought for the first time into official relations with the London & North-Western Railway, which had undertaken to work the Newport, Abergavenny, and Hereford line, and he ultimately passed into the service of that company, when in 1862, jointly with the Great Western, it leased the railway of which he was manager. In 1864 he was moved to Euston as general goods manager, in 1872 he became chief traffic manager, and in 1880 he was appointed full general manager; this last post he retained until his death, which occurred on 26th March 1893 at Edgware. Sir George Findlay was the author of a book on the *Working and Management of an English Railway*, which contains a great deal of information, some of it not easily accessible to the general public, as to English railway practice about the year 1890.

Finistère, the most westerly department of France, washed by the English Channel and the Atlantic Ocean.

Area, 2730 square miles, with 43 cantons and 293 communes. Population, 707,820 in 1886, 739,648 in 1896, and 763,193 in 1901. Births in 1899, 23,884, of which 588 illegitimate; deaths, 17,108; marriages, 6125. The schools numbered (1896) 839, with 113,000 pupils; 16 per cent. of the population was illiterate. Quimper, the capital, with 19,441 inhabitants, and Brest, a military station, with 81,948 inhabitants, are the chief towns. The area of cultivated land in 1896 amounted to 1,027,994 acres, of which 773,467 acres were plough-land. In 1899 the produce of wheat was valued at £638,000; of rye, £237,000; of barley, £180,000; of oats, £340,000; potatoes, £998,000; mangold-wurzel, £130,000; natural pastures and grass lands, £640,000. Finistère cultivates with success flax, which in 1899 returned the value of £44,000, and hemp, which produced £46,000. Its main source of prosperity, however, is the rearing of horses, which in 1899 numbered 112,270 head. Its cattle totalled 432,680; its sheep, 69,400; and its pigs, 112,430. The department is not rich in metals, and its industry is restricted to some cloth factories.

Finland, Grand Duchy of, a part of the Russian empire, situated between the Gulfs of Bothnia and Finland, and including, moreover, a large territory in Lapland. It touches at its south-eastern extremity the government of St Petersburg, includes the northern half of Lake Ladoga, and is separated from the Russian governments of Arkhangelsk and Olonets by a sinuous line which follows, roughly speaking, the water-parting between the rivers flowing into the Baltic Sea and the White Sea. In the north of the Gulf of Bothnia it is separated from Sweden and Norway by a broken line which takes the course of the valley of the Torneå river up to its sources, thus falling only 21 miles short of reaching the head of the Norwegian Lyngen-fjord; then it runs south-east and north-east down the Tana and Pasis-joki, but does not reach the Arctic Ocean, and 13 miles from the Varanger-fjord it turns southwards. Finland includes in the south-west the Åland archipelago—its frontier approaching within 8 miles from the Swedish coast—as well as the islands of the Gulf of Finland, Hogland, Tytärs, &c. Its utmost limits are: 59° 48′—70° 6′ N. lat., and 19° 2′—32° 50′ E. long. The area of Finland, in square miles, is as follows (*Atlas de Finlande*, 1899):—

Government.	Continent.	Islands in Lakes.	Islands in Seas.	Lakes.	Total.
Nyland . . .	4,062	24	210	286	4,582
Åbo-Björneborg	7,594	8	1331	400	9,333
Tavastehus . .	6,837	97	...	1,400	8,334
Viborg . . .	11,630	362	130	4,502	16,624
St Michel . .	5,652	1018	...	2,149	8,819
Kuopio . . .	13,160	643	...	2,696	16,499
Vasa	14,527	62	203	1,313	16,105
Uleåborg . .	60,348	171	94	3,344	63,957
Total . .	123,810	2385	1968	16,090	144,253

Orography.—A line drawn from the head of the Gulf of Bothnia to the eastern coast of Lake Ladoga divides Finland into two distinct parts, the lake region and the nearly uninhabited hilly tracts belonging to the Kjölen mountains, to the plateau of the Kola peninsula, and to the slopes of the plateau which separates Finland proper from the White Sea. At the head-waters of the Torneå, Finland penetrates as a narrow strip into the heart of the Kjölen highlands, where the Haldefjäll (Lappish Halditschokko) reaches 4115 feet above the sea, and is surrounded by other *fjälls*, or flat-topped summits, of from 3300 to 3750 feet of altitude. Extensive plateaus (1500–1750 feet), into which Lake Enare, or Inari, and the valleys of its tributaries are deeply sunk, and which take the character of a mountain region in the Saariselkä (highest summit 2360 feet), occupy the remainder of Lapland. Along the eastern border the dreary plateaus of Olonets reach on Finnish territory altitudes of from 700 to 1000 feet. Quite different is the character of the pentagonal space comprised between the Gulfs of Bothnia and Finland, Lake Ladoga, and the above-mentioned line traced through the Lakes Uleå and Piellis. The meridional ridges which formerly used to be traced here along the main water-partings do not exist in reality, and the country appears on the hypsometrical map in the *Atlas de Finlande* as a plateau of 350 feet of average altitude, covered with countless lakes, lying at altitudes of from 250 to 300 feet. The three main lake-basins of Näsi-järvi, Päjäne, and Saima are separated by low and flat hills only; but one sees distinctly appearing on the map a line of flat elevations running south-west to north-east along the north-west border of the lake regions from Lauhanvuori to Kajana, and reaching from 650 to 825 feet of altitude. A regular gentle slope leads from these hills to the Gulf of Bothnia (Osterbotten), forming vast prairie tracts in its lower parts.

A notable feature of Finland are the *åsar* or narrow ridges of morainic deposits, more or less reassorted on their surfaces. Some of them are relics of the longitudinal moraines of the ice-sheet, and they run north-west to south-east, parallel to the striation of the rocks and to the countless parallel troughs excavated by the ice in the hard rocks in the same direction; while the Lojo ås, which runs from Hangöudd to Vesi-järvi, and is continued farther east under the name of Salpausselkä, parallel to the shore of the Gulf of Finland, are remainders of the frontal moraines, formed at a period when the ice-sheet remained for some time stationary during its retreat. As a rule these forest-clothed *åsar* rise from 30 to 60 and occasionally 120 feet above the level of the surrounding country, largely adding to the already great picturesqueness of the lake region; railways are traced in preference along them.

Lakes and Rivers.—A labyrinth of lakes, covering 11 per cent. of the aggregate territory, and connected by short and rapid streams (*fjärden*), covers the surface of South Finland, offering great facilities for internal navigation, while the connecting streams supply an enormous amount of motive-power. The chief lakes are: Lake Ladoga, of which the northern half belongs to Finland; Saima (three and a half times larger than Lake Leman), whose outlet, the Vuoksen, flows into Lake Ladoga, forming the mighty Imatra rapids, while the lake itself is connected by means of a sluiced canal with the Gulf of Finland; the basins of Pyhä-selkä, Ori-vesi, and Piellis-järvi; Päjäne, surrounded by hundreds of smaller lakes, and the waters of which are discharged into the lower gulf through the Kymmene river; Näsi-järvi and Pyhä-järvi, whose outflow is the Kumo-elf, flowing into the Gulf of Bothnia; Uleå-träsk, discharged by the Uleå into the same gulf; and Enare, belonging to the basin of the Arctic Ocean. Two large rivers, Kemi and Torneå, enter the head of the Gulf of Bothnia, while the Uleå is now navigable throughout, owing to improvements in its channel.

Geology.—Finland is nearly entirely built up of oldest crystalline rocks. Cambrian, Silurian, Devonian, and Carboniferous deposits are only found on the coasts of the Gulf of Finland and Lake Ladoga, as also along the coasts of the Arctic Ocean (probably Devonian), and in the Kjölen. Eruptive rocks of Palæozoic age are met with in the Kola peninsula (nephelin-syenites) and at Kuusamo (syenite). The remainder of Finland is built up of the oldest known crystalline rocks belonging to the Archæozoic or Algonkian period. The eldest of them seem to be the granites of East Finland, whose disaggregation gave origin to the *Ladoga schists* and various deposits of the same period, whose primitive position was altered by subsequent vigorous foldings. Then the country came once more under the sea, and the débris of the previous formation, mixed with débris of eruptive rocks originated from many volcanoes situated then in West Finland, formed the so-called *Bothnian series.* New masses of granites protruded next from underneath, and the Bothnian deposits underwent foldings in their turn, while denudation was again at work on a grand scale. A new series of *Jatulian deposits* was formed next, and a new system of foldings followed; but these were the last in this part of the globe. The *Jotnian series* of deposits, which were formed next, remain still undisturbed. No marine deposits younger than those just mentioned—all belonging to a pre-Cambrian epoch—are found in the continental portion of Finland. The plateau character of vast portions of the surface must have been acquired during the extremely long period during which the country remained a continent. The whole of Finland is covered with Glacial and post-Glacial deposits, the former of which, representing the bottom-moraine of the ice-sheet, are covered with Glacial and post-Glacial clays (partly of lacustrine and partly of marine origin) only in the peripheral coast-region—or in separate areas in the interior depressions. Some Finnish geologists—Sederholm for one—consider it probable that during the Glacial period an Arctic sea (*Yoldia* sea) covered all southern Finland and Skånia (in Sweden), thus connecting the Atlantic Ocean with the Baltic and the White Sea by a broad channel; but no fossils from that sea have been found anywhere in Finland. On the contrary, quite certain traces of submergence under a post-Glacial Littorina sea (containing shells now living in the Baltic) are found up to 150 feet along the Gulf of Finland, and up to 260, or perhaps 330 feet, in Osterbotten. Traces of a large inner post-Glacial lake, similar to Lake Agassiz of North America, have lately been discovered. The country is still continuing to rise, but at an unequal rate; of nearly 3·3 feet in a century in the Gulf of Bothnia (Kvarken), from 1·4 to 2 feet in the south, and nearly zero in the Baltic provinces.

Climate.—Owing to the prevalence of moist west and south-west winds the climate of Finland is less severe than it is farther east in corresponding latitudes. The and country lies thus between the annual isotherms of 41° 28° Fahr., which run in a W.N.W.-E.S.E. direction. In January the average monthly temperature varies from 9° Fahr. about Lake Enare to 30° along the south coast; while in July the difference between the monthly averages is only eight degrees, being 53° in the north and 61° in the south-east. Everywhere, and especially in the interior, the winter lasts very long, and early frosts (June 12–14 in 1892) often destroy the crops. The amount of rain and snow is from 25½ inches along the south coast to 13·8 inches in the interior of southern Finland.

Vegetation.—The flora of Finland has been most minutely explored, especially in the south, and the Finnish botanists were enabled to divide the country into twenty-eight different provinces, giving the numbers of phanerogam species for each province. These numbers vary from 318 to 400 species in Lapland, from 508 to 651 in Karelia, and attain 752 species for Finland proper; while the total for all Finland attains 1132 species. Alpine plants are not met with in Finland proper, but are represented by from 32 to 64 species in the Kola peninsula.

Fauna.—The fauna has also been explored in great detail both as regards the vertebrates and the invertebrates, and specialists will find the necessary bibliographical indications in *Travaux géographiques en Finlande*, published for the London Geographical Congress of 1895.

Forests.—The chief forest trees of Finland are the Scotch fir (*Pinus sylvestris*, L.), the fir (*Picea excelsa*, Link.); two species of birch (*B. verrucosa*, Ehrh., and *B. odorata*, Bechst.), as well as the birch-bush (*B. nana*); two species of *Alnus* (*glutinosa* and *incana*); the oak (*Q. pedunculata*, Ehrh.), which grows only on the south coast; the poplar (*Populus tremula*); and the Siberian larch, introduced in culture in the 18th century. Over 6,000,000 trees are cut every year to be floated to thirty large saw-mills, and about 1,000,000 to be transformed into paper pulp. The total export of timber was valued in 1897 at 82,160,000 marks. It is estimated, however, that the domestic use of wood (especially for fuel) represents nearly five times as many cubic feet as the wood used for export in different shapes. The total area under forests is estimated at 63,050,000 acres, of which 34,662,000 acres belong to the State.

Population.—The population of Finland, which was 429,912 in 1751, 832,659 in 1800, and 1,636,915 in 1850, was on the 31st December 1895, 2,520,437, of whom there were 1,276,586 women, and 272,415 lived in towns. The distribution of population in various provinces was as follows:—

31st December 1895.	Population.	Density per sq. Mile.
Åbo-Björneborg	419,369	47
Kuopio	300,291	22
Nyland	264,243	61
St Michel	185,098	28
Tavastehus	276,010	40
Uleåborg	260,763	4
Viborg	379,115	33
Vasa	435,548	30
Total	2,520,437	20

The movement of the population varies very much from year to year in accordance with the state of crops, the number of births having varied in the years 1892–96 from 76,206 to 84,010, the number of deaths from 46,709 to 57,486, and the excess of births over deaths from 18,947 in 1892 to 37,301 in 1895. Emigration proper was estimated at about three thousand every year before 1898, but it largely increased then, owing to Russian encroachments on Finnish autonomy. In 1899 the emigrants numbered 12,357; in 1900, 10,642; in 1901, 12,659; and for 1902 the number was still larger.

The bulk of the population are Finns (2,169,000 in 1895) and Swedes (341,500). Of Russians there were only 7000, chiefly in East Finland (Karelia), and 1150 Laps. Both Finns and Swedes belong to the Lutheran faith, there being only 46,509 Greek Orthodox and Raskolniks (Nonconformists) Finns, chiefly in Karelia.

The distribution of population in different classes is as follows: Nobles, 0·1 per cent.; clergy, 0·3; burghers, 3·1; peasants, 26·1; others, 70·4. Of these different classes only the first four elect representatives to the Diet.

The chief towns of Finland are: Helsingfors, capital of Finland, and chief town of the province (*län*) of Nyland, chief seaport (73,820 inhabitants); Åbo, chief town of the Åbo-Björneborg province, important seaport (34,339); Tammerfors, manufacturing town of Tavastehus län (25,338); Viborg, chief town of province of same name, important seaport (23,026); Uleåborg, capital of province (13,770); Vasa, or Nikolaistad, capital of Vasa län (12,384); Björneborg (11,669); Kuopio, capital of province (9566); and Tavastehus, capital of province (5322).

Agriculture gives occupation to 77 per cent. of the inhabitants; however, only 117,704 persons are owners of the soil, and 92,838 out of them own less than 62½ acres, 32,711 less than 12½ acres. There are, besides, 70,444 farmers, mostly paying their rent in labour, and a large number of *Ansässige* (*inhysingar*), *i.e.*, agricultural labourers, only casually employed, and various classes of farm-servants. Efforts have lately been made by enlightened Finnish patriots to facilitate the acquisition of land by the labourers.

The crops, which are chiefly rye and oats in the south, and barley in the north, up to 68° 30′, as also some wheat, vary very much from year to year, and yielded for the twelve years 1884–95 a maximum of 14·4 bushels of all cereals per head of total population, and a minimum (in 1892) of 11 bushels. To these, from 4 to 7 bushels of potatoes per inhabitant must be added. An average crop may be taken at 4,202,000 quarters of all cereals, *i.e.*, twice as much as it was in 1861. Every year grain has, however, to be imported to the amount of about 66 ℔ per head of population. Agricultural machinery is mostly of the old type.

Dairy farming is on the increase, and the foreign exports of butter attained in 1896 nearly 13,000 tons (12 ℔ per head of rural population). There were in 1898 1,298,990 head of cattle (fifty-seven head per each 100 of rural population), 302,565 horses, 1,092,420 sheep, 214,946 swine, 114,730 reindeer, and 441,000 poultry.

Measures have been taken since 1892 for the improvement of agriculture, and the state keeps now twenty-six agronomists and instructors for that purpose. There are two high schools, one experimental station, twenty-two middle schools, and forty-eight lower schools of agriculture; besides ten horticultural schools are being created. Agricultural societies exist in each province.

Fishing is an important item of income. Over 17,000 tons of different fish (8350 tons of herring) are obtained every year. The value of exports of fish, &c., was 2,909,000 marks in 1898, but from 1,000,000 to 1,800,000 marks' worth of fish is also imported every year.

Industry is of recent origin. There are 91,055 workers, miners, and artizans engaged in all industries, in 7787 separate industrial establishments, the aggregate production of which was valued at 283,671,147 marks in 1898. The chief of them are: wood (22,522 workers, 71,216,455 marks of annual production), articles of food (10,099 workers, 54,016,941 marks), metallurgy and mechanical works (17,198 workers, 44,642,832 marks), textiles (9677 workers, 33,147,415 marks), paper (6254 workers, 22,230,147 marks), and leather (3431 workers, 15,974,617 marks).

Some gold is being obtained in Lapland, on the Ivalajoki (4·6 kilogrammes in 1898), some silver on Lake Ladoga (455 kilogrammes), copper (253 tons) and tin (21 tons) at Pitkäranta, and iron. The last is obtained partly from mines (19,145 tons of ore, 20,000 tons more imported from Sweden), but chiefly from the lakes (50,000 to 75,000 tons of ore). In 1898, 26,679 tons of cast iron (32,811 in 1897) were obtained, and while 12,722 tons of it were exported to Russia, 21,702 tons of cast iron and 23,235 tons of iron were imported from Sweden and Great Britain, the total consumption of iron having regularly risen so as to reach 43,872 tons in 1898. The textile industries are making rapid progress, and their produce, notwithstanding the high duties, is exported to Russia. The fabrication of paper pulp out of wood is also rapidly growing, the total annual production being now over 50,000 tons, out of which 38,000 tons are exported. As to the timber trade, there are no less than 120 large saw-mills (eighteen only with water-power) and 370 small ones (215 with water-power), and over 900 carpentry establishments.

Roads, Railways, Canals.—The *roads*, attaining an aggregate length of 27,500 miles, are kept as a rule in very good order. The first *railway* was opened in 1862, and the next, from Helsingfors to St Petersburg, in 1870 (cost only 113,000 marks per mile). Railways of a lighter type began to be built since 1877, and now Finland has 1560 miles of railways belonging to the state and 160 miles to private companies, the state debt contracted for that purpose being 112,430,000 marks. A new line connects Helsingfors with Åbo. The gross income from the state railways is 25,047,000, and the net income 7,544,000 marks. Finland has an extensive and well-kept system of *canals*, of which the sluiced canal connecting Lake Saima with the Gulf of Finland is the chief one. It permits ships navigating the Baltic to penetrate 270 miles inland, and is passed every year by from 4980 to 5200 vessels. Considerable works have also been made to connect the different lakes and lake-basins for inland navigation, a sum of 25,000,000 marks having been spent for that purpose.

For *postal service* Finland had in 1898 820 post-offices, the total of letters, papers, &c., transported attaining 34,000,000.

The *telegraphs* (3300 miles) chiefly belong to Russia, excepting the railway telegraphs (2970 miles). Telephones have taken a wide extension both in the towns and between the different towns of southern Finland, the telephone net of the chief society having a length of 3180 miles; the cost of the yearly subscription varies from forty to sixty marks, and is only ten marks in the smaller towns.

Commerce.—The foreign trade of Finland has been steadily growing, reaching in 1899 the following items in marks:—

	From or to Russia.	From or to Other Countries.	Totals.
Imports . .	85,100,000	165,900,000	251,000,000
Exports . .	57,300,000	130,000,000	187,300,000

The chief trade of Finland is with Russia, and next with Britain, Germany, Denmark, France, and Sweden. The main imports are: cereals and flour (44,449,000 marks), metals (22,774,000), machinery (19,334,000), textiles (19,286,000), raw cotton, wool, and twist (10,742,000). The chief articles of export are: timber and wood articles (93,490,000 marks), butter and other farm produce (28,987,000), paper and paper pulp (17,213,000), some tissues, metallic goods, leather, &c.

The ports of Finland were entered in 1898 by 8566 ships of more than nineteen tons, representing an aggregate tonnage of 1,919,000 tons; 5878 of them (862,000 tons) were Finnish. The chief ports are Helsingfors, Åbo, Viborg, Hangö, and Vasa. The commercial fleet numbered, in 1898, 1896 sailing ships (271,824 tons) and 236 steamers (41,043 tons).

Education.—Great strides have been made since 1866, when the new education law was passed, to spread education in the country. Rudimentary teaching in reading, occasionally writing, and the first principles of Lutheran faith are given in the maternal house, or in "maternal schools" (235 in number), or by ambulatory schools (951), under the control of the clergy, who make the necessary examination in the houses of every parish. This education is received by nearly all Lutheran children, *i.e.*, by 404,745 children out of 413,867 of from seven to fifteen years of age, and by 5442 out of 7763 Greek Orthodox children of the same age. All education above that level is in the hands of the Educational Department and School Boards elected in each parish, each rural parish being bound (since 1898) to be divided into a proper number of school districts and to have a school in each of them, the state contributing to these expenses 800 marks a year for each male and 600 marks for each female teacher, or 25 per cent. of the total cost in urban communes. In the towns, 12,725 boys and 13,206 girls received in 1898–99 education in such schools from 795 teachers. In the rural communes there were 1650 schools of that standard, with a staff of 1888 teachers, and with 72,991 pupils (32,769 girls). There are besides twenty-two superior folk-schools (about 8000 pupils), all due to private initiative. Of schools for teachers there are now ten (five male, five female; eight Finnish, two Swedish). Secondary education, formerly instituted on two separate lines, classical and scientific, has been reformed so as to give more prominence to scientific education, even in the classical (linguistic) lyceums or gymnasia. There are now fifteen classical and nine "modern" (scientific) gymnasia (4723 pupils), and six "elementary" schools, containing each the three or four first forms of the gymnasia (431 pupils, of whom 155 are girls). There are besides twelve gymnasia (high schools) for girls, with 1732 pupils, and ninety private secondary schools (2916 boys and 4869 girls). For higher education there is the university of Helsingfors (formerly the Åbo Academy), which had, in 1900, 2318 students (363 ladies) and 119 professors and docents. Besides the Helsingfors polytechnic there are a number of higher and lower technical, commercial, and navigation schools. Finland has several scientific societies enjoying a world-wide reputation, as the Finnish Scientific Society, the Society for the Flora and Fauna of Finland, several medical societies, two societies of literature, the Finno-Ugrian Society, the Historical and Archæological Societies, one juridical, one technical, and two geographical societies. All of these, as also the Finnish Geological Survey, the Forestry Administration, &c., issue publications well known to the scientific world. The numerous local branches of the Friends of the Folk-School and the Society for Popular Education display great activity, the former by aiding the smaller communes in establishing schools, and the latter in publishing popular works, starting their own schools (twenty-one in 1900) as well as free libraries (in nearly every commune), and organizing lectures for the people. The university students take a lively part in this work.

Finances.—The budget of Finland, in an average for the three years 1895–97, was 59,744,777 marks of revenue, to which an average of 5,850,000 marks obtained by railway loans has to be added. As to the expenditure, it attained during the same three years an average of 46,597,693 marks of ordinary expenditure, and 8,643,843 of extraordinary for new railways. The estimates of expenditure for the following three years were: ordinary, 51,863,206 marks; extraordinary, 11,388,333; total, 63,251,539 marks. The public debt (3 and 3½ per cent.) reached, on 1st January 1900, 112,432,178 marks. The expenditure of the towns was 16,122,000, and of the rural communes 5,358,000 marks. The municipal and communal debts attained the sum of 31,152,000 marks.

Government and Administration.—After the year of annexation to Russia, 1809, up till 1898, Finland was considered as a separate state, the head of which, or grand duke, is the Emperor of Russia, and which is governed by the grand duke and the Diet, composed of representatives of the four estates—nobility, clergy, burghers, and peasants (30 per cent. only of the population having the franchise). The finances, the judicial, educational, clerical, and economic administration were entirely in the hands of the Diet and the Finnish senate, nominated by the Emperor (see *Ency. Brit.*, 9th ed.). The minister of war, however, had to be the Russian war minister, and the minister of foreign affairs the Chancellor of the Russian empire. Several encroachments, however, have been made since upon that independent organization: the posts of Finland were brought under the Russian post-administration, and an Imperial decree promulgated in 1898 established the right of the Imperial power to recognize certain matters (and specially military service) as Imperial matters, and to act accordingly without the consent of the Diet, while the use of the Russian language was to be rendered obligatory in various branches of the administration and the courts. This attempt to Russify Finland led to a serious agitation in protest, but without success; and many Finns left the country rather than submit.

Ethnology, Ethnography, Archæology.—Considerable researches have been accomplished since about 1850 in these subjects, on a scale which has no parallel in any other country. The study of the prehistoric population of Finland—Neolithic (no Palæolithic finds have yet been made)—of the Age of Bronze and the Iron Age has been carried on with great zeal. At the same time the folk-lore, Finnish and partly Swedish, has been worked out with wonderful completeness (see *L'Œuvre demi-séculaire de la Société de Littérature Finnoise et le mouvement national Finnois*, by Dr E. G. Palmén, Helsingfors, 1882, and K. Krohn's Report to the London Folk-lore Congress of 1891). The work that was begun by Porthan, Z. Topelius, and especially E. Lönnrot (1802–1884), for collecting the popular poetry of the Finns, was continued by Castrén (1813–1852), Europaeus (1820–1884), and V. Porkka (1854–1889), who extended their researches to the Finns settled in other parts of the Russian empire, and collected a considerable number of variants of the Kalevala and other popular poetry and songs. In order to study the different eastern kinsfolk of the Finns, Sjögren (1792–1855) extended his journeys to North Russia, and Castrén to West and East Siberia (*Nordische Reisen und Forschungen*), and collected the materials which permitted himself and Schiefner to publish grammatical works relative to the Finnish, Lappish, Zyrian, Tcheremiss, Ostiak, Samoyede, Tungus, Buryat,

LONDON FIRE BRIGADE, HORSED ESCAPE.

LONDON FIRE BRIGADE STATION.

Karagas, Yenisei-Ostiak, and Kott languages. Ahlqvist (1826–1889), and quite a phalanx of linguists, continued their work among the Vogules, the Mordves, and the Obi-Ugrians. And finally, the researches of Aspelin (*Foundations of Finno-Ugrian Archœology*, in Finnish, and *Atlas of Antiquities*) led the Finnish ethnologists to direct more and more their attention to the basin of the Yenisei and the Upper Selenga. A series of expeditions (of Aspelin, Snellman, and Heikel) were consequently directed to those regions, especially since the discovery by Yadrintseff of the remarkable Orkhon inscriptions (see MONGOLIA), which finally enabled the Danish linguist, V. Thomsen, to decipher these inscriptions, and to discover that they belonged to the Turkish Iron Age. (See *Inscriptions de l'Iénissei recueillies et publiées par la Société Finl. d'Archéologie*, 1889, and *Inscriptions de l'Orkhon*, 1892.)

See also RUSSIA. Full bibliographical indexes of recent works as well as excellent general descriptions of Finland, will be found in *Travaux géographiques exécutés en Finlande*, published for the London Geographical Congress of 1895. Other works are *Atlas de Finlande*, with French *Texte*, published in 1899 by the Geographical Society of Finland; *Notices sur la Finlande*, published in 1900 for the Paris Exhibition; *Finland in the Nineteenth Century*, published on the same occasion; *La Constitution du Grand-Duché de Finlande; recueil de lois fondamentales*, &c.; and an excellent illustrated and detailed work *Finlandia* (1898), in which the country and its life are very well described, and the constitutional question is documentally dealt with so as to answer the arguments of the Russian imperialists (Ordin, &c.); this work contains a very complete bibliography in all branches. A good English book on the constitutional history is *Finland and the Tsars*, by JOSEPH FISHER, 2nd ed., London, 1900. (P. A. K.)

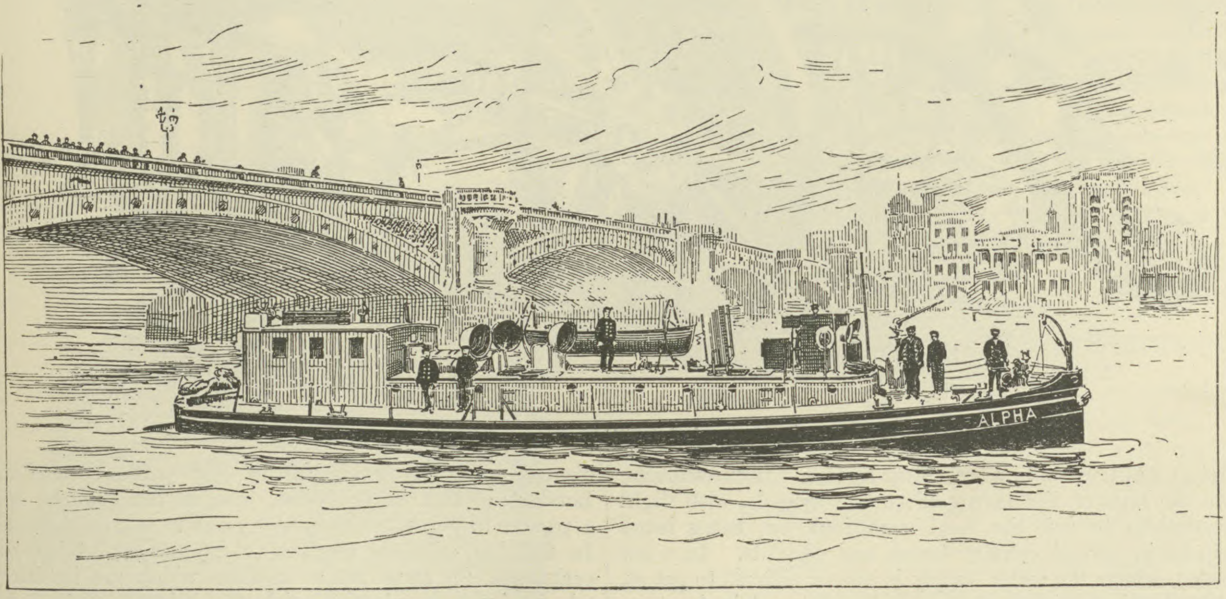
Finsterwalde, a town of Prussia, on the Schakebach, emptying into the Little Elster, 28 miles west-south-west of Cottbus by rail, in the circle of Luckau, government district of Frankfurt. The town has a Gothic church (1581), a castle, two girls' schools, cloth and cigar factories, iron-foundries, flour and saw mills, machinery factories, screws, &c. Population (1890), 8133; (1900), 10,726

FIRE AND FIRE EXTINCTION.

UNITED KINGDOM

In England it is only in recent years that the matter of fire protection on what may be termed efficient lines has been seriously considered. A committee of the House of Commons reported in July 1900 that, except in the large cities and towns, the fire arrangements, where any arrangements exist at all, were often inadequate, and that in the majority of places and districts there were practically no arrangements for protection against fire. The committee accordingly called attention to the need of legislation upon the subject.

Fire arrangements may be regarded from two points of view, *i.e.*, the saving of life, and the preservation of property; and it is possible for a force to be equipped with greater consideration to the saving of property than to the saving of life, or *vice versâ*. Roughly speaking, the appliances for life saving, such as ladders, poles, ropes, &c., are utilized more or less in saving property, as they enable firemen to get close to a fire, whether life has to be saved or not. On the other hand, in country towns, it may be argued that provision of life-saving appliances may, to a certain extent, be disregarded, inasmuch as statistics show that very few, if any, deaths result from fire. In Great Britain and Ireland the fire service is recognized as a public service, and such questions as those of payments to brigades, of the amount of pecuniary assistance (if any) that insurance companies should contribute to the cost of brigades, of the protection of the fireman's uniform under the Uniforms Act 1894, of the powers given to the officers commanding brigades, &c., will probably be matters of legislation in the near future. There is no general statute, but London and a few of the larger cities work under their special and local Acts of Parliament. The Fire Brigade Act of 1865, a comparatively short and simple statute, gives the chief officer of the London fire brigade extensive authority to act on the occasion of fire, including powers "to take any measures

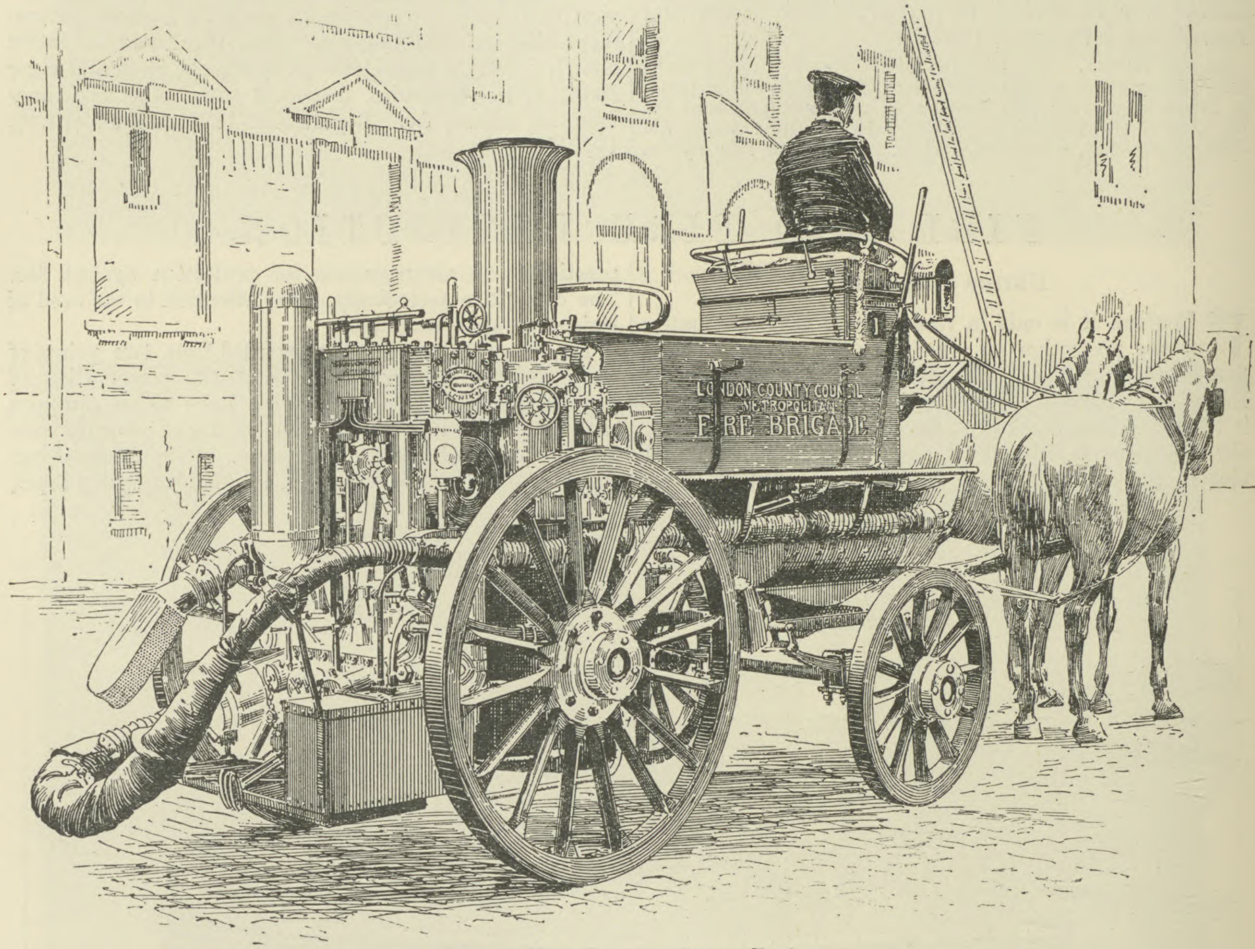


LONDON FIRE BRIGADE STEAM-FLOAT *ALPHA*.

that appear expedient for the protection of life and property."

The monthly summary for 1900 and the summary of causes of fire in 1900 (pp. 401–2) give an idea of the work done by the London fire brigade. The county of London, which is about 130 square miles in extent, contains sixty-nine stations, each commanded by an officer, and having life-saving and fire-extinguishing appliances adequate for dealing with a moderate-sized fire in that particular district. When a call is received at one of these stations (which are, generally speaking, about a mile apart) the whole strength of that station attends, and appliances are sent on from neighbouring stations to reinforce, according to the call received and the risk of the locality. In London, every machine, whether horsed-escape, fire-ladder, or steamer, is sent away as a complete unit, with a sufficiency of men, hose, &c., to get to work immediately on arrival. The London horsed-escape carries a 50-feet life-saving ladder, a coachman and four firemen, and is never sent out of the particular area for the protection of which it is provided.

The London County Council has, in recent years, spent, and continues to spend, large sums of money in improving the fire brigade, both on land and on the river, equipping it with the very best machines to suit the peculiarities of the water supply and other circumstances peculiar to London. Illustrations are given of a horsed-escape and a steam engine, and of the fire-float *Alpha*, the

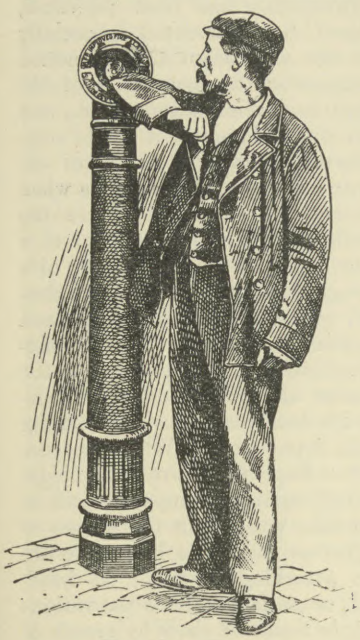


London Fire Brigade Steam Engine.

latest addition to London's river service. Improvements, on the lines of the metropolitan fire brigade, with slight variations to suit the local conditions, are being introduced in several country towns and districts. In a few cases, where the water supply is bad or difficult to get at, the chemical engine, such as is largely used in America, has been tried, but it cannot be said to have found favour generally. The smalier types of this machine, carried and worked by hand, are frequently used for indoor purposes, and it is a matter for the consideration of the householder whether these appliances, or some form of hand-pump, with buckets, afford the best "first aid" for indoor work in fire extinguishing pending the arrival of qualified firemen, who should invariably be promptly called on an outbreak of fire being discovered.

Fire-alarm posts, giving facilities for telephonic communication, of the simplest possible pattern are placed at distances varying from 300 to 800 yards throughout London, so that in few cases, save in the suburbs, has a person to run more than 400 yards to call the brigade. In addition, calls are received (*a*) by means of telephone exchanges, (*b*) from police stations which are in direct telephonic communication with the brigade, and (*c*) by persons running to fire stations. We give illustrations of the latest pattern of London alarm posts, and the method of using the telephone attachment.

One of the principal considerations with any brigade is to get the earliest possible call to a fire, and several forms of automatic alarm have been devised. Whether an electric bell be set ringing by the expansion of a thin wire under the influence of the heat produced by the fire, by the rising of mercury in a thermometer, by the melting of some particular compound at a low temperature, or by the fusing or metallic joining of the circuit wires, is a matter of choice to the occupier; but the main objects to him are (1) the reduction of his fire insurance premium, and (2) the reduction of loss to a minimum should an outbreak occur. It is possible that considerable advantage would accrue by the installation of an automatic alarm which would, at an early stage, attract the attention of the police on duty, who could verify the existence of a fire and then immediately call the brigade.



Fire-Alarm Post.

The method of insuring a deluge of water in the early stages of a fire is also proving itself, in certain cases, of advantage. This system is called the Sprinkler system, and consists of water pipes so traversing a building that on the application of heat the valve is automatically set free and the water descends in the neighbourhood of the fire. The system, devised in much the same way, of water curtain, or a stream of water striking the side of a building, doorway, or lift, has also been frequently installed, but the governing factor in these cases usually is the reduction of premium allowed to the occupier by the company which insures the premises and contents.

Fire-Alarm Post: Method of using Telephone Attachment.

Experiments have been carried out in London with a view to substituting oil for coal used in working steam engines, and some success has been met with. The practicability of substituting motor power for horses used in the traction of fire appliances is also being considered, and it is hoped that the change will result in economy, to say nothing of increased efficiency.

With a low-pressure water supply the time within which the steam, or other pumping power, can be available is a matter of the greatest importance, especially when coping with an outbreak in high buildings. For such buildings, the system of dry mains is viewed with favour. Under this system pipes to deliver water at suitable points are installed, but are not filled with water until the connexion is made to the water main or pump, as the case may be, outside the building.

The net cost to the ratepayers of the maintenance (including pensions) of the London fire brigade is about equal to a rate of $1\frac{1}{4}$d. in the pound, but in the country generally, where first-class volunteer labour can be obtained, it is quite possible to get a reasonably efficient brigade for something like a rate of a halfpenny in the pound. If this fact were generally appreciated, and districts could lay aside all municipal jealousies and freely help each other in the case of large fires, as is done by London and the larger towns, the result of the property loss would be far different.

The question has been discussed whether fire insurance companies should be legally required to contribute generally to the cost of maintaining fire brigades on some such system as obtains in London, where they pay £35 per million per annum on property insured. On the one hand, it is argued that there should be some general and fair system by which insurance companies should contribute towards the expenses of fire brigades, which in the ratio of their efficiency do so much for the benefit of the companies' shareholders; and on the other hand, it is argued that insuring is an industry of such essential benefit to the community that it is not expedient to tax it. Against the latter view, however, it is urged that if the industry be so profitable, the ratepayers should get the benefit of it, and this might lead either to municipal insurance or to the example of large railway companies, who are their own insurers, being followed by municipal authorities.

The strength of some of the principal brigades is as follows:—

London: 1216, including chief, second, and third officers and all ranks, also workshops, stores, and clerical staff.

Glasgow: 116, including chief officer, superintendent, and all ranks.

Manchester: 100, including chief officer and all ranks.

Belfast: 78, including chief officer and all ranks.

Birmingham: 65, including chief officer and all ranks.

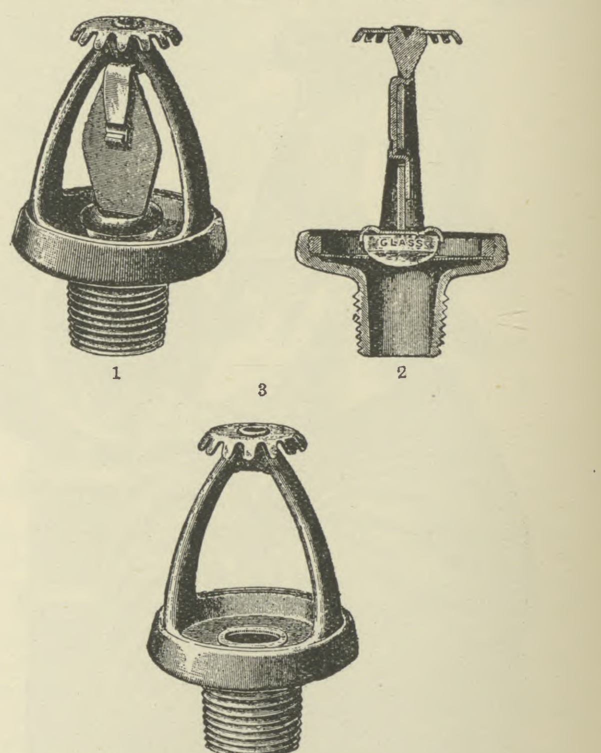
United States.

The freedom from great fires and conflagrations that has marked the years since 1875 in America is the more noteworthy because of the abnormal growth of large towns and cities, the great increase in number of extremely high buildings, and the development of great manufacturing establishments, all of which add enormously to the danger from fire. The fire-proof construction of buildings (see BUILDING) has been perfected, and many appliances have been invented, especially in the United States, for the prevention and extinction of fires. The fire departments in the large cities of the United States are organized on a semi-military basis, and in each city are under the entire charge of a single commissioner or board of commissioners. A "chief of department" is the executive officer on all occasions when the force is called into action. Under him are the "battalion" or "district-chiefs," each in command of a district of the city. Each engine company consists of a captain and lieutenant, engineman and assistant enginemen, and eight horsemen. Each ladder company has a captain, lieutenant, and twelve laddermen. The district-chief's driver is a telegraphist, and on reaching a fire stations himself at the nearest alarm box and opens telegraphic communication with headquarters, thus insuring instant control of the whole department. When the concentration of the force at a large fire leaves the neighbouring districts unprotected, outlying companies still in reserve are brought in and take position in the houses of those already called out, just as regiments in reserve are advanced to support the attacking column. At headquarters a covering board, or map on which the various engine houses are marked, is made to show by means of movable pegs the position of each company in action and in reserve.

Fire Prevention.—The *Automatic Sprinkler* is of conspicuous value in mills and factories, and similar buildings where the risks are great. It consists of lines of



FIGS. 1, 2, 3.—Automatic Sprinkler.

water pipes carried through the building near the ceiling, 8 or 10 feet apart. Sprinkler heads are attached on the upper side of the pipe. The main supply pipe must be large enough to give a discharge at full pressure from all of the sprinklers in the room at once. The sprinkler (Figs. 1, 2, 3) has a half-inch outlet, kept closed by a valve held in place by a device, an essential feature of which is an easily fusible solder. A fire starts and the heat quickly melts the solder; the valve is swept away by the water pressure; the half-inch stream bursts out, and striking against the deflector above is spread in a shower. Under ordinary conditions, from one to four sprinklers will extinguish the fire. In extreme cases all of the sprinklers in a room may be called into action. In the record of all of the American Associated Factory Mutual companies for the five and a half years ending 1st January 1900, it appears that of 563 fires where automatic sprinklers were called into play, 129 (60 without loss) were held by one automatic sprinkler, 88 (31 without loss) by two sprinklers, 61 (21 without loss) by three sprinklers, 44 (10 without loss) by four sprinklers, 40 (6 without loss) by five sprinklers. In the remaining 201 fires held by sprinklers (26 without loss), the sprinklers opening ranged from six to two hundred and fifty. The *Dry-Sprinkler System* is of value only where the water is liable to freeze. The pipes are filled with air under a pressure of say 10 lb. The opening of the sprinkler head by the heat allows the escape of the compressed air; the consequent loss of pressure unlocks a simple arrangement of levers and opens the water valve of the main feed pipe; the water under proper pressure then circulates through all of the sprinkler pipes.

Automatic Fire Alarm.—The system of the Boston Automatic Fire Alarm Company has been perfected during the period 1880–1901, and its efficiency proved. The essential feature is a "thermostat" or heat-detector, contained in a small round box about $2\frac{1}{2}$ inches in diameter with a perforated lid. It consists of a bent spring, made up of a strip of steel and one of brass welded together, the brass upon the outside of the curve. Its action depends on the greater expansion of the brass. One end only of the spring being fast, the heat causes the free end to bend inwards till it closes an electric circuit. These instruments are placed, usually at intervals of about 15 feet each way, upon the ceiling of a room, closet, or nook in the building, and are adjusted to act at any desired temperature, ordinarily at 130° to 150° F. These are connected with each other and with the "transmitter." The heat from even a very small fire rising to the ceiling quickly causes the thermostat to transmit the exact position of the fire to the office of the Company. The force of the fire department is usually on its way to the fire about one minute after the thermostat acts. The receiving, recording, and transmitting apparatus are the same in principle as the larger ones at the city fire alarm headquarters described below. With so sensitive an instrument a certain number of needless alarms seems inevitable, but its value is beyond question. In 1900 more than 600 buildings in Boston and 2000 in New York were equipped with these automatic fire alarms.

The *Fire Alarm System* consists (1) of street or signal boxes on a closed electric circuit, from which signals giving automatically the number of the box are sent to headquarters; (2) various receiving and recording instruments at headquarters; (3) apparatus for transmitting to the several houses of the department the number of the box signalled; and (4) a battery or other adequate source of electric power. The electric fire alarm telegraph, invented by Dr W. F. Channing and Moses G. Farmer, was first adopted in the United States at Boston in 1851. It had then 40 miles of wire in 5 circuits, 45 signal boxes, and 10 bells. In 1899 it had 1500 miles of wire, 624 signal boxes, 20 bells, 104 gongs, 90 tappers, and 35 circuits in use, with equipment for 70 circuits. During the twenty years to 1871 about twenty cities in the United States adopted the fire alarm system. By 1876 the number had increased to seventy-five. In the signal box is a clockwork (Fig. 4), which is set in motion by once pulling down the hook that projects through the inner door. This mechanism breaks and closes an electric circuit by means of a wheel, and thus telegraphs to headquarters four rounds of the number of the box. The box contains a lightning arrester, which also protects the mechanism against the high tension currents of the trolley

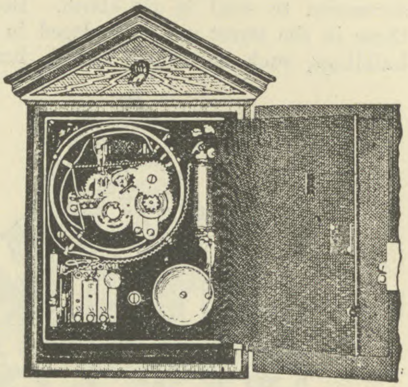


FIG. 4.—Alarm Clock.

and the electric-light wires, a telegraph key, and a call-bell for fire department and police signals. Keyless boxes (Fig. 5) have replaced the locked boxes in districts where they are less liable to be mischievously tampered with, and valuable time is thereby saved. To open the outer door the conspicuous handle is turned to the right, which rings the bell inside, and by calling attention to the fact that the box is being opened, acts as a safeguard against malicious false alarms. The alarm is given by pulling the handle projecting through the inner door, as already mentioned. When boxes are placed within short distances of each other two or more are liable to be pulled at the same moment for the

FIG. 5.—Keyless Box.

same fire. To obviate confusion in the record at headquarters, contiguous boxes are placed on different circuits, so that the number of each is recorded separately.

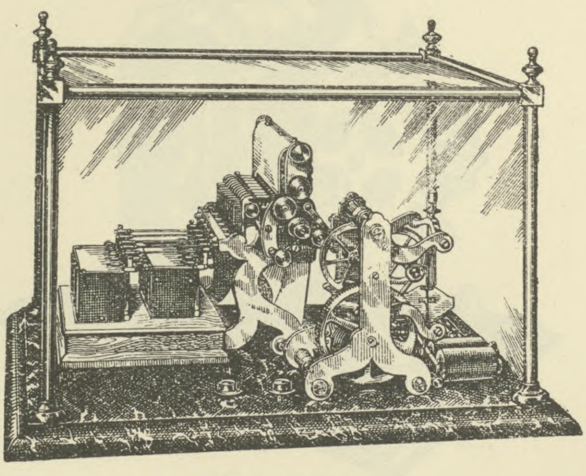

FIG. 6.—Register.

From twenty to twenty-five boxes are usually on a circuit. "Non-interference" boxes are designed to meet the same difficulty; the first box pulled is however the only one whose number is recorded. They are advisable when contiguous boxes are on the same circuit.

"Non-interference-successive" boxes contain a device which holds up all the other boxes until the first has finished its four rounds and then allows each box in succession to send in its alarm. Boxes in addition to those in the street are now placed in many large public buildings, such as school houses, hospitals, hotels and

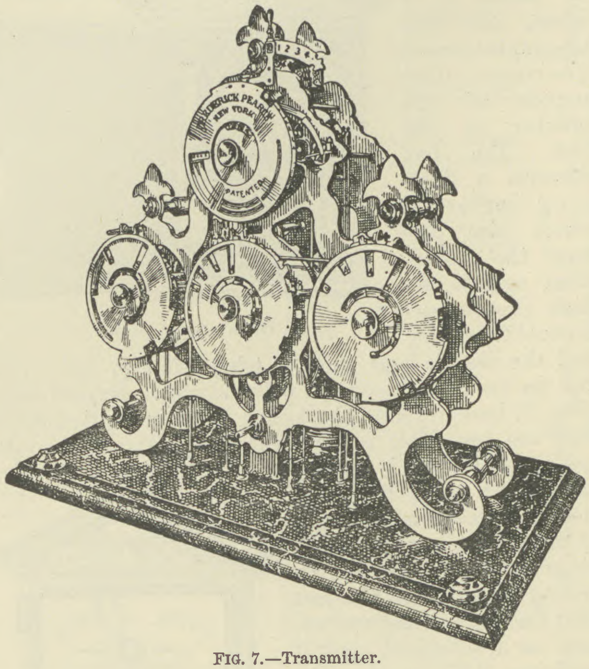

FIG. 7.—Transmitter.

theatres, and in many private buildings. Connected with each box small auxiliary boxes may be placed at various points in the buildings. At the fire alarm headquarters are appliances for transmitting the signals to the several houses of the department. The "register" (Fig. 6) receives through the relay and records the number of the

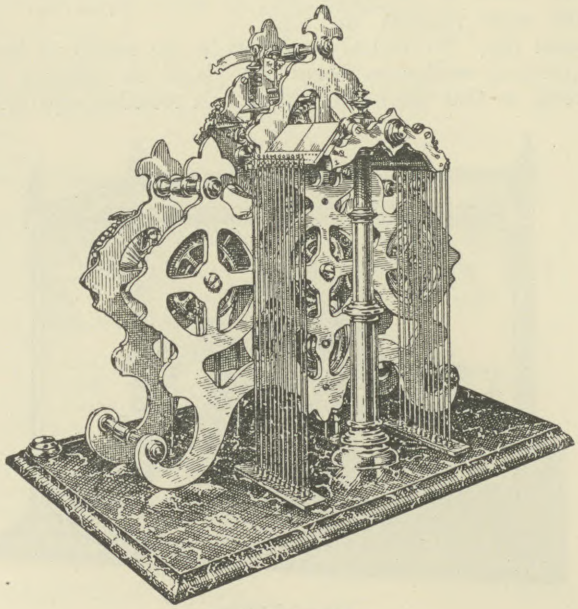

FIG. 8.—Transmitter.

alarm box upon a strip of paper that is automatically run out as soon as the box is started. Simultaneously a vibrating bell connected with the register strikes the same number. The "transmitter" (Figs. 7 and 8) is regulated by an arrangement of dials to strike upon the "tappers" in the department houses the combination of blows that makes up the number of the box. On the first intimation of an alarm the operators at headquarters take their positions, one at the receiver to observe and call out the number, and the other at the transmitter to set the dials as each figure of the number is called out. As soon as one round has been received the transmitter is released and strikes rapidly but distinctly on the tappers in each house three rounds. Before the alarm box has completed its four rounds the engines are well on their way to the fire. As soon as the tapper-transmitter stops, another similar transmitter on a different circuit strikes the alarm on the large gongs in the houses and on such public bells as may be necessary to notify the call-numbers of the suburban companies. The time consumed in sounding the alarm ranges from fifteen to thirty seconds, according as the number of the box is low or high. Electric motor generators have taken the place of the old chemical batteries to furnish the electric currents for all circuits.

Fire Engines.—The practical limit in the size of the horse-drawn engine has been reached. Engines of the first order have steam cylinders 9 inches in diameter and pumps 5½ inches in diameter with an 8-inch stroke in each. They are usually run at 120 ℔ steam pressure, and in practice seldom deliver much over 600 gallons a minute. "Self-propellers" of the latest form have double the capacity of the horse-drawn engine of a few years ago. They have steam cylinders 9½ inches in diameter and pumps 5¾ inches in diameter with an 8-inch stroke in each. At 300 revolutions the pumps will deliver 1036 gallons a minute. They stand in the houses always under a working pressure of steam. They weigh, when fully equipped, a little less than nine tons, but in spite of their great weight they are easily guided, and with an unobstructed roadway can always outstrip the horse-drawn engines. For the protection of shipping and the water front, steam fire boats are necessary. These are always under full steam, and usually lie at their regular dock. Their pumps, 10 inches in diameter with a 10-inch stroke, give at 225 revolutions 6520 gallons a minute. Such a power, the equivalent of nine average engines, makes them a most valuable part of the system.

In order to extend the radius of action, and more effectively to utilize this great power, Boston has a salt water fire system,[1] consisting of about 5000 feet of 12-inch cast-iron pipe, 1 inch thick, laid through the business district adjoining the water front. Each end of this pipe is at deep water accessible to the fire boats. At each end the pipe divides into two 10-inch pipes, each of which has a "boat connexion," with six 3½-inch outlets for attachment of hose. Each outlet has a valve opening inwards. One or both boats can connect, using 3½-inch hose in 15 to 30 feet lengths, with the twelve outlets or any less number. The maximum water pressure at the boat is 200 ℔ on the square inch. Hydrants are placed on the pipe 300 feet apart. The hydrants, known as the Bachelor Hydrant, are unusually heavy throughout, with three 3-inch outlets, each controlled by an independent valve. Each hydrant has an electrical attachment connecting with the fire boat and the headquarters of the department, so that the district chief, whose telegrapher-aid accompanies him to every fire, can control by telegraph the action of the boat, and can send and receive messages to and from headquarters. The pipe is kept full of salt water, but if it is found to be liable to excessive corrosion, it can be filled with fresh water immediately after service. One most valuable feature of this system is the concentration upon a given point of enormous streams of water drawn from an inexhaustible supply. In a test at one half mile from the water front, with one fire boat in service, two streams, each of 1500 gallons per minute, were played simultaneously through 2½-inch nozzles with a nozzle-pressure of 50 ℔, three lines of 3-inch hose being "Siamesed" for each stream. In Cleveland, Milwaukee, Detroit, and Buffalo, systems largely similar have been in successful operation for several years. The pipes in Boston are empty when not in service, at least during cold weather. The

[1] "Salt Water Fire System of Boston," by Frank A. McInnes. *Journal of the New England Water Works Association*, vol. xiii., No. 4.

FIG. 10.—Jumping Net.

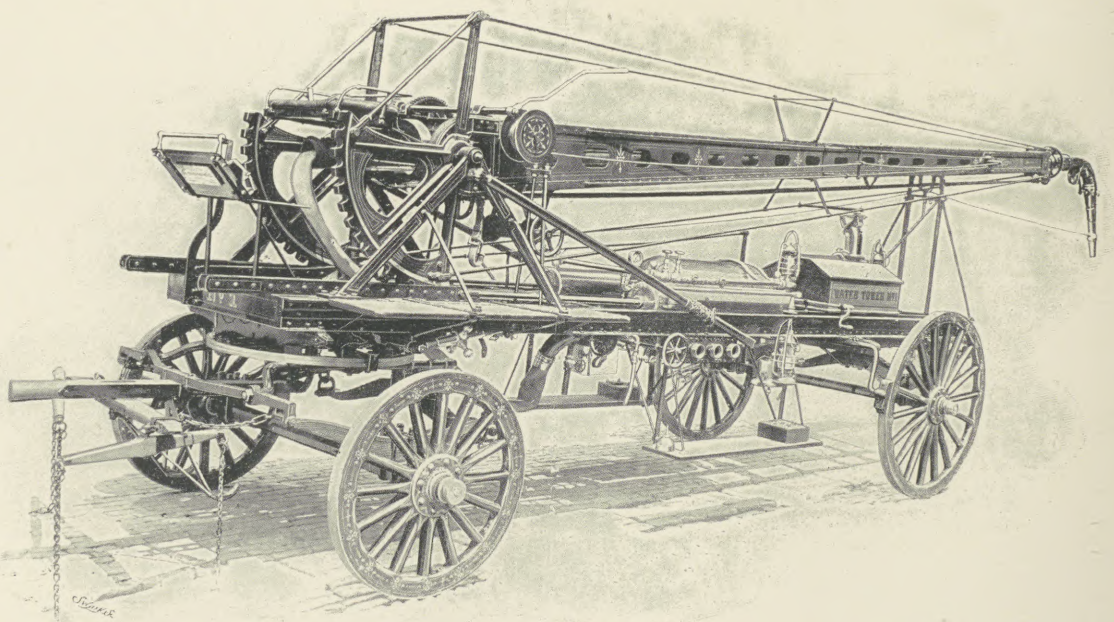

FIG. 11.—Water Tower.

elimination of the factor of frost in this way permits of shallow excavation, and probably prolongs the life of the pipe. The disadvantages are loss of time in filling the line, and the possibility of damage from imprisoned air in the operation of filling.

Chemical Engines and Portable Extinguishers[1] have proved their value in small fires, and are now largely used both in public and in private service. Of the 2130 fires in Boston reported for 1899, 19 per cent. were put out by chemical engines, and 22 per cent. by portable extinguishers. Some modifications in construction have been made, but no change in principle. The claim that the chemical ingredients are in themselves largely effective in quenching the fire has been disputed, but there is no question of the advantages of the instantly generated power. A greater development in the direction of private fire protection for hotels, theatres, and large business establishments, where a competent watchman or attendant is always assumed, is

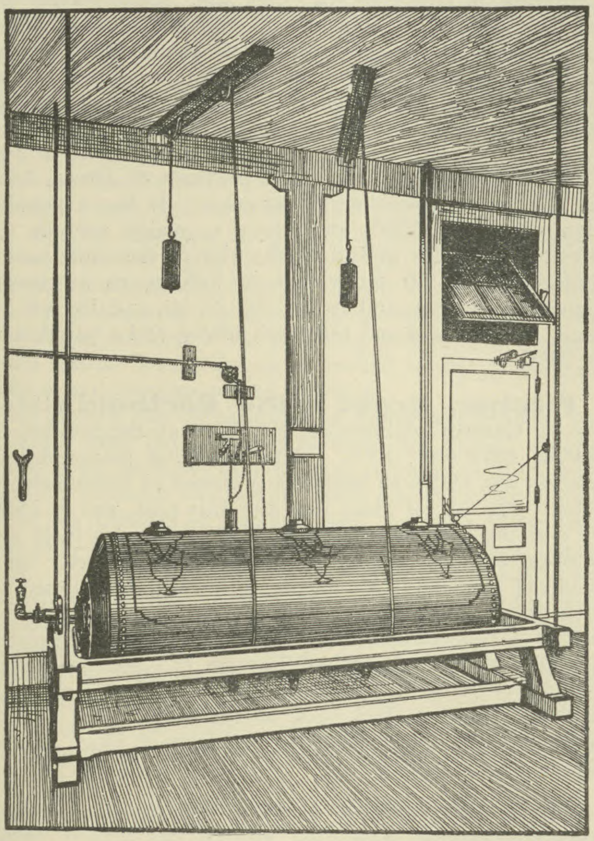

FIG. 9.—Champion Stationary Engine.

shown in the Champion Stationary Engine (Fig. 9). It is placed in the basement, and has special stand pipe connexion with one or more hose-stations on each storey. Each hose-station is covered by a small metal box with glass door. The pulling of the small handle inside releases the weights below; these invert the cylinder, and thereby cause the mixing of the chemicals and the immediate development of a heavy pressure. The process is to break the glass door, pull the handle, turn the valve, and reel off the hose, always attached, with its shut-off nozzle. The cylinder contains 500 gallons or less of the bicarbonate of soda solution. The stream is available in one minute.

Extension or "Aerial" Ladders are increasingly in use. The ladder is a permanent part of the truck which carries it, and is in two or three lengths; it is raised unextended to the proper angle by heavy screws worked by hand-cranks requiring six men; the upper lengths are then extended by a wire rope to the height desired; in use the upper end rests against the building. The details of construction and mechanism are varied by different builders, but the essential principle is the same. A line of hose is usually attached to the ladder and raised with it. The length, when fully extended, is from 90 to 100 feet. The truck carries in addition nine or ten separate ladders of different lengths. It weighs about five tons, and is drawn by three horses abreast.

Hose Waggons, drawn by two horses, have replaced the old hose reel. They carry the hosemen, 1000 feet of $2\frac{1}{2}$-inch hose, a jumping-net, two small portable chemical extinguishers, a door-opener, and the usual tools and minor pieces of apparatus.

The *Jumping Net* (Fig. 10) is made of stout tarred hemp rope, and is about 10 to 12 feet in diameter. It is essential that it be held firmly and fearlessly by a sufficient number of strong men. Firemen are drilled in its use. It has proved effective in saving life. (See Plate.)

By means of a *Water Tower* (Fig. 11, Plate) a powerful stream of water may be carried in a hose independent of the building, and delivered with full force at the height of 55 feet from the ground. The tower consists of a slender but stiff lattice iron frame, about 25 feet long, within which slides the extensible 5-inch round iron tube about 30 feet long that contains the hose. It is permanently mounted upon the waggon, lying horizontally as it is drawn to fires, and weighs all told about five tons. The waggon has an 8-foot gauge to insure a stable base. On reaching the fire the front axle is securely locked and the wheels are blocked. The tower is raised to the vertical by pressure from a carbonic acid gas-generating tank acting upon a piston with a rack geared into a quadrant at the base of the tower. The upper length, the extensible tube, is then raised, drawing up the hose with it, by a hand windlass. The tower is firmly locked. The direction of the stream from the movable pipe with its $2\frac{1}{2}$-inch nozzle can be controlled from below. The nozzle is rotated horizontally by means of an iron rod reaching from the base to the top, where it is geared into a small wheel, a part of the nozzle-pipe; it is raised to about 45° by the force of the stream, and lowered by a wire rope from below. The stout $3\frac{1}{2}$-inch hose of the tower takes its water from a chamber below, in which as many as six engine streams may be concentrated; the maximum volume and pressure are thus insured. The stream delivers upwards of 1000 gallons a minute. When a fire reaches a certain size and intensity, the ordinary $1\frac{1}{2}$- or $1\frac{3}{4}$-inch streams make little impression on it. To get sufficient concentration three or four lines of $2\frac{1}{2}$-inch hose are united or "Siamesed" into one larger one with a 3- or $3\frac{1}{2}$-inch nozzle, by means of a 3-way or 4-way brass casting to which they are coupled. Each inlet has its separate valve.

The *Gorter Battery* is convenient for concentrating as many as six ordinary streams into one. It weighs 1650 lb, and is drawn by one horse. When in action the weight is carried forward on to the shafts, which are fitted with spikes that take hold upon the ground and give the machine stability to withstand a back pressure of 1500 lb to the square inch. The nozzle is moved vertically in a ball-and-socket joint, and horizontally on a roller bearing. It throws a solid 2- to 3-inch stream 200 to 300 feet according to pressure. One man can easily control it, as the back pressure is taken up by the shafts.

Stand Pipes are used in "elevator buildings," which are too high to be commanded from the street or by dragging up the hose inside. The inside stand pipe is for use on a fire that has been promptly discovered. It is generally

[1] See *Ency. Brit.*, ninth edition, vol. ix. pp. 235–236.

connected with the city water system, and kept full of water under ordinary pressure, suitable lengths of hose ready for service being permanently attached on each floor. The outside stand pipe, from 4 to 6 inches in diameter, is for the use of the fire department; it stands empty; it

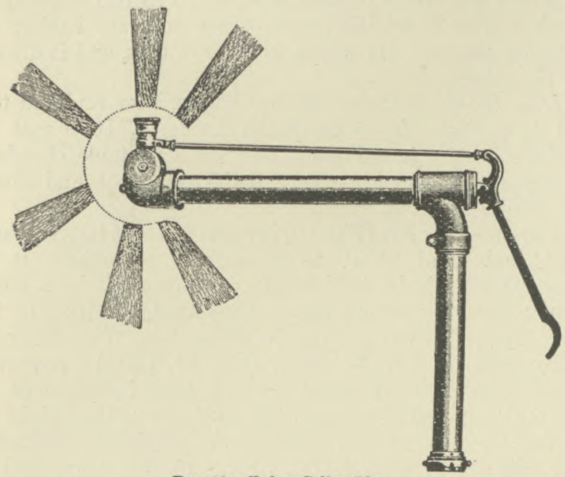

FIG. 12.—Baker Cellar Pipe.

has two or more inlets at or near the level of the sidewalk, to which hose from as many engines can be coupled, and two outlets on each storey to which short lengths of hose can be coupled and carried in through the adjacent windows. It should be placed in conjunction with a fire escape, if there is one, so that it may be easily reached by the fire-escape ladders.

The *Baker Cellar Pipe* (Fig. 12) has been found very effective in cellar fires. The pipe is passed through a hole cut in the floor over the fire; the nozzle is fitted with a ball-and-socket joint, and by means of the handle above the stream may be turned in nearly any direction. The *Bresnan Nozzle* is designed for the same use as the cellar pipe, and is perhaps equally effective; it has a revolving collar with a number of ½- and ⅝-inch outlets, so arranged as to throw streams in every direction and reach with its heavy spray every part of the cellar.

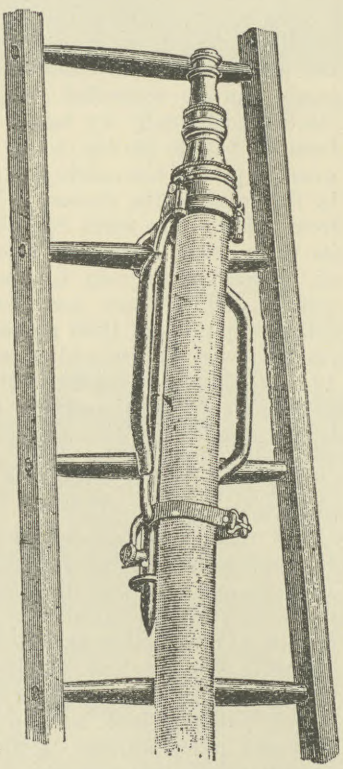

FIG. 13.—Eastman Nozzle Holder.

The *Eastman Nozzle Holder* (Fig. 13) dispenses with long play-pipes. It clasps the hose just below the nozzle, and the point, when fully drawn out, is planted in the ground and counteracts the back pressure from the nozzles, so that by means of the handles, insulated against electricity, one man can easily direct the heaviest stream. When used on a ladder, it may be hung by the hooks on the under side upon a rung or window-sill, and being pivoted at that point, the stream may be turned in any direction inside the window. The nozzle, about 10 inches long, contains in its middle length a short thin tube as a core, the diameter of which is three-fifths that of the nozzle at that point, held centrally by four wings fastened to the nozzle. The effect of this device is to correct the spiral movement of the water as it leaves the hose and to insure a smooth solid stream. By a system of electrical signals the man at the nozzle directs the action of the engine. Two insulated wires pass through the length of the hose, imbedded between two of its layers, and form an electrical circuit connecting a button on the nozzle and a bell and battery on the engine. The circuit is made continuous through the hose by the act of coupling. (A. P. R.)

Firminy, a town in the arrondissement of St Étienne, department of Loire, France, 7½ miles S.W. of St Étienne by rail. It has important coal mines and extensive manufacture of iron and steel goods, including railway material, machinery, and cannon. The mines have an annual output of about 92,000 tons, and give employment to about 4000 workmen. The principal textile industry is that of fancy woollen hosiery. Population (1881), 12,182; (1901), 16,903.

Fírúzkúh, a very small province of Persia, held in fief by the minister of arsenals. It has a population of about 5000, and pays a yearly revenue of about £400. Its capital is the city of the same name, situated about 90 miles east of Tehran, at an elevation of 6700 feet, and in 35° 46′ N. lat. and 52° 48′ E. long. It has post and telegraph offices, and a population of 2500.

Fischer, Ernst Kuno Berthold (1824–——), German philosopher, was born at Sandewalde in Silesia, 23rd July 1824. After studying philosophy at Leipzig and Halle, he became a professor at Heidelberg in 1850. His liberal ideas lost him this post, but in 1856 he obtained a professorship at Jena, where his lucid exposition and the dignity of his personal character soon rendered him highly influential. In 1872 he returned to Heidelberg. His part in philosophy has been that of historian and commentator, for which he was especially qualified by his remarkable clearness of statement. His *History of Modern Philosophy* (1852–77) is perhaps the most accredited modern book on the subject, and he has made valuable contributions to the study of Kant, Bacon, Spinoza, and Lessing.

Fish, Hamilton (1808–1893), American statesman, was born in New York city on 3rd August 1808. He graduated from Columbia College, and in 1830 was admitted to the bar, but practised for only a short time. In 1842 he was elected a Representative in Congress. In 1847 the Whigs elected him as lieutenant-governor of New York. In 1848 he defeated the Democratic candidate for the governorship. He was one of the United States Senators from New York from 1851 to 1857. In 1861 he was associated with John A. Dix, Wm. M. Evarts, Wm. E. Dodge, A. T. Stewart, and other New Yorkers, on the Union Defence Committee. As secretary of state during Grant's two administrations, 1869–77, he contributed to bring about the treaty of Washington, in May 1871, which created a basis for the arbitration of the *Alabama* claims. He was made president of the peace conference between Spain and the allied republics of Peru, Chile, Ecuador, and Bolivia. It was chiefly due to Fish's management in 1873 that the *Virginius* affair did not result in a war between the United States and Spain. He died in Garrison's, New York, on the 7th September 1893.

Fisheries.—In the last quarter of the 19th century the sea fisheries of the United Kingdom underwent a great development, principally in consequence of the application of steam power to fishing boats, and especially to trawling vessels. Necessity was in this case especially the mother of invention, for the industry of steam trawling dates its origin from a period of severe stagnation in the shipping trade in the later 'seventies. Some of the steam-tugs plying at the mouths of the Tyne and Wear resorted to trawling in the neighbourhood as an accessory occupation, and met with such success that the practice spread to other parts of the coast. The unsuitability of these "tug-trawlers" for deep-sea work necessarily placed a limit upon their operations, but the success of their experiments was more than enough to demonstrate the many advantages of steam for trawling purposes. A special type of fishing steamer, fitted with a screw instead of paddles, was soon under construction, enabling steam trawling to be prosecuted in distant as well as in home waters. Built at first of wood, but subsequently of iron, the steam trawler has undergone a continuous series of improvements, which have increased its strength, speed, storage capacity, and seaworthiness to such a pitch that it is now able to undertake the long and hazardous Icelandic voyage with remarkable regularity through winter and summer alike. The substitution of the otter or beamless trawl for the beam-trawl in 1894 also conduced to a great increase in the "catching power" of steam trawlers, especially as regards round fishes, such as cod and haddock, which swim some little distance above the actual sea-bed. The catching power of a modern steam trawler is regarded as equivalent to that of at least eight or ten deep-sea sailing trawlers.

An idea of the development of steam trawling may be gathered from the fact that in 1883 the fishing vessels sailing from the ports of Hull and Grimsby included less than 20 steamers and about 1000 sailing trawlers; in 1900 the number of steamers had increased to no less than 869, while the number of sailing trawlers had fallen to 4. In Scotland also the quantity of fish annually landed by trawlers (almost exclusively steam trawlers) has increased from 5 per cent. of the total in 1890 to 20 per cent. in 1900 (*cf.* Tables IX. and X.). In that country the development of the trawling industry and the prolongation of the herring fishery have brought about a decline of the line fishery, especially in recent years, the annual yield of the line fisheries having steadily fallen from 80,000 tons in 1890 to 38,000 tons in 1900 (*cf.* Table X.). In England and Wales it is difficult to say whether there has been any decline in the line fishery or not, owing to the absence of any discrimination between the products of the various modes of fishing in the official returns.[1] It has, however, been estimated that the number of first-class sailing liners belonging to the east coast of England fell from about 240 in 1889 to about 80 in 1898, while the number of steam liners increased from about 40 in 1889 to 100 in 1896, subsequently falling to 80 in 1898. The evidence of the Fishing Boats Register for 1893, 1899, and 1900 agrees with this estimate in showing a decrease of first-class sailing liners for the whole of England and Wales from 185 to 47, and an increase of steam liners from 56 in 1893 to 67 in 1899, falling to 63 in 1900. Thus if one steam liner be regarded as equivalent in catching power to four sailing liners, the English line fishery was probably holding its own until the year 1897, when it began to decline, apparently owing to the more lucrative character of trawl fishing. But the catch of halibut (an exclusively line-caught fish) has steadily increased throughout this period.

As regards the drift-net fishery, the supply of herrings and mackerel has been well maintained, 1897 having been a record year for mackerel on the south and east coasts of England, 1898 attaining the same distinction for herring in Scotland, while the annual catch of herrings in English waters first exceeded two million cwts. in the years 1899 and 1900. On the other hand, the conditions of the herring fishery have changed considerably during recent years. In Scotland the great summer herring fishery of the east coast has been supplemented by a winter and spring herring fishery which has attained considerable importance both on the east and west coasts, and an immense early summer fishery is now prosecuted on the west coast and in Orkney and Shetland, so that herring fishing is now followed at one part or another of the Scottish coasts during practically every month in the year. Indeed, the crews of many vessels which formerly worked at the herring and line fisheries in alternate seasons of the year now devote their energies almost entirely to the herring fishery, which they pursue in nomad fleets around all the coasts of Great Britain. Scottish crews now attend the English autumn herring fishery in far greater numbers than formerly, and with most successful results. These facts, together with the introduction of steam drift vessels, indicate a marked increase in the aggregate catching power employed in the herring fishery, and go far to explain the exceptionally heavy catches in recent years.

The yield of the Irish fisheries is still unimportant compared with that of the Scottish or English fisheries, but since 1887 a great development of the herring fishery has taken place. An increase of a less marked character is also noticeable in the records of the mackerel fishery, but it would be hazardous to draw conclusions from this feature, owing to the variable quantities of Irish mackerel which have been landed at English ports in the same period.

The total value of the sea fisheries of the United Kingdom in the year 1900, according to the official returns, was as follows:—

Fish Landed in	Excluding Shell-fish.	Including Shell-fish.
England and Wales	£6,610,000	£6,982,000
Scotland	2,326,000	2,401,000
Ireland	279,000	295,000
Total	£9,215,000	£9,678,000

No information is officially collected in England or Ireland as to the value of the vessels and gear employed in the fisheries of these countries, but as data under this head have been collected for some years past by the Fishery Board for Scotland, it is possible to frame a rough, but sufficiently correct, estimate of the total value for the United Kingdom, since the numbers and tonnage of the fishing vessels are known for all three countries.

[1] The need of a properly organized Fishery Department for the United Kingdom has often been urged. If further evidence were necessary, it might be drawn from the fact that although an Order in Council, dated 1869, provided that a Register of Sea Fishing Boats, subject to annual revision, should be *kept*, and should record among other details the "ordinary mode of fishing" of every vessel, the data under this head have never been published by the Commercial Department responsible for them; and the very existence of the data appears to have been unknown to the Board of Trade Inspectors of Sea Fisheries as late as the year 1899 (cf. *Thirteenth Annual Report of Inspectors* for 1898, p. 10). The matter was investigated the following year at the instance of the writer of this article, with the result that the annual reports of the inspectors now contain a valuable table giving authentic information on this head based on the Register. The regretable fact was, however, elicited that the "returns prior to 1893 no longer exist"—a loss which is irreparable for statistical purposes, and appears to have involved a distinct breach of the Order in Council which established the Register in the first place.

The subjoined estimate is based on the returns for 1900. It has been presumed that the average value of fishing gear per ton tonnage of fishing vessels is greater in Scotland than in England, owing to the greater proportion of trawlers among the English vessels, and the smaller cost of trawling gear as compared with nets and long lines:—

Estimate of Value of Fishing Boats and Gear employed in 1900 (the *values* are authenticated for Scotland only).

	Number.	Class of Boat.	Tons.	Value of Boats.		Value of Gear.		Grand Total.
				Per Ton.	Total.	Per Ton.	Total.	
				£	£	£	£	£
England and Wales	1,251	Steamers.	67,484	100	6,748,400	4	269,936	
	8,384	Other boats.	95,009	8	760,792	5	475,495	
					7,509,192		745,431	8,254,623
Scotland	252	Steamers.	9,320	97	904,630	4·2	39,178	
	10,973	Other boats.	108,384	7·7	831,670	6·9	749,819	
					1,736,300		788,997	2,525,297
Ireland	9	Steamers.	95	100	9,500	4	380	
	7,887	Other boats.	28,121	8	224,968	5	140,605	
					234,468		140,985	375,453
United Kingdom (total)	1,512	Steamers.			9,479,960		1,675,413	11,155,373
	27,244	Other boats.						

History.—A brief review may now be given of the history of the administration of the sea fisheries since 1877, and of the attainment of scientific and statistical information in relation thereto.

In 1878 a commission was given to Messrs Buckland and Walpole to inquire into the alleged destruction of the spawn and fry of sea-fish, especially by the use of the beam-trawl and ground-seine.

In 1882 the former Board of British White Herring Fishery was dissolved and the Fishery Board of Scotland instituted, the latter being empowered to take such measures for the improvement of the fisheries as the funds under their administration might admit of. Under the Sea Fisheries (Scotland) Amendment Act of 1885 the Board closed the Firth of Forth and St Andrews Bay against trawlers as an experiment for the purpose of ascertaining the result of such prohibition on the supply of fish on the grounds so protected. The Treasury also, by a further grant of £3000, enabled the Board to purchase the steam-yacht *Garland* as a means of carrying out regular experimental trawlings over the protected grounds. Reports on the results of these experiments have been annually published, and were summarized at the end of ten years' closure in the Board's Report for 1895. Dr Fulton's summary showed that "no very marked change took place in the abundance of food-fishes generally, either in the closed or open waters of the Firth of Forth or St Andrews Bay" as a consequence of the prohibition of trawling. Nevertheless, among flat fishes, plaice and lemon soles, which spawn off-shore, were reported to have decreased in numbers in all the areas investigated, whether closed or open, while dabs and long rough dabs showed a preponderating, if not quite universal, increase.

The results of this classical experiment point strongly to the presumptions (1) that trawling operations in the open sea have now exceeded the point at which their effect on the supply of eggs and fry for the upkeep of the flat fisheries is inappreciable; and (2) that protection of in-shore areas alone is insufficient to check the impoverishment caused by over-fishing off-shore. The importance of these conclusions as regards the future administration of our sea fisheries cannot be too strongly urged. (For critical examinations of Dr Fulton's account see M'INTOSH, *Resources of the Sea*, London, 1899, and GARSTANG, "The Impoverishment of the Sea," *Journal of the Marine Biological Association*, vol. vi., 1900.)

In 1883 a Royal Commission, under the chairmanship of the late Earl of Dalhousie, was appointed to inquire into complaints against the practice of beam-trawling on the part of line and drift-net fishermen. A small sum of money (£200) was granted to the Commission for the purpose of scientific trawling experiments, which were carried out by Professor M'Intosh.

The Report of this Commission was an important one, and its recommendations resulted in the institution of fishery statistics for England, Scotland, and Ireland (1885–87).

In 1884 the Marine Biological Association of the United Kingdom was founded for the scientific study of marine zoology and botany, especially as bearing upon the food, habits, and life-conditions of British food-fishes, crustacea and molluscs. Professor Huxley was its first President, and Professor Ray Lankester, who initiated the movement, succeeded him. A large and well-equipped laboratory was erected at Plymouth, and formally opened for work in 1888. The Fishmongers' Company contribute £200 a year to the Association, and H.M. Government now contribute a sum of £1000. The Association publishes a half-yearly Journal recording the results of its investigations.

In 1886 a Fishery Department of the Board of Trade was organized under the Salmon and Freshwater Fisheries Act of that year. The Department publishes annually a return of statistics of sea-fish landed, a report on salmon fisheries (transferred from the Home Office), and a report on sea fisheries. It consists of several inspectors under an assistant secretary of the Board; it has no power to make scientific investigations or bye-laws and regulations affecting the sea fisheries. In 1894 the administration of the Acts relating to the registration of fishing vessels, &c., was transferred to the Fisheries Department.

In 1888 the Sea Fisheries Regulation Act provided for the constitution (by Provisional Order of the Board of Trade) of local Fisheries Committees having, within defined limits, powers for the regulation of coast fisheries in England and Wales. The powers of District Committees were extended under Part II. of the Fisheries Act, 1891, and again under the Fisheries (Shell Fish) Regulation Act, 1894. Sea fisheries districts have now been created round nearly the whole coast of England and Wales.

In 1893 a Select Committee of the House of Commons took evidence as to the expediency of adopting measures for the preservation of the sea fisheries in the seas around the British Islands, with especial reference to the alleged wasteful destruction of undersized fish. They recommended the adoption of a size-limit of 8 inches for soles and plaice, and 10 inches for turbot and brill, below which the sale of these fishes should be prohibited, on the ground that these limits would approximate to those already adopted by foreign countries.

In 1899 the Agriculture and Technical Instruction (Ireland) Act transferred the powers and duties of the inspectors of Irish fisheries to the Department of Agriculture and Technical Instruction for Ireland. The Department is provided with a steam cruiser, the *Helga*, 375 tons, fully equipped for fishery research, as well as with a floating marine laboratory. Mr Holt, formerly of the Marine Biological Association, was appointed to take charge of the scientific work.

In 1900 another Select Committee of the House of Commons was appointed to consider and take evidence on the proposals of the Sea Fisheries Bill, which had been framed in accordance with the recommendations of the Select Committee of 1893, but had failed to pass in several sessions of Parliament. Owing to marked divergences of opinion on the question whether the low size-limits proposed would be effectual in keeping the trawlers from working on the grounds where small fish congregated, the Committee reported against the Bill, and urged the immediate equipment of the Government Departments with means for undertaking the necessary scientific investigations.

In May 1901 an International Conference of Representatives of the North Sea Powers met at Christiania to draw up final proposals for a scientific exploration of the North Sea in the interests of the fisheries, to be undertaken concurrently by all the countries bordering on the North Sea. The British Government was represented by Sir Colin Scott Moncrieff, K.C.M.G., C.S.I., with Professor D'Arcy Thompson, Mr W. Garstang, and Dr H. R. Mill as advisers. The proposals having been accepted by the participating Governments, the work of systematic exploration was expected to begin in the course of 1902.

Statistics.—The following tables summarize the official statistics of fish landed on the coasts of England and Wales, Scotland and Ireland, and give some information relative to the numbers of fishing-boats and fishermen in the three countries. The Irish statistics of shell-fish must throughout be treated cautiously, owing to the inadequate means at the disposal of the authorities for collecting complete statistics over large sections of the coast.

TABLE I.—Quantity and Average Landing Value of FLAT FISHES landed on the Coasts of ENGLAND and WALES (all caught with trawl-nets, except Halibut).

Year.	Quantity (in Thousands of Cwts.).					Average Price (per Cwt.).

TABLE VII.—Number of Fishing Boats on the Register for 1900 (excluding vessels navigated by oars only), compared with the average number registered in preceding periods.

Year.	England and Wales.		Scotland.		Ireland.		United Kingdom (including Isle of Man and Channel Isles).	
	1st Class.	2nd Class.	1st Class.	2nd Class.	1st Class.	2nd Class.	1st Class.	2nd Class.
1878–1882	3809	6094	3881	8365	462	3333	8503	18,160
1888–1892	3905	4151	3816	6698	443	2929	8464	14,099
1900	3176	3959	3375	6237	364	3818	7124	14,317

Note.—1st Class = boats of 15 tons and upwards; 2nd Class = boats of less than 15 tons, navigated otherwise than by oars only. In England and Wales, the Channel Isles, and Isle of Man, but not in Scotland or Ireland, undecked boats fishing within territorial limits have been exempted from compulsory registration since 1880.

TABLE VIII.—Number (A) of Men and Boys constantly Employed and (B) of other Persons occasionally Employed in Fishing.

Year.	England and Wales.		Scotland.		Ireland.		United Kingdom.	
	A	B	A	B	A	B	A	B
1890	32,503	9312	34,319	20,829	10,121	13,981	78,450	46,337
1895	32,229	8995	31,044	12,329	8,692	18,218	73,090	41,230
1900	31,589	7994	27,288	10,288	8,677	18,982	68,708	37,814

Note.—The above table takes no account of persons employed in unregistered boats, of which there are many in England and Wales.

TABLE IX.—Total Quantity of the more important Bottom Fishes[1] landed at certain Ports in the North Sea from 1891 to 1900.

Year.	Hull, Grimsby, and Boston.	N. Shields, Sunderland, Hartlepool, Scarborough, Yarmouth, Lowestoft, & Ramsgate.	Year.	Hull, Grimsby, and Boston.	N. Shields, Sunderland, Hartlepool, Scarborough, Yarmouth, Lowestoft, & Ramsgate.
	Cwts.	Cwts.		Cwts.	Cwts.
1891	1,565,165	570,818	1896	2,342,740	553,788
1892	1,639,129	579,538	1897	2,399,706	520,944
1893	1,776,338	625,283	1898	2,509,320	508,940
1894	1,971,508	575,180	1899	2,667,008	534,818
1895	2,193,998	623,743	1900	2,866,172	568,751

[1] The Bottom Fishes here included are cod, haddock, hake, ling, soles, turbot, plaice, and halibut, all of which are caught by trawls or lines. The table shows the steady increase of supplies at the ports which are the centres of the steam trawling industry (Hull, Grimsby, and Boston), and which receive the products of the Icelandic and Faröe fisheries, as contrasted with the declining character of the supplies at other ports (N. Shields, &c.), which depend exclusively on the products of the older fishing grounds in the North Sea.

TABLE X.—Catch and Value of Line-caught and Trawled Fish landed in Scotland in 1890, 1895, and 1900.

Year.	Line-caught Fish.		Trawled Fish.

(W. GA.)

Fishery (Law of).—This subject has, (1) its International aspect; (2) its Municipal aspect; and each requires separate consideration.

On the high seas outside territorial waters the right of fishery is now recognized as common to all nations. Claims were made in former times by single nations to the exclusive right of fishing in tracts of open sea; such as that set up by Denmark in respect of the North Sea, as lying between its possessions of Norway and Iceland, against England in the 17th century, and against England and Holland in the 18th century, when she prohibited any foreigners fishing within 15 German miles of the shores of Greenland and Iceland. This claim, however, was always effectively resisted on the ground stated in Queen Elizabeth's remonstrance to Denmark on the subject in 1602, that "the law of nations alloweth of fishing in the sea everywhere even in seas where a nation hath propertie of command." The latest enunciation of this principle is to be found in the award of the Arbitration Court which decided the question of the fur-seal fishery in Bering Sea in 1894. (See Arbitration, International.) The right of nations to take fish in the sea may, however, be restrained or regulated by treaty or custom; and Great Britain has entered into Conventions with other nations with regard to fishing in certain parts of the sea. The provisions of such Conventions are made binding on British subjects by statutes.

Instances of these are the Conventions of 1818 and 1872 between Great Britain and the United States as to the fisheries on the eastern coasts of British North America and the United States within certain limits, and the award of the Bering Sea arbitration tribunal under the treaty of 1892; the Conventions between Great Britain and France in 1839 and 1867 as regards fishing in the seas adjoining these countries, the latter of which will come into force on the repeal of the former; the Convention of 1882 between Belgium, Denmark, France, Germany, Great Britain and Holland, regarding the North Sea fisheries; that of 1887 between the same parties concerning the liquor traffic in the North Sea; and the Declaration regarding the same waters made between Great Britain and Belgium for the settlement of differences between their fishermen subjects in such extra-territorial waters. At the instance of the Swedish Government the British Parliament also passed an Act in 1875 to establish a close time for the seal fishery in the seas adjacent to the eastern coasts of Greenland.

Cases have come before British Courts with regard to the whale fishery in northern and southern seas; and the customs proved to exist among the whaling ships of the nations engaged in a particular trade have been upheld if known to the parties to the action. In territorial waters, on the other hand, fishery is a right exclusively belonging to the subjects of the country owning such waters, and no foreigners can fish there except by convention.

(*a*) *Tidal Waters.*—In British territorial waters, it may be stated, as the general rule, that fishery is a right incidental to the soil covered by the waters in which that right is exercised.

The bed of all navigable rivers where the tide flows and reflows, and of all estuaries or arms of the sea, is vested in the Crown: and, therefore, in Lord Chief Justice Hale's words, "the right of the fishery in the sea and the creeks and arms thereof is originally lodged in the Crown, as the right of depasturing is originally lodged in the owner of the waste whereof he is lord, or as the right of fishing belongs to him that is the owner of a private or inland river." "But," he continues, "though the king is the owner of this great waste, and as a consequent of his propriety hath the primary right of fishing in the sea and the creeks and arms thereof, yet the common people of England have regularly a liberty of fishing therein as a public common of piscary, and may not without injury to their right be restrained of it unless in such places or creeks or navigable rivers where either the king or some particular subject hath gained a propriety exclusive of that common liberty" (*De Jure Maris*, ch. iv.).

This right extends to all fish floating in the sea or left on the seashore, except certain fish known as royal fish, which, when taken in territorial waters, belong to the Crown or its grantee, though caught by another person. These are whales, sturgeons, and porpoises; and grampuses are also sometimes added (whales, porpoises, and grampuses being "fishes" only in a legal sense). In Scotland only whales which are of large size can be so claimed; but the rights of salmon fishing in the sea and in public and private rivers, and those of mussel and oyster fishing, except in private rivers, are *inter regalia*, and are only enjoyable by the Crown or persons deriving title under it. As salmon fishery was formerly practised by nets and engines on the shore, and the mussel and oyster fisheries were necessarily carried on on the shore, the opinion was held at one time that angling for salmon was a public right, but the later decisions have established that the right of salmon fishing by whatever means is a *jus regale* in Scotland. In England, the Crown in early times made frequent grants of fisheries to subjects in tidal waters, and instances of such fisheries belonging to persons and corporations are very common at the present day: but by Magna Carta the Crown declared that "no rivers shall be defended from henceforth, but such as were in defence in the time of King Henry, our grandfather, by the same places and the same bounds as they were wont to be in his time;" and thus bound itself not to create a private fishery in any navigable tidal river. Judicial decision and commentators having interpreted this statute according to the spirit and not the letter, at the present day the right of fishery in tidal waters *primâ facie* belongs to the public, and they can only be excluded by a particular person or corporation on proof of an exclusive right to fish there not later in its origin than Magna Carta; and for this it is necessary either to prove an actual grant from the Crown of that date to the claimant's predecessor in title, or a later grant or immemorial custom or prescription to that effect, from which such an original grant may be presumed. This exclusive right of fishing may be either a franchise derived from the Crown, or may arise by virtue of ownership of the soil covered by the waters.

In Lord Hale's words: "Fishing may be of two kinds ordinarily, viz., fishing with a net, which may be either as a liberty without the soil, or as a liberty arising by reason of and in concomitance with the soil or an interest or propriety of it; or otherwise it is a local fishing that ariseth by or from the propriety of the soil,—such are *gurgites*, wears, fishing-places, *borachiæ*, *stachiæ*, which are the very soil itself, and so frequently agreed by our books. And such as these a subject may have by usage; either in gross, as many religious houses had, or as parcel of or appurtenant to their manors, as both corporations and others have had; and this not only in navigable rivers and arms of the sea but in creeks and ports and havens, yea, and in certain known limits in the open sea contiguous to the shore. And these kinds of fishings are not only for small sea-fish, such as herrings, &c., but for great fish, as salmons, and not only for them but for royal fish. . . . Most of the precedents touching such rights of fishing in the sea, and the arms and creeks thereof belonging by usage to subjects, appear to be by reason of the propriety of the very water and soil wherein the fishing is, and some of them even within parts of the seas" (*De Jure Maris*, ch. v.).

An instance of the former kind of fishery is to be found in the old case of *Royal Fishery of the River Bann* (temp. James I., Davis 655), and the modern one of *Wilson* v. *Crossfield* (1885, 1 T. L. R. 601), where a right of fishery in gross was established; but the latter kind, as Hale says, is much more common, and the presumption is always in its favour; *à fortiori* where the fishing is proved to have been carried on by means of engines or structures fixed in the soil. In England the public have not at common law, as incidental to their right of fishing in tidal waters, the right to make use of the banks or shores for purposes incidental to the fishery, such as beaching their boats upon them, landing there, or drying their nets there (though they can do so by proving a custom from which such a grant may be presumed); but statutes relating to particular parts of the realm, such as Cornwall for the pilchard fishery, give them such rights. In Scotland a right of salmon fishing separate from land implies the right of access to and use of the banks, foreshores, or beach for the purposes of the fishing; and so does white fishing by statute. But otherwise there is no right to do so, *e.g.*, in a public river for trout fishing. A similar privilege is given to Irish fishermen for the purpose of sea fishery by special statute. There is no property in fish in the sea, and they belong to the first taker; and the custom of the trade decides when a fish is taken or not, *e.g.*, in the whale fishery the question whether a fish is "loose" or not has come before English Courts.

(*b*) *Fresh Waters.*—In non-tidal waters in England and Ireland, for the reason given above, the presumption is in favour of the fishery in such waters belonging to the owners of the adjacent lands: "fresh waters of what kind soever do of common right belong to the owners of the soil adjacent, so that the owners of the one side have of common right the property of the soil, and consequently the right of fishing *usque ad filum aquae*, and the owners of the other side the right of soil or ownership and fishing unto the *filum aquae* on their side; and if a man be owner of the land on both sides, in common presumption he is owner of the whole river, and hath the right of fishing according to the extent of his land in length" (Hale, ch. i.). There is a similar presumption that the owner of the bed of a river has the exclusive right of fishery there, and this is so even though he does not own the banks; but these presumptions may be displaced by proof of a different state of things, *e.g.*, where the banks of a stream are separately owned the owner of one bank may show by acts of ownership exercised over the whole stream that he has the fishery over it all. The Crown prerogative of fishery never, it seems, extended to non-tidal waters flowing over the land of a subject, and it could not therefore grant such a franchise to a subject, nor has it any right *de jure* to the soil or fisheries of an inland lake such as Lough Neagh (*Bristow* v. *Cormican*, 1878, 3 App. Cas. 641). The public cannot acquire the right to fish in fresh waters by prescription or otherwise although they are navigable; such a right is unknown to law, because a profit *à prendre in alieno solo* is neither to be acquired by custom nor by prescription under the Prescription Act. It has been decided that the "dwellers" in a parish cannot acquire such a right, being of too vague a class; but the commoners in a manor may have it by custom; and the "free inhabitants of ancient tenements" in a borough have been held capable of acquiring a right to dredge for oysters in a fishery belonging to the corporation of the borough on certain days in each year by giving proof of uninterrupted enjoyment of it from time immemorial, on the presumption that this was a condition to which the grant made to the corporation was subject.

In Scotland the law is similar. The right to fish for trout in private streams is a pertinent of the land adjacent, and owners of opposite banks may fish *usque ad medium filum aquae;* and where two owners own land round a private loch, both have a common of fishing over it. The public cannot prescribe for it, for a written title either to adjacent lands or to the fishery is necessary. A right of way along the bank of a river or loch does not give it, nor does the right of the public to be on or at a navigable but non-tidal river. The right of salmon fishing carries with it the right of trout fishing: and eel fishing passes in the same way.

In England and Ireland private fisheries have been divided into (*a*) several (*separalis*), (*b*) free (*libera*), (*c*) common of piscary (*communis*), whether in tidal or non-tidal waters. The distinction between several and free fisheries has always been uncertain. Blackstone's opinion was that several fishery implied a fishery in right of the soil under the water, while free fishery was confined to a public river and did not necessarily comprehend the soil. He is supported by later writers, such as Woolrych and Paterson. On the other hand, the opinions of Coke and Hale are opposed to this view. "A man may prescribe to have a several fishery in such a water, and the owner shall not fish there; but if he claim to have common of fishery or free fishery the owner of the soil shall fish there" (Co. Littl. 122 A); "one man may have the river and others the soil adjacent: or one man may have the river and soil thereof, and another the free or several fishing in that river" (*De Jure Maris*, ch. i.). Lord Holt, though in one instance he distinguished them, in a later case thought that they were "all one." Later decisions have established the latter view, and it is now settled that although the owner of the several fishery is *primâ facie* owner of the soil of the waters, this presumption may be displaced by showing that the terms of the grant only convey an incorporeal hereditament, and that the words "sole and exclusive fishery" give a several fishery *in alieno solo.* In the words of Mr Justice Willes, "the only substantial distinction is between an exclusive right of fishery, usually called 'several,' and sometimes 'free,' as in 'free warren,' and a right in common with others, usually called 'common of fishery,' and sometimes 'free,' as in 'free port.' A several fishery means an exclusive right to fish in a given place, either with or without the property in the soil" (*Malcolmson* v. *O'Dea*, 1863, 10 H. L.). A common of piscary, or "a right to fish in common with certain other persons in a particular stream," is usually found in manors, the commoners of which may have the right to enjoy it to an extent sufficient for the sustenance of their tenements; but they cannot, except by immemorial special prescription, exclude the lord of the manor therefrom, and have no rights over the soil itself. Decisions also establish that a grant of "fishery" will *primâ facie* pass an exclusive fishery; a grant of soil covered by water or a lease of lands including water will pass the fishery therein; a several fishery will not merge on being resumed by the Crown; and a fishery situate within a manor is presumed to belong to the owners of adjacent land, and not to the lord. A several fishery, as already seen, being an incorporeal hereditament, can only be transferred by deed, and therefore cannot be abandoned, and so acquired by the public, even on proof that the public have, as far back as living memory, exercised the right of fishing in the *locus in quo* to the knowledge of and without interruption from the claimant of the fishery. But to establish a title to a several fishery, a "paper title," *i.e.*, one founded on documentary evidence only, is not sufficient; it must be supported by evidence of acts of ownership in recent times, for otherwise it will be presumed that a person other than the alleged owner is the real owner. If the waters of a tidal river leave their old channel and flow into another, the owner of a several fishery in the old channel cannot claim to have it in the new one; but, on the other hand, the owner of a several fishery can take advantage of a gradual encroachment by the river upon and into the land of a riparian owner, the limits of whose land are ascertained. The owner of an exclusive fishery, whether in tidal or fresh waters, has the right to take as many fish as he can, and may do so by means of fixed engines or dredging, provided that in navigable waters he does not interfere with the right of navigation, and that in navigable and other waters he does not interfere with the fishing rights of his neighbours or infringe the provisions made by old or modern statutes as to the methods of taking the fish, *e.g.*, by weirs. These were forbidden in rivers by Magna Carta and later statutes, and on the seashore by a statute of James I.; but all weirs in navigable fresh waters traceable to a date not later than 25 Edward III. are lawful, for the statutes forbidding weirs do not apply to navigable waters. It seems, however, that at common law any fixed structures put up by the owner of a fishery in his part of a river, which at all prevent the free passage of fish to the waters above or below, give the owners of fisheries therein a right of action against him. So the grantee of an exclusive fishery with rod and line in an unnavigable river can prevent any person from polluting the river higher up and so damaging the fishery. At common law there is no property in fish when enjoying their natural liberty; the taker is entitled to keep them unless they are caught from a tank or small pond; or except in the case of salmon by statute.

Modern statutes now regulate all fisheries, sea or fresh, in territorial or inland waters. As regards sea fishery in England, the Board of Trade has power by order to create sea fisheries districts, comprising any part of the sea within which British subjects have, by international law, the exclusive right of fishing, and to provide for the constitution of a local fisheries committee to regulate the sea fisheries in such district, which can make bye-laws for that purpose. It appoints fishery officers to enforce them, prescribes a close time for sea fish (which does not include salmon as defined in the Salmon Act), has summary jurisdiction over offences committed on the sea coast or at sea beyond the ordinary jurisdiction of a court of summary jurisdiction, can enforce the Sea Fisheries Acts, or regulate, protect, and develop fisheries for all or any kind of shell fish. Special provision is also made by statute for the oyster fishery and herring fishery (applicable also to Scotland), and that of mussels, cockles, lobsters, and crabs (applicable to all the United Kingdom). In Scotland the Fishery Board can constitute sea fishery districts, and boards with like powers to those in England, and has general control over the coast and deep-sea fisheries of Scotland; and there are Acts relative to herring, mussel, and oyster fisheries, and allowing the appropriation of money intended to relieve local distress and taxation towards the encouragement of sea fisheries, and marine superintendence and enforcement of Scottish sea fisheries laws. In Ireland the sea fisheries are under the direction of the Inspectors of Irish Fisheries, who have replaced the former Fishery Commissioners and Special Commissioners for Irish Fisheries; special statutes, besides the general ones applying to all the United Kingdom, deal with oyster fisheries (1845–1884), and mussel fisheries (1898); and one of 1899 appropriates £10,000 for sea fisheries under the head of technical instruction. In all three component parts of the United Kingdom there are also special statutes relative to salmon and freshwater fish: for England, the Salmon and Freshwater Fisheries Acts 1861–1891, and the Freshwater Fisheries Acts 1878 to 1886; for Scotland the chief Salmon Acts are those of 1862–1868, and for trout and freshwater fish those of 1845–1860; for Ireland, the Salmon and Trout Acts 1845–1870, and one of 1895, and the Eels Acts 1842, 1848. A similar scheme is adopted in each case, namely, fishery districts and district boards are set up which regulate the fishing by bye-laws and protect the fish by fixing a close time, and prescribing passes, licenses, inspection and the like, breaches of which are punishable by courts of summary jurisdiction. The supreme authorities in each case are—for England the Board of Trade, for Scotland the Fishery Board, and for Ireland the Inspectors of Fisheries, and in England a certain official number of conservators on such boards are appointed by the County Councils. There are special Acts dealing with the fishing in certain rivers, such as the Thames, Medway, Severn, Tweed and Esk. Throughout the United Kingdom the use of dynamite or other explosive substance to catch or destroy fish in any public fishery is prohibited, as it is also in England in any private waters subject to the Salmon and Freshwater Fisheries Acts 1878, in which it is also forbidden to use poison or other noxious substance for destroying fish. Officers in the army or marines are forbidden (under penalty) to kill fish without written leave from the person entitled to grant it. There are also provisions of the criminal law dealing with the protection of fisheries generally, as well as the provisions of the Acts already mentioned dealing with special kinds of fish.

Special provision is made by the Merchant Shipping Act 1894 for sea fishing boats (except in Scotland and the Colonies), relating to their registration, carrying official papers, carrying boats in proportion to their tonnage, the punishment of offences on board, the wages of their crews, and keeping record of all casualties, punishments and the like on board. As regards trawlers, especially in the case of those of 25 tons and upwards, a statutory form of agreement with the crew is prescribed, as well as accounts of wages and discharges; and skippers and second hands must have certificates of competency, which are granted under similar conditions to those required in the case of seagoing ships and are registered with the Board of Trade. Scottish fishing boats are regulated by a special statute of 1886 (except as regards agreements to pay crew by share of profits, dealt with by the above Act) and by the Sea Fisheries Act of 1868, which applies to all British fishing boats. Particular lights must be carried by fishing boats in navigation.

Fiske, John (1842–1901), American historical, philosophical, and scientific writer, was born in Hartford, Connecticut, 30th March 1842, and died at Gloucester, Massachusetts, 4th July 1901. His name was originally Edmund Fiske Green, but in 1855 he took the name of a great-grandfather, John Fiske. His boyhood was spent with a grandmother in Middletown, Connecticut; and prior to his entering college he had read widely in English literature and history, had surpassed most boys in the extent of his Greek and Latin work, and had studied several modern languages. He graduated at Harvard in 1863, continuing to study languages and philosophy with zeal; spent two years in the Harvard law school, and opened an office in Boston; but soon devoted the greater portion of his time to writing for periodicals. With the exception of one year, he resided at Cambridge, Massachusetts, from the time of his graduation until his death. In 1869 he gave a course of lectures at Harvard on the Positive Philosophy; next year he was history tutor; in 1871 he delivered thirty-five lectures on the Doctrine of Evolution, afterwards revised and expanded as *Outlines of Cosmic Philosophy* (1874); and between 1872 and 1879 he was assistant-librarian. After that time he devoted himself to literary work and lecturing on history. Nearly all of his books were first given to the public in the form of lectures or magazine articles, revised and collected under a general title, such as *Myths and Myth-Makers* (1872), *Darwinism and Other Essays* (1879), *Excursions of an Evolutionist* (1883), and *A Century of Science* (1899). He did much, by the thoroughness of his learning and the lucidity of his style, to spread a knowledge of

Darwin and Spencer in America. His *Outlines of Cosmic Philosophy*, while setting forth the Spencerian system, made psychological and sociological additions of original matter, in some respects anticipating Spencer's later conclusions. Of one part of the argument of this work Fiske wrote in the preface of one of his later books (*Through Nature to God*, 1899): "The detection of the part played by the lengthening of infancy in the genesis of the human race is my own especial contribution to the Doctrine of Evolution." In *The Idea of God as affected by Modern Knowledge* (1885) Fiske discusses the theistic problem, and declares that the mind of man, as developed, becomes an illuminating indication of the mind of God, which as a great immanent cause includes and controls both physical and moral forces. More original, perhaps, is the argument in the immediately preceding work, *The Destiny of Man, Viewed in the Light of his Origin* (1884), which is, in substance, that physical evolution is a demonstrated fact; that intellectual force is a later, higher, and more potent thing than bodily strength; and that, finally, in most men and some "lower animals" there is developed a new idea of the advantageous, a moral and non-selfish line of thought and procedure, which in itself so transcends the physical that it cannot be identified with it or be measured by its standards, and may or must be enduring, or at its best immortal.

It is principally, however, through his work as a historian that Fiske's reputation will live. His historical writings, with the exception of a small volume on *American Political Ideas* (1885), an account of the system of *Civil Government in the United States* (1890), *The Mississippi Valley in the Civil War* (1900), a school history of the United States, and an elementary story of the Revolutionary war, are devoted to studies, in a unified general manner, of separate yet related episodes in American history. The volumes have not appeared in chronological order of subject, but form a nearly complete colonial history, as follows: *The Discovery of America, with some Account of Ancient America, and the Spanish Conquest* (1892, 2 vols.); *Old Virginia and her Neighbors* (1897, 2 vols.); *The Beginnings of New England; or, The Puritan Theocracy in its Relations to Civil and Religious Liberty* (1889); *Dutch and Quaker Colonies in America* (1899); *The American Revolution* (1891, 2 vols.); and *The Critical Period of American History, 1783–1789* (1888). Of these the most original and valuable is the *Critical Period* volume, a history of the consolidation of the States into a government, and of the formation of the constitution. (C. F. R.)

Fitchburg, a city of Worcester County, Massachusetts, U.S.A., in 42° 35′ N. and 71° 50′ W., on the North Branch of the Nashua river, at an altitude of 433 feet. The site is hilly, and the city is built irregularly; the waterworks, owned by the city, derive their supply by gravity from Scott brook. It is on the main line of the Fitchburg Railroad, and on a branch of the New York, New Haven, and Hartford Railroad. Its manufactures are considerable; in 1895 there were 264 establishments, with a total capital of $8,079,412, employing 6185 hands, and producing goods valued at $10,629,400. The principal items of manufacture were worsted, cotton, iron and steel goods, and paper. Population (1880), 12,429; (1890), 22,037; (1900), 31,531, of whom 10,917 were foreign-born. The death-rate in 1900 was 13·6.

FitzGerald, Edward (1809–1883), the poet of Omar Khayyám, was born, as Edward Purcell, at Bredfield House, in Suffolk, on the 31st of March 1809. His father, John Purcell, who had married a Miss FitzGerald, assumed in 1818 the name and arms of his wife's family. From 1816 to 1821 the FitzGeralds lived at St Germain and at Paris, but in the latter year Edward was sent to school at Bury St Edmunds. In 1826 he proceeded to Trinity College, Cambridge, where, some two years later, he became acquainted with Thackeray and W. H. Thompson. With Tennyson, "a sort of Hyperion," his intimacy began about 1835. In 1830 he went to live in Paris, but in 1831 was in a farm-house on the battlefield of Naseby. He adopted no profession, and lived a perfectly stationary and rustic life, presently moving into his native county of Suffolk, and never again leaving it for more than a week or two. Until 1835 the FitzGeralds lived at Wherstead; from that year until 1853 the poet resided at Boulge, near Woodbridge; until 1860 at Farlingay Hall; until 1873 in the town of Woodbridge; and then until his death at his own house hard by, called Little Grange. During most of this time FitzGerald gave his thoughts almost without interruption to his flowers, to music, and to literature. He allowed friends like Tennyson and Thackeray, however, to push on far before him, and long showed no disposition to emulate their activity. In 1851 he published his first book, *Euphranor*, a Platonic dialogue, born of memories of the old happy life at Cambridge. In 1852 appeared *Polonius*, a collection of "saws and modern instances," some of them his own, the rest borrowed from the less familiar English classics. FitzGerald began the study of Spanish poetry in 1850, when he was with Professor E. B. Cowell at Elmsett, and that of Persian in Oxford in 1853. In the latter year he issued *Six Dramas of Calderon*, freely translated. He now turned to Oriental studies, and in 1856 he anonymously published a version of the *Salámán and Absál* of Jámi in Miltonic verse. In March 1857 the name with which he has been so closely identified first occurs in FitzGerald's correspondence—"Hafiz and *Omar Khayyám* ring like true metal." On the 15th of January 1859 a little anonymous pamphlet was published as *The Rubáiyát of Omar Khayyám.* In the world at large, and in the circle of FitzGerald's particular friends, the poem seems at first to have attracted no attention. The publisher allowed it to gravitate to the fourpenny or even (as he afterwards boasted) to the penny box on the bookstalls. But in 1860 Rossetti discovered it, and Mr Swinburne and Lord Houghton quickly followed. The *Rubáiyát* became slowly famous, but it was not until 1868 that FitzGerald was encouraged to print a second and greatly revised edition. Meanwhile he had produced in 1865 a version of the *Agamemnon*, and two more plays from Calderon. In 1880–81 he issued privately translations of the two Œdipus tragedies; his last publication was *Readings in Crabbe*, 1882. From 1861 onwards FitzGerald's greatest interest had centred in the sea. In June 1863 he bought a yacht, "The Scandal," and in 1867 he became part-owner of a herring-lugger, the "Meum and Tuum." For some years, till 1871, he spent the months from June to October mainly in "knocking about somewhere outside of Lowestoft." In this way, and among his books and flowers, FitzGerald gradually became an old man. On the 14th of June 1883 he passed away painlessly in his sleep. He was "an idle fellow, but one whose friendships were more like loves." In 1885 a stimulus was given to the steady advance of his fame by the fact that Tennyson dedicated his *Tiresias* to FitzGerald's memory, in some touching reminiscent verses to "Old Fitz." This was but the signal for that universal appreciation of Omar Khayyám in his English dress, which has been one of the curious literary phenomena of recent years. The melody of FitzGerald's verse is so exquisite, the thoughts he rearranges and strings together are so profound, and the general atmosphere of poetry in which he steeps his version is so pure, that no surprise need be expressed at the universal favour which the poem has met with among critical readers. But its popularity has gone much deeper than this; it is now probably better known to the general public than any single poem of its class published since the year 1860, and its admirers have almost transcended commonsense in the extravagance of their laudation. FitzGerald married, in middle life, Lucy, the daughter of Bernard Barton, the Quaker poet. Of FitzGerald as a man practically nothing was known until, in 1889, Mr W. Aldis Wright, his intimate friend and literary executor, published his *Letters and Literary Remains* in three volumes. This was followed in 1895 by the *Letters to Fanny Kemble.* These letters constitute a fresh bid for immortality, since they discovered that FitzGerald was a witty, picturesque, and sympathetic letter-writer. One of the most unobtrusive authors who ever lived, FitzGerald has, nevertheless, by the force of his extraordinary individuality, gradually influenced the whole face of English *belles-lettres*, in particular as it was manifested between 1890 and 1900. (E. G.)

Fitzroy, a city of Victoria, Australia, in the county of Bourke, 2 miles north-east of and suburban to Melbourne, with which it is connected by rail. It has several churches, a town hall, and public recreation ground, and is well served with tramways. Population (1881), 23,118; (1901), 31,610.

Fiume, a port and municipal town in Hungary. It has a rapidly growing commercial and maritime trade. In 1900 the number of vessels entered and cleared was 21,772, of 3,365,480 tons; the value of the imports was 90·8 million, that of the exports 165 million crowns. The Government has spent in the construction of the harbour 71·7 millions of crowns, and grants yearly subventions to the Royal Hungarian Steamship Navigation Company "Adria," as well as to the other smaller shipping enterprises, the registration port of which is Fiume. Population (1900), 38,955.

Fivizzano, a town of Tuscany, Italy, in the province of Massa and Carrara, on the W. slope of the Apennines, 17 miles E.N.E. from Spezia. It has mineral springs, one sulphurous (74°·7 Fahr.), another saline (54°·5); also marble quarries, silk spinning and weaving, lime-kilns, and olive-oil mills. Population about 13,800.

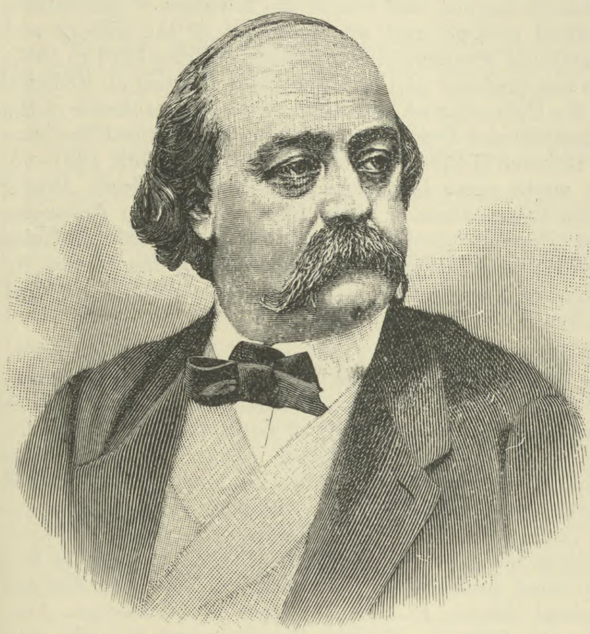
Flanders, two provinces of Belgium. I. WEST FLANDERS (Flemish, *West-Vlaanderen;* French, *Flandre occidentale*), bordering the North Sea, along a coast-line 42 miles long, France, the provinces of Hainaut and East Flanders, and the kingdom of Holland. The western part of the ancient Countship of Flanders, it was, when under the government of France, called the *département de la Lys.* Seawards, West Flanders is fringed by a line of dunes, along which, on the inland side, extend polders or alluvial lands. The subsoil of the province is sandy, but the surface has become modified in consequence of excellent cultivation. The land is a low-lying plain, except along the southern frontier, which presents a chain of hills over 300 feet high. The principal crops are cereals, flax, hemp, colza, chicory, tobacco. The live stock feeding on its good pastures numbers 200,000 head. The industries include agriculture, occupying 24 per cent. of the population, flax, cloth, table-linen, and lace, the manufacture of chicory and oils, of linen and colza, sea-fishing, employing 400 smacks and 2000 men. The coast is dotted with popular bathing-places—Ostend, Blankenberghe, Heyst, Knocke, Mariakerke, &c. The province is divided into eight administrative arrondissements. The chief towns are Bruges (with 53,000 inhabitants), the capital of the province, Ostend (38,500 inhabitants), Courtrai (33,500 inhabitants). The province has an area of 1249 square miles. The arrondissement of Courtrai is the one of densest population, 1134 to the square mile. The population of West Flanders, 696,651 in 1875, had increased by 113,793 in 1899, an increase of 16 per cent. (810,444, or 649 to the square mile).

II. EAST FLANDERS (Flemish, *Oost-Vlaanderen;* French, *Flandre orientale*), bordering on West Flanders, Hainaut, Brabant, and Antwerp, and the kingdom of Holland. The eastern part of the Countship of Flanders, established in the 9th century, was under the government of France (1795–1814) known as the *département de l'Escaut.* The land spreads out low and flat, rising a little towards the south. Muddy in the south, sandy in the north, the soil, by persistent cultivation, has been rendered fertile, more especially in the land of Waes, situated on the left of the Lower Escaut. The principal crops are cereals, flax, hemp, colza, and hops. The live stock includes 225,000 head of cattle and 200,000 pigs. More than a quarter of the population is engaged in agriculture. Other industries are the cotton manufacture, having Ghent for its principal seat; the industry in flax, thread, and cloths; the manufacture of woollen textures, pure and mixed with cotton; and roperies. The province is divided into six administrative arrondissements, having for their capitals Ghent (with 163,000 inhabitants), Eecloo (13,000 inhabitants), St Nicolas (30,300), Termonde (10,000), Alost (29,700), and Audenarde, or Oudenarde (8900). The province has an area of 1158 square miles. The arrondissement of Ghent has the greatest density of population, 1111 to the square mile. The population of the province, 868,228 in 1875, had added to that amount 166,203 by 1899 (1,034,431, or 893 to the square mile), an increase of 19 per cent.

Flatbush, formerly a township on Long Island, New York, near Brooklyn, and annexed to that city, with other parts of King's County, in 1894. (See BROOKLYN.)

Flaubert, Gustave (1821–1880), French novelist, was born at Rouen, on the 12th of December 1821. His father, in whom many traits are reproduced in "Charles Bovary," was a surgeon in practice at Rouen; his mother was connected with some of the oldest Norman families. He was educated in his native city, and did not leave it until 1840, when he came up to Paris to study law. He is said to have been idle at school, but to have been occupied with literature from the age of eleven. Flaubert in his youth "was like a young Greek," full of vigour of body and a certain shy grace, enthusiastic, intensely individual, and apparently without any species of ambition. He loved the country, and Paris was extremely distasteful to him. He made the acquaintance of Victor Hugo, and towards the close of 1840 he travelled in the Pyrenees and Corsica. Returning to Paris, he wasted his time in sombre dreams, living on his patrimony. In 1846, his mother being left quite alone through the deaths of his father and his sister Caroline, Flaubert gladly abandoned Paris and the study of the law together, to make a home for her at Croisset, close to Rouen. This estate, a house in a pleasant piece of ground which ran down to the Seine, became Flaubert's home for the remainder of his life. From 1846 to 1854 he carried on relations with the poetess, Mlle. Louise Colet; their letters have been preserved, and according to M. Faguet, this was the only sentimental episode of any importance in the life of Flaubert, who never married. His principal friend at this time was Maxime Du Camp, with whom he travelled in Brittany in 1846, and through the East in 1849.

Greece and Egypt made a profound impression upon the imagination of Flaubert. From this time forth, save for occasional visits to Paris, he did not stir from Croisset. On returning from the East, in 1850, he set about the composition of *Madame Bovary*. He had hitherto scarcely written anything, and had published nothing. The famous novel took him six years to prepare, but was at length submitted to the *Revue de Paris*, where it appeared in serial form in 1856. The Government brought an action against the publisher and against the author, on the charge of immorality, but both were acquitted; and when *Madame Bovary* appeared in book-form it met with a very warm reception. Flaubert now



GUSTAVE FLAUBERT.
(*From a photo. by P. Nadar, Paris.*)

settled down to the archæological studies which were required to equip him for *Salammbô*, which, however, in spite of the author's ceaseless labours, was not finished until 1862. He then took up again the study of contemporary manners, and, making use of many recollections of his youth and childhood, wrote *L'Éducation Sentimentale*, the composition of which occupied him seven years; it was published in 1869. Up to this time the sequestered and laborious life of Flaubert had been comparatively happy, but misfortunes began to gather around him. He felt the anguish of the war of 1870 so keenly that the break-up of his health has been attributed to it; he began to suffer greatly from a distressing nervous malady. His best friends were taken from him by death or by fatal misunderstanding; in 1872 he lost his mother, and his circumstances became greatly reduced. He was very tenderly guarded by his niece, Mme. Commonville; he enjoyed a rare intimacy of friendship with George Sand, and occasionally he saw his Parisian acquaintances, Zola, A. Daudet, Tourgenieff, the Goncourts; but nothing prevented the close of Flaubert's life from being desolate and melancholy. He did not cease, however, to work with the same intensity and thoroughness. *La Tentation de St Antoine*, which he had begun so long before as 1857, was at length completed and sent to press in 1874. In that year he was subjected to a disappointment by the failure of his drama *Le Candidat*. In 1877 Flaubert published, in one volume, *Un cœur simple*, *La légende de Julien l'Hospitalier*, and *Herodias*. After this something of his judgment certainly deserted him; he spent the remainder of his life in the toil of building up a vast satire on the futility of human knowledge and the omnipresence of mediocrity, which he left a fragment. This is the depressing and bewildering *Bouvard et Pécuchet*, which, by a curious irony, he believed to be his masterpiece. Flaubert had rapidly and prematurely aged since 1870, and he was quite an old man when he was carried off by a stroke of apoplexy at the age of only 58, on the 8th of May 1880. He died at Croisset, but was buried in the family vault in the cemetery of Rouen. A beautiful monument to him by Chapu was unveiled at the Museum of Rouen in 1890. The personal character of Flaubert offered various peculiarities. He was shy, and yet extremely sensitive and arrogant; he passed from silence to an indignant and noisy flow of language. The same inconsistencies marked his physical nature; he had the build of a guardsman, with a magnificent Viking head, but his health was uncertain from childhood, and he was neurotic to the last degree. This ruddy giant was secretly gnawn by misanthropy and disgust of life. His hatred of the "bourgeois" began in his childhood, and developed into a kind of monomania. He despised his fellow-men, their habits, their lack of intelligence, their contempt for beauty, with a passionate scorn which has been compared to that of an ascetic monk. Flaubert's curious modes of composition favoured and were emphasized by these peculiarities. He worked in sullen solitude, sometimes occupying a week in the completion of one page, never satisfied with what he had composed, violently tormenting his brain for the best turn of a phrase, the most absolutely final adjective. It cannot be said that his incessant labours were not rewarded. His private letters show that he was not one of those to whom easy and correct language is naturally given; he gained his extraordinary perfection with the unceasing sweat of his brow. One of the most severe of academic critics admits that "in all his works, and in every page of his works, Flaubert may be considered a model of style." That he was one of the greatest writers who ever lived in France is now commonly admitted, and his greatness principally depends upon the extraordinary vigour and exactitude of his style. Less perhaps than any other writer, not of France, but of modern Europe, Flaubert yields admission to the inexact, the abstract, the vaguely inapt expression which is the bane of ordinary methods of composition. He never allowed a *cliché* to pass him, never indulgently or wearily went on, leaving behind him a phrase which "almost" expressed his meaning. Being, as he is, a mixture in almost equal parts of the romanticist and the realist, the marvellous propriety of his style has been helpful to later writers of both schools, of every school. The absolute exactitude with which he adapts his expression to his purpose is seen in all parts of his work, but particularly in the portraits he draws of the figures in his principal romances. The degree and manner in which, since his death, the fame of Flaubert has extended, form an interesting chapter of literary history. The publication of *Madame Bovary* in 1857 had been followed by more scandal than admiration; it was not understood at first that this novel was the beginning of a new thing, the scrupulously truthful portraiture of life. Gradually this aspect of his genius was accepted, and began to crowd out all others. At the time of his death he was famous as a realist, pure and simple. Under this aspect Flaubert exercised an extraordinary influence over E. de Goncourt, Alphonse Daudet, and M. Zola. But even since the decline of the realistic school Flaubert has not lost prestige; other facets of his genius have caught the light. It has been perceived that he was not merely realistic, but real; that his clairvoyance was almost boundless; that he saw certain phenomena more clearly than the best of observers had done. Flaubert is a writer who must always appeal more to other authors than to the world at large, because the art of writing, the indefatigable pursuit of perfect expression, were always before him, and because he hated the lax felicities of improvization as a disloyalty to the most sacred procedures of the literary artist. (E. G.)

Flèche, La, chief town of arrondissement, department of Sarthe, France, 27 miles S.S.W. of Le Mans by rail, on a tributary of the Maine. The chief object of interest is the Prytanée, a famous school for the sons of officers, with accommodation for 600 pupils, occupying the buildings of an ancient Jesuit College. It stands in a fine park, and has a library of 20,000 volumes. In the market-place is a bronze statue of Henry IV. Starch, goloshes, sabots, and paper are manufactured. Population (1881), 6967; (1901), 10,519.

Fleetwood, a seaport and watering-place in the Blackpool parliamentary division of Lancashire, England, at the mouth of the Wyre, 8 miles north by east of Blackpool by rail. St Peter's church has been enlarged, and there are now market-buildings, and a free library and public hall. In the neighbourhood are salt works. The dock is provided with railways, and machinery for facilitating traffic; a large grain elevator has been erected. The shipping traffic is chiefly in the coasting and Irish trade. Regular communication with Scotland has been established. In 1900 the registered vessels belonging to the port were 81 sailing vessels of 5142 tons net, and 35 steamers of 4469 tons net; total, 116 vessels of 9611 tons. In 1900, 2607 vessels of 530,277 tons entered, and 2614 vessels of 548,698 tons cleared. Value of imports in the foreign and colonial trade (1900), £879,112; of exports of produce and manufactures of United Kingdom, £14,828. Area of urban district, 2510 acres. Population (1881), 6733; (1891), 9274; (1901), 12,093.

Flemington and Kensington, a borough of Victoria, Australia, in the county of Bourke, 3 miles north-west of and suburban to Melbourne, with one of the finest race-courses in the world. It has the city cattle market and abattoirs, the latter erected at a cost of about £60,000. Population (1901), 10,947.

Flensburg, a seaport town of Prussia, province of Schleswig-Holstein, at the head of the Flensburg Fjord of the Baltic, 39 miles by rail north by east from Rendsburg. It is a busy centre of trade and industry, importing coals and other commodities. In 1898 the port was cleared by 2049 vessels of 191,130 tons. The church of St Nicholas, built about 1390, was restored in 1894, and provided with a tower 295 feet high; the 13th century church of St Mary has also been provided with a tower 230 feet high. There are new law courts (1884) and a new theatre (1894). A technical school of wood-carving, a school of marine engineering, two schools of navigation, an agricultural school, and a commercial school are the principal educational adjuncts of a special character. Population (1885), 33,313; (1895), 40,840; (1900), 48,907.

Flers, a town in the arrondissement of Domfront, department of Orne, France, 37 miles, in direct line, north-west of Alençon, on the railway from Paris, and an affluent of the Noireau. There are a fine Norman church, a castle (restored) founded in the 5th century, a communal college, an industrial school, and a chamber of commerce. Manufactures are very important, and include a variety of cotton and linen fabrics, of which the annual value is about £1,500,000, also drugs and chemicals; and there are large brick and tile works, flour mills, and dyeworks. Population (1881), 9494; (1901), 13,683.

Flint, capital of Genesee County, Michigan, U.S.A., in 43° 01′ N. and 83° 41′ W., on Flint river, at an altitude of 709 feet. It is on the Grank Trunk and the Flint and Pere Marquette railways. The Michigan Institute for the Deaf and Dumb is situated here. Flint is largely a lumber town. It contains several large saw-mills, and produces much manufactured lumber. Population (1880), 8409; (1890), 9803; (1900), 13,103, of whom 2165 were foreign-born, and 257 negroes.

Flint, Austin (1812–1886), American physician, was born at Petersham, Massachusetts, 20th October 1812. He graduated at the medical department of Harvard University in 1833. He established the Buffalo *Medical Journal*, was one of the founders of the Buffalo Medical College, and was professor of the Theory and Practice of Medicine in that institution from 1847 to 1853. He was professor of the Theory and Practice of Medicine in the University of Louisville, 1852–56; professor of the Principles and Practice of Medicine and Clinical Medicine in Bellevue Hospital Medical College, New York, 1861–86. He wrote many text-books on medical subjects, among these being, *Diseases of the Heart* (1859-70); *Principles and Practice of Medicine* (1866); *Clinical Medicine* (1879); and *Physical Exploration of the Lungs by means of Auscultation and Percussion* (1882). He died in New York on 13th March 1886.

Flint, Austin (1836——), American physician, son of the foregoing, was born at Northampton, Mass., on 28th March 1836. He was educated at Harvard University and at the University of Louisville, Ky. (1854–56). He graduated at the Jefferson Medical College, Philadelphia, in 1857. In 1858 he became professor of Physiology and Microscopic Anatomy in the University of Buffalo, and in the year following professor of Physiology in the New York Medical College. In 1860 he was appointed professor of Physiology in the New Orleans Medical School; in 1861 professor of Microscopic Anatomy in Bellevue Medical Hospital; and in 1862 professor of Physiology in the Long Island College Hospital. He was better known as a teacher and writer on the subject of physiology than as a practitioner of medicine. His most exhaustive work, *Physiology of Man* (5 vols., 1866–74), never attained the popularity of his *Text-book of Human Physiology* (1876), which was for many years a standard text-book in the majority of American medical colleges. Among his other publications, the best known are, *Chemical Examination of the Urine in Disease* (1870), *Effects of Severe and Protracted Muscular Exercise* (1871), and *Service of Muscular Power* (1878).

Flintshire, a maritime county of North Wales, consists of a main and a detached portion. The main portion is bounded N.W. by the estuary of the Dee and Cheshire, and S.E., S., and S.W. by Denbigh. The detached portion, 8 miles to the S.E. of the main portion, is surrounded by Cheshire, Shropshire, and Denbigh.

Area and Population.—The area of the ancient county is 164,050 acres, or 256 square miles. Population (1881), 80,441; (1891), 77,277, of whom 38,242 were males and 39,035 females, the number of persons per square mile being 302, and of acres to a person 2·12; (1901), 81,725. The area of the administrative county, as given in the census returns of 1891, is 164,051 acres, with the same population as the ancient county; but in 1896 the part of the parish of Threapwood in Flint was transferred to Chester and in 1897 part of the parish of Llanarmon yn Yale, and part of the parish of Erbistock, were transferred to Denbigh, while part of the parish of Nannerch in Denbigh was added to Flint. The area of the registration county is 73,380 acres, with a population in 1891 of 42,565. Within this area the decrease of population between 1881 and 1891 were 7·01 per cent. The excess of births over deaths between 1881 and 1891 was 4592, but the resident population decreased by 3209.

The following table gives the number of marriages, births, and deaths, with the number and percentage of illegitimate births for 1880, 1890, and 1898 :—

Year.	Marriages.	Births.	Deaths.	Illegitimate births.	
				No.	Per cent.
1880	241	1426	877	80	5·6
1890	280	1123	848	69	6·1
1898	269	1192	762	45	3·8

In 1891 there were in the county 326 natives of Scotland, 912 natives of Ireland, and 263 foreigners, while 12,862 persons could speak English, 10,484 Welsh, and 16,879 English and Welsh.

Constitution and Government.—The county returns one member to parliament, and it also includes the Flint district of boroughs (consisting of Caergwrle, Caerwys, Flint, Holywell, Mold, Overton, Rhuddlan, and St. Asaph) and a small part of the parliamentary borough of Chester. There is one municipal borough, Flint. The urban districts are : Buckley, Connah's Quay, Holywell, Mold, Prestatyn, and Rhyl. Flintshire is in the North Wales and Chester Circuit, and assizes are held at Mold. The borough of Flint has a separate commission of the peace, but no separate court of quarter sessions. The ancient county, which is partly in the dioceses of Chester, Lichfield, and St. Asaph, contains 46 entire ecclesiastical parishes or districts and parts of eleven others.

Education.—The number of elementary schools on 31st August 1899 was 99, of which 15 were board and 84 voluntary schools, the latter including 66 National Church of England schools, 8 Roman Catholic, and 10 "British and other." The average attendance at board schools was 2297, and at voluntary schools 9877. The total school board receipts for the year ended 29th September 1899, were over £10,179. The income under the Agricultural Rates Act was over £617.

Agriculture.—About three-fourths of the total area of the county is under cultivation, and of this about three-fifths is in permanent pasture. About one-half of the acreage under corn crops is occupied by oats, wheat and barley occupying each less than a fourth. Since 1880 the corn acreage has decreased more than a fourth, the decrease being chiefly in the acreage under wheat, but partly in that under barley, while the acreage under oats has slightly increased. The principal green crops are turnips and potatoes, which occupy respectively a little less than two-sevenths and four-sevenths of the acreage. The following table gives the larger main divisions of the cultivated area at intervals from 1880 :—

Year.	Total area under cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	128,738	30,007	8100	17,095	70,937	2599
1885	128,346	28,763	8562	14,556	74,978	1487
1890	128,206	26,712	8217	16,879	75,131	1221
1895	126,392	23,759	8166	17,485	76,263	618
1900	126,662	22,029	7405	23,774	72,812	600

The following table gives particulars regarding the principal live stock for the same years :—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	5593	28,537	13,378	65,561	11,816
1885	5694	32,130	14,801	59,884	14,734
1890	5974	32,399	15,392	71,752	19,008
1895	6992	33,609	16,054	68,744	19,664
1900	6743	38,426	17,174	86,215	18,124

Industries and Trades.—According to the annual report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 4957, as compared with 4463 in 1896. Of these 4152 were employed in non-textile factories. Hardly any fishing is carried on. The total number employed in connexion with mines and quarries in 1899 was 4192. In the same year 181,828 tons of clay were raised, and 40,283 tons of limestone. The following table gives particulars regarding the output of coal, lead, and zinc in 1890 and 1899 :—

Year.	Coal.		Lead.		Zinc.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.
1890	754,149	£311,086	5222	£48,419	1117	£7449
1899	682,630	£264,519	7617	£79,095	4728	£34,693

(T. F. H.).

Floquet, Charles Thomas (1828–1896), French statesman, was born at St. Jean-Pied-de-Port (Basses-Pyrénées), on the 2nd October 1828. He studied law in Paris, and was called to the Bar in 1851. The *coup d'état* of that year aroused the strenuous opposition of Floquet, who had, while yet a student, given proof of his Republican sympathies by taking part in the fighting of 1848. He made his name by his brilliant and fearless attacks on the Government in a series of political trials, and at the same time contributed to the *Temps* and other influential journals. When the Tsar Alexander II. visited the Palais de Justice in 1867, Floquet was said to have confronted him with the cry "Vive la Pologne, monsieur !" He delivered a scathing indictment of the Empire at the trial of Pierre Bonaparte for killing Victor Noir in 1870, and took a prominent part in the Revolution of 4th September, as well as in the subsequent defence of Paris. In 1871 he was elected to the National Assembly by the department of the Seine. He opposed the measures of the Government, and formed the *Ligue d'union républicaine des droits de Paris.* He was thrown into prison, but was soon released. He became editor of the *République Française*, was chosen President of the Municipal Council, and in 1876 was elected deputy for the eleventh arrondissement by 22,000 votes out of 24,000. He took a prominent place among the extreme Radicals, and became president of the group of the "Union républicaine." In 1882 he held for a short time the post of Prefect of the Seine. In 1885 he succeeded M. Brisson as President of the Chamber. This difficult position he filled with such tact and impartiality that he was re-elected the two following years. Having approached the Russian Ambassador in such a way as to remove the prejudice existing against him in Russia since the incident of 1867, he rendered himself eligible for office ; and on the fall of the Tirard Cabinet in 1888 he became President of the Council and Minister of the Interior in a Radical ministry, which pledged itself to the Revision of the Constitution, but was forced to combat the proposals of General Boulanger. Heated debates in the Chamber culminated on 13th July in a duel between Floquet and Boulanger, in which the latter was wounded. In the following February the Government fell on the question of Revision, and in the new Chamber of November Floquet was re-elected to the presidential chair. The Panama scandals, in which he was compelled to admit his implication, dealt a fatal blow to his career : he lost the Presidency of the Chamber in 1892, and his seat in the House in 1893, but in 1894 was elected to the Senate. He died in Paris on 18th January 1896.

See *Discours et opinions de M. Charles Floquet*, edited by Albert Faivre (1885). (H. Sy.)

Florence (Italian, *Firenze ;* ancient, *Florentia*), formerly capital of the Grand Duchy of Tuscany, capital of Italy from 1864 to 1870, and now chief town of the province to which it gives its name, 120 miles north of Rome, on the river Arno. Florence is an archiepiscopal see, and headquarters of the Sixth Italian Army Corps. In 1899 the population was estimated at 216,051. The area of the city has been greatly extended by new quarters which have arisen outside the old *octroi* circle, and especially towards Porta San Gallo and Porta alla Croce. These new quarters are inhabited both by the population of the old centre of the city, which has been demolished and rebuilt, and the new inhabitants who come to Florence, especially from the surrounding province. This transformation of the city long preoccupied the municipal council and the people of Florence. The fate of the centre of Florence became a burning question, in which much interest was taken outside Florence, and especially in England. The problem at the moment of the reconstruction of the centre in

1888 appeared extremely difficult. The centre had become, from a hygienic point of view, almost uninhabitable, and was a nest of the lowest and most corrupted portion of the Florentine populace. It was necessary to execute a sanitary reform, and at the same time to respect as much as possible of the old quarter that possessed a real historical or artistic interest. The solution has been characterized by greater care for sanitary reform than for artistic and historical considerations. Unfortunately the new buildings of the centre are, as a rule, ugly, and out of keeping with the historical character of the city. The new quarters outside the gates are better in every respect, and especially the so-called *viali* or boulevards which surround the city. This part of Florence has the appearance of a quiet, well-to-do residential town. The Florentine Art Galleries, and in particular the Uffizi and the Galleria d'Arte Antica e Moderna, have undergone several improvements. In the Uffizi the pictures have been rearranged in strict chronological order. On the first floor four new rooms have been opened for the portraits of famous painters, according to epoch and nationality. A large number of the most celebrated modern painters of all countries have presented their portraits to the gallery. A new stairway has been built from these rooms to the second storey, where the great artistic collections, including that of Tuscan art, are situated. In the gallery of ancient and modern art in Via Ricasoli, by the side of the Fine Arts Academy, three new rooms have been opened. The Perugino and Botticelli rooms deserve special mention, since they contain the principal works of those great masters. The great hall on the first floor has been divided into three rooms, containing the works of the Tuscan masters from the 13th to the 18th centuries chronologically arranged and classified. In the Pitti Gallery a magnificent new stairway and a new vestibule have been constructed by royal munificence.

Florentine artistic treasures have recently been increased by the discovery of several old paintings of great importance in the churches and palazzi of the city and in the neighbouring villas. One of these paintings was a Ghirlandajo, discovered in the church of the Ognissanti. This discovery aroused great interest, both on account of the fame of the master and from the fact that among the figures in the picture is that of Amerigo Vespucci as a young man. By a coincidence the discovery was made shortly before the fourth centenary celebration of Vespucci's discovery of America. Another valuable work came to light in 1899 in the church of the Santissima Annunziata. It is a fresco by Andrea del Castagno, representing St Jerome in the desert. In the famous Villa al Gallo, once occupied by Galileo, several painted figures were discovered, and were first attributed to Botticelli, but after maturer study to Pollajolo. Further, in the Pitti storehouse a painting, also attributed to Botticelli, though possibly the work of one of his pupils, was found in 1899. The important National Library, situated near the Uffizi, has received constant attention. The library, the largest in Italy, is constantly increasing in dimensions, and at present contains nearly 1,000,000 books and pamphlets, 19,000 manuscripts, 957 parchments, 300,000 letters and autographs, 22,800 musical works, 25,000 portraits, and 1700 maps, besides prints and engravings. This enormous accumulation of valuable material outgrew the space at the disposal of the library. A number of Government commissions successively reported in favour of a new library building, for which the Florentine municipality offered the site in the centre of the city. After long delays the offer was accepted, a state subsidy granted, and the construction of the new edifice authorized.

Great care has been bestowed upon the Florentine schools and gymnasia. Besides numerous elementary schools Florence now possesses three lyceums and gymnasia, named after the three greatest Florentines—Dante, Michelangelo, and Galileo Galilei. There are, besides, technical, commercial, and professional schools; schools for female professional training, an academy of fine arts, a musical conservatory, a school of social science (founded by the late Marquis Alfieri di Sostegno for intending diplomatists), a school of recitation, and an Institute of Superior Studies. This latter institute serves as a university, although it possesses only the faculties of letters, medicine, and social science. Nevertheless in regard to philological and philosophical studies it holds the first place in Italy. The Institute of Superior Studies has, in fact, succeeded in reawakening in Italy the love for classical literature, and has taken the initiative in promoting public lectures on the Greek Theatre. The professors of the Institute have also displayed praiseworthy activity in promoting the cult of Dante and the study of the *Divina Commedia* in his native city. The influence of this Florentine initiative has been felt throughout Italy, so that the study of Dante may now be said to be more flourishing in the peninsula than ever before. A society for public art, founded in Florence and extended to other Italian cities, exercises considerable influence in the æsthetic questions connected with industries and public buildings. The development of painting, sculpture, and architecture has not kept pace with that of literature. The only really important work accomplished during recent years has been the façade of the cathedral (Sta Maria del Fiore), executed by Tuscan artificers from the designs of the architect De Fabris. During the long work the marble masons acquired a skill hardly inferior to that displayed in Renaissance structures. Begun in 1875, the façade was unveiled in 1888. In other respects Florentine art has declined, as is proved by the new buildings of the centre and by the modern monuments erected in the squares. Industries have not shown any considerable tendency to develop. Florence still feels the effect of the transfer of the capital to Rome. Local trade has increased, but manufactures on a large scale are still lacking. Florence still remains the capital of an agricultural district, and the Piazza della Signoria and the Loggie del Mercato Vecchio still serve as the rendezvous for peasants and factors. The decadence of the straw-plaiting industry in the surrounding districts has made its effects felt also in the city. Perhaps the only really important Florentine industry is represented by the porcelain works of Signor Cantagalli and by the manufactory formerly belonging to the Marchese Ginori di Doccia, but now the property of a Milanese porcelain firm, Richard & Co.

Florence, capital of Lauderdale County, Alabama, U.S.A., on the northern bank of the Tennessee river, at the foot of Muscle Shoals Canal, at an altitude of 563 feet. The Southern and the Louisville and Nashville railways intersect here. It contains several minor educational institutions, the Southern Female University, the Synodical Female College, and the State Normal College. Population (1880) 1359; (1890) 6012; (1900) 6478, of whom 90 were foreign-born, and 1952 negroes.

Flores, an island of the Dutch East Indies, with an area of 5838 square miles. The coasts have deep bays and extensive rounded gulfs, where are situated the principal villages (kampongs). On the north coast are Bari, Reo, Maumer, and Geliting; on the east, Larantuka; and on the south, Sikka and Endeh. The existence of slate, chalk, and sandstone, eruptive rock, volcanoes, and heights stretching west and east, indicates a similar structure to that of the other Sunda Islands. Several volcanoes are still active. The rivers, known only at their mouths, seem to be unnavigable. The climate has a mean temperature of 77° to 80° F. and a yearly rainfall of 43 inches to 47 inches. For administrative purposes the island is divided into West Flores (Mangerai), attached to the government of Celebes, and Middle and East Flores (Larantuka and dependencies), attached to the residency of Timor. The population (250,000) live by trade, fishing, salt-making, shipbuilding, and the cultivation of rice, maize, and palms in the plain, but there is little industry.

Florianopolis, a city and port of Brazil, formerly called Desterro, capital of the State of Santa Catharina. It is situated on the island of Santa Catharina and has a population estimated at from 22,000 to 27,000. It is an agriculture centre. In 1897 the port was visited by 335 ships of 151,098 tons burden.

Florida, the most southern State of the United States of America, projecting as a peninsula between the Atlantic Ocean on the east, and the Gulf of Mexico on the west. The chief political event of late years was the framing of a new State constitution by a Convention which assembled at the capital at Tallahassee, in June 1885, with Samuel Pasco as President, and its subsequent ratification by the people. Under the former constitution the State and county officers, with few exceptions, were appointed by the governor; and the terms of the justices of the Supreme Court were for life. The new constitution made all the principal officers elective except the circuit judges, and changed the life term to a term for six years. Other fundamental changes were introduced. The governor cannot be immediately re-elected; in case of a vacancy during his term, the succession falls first upon the President of the Senate, and secondly upon the Speaker of the House of Representatives. The legislature meets biennially, and is composed of thirty-two senators and sixty-eight representatives. The legislature was authorized to make the payment of a poll-tax a prerequisite for voting, and has exercised this authority. The poll-tax cannot exceed one dollar annually, and is applied towards the support of the public schools. Authority was also given to enact laws for the correction of abuses and the prevention of unjust discrimination and excessive charges by common carriers. A Railway Commission was accordingly provided for, consisting of three members, who serve for a term of four years, and are elected by the people. The State has been Democratic in politics since 1876.

Population, Taxation, and Indebtedness.—The population of the State was, in 1880, 269,493, and in 1890, 391,422. In 1895 it was 464,639, of whom 271,561 were white and 193,078 coloured. In 1900 it was 528,542, an increase during the decade of 137,120, or 35 per cent. The total land surface is approximately 54,240 square miles, and the average number of persons to the square mile was 9·7 in 1900, as compared with 7·2 in 1890. Of the total population 275,246 were males and 253,296 females, 504.710 were native-born and 23,832 foreign-born, 297,333 white and 231,209 coloured (including 230,730 negroes, 120 Chinese, 1 Japanese, and 358 Indians). Out of 139,601 males 21 years of age and over, 30,729 were illiterate (unable to write), of whom 6558 were white and 24,171 were negroes. The death-rate of the entire State in 1900, on the basis of the deaths reported to the United States census enumerators in that year, was about 12·2. There were, in 1900, 92 incorporated cities, towns, and villages, of which only 14 had a population of over 2000, and only 4 a population of over 5000. These 4 were: Jacksonville, with 28,429 inhabitants; Pensacola, with 17,747; Key West, with 17,114; and Tampa, with 15,839. Between 1890 and 1900 the inhabitants in cities of over 8000 increased from 47,031 (12 per cent. of the total population) to 79,129 (15 per cent. of the total population), an increase considerably greater than that shown in the rural districts. In 1880 the value of real and personal property was $31,157,846; in 1899 it was $93,527,353·79. The rate of State taxation in 1880 was seven mills; in 1900 it was five mills for all State purposes. There is no floating debt, and the cash on hand belonging to the different State funds, 1st January 1901, was $370,559·46. The total bonded indebtedness is made up of 7 per cent. bonds of 1871 to the amount of $350,000, and 6 per cent. gold bonds of 1873 to the amount of $925,000, giving a total of $1,275,000. Of the bonds of 1871, on 1st January 1901, $82,300 were in the sinking fund; $255,700 were in the school, seminary, and college funds; and $12,000 were in the hands of individuals. Of the bonds of 1873, $160,200 were in the sinking fund; $586,000 were in school, seminary, and college funds; and $178,800 in the hands of individuals. The total of both issues in the hands of individuals on 1st January 1901 was thus $190,800.

Education.—In 1880 there were 1131 schools with 38,415 pupils, and the annual expenditure was $141,934·16. In 1896, out of a total average attendance of 66,135, 41,992 were whites and 24,143 were coloured. In 1900 there were 2443 schools with 108,874 pupils enrolled, and the annual expenditure was $765,777·42. The number of persons of school age (5 to 20 years inclusive) was 197,600. Two normal schools were provided for by the constitutional convention of 1885. One of these, for white teachers, has been located at De Funiak, the other, for coloured teachers, at Tallahassee. Both are in successful operation. In 1883 an institute for the deaf and blind was established at St Augustine, with separate departments for the two races. Facilities for advanced education are provided for coloured students at the following institutions: Edward Waters College, Jacksonville; Florida Baptist Institute, Jacksonville; Florida Institute, Live Oak; Cookman Institute, Jacksonville. There are three educational institutions for advanced students, which owe their origin to the liberality of Congress—the East Florida Seminary at Gainesville, the Seminary West of the Suwannce at Tallahassee, and the State Agricultural College at Lake City; the last, in 1898, had 203 students, of whom 150 were males; and fifteen instructors, of whom thirteen were men. In addition to the proceeds of the funds, and the Congressional appropriations from which these derive the larger part of their support, they are aided with annual appropriations from the State treasury. The South Florida Military and Educational Institute at Bartow is partly supported by the State, and has a curriculum equal to that of like institutions in other States. A university and two colleges have been chartered by the State; the John B. Stetson University (in 1887) at Deland, with a faculty in 1898 of twenty-five instructors, fourteen of whom were men, and 191 students, 115 of whom were men; Rollins College (in 1885) at Winter Park, with a faculty of twenty instructors; and the Methodist Conference College, Leesburg, with a faculty of seven instructors.

Religion.—The leading religious denominations are: Methodists, who in 1890 reported 70,458 communicants; Baptists, 41,647; Catholics, 16,867; Presbyterians, 4574; and Episcopalians, 4225. The total number of communicants was 141,734. There were 1971 Church organizations, with 1793 edifices, valued at $2,424,423.

Railways.—In 1880 there were 518 miles of railway, and in 1900, 3231 miles. Six daily mail trains pass each way along three trunk lines from New York, through Jacksonville and Live Oak, to their terminal points at Tampa and Miami. During the tourist season an extra train on each line furnishes the most approved conveniences and facilities of modern travel to those who visit the State. Meanwhile many millions have been expended in the improvement and extension of terminal facilities at Pensacola and Tampa. These outlays are still going on, and are rendered necessary by the increased commercial intercourse with Cuba and Porto Rico, which has resulted from the war with Spain.

Fruits.—In the closing years of the 19th century Florida was visited by a series of cold winters that did great damage, especially to the orange crops. In December 1894 the ungathered fruit was destroyed as far south as Indian River; and in the following February, when the sap was rising, the younger trees were killed to the roots, except in the most southern part of the orange belt. In February 1899 snow fell to the depth of several inches as far south as Tampa, a novel sight to the native of Florida who had never been out of his State. In spite of these vicissitudes, however, such older trees as received proper attention and cultivation recovered. Before these calamitous visitations the record shipment for one year amounted to 5,000,000 boxes. It has been urged that these cold spells are caused by the clearing of forests, which has opened a path for the blizzards from the north, and that they thus indicate a permanent change in the climate; but similar disasters occurred in the earlier days. It seems likely that in the long cycles of meteorological changes citrus fruits may again bloom and bear their golden harvests, even in the northern part of the State. In 1897, 117,910 crates of pine-apples, valued at $160,662, were shipped from the State, and 58,194 barrels of pears, valued at $65,243. The northern part of the State is famous for its water-melons, which find a ready market at the north in the early part of the season; in Jefferson County many acres are planted for the seed, which is in great demand all over the United States.

Tobacco.—The manufacture of cigars, begun at Key West, has grown to enormous proportions. The cigars there made by Cuban workmen were of such excellent quality that the name of Key West became a valuable trade mark all over the country. Factories were subsequently established at Quincy, Jacksonville, Tampa, Ocala, and other points. In 1897, 261,663,000 cigars were manufactured, with a value of $16,161,310.

Mineral Products.—The principal mineral products added to the resources of the State in late years are phosphate, fuller's earth, and kaolin. In 1897, 30,000 tons of fuller's earth, of the value of $360,000, were shipped to other markets, and 69,000 sacks of kaolin, valued at $40,800. Phosphate was discovered about 1880, but its value and importance did not attract the attention of capitalists till 1890, when mines were opened at Dunellon and other places. Florida is now one of the large phosphate-producing districts of the world. From January 1891 to January 1899, 3,433,781 tons were mined, and during the fiscal year ending 30th June 1899, 515,498 tons of the crude product, valued at $4,043,775, were shipped from the ports of Florida to foreign countries. (See SOUTH CAROLINA.)

Other Products.—In 1900 there were in the State 519,524 acres given up to Indian corn, and producing 4,156,192 bushels, valued at $2,493,715; 33,470 acres of oats, yielding 378,211 bushels, valued at $189,106; and (in 1899) 149,403 acres of cotton, yielding, during the season of 1899–1900, 41,855 bales, valued at $2,189,805. The cotton ginned from the crop of 1900 amounted to 55,696 commercial bales, of a total gross weight of 24,308,127 ℔. On the 1st of January 1900 the number and value of farm animals in Florida, according to the Year-Book of the United States Department of Agriculture, were as follows: 38,050 horses, $1,776,778; 76,074 sheep, $128,870; 8521 mules, $610,096; 113,108 milch cows, $1,888,904; 299,712 other cattle, $2,512,036. The exports of timber and lumber during the year ending 30th June 1899 were valued at more than $7,500,000. There has been a marked increase in the production of naval stores, and many new turpentine farms and stills are in successful operation. Fleets of schooners and smaller vessels and many thousand men are employed in the fisheries at the different ports of the State. Many Pensacola vessels are engaged in the snapper fisheries; they frequently sail twenty-five hundred miles in a single trip; the fish are packed in ice, and shipped to all parts of the United States. In 1890 the value of this industry was $1,339,869, and it has grown largely since then. The sponge fisheries yield a quarter of a million dollars annually.

Commerce.—Regular lines of steamers run from Jacksonville to Charleston and New York, from Tampa to Key West and Havana; from Fernandina to Brunswick, Ga.; from Key West to New York and Galveston, New Orleans, and Havana, as well as from other ports. The exports of the leading ports have increased as follows:—

	1884.	1899.
Apalachicola	$230,334	$396,436
Fernandina	169,457	2,424,296
Jacksonville	35,733	176,305
Key West	412,318	1,742,313
Pensacola	2,581,426	14,214,690
Tampa	173,496	956,235
	$3,602,764	$19,910,275

During the decade from 1890 to 1900 Congress authorized the expenditure of $5,800,000 for the improvement and maintenance of rivers and harbours.

Banks.—In 1900 there were sixteen national banks, with a capital and surplus of $1,762,600, and deposits of $6,694,036·43; twenty-two State banks, with a capital and surplus of $871,086, and deposits of $2,912,534; and one savings bank, with a capital and surplus of $25,000, and deposits of $233,341.

The mild climate of Florida through the winter months has led to the influx of large numbers of tourists, and to the erection since 1885 of mammoth hotels costing millions of dollars, especially at St Augustine, Palm Beach, Ormond, Miami, and Tampa. (S. PA.)

Floridsdorf, or FLORISDORF, chief town in the government district of the same name in Lower Austria. It was formerly a village, commune, and station on the Northern railway, about three miles from Vienna. In 1890 it had 6123 inhabitants, but in 1896 it was made the seat of the government district of the same name, some adjoining villages being incorporated. This raised the population to 23,000, and in 1900 to 36,599, chiefly German and Catholic (estimated at 6 per cent. Czech, 4 per cent. Jewish, and 1·5 per cent. Protestant). In 1866 the Austrians occupied a fortified camp at Floridsdorf in anticipation of the Prussian advance on Vienna after the battle of Sadowa. The attack was averted, however, by the conclusion of the armistice. Floridsdorf is a busy industrial centre, its principal manufactures being machinery and liqueurs.

Flotow, Friedrich Ferdinand Adolf von, FREIHERR (1812–1883), a voluminous and popular German composer of operetta, was born on his father's estate at Teutendorf, in Mecklenburg, 27th April 1812. Destined originally for the diplomatic profession, his passion for music induced his father to send him to Paris to study under Reicha. But the outbreak of the Revolution in 1830 caused his return home, where he busied himself writing chamber-music and operetta until he was able to return to Paris. There he produced *Pierre et Cathérine*, *Rob Roy*, *La Duchesse de Guise*, but made his first real success with *Le Naufrage de la Méduse* at the Renaissance Théâtre in 1838. Greater, however, was the success which attended *Stradella* (1844) and *Martha* (1847), which made the tour of the world. In 1848 Flotow was again driven home by the Revolution, and in the course of a few years he produced *Die Grossfürstin* (1850), *Indra* (1853), *Rübezahl* (1854), *Hilda* (1855), and *Albin* (1856). From 1856 to 1863 he was director (Intendant) of the Schwerin opera, but in the latter year he returned to Paris, where in 1869 he produced *L'Ombre*. From that time to the date of his death he lived in Paris or on his estate near Vienna. He died 24th January 1883. Of his concert-music only the *Jubelouvertüre* is now ever heard. His strength lay in the facility of his melodies and in their often piquant dress. (R. H. L.)

Flower, Sir William Henry (1831–1899), English biologist, was born at Stratford-on-Avon on 30th November 1831. Choosing medicine as his profession, he began his studies at University College, London, where he showed special aptitude for physiology and comparative anatomy, and took his M.B. degree at the age of twenty. He then joined the Army Medical Service, and went out to the Crimea as assistant-surgeon, receiving the medal with four clasps. On his return to England he became a member of the surgical staff of the Middlesex Hospital, London, but within a few years gave up his post there in order to succeed Quekett as curator of the Hunterian Museum of the Royal College of Surgeons of England. In 1869 he was chosen Hunterian Professor, and in 1884, on the death of Owen, was appointed to the directorship of the Natural History Museum at South Kensington. He died in London on 1st July 1899. Sir William Flower's services to science were twofold. In the first place, he made valuable contributions to structural anthropology, publishing, for example, complete and accurate measurements of no less than 1300 human skulls. As a comparative anatomist, again, he ranked high, devoting himself especially to the study of the mammalia. In the second place, he was a leading authority on the arrangement of museums. The greater part of his life was spent in their administration, and in consequence he held very decided views as to the principles upon which the specimens should be set out. He insisted on the importance of distinguishing between collections intended for the use of specialists and those designed for the instruction of the general public, pointing out that it was as futile to present to the former a number of merely typical forms as to provide the latter with a long series of specimens differing only in the most minute details. His ideas, which were largely and successfully applied to the museums of which he had charge, gained wide approval, and their influence entitles him to be looked upon as a reformer who did much to improve the methods of museum arrangement and management. In addition to numerous original papers, he was the author of several books on zoological subjects, and of one dealing with topics connected with museums; he also wrote many articles for the ninth edition of this *Encyclopædia*, that on the Mammalia being the most elaborate. (H. M. R.)

Flushing (Dutch, VLISSINGEN), a fortified seaport on the island of Walcheren, in the province of Zealand, Holland, 50 miles south-west of Rotterdam, at the mouth of the estuary of the Western Scheldt. There is regular steam communication with Queenborough. Its considerable manufacture of machinery (employing about 1000 workmen), its state railway-workshops, and its *depôt* of the Krupp iron and steel works (Essen, Prussia) contribute to its prosperity. An aqueduct conveys excellent fresh water for the ships. The navigation of the port, however, is far behind that of Rotterdam and Antwerp, the tonnage in 1899 being 1,870,000 tons, or about 7·9 per cent. of that of the kingdom. The principal imports are now grain, colonial produce, wine, wood, and manufactures for the shipping trade. Of late years Flushing has acquired considerable popularity as a bathing resort, attracting visitors even from Germany. A chamber of antiquities has been opened in the Town Hall. Population in 1900, 18,896.

Flushing (NEW YORK). See NEW YORK CITY.

Focşani, chief town of the district of Putna, Rumania, 125 miles from Bucarest, on the river Milcov, which formed the ancient frontier of the former principalities of Moldavia and Wallachia. It is the seat of a court of first instance, has 27 orthodox churches, 1 Catholic, 2 Armenian churches, and 2 synagogues, and is the headquarters of the 6th Army Corps. Focşani is a commercial centre of some importance, the chief industries being oil and soap manufacture and tannery. A large and important wine trade is also carried on. The annual fair is held on the 29th of April. There is a Chamber of Commerce. Government explorations in the vicinity of this town show it to be rich in mineral sources, such as iron, copper, coal, and petroleum. Population (1895), 21,000; (1900), 23,783, of whom 6000 were Jews. The line Focşani–Galatz is covered by a very strong line of fortifications of the most modern type.

Fogazzaro, Antonio (1842——), Italian novelist and poet, was born at Vicenza in 1842. He was a pupil of the Abate Zanella, one of the best of the modern Italian poets, whose tender, thoughtful, and deeply religious spirit has continued to animate his literary productions. He commenced his literary career with *Miranda*, a poetical romance (1874), followed in 1876 by *Valsolda*, which, republished in 1886 with considerable additions, constitutes perhaps his principal claim as a poet, which is not inconsiderable. To the classic grandeur of Carducci and D'Annunzio's impetuous torrent of melody Fogazzaro opposes a Wordsworthian simplicity and pathos, contributing to modern Italian literature wholesome elements of which it would otherwise be nearly destitute. He has, however, attained far more celebrity as a novelist. His novels, *Malombra*, *Daniele Cortis*, *Mistero del Poeta*, obtained considerable literary success upon their first publication, but did not gain universal popularity until they were discovered and taken up by French critics in 1896. The demand then became prodigious, and a new work, *Piccolo Mondo Antico*, which critics far from friendly to Fogazzaro's religious and philosophical ideas have pronounced the best Italian novel since *I Promessi Sposi*, has gone through thirty editions. Fogazzaro's conservative attitude accounts for his success with large classes of Italian society, but there is much in his delicate and graceful talent independent of the controversies of his time. His biography, with essays illustrative of his characteristics, has been written by Signor Molmenti.

Foggia, a growing town and episcopal see of Italy (Apulia), capital of the province of Foggia, an important railway centre 123 miles by rail E.N.E. from Naples. It possesses a botanical garden, a technical school (1872), and a monument to the local patriot Lanza (1784–1860), and has large ironworks and foundries, and manufactures macaroni and liquorice. Population of town (1881), 40,283; (1901), 53,351; of province (1881), 356,267; (1901), 418,510.

Foli (Foley), Allan James (1837–1899), Irish bass singer, was born at Cahir, Tipperary, 7th August 1837; originally a carpenter, he studied under Bisaccia at Naples, and made his first appearance at Catania in 1862. From the opera in Paris he was engaged by Mapleson for the season of 1865, and appeared with much success in various parts. He sang in the first performance of *The Flying Dutchman* (Daland) in England in 1870, and in the first performance of Gounod's *Redemption* in 1882. He was distinguished in opera and oratorio alike for his vigorous, straightforward way of singing, and was in great request at ballad concerts. He died 20th October 1899.

Foligno or **Fuligno,** a town and bishop's see of Italy (Umbria, province of Perugia), 25 miles S.E. from Perugia by rail. There are a picture gallery, with works by the masters of the Umbrian school, an industrial arts school (1873), and numerous private mansions of architectural interest. Population about 19,000.

Folkestone, a parish, municipal borough, and seaport in the eastern division of Kent, England, 71 miles S.S.E. of London. It is included in the parliamentary borough of Hythe. Recent erections are Established and Roman Catholic churches, a Congregational hall, a Victoria hospital, a free library and museum, the Harveian Institute (for youths), a "Home of Rest" for ladies, a convalescent home, a Masonic hall, public baths, the Victoria pier promenade, and a bronze statue of Harvey (1881). An infectious diseases sanatorium has been enlarged. Radnor park (20 acres) was opened in 1886. Several lifts facilitate intercourse between the beach and the cliffs. The port was made a customs-port in 1882. The registered shipping is unimportant, but in 1888, 1268 vessels of 209,938 tons entered, and 1760 vessels of 212,468 tons cleared, while in 1898, 2420 vessels of 483,626 tons entered, and 2388 of 478,467 tons cleared. Area of urban district, 2321 acres. Population (1881), 18,816; (1891), 23,711; (1901), 30,694.

Fond du Lac, capital of Fond du Lac County, Wisconsin, U.S.A., in 43° 47′ N. and 88° 28′ W., at the southern end of Winnebago Lake, at the mouth of Fond du Lac river, at an altitude of 770 feet. The city is regularly laid out on a level plan, is supplied with water from artesian wells, and is served by three railways, the Chicago and North-Western, the Chicago, Milwaukee, and St Paul, and the Wisconsin Central. It has extensive manufactures of lumber and agricultural implements and machines. Population (1880), 13,094; (1890), 12,024; (1900), 15,110.

Fonsagrada, a town of Spain, in the east of the mountainous province of Lugo, on the river Navia. There is trade in wheat, wine, hemp, potatoes, and fruit. Much live stock is reared in this extensive township. The industries are linen and rough frieze manufacture, and cheese and butter making. The population, which was 17,200 in 1897, shows a tendency to decrease through emigration.

Fonseca, Manoel Deodoro da (1827–1891), first President of the United States of Brazil, born at Alagoas on 5th August 1827, was the third son of Lieut.-Colonel Manoel Mendes da Fonseca (died 1859). He was educated at the military school of Rio de Janeiro, and had attained the rank of captain in the Brazilian army when war broke out in 1864 against Montevideo, and afterwards against Solano Lopez, dictator of Paraguay. His courage gained him distinction, and before the close of the war in 1870 he reached the rank of colonel, and some years later that of general of division. After enjoying several military commands, he was nominated in 1886 governor of the province of Rio Grande do Sul. In this position he threw himself heartily into politics, espoused the republican opinions then becoming prevalent, and sheltered their exponents with his authority. After a fruitless remonstrance, the Government at the close of the year removed him from his post, and recalled him to the capital as director of the service of army material. Finding that even in that post he still continued to encourage insubordination, the minister of war, Alfredo Chaves, dismissed him from office. On 14th May 1887, in conjunction with the Viscount de Pelotas, Fonseca issued a manifesto in defence of the military officers' political rights. From that time his influence was supreme in the army. In December 1888, when the Conservative Correa d'Oliveira became prime minister, Fonseca was appointed to command an army corps on the frontier of Matto Grosso. In June 1889 the ministry was overthrown, and on a dissolution an enormous Liberal majority was returned to the Chamber of Deputies. Fonseca returned to the capital in September. Divisions of opinion soon arose within the Liberal party on the question of provincial autonomy. The more extreme desired the inauguration of a complete federal system. Amongst the most vehement was Ruy Barbosa, the journalist and orator, and after some difficulty he persuaded Fonseca to head an armed movement against the Government. The insurrection broke out on 15th November 1889. The Government commander, Almeida Barreto, hastened to place himself under Fonseca's orders, and the soldiers and sailors made common cause with the insurgents. The affair was almost bloodless, the minister of marine, baron de Ladario, being the only person wounded. Fonseca had only intended to overturn the ministry, but he yielded to the insistency of the republican leaders and proclaimed a republic. A provisional government was constituted by the army and navy in the name of the nation, with Fonseca at its head. The council was abolished, and both the Senate and the Chamber of Deputies were dissolved. The emperor was requested to leave the territory of Brazil within twenty-four hours, and on 17th November was embarked on a cruiser for Lisbon. On 20th December a decree of banishment was pronounced against the Imperial family. So universal was the republican sentiment that there was no attempt at armed resistance. The provisional government exercised dictatorial powers for a year, and on 25th February 1891 Fonseca was elected President of the republic. He was, however, no politician, and possessed indeed little ability beyond the art of acquiring popularity. His tenure of office was short. In May he became involved in an altercation with Congress, and in November pronounced its dissolution, a measure beyond his constitutional power. After a few days of arbitrary rule insurrection broke out in Rio Grande do Sul, and before the close of November Fonseca, finding himself forsaken, resigned his office. From that time he lived in retirement. He died at Rio de Janeiro on 23rd August 1892.

(E. I. C.)

Fontainebleau, chief town of arrondissement, department of Seine-et-Marne, France, 9 miles S. by E. of Melun, on the railway from Paris to Lyons. The palace is now the summer residence of the President of the Republic, and a school of practical artillery is installed in a section of the buildings. The Forest of Fontainebleau covers an area of 42,500 acres. Population (1881), 9621; (1896), 10,788; (1901), 10,923, or, including military, 14,160.

Fontenay-sous-Bois, a town in the arrondissement of Sceaux, department of Seine, France, 2½ miles east of the Outer Circle of Paris, and about half a mile north-west of Fort Nogent, on the railway from Paris to Brie-Comte-Robert. It has a 16th century church, with fine Gothic arches. Population (1881), 3586; (1896), 5992; (1901), 9320.

Foochow (or FUCHAW), a treaty port in the province of Fuhkien, China. The trade of the port has declined in recent years owing to the falling off in the export of tea. In 1880 the export of this staple article of trade reached 98 million ℔, the greater part of which came to England. In 1898 the export had fallen off to 36 million ℔, of which only about a quarter came to England. The total value of the trade for 1899, as given in the customs returns, was H. taels 17,352,000 (£2,603,000). In 1880 the total of the trade was H. taels 15,758,000, equivalent at the then value of the tael to £3,832,000. The Min river on which Foochow is built has silted up to such an extent that steam-vessels for many years have been compelled to load and discharge their cargoes at a place called Pagoda anchorage, some ten miles below the city. Near this point the Chinese Government established an arsenal and ship-building yard, which between 1870 and 1880 turned out some twenty-five or thirty small gunboats. In 1884 it was partially destroyed in the attack by the French fleet on the Chinese squadron lying in the harbour, and for a number of years after that event the workshops and machinery, which had cost an immense amount of money, were allowed to stand idle and go to decay. An attempt was made after the Japanese war to revive the establishment, a staff of French engineers having again been engaged for the purpose. On the 1st August, 1895, a horrible attack was made on an English mission station near the inland city of Kucheng, 120 miles west of Foochow. Nine missionaries, of whom eight were ladies, were massacred, and only one or two escaped. Most of the ringleaders in this outrage were brought to justice. The population of Foochow is estimated at 1,000,000, and the number of foreign residents, including missionaries in the interior, at about 530.

Football.—1. *Association.* Though the rules governing the actual play have undergone singularly few, and those not very material, variations, the evolution of Association football since 1875 has brought in its train many important changes. The whole constitution of the Association itself, in the first place, has been considerably altered. What used to be a purely sporting administration controlling the game in the interests of players wholly and solely, for its own sake and as a healthy recreation, has by the force of circumstances become an unwieldy body, with many varied responsibilities involving the control of details quite outside the scope of a legislative tribunal. The institution of the Football Association Cup in 1871 may be held to have been primarily accountable for the conversion. For a time the competition was mostly limited to South of England teams. The game was then an amateur sport. Even at the most important matches spectators were comparatively few, and "gate money," enabling clubs to provide for the payment of the expenses of players on the most limited scale, was practically unknown. It was not till the entry of the Lancashire clubs into the competition that the Association Cup began to arouse any general interest. Until 1881 the final had been left entirely to southern teams. The excellent form shown by the Blackburn Rovers, who were only beaten, after a hard struggle, by the bare majority of a goal by the Old Etonians at the Oval in 1882, came as something of a revelation. The next year saw the cup won for the first time by a northern team, the Blackburn Olympic, who were able to outstay the Old Etonians and beat them after one and a half hours' play. This was the beginning of a new era. For three years in succession the Blackburn Rovers held the cup; and so complete was the ascendancy of the North that it was not till 1900 that a southern club got into the final tie, though in 1901 the cup was at last secured for the South by Tottenham Hotspur. For nineteen years the cup had remained solely in the hands of northern or Midland clubs. The early triumphs of the Lancashire teams had far-reaching effects. It soon became evident that the spirit of the amateur rules on which the cup competition was based was being violated. Attempts were made by the executive to check the illicit payment of players. When they failed, the only alternative was to recognize professionalism and bring it under adequate control. The advocates of open professionalism had to wait some time before they carried their point. Its opponents certainly did not allow it to be legalized without a stubborn fight. Gradually, however, they had to yield before the force of public opinion, and by 1890 the professional player had come to be officially recognized by the Football Association of England. For a time Scotland, Wales, and Ireland refused to acknowledge him; and the Scottish executive unsuccessfully tried to induce the English authorities to agree to his exclusion from the English elevens in international contests. As it was, they were the last to give way, and professionalism had been recognized in Wales and Ireland before Scotland perforce had to agree to it. Since 1889 the professional player has played a part, and an increasingly important part, in Association football. Up to 1902 he had been kept well under control, and the forebodings of the evil he was to do to the game had certainly not been realized. A player receiving more than his actual expenses for playing in a match is a professional, and must be registered with the Football Association as such. Even wages absolutely lost are not allowed, and no professional can revert to his old amateurism until he has been properly reinstated by the Football Association, which naturally requires to be thoroughly satisfied of the good faith of every application before it is even considered. How professionalism has developed in the years which have passed since its recognition may be gathered from the fact that in 1899–1900 no fewer than seven thousand were registered with the Football Association. This, it may be added, refers only to English players, and does not include those who are registered with Scotland, Wales, and Ireland, which may fairly be computed to number several thousands more. The development of the Association itself between 1875 and 1902 has of course corresponded with the increase in the popularity of the game itself. In 1875 the official register showed only ninety-four clubs under its direct control. In 1900 the managing body consisted of a president, four vice-presidents, a treasurer, and sixteen delegates, elected from the various districts into which the Association has been subdivided for electoral purposes. In addition to representatives of every affiliated association having jurisdiction over fifty or more clubs, varying in number according to the numerical strength of the clubs under their control, at its full strength the Council of the Football Association includes some forty or fifty persons. Such a body as this has proved very cumbersome for practical purposes, and latterly the bulk of the work has been done by a Consultative Committee, composed of the officers and twelve other delegates selected by them. Besides the Cup Competition the Association has latterly had the control of three international matches, those with Scotland, Wales, and Ireland, of the trial match North *v.* South, and during the last few years of a Second Cup Competition confined to amateurs alone. The Scottish match has been played uninterruptedly since 1872. That with Wales was not originated till seven years later, while the Irish fixture does not appear on the list until 1882. The Irish and Welsh matches, as well as that between North and South and the Amateur Cup Competition, are all of them essentially the product of the Association's work during the last quarter of the 19th century.

The whole policy of legislation in Association football of late years has been naturally to make the game faster by bringing every one into full play. The great aim accordingly has been to encourage combination and to discourage purely individual efforts. In the early days, though there was a certain amount of cohesion, a player had to rely mainly on himself. Even up to the middle of the 'seventies dribbling was looked upon as the great desideratum; it was the essential for a forward, just as long kicks were the main object of a back. The development of the game was of course bound to change all that. The introduction of passing, long or short, but long in particular, placed the dribbler pure and simple at a discount, and necessitated methods with which he was mostly unacquainted. Combined play gradually came to be regarded as the keynote to success. Instead of one full back, as was originally the case, and one half-back, the defence gradually developed by the addition first of a second half, then of a second full back, and still later of a third half-back, until it came to show, in addition to the goalkeeper of course, two full backs and three half-backs. The eight forwards who used to constitute the attack in the earliest days of the Association have been reduced by degrees, as the science of the game became understood, until they now number only five. The effect of the transition has been to put the attack and defence on a more equal footing, and as a natural consequence to make the game more open and thereby generally more interesting and attractive. Association football is indeed, from the standpoint of the spectator, a much brighter game than it was in its infancy, the result of the new methods bringing every one of the eleven players into full relief throughout the game. The players who, as a rule, make or mar the success of a side in modern football are the centre forward and the centre half-back. They are the pivot on which the attack and the defence respectively turn. Instead of close dribbling and following up, the new formation makes for accuracy of passing among the forwards, with intelligent support from the half-backs. The net result is practically the effective combination of the whole side. To do his part as it ought to be done every member of an eleven must work in harmony with the rest, and on a definite system, in all cases subordinating his own methods and personal interests to promote the general wellbeing of the side.

In its main principles the Association game itself has altered very little since 1880. The usual dimensions for a ground are 120 yards long by 80 yards wide, and the goals are still eight yards in width with a cross bar from post to post and eight feet from the ground. The game is started by a place kick from the centre of the field of play, and none of the opposite side is allowed to approach within ten yards of the ball when it is kicked off. When the ball passes over the touch line it has to be thrown in by one of the opposite side, and can be returned into the field of play in any direction. If it passes over the goal line at any time without touching one of the defending side, it has to be kicked out by the goalkeeper or one of the backs from a line marked in front of goal, the spot selected being in front of the post nearest the point where the ball left the field of play. But should it touch one of the defending side in its transit over the goal line the attacking side has the privilege of a free kick from the corner flag (a "corner kick"). This is often a great advantage, but such free kick does not produce a goal unless the ball touches one of the other players on its way to the post. Ordinarily a goal is scored when the ball goes through the post, not being thrown, knocked on, or carried. The regulation duration of a game is an hour and a half, and ends are changed at forty-five minutes. The side winning the toss has the choice of ends or kick-off, and the one obtaining the majority of goals wins. A goal cannot be scored from a free kick unless a player of the defending side wilfully handles the ball, or a player of the attacking side is intentionally tripped, charged from behind, pushed, or held by an opponent within the twelve-yards goal line. The referee in such cases has power to award a free kick within the twelve-yards line of the defending side. In a penalty kick no one but the goalkeeper is allowed to play the ball, so that the result is an almost certain goal. A player is always in play as long as there are three of the opposite side between him and the opposite goal *at the time the ball is kicked.* This rule gives much trouble to the young player, though why it should do so it is not easy to say. The rule is simple if the words in italics are remembered. The ball must not be carried, knocked, or wilfully handled under any pretence whatever, save by the goalkeeper, who is allowed to use his hands in defence of his goal, either by knocking on or throwing, within his own half of the field of play. Thus far he is entitled to go in maintaining his goal, but if he carry the ball, the penalty is a free kick. There are other infringements of the rules which also involve the penalty of a free kick, among them the serious offences of tripping, hacking, and jumping at a player. Players are not allowed to wear nails in their boots (except such as have their heads driven in flush with the leather), or metal plates, or gutta-percha, and any player discovered infringing this rule is liable to be prohibited from taking further part in a match. No player is allowed to play except in practice matches, when no gate money can be taken, from 1st May to 31st August. But in Scotland the "close season" runs from 15th May to 15th August. (C. W. A.)

2. *Rugby Union.*—From early times a rudimentary game of football had been a popular form of sport in many parts of Great Britain, and in the old-established schools football had been a regular game among the boys. In different schools there arose various developments of the original game; or rather, what, at first, must have been a somewhat rough form of horse-play with a ball began to take shape as a definite game, with a definite object and definite rules. Rugby school had developed such a game, and from football played according to Rugby rules has arisen Rugby football. It was about the middle of the 19th century that football—up till that time a regular game only among schoolboys—took its place as a regular sport among men. To begin with, men who had played the game as schoolboys formed clubs to enable them to continue playing their favourite school game, and others were induced to join them; while in other cases, clubs were formed by men who had not had the experience of playing the game at school, but who had the energy and the will to follow the example of those who had had this experience. In this way football was established as a regular game, no longer confined to schoolboys. When football was thus first started, the game was little developed or organized. Rules were very few, and often there was great doubt as to what the rules were. But, almost from the first, clubs were formed to play football according to Rugby rules—that is, according to the rules of the game as played at Rugby school. But even the Rugby rules of that date were few and vague, and indeed almost unintelligible to those who had not been at Rugby school. Still, the fact that play was according to Rugby rules produced a certain uniformity; but it was not till the establishment of the English Union, and the commencement of international matches, that a really definite code of rules was drawn up.

It is an interesting question to ask why it was that the game of Rugby school became so popular in preference to the games of other schools, such as Eton, Winchester, or Harrow. It was probably very largely due to the reputation and success of Rugby school under Dr Arnold, and this also led most probably to its adoption by other schools; for in 1860 many schools besides Rugby played football according to Rugby rules. The rapidity with which the game spread was remarkable. The Blackheath club, the senior club of the London district, was established in 1860, and Richmond, its great rival, shortly afterwards. Before 1870, football clubs had been started in Lancashire and Yorkshire; indeed the Sheffield football club dates back to 1855. Likewise, in the universities of Oxford and Cambridge, Rugby football clubs had been formed before 1870, and by that date the game had been implanted both in Ireland and South Wales; while in Scotland, before 1860, football had taken a hold. Thus by 1870 the game had been established throughout the United Kingdom, and in many districts had been regularly played for a number of years. Rapid as, in some ways, had been the spread of the game between the years 1850 and 1870, it was as nothing to what happened in the following twenty years; for by 1890 Rugby football, together with Association football, had become the great winter amusement of the people, and roused universal interest; while to-day, though there are no statistics to prove the assertion, it is no exaggeration to say that on any fine Saturday afternoon in winter there are tens of thousands of people playing football, while those who watch the game can be counted by the hundred thousand. The causes that led to this great increase in the game and interest taken in it were, undoubtedly, the establishment of the various national Unions and the international matches; and, of course, the local rivalry of various clubs, together with cup or other competitions prevalent in certain districts, was a leading factor. The establishment of the

English Union led to a codification of the rules without which development was impossible. The international matches roused patriotic enthusiasm, and club matches roused local rivalries, which have so strong a hold upon the people.

In the year 1871 the English Rugby Union was founded in London. This Union was an association of some clubs and schools which joined together and appointed a committee and officials to draw up a code of rules of the game. From this beginning the English Rugby Union has become the governing body of Rugby football in England, and has been joined by practically all the Rugby clubs in England, and deals with all matters connected with Rugby football, notably the choosing of the international teams. In 1873 the Scottish Football Union was founded in Edinburgh on the same lines, and with the same objects, while in 1880 the Welsh Football Union, and in 1881 the Irish Rugby Football Union, were established as the national Unions of Wales and Ireland, though in both countries there had been previously Unions not thoroughly representative of the country. All these Unions became the chief governing body within their own country, and one of their functions was to make the rules and laws of the game; but as this had been done to start with by the English Union, the others adopted the English rules, with amendments to them from time to time. This state of affairs had one element of weakness—viz., that since all the Unions made their own rules, if ever a dispute should arise between any of them, a deadlock was almost certain to ensue. Such a dispute did occur in 1884 between the English and Scottish Unions. This dispute eventually turned on the question of the right of the English Union to make and interpret the rules of the game, and to be the paramount authority in the game, and superior to the other Unions. Scotland, Ireland, and Wales resisted this claim, and finally, in 1889, Lord Kingsburgh and Major Marindin were appointed as a commission to settle the dispute. The result was the establishment of the International Board, which consists of representatives from each Union—six from England, two from each of the others—whose duties were to settle any question that might arise between the different Unions, and to settle the rules under which international matches were to be played, these rules being invariably adopted by the various Unions as the rules of the game.

With the establishment of the International Board, the organization of the game was complete. Still harmony did not prevail, and in 1895 occurred a definite disruption. A number of leading clubs in Yorkshire and Lancashire broke off from the English Union and formed the Northern Union, which since that date has had many accessions, and has become the leading body in the North of England. The question in dispute was the payment of players. Football was originally played by men for the sheer love of the game, and by men who were comparatively well-to-do, and who could give the time to play it; but with the increasing popularity of the game, it became the pastime of all classes of the people, and clubs began to grow rich by "drawing big gates,"—that is, large numbers of spectators, frequently many thousands in number, paid for the privilege of witnessing the match. In these circumstances the temptation arose to reimburse the player for any out-of-pocket expenses he might be put to for playing the game, and thus it became universally recognized as legitimate to pay a player's expenses to and from a match. But in the case of working men it often meant that they lost part of their weekly wage when they had to go a distance to play a match, or to go on tour with their club—that is, go off for a few days and play one or two matches in different parts of the country—and consequently the claim was made on their behalf to recoup them for their loss of wage; while at the same time rich clubs began to be willing to offer inducements to good players to join their club, and these inducements were generally most acceptable in the form of money. In Association football, professionalism—*i.e.*, the hiring and paying of a player for his services—had been openly recognized. A large section of the English Union—the amateur party—would not tolerate anything that savoured of professionalism, and regarded payments made to a player for broken time as illegitimate. The result was the formation of the Northern Union, which allowed such payments, and has practically recognized professionalism. This body has also slightly altered the laws of the game, and probably in the future the two games will be widely different. In Scotland and Ireland Rugby footballers are strongly amateur; but wherever Rugby football is the popular game of the artisan, the professional element is strong, and possibly the Northern Union will be joined by clubs in other districts of England and Wales.

Besides legislation, one of the functions of the Unions is to select international teams. On 27th March 1871 the first international match was played between England and Scotland in Edinburgh. This was a match between teams picked from English and Scottish players. These matches from the first roused widespread interest, and were a great stimulus to the development of the game. With the exception of a few years, when there were disputes between their respective Unions, all the countries have annually played one another—England having played Scotland since 1871, Ireland since 1875, and Wales since 1880. Scotland commenced playing Ireland in 1877 and Wales in 1883, while Ireland and Wales met first in 1882 and then in 1884, and since 1887 have played annually. The qualifications of a player for any country were at first vaguely considered to be birth; but they were never definitely settled, and there has been a case of a player playing for two countries. In 1894, however, the International Board decided that no player was to play for more than one country, and this has been the only pronouncement on the question; and though birth is still looked upon as the main qualification, it is not essential. Though international matches excite interest throughout the United Kingdom, the matches between two rival clubs arouse just as much excitement in their district, particularly when the clubs may be taken as representatives of two neighbouring rival towns. But when to this rivalry there is added the inducement to play for a cup, or prize, the excitement is much more intense. Among Rugby players cup competitions have never been so popular as among Association, but the competition for the Yorkshire Cup was very keen in the days before the establishment of the Northern Union, and this undoubtedly was the main cause of the popularity of the game in that county. Similarly the competition for the South Wales Cup from 1878 to 1887 did a great deal to establish the game in that country. The method of carrying on these competitions is, that all the clubs entered are drawn by lot, in pairs, to play together in the first round; the winners of these ties are then similarly drawn in pairs for the next round, until for the final round there is only one pair left, the winner of which takes the cup. An elaboration of this competition is the "League system" of the Association game. This, likewise, has not been popular with Rugby players. Still it is prevalent in many districts, especially where clubs are anxious to draw big gates. In the League system a certain number of clubs form a league to play one another twice each season; two points are counted for a win, and one for a draw. The club which at the end of the season comes out with most points wins the competition. The advantage of this system over a cup competition is, that interest is kept up during the whole season, and one defeat does not debar a club from eventually coming out first.

It is said that wherever Britons go they take their games with them, and this has certainly been the case with Rugby football, for even in India it is played. But it has not yet been firmly established out of Great Britain. In the United States of America there is a form of football—a development of football according to Rugby rules, but now totally different from Rugby football (see below). Such, too, is the case in Australia. Still, in 1888, an English team of Rugby players had a tour in Australia and New Zealand, playing matches under both Rugby and Australian rules, and in 1889 a team of New Zealand native football players, popularly called the Maoris, came over to England. In 1891 a team went to South Africa under the auspices of the Rugby Union. It is perhaps in South Africa where Rugby is most likely to flourish out of Great Britain; but even there the climatic conditions and state of the ground are against the game. In Germany the game has been established, but it has been taken up in Paris with more vigour than in any place on the Continent, and already many matches have been played between British and Parisian clubs.

The game itself is essentially a winter pastime, as two requisite conditions for its enjoyment are a cool atmosphere and a soft though firm turf. The field of play is an oblong, not more than 110 yards long nor more than 75 yards broad, and it usually approximates to these dimensions. The boundaries are marked by lines, called touch lines, down the sides, and goal lines, along the ends. The touch lines are continued beyond the goal lines for a distance of not more than 25 yards; and parallel to the goal line and behind it, at a distance of not more than 25 yards, is drawn a line called the dead ball line, joining the ends of the touch lines produced. On each goal line, at an equal distance from the touch lines, are erected two posts, termed goal posts, exceeding 11 feet in height, and as a rule generally much more—averaging perhaps from 20 to 30 feet from the ground, and placed 18 feet 6 inches apart. At a height of 10 feet from the ground they are joined by a cross bar; and the object of the game is to kick the ball over the cross bar between the upright posts, and so obtain a goal. The ball is oval in shape, and the official dimensions are—length, 11 to $11\frac{1}{4}$ inches; length circumference, 30 to 31 inches; width circumference, $25\frac{1}{2}$ to 26 inches; weight, 13 to $14\frac{1}{2}$ ounces. It is made of india-rubber inflated, and covered with a leather case. Half-way between the two goal lines there is sometimes drawn the half-way line, but more usually it is marked by flags on the touch line; and 25 yards from each goal line there is similarly marked the 25-yards line. In the original game the side that had gained the majority of goals won the match, and if no goal had been scored, or an equal number, the game was said to be left drawn; but a modification was adopted before long. A goal can be kicked from the field of play; but from the very first a try at goal could be obtained by that side one of whose players either carried the ball across his opponents' goal line and then touched it down, or touched it down, after it had been kicked across the goal line, before any of his opponents. The try at goal consisted in one of the successful side attempting to kick the ball over the bar, while the opponents had to take their stand behind their goal line. Frequently a goal was kicked; very often not. The modification, first allowed, was to count that side the winner which had gained the majority of tries, provided no goal or an equal number of goals had been scored; but a majority of one goal took precedence of any number of tries. But this, too, was afterwards abolished, and a system of points instituted by which the side with the majority of points wins.

In the game itself, not only may the ball be kicked in the direction of the opponents' goal, but it may also be carried; but it must not be thrown forward—that is, in the direction of the opponents' goal—though it may be thrown back. Thus the game is really a combination of football and handball. The main principle in the play is that any one who is onside—that is, not offside—may take part. A player is offside if he gets in front of the ball—that is, on the opponents' side of the ball, nearer the opponents' goal line; when in this position, he must not interfere with an opponent or touch the ball under penalty. The main feature of the game is the scrummage. In old days at Rugby school there was practically no limit to the numbers of players on each side, and not infrequently there would be a hundred or more players on one side. This was never prevalent in club football; twenty a-side was the usual number to start with, reduced in 1877 to fifteen a-side, the number still maintained. In the old Rugby big sides the ball got settled amidst a mass of players, and each side attempted to drive it through this mass by shoving, kicking, and otherwise forcing their way through with the ball in front of them. This, then, was the origin of the scrummage, a feature still characteristic of the game.

The game is played usually for one hour, or one hour and ten minutes, sometimes for one hour and a half. Each side defends each goal in turn for half the time of play. Play is started by one side kicking the ball off from the centre of the field in the direction of the opponents' goal. The ball is then caught by one of the other side, who either kicks it, or runs with it. In running he goes on until he is "tackled," or caught, by one of his opponents, unless he should choose to "pass" or throw it to another of his own side, who may either kick, or run, or pass as he chooses. The ball in this way is kept moving until it crosses the touch line, or goal line, or is tackled. If the ball crosses the touch line, both sides line up at right angles to the point where it crossed the line, and the ball is thrown in straight either by one of the same side whose player carried the ball across the touch line, or, if the ball was kicked or thrown out, by one of the opposite side. If the ball crosses the goal line, either a try is gained, as explained above, or if the defending side touch it down first, the other side retire to the line 25 yards from the goal line, and the defending side kick it up the field. If the ball is tackled, the player carrying the ball gets up as soon as possible, and certain players of each side, called the forwards, at once form the scrummage, by putting down their heads, and getting ready to shove against one another. They shove as soon as the ball is put down between the two front rows. In the scrummage the object is, by shoving the opponents back or otherwise breaking away with the ball in front, to carry the ball in the direction of the opponents' goal line by a series of short kicks in which the players run after the ball as fast as possible, while their opponents lie in wait to get the ball, and either by a kick or other device stop the rush. Instead, however, of the forwards breaking away with the ball, sometimes they let the ball come out of the scrummage to certain of their own side posted outside, called half-backs, who either kick or run with it, or pass it to the three-quarter-backs, and so the game proceeds until the ball is once more "dead" —that is, brought to a standstill. The scrummage appears to be an uninteresting manœuvre, and a strange relic of bygone times; but it is not merely a manœuvre in which weight and strength alone tell—it also needs a lot of dexterity in moving the ball with the feet applying the weight to best advantage, and also in outflanking the opposing side, as it were—usually termed wheeling—directing all the force to one side of the scrummage, and thus breaking away. Of the fifteen players who compose a side, the usual arrangement is that eight are called forwards, and form the scrummage; two half-backs are posted immediately outside the scrummage; and four three-quarter-backs, a little behind the halves, stretch in a line across the field, their duties being mainly to run and kick and pass, and prevent the opponents from doing the same. Behind the three-quarters comes the full back, or back, a single individual to maintain the last line of defence; his duties are entirely defensive, either to tackle an opponent who has managed to get through, or, more usually, to catch and return long kicks. As a rule the game is a lively one, for the players are rarely at rest; if there is much scrummaging, it is called a slow game, but, if much running and passing, a fast or an open game. The spectator, unless he be an expert, prefers the open game; but in any case the game is always a hard and exciting struggle, frequently with the balance of fortune swaying very rapidly from one side to the other, so that it is a matter of no surprise to find the British public so ardently attached to it.

Any one interested in the evolution of the game must be referred —if, indeed, such reference is nowadays needed—to *Tom Brown's Schooldays*, where he will find a vivid description of the old Rugby game. The ephemeral literature on Football is enormous, but there are not many good works on the game. The best is *Football: The Rugby Union Game*, by Rev. F. Marshall. In the *Encyclopædia of Sport* and in the *Badminton Library* volume on Football there are articles of more than ephemeral interest. (C. J. N. F.)

(3) *United States.*—Football in America has had a peculiar history, and one showing the great tenacity of life possessed by this sport. At first such football as was played consisted merely in kicking the ball, and the play was without system. In the years 1871–72 certain rules were formulated, but they did not correspond to those in any other country, and were not on the whole satisfactory. Some of the colleges (to which the sport, until recently, was largely confined) formed an association, and adopted these rules. In 1875 Harvard and Yale met under rules taken partly from the Rugby Union and partly from the American game. These proved unsatisfactory, and the next year Harvard and Yale adopted the Rugby Union rules in their entirety. This was the foundation of the present American game. The players found that the Rugby Union rules, while much more satisfactory than anything that had been used, depended in a great measure upon traditional understanding and interpretations. American players were unwilling to be guided by anything except written regulations, and hence it was necessary to add to and explain the rules. Annual conventions were therefore held, and the rules were amplified and from time to time altered. Other colleges joined the Association, and the game became well established in the college world. The roughness and brutality displayed in playing were strongly commented upon in the newspapers, and at that time it was difficult to say whether the game would survive or not; but in another ten years it had made great progress, and then again it became the object of further newspaper assaults, and the Harvard team, through the action of the University authorities, was withdrawn from participation. This withdrawal lasted, however, for only a year. From that time the game has been characterized by lessening tendencies to roughness, by increasing skill, and by greater satisfaction to players and spectators. For some time past it has been, perhaps, the most popular sport in the college calendar, and has drawn crowds of from 35,000 to 40,000 people at the principal games. The Association disbanded some years ago, but a Rules Committee, invited by the University Athletic Club of New York, has made the necessary changes in the rules from time to time, and these have been accepted by the country at large. In the West associations have been formed, and still exist; but the game in the East is played principally under separate agreements between the contesting universities, all playing, however, under one code of rules.

The rules provide for a field 330 feet long by 160 feet wide, upon which teams composed of eleven men each contend for a period of two thirty-five minute halves, the total score at the end of the second half determining the victor. The scoring is by goals, touch-downs, and safety touch-downs. A goal is scored when the ball is kicked through the upright goal-posts and above the cross-bar connecting the posts at a distance of 10 feet above the ground; a touch-down when the ball is carried and touched to the ground behind the goal line; a safety touch-down when the opponent is forced to carry the ball across his own goal line. The points and their values are: Goal from touch-down, 6 points; goal from field-kick, 5 points; touch-down from which no goal is kicked, 5 points; safety by opponents, 2 points. Any player when on-side can run with the ball, and his opponent may tackle him; if stopped, he must put the ball down, and a line-up or scrimmage is then formed. The ball may also be advanced by kicking. Infringement of the rules constitutes a foul, and various penalties are imposed.

Upon the above simple framework there has been built a most intricate system of play. The principle of the game is absolutely clear to the spectator, and therein lies its especial charm. There stands out boldly one cardinal object, namely, to advance the ball towards the opponent's goal. When this advance is attempted by means of kicking, the ball is usually sent as far as possible down into the opponent's territory, two or three men of the kicking side following it, and, in case it is muffed, endeavouring to secure it, or, if it be caught, to prevent the catcher from carrying it back on a run or returning the kick. The kicking game is most employed when the wind favours. It is also used to relieve the running game. A rule of the sport makes it obligatory upon the side which has failed to advance the ball five yards in three running attempts to surrender it. Hence it is usually to the advantage of the side in possession of the ball, when they have failed in two running attempts, and it looks unlikely that they would succeed in a third, to kick the ball as far as possible into the opponent's territory rather than to surrender it within a yard or so of its immediate position. The running game is more involved than the kicking game, it being the object of the captain to use all possible means to assault the opponents at points of weakness, to enable his runner to encircle the ends of the opponent's line, or to pierce that line at points where the attack can gather the most force, and the defence exhibits the least resistance. Certain signals are used which, presumably unknown to the opponents, indicate to the assaulting side just what the method of assault is to be, and thus enable the men to concentrate suddenly at the one point. This concentration is not finally brought about until after the ball has been put in play, so that the opponents have little chance to anticipate it.

The ball is handled with great accuracy, one man being selected to place the ball on the ground in a scrimmage and to snap it back with his hand to another player who delivers it, usually by a hand-pass or a short throw, to such individual as has been selected for the particular play. No man can pass the ball towards his opponent's goal, and any man is off-side and out of the play if he gets between the ball and his opponent's goal. He cannot then touch the ball until it touches an opponent, or until the man of his own side who has kicked it runs up ahead of him.

In order to measure properly the distance gained or lost the field is marked with white lines every five yards.

The officials consist of an umpire, whose principal duty it is to decide regarding fouls; a referee, who decides questions relating to the progress of the ball and the play; timekeepers and linesmen, who keep the time of the play and mark the exact progress of the ball for the benefit of the referee. The American game is far more involved and intricate than the Rugby, but offers correspondingly greater field for skilful play. Amateur athletic clubs have taken up the sport, and it is now the principal fall game throughout the United States. (W. Ca.)

Forbes, Archibald (1838–1900), British war correspondent, was the son of a Presbyterian minister in Morayshire. He was born 17th April 1838, and educated at Aberdeen University. Entering the Royal Dragoons as a private, he gained, while in the service, considerable practical experience of military life and affairs. Being invalided from his regiment, he settled in London, and adopted the journalistic profession. When the Franco-German war broke out in 1870, Forbes was sent to the front as war correspondent to the *Morning Advertiser*, and in this capacity he gained valuable information as to the plans of the Parisians for withstanding a siege. Transferring his services to the *Daily News*, his brilliant feats in the transmission of intelligence drew world-wide attention to his despatches. He was with the German army from the beginning of the campaign, and he afterwards witnessed the rise and fall of the Commune. His war correspondence in the *Daily News* was republished. Forbes afterwards proceeded to Spain, where he chronicled the outbreak of the second Carlist war; but his work here was interrupted by a visit to India, where he spent eight months upon a mission of investigation into the Bengal Famine of 1874. Then he returned to Spain, and followed at various times the Carlist, the Republican, and the Alfonsist forces. As representative of the *Daily News* he accompanied the Prince of Wales in his tour through India in 1875–76. Forbes went through the Servian campaign of 1876, and was present at all the important engagements. In the Russo-Turkish campaign of 1877 he achieved striking journalistic successes at great personal risk. Attached to the Russian army, he witnessed most of the principal operations, and remained continuously in the field until attacked by fever. His letters, together with those of his colleagues, MacGahan and Millet, were republished by the *Daily News*. On recovering from his fever, Forbes proceeded to Cyprus, in order to witness the British occupation. The same year (1878) he went to India, and in the winter accompanied the Khyber Pass force to Jelalabad. He was present at the taking of Ali Musjid, and marched with several expeditions against the hill tribes. Burma was Forbes's next field of adventure, and at Mandalay, the capital, he had several interesting interviews with King Thibaw. He left Burma hurriedly for South Africa, where, in consequence of the disaster of Isandlwana, a British force was collecting for the invasion of Zululand. He was present at the victory of Ulundi, and his famous ride of 120 miles in fifteen hours, by which he was enabled to convey the first news of the battle to England, remains one of the finest achievements in journalistic enterprise. Forbes subsequently delivered many lectures on his war experiences to large audiences. His closing years were spent in literary work. He had some years before published a military novel entitled *Drawn from Life*, and a volume on his experiences of the war between France and Germany. These were now followed by numerous publications, including *Glimpses through the Cannon Smoke*, 1880; *Souvenirs of some Continents*, 1885; *William I. of Germany: a Biography*, 1888; *Havelock*, in the "English Men of Action" Series, 1890; *Barracks, Bivouacs, and Battles*, 1891; *The Afghan Wars* (1839–80), 1892; *Czar and Sultan*, 1895; *Memories and Studies of War and Peace*, 1895, in many respects autobiographic; and *Colin Campbell, Lord Clyde*, 1896. He died 30th March 1900. (G. B. S.)

Forbes, a town in the county of Ashburnham, New South Wales, Australia, about 289 miles west from Sydney, on the Lachlan river, and with a station on the Western Railway. Its importance as a commercial centre is increasing owing to its advantageous position between the northern and southern markets. Its altitude is 1120 feet. The mean temperature for the year is 62·2° F.; that of January is 78·6°; of July, 47·3°. Population about 3500.

FORESTS AND FORESTRY.

Although most people know what a forest is, a definition of it which suits all cases is by no means easy to give. Manwood, in his treatise of the *Lawes of the Forest*, 1598, defines a forest as "a certain territory of woody grounds, fruitful pastures, privileged for wild beasts and fowls of forest, chase, and warren, to nest and abide in, in the safe protection of the king, for his princely delight and pleasure." This primitive definition has, in modern times, when the economic aspect of forests came more into the foreground, given place to others, so that forest may, in a general way, now be described as "an area which is for the most part set aside for the production of timber and other forest produce, or which is expected to exercise certain climatic effects, or to protect the locality against injurious influences."

As far as conclusions can now be drawn, it is probable that the greater part of the dry land of the earth was, at some time, covered with forest, which consisted of a variety of trees and shrubs grouped according to climate, soil, and configuration of the several localities. When the old trees reached their limit of life, they disappeared, and younger trees took their place. The conditions for an uninterrupted regeneration of the forest were favourable, and the result was vigorous production by the creative powers of soil and climate. Then came man, and by degrees interfered, until in most countries of the earth the area under forest has been considerably reduced. The first decided interference was probably due to the establishment of domestic animals; men burnt the forest to obtain pasture for their flocks. Subsequently similar measures on an ever-increasing scale were employed to prepare the land for agricultural purposes. More recently enormous areas of forest were destroyed by reckless cutting and subsequent firing in the extraction of timber for economic purposes.

It will readily be understood that the distribution and character of the now remaining forests must differ enormously. Large portions of the earth are still covered with dense masses of tall trees, while others contain low scrub, grass land, or are desert. As a general rule, natural forests consist of a number of different species intermixed; but in some cases certain species, called gregarious, have succeeded in obtaining the upper hand, thus forming more or less pure forests of one species only. The number of species differs very much. In many tropical forests hundreds of species may be found on a comparatively small area, in other cases the number is limited. Burma has several thousand species of trees and shrubs, Sind has only ten species of trees. Central Europe has about forty species, and the greater part of Northern Russia, Sweden, and Norway contains forests consisting of about half-a-dozen species. Elevation above the sea acts similarly to rising latitude, but the effect is much more rapidly produced. Generally speaking, it may be said that the tropics and adjoining parts of the earth, wherever the climate is not modified by considerable elevation, contain broad-leaved species, Palms, Bamboos, &c. Here most of the best and hardest timbers are found, such as Teak, Mahogany, and Ebony. The northern countries are rich in Conifers. Taking a section from Central Africa to North Europe, it will be found that south and north of the Equator there is a large belt of dense hardwood forest; then comes the Sahara, then the coast of the Mediterranean with forests of Cork Oak; then Italy with Oak, Olive, Chestnut, gradually giving place to Ash, Sycamore, Beech, Birch, and certain species of Pine; then Switzerland and Germany, where Silver Fir and Spruce gain ground. Silver Fir disappears in Central Germany, and the countries around the Baltic contain forests consisting chiefly of Scotch Pine, Spruce, and Birch, to which, in Siberia, Larch must be added, while the lower parts of the ground are stocked with Hornbeam, Willow, Alder, and Poplar. Australia, again, has its own particular flora of Eucalypts, of which nearly 200 species have been distinguished, as well as Wattles. Some of the Eucalypts attain an enormous height, a tree 472 feet high having been measured. Apart from a limited number of broad-leaved species, the Conifers have become the most important timber trees in the economy of man. They are found in greatest quantities in the countries around the Baltic and in North America. An endless variety of different types of forest are found in different parts of the earth.

Utility of Forests.—In the economy of man and of nature forests are of direct and indirect value, the former chiefly through the produce which they yield, and the latter through the influence which they exercise upon climate, the regulation of moisture, the stability of the soil, the healthiness and beauty of a country, and allied subjects. The *indirect* utility will be dealt with first. A piece of land bare of vegetation is, throughout the year, exposed to the full effect of sun and air currents, and the climatic conditions which are produced by these agencies. If, on the other hand, a piece of land is covered with a growth of plants, and especially with a dense crop of forest vegetation, it enjoys the benefit of certain agencies, which modify the effect of sun and wind on the soil and the adjoining layers of air. These modifying agencies are as follows: (1) The crowns of the trees intercept the rays of the sun, and the falling rain obstructs the movement of air currents, and reduces radiation at night; (2) the leaves, flowers, and fruits, augmented by certain plants which grow in the shade of the trees, form a layer of mould, or humus, which protects the soil against rapid changes of temperature, and greatly influences the movement of water in it; and (3) the roots of the trees penetrate into the soil in all directions, and bind it together. The effects of these agencies have been observed from ancient times, and widely differing views have been taken of them. Of late years, however, more careful observations have been made at so-called parallel stations, that is to say, one station in the middle of a forest, and another outside at some distance from its edge, but otherwise exposed to the same general conditions, and in this way the following results have been obtained: (1) Forests reduce the temperature of the air and soil to a moderate extent, and render the climate more equable; (2) they increase the relative humidity of the air, and reduce evaporation; (3) they tend to increase the precipitation of moisture. As regards the actual rainfall, their effect in low lands is *nil* or very small; in hilly countries it is probably greater, but definite results have not yet been obtained, owing to the difficulty of separating the effect of forests from that of other factors. (4) They help to regulate the water supply, produce a more sustained feeding of springs, tend to reduce violent floods, and render the flow of water in rivers more continuous; (5) they assist in preventing denudation, erosion, landslips, avalanches, the silting up of rivers and low lands, and the formation of sand dunes; (6) they reduce the velocity of air currents, protect adjoining fields against cold or dry winds, and afford shelter to cattle, game, and useful birds; (7) they may, under certain conditions, improve the healthiness of a country, or help in its defence; (8) they increase the beauty of a country, and produce a healthy æsthetic influence upon the people.

The direct *utility* of forests is chiefly due to their produce, the capital which they represent, and the work which they provide. The principal produce of forests consists of timber and firewood. Both are necessaries for the daily life of the people. In modern times iron and other materials have to a considerable extent replaced timber, while coal, lignite, and peat compete with firewood; nevertheless wood is still indispensable, and likely to remain so. This is borne out by the statistics of the most civilized nations. Whereas the population of Great Britain and Ireland during the period 1880–1900, increased by about 20 per cent., the imports of timber, during the same period, increased by 45 per cent.; in other words, every head of population in 1900 used more timber than twenty years earlier. Germany produced in 1880 about as much timber as she required; in 1899 she imported upwards of 4,600,000 tons, valued at £14,000,000, and her imports are rapidly increasing, although the yield capacity of her own forests is much higher now than it was formerly. Wood is now used for many purposes which formerly were not thought of. The manufacture of the wood pulp annually imported into Britain consumes at least 2,000,000 tons of timber. A texture closely resembling silk is now actually made of wood. The variety of other, or minor, produce yielded by forests is very great, and much of it is essential for the well-being of the people and for various industries. The yield of fodder is of the utmost importance in countries subject to periodic droughts; in many places field crops could not be grown successfully without the leaf-mould and brushwood taken from the forests. As regards industries, attention need only be drawn to such articles as commercial fibre, tanning materials, dye-stuffs, lac, turpentine, resin, caoutchouc, guttapercha, &c. Great Britain and Ireland alone import every year such materials to the value of more than £8,000,000.

The *capital* employed in forests consists chiefly of the value of the soil and growing stock of timber. The latter is, ordinarily, of much greater value than the former wherever a sustained annual yield of timber is expected from a forest. In the case, for instance, of a Scotch Pine forest, the value of the growing stock is, under the abovementioned condition, from three to five times that of the soil. The rate of interest yielded by capital invested in forests differs, of course, considerably according to circumstances, but on the whole it may, under proper management, be placed equal to that yielded by agricultural land; it is lower than the agricultural rate on the better classes of land, but higher on the inferior classes. Hence the latter are specially indicated for the forest industry, and the former for the production of agricultural crops. Forests require *labour* in a great variety of ways, such as (1) general administration, formation, tending, and harvesting; (2) transport of produce; and (3) industries which depend on forests for their prime material. The labour indicated under the first head differs considerably according to circumstances, but its amount is always smaller than that required if the land is used for agriculture. Hence forests provide additional labour only if they are established on surplus lands. Owing to the bulky nature of forest produce its transport forms a business of considerable magnitude, the amount of labour being perhaps equal to half that employed under the first head. The greatest amount of labour is, however, required in the working up of the raw material yielded by forests. In this respect attention may be drawn to the chair industry in and around High Wycombe in Buckinghamshire, where more than 20,000 labourers are employed in converting the Beech, grown on the adjoining chalk hills, into chairs and tools of many patterns. Complete statistics for Great Britain are not available under this head, but it may be mentioned that in Germany the people employed in the forests amount to 2·3 per cent.; those employed on transport of forest produce, 1·1 per cent.; labourers employed on the various wood industries, 8·6 per cent.; or a total of 12 per cent. of the population of the country. An important feature of the work connected with forests and their produce is that a great part of it can be made to fit in with the requirements of agriculture; that is to say, it can be done at seasons when field crops do not require attention. Thus the rural labourers or small farmers can earn some money at times when they have nothing else to do, and when they would probably sit idle if no forest work were obtainable.

Whether, or how far, the utility of forests is brought out in a particular country depends on its special conditions, such as (1) the position of a country, its communications, and the control which it exercises over other countries, such as colonies; (2) the quantity and quality of substitutes for forest produce available in the country; (3) the value of land and labour, and the returns which land yields if used for other purposes; (4) the density of population; (5) the amount of capital available for investment; (6) the climate and configuration, especially the geographical position, whether inland or on the border of the sea, &c. No general rule can be laid down, showing whether forests are required in a country, or, if so, to what extent; that question must be answered according to the special circumstances of each case. The subjoined table shows the forests of various European states:—

Countries.	Area of Forests, in Acres.	Percentage of Total Area of Country under Forest.	Percentage of Forest Area belonging to the State.	Forest per Head of Population, in Acres.
1. Sweden	48,000,000	44	27	8·9
2. Norway	17,000,000	21	12	8·4
3. Russia, including Finland	516,000,000	40	61	5·9
4. Bosnia and Herzegovina	6,790,000	53	70	4·9
5. Bulgaria	10,650,000	45	...	3·2
6. Spain	20,960,000	17	84	1·3
7. Hungary	22,420,000	28	16	1·3
8. Austria proper	23,990,000	32	7	1·0
9. Servia	2,390,000	20	...	1·0
10. Rumania	5,030,000	17	47	1·0
11. Greece	2,030,000	16	80	·9
12. Luxembourg	190,000	30	...	·9
13. Switzerland	2,100,000	20	4	·7
14. Germany	34,490,000	26	33	·7
15. France	23,530,000	18	12	·6
16. Italy	10,110,000	14	4	·3
17. Denmark	600,000	6	24	·2
18. Great Britain	3,030,000	4	3	·1
19. Belgium	1,250,000	17	5	·1
20. Portugal	770,000	3	8	·1
21. Holland	570,000	7	...	·1
22. Turkey	6,180,000	8	...	...
	758,080,000	31	...	2

These data exhibit considerable differences, since the percentage of the forest area varies from 3 to 53; and Russia, Sweden, and Norway may as yet have more forest than they require for their own population. On the other hand, Great Britain and Ireland, Denmark, Portugal, Holland, and even Belgium, France, and Italy have not a sufficient forest area to meet their own requirements; at the same time, they are all sea-bound countries, and importation is easy, while most of them are under the influence of moist sea winds, which reduces to a subordinate position the importance of forests for climatic reasons.

Intimately connected with the area of forests in a country is the state of ownership—whether they belong to the state, corporations, or to private persons. Where, apart from the financial aspect and the supply of work, forests are not required for the sake of their indirect effects, and where importation from other countries is easy and assured, the Government of the country need not, as a rule, trouble itself to maintain or acquire forests. Where the reverse conditions exist, and especially where the cost of transport over long distances becomes prohibitive, a wise administration will take measures to assure the maintenance of a suitable proportion of the country under forest. This can be done either by maintaining or constituting a suitable area of state forests, or by exercising a certain amount of control over corporation and even private forests. Such measures are more called for in continental countries than in those which are sea-bound, as is proved by the above statistics.

The subjoined table shows the net imports and exports of European countries (average data, calculated from the returns of recent years, whenever available):—

Countries.	Quantities in Tons.		Values in £ sterling.	
	Imports.	Exports.	Imports.	Exports.
Great Britain and Ireland	9,290,000	..	22,190,000	..
Germany	4,600,000	..	14,820,000	..
France	1,230,000	..	3,950,000	..
Belgium	1,020,000	..	4,100,000	..
Denmark	470,000	..	1,250,000	..
Italy	420,000	..	1,250,000	..
Spain	210,000	..	1,180,000	..
Holland	180,000	..	720,000	..
Switzerland	170,000	..	590,000	..
Portugal	60,000	..	200,000	..
Bulgaria	50,000	..	50,000	..
Greece	35,000	..	130,000	..
Servia	15,000	..	15,000	.
Rumania	..	60,000	..	180,000
Norway	..	1,040,000	..	1,870,000
Austria-Hungary, with Bosnia & Herzegovina	..	3,670,000	..	10,800,000
Sweden	..	4,460,000	..	7,930,000
Russia with Finland	..	5,900,000	..	8,900,000
Total	17,750,000	15,130,000	50,445,000	29,680,000
Net Imports	2,620,000	..	20,765,000	..

Supply of Timber—Imports and Exports.—The only timber-exporting countries of Europe are Russia, Sweden, Norway, Austria-Hungary, and Rumania; all the others either have only enough for their own consumption, or import timber. Great Britain and Ireland import now upwards of 9,000,000 tons a year, Germany about 4,600,000 tons, and Belgium about 1,000,000 tons. Holland, France, Portugal, Spain, and Italy are all importing countries, and so are Asia Minor, Egypt, and Algeria. The west coast of Africa exports hardwoods, and imports coniferous timber. The Cape and Natal import considerable quantities of Pine and Fir wood. Australasia exports hardwoods and a little Kauri Pine from New Zealand, but imports far larger quantities of light Pine and Fir timber. British India and Siam export Teak and small quantities of fancy woods. The West Indies and South America export hardwoods, and import Pine and Fir wood. The United States of America will not much longer be a genuine exporting country, since it imports already almost as much timber from Canada as it exports. Canada exports considerable quantities of timber. The Dominion has still a forest area of 1,250,000 square miles, equal to 38 per cent. of the total area, and giving 165 acres of forest for every inhabitant. Although only about one-third of the forest area can be called regular timber lands, Canada possesses an enormous forest wealth, with which she might supply permanently nearly all other countries deficient in material, if the governing bodies in the several provinces would only determine to stop the present fearful waste caused by axe and fire, and to introduce a regular system of management. As matters stand, the resources of the most valuable timber of Canada, the White or Weymouth Pine (*Pinus Strobus*), are nearly exhausted, the great stores of Spruce in the eastern provinces are being rapidly destroyed, and the forests of Douglas Fir in the western provinces have been attacked for export to the United States and elsewhere.

Taking the remaining stocks of the whole earth together, it may be said that a sufficient quantity of hardwoods is available, but the only countries which are able to supply coniferous timber for export on a considerable scale are Russia, Sweden, Norway, and Canada. As these countries have practically to supply the rest of the world, and as the management of their forests is far from satisfactory, the question of supplying light Pine and Fir timber, which form the very staff of life of the wood industries, must become a very serious matter before many years have passed. Unmistakable signs of the coming crisis are everywhere visible to all who wish to see, and it is difficult to overstate the gravity of the problem, when it is remembered, for instance, that 87 per cent. of all the timber imported into Great Britain consists of light Pine and Fir, and that most of the other importing countries are similarly situated. In some of these countries little or no room exists for the extension of wood land, but this statement does not apply to Great Britain and Ireland, which contain upwards of 12,000,000 acres of waste land, and 12,500,000 acres of mountain and heath land used for light grazing. One-fourth of that area, if put under forest, would produce all the timber now imported, which can be grown in Britain, that is to say, about 95 per cent. of the total. The subjoined table shows the movements of timber within the greater part of the British Empire, based on a few years' average :—

Countries.	Annual Average during the Years 1890–94.		Annual Average during the Years 1895–99.	
	Imports, value in £.	Exports, value in £.	Imports, value in £.	Exports, value in £.
Great Britain and Ireland . . .	17,595,000	..	22,190,000	..
New South Wales .	467,000	..	311,000	..
Victoria . . .	831,000	..	231,000	..
South Australia . .	250,000	..	198,000	..
Ceylon	..	22,000	21,000	..
Mauritius . . .	41,000	..	37,000	..
Natal	99,000	..	176,000	..
Cape of Good Hope .	160,000	..	416,000	..
Jamaica . . .	57,000	..	55,000	..
Barbadoes . . .	65,000	..	33,000	..
Trinidad . . .	41,000	..	40,000	..
British Guiana . .	41,000	..	27,000	..
Queensland . . .	..	11,000	..	5000

Forest Management.—In early times there was practically no forest management. As long as the forests occupied considerable areas, their produce was looked upon as the free gift of nature, like air and water; men took it, used it, and even destroyed it without let or hindrance. With the gradual increase of population and the consequent reduction of the forest area, proprietary ideas developed; people claimed the ownership of certain forests, and proceeded to protect them against outsiders. Subsequently the law of the country was called in to help in protection, leading to the promulgation of special forest laws. By degrees it was found that mere protection was not sufficient, and that steps must be taken to enforce a more judicious treatment, as well as to limit the removal of timber to what the forests were capable of producing permanently. The teaching of general science and of political economy was brought to bear upon the subject, so that now forestry has become a special science. This is recognized in many countries, amongst which Germany stands first, closely followed by France, Austria, Denmark, and Belgium. Of non-European countries the palm belongs to British India, and then follow Ceylon, the Cape of Good Hope, and Japan. The United States of America has also turned its attention to the subject. (See separate section below.) Most of the British colonies are, in this respect, as yet in a backward state, and the matter has still to be fought out in Great Britain and Ireland, though many writers have urged the importance of the question upon the public and the Government. There can be no doubt that all civilized countries must, sooner or later, adopt a rational and systematic treatment of their forests. The progress made in this direction up to 1889 was described in the article Forests in the 9th edition of this work (*Ency. Brit.*, vol. ix.). The following additional remarks furnish later information and statistics.

The British Empire.

Great Britain and Ireland. — The forests of Great Britain and Ireland, in spite of the large imports of timber, have not been appreciably extended up to the present time because (1) the rate at which foreign timber has been laid down in Britain is very low, thus keeping down the price of home-grown timber; (2) foreign timber is preferred to home-grown material, because it is of superior quality, while the latter comes into the market in an irregular and intermittent manner; (3) nearly the whole of the waste lands are private property. As regards prices, it can be shown that the lowest point was reached about the year 1888, in consequence of the remarkable development of means of communication, that prices then remained fairly stationary for some years, and that about 1894 a slow but steady rise set in. This was due to the gradual approach of the coming crisis in the supply of coniferous timber to the world. It can be shown that even with present prices the growing of timber can be made to pay, provided it is carried on in a rational and economic manner. Improved sylvicultural methods must be applied, so as to produce a better class of timber, and the forests must be managed according to well-arranged working plans, which provide for a regular and sustained out-turn of timber year by year, so as to develop a healthy and steady market for locally-grown material. Unfortunately the private proprietors of the waste lands are in many cases not in a financial position to plant. Starting forests demands a certain outlay in cash, and the proprietor must forego the income, however small, hitherto derived from the land until the plantations begin to yield a return. In these circumstances the State may well be expected to help in one or all of the following ways:—(1) The equipment of forest schools, where economic forestry, as elaborated by research, is taught; (2) management of the Crown forests on economic principles, so as to serve as patterns to private proprietors; (3) advances should be made to landed proprietors who desire to plant land, but are short of funds, just as is done in the case of improvements of agricultural holdings; and (4) the State might acquire surplus lands in certain parts of the country, such as congested districts, and convert them into forests. Action in these directions would soon lead to substantial benefits. The income of landed proprietors would rise, a considerable sum of money now sent abroad would remain in the country, and forest industries would spring up, thus helping to counteract the ever-increasing flow of people from the country into the large towns, where only too many must join the army of the unemployed. Even within a radius of 50 miles of London 700,000 acres of land are unaccounted for in the official agricultural returns. In Ireland more than 3,000,000 acres are waiting to be utilized, and it is well worth the consideration of the Irish Land Commissioners, whether the lands remaining on their hands, when buying and breaking up large estates, should not be converted into State forests. Such a measure might become a useful auxiliary in the peaceful settlement of the Irish land question. No doubt success depends upon the probable financial results. There are at present no British statistics to prove such success; hence, by way of illustration, it may be stated what the results have been in the kingdom of Saxony, which, from an industrial point of view, is comparable with England. That country has 432,085 acres of State forests, of which about one-eighth are stocked with broad-leaved species, and seven-eighths with conifers. Some of the forests are situated on low lands, but the bulk of the area is found in the hilly parts of the country up to an elevation of 3000 feet above the sea. The average price realized of late years per cubic foot of wood amounts to 5d., and yet to such perfection has the management been brought by a well-trained staff, that the mean annual net revenue, after meeting all expenses, comes to 21s. an acre all round. There can be no doubt that, under the more favourable climate of Great Britain, even better results can be obtained, especially if it is remembered that foreign supplies of coniferous timber must fall off, or, at any rate, the price per cubic foot rise considerably.

British India.—The history of forest administration in India is exceedingly instructive to all who take an interest in the welfare of the British Empire, because it places before the reader an account of the gradual destruction of the bulk of the natural forests, a process through which most other British colonies are now passing, and then it shows how India emerged triumphantly from the self-inflicted calamity. As far as information goes, India was, in the early times, for the most part covered with forest. Subsequently settlers opened out the country along fertile valleys and streams, while nomadic tribes, moving from pasture to pasture, fired alike hills and plains. This process went on for centuries. With the advent of British rule forest destruction became more rapid than ever, owing to the increase of population, extension of cultivation, the multiplication of herds of cattle, and the universal firing of the forests to produce fresh crops of grass. Then railways came, and with their extension the forests suffered anew, partly on account of the increased demand for timber and firewood, and partly on account of the fresh impetus given to cultivation along their routes. Ultimately, when failure to meet the requirements of public works was brought to notice, it was recognized that a grievous mistake had been made in allowing the forests to be recklessly destroyed. Already in the early part of the 19th century sporadic efforts were made to protect the forests in various parts of the country, and these continued intermittently; but the first organized steps were taken about the year 1855, when Lord Dalhousie was governor-general. At that time conservators of forests were appointed in Bombay, Madras, and Burma. Soon afterwards other appointments followed, and in 1864 an organized State department, presided over by the Inspector-General of Forests, was established. Since then the Indian Forest Department has steadily grown, so that it has now become of considerable importance for the welfare of the people, as well as for the Indian exchequer.

The first duty of the Department was to ascertain the position and extent of the remaining forests, and more particularly of that portion which still belonged to the State. Then a special forest law was passed, which was superseded in 1878 by an improved Act, which provided for the legal formation of State forests; the determination, regulation, and, if necessary, commutation of forest rights; the protection of the forests against unlawful acts, and the punishment of forest offences; the protection of forest produce in transit; the constitution of a staff of forest officers, provision to invest them with suitable legal powers, and the determination of their duties and liabilities. The officers who administered the Department in its infancy were mostly botanists and military officers. Some of these became excellent foresters. In order to provide a technically trained staff arrangements were made in 1866 by Sir Dietrich Brandis, the first Inspector-General of Forests, for the training of young Englishmen at the French Forest School at Nancy and at similar institutions in Germany. In 1876 the students were concentrated at Nancy, and in 1885 an English forest school for India was organized in connexion with the Royal Indian Engineering College at Cooper's Hill. The imperial forest staff of India consists of—officers not specially trained before entering the Department, 43; officers trained in France and Germany, 53; officers trained at Cooper's Hill, 102—total, 198.

In 1878 a forest school was started at Dehra Dun, North-Western Provinces, for the training of natives of India as executive officers on the provincial staff. Since then similar schools, though on a smaller scale, have been established at Poona in Bombay and at Tharrawaddy in Burma. A school for Madras will, no doubt, soon follow. Up to date 553 officers of this class have been appointed. In addition, there are about 12,000 subordinates, foresters, and forest guards, who form the protective staff.

The progress made since 1864 is really astonishing. According to the latest available returns, the areas taken under the management of the Department are—reserved State forests, or permanent forest estates, 79,311 square miles; other State forests, 34,606 square miles; or a total of 113,917 square miles, equal to 13 per cent. of the area over which they are scattered. At present, therefore, the average charge of each member of the controlling staff comprises 350,000 acres; that of each executive officer, 130,000 acres; and that of each protective official, 6000 acres. It is the intention to increase the executive and protective staff considerably, in the same degree as the management of the forests becomes more detailed. Of the above-mentioned area the Forest Survey Branch, established in 1872, has up to date surveyed and mapped about 25,000 square miles, and the Survey of India 24,000, or a total of about 49,000 square miles. From 1864 onwards efforts were made to introduce systematic management into the forests, based upon working plans, but as the management had been provincialized, there was no central or continuous control. This was remedied in 1884, when a central Working Plans Office, under the Inspector-General of Forests, was established. This officer has since then controlled the preparation and execution of the plans, a procedure which has led to most beneficial results. Plans referring to about 15,000 square miles are now in operation, and after a reasonable lapse of time there should not be a single forest of importance which is not worked on a well-regulated plan, and on the principle of a sustained yield. While the danger of overworking the forests is thus being gradually eliminated, their yield capacity is increased by suitable sylvicultural treatment and by fire protection. Formerly most of the important forests were annually or periodically devastated by jungle fires, sometimes lighted accidentally, in other cases purposely. Now, 29,000 square miles of forest are actually protected against fire by the efforts of the Department, and it is the intention gradually to extend protection to all permanent State forests. Grazing of cattle is of great importance in India; at the same time it is liable to interfere seriously with the reproduction of the forests. To meet both requirements careful and minute arrangements have been made, according to which at present 32,106 square miles are closed to grazing;

41,001 square miles are closed only against the grazing of goats, sheep, and camels; while 40,810 square miles are open to the grazing of all kinds of cattle. The areas closed in ordinary years form a reserve of fodder in years of drought and scarcity. During famine years they are either opened to grazing, or grass is cut in them and transported to districts where the cattle are in danger of starvation. The service rendered in this way by a wise forest administration should not be underrated, since one of the most serious calamities of a famine—the want of cattle to cultivate the land—is thus if not avoided, at any rate considerably reduced.

The financial results of forest administration in India have been as follows:—

Period	Mean Annual Net Revenue. Rupees.	Percentage of Increase during Period.
1865–70 . .	1,372,733	...
1870–75 . .	1,783,248	30
1875–80 . .	2,224,687	25
1880–85 . .	3,385,745	52
1885–90 . .	5,066,671	50
1890–95 . .	7,370,572	45

The revenue since 1886 has been considerably increased by the annexation of Upper Burma, still the progress made in the rest of India is highly satisfactory. The highest percentage of increase occurred in the period 1880–85. Apart from the net revenue, large quantities of produce are given free of charge, or at reduced rates, to the people of the country. Thus in 1896–97 the net revenue amounted to Rs.7,811,360, while the produce given free to the people was valued at Rs.3,446,500, making a total benefit derived from the State forests during that year equal to Rs.11,257,860. The sales during the same year mounted up to 55 million cubic feet of timber, 150 million cubic feet of fuel, and 172 million bamboos. The receipts from the sale of other forest produce came to 5 million rupees, out of a total gross revenue of Rs.17,856,510.

These results are highly creditable to the Government of India, which has led the way towards the introduction of rational forest management into the British Empire, thus setting an example which ought to be followed by all the British colonies. Above all, action is most urgently needed in Canada, where an enormous State property is threatened by destruction. Apart from India, Ceylon and Cape Colony are perhaps the only colonies where real and substantial progress has been made.

UNITED STATES.

The Forest Regions.—According to Mr Henry Gannett, of the U.S. Geological Survey, the wooded area of the United States, exclusive of Alaska, is 1,094,496 square miles, or 37 per cent. of the total area of the country. It is divided by the great treeless region east of the Rocky Mountains into two grand divisions, which may be called the Eastern and the Western forests. The Eastern forest is characterized by the predominance, on the whole, of broad-leafed trees, the comparative uniformity of its general types over wide areas, and its naturally unbroken distribution. In the Western forest conifers are conspicuously predominant, the individual species often reach enormous and even unequalled dimensions, the forest is frequently interrupted by treeless areas, and the transitions from one type to another are often exceedingly abrupt. Both divisions are botanically and commercially rich in species.

The Eastern forest may conveniently be subdivided into three members:—

(1) The Northern forest, marked by great density and large volume of standing timber, and a comparative immunity, in its virgin condition, from fire. The characteristic trees are Maples, Birches, and Beeches among the hardwoods, and White Pine, Spruce, and Hemlock among conifers.

(2) The Southern forest is on the whole less dense than the Northern, and more frequently burned over. Among its characteristic trees are Oaks, Gums, the Longleaf and other Pines, Bald Cypress, and White Cedar.

(3) The Interior Hardwood forest, which differs comparatively little from adjacent portions of the Northern and Southern forests except in the absence of the conifers, which form the determining (but not the predominant) factors in their composition. Among its trees are the Chestnuts, Hickories, Ashes, and other hardwoods already mentioned.

The Western division has two members:—

(1) The Pacific Coast forest, marked by the great size of its trees and the vast accumulations of merchantable timber. Devastating fires are frequent, especially to the north. Among its characteristic species are the Redwood and the Big Tree (*Sequoia*), the Red Fir, Sugar Pine, Western Hemlock, Western Red Cedar (*Thuja*), and Tideland Spruce.

(2) The Interior Coniferous forest, whose characteristic species are the Western Yellow Pine, Engelmann Spruce, and the Lodgepole Pine. This forest is frequently broken by treeless areas of greater or less extent, especially towards the south, and it suffers greatly from fire. Subarid in character, except to the north and at high elevations, the vast mining interests of the region and its treeless surroundings give this forest an economic value out of proportion to the quantities of timber it contains.

This distribution of the various forests is indicated in the map on p. 435. The other map shows the situation of the Federal forest reserves hereafter mentioned.

The forests of Alaska are not well known. Of great but undefined area, and containing, it is believed, large amounts of the timber necessary to the development of mineral and other resources, they have hitherto been little impaired except by fire. Spruce, Western Hemlock, and Alaska Cedar are among the characteristic trees.

The National Forest Policy.—The forest policy of the United States may be said to have had its origin in 1799 in the enactment of a law which authorized the purchase of timber suitable for the use of the navy, or of land upon which such timber was growing. It is true that laws were in force under the early governments of Massachusetts, New Jersey, and other colonies providing for the care and protection of forest interests in various ways, but these laws were distinctly survivals of tendencies acquired in Europe, and for the most part of little use. It was not until the apparent approach of a dangerous shortage in certain timber supplies became known that the first real step in forest policy was taken by the United States. Successive laws passed from 1817 to 1831 strove to give larger effect to the original enactment, but without permanent influence towards the preservation of the Live Oak (*Quercus virginiana* Mill.), which was the object in view. A long period of inaction followed these early measures. In 1831 the solicitor of the Treasury assumed

a partial responsibility for the care and protection of the public timber lands, and in 1855 this duty was transferred to the Commissioner of the General Land Office, in the Department of the Interior, upon whom it has rested ever since. The effect of these changes upon forest protection was unimportant. When, however, at the close of the Civil War railway building in the United States took on an unparalleled activity, the destruction of forests by fire and the axe increased in a corresponding ratio, and public sentiment became alarmed. Action by several of the States slightly preceded that of the Federal Government, but in 1876 Congress, acting under the inspiration of a memorial from the American Association for the Advancement of Science, authorized the appointment of an officer (Dr Franklin B. Hough) under the Commissioner of Agriculture, to collect and distribute information upon forest matters. His office became in 1886 the Division (on 1st July 1901 the Bureau) of Forestry in what is now the United States Department of Agriculture.

Forest Reservations.—As the railways advanced into the treeless interior public interest in tree-planting became keen. In 1873 Congress passed, and later amended and repealed, the timber-culture Acts, which granted homesteads on the treeless public lands to settlers who planted one-fourth of their entries with trees. Though these measures were not successful in themselves, they directed attention towards forestry. The Act which repealed them in 1891 contained a clause which lies at the foundation of the present forest policy of the United States. By it the President was authorized to set aside "any part of the public lands wholly or in part covered with timber or undergrowth, whether of commercial value or not, as public reservations, and the President shall, by public proclamation, declare the establishment of such reservations and the limits thereof." Some eighteen million acres had been proclaimed as reservations at the time when, in 1896, the National Academy of Sciences was asked by the Secretary of the Interior to make an investigation and report upon "the inauguration of a rational forest policy for the forest lands of the United States." Upon the recommendation of the committee of the Academy President Cleveland established more than twenty-one million acres of new reserves on 22nd February 1897. His action was widely misunderstood and attacked, but to the public interest which it awakened in forest questions is directly due the rapid progress of forestry in the United States since that time.

The proclamation of the Cleveland forest reserves was followed by the enactment on 4th June 1897 of a law which conferred upon the Secretary of the Interior all the principal powers required for the proper management of the reserves through the General Land Office. This law provides for the designation and sale of mature timber, permits the use of timber free of charge in small quantities by settlers and miners, authorizes the Secretary of the Interior to "make such rules and regulations and establish such service as will insure the objects of such reservations, namely, to regulate their occupancy and use, and to preserve the forests thereon from destruction," provides for the exchange of private lands within the forest reserve boundaries for vacant public lands outside, establishes criminal and civil jurisdiction within forest reserves, and provides for the modification of their boundaries. An extremely important provision continues the mining laws of the United States within the reserves. This just and proper clause, which, at the time of its passage, was indispensable for the success of the measure which contained it, must very seriously affect the management of the national forests, since the mining laws confer the right to use the timber on any mineral claim for the development of that claim.

Government Forest Administration.—Under this law the Department of the Interior has organized in the General Land Office a scheme of forest administration with the protection of the reserves as its chief objective. Some progress in the sale of timber has also been made. The appropriation for the forest work of the General Land Office for the year 1901–1902 was $300,000. The force employed consists of one inspector, nine superintendents, ten to fifteen supervisors in winter and thirty-five to forty in summer, and a varying number of forest rangers, which in summer attains 430 men. Protection against fire is its most important function.

The Act of 4th June 1897, which provided an administration for the forest reserves, entrusted the surveying and mapping of their topography and forests to the United States Geological Survey, by which the work has since been prosecuted with admirable success. The estimates and descriptions which it is publishing of the amount and character of the forests of the United States are by far the most intelligent and most trustworthy that have been made. The appropriation for work in the forest reserves during the year 1901–1902 was $125,000.

In addition to the General Land Office and the United States Geological Survey, there is a third Federal organization which deals with forest matters. This is the Bureau of Forestry in the United States Department of Agriculture, to which are assigned all technical forest questions, together with the responsibility for the progress of forestry among private owners of forest lands and among the people at large. It is engaged in the preparation of working plans for the national forest reserves, for the single important State forest preserve, and for private owners (a method of co-operation made necessary by the fact that nearly all the trained foresters in the United States are members of the Bureau), and in assisting tree-planters through practical advice expressed in detailed plans for planting. It studies forest fires, the effect of grazing upon the forest, especially in the forest reserves, and the growth and reproduction of commercially valuable trees, seeks improvements in methods of lumbering, of advantage both to the forest and to its yield, and conducts other forest investigations. Its appropriation for the fiscal year 1898–1899, when work of this character was begun, was $28,520; for 1901–1902 it was $185,440.

The dispersal of the Federal forest work among the three agencies mentioned above, while inevitable at the time it was brought about, is so no longer. Its consolidation under a single head is a necessity of the immediate future. An excellent Forest Fire Law was passed in Congress in 1900.

Forestry among the States.—Among the States, forestry has not yet reached the stage of practical application on the ground. New York holds 1,370,928 acres of forest land, but is for the present unable to apply forest management, although the Forest, Fish, and Game Commission is engaged in the preparation of working plans for the State forests in co-operation with the Bureau of Forestry. The New York legislature has appropriated in all $2,000,000 for the purchase of forest land. A similar policy has been adopted by Pennsylvania, and Minnesota and Michigan have taken steps in the same direction. Altogether fifteen of the States are, or have recently been, directly occupied with forest matters. Laws to prevent damage from forest fires have been enacted by practically all the States, and in general they are of a very satisfactory character. Their enforcement, unfortunately, has been lax. Public sentiment, however, is making very rapid progress. Among the best laws are those of Maine, New Hampshire, Minnesota, New York, Pennsylvania, and Wisconsin. The New York law, for example, provides for the appointment of one or more fire wardens in each town of the counties in which damage by fire is especially to be feared. In other counties supervisors of towns are *ex-officio* fire wardens. A chief fire warden has general supervision of their work. The wardens, half of the cost of whose services is paid by the State, receive compensation only for the time actually employed in fighting fires. They may command the service of any citizen to assist them. Setting fire to woods or waste lands belonging to the State or to another, if such fire results in loss, is punishable by a fine not exceeding $250, or imprisonment not exceeding one year, or both, and damages are provided for the person injured. Since fire is beyond question the most dangerous enemy of forests in the United States, the measures taken against it are of vital importance.

Forest Associations.—Public sentiment in favour of the protection of forests is now widespread and increasingly effective throughout the United States. As the general understanding of the objects and methods of forestry becomes clearer, the tendency, formerly very marked, to confound ornamental tree-planting and botanical matters with forestry proper is rapidly growing less. At the same time, the number and activity of associations dealing with forest matters is increasing with notable rapidity. There are now some twenty-two such associations in the United States, of which the American Forestry Association is the oldest and most influential. Its objects are, first, to bring about a wiser and more conservative treatment of the forest resources of the country, and to promote educational, legislative, and other measures to that end; and secondly, the diffusion of knowledge regarding the conservation, management, and renewal of forests, the methods of reforesting waste lands, the proper utilization of forest products, the planting of trees for ornament, and cognate subjects of arboriculture. This association has been influential in preparing the groundwork of popular interest in forestry, and especially in advocating and securing the adoption of the federal forest reservation policy, the most important step yet taken by the national Government. The Association is growing rapidly in membership and influence. It publishes as its organ a monthly magazine called *The Forester.* The Pennsylvania Forestry Association has been instrumental in placing that State in the forefront of forest progress. Its organ is a bi-monthly publication called *Forest Leaves.* Other States which have associations or societies of special influence in forest matters are California, Massachusetts, Minnesota, Colorado, and Oregon. Arbor Day, instituted in Nebraska in 1872 as a means of interesting children in the planting of trees, has spread until it is now observed in every State and Territory. It continues to serve an admirable purpose.

Forest Instruction.—Elementary instruction in forestry has already made noteworthy progress, especially in State agricultural colleges, of which thirty-eight offer instruction in forest subjects. The University of Minnesota and Berea College, Kentucky, deserve special mention among the institutions which do not attempt to graduate fully trained foresters; of these there are ten in addition to the agricultural colleges. The Biltmore Forest School, in North Carolina, offers a one-year course in technical forestry, and the New York State College of Forestry, organized in 1898 as a part of Cornell University, offers a four-years' undergraduate technical course modelled on German lines and leading to a degree. A tract of thirty thousand acres in the Adirondack Mountains serves as an experimental forest in connexion with the college. The Yale Forest School, which was opened as a department of Yale University in September 1900, offers a two-years' post-graduate course, with abundant field-work both in the Adirondacks and in Pennsylvania and Connecticut. A summer school of forestry, specially adapted to the training of forest rangers, and for advanced and special students, is conducted at Grey Towers, Milford, Pennsylvania, by the professors of the Yale Forest School.

Forestry on Private Lands.—The practice of forestry among private owners is of old date. One of the earliest instances was that of Jared Eliot, who, in 1730, began the systematic cutting of timber land to supply charcoal for an iron furnace at Old Salisbury, Connecticut. The successful planting of waste lands with timber trees in Massachusetts dates from about ten years later. But such examples were comparatively rare until recent times. At present the intelligent harvesting of timber with a view to successive crops, which is forestry, is much more common than is usually supposed. Among farmers it is especially frequent. It was begun among lumbermen by the late E. S. Coe, of Bangor, Maine, who made a practice of restricting the cut of Spruce from his forests to trees 10, 12, or sometimes even 14 inches in diameter, with the result that much of his land yielded, during his life, a second crop as plentiful as the first. Many owners of Spruce lands have followed his example, but until very recently without improving upon it. Systematic forestry on a large scale among lumbermen was begun in the Adirondacks during the summer of 1898 on the lands of Dr W. S. Webb and Hon. W. C. Whitney, of a combined area of over 100,000 acres, under the superintendence of the then Division of Forestry. In these forests Spruce, Maple, Beech, and Birch predominate, but the Spruce alone is at present of the first commercial importance. The treatment is a form of the selection system. Under it a second crop of equal yield would be ripe for the axe in thirty-five years. Spruce and Pine are the only trees cut. The work had been executed, at anyrate up to the year 1902, with great satisfaction to the owners and the lumbering contractors, as well as to the decided benefit of the forest. The lumbering is regulated by the following rules, and competent inspectors are employed to see that they are rigidly carried out:—(1) No trees shall be cut which are not marked. (2) All trees marked shall be cut. (3) No trees shall be left lodged in the woods, and none shall be overlooked by the skidders or haulers. (4) All merchantable logs which are as large as 6 inches in diameter at the small end must be utilized. (5) No stumps shall be cut more than 6 inches higher than the stump is wide. (6) No Spruce shall be used for bridges, corduroy, skids, slides, or for any purpose except building camps, dams, or booms, unless it is absolutely necessary on account of lack of other timber. (7) All merchantable Spruce used for skidways must be cut into logs and hauled out. (8) Contractors must not do any unnecessary damage to young growth in lumbering; and if any is done, they must discharge the men who did it.

These are perhaps the most notable instances of forestry in the United States. Their example is decidedly the most useful and effective one among lumbermen, especially in the Spruce regions of New England and New York, but neither one was the first case of systematic forestry under regular working plans. The first instance was begun in 1891 on about 4000 acres of forest land, forming part of the estate of George W. Vanderbilt, at Biltmore, North Carolina. The working plan has been extended until now it covers nearly 100,000 acres. A professional forester, with a corps of trained rangers under him, is in charge of the work. Protection against fire and the planting of groves, wood-lots, and wind-breaks by individual initiative also deserve mention among private activities in forestry. The latter, in spite of the repeal of the timber-culture laws, is prosecuted on a large scale over considerable portions of the treeless West.

American Practice.—The conditions under which forestry is practised in Europe and in America differ so widely that rules which are received as axiomatic in the one must often be rejected in the other. Among these conditions in America are the highly developed and specialized methods and machinery of lumbering, the greater facilities for transportation and consequent greater mobility of the lumber trade, the vast number of small holdings of forest land, and the enormous supply of low-grade wood in the timbered regions. High taxes on forest properties, cut-over as well as virgin, notably in the north-western pineries, and the firmly established habits of lumbermen, are factors of great importance. From these and other considerations it follows that such generally accepted essentials of European methods of forestry as a sustained annual yield, a permanent force of forest labourers, a permanent road system, and the like, are in most cases utterly inapplicable in the United States at the present day. Methods of forest management, to find acceptance, must there conform as closely as possible to existing methods of lumbering. Rules of marked simplicity, the observance of which will yet secure the safety of the forest, must open the way for more refined methods in the future. For the present a periodic or irregular yield, temporary means of transport, constantly changing crews, and an almost total ignorance of the sylviculture of all but a very few of the most important trees—all combine to enforce the simplest sylvicultural treatment and the utmost concentration of purpose on the two main objects of forestry, which are the production of a net revenue and the perpetuation of the forest. Such concentration has been followed in practice by complete success.

The forests with which the American forester deals are rich in species, usually endowed with abundant powers of reproduction, and, over a large part of their range, greatly dependent for their composition and general character upon the action of forest fires. Except in its most obvious manifestations, the sylvicultural character of the larger number even of the commercially valuable trees is unknown. Of these there may be said to be in round numbers a hundred out of a total forest flora of about 500 species, but many trees not yet of importance in the lumber trade will become so hereafter, as has already happened in many cases. In a forest thus constituted and in existing circumstances the attention of the forester must be concentrated upon the growth and reproduction usually of a single species, and never of more than a very few. Thus the sylvicultural problems which must be solved in the practice of forestry in America are fortunately less complicated than the presence of so many kinds of trees in forests of such diverse types would naturally seem to indicate.

Special Problems.—It is probable that forest fires have had more to do with the character and distribution of forests in America than any other modifying factor except rainfall. With an annual range over thousands of square miles, in many portions of the United States they occur regularly year after year on the same ground. Trees whose thick bark or abundant seeding gives them peculiar powers of resistance, frequently owe their exclusive possession of vast areas purely to the action of fire. On the economic side fire is equally potent. The probability, or often the practical certainty, of fire after the first cut, commonly determines lumbermen to leave no merchantable tree standing. The prevalence of forest fires is thus one of the most effective barriers to the introduction of forestry. Excessive taxation of timber land is another of almost equal effect. Because of it lumbermen hasten to cut, and afterwards often to abandon, lands which they cannot afford to hold. This evil, which only the progress of public sentiment can control, is especially prevalent in certain portions of the White Pine belt. A third problem of crucial importance to the Western forests, but of a different kind, relates to grazing in the national forest reserves. Much of the early opposition to their establishment came from the grazing interests. Now that the maintenance of the reserves is no longer in question, the discussion hinges chiefly upon the admission of sheep within the reserve boundaries. The trend of public sentiment is against it, but their complete exclusion is both undesirable and unlikely, since there are doubtless considerable portions of the reserves where moderate grazing will do no harm. This question has been officially referred to the Bureau of Forestry, and a thorough investigation is in progress.

Lumbering.—The importance of the lumber trade to the prosperity and progress of the United States is difficult to estimate. According to the census of 1890, which was the latest available at the time of writing, the capital invested in logging operations was $60,442,226, the number of employees engaged, 174,152, and their wages, $38,991,794; saw-mills represented an invested capital of $121,562,226, and employed 286,197 persons, whose wages were $87,784,433. The industries dependent on the forest ranked next to agriculture in their contribution to the national wealth. For 1899 the total consumption of wood for the United States is roughly estimated at 18,307,000,000 cubic feet, divided approximately as follows:—Lumber market and manufactures, 2,250,000,000 cubic feet; fuel, 15,000,000,000 cubic feet; railroad ties, 27,000,000 cubic feet; fencing, 30,000,000 cubic feet; other items, 1,000,000,000 cubic feet. For purposes of comparison, 110 cubic feet may be taken as approximately equal to 1000 board feet. All the operations of the lumber trade in the United States are controlled, and to no small degree determined, by the peculiar unit of measure which has been adopted. This unit, the *board foot*, is generally defined as a board 1 foot long, 1 foot wide, and 1 inch thick, but in reality it is equivalent to 144 cubic inches of manufactured lumber in any form. To purchase logs by this measure one must first know about what each log will yield in 1-inch boards. For this purpose a scale or table is used, which gives the contents of logs of various diameters and lengths in board feet. Under such a standard the purchaser pays for nothing but the saleable lumber in each log, the inevitable waste in slabs and sawdust costing him nothing.

The principal lumber tree of the United States is still the White Pine (*Pinus strobus* L.), usually known in Europe as the Weymouth Pine. It has an average height of 110 feet when mature, and an average diameter of somewhat less than 3 feet. Throughout the Northern subdivision of the Eastern forest it is, or has been, commercially the most important factor. At present it has largely disappeared as an element of the standing forests of New England, New York, and Pennsylvania, and from large portions of its western (and more important) range as well. Trustworthy estimates of the amount of White Pine left standing are not available, but it may be accepted that the first grade of virgin timber is very nearly gone. Of late years the size of the merchantable log has rapidly decreased, until at present much of the White Pine brought to the mill is less than ten inches in diameter. A striking and instructive example of the widespread decline of White Pine as a lumber tree, and its gradual replacement by trees formerly of little moment, is afforded by the official figures of production on the

Penobscot river in Maine, which is still called the Pine Tree State. In 1851 the cut of White Pine was 144 million feet, of Spruce 48 million, of Hemlock 11 million. Thirty years later the Pine cut had sunk to 23 million, the Spruce had risen to 118 million, and the Hemlock had surpassed the Pine by a million feet. In 1900 the cut of Pine was less than 23 million, that of Spruce was 102 million, and that of Hemlock 17 million. It is certain that a similar decline in White Pine production will become general. The following table gives the cut of the north-western pineries (on the headwaters of the Mississippi) for the years 1873 to 1900 inclusive :—

1873 . .	3,993,780,000	1887 . .	7,757,916,784
1874 . .	3,751,306,000	1888 . .	8,388,716,460
1875 . .	3,968,553,000	1889 . .	8,183,050,755
1876 . .	3,879,046,000	1890 . .	8,597,659,352
1877 . .	3,595,333,496	1891 . .	7,879,948,349
1878 . .	3,629,472,759	1892 . .	8,594,222,802
1879 . .	4,806,943,000	1893 . .	7,326,263,782
1880 . .	5,651,295,000	1894 . .	6,821,516,412
1881 . .	6,768,856,749	1895 . .	7,050,669,235
1882 . .	7,552,150,744	1896 . .	5,725,763,035
1883 . .	7,624,789,786	1897 . .	6,233,454,000
1884 . .	7,935,033,054	1898 . .	6,155,300,000
1885 . .	7,053,094,555	1899 . .	6,056,508,000
1886 . .	7,425,368,443	1900 . .	5,485,261,000

Already very many of the White Pine lumbermen and mill-men have removed to the Southern States and the Pacific Coast, driven away by the exhaustion of their supplies. White Pine, as a rule, is cut in the summer and autumn, skidded (dragged to convenient places and piled along the roads) by horses in the early winter, hauled on sleds over ice-coated temporary roads to the banks of streams in the late winter and early spring, and finally driven (floated) down to the booms (chains of floating logs firmly anchored to hold the "drive") near the mill. The mill machinery, as well as the tools and appliances used in felling the trees, and in the various stages of transport from the stump to the mill, and from the mill to the consumer, are usually of the first grade of practical utility.

Second to the White Pine, among the coniferous lumber trees of the Northern forest, is the Spruce (*Picea rubens* Sargent), now, however, used for the most part in the manufacture of paper pulp, for which purpose Poplar (chiefly *Populus tremuloides* Michx. and *P. grandidentata* Michx.) and several other woods are also employed, but on a less gigantic scale. The total consumption of wood for paper in the United States in 1900 approached closely to the equivalent of one billion board feet, of which amount from 10 to 15 per cent. was imported from Canada.

The hardwood product of the country, including fuel, is enormous, but no accurate figures are available. Derived from each of the great divisions of the Eastern forest, and consumed in vast quantities for domestic purposes, its grand total can only be surmised. It is known, however, that Michigan, Wisconsin, and Minnesota, which are the principal sources of White Pine, produced in 1900 more than 900 million board feet of hardwood. Their output has doubled since 1896.

The most widely known lumber tree of the Southern forest is the Longleaf Pine (*Pinus palustris* Mill.), mistakenly called Pitch Pine in Europe, whose timber is probably superior in strength and durability to that of any other member of the genus *Pinus*. The average size of the mature Longleaf Pine is 90 feet in height and 20 inches in diameter. Other important lumber trees are the Shortleaf, Loblolly, and Cuban Pines, the Bald Cypress, and the White Cedar (*Chamæcyparis thyoides* (L.) B.S.P.) among the conifers, and the Yellow or Tulip Poplar and various oaks among broad-leafed trees. Except for the wire cable logging of the Cypress and other swamp trees, the transportation of logs is, on the whole, less highly specialized here than in the Northern forest. The more valuable timber as a rule is in the lower and more level regions, and the proportion of carriage by rail is consequently greater.

Satisfactory statistics of the standing timber or the lumber product of the Southern forest are not available. The report of the Yellow Pine Clearing House gives the total cut of the various southern lumber Pines by 136 firms in eight States during 1900 at 1,878,831,109 board feet, but these figures are incomplete. The production of naval stores as it is carried on in the forests of Longleaf Pine is rapidly destructive to the standing timber, and is directly responsible for disastrous fires. It supplies, however, an important item in the revenue from the Southern forest. In 1900 the value of the exports to foreign countries, in spite of a notable shrinkage, was $13,030,232. The domestic consumption is very large.

In the Pacific Coast forest the principal lumber trees, among many of great importance, are Red Fir, sometimes called Douglas Fir (*Pseudotsuga taxifolia* (Lam.) Britton), in Oregon and Washington, and Redwood in California. The average sizes of these trees when mature are approximately, for the Red Fir, 200 feet high and 4 feet in diameter, and for the Redwood, 225 feet high and 8 feet in diameter. The annual lumber product of the Coast is difficult to state in exact figures. That of Washington for 1900 exceeded one billion board feet, that of Oregon was 898,160,000, while the Redwood product of three counties in California for the same year exceeded 200 million feet. The timber standing in these States, according to Mr Henry Gannett, is in Washington, upon the present basis of estimate, 114,778 million feet B.M. (board measure), in Oregon 234,653 million feet, in California (Redwood only) 97,505 million feet. California has great bodies of timber outside the Redwood belt.

Logging in the Pacific Coast forest is usually by wire cable. The logs are skidded partly by cables operated by donkey engines, which drag themselves through the forest wherever they are required, partly by stationary donkeys of larger size, the cables of which are often more than half a mile in length. The final journey to the mill is commonly by rail. Extreme skill in the handling of enormous weights and powerful machinery is a conspicuous characteristic of lumbering in Washington, Oregon, and especially in California, where the logs of Redwood and of Big Tree are often more than 10 feet in diameter. Flumes for the transportation of manufactured lumber by water are frequent in this region, where some of them attain a length of 40 miles. Mills of great size, built on piles over tide-water, and so arranged that their product is delivered directly from the saws and dry kilns to the lumber vessels moored alongside, supply a rapidly growing coastwise and foreign trade. Certain products of the Coast forest, notably Cedar shingles and Fir timbers, have already made their way overland into the markets of the central and eastern States.

The most important lumber trees of the Interior Coniferous forest are the Western Yellow Pine, the Red Fir, and the Engelmann Spruce. The Red Fir, here extremely variable in size and value, reaches in this forest average dimensions of perhaps 70 feet in height and 2 feet in diameter, the Western Yellow Pine 90 feet by 3 feet, and the Engelmann Spruce 60 feet by 2 feet. Mining, railroad, and domestic uses chiefly absorb the annual timber product, which is considerable in quantity, and of vast importance to the local population.

For the twelve months ending with December 1900, the United States imported wood and manufactures of wood to the value of $20,156,641. The corresponding value of exports for the same period was $52,636,808.

Forfar, a royal and parliamentary burgh (Montrose group) of Forfarshire, Scotland, is 14 miles N.N.E. of Dundee by rail. The manufactures include jute, linen, and iron-founding. The parish church was renovated in 1900. Recent erections are a United Free church, an Episcopal church, and a Baptist chapel. Population of royal burgh (1881), 13,579; (1901), 12,061.

Forfarshire, or ANGUS, a maritime county of East Scotland, bounded N. by Aberdeen and Kincardine, E. by the German Ocean, S. by the Firth of Tay, and W. by Perthshire.

Area and Population.—In 1891, 568½ acres of the Perthshire parish of Caputh were added to three Forfarshire parishes, and the whole parish of Fowlis Easter and the Perthshire part of the parish of Liff, Benvie and Invergowrie, were transferred to Forfar; and to Perth from Forfar, part of Alyth, Coupar-Angus, and Kettins. The Kincardine part of the parish of Edzell was transferred to the Kincardine parish of Fettercairn. The area of the county, according to the latest official estimate, is (excluding foreshore) 562,162 acres, or about 878 square miles. The population was in 1881, 266,360; in 1891, 277,788; in 1891, on the above area, 277,735, of whom 125,414 were males and 152,321 females; in 1901, 284,078. On the old area, taking land only (560,186 acres, or 875·3 square miles), the number of persons to the square mile in 1891 was 317, and the number of acres to the person 2·0. In the registration county the population increased between 1881 and 1891 by 4·3 per cent. Between 1881 and 1891 the excess of births over deaths was 31,815, and the increase of the resident population 11,443. The following table gives particulars of births, deaths, and marriages in 1880, 1890, and 1899:—

Year.	Deaths.	Marriages.	Births.	Percentage of Illegitimate
1880	5705	1818	8862	9·9
1890	5997	1921	7990	9·62
1899	5285	2162	7930	8·4

The following table gives the birth-rate, marriage-rate, and death-rate per thousand of the population for a series of years:—

	1880.	1881-90.	1890.	1891-98.	1899.
Birth-rate . .	33·27	30·89	28·61	28·61	27·67
Death-rate . .	21·42	19·30	21·47	19·27	18·44
Marriage-rate .	6·83	6·77	6·87	7·17	7·54

In 1891 the number of Gaelic-speaking persons in the county was 1438, and of foreigners 376. Valuation in 1889-90, £603,115; 1899-1900, £618,666.

Administration.—The county returns a member to Parliament. Dundee (160,871) returns two members, and Montrose, Arbroath, Brechin, and Forfar form, with Bervie in Kincardine, the Montrose group of parliamentary burghs. Dundee is a royal burgh, a city, and (since 1894) a county of a city, and other royal burghs are Montrose (12,401), Forfar, the county town (12,061), Brechin (8941), and Arbroath (22,372). There are 55 civil parishes, forming one combination. The number of paupers and dependents in September 1899 was 5923. Forfarshire is a sheriffdom, and there is a resident sheriff-substitute at Dundee and another at Forfar, and courts are held also at Arbroath.

Education.—Sixty school boards manage 148 schools, which had in 1898-99 an average attendance of 38,856, while 23 voluntary schools, of which 8 are Roman Catholic and 4 Episcopal, had 7211. There are 3 secondary schools at Dundee, and one each at Montrose, Arbroath, Brechin, and Forfar; academies with elementary departments at Broughty-Ferry and Kirriemuir, and one other school in Dundee and 12 in the county earned grants for giving higher education in 1898. There are technical schools at Dundee and Arbroath. The county council and Dundee and Arbroath town councils expend the "residue" grant in subsidizing science and art and technical schools and classes, including Dundee university college, textile school, technical institute, navigation school, and workshop schools, and Arbroath technical school, and cookery, dairy, dress-cutting, veterinary science, plumbing, and laundry classes at various centres.

Agriculture.—The percentage of land under cultivation in 1898 was 44·8. Oats are the principal but a declining crop, while the barley acreage continues to increase with fair steadiness. The wheat acreage, considerably reduced between 1875-1900, does not show a tendency to fall further; it was, for instance, 500 acres more in 1898 than in 1897. The following table gives the principal acreages at intervals of five years from 1880:—

Year.	Area under Crops.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	253,373	94,793	53,439	81,396	23,051	694
1885	254,012	93,231	50,128	82,965	27,360	328
1890	253,723	89,817	49,546	85,798	28,328	80
1895	252,200	87,837	48,524	84,823	30,771	51
1899	251,276	88,144	47,221	86,634	28,936	108

The following table gives particulars of the live stock during the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or Calf	Sheep.	Pigs.
1880	10,443	46,304	11,685	122,856	5132
1885	9,612	50,406	12,310	132,167	6997
1890	9,947	55,401	12,397	152,203	7547
1895	10,653	49,163	11,634	146,329	7951
1899	10,028	51,668	12,536	167,219	6743

Of the 2637 holdings in 1895, the date of the last return, the average size was 96 acres. The percentage under 5 acres was 15·74, between 5 and 50 acres 35·76, and over 50 acres 48·50. The number of farms between 50 and 100 acres was 399; between 100 and 300, 687; between 300 and 500, 166; and over 500 acres, 27. The bothy system of housing farm servants still prevails in this county to a considerable extent, though the farm buildings are equal to any to be found elsewhere in Scotland. In 1898, 31,972 acres were under wood, 2685 having been planted since 1881. At the census of 1891, 9848 men and 579 women were returned as being engaged in agriculture.

Industries and Trade.—Shipbuilding (see DUNDEE) and manufactures of confectionery, jams, leather, machinery, soap, and chemicals, are all now important industries. In 1891, 52,345 men and 44,208 women were engaged in pursuits connected with industry, and of these 17,615 men and 34,398 women were associated with the manufacture of textiles. There is a number of sandstone quarries; the output was in 1895, 112,588 tons, valued at £56,446, and in 1899, 142,948 tons, valued at £64,990. The fisheries of the county are of considerable importance. All the ports of the county and one or two belonging to Kincardine are included in the

Montrose fishery district, statistics of which are given in the following table:—

Year.	Boats.			Value of Gear.	Resident Fishermen and Boys.	Total Value of all Fish.
	No.	Tons.	Value.			
1890	636	5084	£46,449	£29,709	1254	£85,593
1898	567	6700	£56,331	£32,608	1149	£75,633
1899	543	6377	£98,581	£30,252	1201	£95,877

In 1899 the number of persons connected with the various branches of the sea fisheries in the district was 3279. A considerable number of new branch railways has been opened since 1875, the total addition to the county mileage being over 60 miles.

(W. WA.)

Forlì, a town and episcopal see of Italy (Emilia), capital of the province of Forlì, on the Via Emilia, and 40 miles south-east of Bologna by rail. Its principal industries are iron-works, foundries, and silk factories. Further, there are an industrial institute and a technical school. Population: of town (1881), 40,934; (1901), 43,457; of province (1881), 251,110; (1901), 279,072.

Form (in Music).—Every work of art possesses, of necessity, some design by means of which a sense of unity and connexion can be imparted to its different features; the various means by which this sense of unity is arrived at in music are known by the generic name of "form." Certain principles of form are common to all music, but the fully developed scheme on which Haydn, Mozart, and Beethoven wrote their symphonies, sonatas, and quartettes, and which is known as "sonata" or "first movement" form, did not make its appearance until the beginning of the 18th century. Before a form could be invented it was necessary that there should be material worth pouring into the mould. By 1729 the material was ready; Bach had brought melodic and harmonic invention to a pitch which has never been surpassed, and, further, it was Bach who largely helped to establish our present system of key-centres, which enabled musical movements on a large scale to revolve round a definite pivot. It is, therefore, not surprising to find, coincidentally with Bach's death, a sudden development of the "sonata" form.

The origin of this form may be found in the simple formula A, B, A, or statement, variety, and symmetry. But these principles of construction are common to all music; the particular species from which the Beethoven first-movement may be said to have descended is well represented by the tune *Barbara Allen.* This tune is divided into two halves, and these halves again into two sections. The first section consists of a phrase in the tonic, the second of one in the dominant, the third is a free passage leading back to the tonic, and the last is a repetition of the second in the tonic key. The Italian composers, Corelli (*b.* 1653) and Domenico Scarlatti (*b.* 1683), finding the fugue forms of their contemporaries unsuitable to their essentially melodic style, adopted the scheme above described. However, the form of *Barbara Allen* is obviously unsatisfactory when applied to a more extended movement, for the reason that there is no restatement of the first and principal phrase. This defect was remedied by making the third section a repetition, so far as possible, of the first, but modulating from dominant to tonic instead of from tonic to dominant. Meanwhile another development of the original form was growing up, chiefly among the German successors of Bach, such as Krebs (*b.* 1713). This scheme repeats the original subject where it will have its greatest effect, namely, at the return to the tonic key; the third section remains free as in the primitive design, but both first and second sections are repeated in the last quarter of the movement. This scheme was finally established by Emmanuel Bach and perfected by Mozart and Haydn. These two composers are responsible for the development of the third section; even Haydn often treated this part of the movement as a mere episode, having no thematic connexion with the rest of the movement. But already the idea of treating this section as an extension of themes already stated was prevalent. When this part of the movement consisted of the repetition of the first section it had been found necessary to alter and extend it so as to compass the altered modulation, so that the "free" section had already come to be considered a period of development rather than of restatement or digression. The following is an analysis of the "first-movement" form as perfected by Mozart.

1. *Tonic Section.*—A subject in the tonic key called the "first subject," either ending with a half close or followed by a passage leading to the dominant key (or relative major if the first key is minor). This passage is called the "first episode."

2. *Dominant* (or relative major) *Section.*—A subject in this key called the "second subject,"[1] followed by the "second episode," usually of a less melodious character, in which transient modulations sometimes occur. The first half of the movement is brought to a full close in the second key by a short phrase called the "cadence figure" or "codetta."

This half of the movement, consisting of sections 1 and 2, is repeated.

3. *Development Section*, or "Free Fantasia."—This consists of an extension and development of the themes already heard, passing through a definite succession of keys, until the tonic is once more reached.

4. *Recapitulation Section.*—The whole or a part of the first subject and first episode is restated, the latter being altered so as to remain in the tonic. The second subject, second episode, and codetta are also restated in the tonic key. These two sections (Free Fantasia and Recapitulation) are also occasionally repeated and a short coda added. This coda was originally introduced only when the second half of the movement was repeated, but it finally became universal.

In Beethoven's hands this scheme ceased to be an aggregation of items and became a united whole, in which the various sections are so welded together that it is impossible to see the join. He soon discarded the old system of tonic and dominant, and often introduces his second subject in remote keys such as the mediant; further, while he gives each section its relative importance, yet each passage has its own value, and the "padding" of earlier writers disappears. Moreover, though the principle of restatement is still part of his scheme, yet he never degrades it into a mere transcription of notes. But, perhaps, Beethoven's greatest innovation was his extension of the coda. Before his time the coda was little more than a few bars of tonic and dominant to emphasize the key and to avoid the bathos of ending up twice the same way; Beethoven's codas are long perorations, forming a climax to all that has gone before.

[1] Sometimes this is only a new version of the first subject.

The last three movements of a sonata are often written in the same form as the first; indeed, the scherzo (or minuet) and trio are always two short movements in this form, alternating with each other. But the slow movements and finales are often written in the aria, rondo, or variation forms. The Aria form reproduces the formula A, B, A in its simplest form, consisting of a section in one key, an episode in another, and a restatement of the original section with or without a coda. The Rondo is an extension of the aria. A musical paragraph is repeated several times, an episode intervening between each repetition. This form remained somewhat bald and obvious until Beethoven took it in hand. He made it approximate to the first-movement form by making the first episode into a regular second subject, the second episode into a development section, and the third episode into a recapitulation of the second subject. The Variation form requires no explanation from the structural point of view.

Beethoven seems to have brought "sonata form" to its furthest limits of development; even Brahms's innovations are those of style rather than of structure. The immediate successors of Beethoven gave their attention chiefly to poetic and dramatic expression, and invented new forms to suit their needs, but all these forms, whether exemplified by Schumann's *Kinderscenen* or Wagner's prelude to *Tristan und Isolde*, will be found to be ultimately built on the same ground-work as Beethoven's sonatas or *Barbara Allen.* (R. V. W.)

Formosa.—This island, called Taiwan by the Japanese, into whose possession it came after their war with China in 1895, is 225 miles long by from 60 to 80 miles broad, has a coast-line measuring 731 miles, an area of 13,429 miles—being thus nearly the same size as Kiushiu, the most southern of the four chief islands forming the Japanese empire proper—and a population of 2,729,503, and extends from 20° 56′ N. lat. to 25° 15′, and from 120° E. long. to 122°. Along the western coast is a low alluvial plain, not exceeding 20 miles in width at its widest part; on the east coast there is a rich plain called Gilan, and there are also some fertile valleys in the neighbourhood of Kwarenko and Pinan, but the rest of the island is mountainous and covered with virgin forest.

Mountains.—Since Formosa has been added, Fuji-yama ceases to be Japan's highest mountain, and sinks to the place of third on the list. Mount Morrison (14,270 feet) —which the Japanese have re-named *Niitake-yama* (New High Mountain)—stands first, and Mount Sylvia (12,480 feet)—to which they have given the name of *Setzu-zan* (Snowy Mountain) — comes second. Mount Morrison stands nearly under the Tropic of Cancer. It is not volcanic, but consists of argillaceous schist and quartzite. A recent ascent, made by Dr Honda of the Imperial University of Japan, showed that, up to a height of 6000 feet, the mountain is clothed with primeval forests of palms, banyans, cork trees, camphor trees, tree ferns, interlacing creepers and dense thickets of rattan or stretches of grass higher than a man's stature. The next interval of 1000 feet has gigantic cryptomerias and chamœcyparis; then follow pines; then, at a height of 9500 feet, a broad plateau, and then alternate stretches of grass and forest up to the top, which consists of several small peaks. There is no snow. Mount Morrison, being surrounded by high ranges, is not a conspicuous object. Mount Sylvia lies in 24° 30′ N. lat. It has not been ascended by persons competent to give any account of its condition. There are many other mountains of considerable elevation. In the north we have Getsurôbi-san (4101 feet); and on either side of Setzu-zan, with which they form a range running due east and west across the island, are Jusampun-zan (4698 feet) and Hari-zan (7027 feet). Twenty-two miles due south of Hari-zan stands Hakumôsha-zan (5282 feet), and just 20 miles due south of Hakumôsha-zan begins a chain of three peaks, Suisha-zan (6200 feet), Hôo-zan (4928), and Niitake-yama. These five mountains, Hari-zan, Hakumôsha-zan, Suisha-zan, Hôo-zan, and Niitake-yama, stand almost exactly under 121° E. long., and being in the very centre of the island, may be said to form its backbone. Yet farther south, and still lying in line down the centre of the island, are Sankyakunan-zan (3752 feet), Shurôgi-zan (5729 feet), Pôren-zan (4957 feet), and Kadô-zan (9055 feet), and, finally, in the south-east we have Arugan-zan (4985 feet). These, it will be observed, are all Japanese names, and the heights have been determined by Japanese observers. In addition to these remarkable inland mountains, Formosa's eastern shores show magnificent cliff scenery, the bases of the hills on the seaside taking the form of almost perpendicular walls as high as from 1500 to 2500 feet.

Rivers and Lakes.—Owing to the precipitous character of the east coast few rivers of any size find their way to the sea in that direction. The west coast, on the contrary, has many streams, but the only two of any considerable length are the Kotansui, which rises on Shurôgi-zan, and has its mouth at Tôkô after a course of some 60 miles, and the Scira, which rises on Hakumôsha-zan, and enters the sea at a point 57 miles farther north after a course of 90 miles. So far as is known, there are no lakes, but a great part of the interior of the island remains still unexplored.

Climate.—The climate is damp, hot, and malarious. In the north, the driest and best months are October, November, and December; in the south, December, January, February, and March. The sea immediately south of Formosa is the cradle of innumerable typhoons, but the high mountains of the island protect it partially against the extreme violence of the wind.

Towns.—The chief town is Taipeh (called by the Japanese Taihoku), which is on the Tamsui-yei river, and has a population of about 118,000, including 5850 Japanese. Taipeh may be said to have two ports; one, Tamsui, at the mouth of the river Tamsui-yei, 10 miles distant on the north-west coast, the other Kelung (called by the Japanese Kiirun), on the north-east shore, with which it is connected by rail, a run of some 18 miles. The foreign settlement at Taipeh lies outside the walls of the city, and is called Twatutia (Taitotei by the Japanese). Kelung is an excellent harbour, and the scenery is very beautiful. Tamsui (called Tansui by the Japanese) is usually termed Hobe by foreigners. It is the site of the first foreign settlement, has a population of about 7000, but cannot be made a good harbour without considerable expenditure. On the west coast there is no place of any importance until reaching Anping (23° N. lat.), a port where a few foreign merchants reside for the sake of the sugar trade. It is an unlovely place, surrounded by mud flats, and a hotbed of malaria. It has a population of 4000 Chinese and 200 Japanese. At a distance of some 2½ miles inland is the former capital of Formosa, the walled city of Tainan, which has a population of 100,000 Chinese, 2300 Japanese, and a few British merchants and missionaries. Connected with Anping by rail (26 miles) and lying south of it is Takao, a treaty port. It has a population of 6800, and is prettily situated on two sides of a large lagoon. Six miles inland from Takao is a prosperous Chinese town called Fêngshan (Japanese, Hôzan). The anchorages on the east coast are Suo, Kwarenkô, and Pinan, which do not call for special notice. Forty-seven miles east of the extreme south coast there is a little island called Botel-tobago (Japanese, Kôtô-sho), which rises to a height of 1914 feet, and is inhabited by a tribe whose customs differ essentially from those of the natives on the main island.

Administration.—The island is treated as an outlying territory; it has not been brought within the full purview of the Japanese constitution. Its affairs are administered by a governor-general, who is also commander-in-chief of the forces, by a bureau of civil government, and by four prefectural governors; its finances are not included in the general budget of the Japanese empire; it is garrisoned by a mixed brigade taken from the home divisions; its tribunals of justice are organized independently of the system followed in Japan proper; and its currency is on a silver basis. One of the first abuses with which the Japanese had to deal was the excessive use of opium by the Chinese settlers. To interdict the importation of the drug altogether, as is done in Japan, was the step advocated by Japanese public opinion. But, influenced by medical views and by the almost insuperable difficulty of enforcing any drastic import veto in the face of Formosa's large communications by junk with China, the Japanese finally adopted the middle course of licensing the preparation and sale of the drug, and limiting its use to persons in receipt of medical sanction. Steps have been taken also to convert the manufacture and export of camphor into an official monopoly, which is now farmed to a British firm, acting in conjunction with Japanese merchants; and China's example has been followed in the case of salt, transactions connected with that necessary being monopolized by the Government.

Finance.—In 1897, two years after Japan took possession, the revenue collected was $6\frac{1}{2}$ million yen, and the expenditure totalled $16\frac{1}{2}$ millions, independently of military and naval outlays. The deficiency of 10 millions on the side of revenue had to be defrayed by the imperial treasury. In 1900 the revenue collected was 13 million yen, approximately, and the expenditures aggregated 20 millions, but only $2\frac{1}{2}$ millions of the deficit were furnished by the imperial treasury, the remaining $4\frac{1}{2}$ millions being obtained by floating bonds. Over 7 millions of the expenditure was on account of public works, so that the floating of a loan was a legitimate operation. Government industries —that is to say, the monopolies of camphor, salt, and opium, and the working of railways—constituted one of the chief sources of revenue increase, the gross earnings under these headings being $9\frac{1}{4}$ million yen, and the expenditures, $5\frac{1}{2}$ millions. There were also considerable increments in the yield of customs duties and internal taxes, though it may be noted that the whole of the direct taxes levied do not aggregate more than $1\frac{3}{4}$ million yen. Up to the close of 1900, the island had cost Japan 100 millions of yen. The Japanese do not show much inclination to emigrate to Formosa. The number of Japanese residing there is only 9324, and the number that emigrated thither in 1899 was 3850.

Railways.—An extensive scheme of railway construction has been planned, the four main lines projected being (1) from Takow to Tainan; (2) from Tainan to Kagi; (3) from Kagi to Chianghoa; and (4) from Chianghoa to Kelung; these four forming, in effect, a main trunk road running from the south-west to the north-east, its course being along the foot of the mountains that border the western coast-plains. The Takow–Tainan section (26 miles) was opened to traffic on 3rd November 1900, and work on the other sections is progressing. Harbour improvements also are projected, but in Formosa, as in Japan proper, paucity of capital constitutes a fatal obstacle to rapid development.

Foreign Traffic.—The following figures show the state of foreign trade during the three years ended 1899 :—

	Exports.	Imports.	Total.
1897	£1,275,929	£1,265,929	£2,541,858
1898	1,282,718	1,687,919	2,970,637
1899	1,111,492	1,427,309	2,538,801

There are thirteen ports of export and import, but 75 per cent. of the total business is done at Tamsui. Tea and camphor are the staple exports. The greater part of the former goes to Amoy for re-shipment to the West, but it is believed that if harbour improvements were effected at Tamsui so as to render it accessible for ocean-going steamers, shipments would be made thence direct to New York. The camphor trade being now a Government monopoly, the quantity exported is under strict control.

History.—The original inhabitants appear to have come from Malay, and to have settled along the western coast. Towards the close of the 17th century a stream of Chinese immigration set in—Hakkas from Canton and Hoklas from Fohkien—who, dispossessing their semi-savage predecessors, drove them to the thickly wooded hills at the base of the high mountains, or into the still less accessible regions beyond. A more debased population than the peoples thus struggling for supremacy could scarcely be conceived. The aborigines, to whom the Chinese gave the name *Sheng-fan*, or "wild savages," deserved the appellation in some respects, for they lived by the chase and had little knowledge even of husbandry; while the Chinese themselves, uneducated labourers, acknowledged no right except that of might. A long era of conflict ensued between the Chinese and the aborigines. The latter were not implacably cruel or vindictive. They merely clung to their homesteads, and harboured a natural resentment against the raiders who had dispossessed them. Their disposition was to leave the Chinese in unmolested possession of the plain. But some of the most valuable products of the island, as camphor and rattan, are to be found in the upland forests, and the Chinese, whenever they ventured too far in search of these products, fell into ambushes of hill-men who neither gave nor sought quarter, and who regarded a Chinese skull as a specially attractive article of household furniture. Reconciliation never took place on any large scale, though it is true that, in the course of time, some fitful displays of administrative ability on the part of the Chinese, and the opening of partial means of communication, led to the pacification of a section of the *Sheng-fan*, who thenceforth became known as *Pepohoan*, or "civilized aborigines." In 1874 the island was invaded by the Japanese for the purpose of obtaining satisfaction for the murder of a shipwrecked crew who had been put to death by one of the semi-savage tribes on the southern coast, the Chinese Government being either unable or unwilling to punish the culprits. A war was averted through the good offices of the British minister, and the Japanese retired on payment of an indemnity. In 1884, in the course of belligerent proceedings arising out of the Tongking dispute, the forts at Keelung on the north were bombarded by the French fleet, and the place was captured and held for some months by French troops. An attack on the neighbouring town of Tamsui failed, but a semi-blockade of the island was maintained by the French fleet during the winter and spring of 1884–85. The troops were withdrawn on the conclusion of peace in June 1885. In 1895 the island was ceded to Japan by the treaty of Shimonoseki at the close of the Japanese war. The resident Chinese officials, however, refused to recognize the cession, declared a republic, and prepared to offer resistance. It is even said they offered to transfer the sovereignty to Great Britain if that Power would accept it. A formal transfer to Japan was made in June of the same year in pursuance of the treaty, the ceremony taking place on board ship outside Keelung, as the Chinese commissioners did not venture to land. The Japanese were thus left to take possession as best they could, and some four months elapsed before they effected a landing on the south of the island. Takow was bombarded and captured on the 15th October, and the resistance collapsed. Liu Yung-fu, the notorious Black Flag general, and the backbone of the resistance, sought refuge in flight. The general state of the island when the Japanese assumed possession, was that the plain of Gilan on the eastern coast and the hill-districts were inhabited by semi-barbarous folk, the western plains by Chinese of a degraded type, and that between the two there existed a traditional and continuous feud, leading to mutual displays of merciless and murderous violence. By many of these Chinese settlers the Japanese conquerors, when they came to occupy the island, were regarded in precisely the same light as the Chinese themselves had been regarded from time immemorial by the aborigines. Insurrections occurred frequently, the insurgents receiving secret aid from sympathizers in China, and the difficulties of the Japanese being increased not only by their ignorance of the country, which abounds in fastnesses where bandits can find almost inaccessible refuge, but also by the unwillingness of experienced officials to abandon their home posts for the purpose of taking service in the new territory. Gradually, however, the various obstacles are being overcome, and though some years must still elapse before the reign of peace and good order is thoroughly established, all the evidences point to ultimate success. (F. By.)

Formosa, a territory of the Argentine Republic bordering Bolivia and Paraguay. The official area at the census of 1895 was 41,402 square miles, and the population in 1895, 4829. The capital, Formosa, founded in 1879 on the Rio Paraguay, has a population of about 1000. The province is divided into five administrative divisions. In 1895 only 778 acres of land were planted in cereals, but the territory had 41,424 head of cattle.

Forres, a parliamentary burgh (Inverness group). with the privileges of a royal burgh, near the river Findhorn, in the county of Elgin, Scotland, 12 miles west by south of Elgin by rail. It is one of the healthiest spots in Scotland, and has the lowest rainfall in the country. The chief trade is in cattle. Industries are varied, but unimportant. There is a public hall, a museum containing a collection of the Old Red Sandstone fossils of the district, a mechanics' institute, an agricultural hall, market buildings and auction mart, a cottage hospital, and a Nelson Monument (1806). There is a well-endowed secondary school. Population (1881), 4030; (1901), 4313.

Forrest, Sir John (1847——), West Australian statesman and explorer, son of William Forrest, of Bunbury, West Australia, was born at Bunbury, 22nd August 1847, and educated at Perth, W.A. In 1865 he became connected with the Government Survey Department at Perth, and in 1869 led an exploring expedition into the interior in search of D. Leichardt, penetrating through bush and salt-marshes as far inland as 123° E. long. In 1870 he again made an expedition from Perth to Adelaide, along the southern shores. In 1874, with his brother ALEXANDER FORREST (born 1849), he explored eastwards from Champion Bay, following as far as possible the 26th parallel, and striking the telegraph line between Adelaide and Port Darwin; a distance of about 2000 miles was covered in about five months with horses and without carriers, a particularly fine achievement (see AUSTRALIA, *Exploration*). John Forrest also surveyed in 1878 the north-western district between the rivers Ashburton and Lady Grey, and in 1882 the Fitzroy district. In 1876 he was made deputy surveyor-general, receiving the thanks of the colony for his services and a grant of 5000 acres of land; for a few months at the end of 1878 he acted as commissioner of Crown lands and surveyor-general, being given the full appointment in 1883, and retaining it till 1890. When the colony obtained in 1890 its constitution of self-government, Mr Forrest (who was knighted in 1891) became its first premier, and for ten years held that position, his influence in West Australia being one of an almost autocratic character, owing to the robust vigour of his personality and his success in enforcing his views (see WEST AUSTRALIA, *History*). In 1877 he was made a member of the Privy Council. Sir John Forrest married in 1876 Margaret Hamersley. He has published *Explorations in Australia* (1876) and *Notes on Western Australia* (1884–87).

Forssell, Hans Ludvig (1843–1901), Swedish historian and political writer, the son of Adolf Forssell, a distinguished mathematician, was born at Gefle, where his father was professor, on 14th January 1843. At the age of sixteen he became a student in Upsala University, where he distinguished himself, and where, in 1866, having taken the degree of doctor, he was appointed reader in history. At the age of thirty, however, Forssell, who had already shown remarkable business capacity, was called to Stockholm, where he filled one important post after another in the Swedish civil service. In 1875 he was appointed head of the Treasury, and in 1880 was transferred to the department of Inland Revenue, of which he continued to be president until the time of his death. In addition to the responsibilities which these offices devolved upon him, Forssell was constantly called to serve on royal commissions, and his political influence was immense. In spite of all these public duties, which he carried through with the utmost diligence, Forssell also found leisure for an abundant literary activity. Of his historical writings the most important were: *The Administrative and Economical History of Sweden after Gustavus I.* (1869–75) and *Sweden in 1571* (1872). He was also for several years, in company with the poet Wirsén, editor of the *Swedish Literary Review.* He published two volumes of *Studies and Criticisms* (1875, 1888). In the year 1881, at the death of the historian Anders Fryxell, Forssell was elected to the vacant seat on the Swedish Academy. The energy of Forssell was so great, and he understood so little the economy of strength, that he unquestionably overtaxed his vital force. His death however, which occurred with great suddenness on the 2nd of August 1901, while he was staying at San Bernardino in Switzerland, was wholly unexpected. There was little of the typical Swedish urbanity in Forssell's exterior manner, which was somewhat dry and abrupt. Like many able men who have from early life administered responsible public posts, there appeared a certain want of sympathy in his demands upon others. His views were distinct, and held with great firmness; for example, he was a free-trader, and his consistent opposition to what he called "the new system" had a considerable effect on Swedish policy. He was not exactly an attractive man, but he was a capable, upright, and efficient public servant. In 1867 he married Miss Zalamith Emeroth, a daughter of the well-known pomologist of Upsala; she survived him, with two sons and two daughters. (E. G.)

Forst, a town of Prussia, on the Görlitzer Neisse, 13 miles east by south of Cottbus by rail, in the circle of Sorau, Government district of Frankfurt. It has 2 Evangelical, an Old-Lutheran, a Catholic, and an Apostolic churches, a progymnasium with *real* progymnasium, a higher-grade girls' and a burgher school, and over 100 woollen cloth and buckskin factories. Population (1890), 23,539; (1900), 32,075.

Forster, John Cooper (1823–1886), British surgeon, was born in 1823 in Lambeth, London, where his father and grandfather before him had been local medical practitioners. He entered Guy's Hospital in 1841 (M.R.C.S., 1844; F.R.C.S., 1849) was appointed demonstrator of anatomy in 1850, assistant-surgeon 1855, and surgeon 1870. In 1884 he became president of the College of Surgeons. He was a prompt and sometimes bold operator. In 1858 he performed practically the first gastrostomy in England for a case of cancer of the œsophagus. Among his best-known papers were discussions of acupressure, syphilis, hydrophobia, intestinal obstruction, modified obdurate hernia, torsion, and colloid curve of the large intestine; and he published a book on *Surgical Diseases of Children* in 1860, founded on his experience as surgeon to the Hospital for Children and Women in Waterloo Road. He died suddenly in the south of France in March 1886.

Forster, William Edward (1818–1886), British statesman, was born of Quaker parents at Bradpole in Dorsetshire, 11th July 1818. He was educated at the Friends' school at Tottenham, where his father's family had long been settled, and on leaving school he was put into business. He declined, however, on principle to enter a brewery. Becoming in due time a woollen manufacturer in a large way at Bradford, Yorkshire (from which after his marriage he moved to Burley-in-Wharfedale), he soon made himself known as a practical philanthropist. In 1846–47 he accompanied his father to Ireland, as distributor of the Friends' relief fund for the famine in Connemara, and the state of the country made a deep impression on him. In 1849 he wrote a preface to a new edition of Clarkson's *Life of William Penn*, defending the Quaker statesman against Macaulay's criticisms. In 1850 he married Jane Martha, eldest daughter of the famous Dr Arnold of Rugby. She was not a Quaker, and her husband was formally excommunicated for marrying her, but the Friends who were commissioned to announce the sentence "shook hands and stayed to luncheon." Forster thereafter ranked himself as a member of the Church of England, for which, indeed, he was in later life charged with having too great a partiality. There were no children of the marriage, but when Mrs Forster's brother, William Arnold, died in 1859, leaving four orphans, the Forsters adopted them as their own. One of these children was Mr H. O. Arnold-Forster, afterwards M.P. and secretary to the Admiralty.

Mr Forster gradually began to take an active part in public affairs by speaking and lecturing. In 1858 he gave a lecture before the Leeds Philosophical Institution on "How we Tax India." In 1859 he stood as Liberal candidate for Leeds, but was beaten. But he was highly esteemed in the West Riding, and in 1861 he was returned unopposed for Bradford. In 1865 (unopposed) and 1868 (at the head of the poll) he was again returned. He took a prominent part in Parliament in the debates on the American Civil War, and in 1868 was made under-secretary for the Colonies in Earl Russell's ministry. It was then that he first became a prominent advocate of Imperial federation. In 1866 his attitude on parliamentary reform attracted a good deal of attention. His speeches were full of knowledge of the real condition of the people, and contained something like an original programme of Radical legislation. "We have other things to do," he said, "besides extending the franchise. We want to make Ireland loyal and contented; we want to get rid of pauperism in this country; we want to fight against a class which is more to be dreaded than the holders of a £7 franchise—I mean the dangerous class in our large towns. We want to see whether we cannot make for the agricultural labourer some better hope than the workhouse in his old age. We want to have Old England as well taught as New England." In these words he heralded the Education campaign which occupied the country for so many years afterwards. Directly the Reform Bill had passed, the necessity of "inducing our masters to learn their letters" (in Robert Lowe's phrase) became pressing. Mr Forster and Mr Cardwell, as private members in opposition, brought in Education Bills in 1867 and 1868; and in 1868, when the Liberal party returned to office, Mr Forster was appointed vice-president of the Council, with the duty of preparing a Government measure for national education. The Elementary Education Bill (see Education) was introduced on 17th February 1870. The religious difficulty at once came to the front. The Manchester Education Union and the Birmingham Education League had already formulated in the provinces the two opposing theories, the former standing for the preservation of denominational interests, the latter advocating secular rate-aided education as the only means of protecting Nonconformity against the Church. The Dissenters were by no means satisfied with Forster's "conscience clause" as contained in the Bill, and they regarded him, the ex-Quaker, as a deserter from their own side; while they resented the "25th clause," permitting school boards to pay the fees of needy children at denominational schools out of the rates, as an insidious attack upon themselves. By the 14th of March, when the second reading came on, the controversy had assumed threatening proportions; and Mr Dixon, the Liberal member for Birmingham and chairman of the Education League, moved an amendment, the effect of which was to prohibit all religious education in board schools. The Government made its rejection a question of confidence, and the amendment was withdrawn; but the result was the insertion of the Cowper-Temple clause as a compromise before the Bill passed. Extremists on both sides abused Forster, but the Government had a difficult set of circumstances to deal with, and he acted like a prudent statesman in contenting himself with what he could get. An ideal Bill was impracticable; it is to Forster's enduring credit that the Bill of 1870, imperfect as it was, established at last some approach to a system of national education in England without running absolutely counter to the most cherished English ideas and without ignoring the principal agencies already in existence.

Forster's next important work was in passing the Ballot Act of 1872, but for several years afterwards his life was uneventful. In 1874 he was again returned for Bradford, in spite of Dissenting attacks, and he took his full share of the work of the Opposition Front Bench. In 1875, when Mr Gladstone "retired," he was strongly supported for the leadership of the Liberal party, but declined to be nominated against Lord Hartington. In the same year he was elected F.R.S., and made Lord Rector of Aberdeen University. In 1876, when the Eastern question was looming large, he visited Servia and Turkey, and his subsequent speeches on the subject were marked by studious moderation, distasteful to extremists on both sides. On Mr Gladstone's return to office in 1880 he was made

Chief Secretary for Ireland, with Lord Cowper as Lord-Lieutenant. He carried the Compensation for Disturbance Bill through the Commons, only to see it thrown out in the Lords, and his task was made more difficult by the agitation which arose in consequence. During the gloomy autumn and winter of 1880–81, Forster's energy and devotion in grappling with the situation in Ireland (see IRELAND) were indefatigable, his labour was enormous, and the personal risks he ran were many; but he enjoyed the Irish character in spite of all obstacles, and inspired genuine admiration in all his coadjutors. On 24th January 1881 he introduced a new Coercion Bill in the House of Commons, to deal with the growth of the Land League, and in the course of his speech declared it to be "the most painful duty" he had ever had to perform, and one which would have prevented his accepting his office if he had known that it would fall upon him. The Bill passed, among its provisions being one enabling the Irish Government to arrest without trial persons "reasonably suspected" of crime and conspiracy. The Irish party used every opportunity in and out of Parliament for resenting this Act, and Forster was kept constantly on the move between Dublin and London, conducting his campaign against crime and anarchy and defending it in the House of Commons. His scrupulous conscientiousness and anxiety to meet every reasonable claim availed him nothing with such antagonists, and the strain was intense and continuous. He was nicknamed "Buckshot" by the Nationalist press, on the supposition that he had ordered its use by the police when firing on a crowd. On 13th October Mr Parnell was arrested, and on the 20th the Land League was proclaimed. From that time Forster's life was in constant danger, and he had to be escorted by mounted police when he drove in Dublin. Early in March 1882 he visited some of the worst districts in Ireland, and addressed the crowd at Tullamore on the subject of outrages, denouncing the people for their want of courage in not assisting the Government, but adding, "whether you do or not, it is the duty of the Government to stop the outrages, and stop them we will." Forster's pluck in speaking out like this was fully appreciated in England, but it was not till after the revelations connected with the Phoenix Park murders that the dangers he had confronted were properly realized and it became known that several plans to murder him had only been frustrated by the merest accidents. On 2nd May, Mr Gladstone announced that the Government intended to release Mr Parnell and his fellow-prisoners in Kilmainham, and that both Lord Cowper and Mr Forster had in consequence resigned; and the following Saturday Forster's successor, Lord Frederick Cavendish, was, with Mr Burke, murdered in Phoenix Park. It was characteristic of the man that Forster at once offered to go back to Dublin temporarily as Chief Secretary, but the offer was declined. His position naturally attracted universal attention towards him, particularly during the debates which ensued in Parliament on the "Kilmainham Treaty." But Mr Gladstone's influence with the Liberal party was paramount, in spite of the damaging appearance of the compact made with Parnell, and Forster's pointed criticisms only caused thoroughgoing partisans to accuse him of a desire to avenge himself. It was not till the next session that he delivered his fiercest attack on Parnell in the debate on the Address, denouncing him for his connexion with the Land League, and quoting against him the violent speeches of his supporters and the articles of his newspaper organs. It was on this occasion that Parnell, on Forster's charging him, not with directly planning or perpetrating outrages or murder, but with conniving at them, ejaculated "It's a lie"; and, replying on the next day, the Irish leader, instead of disproving Forster's charges, bitterly denounced his methods of administration. Though, during the few remaining years of his life, Forster's political record covered various interesting subjects, his connexion with these stormy times in Ireland throws them all into shadow. He died on 6th April 1886, on the eve of the introduction of the Home Rule Bill, to which he was stoutly opposed. In the interval there had been other questions on which he found himself at variance with Gladstonian Liberalism, for instance, as regards the Sudan and the Transvaal, nor was he inclined to stomach the claims of the Caucus or the Birmingham programme. When the Redistribution Act divided Bradford into three constituencies, Forster was returned for the Central division, but he never took his seat in the new Parliament.

Forster, like John Bright, was an excellent representative of the English middle-class in public life. Patriotic, energetic, independent, incorruptible, shrewd, fair-minded, he was endowed not only with great sympathy with progress, but also with a full faculty for resistance to mere democraticism. He was tall (the Yorkshiremen called him "Long Forster") and strongly though stiffly built, and, with his simple tastes and straightforward manners and methods, was a typical North-country figure. His oratory was rough and unpolished, but full of freshness and force and genuine feeling. It was Forster who, when appealing to the Government at the time of Gordon's danger at Khartum, spoke of Mr Gladstone as able "to persuade most people of most things, and himself of almost anything," and though the phrase was much resented by Mr Gladstone's *entourage*, the truth that underlay it may be taken as representing the very converse of his own character. His personal difficulties with some of his colleagues, both in regard to the Education Act of 1870 and his Irish administration, must be properly understood if a complete comprehension of his political career is to be obtained. For an account of them we need only refer to the *Life of the Right Hon. W. E. Forster*, by Sir T. Wemyss Reid (Chapman & Hall), an admirable and sympathetic biography. (H. CH.)

Fort Dodge, capital of Webster County, Iowa, U.S.A., on Des Moines River, at an altitude of 1015 feet. It is at the intersection of four railways, the Chicago, Rock Island, and Pacific, the Illinois Central, the Minneapolis and St Louis, and the Mason City and Fort Dodge. It is the centre of a rich farming country, and enjoys a large trade as a supply and distributing point. Population (1880), 3586; (1890), 4871; (1900), 12,162, of whom 1832 were foreign-born, and 112 negroes.

Fort Donelson, Tennessee, U.S.A., a post erected by the Confederates during the Civil War, on the left bank of Cumberland River, 40 miles above its mouth, for the control of its navigation. It was taken by the Union forces under General Grant, on 16th February 1862, after a severe battle, in which each side lost about 2000 men. Some 14,000 Confederate troops were surrendered, besides large stores and munitions of war.

Fort Fisher, an earthwork constructed during the Civil War by the Confederates to defend the entrance to Cape Fear River below Wilmington, North Carolina, U.S.A. Being the chief defence of the city of Wilmington, which was then the principal port of blockade-runners, it was necessary to reduce it. This was finally accomplished by a combined land and naval attack on 15th January 1865, but at a loss to the Union forces of about 1000 men in killed, wounded, and missing. The Confederates lost about 2500 men, of whom 500 were killed or wounded.

Fort Madison, capital of Lee County, Iowa, U.S.A., on the western bank of the Mississippi river, at an altitude of 522 feet. It has three railways—the Atchison, Topeka, and Santa Fé; the Chicago, Burlington, and Quincy; and the Chicago, Fort Madison, and Des Moines. It contains the works of the first named of these lines, besides meat-packing houses and manufactories of agricultural implements. The city is on the site of a fort built in the early part of the century. Population (1880), 4679; (1890), 7901; (1900), 9278, of whom 1025 were foreign-born, and 230 negroes.

Fort Scott, capital of Bourbon County, Kansas, U.S.A., in 37° 50′ N. and 94° 42′ W., on the Marmaton river, which here is not navigable, at an altitude of 800 feet. Its site is a level plain, and the plan is regular. It is the point of intersection of the Kansas City, Fort Scott, and Memphis, the Missouri, Kansas, and Texas, and the Missouri Pacific railways, and has in consequence great traffic. Population (1880), 5372; (1890), 11,946; (1900), 10,322, of whom 474 were foreign-born, and 1205 negroes.

Fort Smith, capital of Sebastian County, Arkansas, U.S.A., in 35° 23′ N. and 94° 26′ W., on the south bank of the Arkansas river, at an altitude of 421 feet. It has a level site on the river bank, but the street plan is irregular. It is divided into five wards, and is on four railways, the St Louis, Iron Mountain, and Southern, the St Louis and San Francisco, the Port Arthur, and the Arkansas Central. It occupies a commanding position for trade, and for a time had a rapid growth. Population (1880), 3099; (1890), 11,311; (1900), 11,587, of whom 684 were foreign-born, and 2407 negroes.

Fort Sumter, an old military post in the harbour of Charleston, South Carolina, U.S.A. It is on a shoal at the entrance to the inner harbour, and is famous principally because of the Confederate attack on it, 12th April 1861, which opened the Civil War. It was surrendered to the Confederates on 14th April, the garrison, under the command of Major Robert Anderson, marching out with the honours of war. It was bombarded and assaulted by the Northern troops later, but was not captured until the fall of Charleston in February 1865.

Fort Wayne, capital of Allen County, Indiana, U.S.A., in 41° 05′ N. lat. and 85° 04′ W. long., where the junction of the St Mary and the St Joseph form the Maumee, at an altitude of 778 feet. The city is divided into ten wards. Its site is level, the street plan regular, and the streets are well paved, largely with brick and asphaltum, and there is a good water supply. It is a railway centre of importance, no fewer than seven railways passing through it or terminating here, and giving the city a trade in all directions. Its manufactures are in great portion connected with railway transportation, since several of its railways maintain car shops here. The capital invested in manufactures in 1890 was $7,000,000, employing 6000 hands, and with a product valued at $9,300,000. Of this, $1,726,117 consisted of car construction and repair. The value of foundry and machine shop products was $1,866,467. The assessed valuation of real and personal property, on a basis of about 70 per cent. of the full value, was, in 1900, $23,984,540, the net debt of the city was but $658,165, and the rate of taxation $21·20 per $1000. Population (1880), 26,880; (1890), 35,393; (1900), 45,115, of whom 6791 were foreign-born, and 276 negroes.

Fort William, the principal town of Thunder Bay district, Ontario, Canada, 426 miles (by rail) E.S.E. of Winnipeg, on the Kaministiquia river, about a mile from its *débouchement* into Lake Superior. It will be the eastern terminus of the Canadian Northern transcontinental railway, and is the western terminus of two steamship lines. It contains large grain elevators with a capacity of 5,250,000 bushels, railway repair shops, and docks, and has a large export trade in grain and other farm produce. The total shipping for the year 1899–1900 was 605 vessels, with a tonnage of 757,204 tons; exports, $3,671,154; imports, $1,164,482. Population (1901), 4800.

Fort Worth, capital of Tarrant County, Texas, U.S.A., in 32° 45′ N. and 97° 20′ W., on the south bank of the West Fork of Trinity River, at an altitude of 600 feet. The site of the city is level, the street plan is regular, and the streets are macadamized. The city is divided into six wards, and has a water supply owned and operated by it. Eight railways enter it from all sides, giving it great commercial importance far beyond its importance as a manufacturing city. In 1890 there was invested in manufactures a capital of $3,194,032, employing 2743 hands, with products valued at $6,826,083. These are of varied character, the principal being flour. Fort Worth is the seat of Fort Worth University and of the Polytechnic College, both Methodist-Episcopal institutions. The former, founded in 1881, had, in 1899, 31 instructors and 393 students, the majority of whom were in the preparatory department. The latter, founded in 1891, had, in 1899, 14 instructors and 308 students, also mainly in the preparatory department. The assessed valuation of property, real and personal was, in 1898, $15,099,720; the net debt of the city was $1,969,512; and the rate of taxation was $25·50 per $1000. Population (1880), 6663; (1890), 23,076; (1900), 26,688, of whom 1793 were foreign-born, and 4249 negroes.

Fortaleza, a town of Brazil, known to foreigners as Ceará, and capital of the State of Ceará. Population, 48,000. It is a well laid out and well built city. It is the principal port of export of the products of the State, these consisting principally of rubber, vegetable-wax (camauba), coffee, sugar, cotton, rum, rice, beans, fruits, hides, &c. It has a railway running to Quixeramobim-Quizada, 177 miles.

Forth, The, a river and firth of Scotland, measuring from the confluence of its two sources above Aberfoyle to the German Ocean 103⅗ miles. The steam ferries have been largely superseded by the opening of the Forth Bridge. The fall of the Tay Bridge in 1879 caused the suspension bridge commenced at Queensferry in 1878 to be abandoned; but in 1882 the work of spanning the river was again authorized by Parliament, and was undertaken at the same spot by the Forth Bridge Railway Company, formed by the Great Northern, North-Eastern, Midland, and North British companies. The bridge, which is constructed of Siemens-Martin steel, was built on the cantilever system. There are three main piers, each having a height of about 360 feet above high water, the small island of Inchgarvie forming the foundation for the central one. The clear distance between the piers is 1710 feet, and a headway at high water of 150 feet for a distance of 500 feet is given at the central portion of each span. The short arms of the cantilevers on the northern and southern shores are 680 feet long, and beyond this the bridge is continued on each side of the river by means of a viaduct. The engineers in chief were Sir John Fowler and Sir Benjamin Baker, and the principal contractor was Sir William Arrol. The work, including the approach railways, cost approximately £3,000,000, and the bridge was opened in March 1890. The river is also spanned by a railway bridge at Alloa.

FORTIFICATION.

1. Field.

Modern military history shows clearly the constant increase in the value of extemporized field defences; yet in spite of this, little real interest has been taken in the subject. The lesson of the American Civil War, that a line of trenches defended by two ranks of men with rifles could not be carried by direct attack, seemed to come as a fresh surprise with each succeeding war, until it was finally taught at Plevna. Even after this, although the European nations began to provide their troops with portable entrenching tools, little attempt was made to turn them to practical use. Such attempts would probably have shown that in the endeavour to avoid encumbering armies with transport for entrenching tools, an unsatisfactory compromise had been arrived at, since no portable tool, small enough to be constantly carried by the soldier, is of any practical use for entrenching, except in the very lightest soil. In the quiet years which followed 1877, and amid the babel of speculation as to the effect of the constant improvements in firearms, the old lesson began to be forgotten. Many voices were raised against the use of field defences, on the grounds that, as at Plevna, they led to strategical mistakes; that the use of stationary defences could not be reconciled with the rapidity of manœuvre which had now become the sole essential; and that troops could not remain in shelter trenches under the fire of modern artillery. Meanwhile, by constant improvements, the effectiveness of guns and rifles against troops in the open was steadily being increased. At the same time, on account of flatter trajectories, the increased tendency to ricochet, and in the British service the abandonment of common shell for field guns, their power against earthworks was if anything diminishing, and the introduction of smokeless powder gave the advantage of concealment to troops and guns behind cover, as against those advancing across the open. These considerations, added to previous experience, might have made it clear that in future wars field defences properly conceived and skilfully planned would be more effective than ever.

The South African War should set these questions at rest, and when its lessons have been fully learnt there can be no doubt that the use of entrenchments will rank as one of the first necessities of warfare. This use will be extended to the attack. The direct attack will seldom be attempted, and the endeavour of the assailant will be to outflank the defender. Since it is clear that a small force entrenched can resist the attack of a stronger one, it is open to the attack to leave a weak force entrenched in front of the enemy's main position, while endeavouring to get round his flank. The defence may reply in the same way, and the question will be which side shall be quickest in extending and pushing forward its flank works. In such a contest, mobility will be of the greatest importance. Such is the disparity of strength between the attack and the entrenched defence, that under certain conditions of ground it is even conceivable that the weaker force might surround and imprison the stronger. If a frontal attack is unavoidable, the assaulting troops, when checked within a certain distance of the position, should not retire, but hold on to what they have gained, extemporizing such cover as they can; and at nightfall entrench themselves there. By this means a secure position will be established close up to that of the enemy, and more troops can be collected there. If it is not close enough, a further advance may be made by night, or saps may be pushed forward until the distance will allow of a bayonet rush.

The methods of field fortification which prevailed till some years after the Franco-German War were practically those of the beginning of the 19th century. Since then they have been very much simplified. For instance, "lines of redans" or "lines *en crémaillère*," and redoubts of intricate design, are no longer contemplated in practice, though still found in many text-books. The refinements of these works belonged to the period of short-range weapons.

In order to understand present ideas, it is necessary first of all to know what are the powers of existing guns and rifles.

Artillery.—Field artillery projectiles may be roughly divided into two classes: shrapnel and common shell. The bullets of

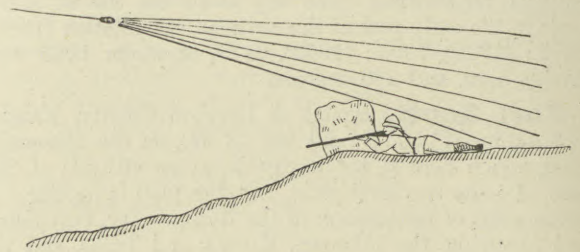

Fig. 1.

the former depend for their destructive power on the remaining velocity of the shell at the time when it is burst; the fragments of the latter are driven by the bursting charge of the shell. It follows that shrapnel bullets always fly forward, forming what is called a "cone of dispersion" about the line of flight of the shell. At a long range, when the shell falls at a steep angle, shrapnel bullets have not enough velocity to be effective. It is usually taken that the steepest slope of effective shrapnel is about one in three ($\frac{1}{3}$). Thus a man lying behind a boulder 3 feet high (see Fig. 1) would be protected against a shrapnel bullet; similarly a man in the trench shown in Fig. 2 would be safe.

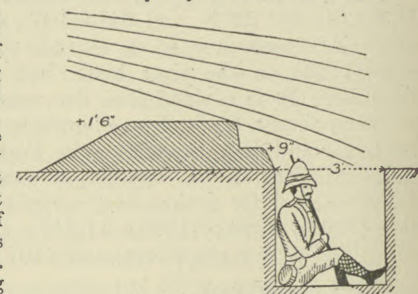

Fig. 2.

Common shell, if burst in the air, retain some forward velocity, but have more lateral spread than shrapnel. If burst on the ground the splinters may fly in any direction. They have more searching power than shrapnel, as will be seen from Fig. 3, but it is more difficult to time them properly.

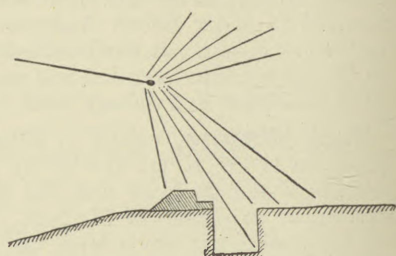

Fig. 3.

Howitzers usually fire common shell with percussion fuse. The effect of a high explosive bursting charge, as compared with gunpowder, is to give a more powerful shock of discharge, to break the shell into more splinters, and drive them harder. It also gives off poisonous fumes. A shell bursting in the trench, as in Fig. 4, would rake it from end to end; but

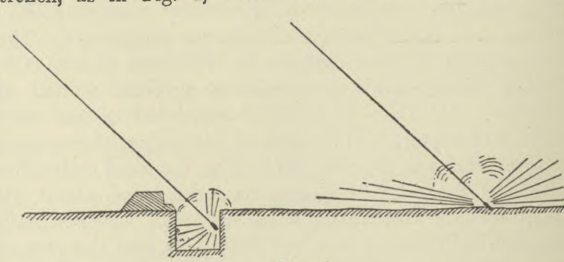

Fig. 4.

it will be observed that, in order to get its effect, it must fall *in* the trench.

The penetrative power of shrapnel bullets and of splinters is slight; from 6 inches to 1 foot of earth will suffice to keep out either.

Rifles.—Small-bore rifles depend for effect on their penetration, their trajectory being so flat that at ordinary ranges they have practically no searching power. A penetration table for the Lee-Enfield rifle is given below. It is much the same as that for other small-bore rifles.

Material.	Earth Un-rammed.	Sand.	Brick-work.	Soft Wood (Fir).	Hard Wood (Oak).	Hardened Steel Plate.	Fine Shingle in Boxes.
Maximum observed penetration (inches).	22	18	4½	42	24	$\frac{5}{16}$	4

It follows from the above, that in order to have protection against artillery fire, men must be close behind the covering parapet; and the parapet should not be less than 2 feet thick at the top (if of earth) to keep out rifle bullets. Overhead cover, when provided, against shrapnel and splinters, should consist of 6 inches to 1 foot of earth. No extemporized cover will keep out howitzer shell. If time admits, the trench should be deep and wide enough to admit of free passage, without the defenders being seen from the front.

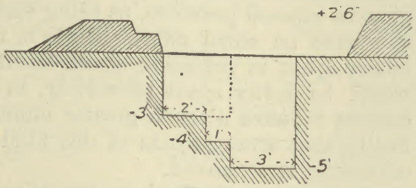

Fig. 5.

These considerations, together with the time, labour, and tools available, determine the section of shelter trenches. Fig. 2 shows the latest pattern of shelter trench adopted in the British service for execution when time presses. It can be made with the small entrenching tool in about three hours in moderately easy soil. This trench might be subsequently enlarged, as shown in Fig. 5.

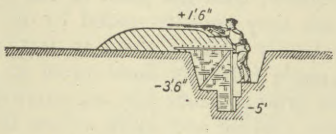

Fig. 6.

Fig. 6 shows how overhead cover might be provided. Such cover requires a large quantity of material, but if it can be made it is very useful, both for protection and shelter. Splinter-proof partitions, as shown in elevation in Fig. 6, are most useful for localizing the effects of shell explosions.

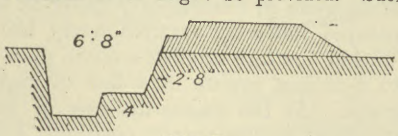

Fig. 7.

Fig. 7 is a German type of shelter trench.

Fig. 8 shows a protected look-out.

Fig. 9 is a section used by the Boers. It gives excellent cover from view, because the defenders' heads have an immediate background, but would not be suitable to most British sites, for want of command.

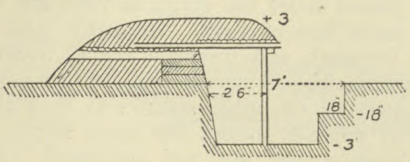

Fig. 8.

All these developments of the simple shelter trench require time, and much labour for the collection of materials; but it must be remembered, that though defences have sometimes to be extemporized in face of the enemy, yet all history shows that occasions have been more frequent when one or two days have been available for preparing a position on some line of advance to which the enemy is committed. (For instance, Deligrad, 1876, Shipka, Magersfontein, and Colenso.) Also as the enemy seldom abandons the assault of a position after the first trial, there is usually time for improvement of the works.

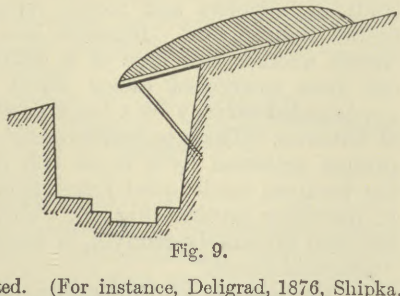

Fig. 9.

Trace or Siting of Trenches.—The system on which trenches are laid out is now much simplified by the fact that the decisive effect of the defenders' fire is obtained several hundred yards to the front. Thus, short faces flanking the front of the trench are not required; though if a cross fire over the front from neighbouring trenches can be arranged, the resistance will be greatly strengthened. The siting of the trenches will depend on the ground. The position generally should be on high ground, both for the sake of a clear view of the enemy's advance, and for concealment of the dispositions of the defence. When the high ground slopes steeply to a level plain, the front trenches may be on the level, and the artillery above them. In this way the trenches may be concealed from the enemy's artillery, and will gain the advantage of a grazing fire over the plain. With this arrangement, and for any position on the forward slope of the hill, the supports (which in any case must be entrenched) must either be very close to the front line, or must

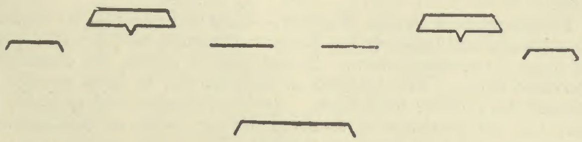

Fig. 10.

have access to it by a connecting trench, or at all events a screen. The reserves would probably have to occupy a second line of defensible trenches. On ground which has few marked features, to take the extreme case, a long straight ridge, narrow or flat at the top, the typical dispositions of the firing line may be divided into three classes, viz. (1) A long straight line of trenches on the forward edge, relying for support on the counter stroke of local reserves; (2) a line of trenches with redoubts among them, as *points d'appui;* (3) groups of trenches, with intervals between them to be defended by the flank trenches of the groups. In this case the nucleus of the group will often be a redoubt.

Fig. 11.

It is considered by the Germans that the *redoubt* is a form of work which will not often be used in future. The French (Fig. 10), and Austrians (Fig. 11), on the other hand, prescribe redoubts in connection with wing trenches.

Such simple positions, however, lending themselves to pure theory, will not often occur; especially as cases where the lie of the country more or less prescribes one line of advance for the enemy, will generally be found in rough ground. In broken and hilly ground there will be little choice of position for the trenches. Hills with convex slopes are not very suitable for defence, because the field of fire on the slope is always limited, sometimes dangerously so. Concave slopes, on the other hand, are generally accompanied by very rough ground, which is most suitable for concealment of trenches and reserve troops. They have the drawback that the top of the slope being very steep, troops in that position must expose themselves a good deal in firing upon the attack in its last stages. In defending such ground, the Boers have used trenches in all three of the positions shown at *a*, *b*, and *c* in Fig. 12.

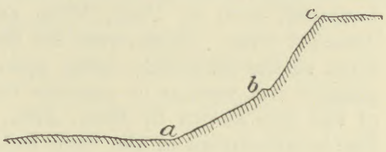

Fig. 12.

Redoubts, if used in connexion with trenches, will generally be of very simple trace adapted to the ground, and their parapets will be of shelter-trench section, so that they may be inconspicuous. In isolated positions, as when they are meant for posts on lines of communication, the parapets must be high enough to screen the interior from view, and a good obstacle must be provided. Guns should not be placed in redoubts. Epaulments may sometimes be provided for them, but concealment is their best protection.

Accidents of Ground.—The right use of these demands both judgment and training. *Hedges* when high and thick enough for concealment will be of great use, especially in connexion with smokeless powder. *Walls*, though penetrable by shells, afford concealment, and give protection against musketry. They may therefore be occupied. They can be made very strong by adding a bank of earth in front of them. *Houses* when in the line of battle are of little use for defence. They will attract artillery fire and become untenable. The ruins may be defended during the last stage of the attack, but it will not be worth while to prepare the house beforehand. The value of *woods* to the defence has altered little. They will still give a measure of defence against artillery fire, and they have the great advantage of concealing the dispositions of the defence. *Villages* are not likely to suffer more than formerly from artillery. High explosive common shell has more destructive but less incendiary power than the old powder shell.

Invisibility.—This is a point to be studied carefully in the arrangement of defence works. Not merely should trenches and other works be concealed by making them like the surrounding ground, with bushes, sods, &c., but marked accidents of the ground should be avoided, such as the meeting line between plough and pasture land, or the meeting of planes of surface of different inclination, where the lights will fall differently. Hedges may be a useful screen for guns, but the guns should be some distance behind them, so that it may be difficult to judge the range.

Obstacles.—Those made by digging should, as a rule, be avoided, on account of the labour involved. Abatis are useful where wood is plentiful, but the obstacle of the future is undoubtedly barbed wire.

Fortification in Savage Warfare.—This will as a rule be confined to obstacles and parapets for defence of camps, and forts for posts on lines of communication. In the case of camps the obstacle is the chief thing. The parapets of forts should be high enough to conceal the interior from view. As the defenders will probably be few, the old methods of flanking defence, such as bastions and caponiers, are sometimes employed. The water supply must be accessible and protected, and all other arrangements made for the comfort of the defenders, who may be shut in perhaps for a week at a time, in a tropical climate. (L. J.)

2. Permanent Land.

Recent years have witnessed extensive changes in the art of permanent fortification owing to the great development of detached forts and entrenched camps. In the early part of the 19th century, detached forts were used to occupy commanding points which were dangerous to the main fortress, but too far from the enceinte to be included in it. After the Crimean War Great Britain surrounded certain fortresses with a ring of detached forts, placed at a sufficient distance to prevent an enemy from bombarding the main position before he had penetrated the line of forts. The fortresses thus became entrenched camps, and the large area thus enclosed was of great value, in giving space to the garrison to manœuvre, and in increasing the length of the enemy's blockading line. At the time of the Franco-German War some of the principal Continental fortresses, such as Paris, Metz, and Antwerp, possessed detached forts. These were for the most part small editions of the fortresses, being open works with a single parapet and bastion or caponier defence for the ditches, of the type shown in *Ency. Brit.*, 9th ed., vol. ix. pl. 7. The bombardment of the Paris forts gave evidence of the increasing power of artillery, and the distance of the forts from the enceinte was increased. At the same time the attention of engineers was concentrated on improving the cover in the interior of the forts. It was sought to accomplish this by making the forts shallower from front to rear, and by making two parapets, one for infantry and one for artillery. In some cases the guns occupied the upper and in some the lower or front parapet. The result of this was to do away with the large open spaces in the interior of the forts, but not much additional cover against descending shells was gained, as the parapets were still open, that is, the guns fired from behind simple parapets without overhead cover.

In 1886, after the introduction of long shells filled with high explosive, some bombarding experiments carried out in France against the old fort of Malmaison made a great impression throughout the Continent. The effect of the powerful shells upon the old-fashioned slight escarps and the casemates covered with about three feet of masonry was immense. The general result was the formation of two opposite schools of thought, whose differences have not yet been reconciled. Most of the old school decided in favour of bomb-proof cover for the guns in the forts. A few, chiefly of the younger engineers, proposed to take the guns out of the forts and work them from concealed positions in the intervals. In any case the majority of the guns would have to be in the intervals for want of space in the forts. So far the bomb-proof school decidedly preponderates on the Continent of Europe, both among theorists and in the designs accepted by Governments.

The advocates of the removal of all the guns maintain that there is no necessary connexion between the artillery and the forts. They argue that the object of the forts is to form a series of secure positions supplying *points d'appui* for the entrenchments of the defence, and that their *rôle* is to maintain themselves, and defend the intervals by flanking fire. It is not necessarily their duty to take part in the distant artillery combat, thereby attracting to themselves the enemy's fire. It is also contended that unprotected guns in concealed positions are safer than protected guns in exposed positions, as being very difficult to locate, and have an equal effect. Thus it is alleged that the money spent in defensive arrangements, such as cupolas, would be better spent offensively, in guns; that cupola defence requires a much greater number of experts; and finally, that arrangements of this kind add greatly to the difficulties of command.

The bomb-proof school, on the other hand, declare that it is essential that there should be some guns in the forts to resist the enemy's guns as soon as they open fire, and before the provisional arrangements of the defence are complete; that the guns in the intervals will not be safe unless they are surrounded by defended ditches, which is practically putting them in forts; that cupolas can now be made perfectly bomb-proof at a moderate cost; and that arrangements for ammunition supply, &c., can be made simpler and more secure in the forts. The latest designs of the German school and of General Brialmont, which are very similar, consist, in their simplest expression, of triangular forts, with ditches flanked by quick-firing guns in counterscarp galleries, and an open infantry parapet following approximately the line of the ditch. Within the fort are half-a-dozen guns and howitzers of $4\frac{1}{2}$ to 6 inches' calibre in a line of cupolas in front of the gorge. At the angles are one or two more guns, and, dispersed in convenient positions, light quick-firing guns to defend the immediate front, all in cupolas. The cupolas are set in heavy masses of concrete. The magazines are under the guns. The infantry casemates are generally placed under the gorge, in rear, and on the flanks of the main line of guns. Germany, Austria, Italy, Belgium, Denmark, and Rumania are all working more or less on these lines. Russia and Japan so far appear to incline towards the other school: so does Holland, on the score of expense, except for coast forts. The latest French designs are not yet published. The most complete examples of recent designs are to be found among the smaller States, which only lately began to build detached forts. The entrenched camps at Bucarest, Liége and Namur, and Copenhagen are all worth study as complete and recent types. Fig. 1 shows a typical Belgian fort. Rumania has, on the line of the Sereth, another new type of a different nature. There are three entrenched camps which have no forts, but are defended entirely by a large number of small groups of batteries. These batteries consist of short lengths of parapet protected by a broad belt of obstacle. Behind the parapets small quick-firing guns are moved about in travelling cupolas (Fig. 2). This system, which has not been favourably received, is known as the system of "armoured fronts."

In the strategy of fortification, the latest theoretical development is the idea of "fortified regions." These would consist of a quadrilateral of entrenched camps occupying important points, some 15 to 20 miles apart, with a central fortress. There would be room for a large army to manœuvre in safety within this region, and as blockade would be impossible, the army could not be shut in, as it might be in an entrenched camp. The advantages of "fortified regions" can, however, only be realized by powerful field armies; and the real question is how far permanent fortification can aid such armies, and whether expenditure should not be devoted to mobile troops rather than to passive expedients. In details of execution, great attention has been paid to various devices for lessening the effect of shells on bombproofs. Masonry constructions are chiefly in concrete. The thickness of casemate arches is from 6 to 10 feet. Revetted escarps are not much used on front faces on account of their liability to be breached. Counterscarps are lower than formerly, and very massive. There is a tendency to do away with deep ditches and substitute broad belts of wire entanglement or thorn plantations. Electric searchlights and armoured observing stations are generally provided. The distance of the detached forts from the fortress varies from 8000 to as much as 18,000 yards. The distance between forts is laid down as about 3000 yards, but varies very much, according to the ground. (L. J.)

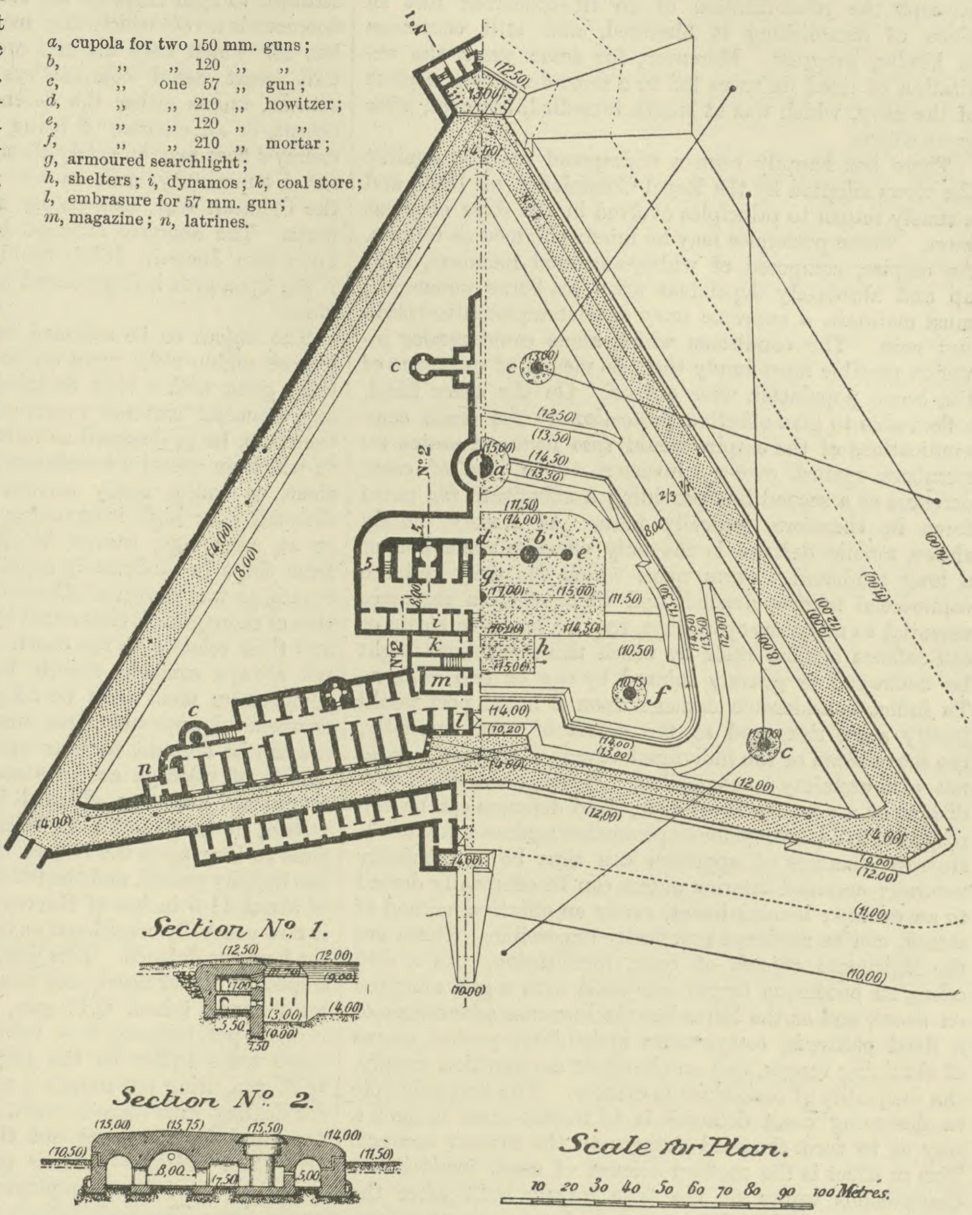

FIG. 1.—Plan and Sections of a Belgian Fort.

3. COAST.

Since about the year 1880 the whole question of coast defence has been the subject of much controversy, out of which certain definite principles are beginning to emerge. The mania for fortification, which gained hold upon Great Britain about the year 1859, produced most unfortunate results. A Royal Commission, appointed to consider and report upon an elaborate series of expensive projects, came to the conclusion that an island state was in some respects more exposed to invasion than one with long land frontiers, and that naval defence could not be trusted, because fleets were liable to be decoyed away when needed, and to be dispersed or rendered ineffective by storms. As a natural consequence, coast fortification usurped a position in the national defences which it had never filled in the past and could not fill in the future. Naval history, naval conditions, and the rich experience of war being alike ignored by the school which attained power, works were designed, and completed after long delay, which were totally unsuited to the purposes for which they were intended. The plain lessons of the Crimean War were unheeded, and monumentalism became the ideal of coast defences, although the performance of the little Telegraph Battery at Sebastopol, confirming much previous experience, should have amply sufficed to moderate the ambitions of military engineers. A false policy having been inaugurated, and the costly erections which it inspired having been begun, it was long before other views could obtain a hearing. Great Britain was thus saddled with

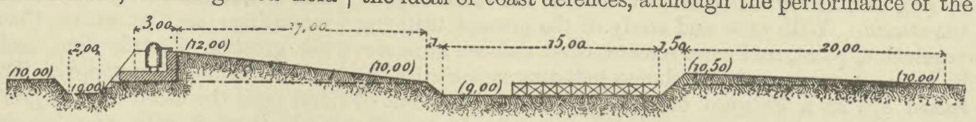

FIG. 2.—Section of Battery for Movable Cupola.

a large number of works which were obsolete before they were begun, and which have since been obstacles to effective coast defence. The natural tendency to attempt the rehabilitation of an ill-conceived fort in place of demolishing it hindered, and still continues to hinder, progress. Moreover, for some years the exaltation of fixed defences led to a most dangerous neglect of the navy, which was at length remedied, however, after great efforts.

There has happily been a widespread reaction against the views adopted by the Royal Commission of 1860, and a timely return to principles evolved in the days of great wars. Those principles may be briefly summed as follows. An empire, composed of widely-scattered members, built up and absolutely dependent upon sea-borne commerce, must maintain a supreme navy or contemplate disruption and ruin. The conditions which alone could render invasion possible must imply that the means of existence of the home population were cut off. On the other hand, a fleet able to give effective protection to the ocean communications of the empire would *ipso facto* guarantee its members against over-sea invasion. The idea of coast defences as a second line providing a substitute for naval force is, therefore, radically false. As history plainly shows, mobile defence is the only effective protection of a long sea-board. Ports upon which the navy and the commercial marine depend, and which contain resources essential to maritime operations, require, however, means of self-defence against raids by which those resources might be destroyed or gravely injured by one or two cruisers. To inflict considerable damage upon a naval port would justify some risk, and at the outset of war especially, the movements of the individual vessels of an enemy could not with certainty be controlled. If the geographical conditions of a port are favourable, fixed defences can be employed with advantage for its protection against naval raids. Narrow channels of approach can thus be economically secured; cramped interior waters can be effectually denied to an enemy; bombardment, rarely an effective method of attack, can be rendered practically impossible. These are the legitimate objects of coast fortification. As a ship offers an enormous target compared with a gun mounted on shore, and as the latter has the immense advantages of a fixed platform, comparative invisibility, perfect means of obtaining ranges, and an abundant ammunition supply, the inequality of conditions is evident. The first principle in designing coast defences is to mount guns in such a way as to turn these advantages to the utmost account. This in effect is the modern science of coast fortification. Conspicuous works of the type largely built after the Crimean War and in defiance of its lessons are, therefore, to be avoided. The object should be to give the guns such dispersion that they can be put out of action only by direct hits, to blend the works in which they are mounted as far as possible with the natural features of the coast line, and to utilize high sites, if such are available, even at some sacrifice of range, in order to increase the accuracy of fire, and at the same time to add to the difficulties of the attack. With care and study of the ground, utilizing vegetation, paint, and even screens, coast defence guns can be in most cases rendered almost indistinguishable by the naked eye at a distance of a mile. At the moment of firing, their positions of course become defined; but the difficulty of locating them sufficiently for accurate laying on board ship may nevertheless be considerable. In selecting sites for shore guns, it is necessary not merely to study the chart, but to take practical navigation into account, and to understand thoroughly what manœuvres a ship can accomplish and what she must perforce avoid. In discussions of questions of coast defence, it is sometimes assumed that attack upon fortified ports is the special and peculiar function of ships of war and the delight of naval commanders. Ships are, however, constructed to fight ships on the sea, and the attack of coast defences is a *rôle* which they may be called upon to play, but for which they are not well fitted. History shows that great naval commanders invariably eschew such attacks, unless either the defences are hopelessly incompetent, or all chances of being brought to action by the enemy's fleet may be safely dismissed. Only overpowering naval superiority, such as was asserted by the Allies in the Crimean War, can justify naval attacks on fortified ports. The abortive attempt by the American squadron upon San Juan in 1898 would have had serious results if the Spaniards had possessed a few well-handled modern guns.

The object to be attained by coast defences is thus to impose undue risks upon an enemy's ships seeking to use their guns with a view to injure a dockyard, shipping, or any essential national resources. The shore guns must, therefore, be so disposed as to bring their fire upon waters in which an enemy's vessels can take up positions enabling them to inflict really serious damage. Unaimed fire, directed over high intervening ground upon a dockyard or an anchorage, cannot be effective, and fire delivered from ships in moderately rapid motion is necessarily inaccurate, as was shown at Alexandria in 1882. The disposition of shore guns is thus noted by natural features of ground and their relation to the chart. The best natural sites do not always conform exactly to the requirements, and a compromise must then be adopted. For the defence of channels of approach sites would be chosen from which fire can be brought to bear upon a ship where the difficulties of pilotage are greatest. Where, as at Malta or Esquimalt, an easy channel leads into sheltered inner waters, it is desirable to bring the fire of two or three guns to bear upon the latter. The craze for monster guns has happily passed, and the 9·2-inch gun, with a penetration of about 11·5 inches of Harveyized armour at 2000 yards, is now generally considered as the largest ordnance required for harbour defence. This gun, as now mounted, will have a speed of fire of nearly one round per minute. The exceedingly handy 6-inch Q.F. gun, with a rate of about five rounds per minute, is a valuable addition, and will in some cases suffice as the staple armament. The 12-pr. Q.F. gun, firing ten rounds a minute, is admirably adapted for dealing with torpedo craft, for clearing the decks and tops, and for searching out the unarmoured portions of any ship. Muzzle-loading guns of old type, specially mounted, have been employed in many cases for high angle fire. The deck attach is naturally attractive, and such guns can be so concealed as to be absolutely secure from all injury. On the other hand, their fire must be directed by position-finders, and is slow and somewhat inaccurate. For convenience of working, it is undesirable to group guns of different types together. Rapid and accurate fire, combined with the highest degree of invisibility attainable, is the best protection of the shore guns. Modern mountings (see ORDNANCE, *Carriages*) are designed to give the greatest possible ease, and convenience of handling, and of ammunition supply. The 9·2-inch gun of 28¼ tons, and even the older 10-inch gun of 32 tons, can be trained and elevated with ease by one man, and in all recent mountings the laying number can work both gears, large movements being performed by alternative under-cover gear. The adoption of auto-sights with telescopes has greatly increased both the accuracy and the speed of coast defence guns. There has been a tendency to over-elaborate the tactical manipulation of coast artillery and to centralize the command of guns. The main requirement is to inflict the maximum number of hits in the shortest time, and auto-sights, together with smokeless powder, enable the gun to resume its individuality of action subject only to general control. Expert gun-layers and well-drilled detachments are thus of cardinal importance, and as a general rule the less interference they receive from any authority other than the battery commander on the spot the better.

Coast defence works are now simple in design, the objects being to merge them in the natural features of the shore line, to protect the vitals of the gun mountings, and to facilitate the supply of ammunition. Great forts, in which it was sought to combine the functions of the coast battery with those of a fortress, are no longer in favour. The self-defence of the coast battery against a landing party must, therefore, depend mainly upon a mobile infantry force, while the battery itself is usually protected by entanglements, sunken unclimbable fences, and machine guns. Mobile infantry garrisons of fortified ports are no new requirement, although this need has frequently been too little regarded. A fort is generally useless outside the *rayon* of its fire, and it may easily become a trap from which escape can be prevented. Even a small landing party, free to act for a short time, can effect much more destruction than any naval fire.

The only effective form of coast protection in the broad sense is that provided by a mobile navy. Naval raids on important harbours must, however, be guarded against by fixed defences, the scale of which can be extremely moderate, provided that guns and works are good, and that well-trained men are available. With such harbour defences, bodies of mobile infantry must be associated. Small fixed defences, armed with thoroughly effective guns, well manned and maintained in complete readiness for war, can fulfil all the requirements of the British empire. Large and costly schemes defeat their proposed objects, and being generally in an incomplete state and frequently undermanned, they are fertile sources of weakness. (G. S. C.)

4. United States.

The manner in which the fortifications of the United States are planned and constructed is controlled by Congress, and is subject to change at any time. At present the work is under the direction of the Secretary of War, certain definite duties being assigned to the different bureaux of the War Department. The selection of the sites to be fortified, the preparation of plans, including the determination of the number, calibre, and mounts of the guns, the construction and repair of the permanent parts of the works, the provision of torpedo material, and the planting and operation of the mine-fields, are part of the duties of the Corps of Engineers of the army; the armament, ammunition, and, in general, the instruments needed for the service of the guns, are procured and distributed by the Ordnance Department of the army; the barracks, quarters and other buildings needed for the garrison, are supplied by the Quartermaster's Department of the army. The works when finished are turned over to the artillery arm of the service. The selection of the types of guns and other implements to be adopted by the Government is entrusted to the Board of Ordnance and Fortification, acting under the control and supervision of the Secretary of War, and consisting now of the commanding general of the army, one officer each from the Corps of Engineers, the Ordnance Department, and the artillery, and one civilian.

The permanent fortifications of the United States have all been built to protect points on the sea-coast or lake frontier against naval attack. The great development on the coast-line renders it out of the question to protect every point at which a hostile landing is possible. The principles which have been kept in view in the defence of the coast were enunciated in 1826 by a Board of Engineers appointed in 1816 to examine the sea-coast, and propose plans for defensive works. The Board held that the means of defence consisted of, 1st, a navy; 2nd, fortifications; 3rd, interior communications by land and water; 4th, a regular army and militia. The duty of the navy was regarded as active and offensive, requiring the aid of fortifications to secure its bases on the coast. The interior communications were considered necessary as means of concentration and supply. The army and militia were held to be the vital principles of the system, and the objects of the fortifications were stated as follows:—

"Fortifications must close all important harbours against an enemy, and secure them to our military and commercial marine; second, must deprive an enemy of all strong positions where, protected by naval superiority, he might fix permanent quarters in our territory, maintain himself during the war, and keep the whole frontier in perpetual alarm; third, must cover the great cities from attack; fourth, must prevent, as far as practicable, the great avenues of interior navigation from being blockaded at their entrances into the ocean; fifth, must cover the coastwise and interior navigation by closing the harbours and the several inlets from the sea which intersect the lines of communication, and thereby further aid the navy in protecting the navigation of the country; and, sixth, must protect the great naval establishments."

These principles indicate the policy which has been followed by the United States in organizing its coast defences.

The early fortifications of the United States are usually considered by engineers as divided into three systems: the first embracing those built before and during the time of the French Revolution of 1789; the second, those built at the approach of the war of 1812; and the third, those built between 1816 and 1866. Works of the first two systems may be found at nearly all of the harbours which were of importance at the beginning of the 19th century. Castle Williams, Fort Lafayette, and others in New York harbour, are examples. Without costly alteration these works would now be useless for purposes of defence. The third system was inaugurated by the Board of Engineers, the report of which has already been quoted. The works belonging to it were of masonry, with exposed scarps on the sea-fronts, and contained usually two tiers of casemates surmounted by an open barbette battery. As examples may be mentioned Fort Warren at Boston, Fort Adams at Newport, and Forts Wadsworth and Schuyler at New York harbour. None of the works of this system as originally constructed could resist naval ordnance of the present day; but many have been retained as part of the modern defences, usually after extensive remodelling. When work ceased on the third system, about a year before the end of the Civil War, it was already out of date. The use of armour on ships of war was recognized at once in the United States, as well as elsewhere, as compelling some corresponding improvement in coast defences. Masonry could no longer be exposed, even on the sea-fronts, and must either be protected or discarded. After the Civil War the construction of a new system of works began, consisting of open barbette batteries, of strong profile, with earth or sand parapets, and thin breast-high walls. The armament was muzzle-loading, and consisted principally of smooth-bore, cast-iron Rodman guns, of 15, 10, and 8 inches' calibre, of 300-pounder, 200-pounder, and 100-pounder rifled Parrot guns, and of 8-inch converted rifles, made from the 10-inch Rodman gun by reboring and inserting a rifled lining tube; and of mortars of 13-inch and lower calibre. No attempt was made to plate or otherwise reinforce the existing masonry works with iron, this subject being left unsettled, pending further experiment and investigation in the United States and elsewhere. Between 1866 and 1875 Congress appropriated a total sum of nearly $11,000,000 for the construction of new works, this sum being in addition to the cost of the armament. At the same time, the development of a torpedo system, which was regarded as an indispensable adjunct to the shore batteries, was receiving constant attention. In 1875 the work of constructing new batteries was suspended. No further funds for this purpose were appropriated until 1890, although the small sums needed for the preservation and repair of the existing works, and for the experiments and work in the development of the torpedo system, were available for all except about two years of this interval. In 1885, after repeated warnings uttered by the military authorities who had the subject in charge, Congress and the people at large awoke to the fact that the power of ships of war had again increased to such an extent as to render the existing defences practically useless. Congress then directed the formation of a Board, to consist of the Secretary of War, two officers each from the Engineer Corps of the army, the Ordnance Corps of the army, and the line of the navy, and two civilians, to examine and report where fortifications were most needed, and what the character of the defences should be. This Board, known as the Endicott Board, submitted its report in January 1886. It named twenty-seven localities, some of which included two or more harbours, which demanded particular attention at the time, and indicated the strength of the high-power armament and the general character of the batteries for each. It proposed the use of armoured turrets, armoured casemates and barbette batteries, aided in some harbours by floating batteries, the last being carefully distinguished from the armoured sea-going ships of the navy. Submarine mines were regarded as "not accessories of the defence, but essential features," and were recommended for use, together with the necessary flanking batteries and search-lights. Movable torpedoes and torpedo-boats were also included in the plans. The guns proposed were 16, 14, 12, 10 and 8 inches in calibre, supplemented by 12- and 10-inch mortars and smaller rapid-fire guns. All were to be modern breech-loading rifles. These recommendations have been followed in a general way in the construction of coast defences since the report; but the details of the work done differ in many respects from those suggested by the Board.

The Endicott Board.

Four years after the report of the Endicott Board had been rendered, Congress began again to appropriate sums for the construction of new fortifications. Between the years 1890 and 1899, both included, a total sum of $20,150,923.93 was allotted for the engineering expenses of building new gun and mortar batteries, while additional sums, aggregating about $7,000,000, were allotted for purchase of sites, for preparation of the submarine mine system, and for certain other purposes connected with the coast defence. The cost of armament and carriages and the necessary ordnance expenses were not included in the amounts named. During the period in question about $26,000,000 was made available for these purposes. The projects in accordance with which the sums thus appropriated have been expended were prepared under the direction of the Chief of Engineers of the army, subject to the approval of the Secretary of War. As a general rule, the preparation of these projects is assigned by the Chief of Engineers to the Board of Engineers, a body composed of officers of the Corps of Engineers, and especially charged, among other duties, with that of planning and revising, as may be directed by the Chief of Engineers, from time to time, projects of permanent fortifications required for the national defence. The annual report for the year 30th June 1899, of the Chief of Engineers, stated that, "Under the general scheme of national defence outlined by the Endicott Board in its report of 16th January 1886, projects for permanent sea-coast batteries have been adopted for thirty localities in the United States, as follows:—

1. Penobscot River, Maine.
2. Kennebec River, Maine.
3. Portland, Maine.
4. Portsmouth, N.H.
5. Boston, Mass.
6. New Bedford, Mass.
7. Narragansett Bay, R.I.
8. Eastern Entrance to Long Island Sound.
9. New York, N.Y.
10. Philadelphia, Pa.
11. Baltimore, Md.
12. Washington, D.C.
13. Hampton Roads, Va.
14. Wilmington, N.C.
15. Charleston, S.C.
16. Port Royal, S.C.
17. Savannah, Ga.
18. St Johns River, Fla.
19. Key West, Fla.
20. Tampa Bay, Fla.
21. Pensacola, Fla.
22. Mobile, Ala.
23. New Orleans, La.
24. Sabine Pass, Texas.
25. Galveston, Texas.
26. San Diego, Cal.
27. San Francisco, Cal.
28. Mouth of Columbia River, Oregon and Washington.
29. Puget Sound, Wash.
30. Lake Champlain.

"The defence of several additional localities in the United States is now under consideration, for which no formal projects have yet been completed, or approved by the Secretary of War. In addition, considerable study has been given during the year to the subject of coast defences for our insular possessions, resulting in the completion of a project of defence for the harbour of San Juan, Puerto Rico, and of preliminary projects for the defence of Honolulu and Pearl Harbour, Hawaiian Islands. . . ."

"Existing approved projects for sea-coast defences contemplate the emplacement of about 500 heavy guns of 8, 10, 12 and 16 inches' calibre, of about 800 rapid-fire guns, and of about 1000 mortars, at an estimated approximate cost for the engineering work of $55,000,000. . . ."

The status of emplacements for which funds have thus far been provided by Congress was as follows at the close of that fiscal year:—

	12-in.	10-in.	8-in.	Rapid-fire.	12-in. mortars.
Guns mounted	27	83	59	46	176
Ready for armament	39	27	25	115	60
Under construction	19	8	10	122	108
Not yet begun	...	...	...	25	...
Totals	85	118	94	308	344

The emplacements enumerated in this table are situated at 77 places, in thirty different harbours. Practically all of those ports for which projects have been prepared have received a portion of the proposed defence, while at the greater part of them a sufficient number of heavy guns and mortars was installed on 30th June 1899, to make a strong resistance against naval attack. The regular appropriations made annually during the last few years, and the extraordinary appropriations made for the national defence at the outbreak of the war with Spain, have enabled the military authorities to make very gratifying progress with the entire scheme, and have encouraged the hope that in a few years it will be complete. The emplacements for which funds were provided on 30th June 1899, will mount guns of six inches' and heavier calibre as shown below:—

Present state.

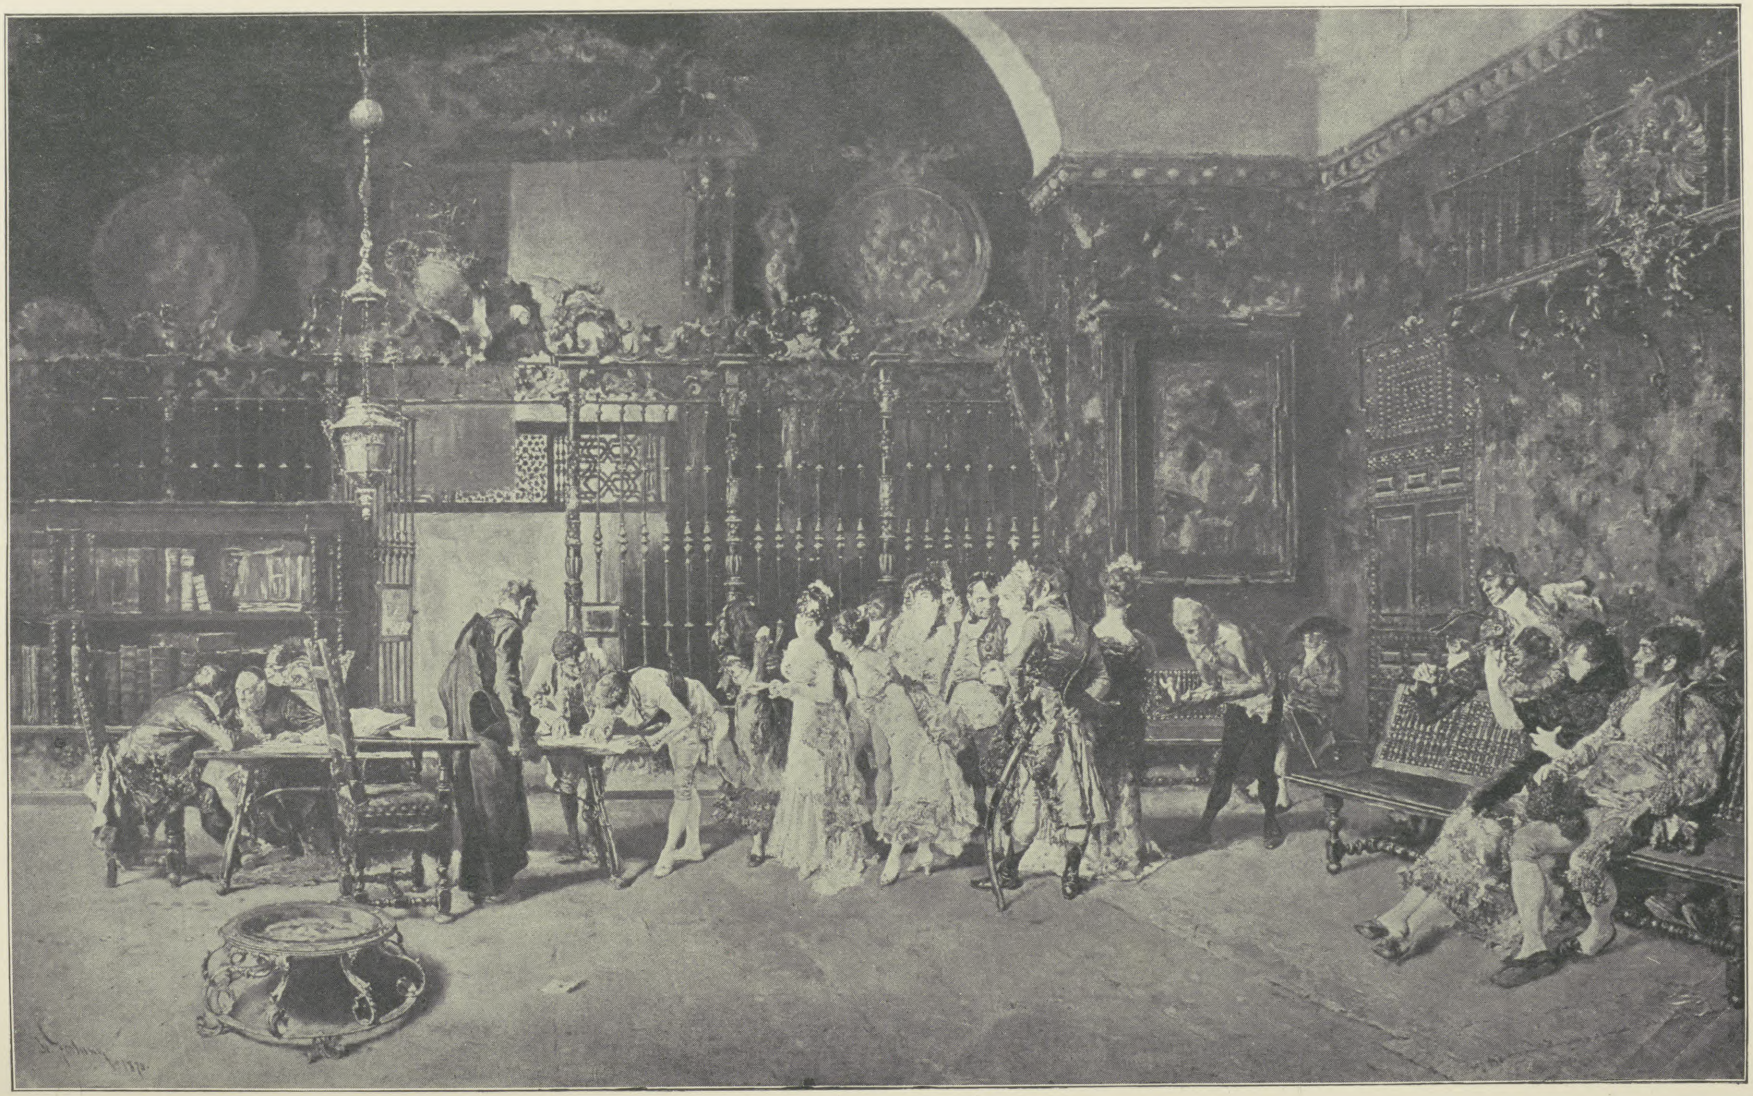
12-in. guns on lift mounts	2
12-in. guns on disappearing carriages	54
12-in. guns on non-disappearing carriages	29
10-in. guns on disappearing carriages	108
10-in. guns on non-disappearing carriages	10
8-in. guns on disappearing carriages	64
8-in. guns on non-disappearing carriages	30
6-in. R.F. guns on disappearing carriages	29
6-in. R.F. guns on non-disappearing carriages	33

The first 12-in. guns to be installed were the two in the lift battery, which was finished in 1895. In this each gun, with its carriage, is mounted on a platform which can be raised and lowered by a direct-acting hydraulic ram. The gun is lowered for loading behind the parapet, which is of sand and concrete, and is then raised by the ram to the firing position. It is fired in barbette, over the parapet. The operations of hoisting the ammunition to the breech of the piece and of ramming are performed by hydraulic power, the water for all of the cylinders being drawn from an accumulator into which it is pumped by steam. The time of ascent or descent of the gun is from 15 to 20 seconds, including the operation of locking the platform. The ammunition-lift is raised in 7 seconds. In a two-gun lift-battery the accumulators can be worked continuously at the rate of two minutes and thirty seconds' interval between shots, for each lift. The cost of the lift battery, as first built, for two guns, was about $455,000, exclusive of the guns. The remaining batteries, mounting guns in barbette on disappearing and non-disappearing carriages, are all of the same general type. The protection is given by a sand parapet in front of a retaining wall of concrete, behind which the guns are mounted. The thickness of the concrete wall in front of the gun is so great that its top forms a sufficient blast slope. Consecutive guns are separated by thick traverses, rising usually only to the level of the interior crest. Ample magazine space is provided, and suitable appliances for hoisting and conveying the ammunition either by hand or by electric power. The guns, as now mounted, are loaded and trained by hand. Experiments have been undertaken to test the advisability of manipulating the guns and carriages by electric power. The batteries are lighted by electricity and have the needful provisions for the installation of range-finding instruments, search-lights, and similar accessories.

The service disappearing carriage now adopted is of the well-known Buffington-Crozier type, the invention of two officers of the Ordnance Department, U. S. Army. By far the greater number of high-power guns in the United States are thus mounted at present, but there is a strong probability that this type of carriage will be less extensively used in the future. In trials for rapidity of fire these carriages have given results as follows:—

8-in. gun, 10 rounds in 12 m. 21 sec.
10-in. gun, 10 rounds in 14 m. 42 sec.
12-in. gun, 10 rounds in 16 m. 57 sec.

The guns were operated and loaded by hand. The trials began with the gun empty, the breech block closed, and the ammunition ready to hand. The mortar batteries mount either 16 or 8 mortars, in four or two pits, containing each four mortars. The pits are protected by a thick sand parapet, held up on the interior by a concrete wall, and are separated from each other by heavy traverses



"THE SPANISH MARRIAGE." BY FORTUNY.

(From a Photograph by J. Lacoste.)

containing bomb-proofs and magazines. In addition to the guns and mortars, batteries mounting one or more pneumatic dynamite guns have been established at San Francisco and Sandy Hook, and are to be placed at Fisher's Island and Port Royal. The heavy guns may be fired either by direct laying by the gunners, or by indirect laying, taking the azimuth and elevation from the position-finding station. The latter method possesses great advantages for the guns mounted on disappearing carriages, or on the gun lift, since the pointing may be done while the gun and detachment are completely covered by the parapet. The mortars are arranged for indirect laying only, the parapet being so high as to conceal the target from the gunner. The batteries have been built in some cases by hired labour, and in others by contract, the former method having given the more satisfactory results. The cost has varied very much, according to the situation. One of the principal items is the concrete, of which a single emplacement, as now built for the different high-power guns on disappearing carriages, contains approximately the following quantity, including magazine, platform, and all accessories :—

For the 12-in. gun . . .	5300 cubic yards.
For the 10-in. gun . . .	3600 cubic yards.
For the 8-in. gun . . .	3200 cubic yards.

The cost of such emplacements, complete, including ammunition lifts and all permanent parts, but not including gun or carriage, may be taken at between $30,000 and $45,000 for one 8-in. gun, between $35,000 and $50,000 for one 10-in. gun, and between $45,000 and $60,000 for one 12-in. gun. There is no marked difference in the cost of the emplacements as built for the disappearing and non-disappearing mounts. Armoured turrets, though contemplated, have not yet been constructed. The torpedo defence, which is regarded as an indispensable part of the general plan, is disposed in accordance with projects prepared in the same way as those for the artillery defence. Each harbour which is protected by land batteries has provision made for one or more mine-fields as well, situated in such manner as to be swept to advantage by the guns on shore. (H. F. H.)

Fortrose, a royal and parliamentary burgh (Inverness group), market town, and fishing port, Inverness-shire, Scotland, $10\frac{1}{2}$ miles N.N.E. of Inverness by rail. A water supply has been introduced, the harbour repaired, a new pier built, whilst a volunteer drill hall, a new academy, and a new United Free church have been erected. The schools include an academy. Population (1881), 874; (1901), 1179.

Fortune, Robert (1813–1880), British botanist and traveller, was born in Berwickshire on 16th September 1813. He was employed in the Botanical Garden at Edinburgh, and afterwards in the Royal Horticultural Society's Garden at Chiswick, and upon the termination of the Chinese War in 1842 was sent out by the Society to collect plants in China. His travels resulted in the introduction to Europe of many beautiful flowers; but another journey, undertaken on behalf of the East India Company, had much more important consequences, occasioning the successful introduction into India of the tea-plant, whose produce now competes so successfully with the tea of China. In subsequent journeys he visited Formosa and Japan, described the culture of the silkworm and the manufacture of rice paper, and introduced many trees, shrubs, and flowers now generally cultivated in Europe. The incidents of his travels were related in a succession of interesting books. He died in London, 13th April 1880.

Fortuny, Mariano Jose Maria Bernardo (1838–1874), Spanish painter, was born at Reus on 11th June 1838. His parents, who were in poor circumstances, sent him for education to the primary school of his native town, where he received some instruction in the rudiments of art. When he was twelve years old his parents died and he came under the care of his grandfather, who, though a joiner by trade, had made a collection of wax figures, with which he was travelling from town to town. In the working of this show the boy took an active part, modelling and painting many of the figures; and two years later, when he reached Barcelona, the cleverness of his handiwork made so much impression on some people in authority there that they induced the municipality to make him an allowance of forty-two francs monthly, so that he might be enabled to go through a systematic course of study. He entered the Academy of Barcelona and worked there for four years under Claudio Lorenzale, and in March 1857 he gained a scholarship that entitled him to complete his studies in Rome. Then followed a period of more than two years, during which he laboured steadily at copies of the old pictures to which he had access at Rome. To this period an end was put by the outbreak of the war between Spain and the emperor of Morocco, as Fortuny was sent by the authorities of Barcelona to paint the most striking incidents of the campaign. The expedition lasted for about six months only, but it made upon him an impression that was powerful enough to affect the whole course of his subsequent development, and to implant permanently in his mind a preference for the glitter and brilliancy of African colour. He returned to Spain in the summer of 1860, and was commissioned by the city of Barcelona to paint a large picture of the capture of the camps of Muley-el-Abbas and Muley-el-Hamed by the Spanish army. After making a large number of studies he went back to Rome, and began the composition on a canvas fifteen metres long; but though it occupied much of his time during the next few years, he never finished it. He busied himself instead with a wonderful series of pictures, mostly of no great size, in which he showed an astonishing command over vivacities of technique and modulations of colour. He visited Paris in 1868, and shortly afterwards married the daughter of Frederigo Madrazo, the Director of the Royal Museum at Madrid. Another visit to Paris in 1870 was followed by a two years' stay at Granada, but then he returned to Rome, where he died somewhat suddenly on 21st November 1874 from an attack of malarial fever, contracted while painting in the open air at Naples and Portici in the summer of 1874.

The work which Fortuny accomplished during his short life is distinguished by a superlative facility of execution and a marvellous cleverness in the arrangement of brilliant hues, but the qualities of his art are those that are attainable by a master of technical resource rather than by a deep thinker. His insight into subtleties of illumination was extraordinary, his dexterity was remarkable in the extreme, and as a colourist he was vivacious to the point of extravagance. At the same time, in such pictures as "La Vicaria" and "Choosing a Model," and in some of his Moorish subjects, like "The Snake Charmers" and "Moors playing with a Vulture," he showed himself to be endowed with a sensitive appreciation of shades of character, and a thorough understanding of the peculiarities of a national type. His love of detail was instinctive, and he chose motives that gave him the fullest opportunity of displaying his readiness as a craftsman.

Fostoria, a city of Seneca County, Ohio, U.S.A., nearly south of Toledo, at an altitude of 773 feet. It has large flour mills and glass-works, the latter being aided by its supply of natural gas. Fostoria is the point of intersection of five railway lines, making it an important railway centre. Population (1880), 3569; (1890), 7070; (1900), 7730, of whom 584 were foreign-born, and 168 negroes.

Fougères, chief town of arrondissement, department of Ille-et-Vilaine, France, 29 miles north-east of Rennes, on railway from Vitré to Mont St Michel. An equestrian statue of General de la Riboisière (died 1812) was erected in 1893, and there is a monument to the soldiers who fell in 1870–71. Population (1881), 13,125; (1891), 16,781; (1901), 20,952.

Fourier's Series are those series which proceed according to sines and cosines of multiples of a variable, the various multiples being in the ratio of the natural numbers; they are used for the representation of a function of the variable for values of the variable which lie between prescribed finite limits. Although the importance of such series, especially in the theory of vibrations, had been recognized by D. Bernoulli, Lagrange, and other mathematicians, and had led to some discussion of their properties, Fourier (see FOURIER, JEAN BAPTISTE JOSEPH, *Ency. Brit.*, ninth edition, vol. ix.) was the first clearly to recognize the arbitrary character of the functions which the series can represent, and to make any serious attempt to prove the validity of such representation; the series are consequently usually associated with the name of Fourier. More general cases of trigonometrical series, in which the multiples are given as the roots of certain transcendental equations, were also considered by Fourier.

Before proceeding to the consideration of the special class of series to be discussed, it is necessary to define with some precision what is to be understood by the representation of an arbitrary function by an infinite series. Suppose a function of a variable x to be arbitrarily given for values of x between two fixed values a and b; this means that corresponding to every value of x such that $a \leqq x \leqq b$, with the possible exception of a finite number of values of x, a definite arithmetical value of the function is assigned by means of some prescribed set of rules. A function so defined may be denoted by $f(x)$; the rules by which the values of the function are determined may be embodied in a single explicit analytical formula, or in several such formulæ applicable to different portions of the interval, but it would be an undue restriction of the nature of an arbitrarily given function to assume *à priori* that it is necessarily given in this manner, the possibility of the representation of such a function by means of a single analytical expression being the very point which we have to discuss. The variable x may be represented by a point at the extremity of an interval measured along a straight line from a fixed origin; thus we may speak of the point c as synonymous with the value $x=c$ of the variable, and of $f(c)$ as the value of the function assigned to the point c. For any finite number of points between a and b the function may be discontinuous, *i.e.*, it may at such points undergo abrupt changes of value. The only discontinuities here considered will be those known as ordinary discontinuities. Such a discontinuity exists at the point c if $f(c+\epsilon)$, $f(c-\epsilon)$ have distinct but definite limiting values as ϵ is indefinitely diminished; these limiting values are known as the limits on the right and on the left respectively of the function at c, and may be denoted by $f(c+0)$, $f(c-0)$. The discontinuity consists therefore of a sudden change of value of the function from $f(c-0)$ to $f(c+0)$, as x increases through the value c. If there is such a discontinuity at the point $x=0$, we may denote the limits on the right and on the left respectively by $f(+0)$, $f(-0)$.

Suppose we have an infinite series $u_1(x)+u_2(x)+\ldots+u_n(x)+\ldots$ in which each term is a function of x, of known analytical form; let any value $x=c(a \leqq c \leqq b)$ be substituted in the terms of the series, and suppose the sum of n terms of the arithmetical series so obtained approaches a definite limit as n is indefinitely increased; this limit is known as the sum of the series. If for every value of c such that $a \leqq c \leqq b$ the sum exists and agrees with the value of $f(c)$, the series $\sum_1^\infty u_n(x)$ is said to represent the function $f(x)$ between the values a, b of the variable. If this is the case for all points within the given interval with the exception of a finite number, at any one of which either the series has no sum, or has a sum which does not agree with the value of the function, the series is said to represent "in general" the function for the given interval. If the sum of n terms of the series be denoted by $S_n(c)$, the condition that $S_n(c)$ converges to the value $f(c)$ is that corresponding to any finite positive number δ as small as we please, a value n_1 of n can be found such that if $n \geqq n_1$, $|f(c)-S_n(c)| < \delta$.

Functions have also been considered which for an infinite number of points within the given interval have no definite value, and series have also been discussed which at an infinite number of points in the interval cease either to have a sum, or to have one which agrees with the value of the function; the narrower conception above will however be retained in the treatment of the subject in this article, reference to the wider class of cases being made only in connexion with the history of the theory of Fourier's Series.

Uniform Convergence of Series.—If the series $u_1(x)+u_2(x)+\ldots+u_n(x)+\ldots$ converge for every value of x in a given interval a to b, and its sum be denoted by $S(x)$, then if corresponding to a finite positive quantity δ as small as we please a finite number n_1 can be found such that the arithmetical value of $S(x)-S_n(x)$, where $n \geqq n_1$ is less than δ, for every value of x within the given interval, the series is said to converge uniformly within that interval. It may however happen that as x approaches a particular value the number of terms of the series which must be taken so that $|S(x)-S_n(x)|$ may be $<\delta$, increases indefinitely; the convergence of the series is then infinitely slow in the neighbourhood of such a point, and the series is not uniformly convergent throughout the given interval. If the number of such points in the neighbourhood of which the series ceases to converge uniformly be finite, they may be excluded by taking intervals of finite magnitude as small as we please containing such points, and considering the convergence of the series in the given interval with such sub-intervals excluded; the convergence of the series is now uniform throughout the remainder of the interval. The series is said to be *in general* uniformly convergent within the given interval a to b if it can be made uniformly convergent by the exclusion of a finite number of portions of the interval, each such portion being arbitrarily small. It is known that the sum of an infinite series of continuous terms can be discontinuous only at points in the neighbourhood of which the convergence of the series is not uniform, but non-uniformity of convergence of the series does not necessarily imply discontinuity in the sum.

Form of Fourier's Series.—If it be assumed that a function $f(x)$ arbitrarily given for values of x such that $0 \leqq x \leqq l$ is capable of being represented in general by an infinite series of the form

$$A_1 \sin\frac{\pi x}{l} + A_2 \sin\frac{2\pi x}{l} + \ldots + A_n \sin\frac{n\pi x}{l} + \ldots,$$

and if it be further assumed that the series is in general uniformly convergent throughout the interval 0 to l, the form of the coefficients A can be determined. Multiply each term of the series by $\sin\frac{n\pi x}{l}$, and integrate the product between the limits 0 and l, then in virtue of the property $\int_0^l \sin\frac{n\pi x}{l}\sin\frac{n^1\pi x}{l}dx=0$, or $\frac{1}{2}l$, according as n^1 is not, or is, equal to n, we have $\frac{1}{2}lA_n=\int_0^l f(x)\sin\frac{n\pi x}{l}dx$, and thus the series is of the form $\frac{2}{l}\sum_1^\infty \sin\frac{n\pi x}{l}\int_0^l f(x)\sin\frac{n\pi x}{l}dx$. (1)

This method of determining the coefficients in the series would not be valid without the assumption that the series is in general uniformly convergent, for in accordance with a known theorem the sum of the integrals of the separate terms of the series is otherwise not necessarily equal to the integral of the sum. This assumption being made, the other assumption of the possibility of the expansion insures that $f(x)$ is such that the integrals $\int_0^l f(x)\sin\frac{n\pi x}{l}dx$ have a definite meaning.

Before we proceed to examine the justification for the assumptions made, it is desirable to examine the result obtained, and to deduce other series from it. In order to obtain a series of the form

$$B_0 + B_1\cos\frac{\pi x}{l} + B_2\cos\frac{2\pi x}{l} + \ldots + B_n\cos\frac{n\pi x}{l} + \ldots$$

for the representation of $f(x)$ in the interval 0 to l, let us apply the series (1) to represent the function $f(x)\sin\frac{\pi x}{l}$; we thus find

$$\frac{2}{l}\sum_1^\infty \sin\frac{n\pi x}{l}\int_0^l f(x)\sin\frac{\pi x}{l}\sin\frac{n\pi x}{l}dx,$$

or

$$\frac{1}{l}\sum_1^\infty \sin\frac{n\pi x}{l}\int_0^l f(x)\left\{\cos\frac{(n-1)\pi x}{l}-\cos\frac{(n+1)\pi x}{l}\right\}dx.$$

On rearrangement of the terms this becomes

$$\frac{1}{l}\sin\frac{\pi x}{l}\int_0^l f(x)dx+\frac{2}{l}\sum\sin\frac{\pi x}{l}\cos\frac{n\pi x}{l}\int_0^l f(x)\cos\frac{n\pi x}{l}dx,$$

hence $f(x)$ is represented for the interval 0 to l by the series of cosines

$$\frac{1}{l}\int_0^l f(x)dx+\frac{2}{l}\sum_1^\infty\cos\frac{n\pi x}{l}\int_0^l f(x)\cos\frac{n\pi x}{l}dx \quad . \quad . \quad (2)$$

We have thus seen, that with the assumptions made, the arbitrary function $f(x)$ may be represented, for the given interval, either by a series of sines, as in (1), or by a series of cosines, as in (2). Some important differences between the two series must, however, be noticed; in the first place, the series of sines has a vanishing sum when $x=0$ or $x=l$, it therefore does not represent the function at the point $x=0$, unless $f(0)=0$, or at the point $x=l$, unless $f(l)=0$, whereas the series (2) of cosines may represent the function at both these points. Again, let us consider what is represented by (1) and (2) for values of x which do not lie between 0 and l; as $f(x)$ is given only for values of x between 0 and l, the series at points beyond these limits have no necessary connexion with $f(x)$ unless we suppose that $f(x)$ is also given for such general values of x in such a way that the series continue to represent that function. If in (1) we change x into $-x$, leaving the coefficients unaltered, the series changes sign, and if x be changed into $x+2l$, the series is unaltered; we infer that (1) is an odd function of x and is periodic of period $2l$; thus (1) will represent $f(x)$ in general for values of x between $\pm\infty$, if $f(x)$ is odd and has a period $2l$. If in (2) we change x into $-x$, the series is unaltered, and it is also unaltered by changing x into $x+2l$; from this we see that (2) represents $f(x)$ for values of x between $\pm\infty$, only if $f(x)$ is an even function, and is periodic of period $2l$. In general a function $f(x)$ arbitrarily given for all values of x between $\pm\infty$ is neither periodic nor odd, nor even, and is therefore not represented by either (1) or (2) except for the interval 0 to l.

From (1) and (2) we can deduce a series containing both sines and cosines, which will represent a function $f(x)$ arbitrarily given in the interval $-l$ to l, for that interval. We can express by (1) the function $\frac{1}{2}\{f(x)-f(-x)\}$ which is an odd function, and thus this function is represented for the interval $-l$ to $+l$ by

$$\frac{2}{l}\sum \sin\frac{n\pi x}{l}\int_0^l \tfrac{1}{2}\{f(x)-f(-x)\}\sin\frac{n\pi x}{l}dx;$$

we can also express $\frac{1}{2}\{f(x)+f(-x)\}$, which is an even function, by means of (2), thus for the interval $-l$ to $+l$ this function is represented by

$$\frac{1}{l}\int_0^l \tfrac{1}{2}\{f(x)+f(-x)\}dx+\frac{2}{l}\sum_1^\infty \cos\frac{n\pi x}{l}\int_0^l \tfrac{1}{2}\{f(x)+f(-x)\}\cos\frac{n\pi x}{l}dx.$$

It must be observed that $f(-x)$ is absolutely independent of $f(x)$, the former being not deducible from the latter by putting $-x$ for x in a formula; both $f(x)$ and $f(-x)$ are functions given arbitrarily and independently for the interval 0 to l. On adding the expressions together we obtain a series of sines and cosines which represents $f(x)$ for the interval $-l$ to l. The integrals

$$\int_0^l f(-x)\cos\frac{n\pi x}{l}dx,\quad \int_0^l f(-x)\sin\frac{n\pi x}{l}dx$$

are equivalent to

$$-\int_0^{-l} f(x)\cos\frac{n\pi x}{l}dx,\quad +\int_0^{-l} f(x)\sin\frac{n\pi x}{l}dx,$$

thus the series is

$$\frac{1}{2l}\int_{-l}^l f(x)dx+\frac{1}{l}\sum_1^\infty \cos\frac{n\pi x}{l}\int_{-l}^l f(x)\cos\frac{n\pi x}{l}dx$$
$$+\frac{1}{l}\sum_1^\infty \sin\frac{n\pi x}{l}\int_{-l}^l f(x)\sin\frac{n\pi x}{l}dx,$$

which may be written

$$\frac{1}{2l}\int_{-l}^l f(x^1)dx^1+\frac{1}{l}\sum_1^\infty\int_{-l}^l f(x^1)\cos\frac{n\pi(x-x^1)}{l}dx^1 \quad . \quad . \quad (3)$$

The series, (3) which represents a function $f(x)$ arbitrarily given for the interval $-l$ to l, is what is known as Fourier's Series, the expressions (1) and (2) being regarded as the particular forms which (3) takes in the two cases, in which $f(-x)=-f(x)$, or $f(-x)=f(x)$ respectively. The expression (3) does not represent $f(x)$ at points beyond the interval $-l$ to l, unless $f(x)$ has a period $2l$. For a value of x within the interval, at which $f(x)$ is discontinuous, the sum of the series may cease to represent $f(x)$, but as will be seen hereafter, has the value $\frac{1}{2}\{f(x+0)+f(x-0)\}$, the mean of the limits at the point on the right and the left. The series represents the function at $x=0$, unless the function is then discontinuous, in which case the series is $\frac{1}{2}\{f(+0)+f(-0)\}$; the series does not necessarily represent the function at the points l and $-l$, unless $f(l)=f(-l)$, its sum at either of these points, is $\frac{1}{2}\{f(l)+f(-l)\}$.

Examples of Fourier's Series.—(*a*) Let $f(x)$ be given from 0 to l, by $f(x)=c$, when $0\leq x<\frac{1}{2}l$, and by $f(x)=-c$ from $\frac{1}{2}l$ to l; it is required to find a sine series, and also a cosine series, which shall represent the function in the interval.

We have

$$\int_0^l f(x)\sin\frac{n\pi x}{l}dx=c\int_0^{\frac{1}{2}l}\sin\frac{n\pi x}{l}dx-c\int_{\frac{1}{2}l}^l \sin\frac{n\pi x}{l}dx$$
$$=\frac{cl}{n\pi}(\cos n\pi-2\cos\tfrac{1}{2}n\pi+1).$$

This vanishes if n is odd, and if $n=4m$, but if $n=4m+2$ is equal to $\frac{4cl}{n\pi}$, the series is therefore

$$\frac{4c}{\pi}\left(\frac{1}{2}\sin\frac{2\pi x}{l}+\frac{1}{3}\sin\frac{6\pi x}{l}+\frac{1}{5}\sin\frac{10\pi x}{l}+\ .\ .\ .\right).$$

For unrestricted values of x, this series represents the ordinates of the series of straight lines in Fig. 1, except that it vanishes at the points 0, $\frac{1}{2}l$, l, $\frac{3}{2}l$ . . .

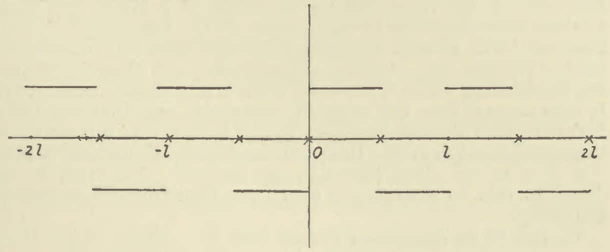

Fig. 1.

We find similarly that the same function is represented by the series

$$\frac{4c}{\pi}\left(\cos\frac{\pi x}{l}-\frac{1}{3}\cos\frac{3\pi x}{l}+\frac{1}{5}\cos\frac{5\pi x}{l}-+\ .\ .\ .\right)$$

during the interval 0 to l; for general values of x the series represents the ordinate of the broken line in Fig. 2, except that it vanishes at the points $\frac{1}{2}l$, $\frac{3}{2}l$ . . .

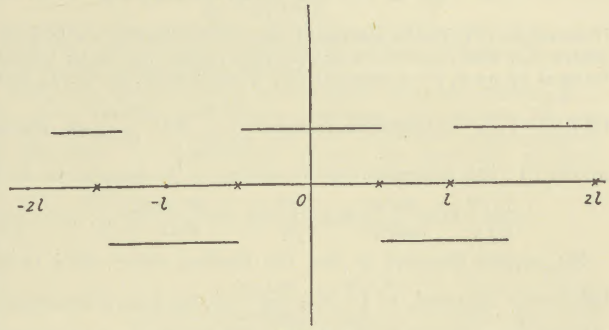

Fig. 2.

(*b*) Let $f(x)=x$ from 0 to $\frac{1}{2}l$, and $f(x)=l-x$, from $\frac{1}{2}l$ to l; then

$$\int_0^l f(x)\sin\frac{n\pi x}{l}dx=\int_0^{\frac{1}{2}l}x\sin\frac{n\pi x}{l}dx+\int_{\frac{1}{2}l}^l(l-x)\sin\frac{n\pi x}{l}dx$$
$$=-\frac{l^2}{2n\pi}\cos\frac{n\pi}{2}+\frac{l^2}{n^2\pi^2}\sin\frac{n\pi}{2}+\frac{l^2}{n\pi}\left(\cos\frac{n\pi}{2}-\cos n\pi\right)$$
$$+\frac{l^2}{n\pi}\cos n\pi-\frac{l^2}{2n\pi}\cos\frac{n\pi}{2}+\frac{l^2}{n^2\pi^2}\sin\frac{n\pi}{2}=\frac{2l^2}{n^2\pi^2}\sin\frac{n\pi}{2}$$

hence the sine series is

$$\frac{4l}{\pi^2}\left(\sin\frac{nx}{l}-\frac{1}{3^2}\sin\frac{3\pi x}{l}+\frac{1}{5^2}\sin\frac{5\pi x}{l}-\ .\ .\ .\right)$$

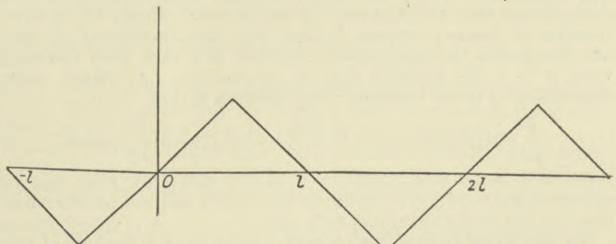

Fig. 3

For general values of x, the series represents the ordinate of the row of broken lines in Fig. 3.

The cosine series, which represents the same function for the interval 0 to l, may be found to be

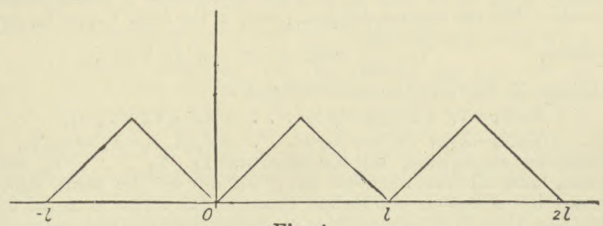

Fig. 4.

$$\frac{1}{4}l-\frac{2l}{\pi^2}\left(\cos\frac{2\pi x}{l}+\frac{1}{3^2}\cos\frac{6\pi x}{l}+\frac{1}{5^2}\cos\frac{10\pi x}{l}+\ .\ .\ .\right)$$

*

This series represents for general values of x the ordinate of the set of broken lines in Fig. 4.

Dirichlet's Integral.—The method indicated by Fourier, but first carried out rigorously by Dirichlet, of proving that with certain restrictions as to the nature of the function $f(x)$, that function is in general represented by the series (3), consists in finding the sum of $n+1$ terms of that series, and then investigating the limiting value of the sum, when n is increased indefinitely. It thus appears that the series is convergent, and that the value towards which its sum converges is $\frac{1}{2}\{f(x+0)+f(x-0)\}$, which is in general equal to $f(x)$. It will be convenient throughout to take $-\pi$ to π as the given interval; any interval $-l$ to l may be reduced to this by changing x into lx/π, thus there is no loss of generality.

We find by an elementary process that

$$\tfrac{1}{2}+\cos(x-x^1)+\cos 2(x-x^1)+\ .\ .\ .\ +\cos n(x-x^1)$$
$$=\frac{\sin\frac{2n+1}{2}(x^1-x)}{2\sin\frac{1}{2}(x^1-x)}$$

hence, with the new notation, the sum of the first $n+1$ terms of (3) is

$$\frac{1}{\pi}\int_{-\pi}^{\pi} f(x^1)\frac{\sin\frac{2n+1}{2}(x^1-x)}{2\sin\frac{1}{2}(x^1-x)}dx^1;$$

if we suppose $f(x)$ to be continued beyond the interval $-\pi$ to π, in such a way that $f(x)=f(x+2\pi)$, we may replace the limits in this integral by $x+\pi$, $x-\pi$ respectively; if we then put $x^1-x=2z$, and let $f(x^1)=\mathrm{F}(z)$, the expression becomes $\frac{1}{\pi}\int_{-\frac{\pi}{2}}^{\frac{\pi}{2}}\mathrm{F}(z)\frac{\sin mz}{\sin z}dz$, where $m=2n+1$; this expression may be written in the form

$$\frac{1}{\pi}\int_0^{\frac{\pi}{2}}\mathrm{F}(z)\frac{\sin mz}{\sin z}dz+\frac{1}{\pi}\int_0^{\frac{\pi}{2}}\mathrm{F}(-z)\frac{\sin mz}{\sin z}dz\ .\ .\ . \qquad (4)$$

We require therefore to find the limiting value, when m is indefinitely increased, of $\int_0^{\frac{\pi}{2}}\mathrm{F}(z)\frac{\sin mz}{\sin z}dz$, the form of the second integral being essentially the same. This integral, or rather the slightly more general one $\int_0^h\mathrm{F}(z)\frac{\sin mz}{\sin z}dz$, when $0<h\leqq\frac{1}{2}\pi$, is known as Dirichlet's integral. If we write $\mathrm{X}(z)=\mathrm{F}(z)\frac{z}{\sin z}$, the integral becomes $\int_0^h\mathrm{X}(z)\frac{\sin mz}{z}dz$, which is the form in which the integral is frequently considered.

The Second Mean-Value Theorem.—The limiting value of Dirichlet's integral may be conveniently investigated by means of a theorem in the integral calculus known as the second mean-value theorem. Let a, b be two fixed finite numbers such that $a<b$, and suppose $f(x)$, $\phi(x)$ are two functions which have finite and determinate values everywhere in the interval except for a finite number of points; suppose further that the functions $f(x)$, $\phi(x)$ are integrable throughout the interval, and that as x increases from a to b the function $f(x)$ is monotonous, *i.e.*, either never diminishes or never increases; the theorem is that

$$\int_a^b f(x)\phi(x)dx=f(a+0)\int_a^\xi\phi(x)dx+f(b-0)\int_\xi^b\phi(x)dx$$

when ξ is some point between a and b, and $f(a)$, $f(b)$ may be written for $f(a+0)$, $f(b-0)$ unless a or b is a point of indetermination for one of the functions $f(x)$, $\phi(x)$.

To prove this theorem, we observe that since the product of two integrable functions is an integrable function, $\int_a^b f(x)\phi(x)dx$ exists, and may be regarded as the limit of the sum of a series

$$f(x_0)\phi(x_0)(x_1-x_0)+f(x_1)\phi(x_1)(x_2-x_1)+\ldots+f(x_{n-1})\phi(x_{n-1})(x_n-x_{n-1})$$

where $x_0=a$, $x_n=b$, and $x_1, x_2\ .\ .\ .\ x_{n-1}$ are $n-1$ intermediate points. We can express $\phi(x_r)(x_{r+1}-x_r)$ in the form $\mathrm{Y}_{r+1}-\mathrm{Y}_r$, by putting

$$\mathrm{Y}_r=\sum_{\mathrm{K}=1}^{\mathrm{K}=r}\phi(x_{\mathrm{K}-1})(x_{\mathrm{K}}-x_{\mathrm{K}-1}),\ \mathrm{Y}_0=0.$$

Writing X_r for $f(x_r)$, the series becomes

$$\mathrm{X}_0(\mathrm{Y}_1-\mathrm{Y}_0)+\mathrm{X}_1(\mathrm{Y}_2-\mathrm{Y}_1)+\ .\ .\ .\ +\mathrm{X}_{n-1}(\mathrm{Y}_n-\mathrm{Y}_{n-1})$$

or $\mathrm{Y}_1(\mathrm{X}_0-\mathrm{X}_1)+\mathrm{Y}_2(\mathrm{X}_1-\mathrm{X}_2)+\ .\ .\ .\ +\mathrm{Y}_n(\mathrm{X}_{n-1}-\mathrm{X}_n)+\mathrm{Y}_n\mathrm{X}_n$.

Now, by supposition, all the numbers $\mathrm{Y}_1, \mathrm{Y}_2\ .\ .\ .\ \mathrm{Y}_n$ are finite, and all the numbers $\mathrm{X}_{r-1}-\mathrm{X}_r$ are of the same sign, hence by a known algebraical theorem the series is equal to $\mathrm{M}(\mathrm{X}_0-\mathrm{X}_n)+\mathrm{Y}_n\mathrm{X}_n$ where M is a number intermediate between the greatest and the least of the numbers $\mathrm{Y}_1, \mathrm{Y}_2, .\ .\ .\ \mathrm{Y}_n$. This remains true however many partial intervals are taken, and therefore when their number is increased indefinitely, and their breadths are diminished indefinitely according to any law, hence we have

$$\int_a^b f(x)\phi(x)dx=\{f(a)-f(b)\}\overline{\mathrm{M}}+f(b)\int_a^b\phi(x)dx$$

when $\overline{\mathrm{M}}$ is intermediate between the greatest and least values which $\int_a^x\phi(x)dx$ can have, when x is in the given interval. Now this integral is a continuous function of its upper limit x, and therefore there is a value of x in the interval, for which it takes any particular value between the greatest and least values that it has. There is therefore a value ξ between a and b, such that $\overline{\mathrm{M}}=\int_a^\xi\phi(x)dx$, hence

$$\int_a^b f(x)\phi(x)dx=\{f(a)-f(b)\}\int_a^\xi\phi(x)dx+f(b)\int_a^b\phi(x)dx)$$
$$=f(a)\int_a^\xi\phi(x)dx+f(b)\int_\xi^b\phi(x)dx.$$

If the interval contains any finite numbers of points of discontinuity of $f(x)$ or $\phi(x)$, the method of proof still holds good, provided these points are avoided in making the subdivisions; in particular if either of the ends be a point of discontinuity of $f(x)$, we write $f(a+0)$ or $f(b-0)$, for $f(a)$ or $f(b)$, it being assumed that these limits exist.

Functions, with Restricted Oscillation.—The condition that $f(x)$, in the mean-value theorem, either never increases or never diminishes as x increases from a to b, places a restriction upon the applications of the theorem. We can however show that a function $f(x)$ which is finite and continuous between a and b, except for a finite number of ordinary discontinuities, and which only changes from increasing to diminishing or *vice versâ*, a finite number of times, as x increases from a to b, may be expressed as the difference of two functions $f_1(x)$, $f_2(x)$, neither of which ever diminishes as x passes from a to b, and that these functions are finite and continuous, except that one or both of them are discontinuous at the points where the given function is discontinuous. Let α, β be two consecutive points at which $f(x)$ is discontinuous, consider any point x_1, such that $\alpha\leqq x_1\leqq\beta$, and suppose that at the points $\mathrm{M}_1, \mathrm{M}_2\ .\ .\ .\ \mathrm{M}_r$ between α and x_1, $f(x)$ is a maximum, and at $m_1, m_2\ .\ .\ .\ m_r$ it is a minimum; we will suppose, for example, that the ascending order of values is $\alpha, \mathrm{M}_1, m_1, \mathrm{M}_2, m_2\ .\ .\ .\ \mathrm{M}_r, m_r, x_1$; it will make no essential difference in the argument if m_1 comes before M_1, or if M_r immediately precedes x_1, m_r, being then the last minimum.

Let $\psi(x_1)=\{f(\mathrm{M}_1)-f(\alpha+0)\}+[f(\mathrm{M}_2)-f(m_1)]+\ .\ .\ .$
$+[f(\mathrm{M}_r)-f(m_{r-1})]+[f(x_1)-f(m_r)]$;

now let x_1 increase until it reaches the value M_{r+1} at which $f(x)$ is again a maximum, then let

$$\psi(x_1)=\{f(\mathrm{M}_1)-f(\alpha+0)\}+[f(\mathrm{M}_2)-f(m_1)]+\ .\ .\ .\ +[f(\mathrm{M}_r)-f(m_{r-1})]+[f(\mathrm{M}_{r+1})-f(m_r)];$$

and suppose as x increases beyond the value M_{r+1}, $\psi(x_1)$ remains constant until the next minimum m_{r+1} is reached, when it again becomes variable; we see that $\psi(x_1)$ is essentially positive and never diminishes as x increases.

Let

$$\chi(x_1)=[f(\mathrm{M}_1)-f(m_1)]+[f(\mathrm{M}_2)-f(m_1)]+\ .\ .\ .\ +[f(\mathrm{M}_r)-f(m_r)],$$

then let x_1 increase until it is beyond the next maximum M_{r+1}, and then let $\chi(x_1)=[f(\mathrm{M}_1)-f(m_1)]+[f(\mathrm{M}_2)-f(m_1)]+\ .\ .\ .$
$+[f(\mathrm{M}_r)-f(m_r)]+[f(\mathrm{M}_{r+1})-f(x_1)]$

thus $\chi(x_1)$ never diminishes, and is alternately constant and variable. We see that $\psi(x_1)-\chi(x_1)$ is continuous as x increases from α to β, and that $\psi(x_1)-\chi(x_1)=f(x_1)-f(\alpha+0)$ and when x_1 reaches β, we have $\psi(\beta)-\chi(x_1)=f(\beta-0)-f(\alpha+0)$. Hence it is seen that between α and β, $f(x)=[\psi(x)+f(\alpha+0)]-\chi(x)$, where $\psi(x)+f(\alpha+0)$, $\chi(x)$ are continuous and never diminish as x increases; the same reasoning applies to every continuous portion of $f(x)$, for which the functions $\psi(x)$, $\chi(x)$ are formed in the same manner; we now take $f_1(x)=\psi(x)+f(\alpha+0)+\mathrm{C}$, $f_2(x)=\chi(x)+\mathrm{C}$, where C is constant between consecutive discontinuities, but may have different values in the next interval between discontinuities; the C can be so chosen that neither $f_1(x)$ nor $f_2(x)$ diminishes as x increases through a value for which $f(x)$ is discontinuous. We thus see that $f(x)=f_1(x)-f_2(x)$, where $f_1(x)$, $f_2(x)$ never diminish as x increases from a to b, and are discontinuous only where $f(x)$ is so. The function $f(x)$ is a particular case of a class of functions defined and discussed by Jordan, under the name "functions with restricted oscillation" (*fonctions à variation bornée*); in general such functions have not necessarily only a finite number of maxima and minima.

Proof of the Convergence of Fourier's Series.—It will now be assumed that a function $f(x)$ arbitrarily given between the values $-\pi$ and $+\pi$, has the following properties:—

(*a*) The function is everywhere finite, and continuous except for a finite number of values of the variable, for which it may be ordinarily discontinuous.

(*b*) The function only changes from increasing to diminishing or *vice versâ*, a finite number of times within the interval; this is usually expressed by saying that the number of maxima and minima is finite.

These limitations on the nature of the function are known as Dirichlet's conditions; it follows from them that the function is integrable throughout the interval.

On these assumptions, we can investigate the limiting value of Dirichlet's integral; it will be necessary to consider only the case of a function $F(z)$ which does not diminish as z increases from 0 to $\frac{1}{2}\pi$, since it has been shown that in the general case the difference of two such functions may be taken. The following lemmas will be required:—

(1) Since

$$\int_0^{\frac{\pi}{2}}\frac{\sin mz}{\sin z}dz=\int_0^{\frac{\pi}{2}}\{1+2\cos 2z+2\cos 4z+\ .\ .\ .\ +2\cos 2nz\}dz=\frac{\pi}{2};$$

this result holds however large the odd integer m may be.

(2) If $0<\alpha<\beta\leqq\frac{\pi}{2}$,

$$\int_\alpha^\beta \frac{\sin mz}{\sin z}dz=\frac{1}{\sin\alpha}\int_\alpha^\gamma \sin mz\,dz+\frac{1}{\sin\beta}\int_\gamma^\beta\sin mz\,dz$$

where $\alpha<\gamma<\beta$, hence

$$\left|\int_\alpha^\beta\frac{\sin mz}{\sin z}dz\right|<\frac{2}{m}\left(\frac{1}{\sin\alpha}+\frac{1}{\sin\beta}\right)<\frac{4}{m\sin\alpha};$$

a precisely similar proof shows that $\left|\int_\alpha^\beta\frac{\sin mz}{z}dz\right|<\frac{4}{m\alpha}$,

hence the integrals $\int_\alpha^\beta\frac{\sin mz}{\sin z}dz$, $\int_\alpha^\beta\frac{\sin mz}{z}dz$, converge to the limit zero, as m is indefinitely increased.

(3) If $\alpha>0$, $\left|\int_\alpha^\infty\frac{\sin\theta}{\theta}d\theta\right|$ cannot exceed $\frac{1}{2}\pi$. For by the mean-value theorem $\left|\int_\alpha^h\frac{\sin\theta}{\theta}d\theta\right|<\frac{2}{\alpha}+\frac{2}{h}$,

hence $\left|L_{h=\infty}\int_\alpha^h\frac{\sin\theta}{\theta}d\theta\right|<\frac{2}{\alpha}$;

in particular if $\alpha\geqq\pi$ $\left|\int_\alpha^\infty\frac{\sin\theta}{\theta}d\theta\right|<\frac{2}{\pi}$.

Again $\frac{d}{d\alpha}\int_\alpha^\infty\frac{\sin\theta}{\theta}d\theta=-\frac{\sin\alpha}{\alpha}$, $\alpha>0$,

therefore $\int_\alpha^\infty\frac{\sin\theta}{\theta}d\theta$ increases as α diminishes, when $0<\alpha<\pi$;

but $L_{\alpha=0}\int_\alpha^\infty\frac{\sin\theta}{\theta}d\theta=\frac{\pi}{2}$, hence $\left|\int_\alpha^\infty\frac{\sin\theta}{\theta}d\theta\right|<\frac{\pi}{2}$,

where $\alpha<\pi$, and $<\frac{2}{\pi}$ where $\alpha\geqq\pi$.

To find the limit of $\int_0^{\frac{\pi}{2}}F(z)\frac{\sin mz}{\sin z}dz$, we observe that it may be written in the form

$$F(0)\int_0^{\frac{\pi}{2}}\frac{\sin mz}{\sin z}dz+\int_0^\mu\{F(z)-F(0)\}\frac{\sin mz}{\sin z}dz+\int_\mu^{\frac{\pi}{2}}\{F(z)-F(0)\}\frac{\sin mz}{\sin z}dz$$

where μ is a fixed number as small as we please, hence if we use lemma (1), and apply the second mean-value theorem,

$$\int_0^{\frac{\pi}{2}}F(z)\frac{\sin mz}{\sin z}dz-\frac{\pi}{2}F(0)$$

$$=\int_0^\mu\{F(z)-F(0)\}\frac{z}{\sin z}\frac{\sin mz}{z}dz$$

$$+\{F(\mu)-F(0)\}\int_\mu^{\xi^1}\frac{\sin mz}{\sin z}dz+\left\{F\left(\frac{\pi}{2}\right)-F(0)\right\}\int_{\xi^1}^{\frac{\pi}{2}}\frac{\sin mz}{\sin z}dz$$

when ξ^1 lies between μ and $\frac{1}{2}\pi$. When m is indefinitely increased, the two last integrals have a zero limit in virtue of lemma (2). To evaluate the first integral on the right-hand side, let $G(z)=\{F(z)-F(0)\}\frac{z}{\sin z}$, and observe that $G(z)$ increases as z increases from 0 to μ, hence if we apply the mean-value theorem

$$\int_0^\mu G(z)\frac{\sin mz}{z}dz=G(\mu)\int_\xi^\mu\frac{\sin mz}{z}dz$$

$$=G(\mu)\int_{m\xi}^{m\mu}\frac{\sin\theta}{\theta}d\theta$$

where $0<\xi<\mu$, since $G(z)$ has a zero limit when $z=0$. It has been shown by Kronecker that ξ cannot be zero.

As m increases ξ varies, being dependent on m and on the nature of $G(z)$, and it may happen that as m is increased indefinitely, ξ may be indefinitely diminished; if this is not the case the limit of $\int_\xi^\mu\frac{\sin mz}{z}dz$ is zero. If however $m\xi$ has a finite limit α, we see by virtue of lemma (3) that the limit of the integral does not exceed $\frac{\pi}{2}G(\mu)$. The fixed quantity μ may be chosen so small that $\left|\frac{\pi}{2}G(z)\right|<\delta$, if $0<z\leqq\mu$, where δ is any prescribed quantity as small as we please. It has now been shown that when m is indefinitely increased $\int_0^{\frac{\pi}{2}}F(z)\frac{\sin mz}{\sin z}dz-\frac{\pi}{2}F(0)$ has a zero limit.

Returning to the form (4), we now see that the limiting value of

$\frac{1}{\pi}\int_0^{\frac{\pi}{2}}F(z)\frac{\sin mz}{\sin z}dz+\frac{1}{\pi}\int_0^{\frac{\pi}{2}}F(-z)\frac{\sin mz}{\sin z}dz$ is $\frac{1}{2}\{F(+0)+F(-0)\}$,

hence the sum of $n+1$ terms of the series

$$\frac{1}{2l}\int_{-l}^{l}f(x)dx+\frac{1}{l}\sum\int_{-l}^{l}f(x^1)\cos\frac{n\pi(x-x^1)}{l}dx$$

converges to the value $\frac{1}{2}\{f(x+0)+f(x-0)\}$, or to $f(x)$ at a point where $f(x)$ is continuous, provided $f(x)$ satisfies Dirichlet's conditions for the interval from $-l$ to l.

Proof that Fourier's Series is in General Uniformly Convergent.—To prove that Fourier's Series converges uniformly to its sum for all values of x, provided that the immediate neighbourhoods of the points of discontinuity of $f(x)$ are excluded, we have from the above,

$$\left|\int_0^{\frac{\pi}{2}}F(z)\frac{\sin mz}{\sin z}dz-\frac{\pi}{2}F(0)\right|<\frac{\pi}{2}G(\mu)+\frac{4}{m\sin\mu}\{F(\mu)-F(0)\}$$

$$+\frac{4}{m\sin\xi^1}\left\{F\left(\frac{\pi}{2}\right)-F(0)\right\}$$

$$<\frac{\pi}{2}\frac{\mu}{\sin\mu}\{f(x+2\mu)-f(x)\}+\frac{4}{m\sin\mu}\{f(x+2\mu)-f(x)\}$$

$$+\frac{4}{m\sin\xi^1}\{f(x+\pi)-f(x)\}.$$

Now as x is excluded from certain portions of the interval in the neighbourhood of discontinuities of $f(x)$, μ may be chosen so small that for every value of x, $\frac{\mu}{\sin\mu}\{f(x+2\mu)-f(x)\}<\epsilon$ where ϵ is an arbitrarily small fixed number; also $f(x+\pi)-f(x)$ is never greater than some fixed finite number A, therefore a value of m can be found such that if m equals or exceeds this value,

$\left|\int_0^{\frac{\pi}{2}}F(z)\frac{\sin mz}{\sin z}dz-\frac{\pi}{2}F(0)\right|<\epsilon^1$, for all values of x considered,

when ϵ^1 is a fixed arbitrarily small number. If x had been allowed to approach very closely a point of discontinuity, a smaller value of μ would have had to be chosen, so that $\frac{\mu}{\sin\mu}\{f(x+2\mu)-f(x)\}<\epsilon$, thus μ would have to be continually diminished for this inequality to hold, and the argument would fail; thus the convergence is not uniform if x is allowed to move right up to a discontinuity.

Case of a Function with Infinities.—The limitation that $f(x)$ must be finite throughout the interval may, under a certain restriction, be removed. Suppose $F(z)$ is infinite at the point $z=e$, and is such that the limits of the two integrals $\int_c^{c\pm\epsilon}F(z)dz$ are both zero, as ϵ is indefinitely diminished, then

$\int_0^{\frac{\pi}{2}}F(z)\frac{\sin mz}{\sin z}dz$ denotes the limit when $\epsilon=0$, $\epsilon^1=0$ of

$\int_0^{c-\epsilon}F(z)\frac{\sin mz}{\sin z}dz+\int_{c+\epsilon^1}^{\frac{\pi}{2}}F(z)\frac{\sin mz}{\sin z}dz$, both these limits existing;

the first of these integrals has $\frac{\pi}{2}F(+0)$ for its limiting value when m is indefinitely increased, and the second has zero for its limit. The theorem therefore holds if $F(z)$ has an infinity up to which it is integrable; this will, for example, be the case if $F(z)$ near the point C is of the form $\chi(z)(z-e)^{-\mu}+\psi(z)$, where $\chi(e)$, $\psi(e)$ are finite, and $0<\mu<1$. It is thus seen that $f(x)$ may have a finite number of infinities within the given interval, provided the function is integrable through any one of these points; the function is in that case still representable by Fourier's Series.

The Ultimate Values of the Coefficients in Fourier's Series.—If $f(x)$ is everywhere finite within the given interval $-\pi$ to $+\pi$, it can be shown that a_n, b_n, the coefficients of $\cos nx$, $\sin nx$ in the series which represent the function, are such that na_n, nb_n, however great n is, are each less than a fixed finite quantity. For writing $f(x)=f_1(x)-f_2(x)$, we have

$$\int_{-\pi}^{\pi} f_1(x)\cos nxdx = f_1(-\pi+0)\int_{-\pi}^{\xi}\cos nxdx + f_1(\pi-0)\int_{\xi}^{\pi}\cos nxdx$$

hence

$$\int_{-\pi}^{\pi} f_1(x)\cos nxdx = f_1(-\pi+0)\frac{\sin n\xi}{n} + f_1(\pi-0)\frac{\sin n\xi}{n}$$

with a similar expression, with $f_2(x)$ for $f_1(x)$, ξ being between π and $-\pi$; the result then follows at once, and is obtained similarly for the other coefficient.

If $f(x)$ is infinite at $x=c$, and is of the form $\frac{\phi(x)}{(x-c)^K}$ near the point c, where $0<K<1$, the integral $\int_{-\pi}^{\pi} f(x)\cos nx\,dx$, contains portions of the form $\int_c^{c+\epsilon}\frac{\phi(x)}{(x-c)^K}\cos nxdx$ $\int_{c-\epsilon}^{c}\frac{\phi(x)}{(x-c)^K}\cos nxdx$; consider the first of these, and put $x=c+u$, it thus becomes $\int_0^{\epsilon}\frac{\phi(c+u)}{u^K}\cos n(c+u)du$, which is of the form $\phi(c+\theta\epsilon)\int_0^{\epsilon}\frac{\cos n(c+u)}{u^K}du$; now let $nu=v$, the integral becomes

$$\phi(c+\theta\epsilon)\left\{\frac{\cos nc}{n^{1-K}}\int_0^{n\epsilon}\frac{\cos v}{v^K}dv - \frac{\sin nc}{n^{1-K}}\int_0^{n\epsilon}\frac{\sin v}{v^K}dv\right\};$$

hence $n^{1-K}\int_{-\pi}^{\pi} f(x)\cos nxdx$ becomes, as n is indefinitely increased of the form $\phi(c)\left\{\cos nc\int_0^{\infty}\frac{\cos v}{v^K}dv - \sin nc\int_0^{\infty}\frac{\sin v}{v^K}dv\right\}$ which is finite, both the integrals being convergent and of known value. The other integral has a similar property, and we infer that $n^{1-K}a_n$, $n^{1-K}b_n$ are less than fixed finite quantities.

The Differentiation of Fourier's Series.—If we assume that the differential coefficient of a function $f(x)$ represented by a Fourier's Series exists, that function $f'(x)$ is not necessarily representable by the series obtained by differentiating the terms of the Fourier's Series, such derived series being in fact not necessarily convergent. Stokes has obtained general formulæ for finding the series which represent $f'(x)$, $f''(x)$—the successive differential coefficients of an everywhere finite function $f(x)$. As an example of such formulæ, consider the sine series (1); $f(x)$ is represented by

$$\frac{2}{l}\sum \sin\frac{n\pi x}{l}\int_0^l f(x)\sin\frac{n\pi x}{l}dx;$$

on integration by parts we have $\int_0^l f(x)\sin\frac{n\pi x}{l}dx$

$$=\frac{l}{n\pi}\left[f(+0)\pm f(l-0)+\sum\cos\frac{n\pi a}{l}\{f(a+0)-f(a-0)\}\right]$$
$$+\frac{l}{n\pi}\int_0^l f'(x)\cos\frac{n\pi x}{l}dx$$

where a represent the points where $f(x)$ is discontinuous, hence if $f(x)$ is represented by the series $\sum a_n\sin\frac{n\pi x}{l}$, and $f'(x)$ by the series $\sum b_n\cos\frac{n\pi x}{l}$, we have the relation

$$b_n=\frac{n\pi}{l}a_n-\frac{2}{l}\left[f(+0)\pm f(l-0)+\sum\cos\frac{n\pi a}{l}\{f(a+0)-f(a-0)\}\right]$$

hence only when the function is everywhere continuous, and $f(+0)$, $f(l-0)$ are both zero, is the series which represents $f'(x)$ obtained at once by differentiating that which represents $f(x)$. The form of the coefficient a_n discloses the discontinuities of the function and of its differential coefficients, for on continuing the integration by parts we find

$$a_n=\frac{2}{n\pi}\left[f(+0)\pm f(l-0)+\sum\cos\frac{n\pi a}{l}\{f(a+0)-f(a-0)\}\right]$$
$$+\frac{2l}{n^2\pi^2}\left[f'(+0)\pm f'(l-0)+\sum\sin\frac{n\pi\beta}{l}\{f'(\beta+0)-f'(\beta-0)\}\right]+\&c.$$

where β are the points at which $f'(x)$ is discontinuous.

History and Literature of the Theory.

The history of the theory of the representation of functions by series of sines and cosines is of great interest in connexion with the progressive development of the notion of an arbitrary function of a real variable, and of the peculiarities which such a function may possess; the modern views on the foundations of the infinitesimal calculus have been to a very considerable extent formed in this connexion. [See Functions of a Real Variable.] The representation of functions by these series was first considered in the 18th century, in connexion with the problem of a vibrating cord, and led to a controversy as to the possibility of such expansions. In a memoir published in 1747 (*Memoirs of the Academy of Berlin*, vol. iii.) D'Alembert showed that the ordinate y at any time t of a vibrating cord satisfies a differential equation of the form $\frac{\delta^2 y}{\delta t^2}=a^2\frac{\delta^2 y}{\delta x^2}$, where x is measured along the undisturbed length of the cord, and that with the ends of the cord of length l fixed, the appropriate solution is $y=f(at+x)-f(at-x)$, where f is a function such that $f(x)=f(x+2l)$; in another memoir in the same volume he seeks for functions which satisfy this condition. In the year 1748 (*Berlin Memoirs*, vol. iv.) Euler, in discussing the problem, gave $f(x)=a\sin\frac{\pi x}{l}+\beta\sin\frac{2\pi x}{l}+\ldots$ as a particular solution, and maintained that every curve, whether regular or irregular, must be representable in this form. This was objected to by D'Alembert (1750) and also by Lagrange on the ground that irregular curves are inadmissible. D. Bernoulli (*Berlin Memoirs*, vol. ix., 1753) based a similar result to that of Euler, on physical intuition; his method was criticized by Euler (1753). The question was then considered from a new point of view by Lagrange, in a memoir on the nature and propagation of sound (*Miscellanea Taurensia*, 1759; Œuvres, vol. i.), who, while criticizing Euler's method, considers a finite number of vibrating particles, and then makes the number of them infinite; he did not, however, quite fully carry out the determination of the coefficients in Bernoulli's Series. These mathematicians were hampered by the narrow conception of a function, in which it is regarded as necessarily continuous; a discontinuous function was considered only as a succession of several different functions. Thus the possibility of the expansion of a broken function was not generally admitted. The first cases in which rational functions are expressed in sines and cosines were given by Euler (*Subsidium Calculi Sinuum*, Novi Comm. Petrop., vol. v., 1754–55) who obtained the formulæ

$$\tfrac{1}{2}\phi=\sin\phi-\tfrac{1}{2}\sin 2\phi+\tfrac{1}{3}\sin 3\phi\ldots$$
$$\frac{\pi^2}{12}-\frac{\phi^2}{4}=\cos\phi-\tfrac{1}{4}\cos 2\phi+\tfrac{1}{9}\cos 3\phi\ldots$$

In a memoir presented to the Academy of St Petersburg in 1777, but not published until 1798, Euler gave the method afterwards used by Fourier, of determining the coefficients in the expansions; he remarked that if Φ is expansible in the form $A+B\cos\phi+C\cos 2\phi+\ldots$, then $A=\frac{1}{\pi}\int_0^{\pi}\Phi d\phi$, $B=\frac{2}{\pi}\int_0^{\pi}\Phi\cos\phi d\phi$, &c.

The second period in the development of the theory commenced in 1807, when Fourier communicated his first memoir on the Theory of Heat to the French Academy. His exposition of the present theory is contained in a memoir sent to the Academy in 1811, of which his great treatise the *Théorie Analytique de la Chaleur*, published in 1822, is, in the main, a reproduction. Fourier set himself to consider the representation of a function given graphically, and was the first fully to grasp the idea that a single function may consist of detached portions given arbitrarily by a graph. He had an accurate conception of the convergence of a series, and although he did not give a formally complete proof that a function with discontinuities is representable by the series, he indicated in particular cases the method of procedure afterwards carried out by Dirichlet. As an exposition of principles, Fourier's work is still worthy of careful perusal by all students of the subject. Poisson's treatment of the subject, which is still adopted in English works (see the *Journal de l'école Polytechnique*, vol. xi., 1820, and vol. xii., 1823, and also his treatise, *Théorie de la Chaleur*, 1835), depends upon the equality $\int_{-\pi}^{\pi} f(a)\frac{1-h^2}{1-2h\cos(x-a)+h^2}da$

$$=\frac{1}{2\pi}\int_{-\pi}^{\pi} f(a)da+\frac{1}{\pi}\sum h^n\int_{-\pi}^{\pi} f(a)\cos n(x-a)da$$

where $o<h<1$; the limit of the integral on the left-hand side is evaluated when $h=1$, and found to be $\frac{1}{2}\{f(x+0)+f(x-0)\}$, the series on the right-hand side becoming Fourier's Series. The equality of the two limits is then inferred. If the series is assumed to be convergent when $h=1$, by a theorem of Abel's its sum is continuous with the sum for values of h less than unity, but a proof of the convergency for $h=1$ is requisite for the validity of Poisson's proof; as Poisson gave no such proof of convergency, his proof of the general theorem cannot be accepted. The deficiency cannot be removed except by a process of the same nature as that afterwards applied by Dirichlet. The definite integral has been carefully studied by Schwarz (see two memoirs in his collected works on the Integration of the equation $\frac{\delta^2 u}{\delta x^2}+\frac{\delta^2 u}{\delta y^2}=0$), who showed that the limiting value of the integral depends upon the manner in which the limit is approached. Investigations of Fourier's Series were also given by Cauchy (see his "Mémoire sur les développements des fonctions en séries périodiques," *Mem. de l'Inst.*, vol. vi., also *Œuvres complètes*, vol. vii.); his method, which depends upon a use of complex variables, was accepted, with some modification, as valid by Riemann, but one at least of his proofs is no longer regarded as satisfactory. The first completely satisfactory investigation is due to Dirichlet; his first memoir appeared in *Crelle's Journal* for 1829, and the second, which is a model of clearness, in Dove's *Repertorium der Physik*. Dirichlet laid down certain definite sufficient conditions in regard to the nature of a function which is expansible, and found under these conditions the limiting value of the sum of n terms of the series. Dirichlet's determination of the sum of the series at a point of discontinuity has been criticized by Schläfli (see *Crelle's Journal*, vol. lxxii.) and by Du Bois-Reymond (*Mathm. Annalen*, vol. vii.), who maintained that the sum is really indeterminate. Their objection appears, however, to rest upon a misapprehension as to the meaning of the sum of the series; if x_1 be the point of discontinuity, it is possible to make x approach x_1, and n become indefinitely great, so that the sum of the series takes any assigned value between the two values $f(x_1+0)$, $f(x_1-0)$, whereas we ought to make $x=x_1$ first and afterwards $n=\infty$, and no other way of going to the double limit is really admissible. Other papers by Dircksen (*Crelle*, vol. iv.) and Bessel (*Astronomische Nachrichten*, vol. xvi.), on similar lines to those by Dirichlet, are of inferior importance. Many of the investigations subsequent to Dirichlet's have the object of freeing a function from some of the restrictions which were imposed upon it in Dirichlet's proof, but no complete set of necessary and sufficient conditions as to the nature of the function has been obtained. Lipschitz ("De explicatione per series trigonometricas," *Crelle's Journal*, vol. lxiii., 1864) showed that, under a certain condition, a function which has an infinite number of maxima and minima in the neighbourhood of a point is still expansible; his condition is that at the point of discontinuity β, $|f(\beta+\delta)-f(\beta)| < B\delta^{a}$ as δ converges to zero, B being a constant, and a a positive exponent; and his condition is not necessarily satisfied by a uniformly convergent function. A somewhat wider condition is

$$\underset{\delta=0}{L}\log\delta\{f(\beta+\delta)-f(\beta)\}=0,$$

for which Lipschitz's results would hold. This last condition is adopted by Dini in his treatise (*Sopra la Serie di Fourier*, &c. Pisa, 1880).

The modern period in the theory was inaugurated by the publication by Riemann in 1867 of his very important memoir, written in 1854, *Ueber die Darstellbarkeit einer Function durch eine trigonometrische Reihe*. The first part of his memoir contains a historical account of the work of previous investigators; in the second part, there is a discussion of the foundations of the Integral Calculus, and the third part is mainly devoted to a discussion of what can be inferred as to the nature of a function respecting the changes in its value for a continuous change in the variable, if the function is capable of representation by a trigonometrical series. Dirichlet and probably Riemann thought that all continuous functions were expansible; this view was refuted by Du Bois-Reymond (*Abh. der Bayer. Akad.*, vol. xii. 2). The first to call attention to the importance of the theory of uniform convergence of series in connexion with Fourier's Series was Stokes, in his memoir "On the critical values of the sums of periodic series" (*Camb. Phil. Trans.*, 1847; *Collected Papers*, vol. i.). As the method of determining the coefficients in a trigonometrical series is invalid unless the series converges in general uniformly, the question arose whether series with coefficients other than those of Fourier, exist which represent arbitrary functions. Heine showed (*Crelle's Journal*, vol. lxxi., 1870, and in his treatise *Kugelfunctionen*, vol. i.) that Fourier's Series is in general uniformly convergent, and that if there is a uniformly convergent series which represents a function, it is the only one of the kind. G. Cantor then showed (*Crelle's Journal*, vols. lxxii., lxxiii.) that even if uniform convergence be not demanded, there can be but one convergent expansion for a function, and that it is that of Fourier. In the *Math. Ann.*, vol. v., Cantor extended his investigation to functions having an infinite number of discontinuities. Important contributions to the theory of the series have been published by Du Bois-Reymond (*Abh. der Bayer. Akademie*, vol. xii., 1875, two memoirs, also in *Crelle's Journal*, vols. lxxiv., lxxvi., lxxix.), by Kronecker (*Berliner Berichte*, 1885), by O. Hölder (*Berliner Berichte*, 1885), by Jordan (*Comptes Rendus*, 1881, vol. xcii.), by Ascoli (*Math. Annal.*, 1873, and *Annali di Matematica*, vol. vi.), and by Genocchi (*Atti della R. Acc. di Torino*, vol. x., 1875). Hamilton's memoir on "Fluctuating Functions" (*Trans. R.I.A.*, vol. xix., 1842) may also be studied with profit in this connexion. A memoir by Brodén (*Math. Annalen*, vol. lii.) contains a good investigation of some of the most recent results on the subject.

The foregoing historical account has been mainly drawn from A. Sachse's work, "Versuch einer Geschichte der Darstellung willkürlicher Functionen einer Variabeln durch trigonometrische Reihen," published in *Schlömilch's Zeitschrift für Mathematik*. Supp., vol. xxv., 1880, and from a paper by G. A. Gibson "On the History of the Fourier Series" (*Proc. Ed. Math. Soc.*, vol. xi.). Reiff's *Geschichte der unendlichen Reihen* may also be consulted, and also the first part of Riemann's memoir referred to above. Besides Dini's treatise already referred to, there is a lucid treatment of the subject from an elementary point of view in C. Neumann's treatise, *Ueber die nach Kreis-, Kugel-, und Cylinder-Functionen fortschreitenden Entwickelungen*. Jordan's discussion of the subject in his *Cours l'Analyse* is worthy of attention; an account of functions with restricted oscillation is given in vol. i.; see also a paper by Study in the *Math. Annalen*, vol. xlvii. On the second mean-value theorem papers by Bonnet (*Brux. Mémoires*, vol. xxiii., 1849, *Liouville's Journal*, vol. xiv., 1849), by Du Bois-Reymond (*Crelle's Journal*, vol. lxxix., 1875), by Hankel (*Zeitschrift für Math. und Physik*, vol. xiv., 1869), by Meyer (*Math. Ann.*, vol. vi., 1872), and by Hölder (*Göttingen Anzeigen*, 1894) may be consulted. On the theory of uniform convergence of series, a memoir by Osgood (*American Journal*, vol. xix.) may be with advantage consulted. On the theory of series in general, a memoir by Baire (*Annali di Matematica*, Series III. vol. iii.) is of great importance. (E. W. H.)

Fourmies, a French town, in the arrondissement of Avesnes, department of Nord, 39 miles south-east of Valenciennes by rail, on an affluent of the Sambre. It is now one of the chief centres in France for wool combing and spinning. Three large establishments have, respectively, about 10,000, 12,000, and 19,000 spindles, while there are several others with upwards of 6000 spindles. A great variety of cloths is produced. The glass-works of Fourmies date from 1599, and were the first established in the north of France. Iron is worked in the vicinity, and there are important forges and foundries. Population (1881), 11,016; (1896), 12,957; (1901), 13,828.

Fowler, Sir John (1817–1898), English civil engineer, was born on 15th July 1817 at Wadsley Hall, near Sheffield, his father being a land-surveyor, who, though living in the neighbourhood of Sheffield, was chiefly employed in agricultural matters. At the age of nine John Fowler was sent to Mr Rider's private school near Ecclesfield, where he received a sound elementary education. At sixteen, having always been interested in engineering, he persuaded his father to allow him to go as pupil to John Towlerton Leather, the engineer of the Sheffield water-works. Mr Leather's uncle, Mr George Leather, was engineer of the Great Aire and Calder Navigation Company, of the Goole Docks, and other similar works, and Fowler passed occasionally into his employment, in which he acquired a thorough knowledge of hydraulic engineering. The era of railway construction soon swept both Fowler and his employers into its service, and one of his first employments under Mr G. Leather was to oppose the line of the Midland Railway, chosen by the Stephensons, which left Sheffield on a branch line, and was therefore strongly resented by the inhabitants. The prestige of the Stephensons carried all before it, but in later life Sir John Fowler had the satisfaction of seeing the opposition of his clients justified, and Sheffield placed on the main line. In 1838 he went into the office of Mr John Urpeth Rastrick, one of the leading railway engineers of the day, where he was employed in designing bridges for the line from London to Brighton, and also in surveying for railways in Lancashire. In 1839 he went as representative of Mr G. Leather to take charge of the construction of the Stockton and Hartlepool Railway. He remained as manager of this railway after he had superintended its construction, an experience which he afterwards valued highly as being extremely useful as well as probably unique. In 1844 he began his independent career as an engineer, and from the first was largely employed, more particularly in laying out the small railway systems which eventually were amalgamated under the title of the Manchester, Sheffield, and Lincolnshire. In the course of this work he designed a bridge known as Torksey Bridge, which was disallowed by the Board of Trade inspector, Captain (afterwards Field-Marshal Sir) Lintorn Simmons, R.E. The engineering profession espoused Fowler's side in the controversy which followed, and as a result the verdict of the Board of Trade was modified. The episode was the beginning of a warm friendship between these distinguished representatives of civil and military engineering. Fowler was also engaged in the making of railways in Ireland, and in 1867 he was selected by Mr Disraeli to serve on a commission to advise the Government in respect of a proposal for a state-purchase of the Irish railway system. He also carried out considerable works in relation to the Nene Valley drainage and the reclamation of land at the Norfolk estuary. In 1865 he was elected president of the Institution of Civil Engineers, the youngest president who had ever sat in the chair. He was strongly opposed to the project of a Channel tunnel to France, and in 1872 he endeavoured to obtain the consent of parliament to a Channel ferry scheme, whereby trains were to be transported across the strait in large ferry steamers. The proposal involved the making of enlarged harbours at Dover, and Andrecelles on the French coast. The Bill was thrown out by the casting vote of the chairman of a committee of the House of Lords. In 1875 he was enabled to render, in his private capacity, a signal service to the Italian Government, which was much embarrassed by impracticable proposals pressed on it by Garibaldi for a rectification of the course of the Tiber, and other engineering works. Mr Fowler had several interviews with the Italian patriot, and persuaded him of the impracticable nature of his plan, thereby obtaining for the Government leisure to devise a more reasonable scheme. These, however, were minor employments. Fowler will chiefly be remembered as the engineer of the London Metropolitan Railway and (along with his partner, Sir Benjamin Baker) of the Forth Bridge, and from his engagement for eight years from 1871 as general engineering adviser to the Government of Ismail, the Khedive of Egypt. The Metropolitan was a pioneer effort in underground railways. The noteworthy point about it is, that it was made not by tunnelling, but by excavating from the surface and then covering in the permanent way with buildings and roads. Sir John lived to be one of the engineers officially connected with the deep tunnelling system extensively adopted in London for deep electric railways. Though his engagement in Egypt resulted in the completion of no great work, it is of considerable historical and economic interest. He projected a railway to the Sudan, and also the reparation of the barrage. These and many other plans came to an end owing to financial reasons. But the maps and surveys for the railway were given to the War Office, and proved most useful to Lord Wolseley in his Nile expedition. For this service Fowler was made K.C.M.G. (1885). On the completion of the Forth Bridge he was made a baronet (1890). Sir John Fowler was a great practical rather than a great scientific engineer. He was reaching man's estate when railway construction began, and the hour belonged to the great organizer as well as to the great inventor. He was a man of very catholic powers of enjoyment, his profession, society, sport, and the making of his Highland home at Braemore, being all keen sources of pleasure. He died at Bournemouth on 20th November 1898. (T. M.*)

Fox Channel, an inlet separating the south-western portion of Baffin Land, known as Fox Land, from Southampton Island and Melville Peninsula, extends from about 64° to 69° N. lat. and from 75° to 81° W. long. It is connected with the Gulf of Boothia by Fury and Hecla Strait.

Fox, Sir William (1812–1893), New Zealand statesman, was the third son of George Townshend Fox, deputy-lieutenant for Durham County. He was born in England on 9th June 1812, and educated at Wadham College, Oxford, where he took his B.A. in 1832, proceeding to his M.A. seven years later. Called to the bar in 1842, he emigrated immediately thereafter to New Zealand, where, on the death of Captain Arthur Wakefield, killed in 1843 in the Wairau massacre, he became the New Zealand Company's agent for the South Island. While holding this position he made a memorable exploring march on foot from Nelson to Canterbury, through Cannibal Gorge, in the course of which he discovered the fertile pastoral country of Amuri. In 1848 Governor Grey made Fox attorney-general, but he gave up the post almost at once in order to join the agitation, then at its height, for a free constitution. As the political agent of the Wellington settlers he sailed to London in 1850 to urge their demands in Downing Street. The Colonial Office, however, refused to recognize him, and, after publishing a sketch of the New Zealand settlements, *The Six Colonies of New Zealand*, and travelling in the United States, he returned to New Zealand and again threw himself with energy into public affairs. When government by responsible ministers was at last initiated, in 1856, Fox ousted the first ministry and formed a cabinet, only to be himself beaten in turn after holding office but thirteen days. In 1861 he regained office, and was somewhat more fortunate, for he remained premier for nearly thirteen months. Again, in the latter part of 1863 he took office: this time with Sir Frederick Whitaker as premier, an arrangement which endured for another thirteen months. Fox's third premiership began in 1869 and lasted until 1872. His fourth, which was a matter of temporary convenience to his party, lasted only five weeks in March and April 1873. Soon afterwards he left politics, and, though he reappeared after some years and led the attack which overthrew Sir George Grey's ministry in 1879, he lost his seat in the dissolution which followed in that year, and did not again enter parliament. He was made K.C.M.G. in 1880. For the thirty years between 1850 and 1880 Sir William Fox was one of the half-dozen most notable public men in the colony. Impulsive and controversial, a fluent and rousing speaker, and a ready writer, his warm and sympathetic nature made him a good friend and a troublesome foe. He was considered for many years to be the most dangerous leader of the Opposition in the colony's parliament, though as premier he was at a disadvantage when measured against more patient and more astute party managers. His activities were first devoted to secure self-government for the New Zealand colonists. Afterwards his sympathies made him prominent among the champions of the Maori race, and he laboured indefatigably for their rights and to secure permanent peace with the tribes and a just settlement of their claims. It was during his third premiership that this peace, so long deferred, was at last gained, mainly through the influence and skill of Sir Donald M'Lean, native minister in the Fox cabinet. Finally, after Fox had left parliament he devoted himself, as joint-commissioner with Sir Francis Dillon Bell, to the adjustment of the native land-claims on the west coast of the North Island. The able reports of the commissioners were his last public service, and the carrying out of their recommendations gradually removed the last serious native trouble in New Zealand. When, however, in the course of the native wars from 1860 to 1870 the colonists of New Zealand were exposed to cruel and unjust imputations in England, Fox zealously defended them in a book, *The War in New Zealand* (1866), which was not only a spirited vindication of his fellow-settlers, but a scathing criticism of the generalship of the officers commanding the imperial troops in New Zealand. Throughout his life Fox was a consistent advocate of total abstinence. It was he who founded the New Zealand Alliance, and he undoubtedly aided the growth of the prohibition movement afterwards so strong in the colony. He died 23rd June 1893, exactly twelve months after his wife, Sarah, daughter of William Halcombe. (W. P. R.)

Fraga, a town of Spain, in the province of Huesca, on the river Cinca, on a high-road from Madrid to Barcelona. Population in 1897, 6792. There is trade in wheat, oil, hemp, fruit (for which it is famed), pigs, and cattle, and the local manufactures of linen, wool, soap, frieze, and bricks. Its streets are narrow and steep. The only important buildings are the town hall, the old parish church, formerly a mosque, and several convents.

Framingham, a town of Middlesex County, Massachusetts, U.S.A., has an area of 27 square miles of hilly surface, dotted with lakes and ponds. There are included within it three villages—Framingham Center, Saxonville, and South Framingham, the last being the most important. In this village intersect the Boston and Albany and a branch of the New York, New Haven, and Hartford railways. Population (1880), 6235; (1890), 9239; (1900), 11,302, of whom 2391 were foreign-born.

FRANCE.

1. Geography and Statistics.

On the western shore of Europe, between 51° 5′ and 42° 20′ N. lat., and 4° 42′ W. and 7° 39′ E. long., France is bounded on the N. by the English Channel and the Strait of Dover, on the N.E. by Belgium and Luxembourg, on the E. by Alsace-Lorraine (Germany), Switzerland, and Italy, on the S. by the Mediterranean and Spain, and on the W. by the Atlantic Ocean. Its greatest length, from the eastern extremity of the shore of France on the North Sea to the Serre de la Baque de Bordeillat in the Pyrénées-Orientales, is 605 miles; its greatest breadth, from the Pointe de Corsen on the west of Brittany to the easternmost point of the crest of the Vosges to the east of the village of Lubine, 552 miles. Total area 204,146 square miles (official survey), 207,081 (revised estimate of the ministry of War), or 207,170 (see table below).

Forests.—In relation to its total extent, France presents but a very limited area of forest land, amounting to only 34,220 square miles. Included under the denomination of "forest" are lands—*surfaces boisées*—which are *bush* rather than *forest.* The most wooded parts of France are the plateaux of the east and of the north-east, comprising the Forest de Haye, the Forest of Ardennes, and the Forest of Argonne. In the Parisian region there are the Forests of Compiègne (56 square miles), of Villers-Cotterêts, of Fontainebleau, &c. The Central Mountains and the Jura have still some considerable belts of wood, such as Mercoire, Aubrac, Chaux, no one forest, however, exceeding 45 square miles. The Forêt d'Orléans covers 152 square miles. The Alps and Pyrenees are in large part deforested, but efforts are being made in the way of reafforestation, &c., to minimize the effects of avalanches and sudden floods. Such are the remarkable labours in connexion with the Dévoluy and Cauterets. Between 1870 and 1900 more than 1200 square miles were replanted with various species of trees. The revenue of the forests, public and private, is estimated (1901) at £10,000,000. The value of the forest domain of the state exceeds £48,000,000. The production of the woods and forests, covering altogether about 17·88 per cent. of the entire surface of the country, is reckoned to amount annually to fully 32½ millions of cubic yards—an amount, however, still short by at least 8 millions of the consumption.

Climate.—Climatically, France is distinguished into two principal regions—that of the Atlantic, and that of the Mediterranean climate. It is further subdivided into local climates, generally grouped under the following seven designations:—(1) Parisian or Sequan climate, with a mean temperature of 50° F.; winters cold, summers mild; (2) Breton climate, with a mean temperature of 51·8° F.; winters mild, summers temperate, frequent rain; (3) Girondin climate (characterizing Bordeaux, Agen, Pau, &c.), having a mean of 53·6° F.; mild winters and hot summers; (4) Auvergne climate, comprising Cevennes, Plateau Central, Clermont, Limoges, and Rodez; mean temperature, 51·8° F.; with cold winters and hot summers; (5) Vosges climate (comprehending Épinal, Mézières, and Nancy), having a mean of 48·2° F.; long and severe winters, with hot summers; (6) Rhone climate (experienced by Lyons, Grenoble, and Bourg d'Oisans); mean temperature, 51·8° F.; cold and wet winters, hot summers; (7) Mediterranean climate, ruling at Valence, Nîmes, Nice, and Marseilles; mean temperature, 57·5° F.; mild winters and hot summers. This classification of the climate, which is the one of common acceptation, seems more precise and more practical than the old division according to the different zones of vegetation.

Geology.—Geologically, France may be distributed as follows:—(1) Volcanic regions, comprising the mountains of Auvergne, of Cantal, and of Velay; (2) the regions of Primitive rocks, comprehending the Cevennes, the Plateau Central, Pyrénées Centrales, the Alpine massifs Oisans, and of Mont Blanc, Vendée, and Brittany; (3) the regions of Primary rocks in Brittany, Cotentin, the Western Pyrenees, and Ardennes; (4) the regions of coal in the departments of Nord and Pas-de-Calais, in the Lyonese basin, and in patches in the plateaux of Cevennes; (5) the regions of Jurassic rocks in the Jura, Côte-d'Or, the plateaux adjacent to the Cevennes, Normandy, and the Alps of Vercors and Dévoluy; (6) the regions of Cretaceous rocks in Champagne, Picardy, and Corbières; (7) the regions of Tertiary strata in the Île de France, in the Landes, and in Périgord; (8) the regions of Quaternary layers in the basins of Paris, of Lyons, and of Toulouse.

Utilization of the Soil.—The entire surface of France measuring 204,092 square miles, the part laid out in agriculture, gardens, and prairies comprises 147,322 square miles, and in forests 34,220 square miles; the remainder, or 22,550 square miles, *i.e.*, about 11 per cent. of the whole surface, lying waste or uncultivated.

Flora and Fauna.—The indigenous flora comprises the ash, linden, oak, and chestnut in Northern and Central France; the yew, plane-tree, &c., in Southern France. The indigenous fauna includes the bear, now very rare, but still found in the Alps and the Pyrenees; the wolf, harbouring in the Cevennes and the Vosges mountains; the fox, the marten, the wild boar, the stag, the hare, and the rabbit. Among the birds are the eagle, the kite, the partridge, and the lark. Of the smaller reptiles may be mentioned the viper, the snake, and the lizard.

Geography and Human Culture.—The populations of the high plateaux, of the lands of granitic formation, and of raw climates, such as the people of Limousin or Auvergne in Central France, or of Lorraine in the east, are taller, robuster, ruder, and more weather-beaten, but also less vivacious, less versatile, less disposed to innovation, than are the inhabitants of the great plains of the Seine and the Loire, of maritime Languedoc, and the shores of the Mediterranean. This distinction of type and temperament, exemplified in the most striking manner in the contrast between the Vosgian and the Marseillese men, is carried also into the plane of politics, determining the one set of people as Conservatives, the other as Radicals. The great cities have all, or nearly all, arisen at the confluence of rivers, at easy altitudes, or along the sea coasts where at once the temperature is more moderate and communication with foreign countries of readier and larger attainment. The three great metallurgic areas of France—those of the Nord and Pas-de-Calais, the Saône-et-Loire, and the Lyonnais—are planted on regions of coal formation, and, on the other hand, the domains on which cattle are reared—in Brittany, Lorraine, and the Central Plateau—rest on crystalline or Jurassic strata. On the Cretaceous and Tertiary deposits—in the Île de France, Orléanais, Picardy, the riverine hills of the Garonne and the Gironde—is found the fertile land waving in wheat or mantled with vines.

Population.—The population of France, 36,905,788 in 1876, numbered 36,672,048 in 1881, 38,218,903 in 1886, 38,342,948 in 1891, 38,517,975 in 1896, and 38,595,500 in 1901. The following table gives the area in English square miles of each of the eighty-seven departments, with its population according to the census returns of 1881, 1896, and 1901 (provisional):—

Departments.	Area: English Square Miles.	Population.			Population per Square Mile, 1896.

Total	207,170	37,672,048	38,517,975	38,595,500	186·0

The greater number of the French departments showed a decline in their population from 1881 to 1901. Those in which the decrease of population was most marked were: Basses-Alpes (18,955), Ariège (38,317), Aveyron (37,516), Dordogne (46,492), Eure (33,107), Gers (45,331), Lot (56,533), Orne (50,681), Yonne (40,982), departments all of them purely agricultural, lacking large cities as nuclei for population to rally round. The departments, on the other hand, showing an increase in their population were those in which the industries are developed, and in which, consequently, are centres of large population. While 38,517,975 represented the legal population (present and absent) of

France at the census of 1896, the population actually present at that date was only 38,269,011, or 248,964 less.

Of the population in 1896, 18,922,651 were males and 19,346,360 females, an excess of females over males of 423,709, *i.e.*, a little more than 11 per 1000, or about 506 females to every 494 males: a normal population pretty closely exemplified in all past censuses. The departments in which the female surplusage was most notable were Seine, with 151,073, or 9·5 per cent., more females than males out of a population of 3,308,007. Next, in less proportions, were Seine-Inférieure, with a surplus of 28,454 females out of a population of 829,364; Somme, with 12,835 females in excess among a population of 540,415; Manche, with a female surplus of 11,148; Haute-Garonne, 15,325; Morbihan, 13,893; Orne, 9868; Nord, 18,115. On the other hand, the male population predominated in Basses-Alpes to the number of 6981 out of a population of 117,619; in Hautes-Alpes, where the males outnumbered the females by 6113; Corsica, with a surplus of 6113 males; Drôme, with 6076 more males than females; Jura, 3139 males in excess; Haute-Rhin (Belfort), 6379; Meurthe-et-Moselle, 22,117.

In respect of nationality again, there were among the 38,269,011 inhabitants in 1896, 37,217,104 persons of French nationality; the remainder, 1,051,907, *i.e.*, 27 per 1000, being foreigners. All the departments included foreigners in their population: Calvados, in the north, numbering 1471; Cher, in the centre, 528; Alpes-Maritimes, in the south-east, 72,265; Bouches-du-Rhône, 94,728; Nord, 259,916; Seine, 191,687. The department having the largest infusion of foreigners is Alpes-Maritimes, in which 72,265, or 25 per cent., of the population is foreign.

The following table shows the distribution of the population according to their condition in respect of marriage:—

Males	Single	10,195,788,	*i.e.*, 266·6	per 1000 inhabitants.
	Married	7,689,997,	,, 201	,, ,,
	Widowers	1,011,313,	,, 26·35	,, ,,
	Divorced	25,553,	,, 0·65	,, ,,
Females	Single	9,465,874,	,, 247·4	,, ,,
	Married	7,728,854,	,, 202	,, ,,
	Widows	2,118,394,	,, 55·4	,, ,,
	Divorced	33,238,	,, 0·81	,, ,,

In respect of age, there were counted in 1896, 3,302,797 boys and 3,297,879 girls of less than ten years of age; 4,969,841 males and 5,065,994 females from ten to twenty-five years of age; and 10,644,637 men and 10,976,426 women from twenty-five years of age upwards. According to another division, there were, in 1896, 6,990,101 males and 7,009,533 females of less than twenty-one years of age; 1,623,805 males and 1,437,618 females from twenty up to twenty-four years of age; and 10,649,013 males and 10,982,487 females from twenty-five years of age and upwards; 40 men and 136 women were centenarians.

The following table shows the distribution of the active population of France according to their occupations in 1896:—

Occupations.	Males.	Females.	Total.
Forestry and agriculture	5,674,713	2,755,346	8,430,059
Manufacturing industries	3,488,077	1,890,292	5,378,369
Trade	1,030,977	572,840	1,603,817
Domestic service	217,197	751,867	969,064
Transport	551,731	160,880	712,611
Public service	584,134	104,959	689,093
Liberal professions	199,546	139,630	339,176
Mining, &c.	222,040	4,775	226,815
Fishing	66,388	5,238	71,626
Unclassed	26,318	20,390	46,708
Grand total	12,061,121	6,406,217	18,467,338

In 1901 there were in France fifteen towns having each more than 100,000 inhabitants. Their growth from 1876 to 1901 is shown in the following table:—

	1876.	1886.	1901.
Paris	1,988,806	2,344,550	2,660,559
Marseilles	318,868	376,143	494,769
Lyons	342,815	401,930	453,145
Bordeaux	215,140	240,582	257,471
Lille	162,775	188,272	215,431
Toulouse	131,642	147,317	147,696
St Étienne	126,019	127,482	146,671
Le Havre	92,068	112,074	129,044
Nantes	122,247	122,750	128,349
Nice	53,397	77,273	125,099
Roubaix	83,661	100,299	124,660
Rouen	104,893	107,163	115,914
Rheims	81,328	97,903	107,730
Nancy	66,303	79,038	102,463
Toulon	61,382	70,122	101,172

In the same years the following thirteen towns, now from 60,000 to 100,000 inhabitants, each had:—

	1876.	1886.	1901.
Amiens	66,896	80,288	90,038
Limoges	59,011	68,477	83,569
Angers	56,846	73,044	82,966
Brest	66,828	70,778	81,948
Nîmes	63,001	69,698	80,355
Tourcoing	33,895	58,209	79,468
Montpellier	55,258	56,765	76,364
Rennes	53,598	66,232	74,006
Dijon	45,607	...	70,428
Grenoble	43,054	52,484	68,052
Orléans	52,157	60,826	67,539
Tours	48,325	...	64,448
Le Mans	45,709	59,585	62,948

There were, besides, forty-one towns each having a population in 1901 of more than 30,000. The rural population in 1896 amounted to 23,492,123, or 60·9 per cent. of the entire population. The rural and urban population in 1872 were, the former 68·7, the latter 31·3 per cent. of the whole. There has accordingly been a very marked withdrawal of population from the country to the cities.

Movement of Population.

There were the following living births in France in the years specified:—

1874.	1881.	1891.	1899.
954,652	937,057	823,905	847,267

The yearly numerical mean of births for each of the following quinquennial periods was:—

1881–86.	1886–91.	1891–96.
932,000	884,000	877,000

These figures indicate a steady decrease.

The following were the numbers of legitimate and illegitimate births in the years specified:—

	1891.	1899.
Legitimate	758,969	772,657
Illegitimate	73,936	74,970

There were the following number of deaths in the years specified:—

1881.	1891.	1899.
828,828	876,882	816,233

The quinquennial mean of deaths fell from 841,000 for the period 1881–86 to 836,000 for the period of 1891–96. In 1881 the number of births exceeded the number of deaths by 108,229, and in 1896 by 93,700. The years 1891, 1892, and 1895 yielded an excess in the number of deaths over the number of births. In 1879 the number of still-born was 39,778; in 1882, 44,352; in 1886, 43,623; in 1891, 42,472; in 1896, 42,054; in 1899, 39,860. The birth-rate in 1899 was 22·1 per 1000; the death-rate 21·2 per 1000.

Marriage and Divorce.—The number of marriages registered in France amounted to 282,079 in 1881, 285,458 in 1891, and 295,752 in 1899, indicating a slight progress in the number of marriages. The number of divorces, 2950 in 1886, rose to 5752 in 1891, and 7179 in 1899.

Emigration.—The following figures of emigration are quoted from the statements of the ministry of the Interior. The statistics of emigration are, however, not drawn up in a strictly regular method, and the figures may therefore be taken with a certain reserve. In 1857–91 there were 285,873 French emigrants; in 1892, 5528; in 1893, 5300; in 1898, 4400.

Immigration.—There are no official annual statistics taken of the immigration into France any more than of the emigration from France. All that can be done is to cite the figures given in the census returns as to the number of foreigners on French territory. The foreigners in France numbered in the years named:—

1881.	1886.	1891.	1896.
1,001,090	1,126,531	1,130,211	1,051,907

In explanation of the last figures, it is to be remembered that the law of 1889 providing for automatic nationalization has contributed somewhat to the apparent diminution in the magnitude of the figures. In 1891 there were in France 39,687 English, 83,333 Germans, 465,860 Belgians, 286,042 Italians, and 83,117 Swiss. It is the Belgians and the Italians who have contributed the greatest number to the alien population in France since 1870.

Constitution.—The constitution of 1875, modified though it was in 1879 and 1884 in certain points, such as the suppression of senatorships which were irremovable and of the election of the Senate itself, has yet in its essential elements remained unchanged. From 1885 to 1889 the election of deputies was made on the plan of the *scrutin de liste départementale*, according to which each elector votes for as many deputies as the entire department returns to the Chamber; but in 1889 the *scrutin uninominal*, or one elector one vote, was re-established. In 1880 there were the following ministries, or heads of the great administrative departments—the Ministries of Justice, of the Interior, of Foreign Affairs, Finance, War, Marine and Colonies, Public Instruction, the Fine Arts and Worship, Agriculture and Commerce, and Public Works. Since then there have been constituted the separate ministries of Agriculture and of the Colonies, ministries which have become of extreme importance. France is divided into 87 departments, 360 arrondissements, 2865 cantons, and about 36,000 communes. The departmental organization has remained unchanged since 1875. Only one slight modification has been effected, the suppression of the arrondissements of St Denis and of Sceaux in the department of the Seine. The powers of the elected assemblies or general councils (*conseils généraux*) and their permanent delegations (*commissions départementales*) have remained to the present unaltered, though there is a large current of opinion in favour of administrative decentralization. On the other hand, the communal organization has been very markedly transformed by the law of 1884, which has increased the prerogatives of the municipal councils. This law, however, does not apply to Paris, which continues to be ruled by the former regulations. The municipal councils, representing the communes, comprise, according to the size of their population, from ten to thirty-six members. They formulate resolutions which either have the executive force of law, or need for their validity the sanction of the prefect. In all towns, whether large or small, the mayors are elected by the municipal council. The mayors are at once *officiers de l'état-civil*, executors of the decisions of the municipal council, judicial magistrates, and representatives of the central power. The number of deputy-mayors (*adjoints*) has been modified by the law of 1884: it is one in a commune of 2500 inhabitants, and two in a commune of from 2501 to 10,000. In communes of greater population there is in addition one deputy-mayor for every 25,000 inhabitants beyond that number, but in no case must the total exceed twelve, excepting at Lyons, where as many as seventeen are allowed.

Justice.—The judicial organization of France has undergone no alteration since the ninth edition of this work was published. According to the Statistics of Justice (1897), justices of the peace had, in 1897, 342,417 causes to hear; the civil tribunals 181,818, of which they settled 142,856; while the courts of appeal had to sit in trial on 21,848, of which 12,047 were determined. The number of judicial distraints (*ventes judiciaires*) was 23,988. The petitions for divorce and legal separation reached the number of 11,940. The commercial courts, again, had 209,066 disputed causes brought before them for decision, and settled 190,966 of them. The applications for bankruptcy and judicial liquidations numbered 17,342. In 1897 there were 3453 persons charged before the assize courts, and of them 980 were condemned for crimes against the person, and 1398 for crimes against property. Of these 2378 persons who were condemned, 2139 were males and 239 females. There were, further, 225,013 persons prosecuted for offences before the correctional courts (*tribunaux correctionnels*), and of these 207,926 were condemned to either fine or imprisonment. Theft alone furnished 43,677 charges; vagrancy and mendicity, 25,783. The common police cases numbered 385,276. The cases of felonious homicide in France throughout the quinquennial period (1892–97) have averaged 1·26 per 1000 inhabitants. The departments furnishing the smallest contingent of such cases were Jura (0·40 per cent. of the total number), Pyrénées-Orientales (0·31), and Mayenne (0·14). The departments, on the other hand, contributing the largest number of such cases were Bouches-du-Rhône (2 per cent. of the total number), Nord (2), Corsica (8), and Seine (9). Fourteen persons were in 1897 condemned to death, and of this number ten had their sentence commuted. The administration of the prisons is regulated by the law of the 9th June 1875, the first article of which enjoins that thenceforth the accused shall be kept separate from one another day and night. The condemned are subjected to individual imprisonment in cases in which the sentence pronounced upon them is for less than a year and a day. In case of the penalty exceeding the term of a year and a day, the condemned may claim the application of the same *régime*, and then by law his sentence is reduced by a quarter. The same law of 1875 has ordained the reconstruction of the metropolitan prisons, but the execution of this ordinance is not yet accomplished. Since the passing of the law of 1885, the *récidivistes*, those, namely, who, having been already condemned become guilty of new crimes or offences, are transported to the French colonies. The penitentiary population of the metropolis in both the central and departmental prisons (*maisons*) amounted on the 1st of January 1899 to the number of 33,695. The produce of prison labour in 1898 exceeded the value of 4,046,000 francs.

Religion.—The total expenditure set down in the state budget towards the support of the four recognized religious confessions (Roman Catholic, Calvinist, Lutheran, and Hebrew), together with the Mussulman confession in Algeria, an expenditure attached sometimes to the ministry of Public Instruction, sometimes to that of the Interior, and sometimes to that of Justice, amounted in 1901 to a little over 43 million francs. In recent years several amendments have been laid before the Chamber, aiming at the suppression of this item of the budget, but all have been rejected.

Roman Catholic.—The *curés*, though appointed by the bishops (whose nomination by the President of the Republic has to be confirmed by the canonical institution of the Pope), have also to be accepted by the Government. There are in France 17 archbishops, receiving a salary each of 15,000 francs ; under them are 67 bishops, with a salary each of 10,000 francs. The archbishops and bishops are assisted by 685 vicars, whose stipends range severally from 2500 to 4500 francs. Attached to each cathedral church, moreover, whether episcopal or archiepiscopal, are chapters of canons—orders doomed to ultimate extinction. In 1901 they numbered 695. The inferior orders comprise the *curés* (drawing salaries of from 1200 to 2400 francs each) to the number of 3451, *desservants* and curates (*vicaires*) to the number of 38,002. The total strength of the Roman Catholic clergy in France accordingly exceeds 42,000 persons. They are recruited from the seminaries, which are distinguished from one another as great and little, according to the grade of instruction they impart. The total grant made by the State to the Roman Catholic clergy amounts to about 41 million francs. The regular clergy are subdivided into congregations, recognized and non-recognized, the latter existing only by the tolerance of the Government. According to statistics published in 1900 by the ministry of the Interior, there were 127 congregations of men, 97 of which are not recognized, and 1276 congregations of women, of which 784 are not recognized. No table of the number of members associated with these has been drawn up, but it is estimated that the number of both sexes is about 150,000. The value of the known real estate belonging to convents is 1071 million francs, and that of the personal estate is at least 8000 million francs. Lastly, notwithstanding legal proscriptions, the Jesuits, reorganized, have established themselves in forty-eight departments.

Protestants.—The two Protestant forms of worship figure in the budget together at about 1,500,000 francs. The Reformed or Calvinist confession includes 628 pastors, who are paid salaries of from 1800 to 3000 francs a year. The Augsburg or Lutheran Church counts 62 pastors, paid at the same rate as the Calvinist pastors.

Jews.—The Hebrew Church costs the State yearly about 150,000 francs. Its service is conducted by 10 chief rabbis, receiving from 4000 to 12,000 francs each ; 24 ordinary rabbis, paid from 1750 to 2500 francs each ; and 23 officiating ministers, with salaries of from 600 to 2000 francs each.

Precise statistics are wanting of the number of followers of each confession. The Roman Catholics of France may be counted at 36 millions, the Protestants at 2 millions. As to the Hebrew Church, its followers are variously estimated at 50,000 and 100,000 ; more probably their number will be about 80,000. The Protestants have their chief seat in the departments of the centre and of the south along the range of the Cevennes. In this region Nîmes is the most important centre. Considerable sprinklings of them are also to be found in the two Charentes, in Dauphiné, in the Seine, and in Franche-Comté. The localities in which the Jews are most common are Paris, Lyons, and Bordeaux. There are also small groups of them in Provence, Lorraine, and Champagne.

Education.—Since the 16th May 1877—a critical date in the history of the Third Republic—profound changes have been introduced into the organization of public instruction. Along with the colonial expansion of France and the remodelling of its army, this transformation in education is the most considerable enterprise undertaken by the Government. To characterize the new departure in few words, public instruction has been developed in all directions and withdrawn as much as possible from the influence of the Church. Education of a primary kind has been made free and obligatory. Paul Bert and Jules Ferry are names associated with a thorough organic reconstruction which provoked many controversies and commotions.

General Organization.—At the head of public instruction is the minister of State, entitled the Grand-Master of the University. He is assisted by the Superior Council of Instruction. This body has been reorganized in a lay sense by the law of the 27th February 1880, and comprehends, in addition to the minister-president, five members of the Institute of France, nine persons designated by writ of the President of the Republic, forty professors of the three degrees of public instruction elected by their colleagues, and four delegates of free education. The whole territory of France is divided into sixteen academical districts, having their centres respectively at the seats of the academies, which by the law of 1896 have been transformed into universities. The capitals of these academic districts are Paris, Aix, Besançon, Bordeaux, Caen, Chambéry, Clermont-Ferrand, Dijon, Grenoble, Lille (formerly Douai), Lyons, Montpellier, Nancy, Poitiers, Rennes, Toulouse. Within the jurisdiction of each rector of a district are the three orders of instruction. He is assisted by an Academic Council which, like the Superior Council, was reorganized in 1880, and comprises, besides the rector-president, the district inspectors and a variable number of members nominated or elected. The district inspectors are each placed at the educational head of the departments constituting his academic district. Like the Superior Council, the Academic Councils exercise functions consultative and disciplinary. The budget of public instruction amounted in 1901 (in round numbers) to 206½ million francs. In 1847 it stood at 18 millions, in 1877 at 57 millions, in 1886 at 150 millions.

Superior Education.—This is given in the first place by the universities, which themselves comprise a variable number of faculties, namely, Law, Medicine, Theology, Letters, and Sciences. The degrees they confer are those of bachelor, licentiate, and doctor. A fellowship (*agrégation*) is a title rather than a degree, giving the right to teach in a secondary State institution. The right of conferring these degrees is reserved to the faculties of the State, the higher education being free, as will appear from certain figures below. In 1900 there were 29,377 students in the faculties of the State, of whom over 12,192 were at Paris University, and 1629 in the Roman Catholic institutes. It is mostly in the faculty of Law that these latter draw students, counting 1109 against 9700 of the State institutions. Other free or public establishments imparting higher education are, in the first category, the *École des Chartes, École des hautes Études*, &c. ; in the second category, the *École des Sciences politiques* and the *Collège des Sciences sociales.*

Secondary Education.—This is imparted by the lycées and colleges of the State and in free institutions. It is subdivided into a classical course, the right of giving instruction in which is earned by the acquisition of the diploma of bachelor in classics (Latin and Greek) ; and a modern course, the right of giving instruction in which belongs to any one having the modern bachelor's diploma (competence in living languages). The professors of public secondary education require to be fellows. They are trained—male professors in the *École normale supérieure* (for the classical branch) or in the *École normale de Cluny* (for the modern branch) ; female professors in the *École normale de Sèvres*. In 1900 there were 109 lycées for boys, 13 of them at Paris ; and 229 *Collèges Communaux*—a total of 338, against 324 in 1877. The total number of pupils amounted to 85,599. The secondary establishments for girls comprised, in 1900, 11,994 pupils. The first lycée dates only from 1881. With respect to the free secondary establishments, the lay ones comprised 10,182 pupils, and the clerical 91,825. The total number of young persons receiving secondary instruction amounted in 1900 to 203,838.

Primary Instruction is, by the law of the 16th June 1881, gratuitous, and by the law of the 28th March 1882, obligatory. Since the passing of the law of the 30th October 1886 primary public instruction may, in principle, be committed to the care only of lay masters and mistresses. The secularization of the schools has not yet, however, been universally accomplished, and there still remain 7000 to 8000 teachers belonging to the religious Congregations. From the age of six to that of thirteen a child is bound to attend a school, public or private, primary instruction being free, unless the parents prefer to have the education imparted at home. Permission to adopt this mode of instruction is given in the *Certificat d'Études.*

Public Schools.—Among them are to be distinguished infant schools (*Écoles maternelles*) ; primary elementary schools receiving children of from six to thirteen years of age—the schools which the laws of 1881 and 1882 had more particularly in view ; and the primary upper schools (*Écoles primaires supérieures*), designed to supplement the general instruction and prepare pupils for professional instruction.

In 1899 the number of pupils in attendance at the public infant schools amounted to 463,202 ; at the primary elementary public schools, 4,169,578 ; at the primary upper schools, 31,602. Altogether, then, these public infant and juvenile educational establishments comprised a population of more than 4,650,000—a register for 1899 which compares favourably with that of 1880, 4,200,000, and that of 1875, which hardly reached four millions. The masters and mistresses of the primary schools, elementary and higher, are trained in the normal departmental schools (*Écoles normales départementales*), which in 1899 counted 8036 male and female student-teachers, pretty equally divided. The professors of the training schools are themselves taken, the men from the higher training primary schools of St Cloud, the women from the schools of Fontenay-aux-Roses.

The budget of primary education, for which, between 1880 and 1901, very remarkable amounts were voted, has risen from 16 million francs in 1875 to 28 millions in 1880, to 86 millions in 1885, to 121 millions in 1890, to 143 millions in 1895, and to 155 millions in 1901.

Free Schools.—Before any one can exercise the functions of a male or female teacher in a free school (*École libre*), it is necessary for him or her to have a certificate of competency (*brevet de capacité*). Such certificate is obtained after passing an examination before a departmental commission, the presidency of which belongs to the academic (district) inspector. The certificate may be either for an elementary or a higher school. The free schools in 1899 comprised 1624 pupils in the higher primary class, 1,369,721 in the elementary primary class, and 284,042 in the infant class of schools, giving a total of more than 1,655,000 pupils. Adding this to the figures of pupils in the public schools, we get, as the sum-total of the infant and juvenile school population of France in 1899–1900, about 6,300,000. In 1875 the corresponding figures were 4,800,000, and in 1880, 5,600,000.

Illiterate.—Owing to the new school laws, the proportion of illiterate persons in France has sensibly declined since 1875, and more especially since 1880. The 20 per cent. of conscripts entered as illiterate in 1875, dropped to 16 per cent. in 1880, 11·4 per cent. in 1885, thence to 7·7 per cent. in 1890, and to 4·8 per cent. in 1898. The illiterate statistics of the wedded tell pretty much the same tale. In the case of the men there were, in 1870, 27 per cent. of those entering the married state unable to either read or write; in 1880 the percentage had fallen to 19, in 1885 to 13, in 1890 to 8, and in 1898 to 5. In the case of women entering the married state, the corresponding percentages for 1870, 1880, 1885, 1890, and 1898 were 39, 24, 21, 13, and 8.

Adult or Evening Schools.—For some years, more particularly since 1892, a great extension has been given to after-school education by the establishment of evening classes for adults. This new departure aims at completing the school education, and, while confirming the learning which pupils have already acquired, it is intended further to benefit the youth of from thirteen to eighteen years of age by enabling them to attend classes in a variety of advanced subjects.

Under this category there were in 1899–1900, 38,191 courses of instruction given—27,842 for men and 10,349 for women. To this number have to be added at least 5000 courses provided by societies of popular instruction, syndicates, and labour bursaries (*bourses de travail*). The attendance at these classes exceeded the number of 950,000.

The Academies.—This summary review of education would scarcely be complete unless something were said about the Institute of France. It consists of five academies—the Académie Française, the Académie des Sciences, the Académie des Inscriptions et Belles Lettres, the Académie des Beaux-Arts, and the Académie des Sciences, Morales et Politiques. Each of these academies comprises forty titular members, elected by their colleagues, with the exception of the Académie des Sciences, which has sixty-three members, and the Académie des Beaux-Arts, forty-one. Each academy, moreover, with the exception of the Académie Française, nominates free members (*membres libres*) and foreign correspondents. The Académie de Médecine is a separate scientific institution (with 100 members), as is also the Société Nationale d'Agriculture.

Charitable Institutions.—The general organization of public charity has undergone no essential alteration. Several new laws, however, have been passed tending to complete the system. As is well known, the giving of relief to the needy is in France regarded as a moral but not a legal obligation. A special department of the ministry of the Interior, designated *Assistance Publique*, is charged with the general superintendence of this duty. The costs of relief to the poor devolve on the State or on the departments, but, above all, on the communes. Under the present constitution it is the commune in fact, and indeed of necessity, in which centres all organization of charity: the commune being in immediate touch with the needy, is enabled promptly to appreciate their wants and to render them relief.

Since the enforcement of the law of 1879 the *bureaux de bienfaisance* are administered by a commission composed of the mayor of the commune, acting as president, and six members. Their number in France amounts to about 18,060, and their yearly expenses reach the figure of 50 million francs. The income is drawn from the revenues of the real estate belonging to the *bureaux*, a poor-tax on playhouses, and donations and legacies of private persons, the last item amounting in 1897 to 43,550,000 francs. The *bureaux de bienfaisance* afford outdoor relief. Hospitals and asylums (*hospices*) receive the sick, and nurse them throughout their period of sickness; infirm and old people and infants are kept as pensioners. These, too, are under the administration of the commission. In 1898 there were 1736 hospital establishments, against 1654 in 1884. The staffs consisted of 34,254 persons, of whom 3373 were physicians and surgeons, and they contained 52,468 inmates. Paris alone has forty-eight such establishments, with 24,278 beds. The revenue of the hospitals and asylums amounted in 1898 to 145,300,000 francs, of which amount 51 millions were derived from their own resources, 32 from communal subventions, and the rest from pure charity. The expenses amounted to 139,233,000 francs.

Charity Children (*Enfants Assistés*).—This class is divided into three categories: First, foundlings really abandoned; second, children receiving help at their homes; third, children morally abandoned, *i.e.*, children of morally abandoned parents—a category dating from the law of 1889. The keeping of these children devolves at once on the State, the departments, and the communes. The total number of children of these three categories amounted in 1897 to 120,177, against 98,000 in 1885; and the total outlay on them was nearly 25 million francs, to which amount the contribution of the State was 4½ millions.

Lunatics.—Although since 1866 no longer legally bound to maintain lunatic asylums, most of the departments have yet kept them. Lunatics are supported either in such departmental asylums, or in the national asylum at Charenton, or in separate quarters of the infirmaries (*hospices*) set apart for them; but they may also be kept privately by their own people. The census of lunatics in 1897 figured at 64,639, of whom 30,355 were males and 34,284 females: 608 of them were entered in the national asylum, and 45,914 in the departmental and communal asylums.

Gratuitous Medical Aid.—This service has been organized and charged to the account of the departments by a law of 1893. By 1895 it had been brought into operation in 83 departments, and is now at work in all of them, more than 20 millions of people profiting by the service. The yearly contribution of the State treasury is 1,450,000 francs.

Old-Age Pensions.—By the law of 1897 the State has to contribute to the old-age pensions, fixed by the departments at not less than 90 and not more than 200 francs per person in favour of people aged seventy and upwards. This contribution must not, however, exceed 50 francs per head, nor be given in more cases than 2 per 1000 of the population. The law remains, then, only an affirmation of principle, which is valued in the budget, to express it in this way, at an inscription of 590,000 francs.

It may be remarked here that the whole contribution of the national treasury to institutions for relief of the poor amounts to only 12,684,000 francs.

Finance.—The minister of Finance exercises jurisdiction over all matters of public finance. He co-ordinates in one general budget the separate budgets prepared by his colleagues of the council of State, and provides ways and means. In principle, the budget of any one financial year has to be laid on the table of the Chamber of Deputies in the course of the ordinary session of the previous year, so that the discussion thereon, opening in October, may close before the 31st December. The financial year in France always begins on the 1st January, although various attempts have been made to postpone the initial date to the 1st of July. The *projet de loi*, laid before the Chamber of Deputies, is submitted to a special commission of thirty-three members elected for one year. This commission appoints a general reporter, and one or more special reporters for each of the ministries. The budget having been voted by the Chamber of Deputies and sent to the Senate, this assembly proceeds after the same fashion, but its financial commission numbers only twenty-seven members. When the budget is not voted within a practicable time, namely, before the 31st December, Parliament grants provisional twelfths, that is to say, the authorization to incur expenses up to the amount of those of the preceding year for one, two, or three months. This practice has of late years become generalized, and has sometimes been carried to as far as sixth-twelfths. The taxes authorized by the financial law are gathered by different bodies of agents; all the sums collected ultimately, however, find their way into the respective treasuries of the arrondissements, and thence into the general treasury. The *trésorier payeur général*, almost always resident at the capital of the department, has to give account at the central office for all the sums collected in his department, and to pay the charges due by the treasury. To this end he is in correspondence with the general direction of the movement of the funds, which has its seat at the ministry in Paris, and organizes the circulation of the public funds throughout the whole territory of the State. The *trésoriers payeurs généraux*, whose reponsibilities are weighty, receive, in the shape of fixed emoluments and allowances, considerable salaries, up to 120 and 130 thousand francs. These salaries have, however, in recent years been sensibly reduced. The taxes collected and the charges of the services paid, the budget is subjected to a double control, that of the *cour des comptes*, whose function it is to overhaul the accounts of the State, the departments, and the communes, and that of Parliament, which passes a vote of definitive settlement.

Expenditure.—Since 1875 the State budget of expenditure has passed through the most drastic fluctuations. This expenditure reached its maximum in 1883, from which date it descended in 1888 and 1889, to mount once more in an almost continuous ascent, yet by gradations of growth not too severe. The credits voted for the discharge of the public services are—at least have been, and may still be—classed under the two distinct heads of *ordinary* and of *extraordinary* budget. The ordinary budget of expenditure is that which has to be met exclusively by the produce of the taxes; the extraordinary budget of expenditure is that which has to be incurred in the way either of an immediate loan or in aid of the funds of the floating debt. Under various names it has existed since 1871.

The progress in the growth of the expenditure of France is shown in the following summary figures, the figures of expenditure for the specified years denoting respectively so many millions of francs:—

1875.	1880.	1885.	1890.	1895.	1901.
2980	3412	3472	3400	3510	3554

To these totals of expenditure the ordinary budget contributed:—

1875.	1880.	1885.	1890.	1895.	1901.
2670	2912	3293	3130	3430	3532

The figures contributed by the extraordinary budget of expenditure were:—

1875.	1880.	1885.	1890.	1895.	1901.
310	500	179	270	80	22

Although the term *budget extraordinaire* is no longer the usual one, there still remains in the State expenditure a good 76 millions of francs in excess of what is included in the ordinary budget.

From 1892, the successive ministers have, after the example of M. Rouvier, followed the practice of what has been named a policy of incorporation (*la politique des incorporations*); that is to say, they have entered in the ordinary budget, each under its own head, the expenditure on war, marine, and public works, items formerly figuring under the head of extraordinary expenditure. By this proceeding, country and Parliament have been enabled to obtain a more precise appreciation of the annual expenditure, a large part being no longer, as before, wrapped up under any disguise.

The following table gives an exact view of the progress of the costs of the principal public services since 1871, the figures representing so many millions of francs:—

	1876.	1884.	1894.	1901.
Public debt	928	1048	1127	1133
Guaranteed interests to railway companies	47	17·5	109·7	17
Sinking fund	164·7	156·5	63·8	37
Algeria	32	45·6	70·1	...[1]
Colonies	28	116	73·8	112
Public relief	15	17·6	17·2	19
Bourses	3·3	4·8	6	7·5
Subventions	47·5	80·7	54·3	54
Maintenance of works and new works	105·7	238·5	92·4	92
Régie	81·4	101·7	112·7	121
Repayments and restitutions	36·8	55	43	32·3
Administration	300	229	231	254
Salaries of the public officers (President, senators, and deputies)	11·6	12·9	13·1	13·3
War	841	690	627·5	691
Marine	164·6	193·8	265·9	327·7
Military pensions	74·4	115·2	134	141
Instruction	51·5	175	181	206
Monopolies	141·6	211	215	230

Distributed among the different ministerial departments, the budget of 1901 showed the following figures in millions of francs:—

Public debt, salaries, and finance	1520	Marine	327
Justice	35	Instruction and Fine Arts	223
Worship	43	Commerce and posts	242
Foreign affairs	16	Colonies	112
Interior	78	Agriculture	44
War	691	Public works	221

Altogether, the great increase since 1875 in the State expenditure has been incurred chiefly under the heads of debt, which in itself absorbs nearly a third of the budget; of the colonies, which have more than tripled their burden on the State; of public works, which are, however, more and more moderating their claims; of public instruction, which has been entirely reorganized; and of war.

Debt.—The public debt is subdivided into funded debt, terminable debt (*dette à terme*), and annuities. The capital of the public debt may be estimated, at the least, at 30 milliards, or £1200,000,000. The loans contracted by the Third Republic alone amount to 13 milliards, or £520,000,000. The costs of the war of 1870–71, which devolved in part on the present *régime*, are estimated at from 9 to 9½ milliards (£360 to £380 millions); and the charges of the colonial wars at nearly a milliard (£40,000,000). The interest on the consolidated debt amounted in 1876 to 743 million francs, in 1884 to 700 millions, in 1894 to 761 millions, and in 1901 to 675 millions. The difference in the amounts for 1894 and 1901 is due to the last conversion, in 1894, of 4½ per cents. to 3½ per cents. The terminable debt, consisting of 3 per cents. redeemable, was set down in 1876 at 116 million francs, in 1884 at 277 millions, in 1894 at 280 millions, and in 1901 at 324 millions. The annuities (*dette viagère*), again, figured in 1869 at 152 million francs, in 1876 at 158 millions, in 1884 at 176 millions, in 1894 at 187 millions, and in 1901 at 226 millions.

Besides this debt, which may be characterized as fixed, there is a floating debt contracted to meet the daily wants of the Treasury, a debt undergoing continuous extinction and reconstitution. In 1891 this floating debt reached the sum of 1077 million francs; in 1893, 953 millions; in 1895, 1282 millions; in 1900, about 1054 millions. It comprises 200,025 different bills, in particular *bons du trésor*, amounting to 100 to 250 millions.

Revenue.—The following table shows the rapid growth of the State revenue of France during the period 1875–1901, the figures for the specified years representing so many millions of francs:—

1875.	1880.	1885.	1890.	1895.	1901.
2705	2956	3056	3229	3428	3554

The revenue of 1901 was derived from the following sources (in millions of francs):—

Direct contributions	482	Customs	438
Taxes assimilated to direct contributions	40	Indirect contributions	649
Registration (*enregistrement*)	554	Sugar	200
Stamps	173	Monopolies	456
Tax on transferable securities (*valeurs mobilières*)	75	Posts telegraphs, and telephones	255
		Domains	55

[1] Since 1st January 1901 Algeria has had a budget of its own.

The following table shows the different parts played by the respective items of taxation in the growth of the State revenue from 1876 to 1901 (in millions of francs):—

	1876.	1884.	1894.	1901.
Direct contributions and taxes assimilated thereto .	412	416	501	522
Registration (of transfers of property, &c.) . .	470	519	548	556
Stamps	154	155	161	173
Tax on investments in public funds or bonds of private companies . . .	35	46	69	75
Customs	225	304	465	438
Indirect contributions . .	603	604	601	649
Sugar	189	171	203	200
Monopolies	352	406	411	456
Posts, &c.	133	163	207	255
Domains	57	43	47	55

Legislation.—During the period between 1875 and 1900 a number of modifications were introduced into the department of taxes. New taxes have been established. By the law of 1889, amended in 1898, a military tax is imposed on young men exempted or partially exempted from military service. This tax has given the revenue an average of 3 million francs yearly. A tax is also levied on velocipedes, yielding, in 1893, 1,350,000 francs. By a law of 1880 a tax, again, is laid on the revenues of religious Congregations, a tax subject to increase. It yields yearly about 3,800,000 francs. Another new tax is that levied, by law of 1893, on bourse operations, bringing to the State revenue some 7 million francs yearly. Then, again, various taxes have been amended in respect of the quotas attached. The assessment on patents was amended in 1889 and 1893, and the big shops have been more heavily taxed than before. The imposts on the revenue from money vested in public funds or private company bonds have been raised from the 3 per cent. fixed by the law of 1872 to 4 per cent. by law of 1890. Succession laws since 1892 have added at least 100 million francs to the yearly proceeds of the customs dues.

Lastly, special mention must be made of the tax laid on house property. From being a distributive impost (*impôt de répartition, i.e.,* fixed as a lump sum by Parliament and then distributed among the arrondissements, communes, and the persons affected) this tax was, by law of 1890, converted into a rating impost (*impôt de quotité—i.e.,* proportional to the revenue estimated to be derived from the buildings).

Projected Reforms.—Of late years the financial system of France has been much criticized. More particularly, repeated attempts have been made to substitute an income tax for the present direct contributions. A Bill in this sense was even brought forward by the Government in 1895. On the other hand, the laws about succession and the liquor law have been modified by the votes of the Chamber of Deputies; but these laws were definitely adopted in 1900 and 1901.

Direct Taxes.—The direct taxes, properly so called, are four in number:—First, the tax on building-property (*impôt foncier sur la propriéte bâtie*), amounting in 1889 to 84 million francs; and the tax on property not built on, amounting in 1900 to 100 millions. Second, the tax on house rent (*contribution personelle mobilière*), consisting, in fact, of two different contributions, one imposing a fixed charge on all citizens alike of each department, the charge, however, varying, according to the department, from 1 franc 50 centimes (=1s. 3d.) to 4 francs 50 centimes (=3s. 9d.); the other, levied on every proprietor or tenant in proportion to the rent of the house he lives in. The total number of properties in France charged in 1900 with the *contribution personelle mobilière* was 9,294,525, 9,193,025 being houses and 101,500 factories, and their lump letting value was 2982 million francs, of which sum 2778 millions was to the account of houses. Third, the contributions on doors and windows, levied in each case on the number of openings, a tax which in 1900 yielded 63 millions. Fourth, the license tax affecting industrial and commercial occupations. It consists of a fixed duty on the total value of one occupation, but varying according to the kind of occupation; and of an assessment in proportion to the letting value of the premises occupied. This tax gave a return in 1900 of 134 million francs, affecting as it did 1,728,200 persons. The department of the Seine by itself yielded 29 million francs, contributed by 174,100 persons. Lozère, on the other hand, at the bottom of the list, shows only 3967 licenses, contributing no more than 60,000 francs. The administration of the direct contributions includes, for the duty of determining the individual quotas, a director to each department assisted by *contrôleurs.* The direct taxes are collected by a *percepteur* residing at the chief town of the canton.

Indirect Contributions.—Under this head are comprised the taxes on "hygienic drinks" (wines and cider), producing 173 million francs; on beer, yielding 27 million francs; and on alcohol, returning to the revenue 300 million francs. There is a whole army of officials employed in the discharge of this service, which is one of the most costly.

Registration.—This tax comprises duties charged on the transfers of property in the way of business (*à titre onéreux*) or sales, bringing in to the Government 205 million francs; on changes in ownership of property effected *à titre gratuit,* in the way of donation or succession, the succession dues alone yield the Treasury 223 million francs yearly. The functionaries engaged in this service are called *conservateurs des hypothèques* and *receveurs.* Some of them are in receipt of high salaries, reaching in the Seine department to as high as 180 and 244 thousand francs.

Departmental Finances.—The French departments, as *personnes morales,* have their own separate budgets. It devolves on them to keep in repair the departmental highways and cross-roads, to support public instruction, and take charge of *enfants assistés.* The departmental expenditure amounts to about 320 million francs, and is met in large part by taxation additional to the four direct contributions.

Communal Finance.—The communes, in the matter of finance, enjoy a still larger autonomy than the departments. Their expenses in 1900, leaving Paris out of the account, amounted altogether to 760 million francs, against 695 millions in 1877. Their indebtedness, moreover, amounts to nearly two milliards. The communal revenue is derived from taxes levied for the superintendence of streets, roads, and buildings (yielding in 1900, 207 million francs), various local taxes, and tolls. Nearly 1500 communes were until 1899–1900 in receipt of revenue from this last source (*octroi*), but since 1st January 1901 the *octroi* has been either finally suppressed or else materially reduced. The gross revenues of the communes, Paris not included, was, in 1900, 181 million francs; with the inclusion of Paris, 333 millions. Next to the capital, the towns drawing the most revenue from the excise imposed on the importation of articles of consumption were Lyons (realizing 11 million francs), Marseilles (11 millions), Bordeaux (6 millions), and Lille (5 millions).

Army.—The recruitment of the army of France is regulated by the law of the 15th July 1889, which, superseding that of 1872, has on the one hand done away with volunteering, and on the other has reduced the period of active service from five to three years. According to the enactment in force, every Frenchman owes his country his personal service for the term of twenty-five years (Titre i.). Every year, in each commune, there is drawn up a list of the young men in it who the year before reached the age of twenty. These men have next to appear before a cantonal revising body (*conseil de révision cantonal*), composed of the prefect or his substitute, a councillor of the prefecture, a councillor-general, a councillor of the arrondissement, a superior officer, a *sous-intendant* (having direction in affairs of pay, provisions, clothing, &c.), the recruiting commandant, and a military doctor. The revising body decide on cases of exemption, of adjournment, and of dispensation. The exempt are young men who by reason of infirmity are unfit either for active or for auxiliary service, to which latter are assigned those in weakly condition included in the yearly contingent. The adjourned are those who, being neither infirm nor weakly, are yet not up to the required standard of vigour. The dispensed, that is, those required to serve only one year, are young men who engage to serve for ten years in a public educational institution; seminarists preparing themselves for the ministry of the Church in one of the recognized confessions; young men who have obtained or are prosecuting their studies with a view to obtaining the licentiate degree in letters or in science, a doctor's degree in law or in medicine, a "prix de Rome" or a prize at the conservatorium of music, or one of various other diplomas specified by the law; young men the practice of whose avocations is necessary to the support of their families, the dispensed in this last case, however, not to amount to more than 5 per cent. of the contingent enlisted for three years.

The soldier must be at least 1 mètre 54 centimètres (60·631 inches) in height (Titre iii.). The law provides for voluntary engagements, *i.e.,* it authorizes young men to anticipate the call to military service, and solicit their incorporation into the army at the age of eighteen years. In such cases, however, they are enrolled for three, four, or five years. The law further provides for the re-enlistment of medalled soldiers, corporals, and non-commissioned officers. Such re-engagements, covering two, three, or five years' effective service, and capable of extension to fifteen years, date from the time of the legal expiry of active service. Soldiers so re-enlisting are entitled to a bounty, to a high daily pay, and at the conclusion of the service to a pension (Titre iv.). The number of the re-enlisted is 16,000.

Effective Strength. — Every French citizen owes his country twenty-five years' service. He passes successively into the active army; into the reserve of the active army, in which he completes two periods of service of twenty-eight days each; into the territorial army and its reserve, in which he completes two periods of thirteen days each. The total peace strength of the active army provided for in the budget was, in 1898 557,000 men, as against 508,000 in 1893, and 488,000 in 1888. The number of conscripts who appeared before the *conseils de révision* was, in 1888, 295,000; in 1893, 330,000; in 1898, 331,000. Of these 331,000, 232,000 passed muster as up to the required standard; 74,000 of them being enrolled for one year, and 158,000 for periods of two and three years. The number of officers, on the other hand, slightly exceeded 28,000. The full war strength of the army of France comprises, according to careful estimates, about 4,250,000 men. Under the law of 1872 the utmost effective strength at disposal in case of mobilization was 3,800,000 men.

Military Organization.—The President of the Republic makes the appointments to all military offices, and may therefore be considered the supreme head of the army, though he does not command it. The command belongs to the Minister of War, who is assisted by the generalíssimo, the actual commander on the field; by the brigade-major (*chef d'état major*), whose business it is to plan the campaign; and by the superior council of war, composed of nine members. The ministry of War is itself divided into branches corresponding to the different services—infantry, cavalry, engineering, commissariat, ammunition, health.

France is divided into two military governments, Paris and Lyons, and into twenty *corps d'armée;* Nancy having been created a new district since the ninth edition was published. Each army corps consists of two divisions of infantry, one brigade of cavalry, one brigade of artillery, one battalion of engineers, and one squadron of the military train, an organization maintained alike in peace and in war.

The active army comprises 163 infantry regiments of the line; 30 battalions of chasseurs-à-pied, stationed preferably in the Alps and the Vosges; 4 regiments of Zouaves; 4 regiments of tirailleurs algériens; 2 régiments étrangères, constituting the légion étrangère, recruited by way of enlistment; 5 battalions of African light infantry; 13 regiments of cuirassiers, 31 of dragoons, 21 of chasseurs, 14 of hussars, 6 of chasseurs d'Afrique, 4 of Spahis; 16 battalions of foot artillery; 40 regiments of horse artillery; 7 regiments of engineers; and 19 squadrons of train. There is further at Paris the légion de la Garde Républicaine, the régiment des sapeurs pompiers, also for the whole of the territory, and 19 legions of Gendarmerie.

In 1898 the infantry of the line were numbered at 273,000 men; the Zouaves at 13,000; the tirailleurs algériens at 15,000; the légion étrangère at 10,000; the chasseurs-à-pied at 29,000; the light infantry at 8000—or some 348,000 men as the total strength. The dragoons, cuirassiers, chasseurs, and hussars made up 66,000 men; the chasseurs d'Afrique and Spahis, 9000—or a total of 75,000. The foot artillery mustered 14,000 soldiers, and the horse artillery 64,000, to which had to be added 4000 artillery artificers—a total of 82,000. The engineers were set down (1898) at 15,000, and the train at 13,000. There are various other corps forming the complement.

According to the budget for 1900, the total effective of the French army was 539,515 men, exclusive of 25,693 for the gendarmerie and Garde Républicaine. The total number of officers was in addition 29,740.

The mean strength of a regiment of the line stands at about 1800 men; that of a regiment of cavalry at 850; that of a regiment of mounted artillery at 1600.

Military Schools.—The higher military school is intended for the training of staff officers, who are said to be "brevetés." It receives students who have passed a competitive examination at which officers of all arms are represented. It enrols yearly 70 to 90 new officers, whom it keeps in training for two years. The function of the polytechnic school (*École polytechnique*) is to prepare artillery and engineer officers. It admits yearly 225 students, the period of whose training is two years. At the end of this course, those who have gained inclusion in the first class are free to enter the corps des ingénieurs de l'état (roads and bridges, mines, &c.). The military school of St Cyr, receiving annually 450 young men, has the task of training infantry and cavalry officers. Its course of study is also for two years. Other military schools are the military prytaneum of La Flèche, the artillery and engineer school at Fontainebleau, the cavalry school at Saumur, an ammunition school, a military medical and pharmaceutical school, at the Val de Grâce in Paris, l'école du service de santé militaire at Lyons, the school of commissariat at Vincennes, an école normale de gymnastique, shooting artillery and pyrotechnic schools, a military infantry school at St Maixent, a school of artillery at Versailles, and various preparatory schools for soldiers' children.

Fortified Places.—The region of the north of France, along a frontier of 341 miles, is defended by Dunkirk, Calais, Lille, Valenciennes, and Maubeuge, fortresses of the first class; the entrenched camp of Laon, first class; La Fère, second class; Paris, third class. The Lorraine frontier on the north-east is defended by the entrenched camps of Toul and Verdun, first class; Reims, second class. The Vosges frontier, 93 miles in length, is protected by the first-class fortresses of Épinal and Toul, and the second-class fortification of Langres, on the Plateau de Langres. The Jura frontier, 180 miles long, is guarded by the stronghold of Pontarlier and the entrenched camp of Besançon, as also by the second-class forts of Dijon, planted on the escarpments of the Côte-d'Or. The frontier at the Alps is 427 miles long. Its fortifications are Albertville, Grenoble, Briançon, and Nice. And an enemy, if he succeeded in forcing the valleys of the Isère and the Durance, would still find himself confronted by the great entrenched camp of Lyons, resting against the mountains of Lyonnais. On the south, the Pyrenean frontier, extending 354 miles, is fortified only at its two extremities — Perpignan and Montlouis in the east, Bayonne in the west.

Navy.—The personal establishment of the French navy is recruited in part by voluntary enlistment, in part by appropriation to the naval service of a proportion of the yearly army contingent, in part by "maritime inscription," in which are enrolled the names of all lads and men from eighteen to fifty years of age engaged in fishing or in navigation. The number thus enrolled was, in 1899, 219,000, of whom the quarter of Marseilles alone furnished 11,800.

Personnel.—The officers of the French navy in 1899 included 15 vice-admirals, 30 rear-admirals, 125 *capitaines de vaisseau*, 215 *capitaines de frégate*, 754 lieutenants, 531 ensigns, and 219 cadets —in all 1889 officers. The rank and file was made up in 1899 of 1352 boatswains (*premiers maîtres*), 4910 boatswains' mates (*seconds maîtres*), 8921 *quartiers maîtres*, and 29,161 sailors; giving a total of 44,344 men. Lastly, the infantry in the service of the navy consists of thirteen regiments, with 1642 officers and 25,110 men; the artillery of two regiments, with 690 officers and 7411 men.

The French fleet on the 1st January 1899 consisted of—

- 34 armoured battleships of 341,747 tons, 274,119 horse-power, and 1425 guns;
- 5 armoured cruisers of 29,130 tons, 18,935 horse-power, and 126 guns;
- 7 coast-defence vessels of 33,084 tons, 21,513 horse-power, and 68 guns;

8 armed cruisers (of a different class from the above, 5) 2 fast cruisers 6 cruisers, 1st class 16 cruisers, 2nd class 18 cruisers, 3rd class	having a total tonnage of 228,000, a total horse-power of 286,000, and 1334 guns.

The navy further included 10 torpedo-boat destroyers, 19 gunboats, 22 advice boats, 24 transports, 14 sloops, 10 torpedo despatch boats, 263 torpedoes, and 3 submarine boats.

Altogether, the entire French fleet amounted to 461 vessels of 701,782 tons, 1,025,793 horse-power, with 3766 guns; and, in process of construction, 1 battleship, 8 cruisers, 5 torpedo-destroyers, &c. The programme of new construction to be continued or undertaken in 1899 comprised the following ships building in dockyards:—7 battleships, 14 first-class armoured cruisers, 4 fast cruisers, 1 second-class protected cruiser, 2 third-class protected cruisers, 1 first-class sloop, 2 torpedo-gunboats, 2 gunboats, 1 aviso (advice)-transport, 8 submarine boats, 6 first-class torpedo boats, 10 torpedo cruisers, 11 sea-going torpedo boats of 150 tons, 22 first-class torpedo boats of 86 to 90 tons, 11 torpedo boats of 85 tons, and 6 small torpedo boats—at an estimated cost, altogether, of £8,724,247. The expense of naval construction amounted from 1871 to 1880 to 245 million francs; from 1881 to 1890, to 387 millions; from 1891 to 1899, to 685 millions.

Naval Schools.—The *École supérieure de Marine*, corresponding to the *École supérieure de Guerre*, was after a short existence suppressed. The *École Navale* is intended for the training of officers.

Lads from fourteen to seventeen years of age are admitted to this institution, which has its seat at Brest. After completing their course in this school, the young officers go to pass a year on the *frégate École*. In addition there are schools of naval medicine at Toulon, Brest, and Rochefort, a school of naval warfare at Paris, and a torpedo school (*École des Torpilles*) at Toulon, &c.

Fortifications on the Coast.—Fortified places on the coast are those on the North Sea, namely, Dunkirk and Calais (extending along 43½ miles); those on the English Channel, protecting a stretch of 716 miles—at Boulogne, le Havre, Cherbourg, Granville, and St Malo; those extending 535 miles along the Atlantic—at Brest, Lorient, St Martin de Ré, Île d'Aix, Oléron, Rochelle, Rochefort, Estuary of the Gironde, Socoa; those stretching 388 miles along the Mediterranean coast—at Port Vendres, Cette, Toulon, Marseilles, St Tropez, Antibes, Villefranche.

Colonial Bases of Operation.—*Points d'appui* in the French colonies, serving as bases of operation for the Atlantic, Pacific, and Indian Ocean divisions of the fleet, have, by decree of 1898, been established at Fort de France (Martinique), Dakar (Senegal), Cape St Jacques (Cochin-China), Port Courbet (Tongking), Nouméa (New Caledonia), Diégo Suarez (Madagascar), Saintes (Guadeloupe), Port Phaeton (Tahiti), Libreville (Congo), and Obock.

2. Production and Industry.

Agriculture.—Agriculture figures in the budget at more than 44 million francs, and has been (by decree of 1881 and 1882) distributed into the four divisions of forests, breeding-stud, agriculture, and agricultural hydraulics. Encouragements of every kind, in the shape of premiums, subventions, and indemnities, are given to the rearing of cattle, viticulture, sericulture, the culture of flax and hemp, &c.

The most important movement, however, made in the interest of the agriculture of France since 1875 has been the marked growth of agricultural education. Whereas in 1870 there were but sixty institutes of agricultural tuition and fourteen professorial chairs, the number of such institutes in 1900 was 107, and of professorial chairs, 268. Among the schools imparting superior instruction, there have further to be enumerated an agronomic institute, three veterinary schools, and one school of forestry. The secondary agricultural schools include three national schools of agriculture, one dairy school, one school of industrial cultures, and one of horticulture. Third-class schools include forty-eight practical schools (*Écoles pratiques*), fourteen *fermes Écoles*, and twenty other establishments. Account has further to be made of five *chaires de facultés*, ninety departmental and 131 special professoriates, sixty-six agronomic stations, &c.

Agricultural Area.—According to the decennial official returns of 1892, there were 170,817 square miles laid out in agriculture (crops, grass, forests, and fallow), of which 153,506 square miles denoted private property. The arable land alone amounted to 99,503 square miles.

Cereals.—The area laid out in 1899 in cereals amounted to 28 per cent. of the entire territory. The following table shows the different acreages in France laid out in the cereal crops specified in 1888 and 1899:—

	1888.	1899.
	Acres.	Acres.
Wheat	17,235,991	17,141,806
Mixed Corn	756,779	553,280
Rye	4,023,240	3,577,683
Barley	2,207,439	1,990,827
Oats	9,223,666	9,734,334
Buckwheat	1,501,484	1,447,225
Maize	1,411,494	1,388,481

The mean yearly production of the different cereals for the periods specified was, in millions of bushels:—

	1876–85.	1886–95.	1896–97.
Wheat	279·647	284·563	283·937
Rye	68·684	64·625	56·925
Barley	50·586	47·179	42·281
Mixed Corn	17·107	12·188	7·370
Oats	221·974	239·992	236·780
Maize	26·815	27·310	29·466
Buckwheat	27·769	26·340	24·640

The production of wheat in 1899 was 354,433,000 bushels; mixed corn, 11,604,700 bushels; rye, 65,072,500 bushels; barley, 43,060,400 bushels; oats, 263,030,700 bushels; buckwheat, 22,372,500 bushels; maize, 24,845,500 bushels.

The following table shows in bushels the mean annual production of the different crops per hectare (2·471 acres) for the periods specified, as also the production for 1898:—

	1876–85.	1886–95.	1899.
Wheat	49·44	45·10	53·06
Rye	45·04	40·96	42·68
Barley	54·25	50·87	54·64
Mixed Corn	49·14	44·55	48·57
Oats	69·16	62·70	66·79
Maize	49·96	47·85	38·16
Buckwheat	47·54	45·37	37·19

The entire cereal production in 1899 was valued at 3396 million francs, a total much below that of 1882, which was valued at 5362 millions.

Potatoes and Beetroot.—The potato crop covered in 1899, 3,863,082 acres, against 3,651,036 acres in 1892. The weight of potatoes raised in 1899 amounted to 241,938,802 cwts., valued at £24,638,193. Mangold-wurzel covered in 1899, 11,045,213 acres, and its production amounted to 207,252,460 cwts., valued at £8,504,390. Beetroot (sugar) occupying in 1898 about three-fifths of the ground covered by, and producing about five-sevenths of the amount produced by, mangold-wurzel, yielded the value of £7,424,593.

Clover, &c.—The following table shows the acreages, the amounts produced, and the values of the *prairies artificielles* in 1899:—

Prairies Artificielles.	Acreage.	Amount of Produce in Cwts.	Value in £.
Trefoil	3,041,520	81,099,126	7,714,134
Lucerne	2,221,800	70,234,720	7,737,683
Sainfoin	2,504,400	45,678,640	4,638,160
Meadows and permanent pasture	15,842,400	384,200,097	39,480,000

Industrial Cultures.—The subjoined table shows the respective averages, amounts produced, and values of the various industrial crops in 1899:—

	Acreage.	Bushels of Produce.	Value in £.
Colza	142,236	2,298,272	778,661
Rape	14,248	208,927	62,355
		Cwts.	
Hemp	80,061	427,838[1]	630,005
Flax	46,537	432,515[1]	407,875
Tobacco	42,092	449,128	839,813
Hops	7,728	76,120	166,183

Vineyards.—In 1899 there were 4,504,320 acres covered with vineyards, against 4,446,000 acres in 1892, and 5,424,120 acres in 1882. The great invasion of the phylloxera lasted from 1881 to 1892. If the area now planted in vineyards is less by nearly 2 million acres than it was in 1857, viticulture has nevertheless fought a stubborn battle against the scourge. Certain departments, such as Hérault, Gironde, Aude, and Gard, have been under the necessity of completely renewing their plants. The production of wine in France, 738,782,000 gallons in 1882, 638,814,000 gallons in 1892, 592,174,000 in 1895, 702,746,000 in 1897, amounted to 936,200,000 gallons in 1899. The departments yielding the largest contribution of wine in 1899 were Aude, with 117 million gallons; Gard, with 79 million gallons; Hérault, with 264 million gallons; Pyrénées-Orientales, with 64 million gallons. Gironde and Côte-d'Or, whose Bordeaux and Burgundy wines are in special request, figure in the list of wine-producing places, the former with only 62 million gallons, the latter with 12 million gallons. The average production of wine per hectare (2·471 acres) reached its maximum in 1899 in the Seine (890 gallons), Hérault (1461 gallons), and Bouches-du-Rhône (1740 gallons). The minimum wine production per hectare, on the other hand, was furnished by Corrèze, whose wine contribution was 102 gallons a hectare (or nearly 48 gallons an acre), and Alpes-Maritimes, which yielded 129 gallons per hectare. The average production per hectare throughout France was 578·3 gallons (134·9 gallons an acre).

[1] Seed and fibre.

The total value of the wine production, which amounted to 905 million francs in 1892, 755 millions in 1897, was 1,193,056,820 francs in 1899.

Fruits.—The value of the total crop of chestnuts in the country in 1899 was £1,450,223; walnuts, £533,202; olives, £699,998; cider-apples, £5,190,513; plums, £306,758; mulberry leaves, £416,014.

Silk Culture.—The sericultural production in 1898 amounted to 15,385,376 lb of cocoons; 156,202 lb of cocoons were exported, valued at £33,184, and 7,812,867 lb of raw silk, valued at £5,388,866.

Live Stock.—On the 31st December 1899 the number of farm animals was 2,917,160 horses, 204,750 mules, 357,820 asses, 13,550,880 cattle (including bulls, oxen, cows, and calves), 21,357,660 sheep, 6,305,200 pigs, 1,504,390 goats. According to the census of 1892, there were 47,471,178 farm animals of the value of 5200 million francs; viz., 2,794,529 horses, 217,083 mules, 366,895 asses, 13,708,997 cattle, 21,115,713 sheep, 7,421,073 pigs, and 1,845,088 goats. The census of 1892 valued the horses at 1166 million francs, the asses at 34 millions, the mules at 80 millions, the cattle at 3 milliards, the sheep at 466 millions, the pigs at 500 millions, the goats at 28 millions. Poultry in 1897 figured at the number of 85 millions (54 millions cocks and hens), valued at 166 million francs. Of the products of farm animals in 1899, the milk was estimated at £50,610,409, the wool at £2,230,939, the honey at £451,201, and the wax at £198,030.

Total Agricultural Return.—The gross revenue of the entire agriculture of France, without deduction of expenses, rent, interest, &c., oscillated in 1899 between 11 and 12 milliards of francs. According to the statistics of 1892, the gross production was valued at 314 francs per hectare for cereals, 627 francs per hectare for industrial cultures, 301 for forage plants, and 222 for grass.

Agricultural Allotments.—The decennial statistics of 1892 gave the number of agricultural allotments of all sorts and sizes at 4,792,814, of which 3,387,245 were in the immediate hands of the proprietors, who accordingly engrossed 71 per cent. of the agricultural holdings of France. The remainder, 1,405,569, or 29 per cent. of the total, were cultivated by farmers and *métayers*, *i.e.*, farmers giving part of the produce as rent. The number of proprietary agriculturists in 1892 had decreased by 138,097 from the figure of 1882, which was 3,525,342. The number of farmers and *métayers*, on the other hand, had increased by 95,665. Of the agricultural properties, again, the very small ones of less than 1 hectare (2·47 acres) covered, in 1892, 2·67 per cent. of the entire agricultural land. Small properties of 1 to 10 hectares (2·47 to 247 acres) covered 22·80 per cent. Medium properties of from 247 to 988 acres occupied 28·98 per cent. Large properties (above 988 acres) engrossed 45·55 per cent. of the whole. The figures of 1892, compared with those of 1882, show a slight increase in the number of very small properties (of less than 1 hectare). The small and medium properties, on the other hand, show a decline while the large properties have added to their number.

Agricultural Machines.—In 1892 the number of agricultural machines and motors of every kind was 4,321,000.

Value of French Soil.—From 1882 to 1892 the market value of land markedly declined. The average price of arable land per hectare fell from 2000 to 1600 francs; of viticultural land per hectare, from 2300 to 2100 francs; of meadow land, from 2·900 francs to 2·450 francs.

Sea Fisheries.—The products of the fishing industry were set down for 1896 at the value of 102 million francs, of which 93 millions was to the account of boat-fishing and 9 millions to the account of fishing from land. The Iceland fishing yielded in 1896, 28,600,000 lb, of the value of 6½ million francs; the Newfoundland fishing yielded 40,865,000 lb, valued at 7 million francs. The herring fishery for 1896 was set down at 100,100,000 lb, valued at 9,300,000 francs; the mackerel fishing at 55 millions lb, of 5 million francs' value; sardines at 39,600,000 lb, of 9 million francs' value; tunny at 112,200,000 lb, and 2½ million francs' value; salmon at 550,000 lb, and 1 million francs' value. The oyster culture yielded 2,378,200 lb of oysters, valued at 13,700,000 francs. The equipment of fishing craft has been encouraged, always with considerable success, by means of bounties, and in the year named 1222 undecked vessels and boats gained bounties for being fitted out as fishing craft.

Mineral Production.—The total mineral production, including the yield of its quarries, amounted in 1898 to 81,467,444 tons, of the value, at the place of production, of 640,659,439 francs.

Coal.—The output of combustible material (coal, anthracite, and lignite) in 1898 amounted to 32,356,000 tons, of the (pit-mouth) value of 363,153,417 francs. To this total (including anthracite) coal contributed 31,826,000 tons, lignite figuring with only 530,000 tons. In 1899 the output of coal amounted to 32,500,000 tons. The increase in the production of coal from 1870 to 1899 is shown by the following figures of output, which denote the number of tons:—

1870.	1880.	1890.	1897.	1899.
13,300,000	19,300,000	26,100,000	30,350,000	32,500,000

The output of coal in France, accordingly, more than doubled within the period 1870–99. The supply still, however, comes far short of the demands of industry, which in 1898 consumed nearly 43 million tons, valued at 842½ million francs. The import of coal continues therefore to be very considerable, amounting in 1898 to 11,917,000 tons.

The following table shows the respective contributions of the different basins of France to the total output of coal in 1898:—

Basins.	Mines in Work.	Output in Tons.
Nord and Pas-de-Calais (Valenciennes, Le Boulonnais)	35	19,287,000
Loire (St Étienne and Rave-de-Gier)	46	3,912,000
Bourgogne and Nivernais (Le Creusot, Blanzy, Épinac, &c.)	19	2,341,000
Gard (Alais, Aubenas, le Vigan)	21	1,974,000
Tarn, Aveyron (Aubin, Carmaux, &c.)	19	1,781,000
Bourbonnais (Commentry et Doyet, St Eloy)	14	1,123,000
Auvergne (Brassac, Champagnac, &c.)	13	464,000
Alps (le Drac, Maurienne, &c.)	50	217,000
Vosges (Ronchamp)	2	217,000
Hérault (Graissessac)	6	201,000
Creuse and Corrèze (Ahun, Aublac, &c.)	5	196,000
West (Le Maine, Vouvant, and Chantonnay)	9	119,000

The different coal-mining concessions granted by the Government numbered on the 1st January 1899, 634, extending over 1,364,724 acres, comprised in sixty-four departments. The total number of persons (men, women, and young persons from thirteen to sixteen years of age) engaged in the working of the coal mines in 1898 amounted to 148,600. The average daily wage of the miner in 1898 was 4 francs 23 centimes (about 3s. 6d.). The mean price of the (metric) ton of coal at the pit's mouth was, in 1898, 11 francs 22 centimes (9s. 4d.), as against 13 francs 45 centimes (11s. 2½d.) in 1877. At the centres of consumption 19 francs 86 centimes (16s. 6½d.) in 1898, as against 22 francs 50 centimes (18s. 9d) in 1877.

Peat was extracted in 1898 to the amount altogether of 104,000 tons, of the value of 1,507,000 francs, the department of the Somme alone contributing 33,000 tons.

The iron ore yielded by the mines amounted in 1898 to 4,731,000 tons, of the value, at the place of production, of 16 million francs, against 3,300,000 tons in 1883, and 3,000,000 tons in 1873. The following table shows the departments contributing the greatest quantities to this production, and the respective amounts of their contribution in 1897:—

	Tons.		Tons.
Meurthe-et-Moselle	3,804,000	Lot-et-Garonne	33,000
Saône-et-Loire	146,000	Ariège	26,000
Haute-Marne	146,000	Cher	19,000
Calvados	101,000	Isère	15,000
Pyrénées-Orientales	75,000	Tarn	10,000
Gard	61,000	Aude	10,000
Ardèche	46,000	Var	8,000
Aveyron	39,000		

There were employed 8200 persons in 1898 in iron-mining, at an average daily wage each of 4 francs 34 centimes (3s. 7½d.). The ore sold on an average at 3 francs 39 centimes (3s. 8d.) a ton. Other metallic seams yielded in 1898 altogether 458,200 tons, valued at nearly 16 million francs—argentiferous lead, 320,000 francs; zinc, 7 millions; pyrites, 4 million francs; manganese, 831,000 francs; antimony, 325,000 francs; arsenic, 109,000 francs. The mines of rock-salt, found chiefly in Lorraine and Franche-Comté, supplied, in 1898, 304,000 tons, valued at 4,371,000 francs.

The French quarries yielded in 1898, 42½ million tons of stone and other material, valued at 231,800,000 francs. Of this total value, 152 millions was to the account of building materials — building stone being valued at 49; gravel at 7; limestone at 30; cement, 26; plaster, 12; slate, 20. The industrial materials supplied by the quarries counted for 9 million francs; agricultural for 24 (phosphates alone, 15); paving materials, 36; and ornamental, 10 (marble, 5). The persons engaged in the open-air quarries numbered 108,152, and those in the subterranean quarries, 22,568.

Out of 294,362 persons employed in the coal and other mines and in quarries in 1898, 1722 met with accidents, 342 of them fatal.

Manufactures.—The steam apparatus in use in the various industries in 1898 comprised, exclusive of those employed in railways and boats, 70,755 engines, of 1,441,336 horse-power; 85,839 steam-boilers, and 30,175 receivers.

The increase in the amount of industrial horse-power at work between 1880 and 1898 was as follows:—

1880.	1885.	1890.	1895.	1897.	1898.
544,000	683,000	852,000	1,163,000	1,330,000	1,441,336

The number of industrial establishments, with the respective amounts of horse-power employed by them, in 1898 was as follows:—

Branches of Industry.	No. of Estabs.	No. of Steam-Engines.	Horse-Power.
Textile and Clothing	6,661	7,456	315,190
Metallurgic	5,114	8,454	260,811
Building	7,440	8,649	217,374
Mining and Quarrying	3,167	5,852	197,262
Alimentary	9,605	11,183	150,867
Agricultural	15,976	19,997	120,458
Chemical and Tanning	3,153	3,866	66,447
Paper, Printing, Furniture, &c.	3,464	3,862	62,649
State Services	483	1,436	50,278
Total	55,063	70,755	1,441,336

Metallurgy.—The total production of the industry in metals amounted in 1898 to 4,524,329 tons, valued at 610,680,500 francs (£24,427,220). Of this amount 4,465,000 tons, of the value of 560,615,000 francs (£22,424,620), was on account of iron and steel; and 59,329 tons, of the value of nearly 50 million francs (£2,000,000), on account of other metals. The production in pig-iron alone amounted to 2,525,000 tons, valued at £6,371,680; finished iron, 766,000 tons, of the value of £5,044,360; wrought steel, 1,174,000 tons, valued at £11,008,560. The products of the zinc industry amounted in 1898 to 37,155 tons, valued at nearly 18 million francs; lead, 10,920 tons, valued at nearly 3,700,000 francs; copper, 7834 tons, valued at 11 million francs; nickel, 1540 tons, valued at 4,600,000 francs; aluminium, 565 tons; antimony, 1226 tons. Fine gold was also produced to the amount of 587 lb, and silver to the amount of 199,282 lb.

The following figures show the production in tons of pig-iron for the years specified:—

1880.	1885.	1890.	1895.	1898.
1,725,000	1,631,000	1,734,000	2,004,000	2,525,000

To the total production of pig-iron in 1898 the department of Meurthe-et-Moselle contributed 1,551,000 tons, more than six-tenths of the whole. The department producing the next greatest amount of pig-iron, though at a long interval, was Nord, with 277,000 tons; next, with amounts varying from 106,000 to 75,000 tons, come Saône-et-Loire, Pas-de-Calais, Landes, Gard, and Loire-Inférieure. Twenty-two departments had blast-furnaces at work. To the total production of finished iron, amounting in 1898 to 766,000 tons, Nord alone contributed 297,000 tons; Ardennes, 90,000; Haute-Marne, 68,000; Meurthe-et-Moselle, 45,000; Saône-et-Loire, 47,000. In the total steel production of 1898, Bessemer and Martin steel ingots figured to the amount of 1,433,717 tons, of which Meurthe-et-Moselle contributed 545,333 tons; Nord, 218,000 tons; Saône-et-Loire, 142,919 tons; Pas-de-Calais, 79,964; Loire-Inférieure, 71,902. The most important departments for the production of wrought steel were Nord, producing in 1898 263,000 tons, Meurthe-et-Moselle (233,000), Saône-et-Loire (112,000), Loire (75,000), Pas-de-Calais (64,000). The lead manufactures have been carried on principally in the department of Loire-Inférieure; zinc manufactures in Nord, Aveyron, and Pas-de-Calais; copper in Ardennes, Pas-de-Calais, and Vaucluse. The number of workmen engaged in the manufacture of pig-iron in 1898 was 11,400; finished iron, 24,900; wrought steel, 35,000; in the manufacture of metals other than iron and steel, 3400, leaving out of account the much more numerous *personnel* occupied in secondary elaborations. The iron manufacture has declined since 1878, when it yielded 843,000 tons. In 1882 the iron production reached 1,073,000 tons. From 1888 to 1893 its average yield was 825,000 tons a year. The steel production of 1898 (1,174,000 tons) compares favourably with that of 1895 (715,000 tons), that of 1890 (582,000), that of 1885 (554,000), and that of 1880 (389,000).

Textiles.—The textile industry engrossed, in 1898, 22 per cent. of the total power of the steam-engines at work. Cotton spinning counts 5,300,000 spindles and more than 100,000 operatives. The consumption, figuring at 500,000 quintals (each 220½ lb) in 1877, 675,000 quintals in 1887, amounted to 1,400,000 in 1897. The cotton industry is distributed in three principal groups. The one longest established is that of Normandy, having its centres at Rouen, Havre, Evreux, Falaise, and Flers, comprising 250 factories, 2,200,000 spindles, and 20,000 looms. The group in the north of France sprang up about the middle of the 19th century, and has its centres at Lille, Tourcoing, Roubaix, St Quentin, which last manufactures cambric muslin, and Amiens, in which the manufacture of fustian is developed. More than 1,500,000 spindles are at work in the departments of Nord, Pas-de-Calais, Somme, and Aisne. Lastly, there is the Vosges group, which has experienced a large extension since the loss of Alsace-Lorraine, and now counts 900,000 spindles around Belfort, Épinal, St Dié, and Remiremont. Secondary groups are those of Nantes, Cholet, and Laval in the west, Troyes in Champagne (with 80,000 spindles), and Tarare in Lyonnais.

The *linen and hemp* industry employs 65,000 operatives, working 45,000 looms. It has its seat in the departments of Nord, Somme, Sarthe, and Mayenne.

The *woollen* industry comprises more than 2000 establishments and 120,000 employees. The number of its spindles exceeds three millions. In consequence of the introduction of steam power the number of persons employed has since 1865 been reduced by 120,000. The woollen manufacture is most extensively carried on in the north, where its centres are Roubaix, Tourcoing, Fourmies, disposing of nearly 1,800,000 spindles. Of second rank are Reims and Sedan in the Champagne group of wool-manufacturing places. The department of Marne alone counts 275,000 spindles. Notable also are Tarn, with 75,000 spindles, Elbeuf and Louviers in Normandy.

The *silk* industry engages more than 110,000 persons in the south-eastern departments of Drôme, Ardèche, Gard, Rhône, Loire, and Isère, and its production amounts to the annual value at least of 600 million francs. Lyons owes its prosperity to its enormous manufacture of silk stuffs of every kind. According to the Lyons Chamber of Commerce, the silk production of Lyons in 1899 amounted to the value of 415 million francs, which was also the value of 1898, while its production of pure silk in 1899 exceeded that of 1898 to the value of 700,000 francs. St Étienne is specially noted for its manufacture of ribbons.

The *sugar* industry has advanced even to the point of over-production. To insure the export of its products, a complicated system of bounties has been instituted. Sugar refineries are naturally to be found in the departments of the north, in which the culture of beetroot is general—Nord, Pas-de-Calais, Aisne, Oise, Somme. Refineries have also been set up at the seaports of Nantes, Bordeaux, Marseilles, Dunkirk, and Havre, which, however, since 1893 suffered from a severe sugar crisis. The sugar industry in 1898–99 counted 340 works, employing regularly 42,811 men, 3614 women, and 2186 children, and occasionally over 8000 extra hands. The yield of sugar, 347,785 metric tons in 1887–88, 593,647 tons in 1895–96, and 730,067 tons in 1897–98, amounted in 1898–99 to 737,902 tons, and in 1899–1900 to 805,421 tons.

Alcohol.—To the substances from which alcohol is distilled, grain contributes 18 per cent. of the total product; molasses, 32 per cent.; beetroot, 34 per cent.; and grapes, 2 per cent.; the rest being distilled from fruits, &c. The production amounted to 2,068,000 gallons in 1850, 34,782,000 gallons in 1880, 48,708,000 gallons in 1890, and 48,576,000 gallons in 1898. The consumption of alcohol passed from 2·57 pints per head in 1850 to 3·99 pints in 1860, 4·08 pints in 1870, 4·65 pints in 1880, 7·67 pints in 1890, 7·53 pints in 1897, 7·56 in 1898. The departments producing the most alcohol are Nord (16,208,300 gallons in 1898), Pas-de-Calais (7,370,000 gallons), Seine-Inférieure (2,928,000 gallons), Aisne (6,204,000 gallons).

Beer.—The most important breweries are in the north, at Lille, Cambrai, and Dunkirk, and in the east at Nancy. Since 1892 a very considerable number have also been established around Paris, Lyons, and Marseilles. The production, 66 million gallons in 1830, had increased to 264 millions in 1899.

Trade Unions.—These associations of workmen, authorized in 1884, have since developed very rapidly. In that year numbering only 68, by 1890 they had grown to the number of 1006, including 139,962 members; in 1895 they counted 2163, with a membership of 419,781; and in 1899 they counted 2695 associations, with a membership of 492,647. These figures refer exclusively to associations of workers. If to them be added the unions of employers, mixed unions, and agricultural unions, the total number of trade-unions in 1899 was 7081, with 1,192,260 members. There were in 1899, 65 *Bourses du Travail*, or Federations of trade-unions, with 239,449 members.

Wages.—Taking into account all the different industries, the average daily wage per workman was, according to official returns, in Paris 2s. 11d. from 1840 to 1845, 3s. 9d. from 1860 to 1865, and 5s. 1½d. from 1891 to 1893. In the provinces, the average daily wage per workman for these three periods was respectively 1s. 8½d., 2s. 3½d., and 3s. 4d. The average daily wage of the female worker for these periods was respectively in Paris 1s. 3½d., 1s. 5d., and 2s. 6d.; in the provinces, 10d., 1s. 1d., and 1s. 10d.

Commerce.—After, in 1860, embarking in free trade to the largest extent, France has gradually turned round towards protectionism; this system triumphed in the Customs Law of 1892, which imposed more or less considerable duties on imports—a law associated with the name of M. Méline. While raising the taxes both on agricultural products and manufactured goods, this law introduced, between France and all the Powers trading with her, relations different from those in the past. It left the Government free either to apply to foreign countries the general tariff or to enter into negotiations with them for the application, under certain conditions, of a minimum tariff. The *régime* of protection was further accentuated by raising the impost on corn from 5 to 7 francs per hectolitre (2¾ bushels). This system, however, against which a powerful party wages war, has at various times undergone modifications. On the one hand it became necessary, in face of an inadequate harvest, to suspend in 1898 the application of the law on the import of corn. On the other hand, in order to check the decline of exports and exercise the baleful effects of a prolonged customs war, a commercial treaty was in 1896 concluded with Switzerland, carrying with it a reduction, in respect of certain articles, of the imposts which had been fixed by the law of 1892. An accord was likewise in 1898 effected with Italy, which since 1886 had been in a state of economic rupture with France. Lastly, in July 1899, an accord was concluded with the United States of America. Almost all other countries, moreover, share in the benefit of the minimum tariff, and profit by the modifications it may successively undergo.

The *general* commerce with foreign countries, namely, of all goods entering and leaving France, amounted in 1861 to the value of 5745 million francs, in 1880 to 10,725 millions, in 1885 to 8886 millions, in 1890 to 10,292 millions, in 1895 to 9508 millions, and in 1897 to 9941 millions. In 1899 the general commerce figured at 11,381 million francs—an increase of 1440 millions on the amount of 1897, and of 1947 millions on the quinquennial average of 1894–98. Of the 11,381 million francs representing the general trade of France in 1899, the imports engrossed the larger half, namely, 5848 millions, *i.e.*, 710 millions more than in 1897, the exports being valued at 5533 millions, or 990 millions less than in 1897.

The *special* commerce of France, on the other hand, including, namely, the imports for home use and the exports of home produce, amounted in 1899 to the value of 8670 million francs, against a value of 7354 millions in 1897.

The fluctuations undergone by the special commerce of France in the course of the twenty-three years from 1876 to 1899 are shown in the following table:—

Year.	Imports for Home Use (in Millions of Francs).	Exports of Home Produce (in Millions of Francs).	Imports and Exports.
1876	3988	3575	7563
1880	5033	3467	8500
1885	4088	3088	7196
1890	4437	3753	8190
1895	3720	3374	7094
1897	3956	3598	7554
1898	4472	3511	7983
1899	4518	4152	8670

Divided in three classes, the imports for the years specified were, in millions of francs, as follows:—

	1892.	1895.	1897.	1898.	1899.
Food Products	1400	1036	1029	1506	951
Raw Products	2172	2101	2319	2348	2839
Manufactured Goods	615	583	608	618	728
Total	4187	3720	3956	4472	4518

The corresponding exports were:—

	1892.	1895.	1897.	1898.	1899.
Food Products	759	591	721	663	675
Raw Products	822	874	944	932	1210
Manufactured Goods	1879	1909	1933	1916	2267
Total	3460	3374	3598	3511	4152

The principal articles of import were, in millions of francs:—

Articles.	1892.	1895.	1897.	1899.
Raw Wool	319	308	343·7	467·4
Wine	305	212	280·3	267·4
Cereals	487	162	247·4	143·9
Raw Silk	258	226	266·4	370·6
Coal and Coke	185	167	189·5	258·2
Timber and Wood	103	130	154·6	157
Raw Cotton	207	167	205·7	177·6
Oil Seeds	154	157	135·6	166·1
Raw Hides	147	135	116·5	139·6
Coffee	145	177	105·4	89·6
Ores	64	49	62·7	87·9
Cattle	55	112	41·1	32·1
Sugar, Colonial	37	26	32	32·3
Machinery	55	59	67·6	103·6
Flax	61	60	51·4	56·1
Textiles, Woollen	56	42	40	40·7
Textiles, Silk	62	50	52	65·4
Textiles, Cotton	39	34	36·3	43·8
Horses	18	38	39·6	28·7
Fish (Sea)	32	38	32·9	36·6
Leather	24	28	26	32·9

The principal articles of export for the same years, in millions of francs, were:—

Articles.	1892.	1895.	1897.	1899.
Textiles, Woollen	329	323	265·5	264
Textiles, Silk	249	271	270·9	278·3
Textiles, Cotton	96	118	119·3	174·3
Wine	214	222	232·5	210·2
Raw Silk and Yarn	132	126	117·7	179·9
Raw Wool and Yarn	120	153	172·2	271·7
Small Ware	157	154	160·3	183·7
Leather	114	105	102·8	130·4
Leather Goods	112	83	69·4	75·9
Linen and Clothes	130	96	95·4	142·1
Metal Goods, Tools	82	68	79·5	91·5
Cheese and Butter	88	61	86·0	76·2
Spirits	66	48	51·9	47·6
Raw Sugar	36	25	88·6	65·7
Refined Sugar	55	41	45·4	46·2
Raw Hides	74	94	77·1	122·1
Chemical Products	58	62	75·4	83·7
Pottery and Glass Ware	49	49	56·6	65·3
Machinery	35	37	43·8	61·5
Oils	39	27	24·2	21·3

The following were the countries from which the imports (special trade) were mostly drawn, with their respective values, in millions of francs, for the years indicated:—

Countries.	1895.	1897.	1899.
United States	283	438	427
United Kingdom	496	485	590
Germany	310	309	360
Spain	213	247	239
Belgium	288	288	332
Russia	195	236	179
Argentine Republic	180	211	291
Algeria	246	238	271
British India	163	122	179
Italy	115	132	158
China	137	149	227
Turkey	92	107	102
Australia	69	80	95
Switzerland	67	79	93
Brazil	85	68	72
Austria	73	65	78
Sweden	55	63	70
Chile	55	50	66
Japan	59	81	93
Netherlands	46	39	44
Egypt	30	35	34
Hayti	48	26	31
Uruguay	36	27	27
Rumania	21	25	22

The French colonies, including Algeria, exported altogether into France (special trade) goods to the value of 197 million francs in 1881, 254 millions in 1886, 323 millions in 1891, 331 millions in 1896, 393 millions in 1897, and 461 millions in 1899.

The following are the principal countries receiving the exports of France, with their respective values, in millions of francs, for the years named:—

Countries.	1895.	1897.	1899.
United Kingdom	999	1132	1239
Belgium	497	513	605
Germany	334	380	457
Algeria	203	216	260
United States	289	242	255
Switzerland	163	191	216
Italy	134	151	192
Spain	109	99	148
Brazil	76	61	67
Argentine Republic	44	51	53
Turkey	51	49	49
Netherlands	46	46	51
Russia	22	26	43
Mexico	24	20	28
Egypt	19	24	22
Austria	17	15	20
British India	12	12	20
Denmark	15	16	14
Colombia	20	22	14
Japan	13	12	8

The exports from France (special trade) to the French colonies amounted to the value of 238 million francs in 1881, 246 millions in 1886, 280 millions in 1891, 332 millions in 1896, 358 millions in 1897, 477 millions in 1899. Of the goods to the value of 477 millions exported in 1899, 260 millions' worth was destined to Algeria, 46 millions to French Indo-China, 35 millions to Tunisia, 36 millions to Senegal, and 29 millions to Madagascar and dependencies.

The respective shares taken by the principal cities in its general trade, imports and exports combined, were, in millions of francs, in 1893 and 1899:—

	1893.	1899.
Marseilles	1766	2253
Havre	1646	1905
Paris	706	803
Dunkirk	519	741
Bordeaux	647	683
Boulogne	415	479
Rouen	210	262
Calais	175	249
Dieppe	171	342
Belfort, P.C.	178	208
Tourcoing	174	261

Shipping.—Since 1887 the tonnage of steamers has exceeded the tonnage of sailing vessels in the French mercantile service, the latter remaining almost stationary, contrary to what is the case in neighbouring countries, where the tonnage of sailing ships is on the decline. The French mercantile navy numbered in 1880, exclusive of boats engaged in coast-fishing, 15,058 vessels of 919,298 tons, of which 652 were steamers of 277,759 tons; in 1890, 15,111 vessels of 944,013 tons, of which 1110 were steamers of 499,921 tons; in 1893, 14,190 sailing vessels of 396,582 tons with 69,302 crews, and 1186 steamers of 498,841 tons and 14,374 crews; and in 1899, 14,262 sailing vessels of 450,636 tons with 68,031 crews, and 1227 steamers of 507,120 tons with 21,229 crews. Of the sailing vessels of 1899, 150 (14,507 tonnage) frequented European waters, and 264 (213,078 tonnage) the high seas. Of the steamers of 1899, 237 (197,067 tonnage) frequented European waters, and 173 (274,861 tonnage) the high seas—the rest being in the coasting-trade, port-service, and the fisheries. In 1888, 28,176 vessels (13,537,734 tonnage) entered, and 21,319 (9,354,225 tonnage) cleared the ports of France; in 1895, 24,374 vessels (13,221,595 tonnage) entered, and 20,032 vessels (9,272,889 tonnage) cleared; and in 1899 the entrances were 26,464 vessels (17,087,465 tonnage), of which 7828 vessels (4,297,444 tonnage) were under the French flag, while the clearances numbered 21,292 vessels (12,082,903 tonnage), of which 7527 vessels (4,425,880 tonnage) were under the French flag.

For a number of years the state of her mercantile sea-service has keenly engaged the attention of the public authorities of France. In spite, however, of the considerable assistance given to this interest by the Treasury in the shape of bounties, its condition is still recognized as open to improvement. The year 1899 may be regarded as exceptional.

Roads.—The national roads kept up by the State had altogether a length in 1899 of 24,052 miles. Of these 1466 miles were paved roads. The departmental roads maintained at the expense of the departments covered 19,263 miles. The cross-roads (*chemins vicinaux*), distinguished into three classes (*chemins de grande communication, d'intérêt commun*, and *ordinaires*), extended over 379,043 miles. The roads, national, departmental, and *vicinal*, have therefore altogether a length of over 422,300 miles.

Rivers and Canals.—The internal waterways actually navigated in 1899 had altogether a length of 12,269 kilomètres, or 7620 miles, of which 4608 miles were supplied by rivers and lakes, and 3012 miles by canals. There were, besides, 1826 miles of rivers navigable by rafts. The internal waterways, available at all times for boats drawing as much as 5·9 feet of water, had in 1899 a length altogether of 2934 miles—1297 miles river, and 1637 canal.

Railways.—The total railway lines measured in 1860, 4000 miles; in 1890, 20,666 miles; in 1899, 23,592 miles, besides 2754 miles of purely local railway. The following table, referring to lines of general interest open for traffic, indicates the development of railways in recent years:—

Year.	Length in English Miles.	Construction Cost (£1000).	Receipts (£1000).	Expenses (£1000).	Passengers (100,015).	Goods Carried (1000 tons).
1892	21,661	594,600	47,336	26,511	288,078	95,713
1895	22,505	620,840	50,542	27,362	348,852	100,834
1896	23,018	628,480	51,906	27,464	363,009	104,046
1897	23,152	635,920	53,514	27,871	374,755	108,399
1898	23,324	643,121	54,375	28,301	385,222	119,719
1899	23,592	651,315	58,167	29,513	400,437	126,311

The concessions made to the companies are valid for ninety-nine years, and will all terminate at different dates, from 1950 to 1960, when the lines will revert in full right to the State. Under the convention of 1883, the companies are bound to construct a certain number of new lines, the Treasury guaranteeing a certain dividend, ranging from 35 francs 50 centimes to 56 francs, according to the company, per primary share of 500 francs. The periods of State guarantee close, in the case of four of them, at the end of 1914, of a fifth in 1934, and of the last in 1935.

The receipts of the railways of general interest dropped between 1876 and 1899 from 43,300 francs to 38,400 francs, in consequence of the creation of numerous secondary lines with light traffic, and the net proceeds per kilomètre have likewise fallen from 22,000 to 18,800 francs. The profits of the companies, however, have, on the whole, been sensibly on the increase, amounting in 1899, after deductions of all expenses, to 712 million francs, against 593 millions in 1895. The total railway expenses in 1899 were 737 million francs, covered (with a margin) by 1449 million francs of receipts. The capital of the railways of general interest is estimated at 12 milliards of francs.

Narrow-gauge and normal railways of local interest covered on the 1st January 1900, 2759 miles in length, and the tramways, 2317 miles. The receipts of the local lines amounted to £868,676, and the expenses to £653,500. The receipts of the tramways reached £2,936,393, and the expenses £2,325,988.

Posts and Telegraphs.—The receipts of the post-office in 1899 amounted to £10,277,730, and the expenses to £7,708,164. The number of letters carried, including post-cards and printed matter, amounted in 1899 to 2,250,650,992, against 1,825,642,200 in 1892. Of the total carried in 1899, 904,210,126 were letters, and 1,346,440,866 post-cards and printed matter. Post-office orders, inland, were issued to the value of £44,280,016; international orders were issued for £1,940,221, and postal orders for £1,616,176. Bills were collected by the post-office for £16,345,247. The number of telegrams was 43,626,116, and the number of subscribers to the telephone 46,121, of which 22,468, or nearly a half, fell to the share of Paris. Of the total of 43,626,116 telegrams in 1899, 36,065,254 were internal and 7,560,862 international. The pneumatic tubes in Paris measured (1899) 163 miles; 931 urban telephone systems disposed of 11,521 miles of line and 129,606 miles of wire; 1256 inter-urban circuits had 17,439 miles of line and 46,118 miles of wire.

Banks.—The last renewal of the privilege accorded to the *Banque de France* was made in 1897. It is the only establishment which, in consideration of a permanent advance to the Treasury, and under certain other stipulated conditions, is allowed to issue bank notes of legal tender. Besides its central seat at Paris, the *Banque de France* has ninety-five branches in important provincial towns. Its total transactions in 1899 amounted to the value of 17,834,031,400 francs, in which the share of Paris was 9,154,741,200 francs, and of the branches 8,679,290,200 francs. The bullion in stock on the 1st January 1900 amounted to 3030 million francs, 1873 million francs being in gold and 1157 millions in silver. The notes in circulation amounted to the value of 3,983,493,000 francs. The bullion in hand on 1st February 1901 comprised 2,353,945,593 francs in gold and 1,095,261,297 francs in silver, while the notes in circulation valued 4,445,866,425 francs. The average rate of discount was 3 per cent. in 1899, against 2·70 per cent. in 1892, 3 per cent. in 1887, 3·80 per cent. in 1882. Finally, the shares in the bank in 1899, as at the beginning, numbered 182,500; but the number of shareholders tends gradually to increase, the number being 28,299 in 1899, against 26,742 in 1887.

The transactions of the *Crédit Foncier*, which grants loans on land securities, amounted on the 30th June 1899 to the value of 3,895,081,575 francs. Since it started business in 1853 it has lent money to the amount of 4,406,368,040 francs. In 1897 its loans were 214,812,832 francs, of which 90,510,659 francs were to the communes. Among other banking establishments may be mentioned the *Crédit Lyonnais*, *Société Général*, and *Comptoir d'Escompte*.

Savings Banks.—Since 1895 savings banks have experienced an enormous development. They are administered either by the national savings bank, which since 1882 has been connected with the post-office, and numbered, in 1897, 7416 branch offices, or by the private savings banks. The funds, however, are centralized in the *Caisse des Depôts et Consignations*, which had accounts under this head to the value, on the 31st December 1898, of 3473 million francs.

The deposits in the different savings banks amounted to 630 millions francs in 1870, 1810 millions in 1880, 3113 millions in 1890, 4080 millions in 1896, 4271 in 1897. The total number of depositors was on the 31st December 1897, 9,265,408, and on the 31st December 1897 the depositors at the private savings banks numbered 6,772,582. In 1897 the deposits at the national savings banks amounted to 366 million francs, and the withdrawals to 327 millions. At the private savings banks the deposits in 1897 amounted to the value of 719 million francs, and the repayments to 774 millions.

Money.—Since 1880 there has been but a single mint in France, namely, the Mint in Paris. The last of the provincial mints, that at Bordeaux, was done away with in 1879. The nominal value of the coin minted at Paris for France, the colonies, and foreign countries amounted, in francs, to—

1880.	1885.	1890.	1895.	1899.
200,100,000	8,506,000	22,606,000	148,702,000	140,321,212

From 1795 to 1899 there were struck for the use of France :—

Gold-Pieces.	Value in Francs.
100-franc pieces	60,663,200
50- ,, ,, ...	46,893,450
40- ,, ,, ...	204,432,360
20- ,, ,, ...	8,000,517,800
10- ,, ,, ...	1,041,165,620
5- ,, ,, ...	233,440,130
Total	9,587,112,560

From 1874 to 1899 the coin struck in gold amounted to the value of 1,812,585,560 francs. Since 1839 no 40-franc pieces, and since 1869 no 5-franc pieces, have been struck. The silver coins of France struck from 1795 to 1899 were as follows :—

Silver Coins.	Value in Francs.
5-franc pieces . .	5,060,606,240
2- ,, ,, . .	184,863,534
1- ,, ,, . .	235,558,399
50-centime pieces . .	131,620,003 and 50 centimes.
25- ,, ,, . .	7,671,101 ,, 25 ,,
20- ,, ,, . .	8,252,720 ,, 60 ,,
Total . .	5,628,571,998 and 35 centimes.

Since 1875 silver coins have been struck to the value of 559,326,173 francs. Since 1848 the coinage of 25-centime pieces, since 1869 of 20-centime pieces, and since 1878 of 5-franc crowns (*Écus*) has been suspended. But by way of exception 20-franc pieces were put in circulation in 1889.

Since 1852 bronze coins have been struck to the value of 70,549,872 francs, 40 centimes :—

Bronze Coins.	Value in Francs.
10-centime pieces . .	37,266,576 and 40 centimes.
5- ,, ,, . .	29,882,989 ,, 55 ,,
2- ,, ,, . .	2,061,209 ,, 52 ,,
1- ,, ,, . .	1,339,096 ,, 93 ,,
Total . .	70,549,872 and 40 centimes.

Colonies.—Since 1880 France has been making strenuous efforts to increase her colonial empire, which then comprised :—In Asia—the East-Indian factories of Pondichéry, Karikal, Mahé, Yanaon, and Chandernagore; in Africa—Algeria, Senegal and Goree, Gaboon, the islands of Réunion, Ste Marie de Madagascar, Mayotte, and Nossi-Bé; in America—Martinique, Guadeloupe, St Barthélemy in the Antilles group of West Indian islands, Guiana on the continent of South America, and St Pierre and Miquelon in the North Atlantic; in Oceania—the Marquesas islands, Tahiti, and New Caledonia. At the date of 1880, under the influence especially of Jules Ferry, who was a prime mover in the policy of foreign expansion, colonial experiments were made by France in three different zones of the globe: in Western Africa (in Sudan and Guinea) and in Northern Africa (in Tunis), in the Indian Ocean (in Madagascar), and in the far East (in Annam and Tongking). Following on a short expedition and the treaty of Kasr-es-Saïd or Bardo, signed on the 12th May 1881, Tunis was placed under the protectorate of France. It has now become one of the brightest gems in her crown. The year 1880, again, dates precisely the beginning of the penetration of the Sudan by French influence. The French possessions in the Senegal then reached no farther eastwards than Medina. In 1883 the French possessions touched the Niger. The long wars waged against Ahmadou and Samory brought with them a still further extension of conquest and territory. In 1894 Timbuctoo was occupied. French Guinea is likewise of recent foundation, as is also its appendage of Futa Jallon, to which a number of French officers paid a visit between 1881 and 1885. Since the latter year the Ivory Coast has grown French, a result due to the old settlements of Grand Bassam and Assinie. The region of Kong, constituting its hinterland, was explored by Captain Binger, 1887–89. All this territory was delimited by the Franco-Liberian convention of the 8th December 1892 and the Franco-British convention of the 12th July 1893. In respect of the zone of French influence in West Africa, it has been traced in a general manner by the Franco-British convention of 14th June 1898. This convention has at the same time delimited the frontier of Dahomey on the east side, in completion of the previous accord of August 1889. The western frontier of this colony, on the other hand, has been drawn by the Franco-German convention of the 27th July 1897. Dahomey and its king Behanzin were conquered in 1892. Senegal, Sudan, and Guinea form the general government of French Western Africa, in communication with which there are also the Ivory Coast and Dahomey.

French Congo was constituted as a result of the explorations of M. Savorgnan de Brazza (1875–82). Its delimitation was fixed by the convention of the 5th February 1885 concluded with the International Congo Association, by the protocol of December 1885 agreed on with Germany, and by the Franco-Portuguese protocol of May 1886. In the train of territorial and diplomatic difficulties with the Free State, an accord between King Leopold and M. Hanotaux relative to the region of the upper Ubanghi was signed on the 14th April 1894. The expansion of France in this zone, from 1895 to 1897, was crowned by the mission of Marchand, which in 1898 reached the Bahr-el-Ghazal and the Nile. The Franco-British convention of the 21st March 1899 fixed the delimitation of the Congo towards the north-east.

The large island of Madagascar in the Indian Ocean was, after a first expedition, placed in 1885 under the protectorate of France. Following a second expedition (1894–95), Madagascar was in August 1896 declared a French colony.

French Indo-China has since 1862 comprised the territory of Cochin-China, and since 1863 the protectorate of Cambodia. In consequence of a prolonged campaign (1883–84) and of treaties with Annam (6th June 1884) and China (9th June 1885), the protectorate of the Republican Government was proclaimed over Annam and Tongking. Cochin-China, Annam, Tongking, and Cambodia are united under the authority of a common governor-general.

The following table shows the extent of France's colonial empire. It should be noted that the figures for area and population are, as a rule, only estimates, a remark which especially applies to the West African possessions. Detailed notices of the separate colonies will be found under their several heads:—

Colony.	Year of Acquisition.	Area in Square Miles.	Population. 1896.
In Asia—			
India	1679	197	279,100
Annam	1884	88,780	4,000,000
Cambodia	1862	40,530	1,500,000
Cochin-China	1861	23,160	2,400,000
Tongking and Laos	1884–93	210,370	12,500,000
Total in Asia	...	363,037	20,679,100
In Africa—			
Algeria	1830	184,474	4,430,000
Algerian Sahara	1873–1900	123,500	50,000
Tunis	1881	51,000	1,500,000
Sahara, including Tibesti	1875–1900	1,892,000	1,500,000
Senegal	1637	182,000	1,200,000
Sudan Military Districts	1880	183,000	2,000,000
French Guinea	1843	92,000	1,000,000
Ivory Coast	1843	119,500	2,500,000
Dahomey	1893	59,000	1,000,000
Congo and Gaboon	1884	550,000	8,000,000

Establishments in Oceania	1841–81	1,520	29,000
Total in Oceania	...	9,220	82,000
Grand Total	...	4,227,166	47,351,860

Colonial Budget and Administration.—Besides their local budgets, the French colonies figure in the budgets of the mother-country, with drafts on her Treasury steadily increasing since 1875, and now amounting to more than 106 million francs. Of this amount the expenditure on military occupation accounts for more than three-fifths—actually 72 million francs. Neither Tunis nor Algeria figures in these totals. All the expenses of Tunis are comprised in a budget of its own, dating from 1st January 1901. Algeria has likewise a budget of its own, dating from the same time; but the financial charges of the 19th Army Corps (50 million francs), which has its headquarters at Algiers and subdivisions at Oran and Constantine, are always incumbent upon the capital. It should be remembered, however, that her commercial dealings with Algeria repay France in a measure for the sacrifices which she continues to make. Administratively, the foreign possessions of France are divided into two great categories—colonies and protectorates. The latter include Tongking, Annam, and Tunis, over whose native administration is placed a staff of French control, consisting of a resident-superior at Tunis and a resident at Hué, under whom are *contrôleurs*, vice-residents, *chanceliers de residence*, &c. Some of the colonies send representatives to Parliament. In the case of the older colonies, dating from before the constitution of the Third Republic, the departmental organization of France has been applied in whole or in part. The governor of such a colony is assisted by a general elective council exercising deliberative power—as in Martinique, Guadeloupe, Guiana, &c. In the new colonies the governor is assisted by a consultative assembly, or he may even be left uncontrolled. At the head of every colonial administration is the Ministry of the Colonies, which was only separately constituted in 1894. The Ministry of the Colonies is assisted by an elective superior council having consultative attributes.

Fuller details respecting the productions, industries, commerce, and shipping of the colonies will be found under the headings of the various colonies. It may here, however, be noted that the greater part of the French foreign possessions lies within the hot zones of the globe, and that accordingly the chief colonial products are tropical—coffee, sugar, ground-nuts, rice.

Except in the case of Algeria and Tunis, the trade of France with her possessions is not as a rule proportionately great. But the proportion is rapidly increasing, and France is quickly gaining a commanding share of the commerce of her colonies. The following table gives the value of the trade of France with her possessions in 1896 and 1898:—

From or to	Imports.		Exports.	
	1896.	1899.	1896.	1899.
Algeria	£8,152,000	£11,240,000	£9,780,000	£11,400,000
Tunis	1,044,000	1,398,000	1,640,000	2,150,000
West African Colonies	944,000	1,301,000	1,352,000	1,962,000
Madagascar	168,000	268,000	316,000	1,470,000
Réunion	836,000	918,000	664,000	720,000
French India	196,000	160,000	28,000	205,000
Indo-China	712,000	1,563,000	1,468,000	2,242,000
Oceania	476,000	780,000	300,000	603,000
Guiana	84,000	11,000	416,000	401,000
Martinique	752,000	820,000	540,000	760,000
Guadeloupe	652,000	563,000	528,000	500,000
St Pierre and Miquelon	1,220,000	1,278,000	272,000	301,000
Total	£15,236,000	£20,300,000	£17,304,000	£22,714,000

Colonial Defence.—France has not yet a colonial army properly so-called, although it is a problem she has had under discussion for many years. She has, however, the elements of an army in her troops of marines, which have hitherto carried on all her foreign campaigns, and in the native regiments she levies on the spot—tirailleurs, Senegalese, Sudanese, Congolese, Sakalavese, Tongkingese, Annamese, Sudanese Spahis, &c.

(P. L.)

3. POLITICAL HISTORY (1870–1900).

Fall of the Second Empire.

On the 8th of May 1870 the doom of the Second Empire was determined by an event which was intended to give it a new lease of life—the plebiscite approving of the reforms introduced by the emperor into the constitution. Napoleon III. had in reality sealed the fate of his dynasty four years previously when, cajoled by Bismarck, he had made France look on, a passive spectator of the defeat of Austria by Prussia. After Sadowa France remained the only obstacle to the preponderance of Prussia on the European continent, and a German victory over the French was foreseen as the probable means of consolidating a united Germany under the headship of the ambitious House of Hohenzollern. In the face of this external peril, wantonly evoked by his unsagacious diplomacy, Louis Napoleon set about making his position more secure at home, and, always a dreamer, conceived that a liberalized Empire would conciliate the entire population of France to his rule. The rapidly ageing Emperor had thus disavowed the principles which in the prime of life he had declared to be essential to the government of the country, and M. Emile Ollivier, an ardent opponent of the autocracy which sprang from the *coup d'état* of 1851, became Prime Minister of the Liberal Empire in January 1870. Napoleon III. perceived too late that his waning popularity was not to be recovered by such empirical remedies; so, against the wish of his liberal minister, he had recourse to an appeal to popular opinion, such as eighteen years before had ratified his arbitrary omnipotence. The plebiscite gave an overwhelming majority to the Empire, but it brought on its downfall. The popular victory made Louis Napoleon believe that he still possessed the confidence of the country, and that external glory would restore his shaken authority. The candidature of a prince of Hohenzollern for the throne of Spain, vacant by revolution, provided a pretext for a quarrel between France and Prussia, which was not unwelcome on either side the Rhine. The French Government declared it would never accept the presence of a German sovereign at Madrid. The king of Prussia announced to the French Ambassador that his cousin had withdrawn his candidature, whereupon Napoleon demanded a promise from William I. never to allow it to be renewed. This the King refused, to the joy of Bismarck, who saw in the unprepared state of France an opportunity for the fulfilment of his life-dream. Subsequent revelations indicate that the Prussian chancellor spared no effort to fan the warlike inclination of the French, which had no need to be stimulated by his unscrupulous provocation. The debates in the Corps Législatif in July 1870 show that the French were bent on war. The voices of MM. Thiers, Buffet, and Jules Favre, united in pleading for delay though they represented widely different schools of politics, were drowned in the clamour for immediate hostilities. War was officially declared on the 19th of July 1870 amid the acclamations of the capital, which adopted with enthusiasm the unfortunate phrase of the prime minister, Émile Ollivier, that he entered on the campaign with a "light heart." Six weeks later France had neither a ruler nor a regular army nor a government. The Emperor had drifted into war regardless of diplomatic or military precautions, without allies, and without an organized system of national defence. An unbroken series of German victories culminated at Sedan with the surrender of Napoleon III. and of the French army to the king of Prussia. Three days after the battle of Sedan the Parisian populace, which, clamouring for war, had sent off the troops with joyous cries of "À Berlin!" invaded the Corps Législatif, and demanded the deposition of the Empire.

Government of National Defence, 1870.

The Third Republic may thus be said to date from the revolution of the 4th of September 1870, when the republican deputies of Paris at the Hôtel de Ville constituted a provisional government under the presidency of General Trochu, military governor of the capital. The Empire had fallen, and the Emperor was a prisoner in Germany. As however since the great Revolution regimes in France have been only passing expedients, not inextricably associated with the destinies of the people, but bound to disappear when accounted responsible for national disaster, the surrender of Louis Napoleon's sword to William of Prussia did not disarm the country. Hostilities were therefore continued. The provisional government had to assume the part of a Committee of National Defence, and while insurrection was threatening in Paris, it had, in the face of the invading Germans, to send a delegation to Tours to maintain the relations of France with the outside world. Paris was invested, and for five months endured siege, bombardment, and famine. Before the end of October the capitulation of Metz, by the treason of Marshal Bazaine, deprived France of the last relic of its regular army. With indomitable courage the garrison of Paris made useless sorties, while an army of irregular troops vainly essayed to resist the invader, who had reached the valley of the Loire. The acting Government of National Defence, thus driven from Tours, took refuge at Bordeaux, where it awaited the capitulation of Paris, which took place on the 29th of January 1871. The same day the preliminaries of peace were signed at Versailles, which, confirmed by the Treaty of Frankfort of the 10th of May, transferred from France to Germany the whole of Alsace, excepting Belfort, and a large portion of Lorraine, including the fortified city of Metz, in addition to a money indemnity of two hundred millions sterling.

Foundation of the Third Republic, 1871.

On the 13th of February 1871 the National Assembly, elected after the capitulation of Paris, met at Bordeaux and assumed the powers hitherto exercised by the Government of National Defence. Since the meeting of the States General in 1789 no representative body in France had ever contained so many men of distinction. Elected to conclude a peace, the great majority of its members were monarchists, Gambetta, the rising hope of the republicans, having discredited his party in the eyes of the weary population by his efforts to carry on the war. The Assembly might thus have there and then restored the monarchy had not the monarchists been divided among themselves as royalist supporters of the Comte de Chambord, grandson of Charles X., and as Orleanists favouring the claims of the Comte de Paris, grandson of Louis Philippe. The majority being unable to unite on the essential point of the choice of a sovereign, decided to allow the Republic, declared on the morrow of Sedan, to liquidate the disastrous situation. Conquently, on the 17th of February the National Assembly elected M. Thiers as "Chief of the Executive Power of the French Republic," the abolition of the Empire being formally voted a fortnight later. The old minister of Louis Philippe, who had led the opposition to the Empire, and had been the chief opponent of the war, was further marked out for the position conferred on him by his election to the Assembly in twenty-six departments in recognition of his tour through Europe after the first defeats, undertaken in the patriotic hope of obtaining the intervention of the Powers on behalf of France. M. Thiers composed a ministry, and announced that the first duty of the Government, before examining constitutional questions, would be to reorganize the forces of the nation in order to provide for the enormous war indemnity which had to be paid to Germany before the territory could be liberated from the presence of the invader. The tacit acceptance of this arrangement by all parties was known as the "*pacte de Bordeaux*." Apart from the pressure of patriotic considerations, it pleased the republican minority to have the government of France officially proclaimed a Republic, while the monarchists thought that pending their choice of a monarch it might popularize their cause not to have it associated with the imposition of the burden of war taxation. From this fortuitous and informal transaction, accepted by a monarchical Assembly, sprang the Third Republic, the most durable regime established in France since the ancient monarchy disappeared in 1792.

The Germans marched down the Champs Elysées on the 1st of March 1871, and occupied Paris for forty-eight hours. The National Assembly then decided to remove its sittings to Versailles; but two days before its arrival at the palace, where the king of Prussia had just been proclaimed German emperor, an insurrection broke out in Paris. The revolutionary element, which had been foremost in proclaiming the Republic on the 4th of September, had shown signs of disaffection during the siege. On the conclusion of the peace the triumphal entry of the German troops, the threatened disbanding of the national guard by an Assembly known to be anti-republican, and the resumption of orderly civic existence after the agitated life of a suffering population isolated by siege, had excited the nerves of the Parisians, always prone to revolution. The Commune was proclaimed on the 18th of March, and Paris was declared to be a free town, which recognized no government but that chosen by the people within its walls, the communard theory being that the State should consist of a federation of self-governing communes subject to no central power. Administrative autonomy was not, however, the real aim of the insurgent leaders. The name of the Commune had always been a rallying sign for violent revolutionaries ever since the Terrorists had found their last support in the municipality of Paris in 1794. In 1871 among the communard chiefs were revolutionaries of every sect, who, disagreeing on governmental and economic principles, were united in their vague but perpetual hostility to the existing order of things. The regular troops of the garrison of Paris followed the National Assembly to Versailles, where they were joined by the soldiers of the armies of Sedan and Metz, liberated from captivity in Germany. With this force the government of the Republic commenced the second siege of Paris, in order to capture the city from the Commune, which had established the parody of a government there, having taken possession of the administrative departments and set a minister at the head of each office. The second siege lasted six weeks under the eyes of the victorious Germans encamped on the heights overlooking the capital. The presence of the enemy, far from restraining the humiliating spectacle of Frenchmen waging war on Frenchmen in the hour of national disaster, seemed to encourage the fury of the combatants. The communards, who had begun their reign by the murder of two generals, concluded it, when the Versailles troops were taking the city, with the massacre of a number of eminent citizens, including the archbishop of Paris, and with the destruction by fire of many of the finest historical buildings, including the Palace of the Tuileries and the Hôtel de Ville. History has rarely known a more unpatriotic crime than that of the insurrection of the Commune; but the punishment inflicted on the insurgents by the Versailles troops was so ruthless that it seemed to be a counter-manifestation of French hatred for Frenchmen in civil disturbance rather than a judicial penalty applied to a heinous offence. The number of Parisians killed by French soldiers in the last week of May 1871 was probably 20,000, though the partisans of the Commune declared that 36,000 men and women were shot in the streets or after summary court-martial.

The Commune.

It is from this point that the history of the Third Republic commences. In spite of the doubly tragic ending of the war the vitality of the country seemed unimpaired. With ease and without murmur it supported the new burden of taxation called for by the war indemnity and by the reorganization of the shattered forces of France. M. Thiers was thus aided in his task of liberating the territory from the presence of the enemy. His proposal at Bordeaux to make the "*essai loyal*" of the Republic, as the form of government which caused the least division among Frenchmen, was discouraged by the excesses of the Commune which associated republicanism with revolutionary disorder. Nevertheless, the monarchists of the National Assembly received a note of warning that the country might dispense with their services unless they displayed governmental capacity, when in July 1871 the republican minority was largely increased at the bye-elections. The next month, within a year of Sedan, a provisional constitution was voted, the title of President of the French Republic being then conferred on M. Thiers. The monarchists consented to this against their will; but they had their own way when they conferred constituent powers on the Assembly in opposition to the republicans, who argued that it was a usurpation of the sovereignty of the people for a body elected for another purpose to assume the power of giving a constitution to the land without a special mandate from the nation. The debate gave Gambetta his first opportunity of appearing as a serious politician. The "*fou furieux*" of Tours, whom M. Thiers had denounced for his efforts to prolong the hopeless war, was about to become the chief support of the aged Orleanist statesman whose supreme achievement was to be the foundation of the Republic.

Republicans and Monarchists after the war.

It was in 1872 that M. Thiers practically ranged himself with Gambetta and the republicans. The divisions in the monarchical party made an immediate restoration impossible. This situation induced some of the moderate deputies, whose tendencies were Orleanist, to support the organization of a Republic which now no longer found its chief support in the revolutionary section of the nation, and it suited the ideas of M. Thiers, whose personal ambition was not less than his undoubted patriotism. Having become unexpectedly Chief of the State at seventy-four he had no wish to descend again to the position of a minister of the Orleans dynasty which he had held at thirty-five. So, while the royalists refused to admit the claims of the Comte de Paris, the old minister of Louis Philippe did his best to undermine the popularity of the Orleans tradition, which had been great among the Liberals under the Second Empire. He moved the Assembly to restore to the Orleans princes the value of their property confiscated under Louis Napoleon. This he did in the well-founded belief that the family would discredit itself in the eyes of the nation by accepting two millions sterling of public money at a moment when the country was burdened with the war indemnity. The incident was characteristic of his wary policy, as in the face of the anti-republican majority in the Assembly he could not openly break with the Right; and when it was suggested that he was too favourable to the maintenance of the Republic he offered his resignation, the refusal of which he took as indicating the indispensable nature of his services. Meanwhile Gambetta, by his popular eloquence, had won for himself in the autumn a triumphal progress, in the course of which he declared at Grenoble that political power had passed into the hands of "*une couche sociale nouvelle,*" and he appealed to the new social strata to put an end to the comedy of a Republic without republicans. When the Assembly resumed its sittings, order having been restored in the land disturbed by war and revolution, the financial system being reconstituted and the reorganization of the army planned, M. Thiers read to the house a presidential message which marked such a distinct movement towards the Left that Gambetta led the applause. "The Republic

1872: Thiers and Gambetta.

exists," said the President, "it is the lawful government of the country, and to devise anything else is to devise the most terrible of revolutions."

The year 1873 was full of events fateful for the history of France. It opened with the death of Napoleon III. at Chislehurst; but the disasters amid which the Second Empire had ended were too recent for the youthful promise of his heir to be regarded as having any connexion with the future fortunes of France, except by the small group of Bonapartists. M. Thiers remained the centre of interest. Much as the monarchists disliked him, they at first shrank from upsetting him before they were ready with a scheme of monarchical restoration, and while Gambetta's authority was growing in the land. But when the Left Centre took alarm at the return of radical deputies at numerous bye-elections the reactionaries utilized the divisions in the republican party, and for the only time in the history of the Third Republic they gave proof of parliamentary adroitness. The date for the evacuation of France by the German troops had been advanced, largely owing to M. Thiers' successful efforts to raise the war indemnity. The monarchical majority, therefore, thought the moment had arrived when his services might safely be dispensed with, and the campaign against him was ably conducted by a coalition of Legitimists, Orleanists, and Bonapartists. The attack on M. Thiers was led by the Duc de Broglie, the son of another minister of Louis Philippe and grandson of Madame de Staël. Operations began with the removal from the chair of the Assembly of M. Jules Grévy, a moderate republican, who was chosen president at Bordeaux, and the substitution of M. Buffet, an old minister of the Second Republic who had rallied to the Empire. A debate on the political tendency of the Government brought M. Thiers himself to the tribune to defend his policy. He maintained that a conservative Republic was the only regime possible, seeing that the monarchists in the Assembly could not make a choice between their three pretenders to the throne. A resolution, however, was carried which provoked the old statesman into tendering his resignation. This time it was not declined, and the majority with unseemly haste elected as President of the Republic Marshal MacMahon, Duc de Magenta, an honest soldier of royalist sympathies, who had won renown and a ducal title on the battlefields of the Second Empire. In the eyes of Europe the curt dismissal of the aged liberator of the territory was an act of ingratitude. Its justification would have been the success of the majority in forming a stable monarchical government; but the sole result of the 24th of May 1873 was to provide a definite date to mark the opening of the era of anti-republican incompetency in France which has lasted for a generation, and has been perhaps the most effective guardian of the Third Republic.

Resignation of Thiers.

Marshal MacMahon President of the Republic.

The political incompetency of the reactionaries was fated never to be corrected by the intelligence of its princes or of its chiefs, and the year which saw M. Thiers dismissed to make way for a restoration saw also that restoration indefinitely postponed by the fatal action of the legitimist pretender. The Comte de Paris went to Frohsdorf to abandon to the Comte de Chambord his claims to the crown as the heir of the July Monarchy, and to accept the position of dauphin, thus implying that his grandfather Louis Philippe was a usurper. With the "Government of Moral Order" in command the restoration of the monarchy seemed imminent, when the royalists had their hopes dashed by the announcement that "Henri V." would accept the throne only on the condition that the nation adopted as the standard of France the white flag—at the very sight of which Marshal MacMahon said the rifles in the army would go off by themselves. The Comte de Chambord's refusal to accept the tricolour was probably only the pretext of a childless man who had no wish to disturb his secluded life for the ultimate benefit of the Orleans family which had usurped his crown, had sent him as a child into exile, and outraged his mother the Duchesse de Berry. Whatever his motive, his decision could have no other effect than that of establishing the Republic, as he was likely to live for years, during which the Comte de Paris' claims had to remain suspended. It was not possible to leave the land for ever under the Government improvised at Bordeaux when the Germans were masters of France; so the majority in the Assembly decided to organize another provisional Government on more regular lines, which might possibly last till the Comte de Chambord had taken the white flag to the grave, leaving the way to the throne clear for the Comte de Paris. On the 19th of November 1873 a Bill was passed which instituted the Septennate, whereby the executive power was confided to Marshal MacMahon for seven years. It also provided for the nomination of a commission of the National Assembly to take in hand the enactment of a constitutional law. Before this an important constitutional innovation had been adopted. Under M. Thiers there were no changes of ministry. The President of the Republic was perpetual prime minister, constantly dismissing individual holders of portfolios, but never changing at one moment the whole council of ministers. Marshal MacMahon, the day after his appointment, nominated a cabinet with a vice-President of the Council as premier, and thus inaugurated the system of ministerial instability which has been the most conspicuous feature of the government of the Third Republic. Under the Septennate the ministers, monarchist or moderate republican, were socially and perhaps intellectually of a higher class than those who governed France during the last twenty years of the 19th century. But the duration of the cabinets was just as brief, thus displaying the fact, already similarly demonstrated under the Restoration and the July Monarchy, that in France parliamentary government is an importation not suited to the national temperament.

The Comte de Chambord.

The Septennate.

The Duc de Broglie was the prime minister in MacMahon's first two cabinets which carried on the government of the country up to the first anniversary of M. Thiers' resignation. M. de Broglie's defeat by a coalition of Legitimists and Bonapartists with the Republicans displayed the mutual attitude of parties. The Royalists, chagrined that the fusion of the two branches of the Bourbons had not brought the Comte de Chambord to the throne, vented their rage on the Orleanists, who had the chief share in the Government without being able to utilize it for their dynasty. The Bonapartists, now that the memory of the war was receding, were winning elections in the provinces, and were further encouraged by the youthful promise of the Prince Imperial. The republicans had so improved their position that the Duc d'Audiffret-Pasquier, great-nephew of the chancellor Pasquier, tried to form a coalition ministry with M. Waddington, afterwards ambassador of the Republic in London, and other members of the Left Centre. Out of this uncertain state of affairs was evolved the Constitution which has lasted the longest of all those that France has tried since the abolition of the old monarchy in 1792. Its birth was due to chance. Not being able to restore a monarchy, the National Assembly was unwilling definitively to establish a republic, and as no limit was set by the law on the duration of its powers it might have continued the

Constitution voted, 1875.

provisional state of things had it not been for the Bonapartists. That party displayed so much activity in agitating for a plebiscite, that when the rural voters at bye-elections began to rally to the Napoleonic idea, alarm seized the constitutionalists of the Right Centre who had never been persuaded by M. Thiers' exhortations to accept the Republic. Consequently in January 1875 the Assembly, having voted the general principle that the legislative power should be exercised by a Senate and a Chamber of Deputies, without any mention of the executive regime, accepted by a majority of one a momentous resolution proposed by M. Wallon, a member of the Right Centre. It provided that the President of the Republic should be elected by the absolute majority of the Senate and the Chamber united as a National Assembly, that he should be elected for seven years, and be eligible for re-election. Thus by one vote the Republic was formally established, "the Father of the Constitution" being M. Wallon, who began his political experiences in the Legislative Assembly of 1849, and survived to take an active part in the Senate to the very end of the century.

The Republic being thus established, General de Cissey, who had become prime minister, made way for M. Buffet, but retained his portfolio of War in the new coalition cabinet, which contained some distinguished members of the two central groups, including M. Léon Say. A fortnight previously, at the end of February 1875, were passed two statutes defining the legislative and executive powers in the Republic, and organizing the Senate. These joined to a third enactment, voted in July, form the body of laws known as the "Constitution of 1875," which though twice revised, lasted without essential alteration to the end of the 19th century. The legislative power was conferred on a Senate and a Chamber of Deputies, which might unite in congress to revise the Constitution, if they both agreed that revision was necessary, and which were bound so to meet for the election of the President of the Republic when a vacancy occurred. It was enacted that the President so elected should retain office for seven years, and be eligible for re-election at the end of his term. He was also held to be irresponsible, except in the case of high treason. The other principal prerogatives bestowed on the presidential office by the Constitution of 1875 were the right of initiating laws concurrently with the members of the two chambers; the promulgation of the laws; the right of dissolving the Chamber of Deputies before its legal term on the advice of the Senate, and that of adjourning the sittings of both houses for a month; the right of pardon; the disposal of the armed forces of the country; the reception of diplomatic envoys, and, under certain limitations, the power to ratify treaties. The Constitution relieved the President of the responsibility of private patronage, by providing that every act of his should be countersigned by a minister. The Constitutional Law provided that the Senate should consist of 300 members, 75 being nominated for life by the National Assembly, and the remaining 225 elected for nine years by the departments and the colonies. Vacancies among the life members, after the dissolution of the National Assembly, were filled by the Senate until 1884, when the nominative system was abolished, though the survivors of it were not disturbed. The law of 1875 enacted that the elected senators, who were distributed among the departments on a rough basis of population, should be elected for nine years, a third of them retiring triennially. It was provided that the senatorial electors in each department should be the deputies, the members of the *conseil général* and of the *conseils d'arrondissement*, and delegates nominated by the municipal councils of each commune. As the municipal delegates composed the majority in each electoral college, Gambetta called the Senate the Grand Council of the Communes; but in practice the senators elected have always been the nominees of the local deputies and of the departmental councillors (*conseillers généraux*).

Provisions of the Constitution of 1875.

Scrutin d'arrondissement and scrutin de liste.

The Constitutional Law further provided that the deputies should be elected to the Chamber for four years by direct manhood suffrage, which had been enjoyed in France ever since 1848. The laws relating to registration, which is of admirable simplicity in France, were left practically the same as under the Second Empire. From 1875 to 1885 the elections were held on the basis of *scrutin d'arrondissement*, each department being divided into single-member districts. In 1885 *scrutin de liste* was tried, the department being the electoral unit, and each elector having as many votes as there were seats ascribed to the department without the power to cumulate—like the voting in the City of London when it returned four members. In 1889 *scrutin d'arrondissement* was resumed. The payment of members continued as under the Second Empire, the salary now being fixed at 9000 francs a year in both houses, or about a pound sterling a day. The Senate and the Chamber were endowed with almost identical powers. The only important advantage given to the popular house in the paper constitution was its initiative in matters of finance, but the right of rejecting or of modifying the financial proposals of the Chamber was successfully upheld by the Senate. In reality the Chamber of Deputies has overshadowed the upper house. The Constitution did not prescribe that ministers should be selected from either house of parliament, but in practice the deputies have been in cabinets in the proportion of five to one in excess of the senators. Similarly the very numerous ministerial crises which have taken place under the Third Republic have with the rarest exceptions been caused by votes in the lower chamber. Among minor differences between the two houses ordained by the Constitution was the legal minimum age of their members, that of senators being forty and of deputies twenty-five. It was enacted, moreover, that the Senate, by presidential decree, could be constituted into a High Court for the trial of certain offences against the security of the State.

The Constitution thus produced, the fourteenth since the Revolution of 1789, was the issue of a monarchical Assembly forced by circumstances to establish a republic. It was therefore distinguished from others which preceded it in that it contained no declaration of principle and no doctrinal theory. The comparative excellence of the work must be recognized, seeing that it has lasted. But it owed its duration, as it owed its origin and its character, to the weakness of purpose and to the dissensions of the monarchical parties. The first legal act under the new Constitution was the selection by the expiring National Assembly of seventy-five nominated senators, and here the reactionaries gave a crowning example of that folly which has ever marked their conduct each time they have had the chance of scoring an advantage against the Republic. The principle of nomination had been carried in the National Assembly by the Right and opposed by the Republicans. But the quarrels of the Legitimists with the Duc de Broglie and his party were so bitter that the former made a present of the nominated element in the Senate to the Republicans in order to spite the Orleanists; so out of seventy-five senators nominated by the monarchical Assembly fifty-seven Republicans were chosen. Without this suicidal act the Republicans would have been in a woeful minority in the Senate when parliament met in 1876 after the first elections under the new system of

1876: Political parties under the new Constitution.

parliamentary government. The slight advantage which, in spite of their self-destruction, the reactionaries maintained in the upper house was outbalanced by the republican success at the elections to the Chamber. In a house of over 500 members only about 150 monarchical deputies were returned, of whom half were Bonapartists. The first cabinet under the new Constitution was formed by M. Dufaure, an old minister of Louis Philippe like M. Thiers, and like him born in the 18th century. The premier now took the title of President of the Council, the Chief of the State no longer presiding at the meetings of ministers, though he continued to be present at their deliberations. Although the republican victory at the elections was greatly due to the influence of Gambetta, none of his partisans was included in the ministry, which was composed of members of the two central groups. At the end of 1876 M. Dufaure retired, but nearly all his ministers retained their portfolios under the presidency of M. Jules Simon, a pupil of Victor Cousin, who first entered political life in the Constituent Assembly of 1848, and was later a leading member of the opposition in the last seven years of the Second Empire.

The premiership of M. Jules Simon came to an end with the abortive *coup d'état* of 1877, commonly called from its date the *Seize Mai*. After the election of Marshal MacMahon to the presidency, the clerical party, irritated at the failure to restore the Comte de Chambord, commenced a campaign in favour of the restitution of the temporal power to the Pope. It provoked the Italian Government to make common cause with Germany, as Prince Bismarck was likewise attacked by the French clericals for his ecclesiastical policy. At last M. Jules Simon, who was a liberal most friendly to Catholicism, had to accept a resolution of the Chamber, inviting the ministry to adopt the same disciplinary policy towards the Church which had been followed by the Second Empire and the Monarchy of July. It was on this occasion that Gambetta used his famous expression, "*Le cléricalisme, voilà l'ennemi.*" Some days later a letter appeared in the *Journal Officiel*, dated 16th May 1877, signed by President MacMahon, informing M. Jules Simon that he had no longer his confidence, as it was clear that he had lost that influence over the Chamber which a president of the Council ought to exercise. The dismissal of the prime minister and the presidential acts which followed did not infringe the letter of the new Constitution; yet the proceeding was regarded as a *coup d'état* in favour of the clerical reactionaries. The Duc de Broglie formed an anti-republican ministry, and Marshal MacMahon, in virtue of the presidential prerogative conferred by the law of 1875, adjourned parliament for a month. When the Chamber reassembled the republican majority of 363 denounced the coalition of parties hostile to the Republic. The President, again using his constitutional prerogative, obtained the authorization of the Senate to dissolve the Chamber. Meanwhile the Broglie ministry had put in practice the policy, favoured by all parties in France, of replacing the functionaries hostile to it with its own partisans. But in spite of the administrative electoral machinery being thus in the hands of the reactionaries, a republican majority was sent back to the Chamber, the sudden death of M. Thiers on the eve of his expected return to power, and the demonstration at his funeral, which was described as a silent insurrection, aiding the rout of the monarchists. The Duc de Broglie resigned, and Marshal MacMahon sent for General de Rochebouet, who formed a cabinet of unknown reactionaries, but it lasted only a few days, as the Chamber refused to vote supply. M. Dufaure was then called back to office, and his moderate republican ministry lasted for the remainder of the MacMahon presidency.

The Seize Mai, 1877.

Thus ended the episode of the *Seize Mai*, condemned by the whole of Europe from its inception. Its chief effects were to prove again to the country the incompetency of the monarchists, and by associating in the public mind the Church with this ill-conceived venture, to provoke reprisals from the anti-clericals when they came into power. After the storm, the year 1878 was one of political repose. The first international exhibition held at Paris after the war displayed to Europe how the secret of France's recuperative power lay in the industry and artistic instinct of the nation. Marshal MacMahon presided with dignity over the fêtes held in honour of the exhibition, and had he pleased he might have tranquilly fulfilled the term of his Septennate. But in January 1879 he made a difference of opinion on a military question an excuse for resignation, and M. Jules Grévy, the president of the Chamber, was elected to succeed him by the National Assembly, which thus met for the first time under the Constitutional Law of 1875.

1879: Jules Grévy President of the Republic.

Henceforth the executive as well as the legislative power was in the hands of the republicans. The new President was a leader of the bar, who had first become known in the Constituent Assembly of 1848 as the advocate of the principle that a republic would do better without a president. M. Waddington was his first prime minister, and Gambetta was elected president of the Chamber. The latter, encouraged by his rivals in the idea that the time was not ripe for him openly to direct the affairs of the country, thus put himself, in spite of his immense influence, in a position of official self-effacement from which he did not emerge until the jealousies of his own party-colleagues had undermined the prestige he had gained as chief founder of the Republic. The most active among them was M. Jules Ferry, minister of Education, who having been a republican deputy for Paris at the end of the Empire, was one of the members of the provisional Government proclaimed on 4th September 1870. Borrowing Gambetta's cry that clericalism was the enemy, he commenced the work of reprisal for the *Seize Mai*. His educational projects of 1879 were thus anti-clerical in tendency, the most famous being article 7 of his education bill, which prohibited members of any "unauthorized" religious orders exercising the profession of teaching in any school in France, the disability being applied to all ecclesiastical communities, excepting four or five which had been privileged by special legislation. This enactment, aimed chiefly at the Jesuits, was advocated with a sectarian bitterness which will be associated with the name of Jules Ferry long after his more statesmanlike qualities are forgotten. The law was rejected by the Senate, M. Jules Simon being the eloquent champion of the clericals, whose intrigues had ousted him from office. The unauthorized orders were then dissolved by decree; but though the forcible expulsion of aged priests and nuns gave rise to painful scenes, it cannot be said that popular feeling was excited in their favour, so grievously had the Church blundered in identifying itself with the conspiracy of the *Seize Mai*.

Jules Ferry.

Meanwhile the death of the Prince Imperial in Zululand had shattered the hopes of the Bonapartists, and M. de Freycinet, a former functionary of the Second Empire, had become prime minister at the end of 1879. He had retained M. Jules Ferry at the ministry of Education, but unwilling to adopt all his anti-clerical policy, he resigned the premiership into his hands in September 1880. The constitution of the first Ferry cabinet secured the further exclusion from office of Gambetta. The previous month he had, as president of the Chamber, accompanied M. Grévy on an official visit to Cherbourg, and the acclamations called forth all over France by his speech, which was a hopeful defiance to Germany, encouraged the wily Chief of the State to aid the republican conspiracy against the hero of the Republic. In 1881 the only political question before the country was the destiny of Gambetta. His influence in the Chamber was such that in spite of the opposition of the prime minister he carried his electoral scheme of *scrutin de liste*, descending from the presidential chair to defend it. Its rejection by the Senate caused no conflict between the houses. The check was inflicted not on the Chamber, but on Gambetta, who counted on his popularity to carry the lists of his nominated candidates in all the republican departments in France as a quasi-plebiscitary demonstration in his favour. His rivals dared not openly quarrel with him. There was the semblance of a reconciliation between him and Jules Ferry, and his name was the rallying-cry of the Republic at the general election, which was conducted on the old system of *scrutin d'arrondissement*.

The triumph for the Republic was great, the combined force of reactionary members returned being less than one-fifth of the new Chamber. M. Grévy could no longer abstain from asking Gambetta to form a ministry, but he had bided his time till jealousy of the "occult power" of the president of the Chamber had undermined his position in parliament. Consequently, when on the 14th of November 1881 Gambetta announced the composition of his cabinet, ironically called the "*grand ministère*," which was to consolidate the Republic and to be the apotheosis of its chief, a great feeling of disillusion fell on the country, for his colleagues were untried politicians. The best known was M. Paul Bert, a man of science, who as the "reporter" in the Chamber of the Ferry Education Bill had distinguished himself as an aggressive freethinker, and he inappropriately was named minister of Public Worship. All the conspicuous republicans who had held office refused to serve under Gambetta. His cabinet was condemned in advance. His enemies having succeeded in ruining its composition, declared that the construction of a one-man machine was ominous of dictatorship, and the "*grand ministère*" lived for only ten weeks.

Gambetta Prime Minister.

Gambetta was succeeded in January 1882 by M. de Freycinet, who having first taken office in the Dufaure cabinet of 1877, and having continued to hold office at intervals until 1899, was the most successful specimen of a "*ministrable*"—as recurrent portfolio-holders have been called under the Third Republic. His second ministry lasted only six months. The failure of Gambetta, though pleasing to his rivals, discouraged the republican party and disorganized its majority in the Chamber. M. Duclerc, an old minister of the Second Republic, then became president of the Council, and before his short term of office was run Gambetta died on the last day of 1882, without having had the opportunity of displaying his capacity as a statesman or an administrator. He was only forty-four at his death, and his fame rests on the unfulfilled promise of a brief career. The men who had driven him out of public life and had shortened his existence were the most ostentatious of the mourners at the great pageant with which he was buried, and to have been of his party was in future the popular trade-mark of his republican enemies.

Death of Gambetta.

Gambetta's death was followed by a period of anarchy, during which Prince Napoleon, the son of Jerome, king of Westphalia, placarded the walls of Paris with a manifesto. The Chamber thereupon voted the exile of the members of the families which had reigned in France. The Senate rejected the measure, and a conflict arose between the two houses. M. Duclerc resigned the premiership in January 1883 to his minister of the Interior, M. Fallières, a Gascon lawyer, who eventually became president of the Senate at the end of the century, and he held office for three weeks, when M. Jules Ferry became president of the Council for the second time. Several of the closest of Gambetta's friends accepted office under the old enemy of their chief, and the new combination adopted the epithet "opportunist," which had been invented by Gambetta in 1875 to justify the expediency of his alliance with Thiers. The Opportunists thenceforth formed an important group standing between the Left Centre, which was now excluded from office, and the Radicals. It claimed the tradition of Gambetta, but the guiding principle manifested by its members was that of securing the spoils of place. To this end it often allied itself with the Radicals, and the Ferry cabinet practised this policy in 1883 when it removed the Orleans princes from the active list in the army as the illogical result of the demonstration of a Bonaparte. How needless was this proceeding was shown a few months later when the Comte de Chambord died, as his death, which finally fused the Royalists with the Orleanists, caused no commotion in France.

Opportunism.

The year 1884 was phenomenal in the sense that it passed without a change of ministry. M. Jules Ferry displayed real administrative ability, and as an era of steady government seemed to be commencing, the opportunity was taken to revise the Constitution. The two Chambers therefore met in congress, and enacted that the republican form of government could never be the subject of revision, and that all members of families which had reigned in France were ineligible for the presidency of the Republic—a repetition of the adventure of Louis Bonaparte in the middle of the century being thus made impossible. It also decided that the clauses of the law of 1875 relating to the organization of the Senate should no longer have a constitutional character. This permitted the reform of the Upper House by ordinary parliamentary procedure. So an organic law was passed to abolish the system of nominating senators, and to increase the number of municipal delegates in the electoral colleges in proportion to the population of the communes. The French nation, for the first time since it had enjoyed political life, had revised a Constitution by pacific means without a revolution. Gambetta being out of the way, his favourite electoral system of *scrutin de liste* had no longer any terror for his rivals, so it was voted by the Chamber early in 1885. Before the Senate had passed it into law the Ferry ministry had fallen at the end of March, after holding office for twenty-five months, a term rarely paralleled in the annals of the Third Republic. This long tenure of power had excited the dissatisfaction of jealous politicians, and the news of a slight disaster to the French troops in Tongking called forth all the pent-up rancour which M. Jules Ferry had inspired in various groups. By the exaggerated news of defeat Paris was excited to the brink of a revolution. The approaches of the Chamber were invaded by an angry mob, and Jules Ferry was the object of public hate more bitter than any man had called forth in France since Louis Napoleon on the days after Sedan. Within the Chamber he was attacked in all quarters. The Radicals took the lead, supported by the Monarchists, who remembered the anti-clerical rigour of the Ferry laws, by the Left Centre, not sorry for the tribulation of the group which had supplanted it, and by place-hunting republicans of all shades. The attack was led by a politician who disdained office. M. Clémenceau, who had originally

Revision of the Constitution, 1884.

Tongking.

come to Paris from the Vendée as a doctor, had as a radical leader in the Chamber used his remarkable talent as an overthrower of ministries, and nearly every one of the eight ministerial crises which had already occurred during the presidency of M. Grévy had been hastened by his mordant eloquence.

The next prime minister was M. Brisson, a radical lawyer and journalist, who in April 1885 formed a cabinet of "concentration"—that is to say, it was recruited from various groups with the idea of concentrating all the republican forces in opposition to the reactionaries. M. de Freycinet and M. Carnot, afterwards President of the Republic, represented the moderate element in this ministry, which superintended the general elections under *scrutin de liste.* That system was recommended by its advocates as a remedy for the rapid decadence in the composition of the Chamber. Manhood suffrage, which had returned to the National Assembly a distinguished body of men to conclude peace with Germany, had chosen a very different type of representative to sit in the Chamber created by the Constitution of 1875. At each succeeding election the standard of deputies returned grew lower, till Gambetta described them contemptuously as "*sous-vétérinaires,*" indicating that they were chiefly chosen from the petty professional class, which represented neither the real democracy nor the material interests of the country. His view was that the election of members by departmental lists would ensure the candidature of the best men in each region, who under the system of single-member districts were apt to be neglected in favour of local politicians representing narrow interests. When his death had removed the fear of his using *scrutin de liste* as a plebiscitary organization, parliament sanctioned its trial. The result was not what its promoters anticipated. The composition of the Chamber was indeed transformed, but only by the substitution of reactionary deputies for republicans. Of the votes polled, forty-five per cent. were given to the Monarchists, and if they had obtained one-half of the abstentions the Republic would have come to an end. At the same time the character of the republican deputies returned was not improved; so the sole effect of *scrutin de liste* was to show that the electorate, weary of republican dissensions, was ready to make a trial of monarchical government, if only the reactionary party proved that it contained statesmen capable of leading the nation. So menacing was the situation that the Republicans thought it wise not further to expose their divisions in the presidential election which was due to take place at the end of the year. Consequently, on the 28th of December 1885 M. Grévy, in spite of his growing unpopularity, was elected President of the Republic for a second term of seven years.

Elections of 1885.

The Brisson cabinet at once resigned, and on the 7th of January 1886 its most important member, M. de Freycinet, formed his third ministry, which had momentous influence on the history of the Republic. The new minister of War was General Boulanger, a smart soldier of no remarkable military record; but being the nominee of M. Clémenceau, he began his official career by taking radical measures against commanding officers of reactionary tendencies. He thus aided the Government in its campaign against the families which had reigned in France, whose situation had been improved by the result of the elections. The fêtes given by the Comte de Paris to celebrate his daughter's marriage with the heir-apparent of Portugal moved the republican majority in the Chambers to expel from France the heads of the houses of Orleans and of Bonaparte, with their eldest sons. The names of all the princes on the army list were erased from it, the decree being executed with unseemly ostentation by General Boulanger, who had owed early promotion to the protection of the Duc d'Aumale, and on that prince protesting he was exiled too. Meanwhile General Boulanger took advantage of M. Grévy's unpopularity to make himself a popular hero, and at the review, held yearly on the 14th of July, the anniversary of the fall of the Bastille, his acclamation by the Parisian mob showed that he was taking an unexpected place in the imagination of the people. He continued to work with the Radicals, so when they turned out M. de Freycinet in December 1886, one of their group, M. Goblet, a lawyer from Amiens, formed a ministry, and retained Boulanger as minister of War. M. Clémenceau, however, withdrew his support from the General, who was nevertheless loudly patronized by the violent radical press. His bold attitude towards Germany in connexion with the arrest on the German frontier of a French official named Schnaebele so roused the enthusiasm of the public, that M. Goblet was not sorry to resign in May 1887 in order to get rid of his too popular colleague.

General Boulanger.

To form the twelfth of his ministries, M. Grévy called upon M. Rouvier, an Opportunist from Marseilles, who had first held office in Gambetta's short-lived cabinet. General Boulanger was sent to command a *corps d'armée* at Clermont-Ferrand; but the popular press and the people clamoured for the hero who was said to have terrorized Prince Bismarck, and they encouraged him to play the part of a plebiscitary candidate. There were grave reasons for public discontent. Parliament in 1887 was more than usually sterile in legislation, and in the autumn session it had to attend to a scandal which had long been rumoured. The son-in-law of M. Grévy, M. Daniel Wilson, a prominent deputy who had been an under Secretary of State, was accused of trafficking the decoration of the Legion of Honour, and of using the Elysée, the President's official residence, where he lived, as an agency for his corrupt practices. The evidence against him was so clear that his colleagues in the Chamber put the Government into a minority in order to precipitate a presidential crisis, and on M. Grévy refusing to accept this hint, a long array of politicians, representing all the republican groups, declined his invitation to aid him in forming a new ministry, all being bent on forcing his resignation. Had General Boulanger been a man of resolute courage he might at this crisis have made a *coup d'état*, for his popularity in the street and in the army increased as the Republic sank deeper into scandal and anarchy. At last, when Paris was on the brink of revolution, M. Grévy was prevailed on to resign. The candidates for his succession were two ex-prime ministers, MM. Jules Ferry and de Freycinet, and M. Floquet, a barrister, who had been conspicuous in the early days of the National Assembly for his sympathy with the Commune. The Monarchists had no candidate ready, and resolved to vote for M. Ferry, because they believed that if he were elected his unpopularity with the democracy would cause an insurrection in Paris and the downfall of the Republic. M. de Freycinet and M. Floquet each looked for the support of the Radicals, and each had made a secret compact, in the event of his election, to restore General Boulanger to the War Office. But M. Clémenceau, fearing the election of M. Jules Ferry, advised his followers to vote for an "outsider," and after some manœuvring the congress elected by a large majority M. Sadi Carnot.

The Wilson scandal.

The new President, though the nominee of chance, was an excellent choice. The grandson of Lazare Carnot, the "organizer of victory" of the Convention, he was also a man of unsullied probity. The tradition of his family name, only less glorious than that of Bonaparte in the annals of the Revolution, was welcome to France, almost ready to throw herself into the arms of a soldier of fortune, while his blameless repute reconciled some of those whose opposition to the Republic had been quickened by the mean vices of M. Grévy.

M. Carnot President of the Republic, 1887.

But the name and character of M. Carnot would have been powerless to check the Boulangist movement without the incompetency of its leader, who was getting the democracy at his back without knowing how to utilize it. The new President's first prime minister was M. Tirard, a senator who had held office in six of M. Grévy's ministries, and he formed a cabinet of politicians as colourless as himself. The early months of 1888 were occupied with the trial of M. Wilson, who was sentenced to two years' imprisonment for fraud, and with the conflicts of the Government with General Boulanger, who was deprived of his command for coming to Paris without leave. M. Wilson appealed against his sentence, and General Boulanger was elected deputy for the department of the Aisne by an enormous majority. It so happened that the day after his election a presidential decree was signed on the advice of the minister of War removing General Boulanger from the army, and the Court of Appeal quashed M. Wilson's conviction. Public feeling was profoundly moved by the coincidence of the release of the relative of the ex-President by the judges of the Republic on the same day that its ministers expelled from the army the popular hero of universal suffrage.

As General Boulanger had been invented by the Radicals it was thought that a Radical cabinet might be a remedy to cope with him, so M. Floquet became President of the Council in April 1888, M. de Freycinet taking the portfolio of War which he retained through many ministries.

Boulangism.

M. Floquet's chief achievement was a duel with General Boulanger, in which, though an elderly civilian, he wounded him. Nothing, however, checked the popularity of the military politician, and though he was a failure as a speaker in the Chamber, several departments returned him as their deputy by great majorities. The Bonapartists had joined him, and while in his manifestoes he described himself as the defender of the Republic, the mass of the Monarchists, with the consent of the Comte de Paris, entered the Boulangist camp, to the dismay both of old-fashioned Royalists and of many Orleanists, who resented his recent treatment of the Duc d'Aumale. The centenary of the taking of the Bastille was to be celebrated in Paris by an international exhibition, and it appeared likely that it would be inaugurated by General Boulanger, so irresistible seemed his popularity. In January 1889 he was elected member for the metropolitan department of the Seine with a quarter of a million votes, and by a majority of eighty thousand over the candidate of the Government. Had he marched on the Elysée the night of his election, nothing could have saved the parliamentary Republic; but again he let his chance go by. The Government in alarm proposed the restoration of *scrutin d'arrondissement* as the electoral system for *scrutin de liste.* The change was rapidly enacted by the two Chambers, and was a significant commentary on the respective advantages of the two systems. M. Tirard was again called to form a ministry, and he selected as minister of the Interior M. Constans, originally a professor at Toulouse, who had already proved himself a skilful manipulator of elections when he held the same office in 1881. He was therefore given the supervision of the machinery of centralization with which it was supposed that General Boulanger would have to be fought at the general election. That incomplete hero, however, saved all further trouble by flying the country when he heard that his arrest was imminent. The Government, in order to prevent any plebiscitary manifestation in his favour, passed a law forbidding a candidate to present himself for a parliamentary election in more than one constituency; it also arraigned the General on the charge of treason before the Senate sitting as a high court, and he was sentenced in his absence to perpetual imprisonment. Such measures were needless. The flight of General Boulanger was the death of Boulangism. He alone had saved the Republic which had done nothing to save itself. Its Government had, on the contrary, displayed throughout the crisis an anarchic feebleness and incoherency which would have speeded its end had the leader of the plebiscitary movement possessed sagacity or even common courage.

Boulanger's flight.

The elections of 1889 showed how completely the reactionaries had compromised their cause in the Boulangist failure. Instead of 45 per cent. of the votes polled as in 1885, they obtained only 21 per cent., and the Comte de Paris, the pretender of constitutional monarchy, was irretrievably prejudiced by his alliance with the military adventurer who had outraged the princes of his house. A period of calm succeeded the storm of Boulangism, and for the first time under the Third Republic parliament set to work to produce legislation useful for the State, without rousing party passion, as in its other period of activity when the Ferry education laws were passed. Before the elections of 1889 the reform of the army was undertaken, the general term of active compulsory service was made three years, while certain classes hitherto dispensed from serving, including ecclesiastical seminarists and lay professors, had henceforth to undergo a year's military training. The new parliament turned its attention to social and labour questions, as the only clouds on the political horizon were the serious strikes in the manufacturing districts, which displayed the growing political organization of the socialist party. Otherwise nothing disturbed the calm of the country. The young Duc d'Orléans vainly tried to ruffle it by breaking his exile in order to claim his citizen's right to perform his military service. The cabinet was rearranged in March 1890, M. de Freycinet becoming prime minister for the fourth time, and retaining the portfolio of War. All seemed to point to the consolidation of the Republic, and even the Church made signals of reconciliation. Cardinal Lavigerie, a patriotic missionary and statesman, entertained the officers of the fleet at Algiers, and proposed the toast of the Republic to the tune of the "Marseillaise" played by his *pères blancs.* The royalist Catholics protested, but it was soon intimated that the Archbishop of Algiers' demonstration was approved at Rome. The year 1891 was one of the four in the annals of the Republic which passed without a change of ministry, but the agitations of 1892 were to counterbalance the repose of the two preceding years.

The first crisis arose out of the peacemaking policy of the Pope. Following up his intimation to the Archbishop of Algiers, Leo XIII. published in February 1892 an encyclical, bidding French Catholics accept the Republic as the firmly-established form of government. The papal injunction produced a new political group called the "Ralliés," the majority of its members being Monarchists who rallied to the Republic in obedience to the Vatican. The most conspicuous among them was M. de Mun, an eloquent exponent in the Chamber of legitimism and Christian socialism. The extreme Left mistrusted the adhesion of the new converts to the Republic, and ecclesiastical questions were the constant subjects of acrimonious debates in parliament. In the course of one of them M. de Freycinet found himself in a minority. He ceased to be prime minister, being succeeded by

The Papal encyclical, 1892.

M. Loubet, a lawyer from Montélimar, who had previously held office for three months in M. Tirard's first cabinet; but M. de Freycinet continued to hold his portfolio of War. The confusion of the republican groups kept pace with the disarray of the reactionaries, and outside parliament the frequency of anarchist outrages did not increase public confidence. The only figure in the Republic which grew in prestige was that of M. Carnot, who in his frequent presidential tours dignified his office, though his modesty made him unduly efface his own personality.

When the autumn session of 1892 began, all other questions were overwhelmed by the bursting of the Panama scandal. The company associated for the piercing of the isthmus of Panama, undertaken by M. de Lesseps, the maker of the Suez canal, had become insolvent some years before. Fifty millions sterling subscribed by the thrift of France had disappeared, but the rumours involving political personages in the disaster were so confidently asserted to be reactionary libels, that a minister of the Republic, afterwards sent to penal servitude for corruption, obtained damages for the publication of one of them. It was known that M. de Lesseps was to be tried for misappropriating the money subscribed; but considering the vast sums lost by the public, little interest was taken in the matter till it was suddenly stirred by the dramatic suicide of a well-known Jewish financier closely connected with republican politicians, driven to death it was said by menaces of blackmail. Then succeeded a period of terror in political circles. Every one who had a grudge against an enemy found vent for it in the press, and the people of Paris lived in an atmosphere of delation. Unhappily it was true that ministers and members of parliament had been subsidized by the Panama company. M. Floquet, the president of the Chamber, avowed that when prime minister he had laid hands on £12,000 of the company's funds for party purposes, and his justification of the act threw a light on the code of public morality of the parliamentary Republic. Other politicians were more seriously implicated on the charge of having accepted subsidies for their private purposes, and emotion reached its height when the cabinet ordered the prosecution of two of its members for corrupt traffic of their offices. These two ministers were afterwards discharged, and they seem to have been accused with recklessness; but their prosecution by their own colleagues proved that the statesmen of the Republic believed that their high political circles were sapped with corruption. Finally, only twelve senators and deputies were committed for trial, and the only one convicted was a minister of M. de Freycinet's third cabinet, who pleaded guilty to receiving large bribes from the Panama company. The public regarded the convicted politician as a scapegoat, believing that there were numerous delinquents in parliament, more guilty than he, who had not even been prosecuted. This feeling was aggravated by the sentence passed, but afterwards remitted, on the aged M. de Lesseps, who had involved French people in misfortune only because he too sanguinely desired to repeat the triumph he had achieved for France by his great work in Egypt.

The Panama scandal.

Within the nation the moral result of the Panama affair was a general feeling that politics had become under the Republic a profession unworthy of honest citizens. The sentiment evoked by the scandal was one of sceptical lassitude rather than of indignation. The reactionaries had crowned their record of political incompetence. At a crisis which gave legitimate opportunity to a respectable and patriotic Opposition they showed that the country had nothing to expect from them but incoherent and exaggerated invective. If the scandal had come to light in the time of General Boulanger the parliamentary Republic would not have survived it. As it was, the sordid story did little more than produce several changes of ministry. M. Loubet resigned the premiership in December 1892 to M. Ribot, a former functionary of the Empire, whose ministry lived for three stormy weeks. On the first day of 1893 M. Ribot formed his second cabinet, which survived till the end of March, when he was succeeded by his minister of Education, M. Charles Dupuy, an ex-professor who had never held office till four months previously. M. Dupuy, having taken the portfolio of the Interior, supervised the general election of 1893, which took place amid the profound indifference of the population, except in certain localities where personal antagonisms excited violence. An intelligent Opposition would have roused the country at the polls against the regime compromised by the Panama affair. Nothing of the sort occurred, and the electorate preferred the doubtful probity of their republican representatives to the certain incompetence of the reactionaries. The adversaries of the Republic polled only 16 per cent. of the votes recorded, and the chief feature of the election was the increased return of socialist and radical-socialist deputies. When parliament met it turned out the Dupuy ministry, and M. Casimir-Périer quitted the presidency of the Chamber to take his place. The new prime minister was the bearer of an eminent name, being the grandson of the statesman of 1831, and the great-grandson of the owner of Vizille, where the États du Dauphiné met in 1788, as a prelude to the assembling of the States General the next year. His acceptance of office aroused additional interest because he was a minister possessed of independent wealth, and therefore a rare example of a French politician free from the imputation of making a living out of politics. Neither his repute nor his qualities gave long life to his ministry, which fell in four months, and M. Dupuy was sent for again to form a cabinet in May 1894.

Before the second Dupuy ministry had been in office a month M. Carnot died by the knife of an anarchist at Lyons. He was perhaps the most estimable politician produced by the Third Republic. Although the standard of political life was not elevated under his presidency, he at all events set a good personal example, and to have filled unscathed the most conspicuous position in the land during a period unprecedented for the scurrility of libels on public men was a testimony to his blameless character. As the term of his septennate was near, parliament was not unprepared for a presidential election, and M. Casimir-Périer, who had been spoken of as his possible successor, was elected by the Congress which met at Versailles on 27th June 1894, four days after M. Carnot's assassination. The election of one who bore respectably a name not less distinguished in history than that of Carnot seemed to ensure that the Republic would reach the end of the century under the headship of a President of exceptional prestige. But instead of remaining Chief of the State for seven years, in less than seven months M. Casimir-Périer astonished France and Europe by his resignation. Scurrilously defamed by the socialist press, the new President found that the Republicans in the Chamber were not disposed to defend him in his high office; so, on 15th January 1895, he seized the occasion of the retirement of the Dupuy ministry to address a message to the two houses intimating his resignation of the presidency, which, he said, was endowed with too many responsibilities and not sufficient powers.

Assassination of President Carnot.

M. Casimir-Périer President of the Republic, 1894.

This time the Chambers were unprepared for a presidential vacancy, and to fill it in forty-eight hours was necessarily a matter of hap-hazard. The choice of the congress fell on M. Félix Faure, a merchant of Havre, who, though minister of Marine in the retiring cabinet, was one of the least-known politicians who had held office. The selection was a good one, and introduced to the presidency a type of politician unfortunately rare under the Third Republic—a successful man of business. M. Félix Faure had a fine presence and polished manners, and having risen from a humble origin he displayed in his person the fact that civilization descends to a lower social level in France than elsewhere. Although he was in a sense a man of the people the Radicals and Socialists in the Chambers had voted against him. Their candidate, like almost all democratic leaders in France, had never worked with his hands,—M. Brisson, the son of an attorney at Bourges, a member of the Parisian bar, and perpetual candidate for the presidency. Nevertheless the Left tried to take possession of President Faure. His first ministry, composed of moderate republicans and presided over by M. Ribot, lasted until the autumn session of 1895, when it was turned out and a radical cabinet was formed by M. Léon Bourgeois, an ex-functionary, who when a prefect had been suspected of reactionary tendencies.

M. Félix Faure President of the Republic 1895.

The Bourgeois cabinet of 1895 was remarkable as the first ministry formed since 1877 which did not contain a single member of the outgoing cabinet. It was said to be exclusively radical in its composition, and thus to indicate that the days of "republican concentration" were over, and that the Republic, being firmly established, an era of party government on the English model had arrived. The new ministry, however, on analysis did not differ in character from any of its predecessors. Seven of its members were old office-holders of the ordinary "ministrable" type. The most conspicuous was M. Cavaignac, the son of the general who had opposed Louis Bonaparte in 1848, and the grandson of J. B. Cavaignac, the regicide member of the Convention. Like M. Carnot and M. Casimir-Périer, he was, therefore, one of those rare politicians of the Republic who possessed some hereditary tradition. An ambitious man, he was now classed as a Radical on the strength of his advocacy of the income-tax, the principle of which has never been popular in France, as being adverse to the secretive habits of thrift cultivated by the people, which are a great source of the national wealth. The radicalism of the rest of the ministry was not more alarming in character, and its tenure of office was without legislative result. Its fall, however, occasioned the only constitutionally interesting ministerial crisis of the twenty-four which had taken place since M. Grévy's election to the presidency sixteen years before. The Senate, disliking the fiscal policy of the Government, refused to vote supply in spite of the support which the Chamber gave to the ministry. The collision between the two houses did not produce the revolutionary rising which the Radicals predicted, and the Senate actually forced the Bourgeois cabinet to resign amid profound popular indifference.

The new prime minister was M. Méline, who began his long political career as a member of the Commune in 1871, but was so little compromised in the insurrection that M. Jules Simon gave him an under-secretaryship in his ministry of 1876. After that he was once a cabinet minister, and was for a year president of the Chamber. He was chiefly known as a protectionist; but it was as leader of the Progressists, as the Opportunists now called themselves, that he formed his cabinet in April 1896, which was announced as a moderate ministry opposed to the policy of the Radicals. It is true that it made no attempt to tax incomes, but otherwise its achievements did not differ from those of other ministries, radical or concentration, except in its long survival. It lasted for over two years, and lived nearly as long as the second Ferry cabinet. Its existence was prolonged by certain incidents of the Franco-Russian alliance. The visit of the Tsar to Paris in October 1896, being the first official visit paid by a European sovereign to the Republic, helped the Government over the critical term at which ministries usually succumbed, and it was further strengthened in parliament by the invitation to the President of the Republic to return the Imperial visit at St Petersburg in 1897. The Chamber came to its normal term that autumn; but a law had been passed fixing May as the month for general elections, and the ministry was allowed to retain office till the dissolution at Easter 1898.

Franco-Russian alliance.

The long duration of the Méline Government was said to be a further sign of the arrival of an era of party government with its essential accompaniment, ministerial stability. But in the country there was no corresponding sign that the electorate was being organized into two parties of Progressists and Radicals; while in the Chamber it was ominously observed that persistent opposition to the moderate ministry came from nominal supporters of its views, who were dismayed at one small band of fellow-politicians monopolizing office for two years. The last election of the century was therefore fought on a confused issue, the most tangible results being the further reduction of the Monarchists, who secured only 12 per cent. of the total poll, and the advance of the Socialists, who obtained nearly 20 per cent. of the votes recorded. The Radicals returned were less numerous than the Moderates, but with the aid of the Socialists they nearly balanced them. A new group entitled Nationalist made its appearance, supported by a miscellaneous electorate representing the malcontent element in the nation of all political shades from monarchist to revolutionary-socialist. The Chamber, so composed, was as incoherent as either of its predecessors. It refused to re-elect the radical leader, M. Brisson, as its president, and then refused its confidence to the moderate leader M. Méline. M. Brisson, the rejected of the Chamber, was sent for to form a ministry, on 28th June 1898, which survived till the adjournment, only to be turned out when the autumn session began. M. Charles Dupuy thus became prime minister for the third time with a cabinet of the old concentration pattern, and for the third time in less than five years under his premiership the presidency of the Republic became vacant. M. Félix Faure had increased in pomposity rather than in popularity. His contact with European sovereigns seems to have made him over-conscious of his superior rank, and he cultivated habits which austere republicans make believe to be the monopoly of frivolous courts. The regular domesticity of middle-class life may not be disturbed with impunity when age is advancing, and M. Félix Faure died with tragic unexpectedness on 16th February 1899. The joys of his high office were so dear to him that nothing but death would have induced him to lay it down before the term of his septennate. There was therefore no candidate in waiting for the vacancy; and as Paris was in an agitated mood the majority in the Congress elected M. Loubet President of the Republic, because he happened to hold the second place of dignity in the State, the presidency of the Senate, and was moreover a politician who had the confidence of the republican groups as an adversary of plebiscitary pretensions. His only competitor was M. Méline, whose ambitions were not realized, in spite of the alliance of his Progressist supporters with the Monarchists and Nationalists. The Dupuy ministry lasted till June 1899, when a new cabinet was formed by

1899: Death of President Faure.

M. Loubet President of the Republic.

M. Waldeck-Rousseau, who, having held office under Gambetta and Jules Ferry, had relinquished politics for the bar, of which he had become a distinguished leader. Though a moderate republican, he was the first prime minister to give portfolios to socialist politicians. This was the distinguishing feature of the last cabinet of the century—the thirty-seventh which had taken office in the twenty-six years which had elapsed since the resignation of M. Thiers in 1873.

It is now necessary to go back a few years in order to refer to a matter which, though not political in its origin, in its development filled the whole political atmosphere of France in the closing period of the 19th century. Soon after the failure of the Boulangist movement a journal was founded at Paris called the *Libre Parole.* Its editor, M. Drumont, was known as the author of *La France Juive*, a violent anti-Semitic work, written to denounce the influence exercised by Jewish financiers in the politics of the Third Republic. It may be said to have started the anti-Semitic movement in France, where hostility to the Jews had not the pretext existing in those lands which contain a large Jewish population exercising local rivalry with the natives of the soil, or spoiling them with usury. That state of things existed in Algeria, where the indigenous Jews were made French citizens during the Franco-Prussian war to secure their support against the Arabs in rebellion. But political anti-Semitism was introduced into Algeria only as an offshoot of the movement in continental France, where the great majority of the Jewish community were of the same social class as the politicians of the Republic. Primarily directed against the Jewish financiers, the movement was originally looked upon as a branch of the anti-capitalist propaganda of the Socialists. Thus the *Libre Parole* joined with the revolutionary press in attacking the repressive legislation provoked by the dynamite outrages of the anarchists, clerical reactionaries who supported it being as scurrilously abused by the anti-Semitic organ as its republican authors. The Panama affair, in the exposure of which the *Libre Parole* took a prominent part soon after its foundation, was also a bond between anti-Semites and Socialists, to whom, however, the Monarchists, always incapable of acting alone, united their forces. The implication of certain Jewish financiers with republican politicians in the Panama scandal aided the anti-Semites in their special propaganda, of which a main thesis was that the government of the Third Republic had been organized by its venal politicians for the benefit of Jewish immigrants from Germany, who had thus enriched themselves at the expense of the laborious and unsuspecting French population. The *Libre Parole,* which had become a popular organ with reactionaries and with malcontents of all classes, enlisted the support of the Catholics by attributing the anti-religious policy of the Republic to the influence of the Jews, skilfully reviving bitter memories of the enaction of the Ferry decrees, when sometimes the laicization of schools or the expulsion of monks and nuns had been carried out by a Jewish functionary. Thus religious sentiment and race prejudice were introduced into a movement which was at first directed against capital; and the campaign was conducted with the weapons of scurrility and defamation which had made an unlicensed press under the Third Republic a demoralizing national evil.

Anti-Semitic movement.

An adroit feature of the anti-Semitic campaign was an appeal to national patriotism to rid the army of Jewish influence. The Jews, it was said, not content with directing the financial, and thereby the general policy of the Republic, had designs on the French army, in which they wished to act as secret agents of their German kindred. In October 1894 the *Libre Parole* announced that a Jewish officer of artillery attached to the general staff, Captain Alfred Dreyfus, had been arrested on the charge of supplying a Government of the Triple Alliance with French military secrets. Tried by court-martial, he was sentenced to military degradation and to detention for life in a fortress. He was publicly degraded at Paris in January 1895, a few days before M. Casimir-Périer resigned the presidency of the Republic, and was then transported to the Île du Diable on the coast of French Guiana. His conviction, on the charge of having betrayed to a foreign power documents relating to the national defence, was based on the alleged identity of his handwriting with that of an intercepted covering-letter, which contained a list of the papers thus treasonably communicated. The possibility of his innocence was not raised outside the circle of his friends; the Socialists, who subsequently defended him, even complained that common soldiers were shot for offences less than that for which this richly-connected officer had been only transported. The secrecy of his trial did not shock public sentiment in France, where all civilians charged with crime are interrogated by a judge in private, and where all accused persons are presumed guilty until they have proved their innocence. In a land subject to invasion there was less disposition to criticize the decision of a military tribunal acting in the defence of the nation even than there would have been in the case of a doubtful judgment passed in a civil court. The country was practically unanimous that Captain Dreyfus had got his deserts. A few, indeed, suggested that had he not been a Jew he would never have been accused; but the greater number replied that an ordinary French traitor of Gentile birth would have been forgotten from the moment of his condemnation. The pertinacity with which some of his co-religionists set to work to show that he had been irregularly condemned seemed to justify the latter proposition. But it was not a Jew who brought about the revival of the affair. Colonel Picquart, an officer of great promise, became head of the Intelligence department at the War Office, and in 1896 informed the Minister of his suspicion that the letter on which Dreyfus had been condemned was written by a certain Major Esterhazy. The military authorities, not wishing to have the case reopened, sent Colonel Picquart on foreign service, and put in his place Colonel Henry. The all-seeing press published various versions of the incident, and the anti-Semitic journals denounced them as proofs of a Jewish conspiracy against the French army.

Condemnation of Captain Dreyfus.

At the end of 1897 M. Scheurer-Kestner, an Alsatian devoted to France and a republican senator, tried to persuade his political friends to reopen the case; but M. Méline, the prime minister, declared in the name of the Republic that the Dreyfus affair no longer existed. The fact that the senator who championed Dreyfus was a Protestant encouraged the clerical press in its already marked tendency to utilize anti-Semitism as a weapon of ecclesiastical warfare. But the religious side-issues of the question would have had little importance had not the army been involved in the controversy, which had become so keen that all the population, outside that large section of it indifferent to all public questions, was divided into "Dreyfusards" and "anti-Dreyfusards." The strong position of the latter was due to their assuming the position of defenders of the army, which, at an epoch when neither legislature nor Government inspired respect, and when the Church was the object of polemic, was the only institution in France to unite the nation by appealing to its martial and patriotic instincts. That is the explanation of the enthusiasm of the public for generals and other officers by whom the trial of Dreyfus and

Dreyfusards and anti-Dreyfusards.

subsequent proceedings had been conducted in a manner repugnant to those who do not favour the arbitrary ways of military dictatorship, which, however, are not unpopular in France. The acquittal of Major Esterhazy by a court-martial, the conviction of M. Zola by a civil tribunal for a violent criticism of the military authorities, and the imprisonment without trial of Colonel Picquart for his efforts to exculpate Dreyfus, were practically approved by the nation. This was shown by the result of the general elections in May 1898. The clerical reactionaries were almost swept out of the Chamber, but the overwhelming republican majority was practically united in its hostility to the defenders of Dreyfus, whose only outspoken representatives were found in the socialist groups. The moderate ministry of M. Méline was succeeded in June 1898 by the radical ministry of M. Brisson. But while the new prime minister was said to be personally disposed to revise the sentence on Dreyfus, his civilian minister of War, M. Cavaignac, was as hostile to revision as any of his military predecessors—General Mercier, under whom the trial took place, General Zurlinden, and General Billot, a republican soldier devoted to the parliamentary regime.

The radical minister of War in July 1898 laid before the Chamber certain new proofs of the guilt of Dreyfus, in a speech so convincing that the house ordered it to be placarded in all the communes of France. The next month Colonel Henry, the chief of the Intelligence department, confessed to having forged those new proofs, and then committed suicide. M. Cavaignac thereupon resigned office, but declared that the crime of Henry did not prove the innocence of Dreyfus. Many, however, who had hitherto accepted the judgment of 1894, reflected that the offence of a guilty man did not need new crime for its proof. It was further remarked that the forgery had been committed by the intimate colleague of the officers of the general staff, who had zealously protected Esterhazy, the suspected author of the document on which Dreyfus had been convicted. An uneasy misgiving became widespread; but partisan spirit was too excited for it to cause a general revulsion of feeling. Some journalists and politicians of the extreme Left had adopted the defence of Dreyfus as an anti-clerical movement in response to the intemperate partisanship of the Catholic press on the other side. Other members of the socialist groups, not content with criticizing the conduct of the military authorities in the Dreyfus affair, opened a general attack on the French army,—an unpopular policy which allowed the anti-Dreyfusards to utilize the old revolutionary device of making the word "patriotism" a party cry. The defamation and rancour with which the press on both sides flooded the land obscured the point at issue. However, the Brisson ministry just before its fall remitted the Dreyfus judgment to the criminal division of the Cour de Cassation — the supreme court of appeal in France. M. Dupuy formed a new cabinet in October 1898, and made M. de Freycinet minister of War, but that adroit office-holder, though a civilian and a Protestant, did not favour the anti-military and anti-clerical defenders of Dreyfus. The refusal of the Senate, the stronghold of the Republic, to re-elect M. Scheurer-Kestner as its vice-president, showed that the opportunist minister of War understood the feeling of parliament, which was soon displayed by an extraordinary proceeding. The divisional judges, to whom the case was remitted, showed signs that their decision would be in favour of a new trial of Dreyfus. The republican legislature, therefore, disregarding the principle of the separation of the powers, which is the basis of constitutional government, took the arbitrary step of interfering with the judicial authority. It actually passed a law withdrawing the partly-heard cause from the criminal chamber of the Cour de Cassation, and transferring it to the full court of three divisions, in the hope that a majority of judges would thus be found to decide against the revision of the sentence on Dreyfus.

Political results of Dreyfus agitation.

This flagrant confusion of the legislative with the judicial power displayed once more the incompetence of the French rightly to use parliamentary institutions; but it left the nation indifferent. It was during the passage of the bill that the President of the Republic suddenly died. M. Félix Faure was said to be hostile to the defenders of Dreyfus and disposed to utilize the popular enthusiasm for the army as a means of making the presidential office independent of parliament. The Chambers, therefore, in spite of their anti-Dreyfusard bias, were determined not to relinquish any of their constitutional prerogative. The military and plebiscitary parties were now fomenting the public discontent by noisy demonstrations. The president of the Senate, M. Loubet, as has been mentioned, was known to have no sympathy with this agitation, so he was elected President of the Republic by a large majority at the congress held at Versailles on 18th February 1899. The new President, who was unknown to the public, though he had once been prime minister for nine months, was respected in political circles; but his elevation to the first office of the State made him the object of that defamation which had become the chief characteristic of the partisan press under the Third Republic. He was recklessly accused of having been an accomplice of the Panama frauds, by screening certain guilty politicians when he was prime minister in 1892, and because he was not opposed to the revision of the Dreyfus sentence he was wantonly charged with being bought with Jewish money. Meanwhile the united divisions of the Cour de Cassation were, in spite of the intimidation of the legislature, reviewing the case with an independence worthy of praise in an ill-paid magistracy which owed its promotion to political influence. Instead of justifying the suggestive interference of parliament it revised the judgment of the court-martial, and ordered Dreyfus to be re-tried by a military tribunal at Rennes. The Dupuy ministry, which had wished to prevent this decision, resigned, and M. Waldeck-Rousseau formed a heterogeneous cabinet in which Socialists, who for the first time took office, had for their colleague as minister of War General de Galliffet, whose chief political fame had been won as the executioner of the Communards after the insurrection of 1871. Dreyfus was brought back from the Devil's Island, and in August 1899 was put upon his trial a second time. His old accusers, led by General Mercier, the minister of War of 1894, redoubled their efforts to prove his guilt, and were permitted by the officers composing the court a wide license according to English ideas of criminal jurisprudence. The published evidence did not, however, seem to connect Dreyfus with the charges brought against him. Nevertheless the court, by a majority of five to two, found him guilty, and with illogical inconsequence added that there were in his treason extenuating circumstances. He was sentenced to ten years' detention, and while it was being discussed whether the term he had already served would count as part of his penalty, the ministry completed the inconsequency of the situation by advising the President of the Republic to pardon the prisoner. The result of the second trial satisfied neither the partisans of the accused, who desired his rehabilitation, some of them reproaching him for accepting a pardon, nor his adversaries, whose vindictiveness was unsated by the penalty he had already suffered. But the great mass of the French people, who are always ready to treat a public question with indifference, were

Second trial of Dreyfus.

glad to be rid of a controversy which had for years infected the national life.

The Dreyfus affair was severely judged by foreign critics as a miscarriage of justice resulting from race-prejudice. If that simple appreciation rightly describes its origin, it became in its development one of those scandals symptomatic of the unhealthy political condition of France, which on a smaller scale had often recurred under the Third Republic, and which were made the pretext by the malcontents of all parties for gratifying their animosities. That in its later stages it was not a question of race-persecution was seen in the curious phenomenon of journals owned or edited by Jews leading the outcry against the Jewish officer and his defenders. That it was not a mere episode of the rivalry between Republicans and Monarchists, or between the advocates of parliamentarism and of military autocracy, was evident from the fact that the most formidable opponents of Dreyfus, without whose hostility that of the clericals and reactionaries would have been ineffective, were republican politicians. That it was not a phase of the anti-capitalist movement was shown by the zealous adherence of the socialist leaders and journalists to the cause of Dreyfus; indeed, one remarkable result of the affair was its diversion of the socialist party and press for several years from their normal campaign against property. The Dreyfus affair was utilized by the reactionaries against the Republic, by the clericals against the non-Catholics, by the anti-clericals against the Church, by the military party against the parliamentarians, and by the revolutionary socialists against the army. It was also conspicuously utilized by rival republican politicians against one another, and the chaos of political groups was further confused by it. The controversy was conducted with the unseemly weapons which in France have made parliamentary institutions a by-word and an unlicensed press a national calamity; while the judicial proceedings arising out of it showed that at the end of the 19th century the French conception of liberty was as peculiar as it had been during the Revolution a hundred years before.

Real character of the Dreyfus agitation.

An epilogue to the Dreyfus affair was the trial for treason before the Senate, at the end of 1899, of a number of persons, mostly obscure followers either of M. Déroulède the poet, who advocated a plebiscitary republic, or of the Duc d'Orleans, the pretender of the constitutional monarchy. On the day of President Faure's funeral M. Déroulède had vainly tried to entice General Roget, a zealous adversary of Dreyfus, who was on duty with his troops, to march on the Elysée in order to evict the newly-elected President of the Republic. Other demonstrations against M. Loubet ensued, the most offensive being a concerted assault upon him on the racecourse at Auteuil in June 1899. The subsequent resistance to the police of a band of anti-Semites threatened with arrest, who barricaded themselves in a house in the Rue Chabrol, in the centre of Paris, and, with the marked approval of the populace, sustained a siege for several weeks, indicated that the capital was in a condition not far removed from anarchy. M. Déroulède, indicted at the assizes of the Seine for his misdemeanour on the day of President Faure's funeral, had been triumphantly acquitted. It was evident that no jury would convict citizens prosecuted for political offences, and the Government therefore decided to make use of the article of the Law of 1875, which allowed the Senate to be constituted a High Court for the trial of offences endangering the State. A respectable minority of the Senate, including M. Wallon, the venerable "Father of the Constitution" of 1875, vainly protested that the framers of the law intended to invest the upper legislative Chamber with judicial power only for the trial of grave crimes of high treason, and not of petty political disorders which a well-organized government ought to be able to repress with the ordinary machinery of police and justice. The outvoted protest was justified by the proceedings before the High Court, which, undignified and disorderly, displayed both the fatuity of the so-called conspirators and the feebleness of the Government which had to cope with them. The trial proved that the plebiscitary faction was destitute of its essential factor, a chief to put forward for the headship of the State, and that it was resolved, if it overturned the parliamentary system, not to accept under any conditions the Duc d'Orleans, the only pretender before the public. It was shown that royalists and plebiscitary republicans alike had utilized as an organization of disorder the anti-Semitic propaganda which had won favour among the masses as a nationalist movement to protect the French from foreign competition. The evidence adduced before the High Court revealed, moreover, the curious fact that certain Jewish royalists had given to the Duc d'Orleans large sums of money to found anti-Semitic journals as the surest means of popularizing his cause.

The State trial of 1899.

The last year of the 19th century, though uneventful for France, was one of political unrest. This, however, did not take the form of ministerial crises, as, for the fourth time since responsible cabinets were introduced in 1873, a whole year, from 1st January to 31st December, elapsed without a change of ministry. The prime minister, M. Waldeck-Rousseau, though his domestic policy exasperated a large section of the political world, including one half of the Progressive group which he had helped to found, displayed qualities of statesmanship always respected in France, but rarely exhibited under the Third Republic. He had proved himself to be what the French call "*un homme de gouvernement*"—that is to say, an authoritative administrator of unimpassioned temperament capable of governing with the arbitrary machinery of Napoleonic centralization. His alliance with the Extreme Left and the admission into his cabinet of socialist deputies, showed that he understood which wing of the Chamber it was best to conciliate in order to keep the government in his hands for an abnormal term. The advent to office of Socialists disquieted the respectable and prosperous commercial classes, which in France take little part in politics, though they had small sympathy with the nationalists, who were the most violent opponents of the Waldeck-Rousseau ministry. The alarm caused by the handing over of important departments of the State to socialist politicians arose upon a danger which is not always understood beyond the borders of France. Socialism in France is not a scientific doctrine propagated by earnest reformers, as it is in some European countries. It is a movement appealing to the revolutionary instincts of the French democracy, advocated in vague terms by the members of rival groups or sects. Thus the increasing number of socialist deputies in parliament had produced no legislative results, and their presence in the cabinet was not feared on that account. The fear which their office-holding inspired was due to the immense administrative patronage which the centralized system confides to each member of the Government. French ministers are wont to bestow the places at their disposal on their political friends, so the prospect of administrative posts being filled all over the land by revolutionaries caused some uneasiness. Otherwise the presence of Socialists on the ministerial bench seemed to have no other effect than that of partially muzzling the socialist groups in the Chamber. The Opposition to the Government was

French parties at the close of the 19th century.

heterogeneous. It included the few Monarchists left in the Chamber, the Nationalists, who resembled the Boulangists of twelve years before, and who had added anti-Semitism to the articles of the revisionist creed, and a number of republicans, chiefly of the old Opportunist group, which had renewed itself under the name of Progressist at the time when M. Waldeck-Rousseau was its most important member in the Senate.

The ablest leaders of this Opposition were all malcontent Republicans; and this fact seemed to show that if ever any form of monarchy were restored in France, political office would probably remain in the hands of the accomplished place-hunters of the Third Republic. Thus the most conspicuous opponents of the cabinet were three ex-prime ministers, MM. Méline, Charles Dupuy, and Ribot. These and other republican "ministrables" had their normal appetite for office whetted in 1900 by the international exhibition at Paris. It brought the ministers of the day into unusual prominence, and endowed them with large subsidies voted by parliament for official entertainments. The exhibition was planned on too ambitious a scale to be a financial success. It also called forth the just regrets of those who deplored the tendency of Parisians under the Third Republic to turn their once brilliant city into an international casino. Its most satisfactory feature was the proof it displayed of the industrial inventiveness and the artistic instinct of the French. The political importance of the exhibition lay in the fact that it determined the majority in the Chamber not to permit the foreigners attracted by it to the capital to witness a ministerial crisis. Few strangers of distinction, however, came to it, and not one sovereign of the great Powers visited Paris: but the ministry remained in office, and M. Waldeck-Rousseau had uninterrupted opportunity of showing his governmental ability. The only change in his cabinet took place when General de Galliffet resigned the portfolio of war to General André. The army, as represented by its officers, had shown symptoms of hostility to the ministry in consequence of the pardon of Dreyfus. The new minister of War repressed such demonstrations with proceedings of the same arbitrary character as those which had called forth criticism in England when used in the Dreyfus affair. In both cases the high-handed policy was regarded either with approval or with indifference by the great majority of the French nation, which ever since the Revolution has shown that its instincts are in favour of authoritative government. The emphatic support given by the radical groups to the autocratic policy of M. Waldeck-Rousseau and his ministers was not surprising to those who have studied the history of the French democracy. It has always had a taste for despotism since it first became a political power in the days of the Jacobins, to whose early protection General Bonaparte owed his career. On the other hand liberalism has always been repugnant to the masses, and the only period in which the Liberals governed the country was under the regime of limited suffrage—during the Restoration and the Monarchy of July.

The most important event in France during the last year of the century, not from its political result, but from the lessons it taught, was perhaps the Paris municipal election. The quadrennial renewal of all the municipal councils of France took place in May 1900. The municipality of the capital had been for many years in the hands of the extreme Radicals and the revolutionary Socialists. The Parisian electors now sent to the Hôtel de Ville a council in which the majority were Nationalists, in general sympathy with the anti-Semitic and plebiscitary movements. The nationalist councillors did not, however, form one solid party, but were divided into five or six groups, representing every shade of political discontent, from monarchism to revisionist-socialism. While the electorate of Paris thus pronounced for the revision of the Constitution, the provincial elections, as far as they had a political bearing, were favourable to the ministry and to the Republic. M. Waldeck-Rousseau accepted the challenge of the capital, and dealt with its representatives with the arbitrary weapons of centralization which the Republic had inherited from the Napoleonic settlement of the Revolution. Municipal autonomy is unknown in France, and the town council of Paris has to submit to special restrictions on its liberty of action. The prefect of the Seine is always present at its meetings as agent of the Government, and the minister of the Interior can veto any of its resolutions. The Socialists, when their party ruled the municipality, clamoured in parliament for the removal of this administrative control. But now being in a minority they supported the Government in its anti-autonomic rigours. The majority of the municipal council authorized its president to invite to a banquet, in honour of the international exhibition, the provincial mayors and a number of foreign municipal magnates, including the Lord Mayor of London. The ministers were not invited, and the prefect of the Seine thereupon informed the president of the municipality that he had no right, without consulting the agent of the Government, to offer a banquet to the provincial mayors; and they, with the deference which French officials instinctively show to the central authority, almost all refused the invitation to the Hôtel de Ville. The municipal banquet was therefore abandoned, but the Government gave one in the Tuileries gardens, at which no less than 22,000 mayors paid their respects to the Chief of the State. These events showed that, as in the Terror, as at the *coup d'état* of 1851, and as in the insurrection of the Commune, the French provinces were never disposed to follow the political lead of the capital, whether the opinions prevailing there were Jacobin or reactionary. These incidents displayed the tendency of the French democracy, in Paris and in the country alike, to submit to and even to encourage the arbitrary working of administrative centralization. The elected mayors of the provincial communes, urban and rural, quitted themselves like well-drilled functionaries of the State, respectful of their hierarchical superiors, just as in the days when they were the nominees of the Government; while the population of Paris, in spite of its perennial proneness to revolution, accepted the rebuff inflicted on its chosen representatives without any hostile demonstration. The municipal elections in Paris afforded fresh proof of the unchanging political ineptitude of the reactionaries. The dissatisfaction of the great capital with the government of the Republic might, in spite of the reluctance of the provinces to follow the lead of Paris, have had grave results if skilfully organized. But the anti-republican groups, instead of putting forward men of high ability or reputation to take possession of the Hôtel de Ville, chose their candidates among the same inferior class of professional politicians as the Radicals and the Socialists whom they replaced on the municipal council.

Paris and the provinces.

It is not easy for contemporary spectators to sum up the chief results to France of thirty years of parliamentary Republic. The most striking phenomenon, perhaps, has been the survival of the centralized system of administration with all its arbitrary powers untouched. Its existence side by side with an incompatible parliamentary system has been one of the causes of the failure of the latter. Yet in all the years that the Republicans have been masters of France they have made no effort to decentralize or to weaken the administrative machinery which Napoleon constructed to be manipulated by strong and autocratic hands. One effect of the ill-assorted union of the two systems has been to aggravate the unsound finance which has marked the parliamentary career of the Third Republic. In the Constitution of 1875 there is nothing to prevent private members of parliament from proposing the increase of public expenditure. The greatest economic authorities in France, the last survivors of liberalism like M. Léon Say, have vainly advocated the sound English practice which confines financial initiative to the Government of the day. The deputies, especially the Radicals and the Socialists, have maintained the prerogative of private members to increase the estimates. The chief reason for this has been that under the centralized system every French constituency contains an army of functionaries appointed and paid by the State. Under the parliamentary regime the nomination of these officials has fallen into the hands of members of parliament. Consequently the aim of deputies has been to increase their power of patronage, and to promote the creation of needless posts paid for by the taxpayer, instead of using their influence to cut down expenditure. A less rich and less industrious nation would have succumbed under this wanton drain on its resources. These have been further reduced by the decrease of population under the Third Republic in the majority of the departments, though that of the capital has increased owing to immigration from the provinces. The lack of testamentary liberty in France, and the consequent compulsory division of property, have popularized the principles attributed to Malthus. The decreasing birth-rate, in this period of universal conscription on the Continent, has compromised the security of France, as in a single-handed conflict with Germany her armies would be overwhelmed by mere force of numbers. It is also, according to French pessimists, one of the reasons of the declining influence of France among nations. France contained almost one-fifth of the population of Europe at the beginning of the 19th century, while at its end she had less than one-tenth. The United Kingdom, in spite of its enormous colonial expansion, increased its population between 1800 and 1900 by 156 per cent. The inhabitants of France are only 46 per cent. more numerous than at the beginning of the century, and her vast colonies languish for need of a surplus population to develop them.

Results of the Third Republic.

The alleged decline of the prestige of France under the Third Republic is ascribed to a variety of causes. During the first seven decades of the 19th century, whatever her vicissitudes, France exercised in Europe a great influence, which was scarcely checked even after the hour of defeat in 1815. Until the fall of the Second Empire the French used to say with reason: "Quand la France joue du violon, toute l'Europe se met à danser." The insurrection of the Commune in 1871 evoked no echo beyond the frontier. Europe had ceased to follow the lead of France, at all events in her revolutionary movements, which in 1830 and in 1848 had been followed by political commotions all over the Continent, and even in England. If the disasters which the Republic at its birth inherited from the Empire were the first cause of the depreciated influence of France, it is certain that the Republic has done nothing to restore it, and it is not easy to gainsay French critics who complain that their country has lost prestige under that regime. Some of these pessimists say: the Chief of the State at the end of the 17th century was Louis XIV.; at the end of the 18th century Napoleon Bonaparte; at the end of the 19th century M. Émile Loubet. If it is galling to the pride of the people that France should pass into the 20th century under the headship of an unknown citizen of no achievement, who represents none of the brilliant qualities of the nation, the contrast with the gorgeous dawns of other centuries supplies one consolation. The presence of M. Loubet and of his predecessors at the head of the French executive, in the place of a more decorative monarch or series of monarchs, has been a great factor in the preservation of the peace of Europe. Under the Second Empire France was not boycotted—to use a word which has been adopted in the French language—by the sovereigns of Europe. Under the Third Republic the Chiefs of the State have had no personal relations with crowned heads such as had Napoleon III., for even the relations of the Tsar Nicholas II. with the rulers of the Republic have been of a somewhat patronizing character. But while France during the Second Empire was flattered at having a ruler admitted within the hierarchy of monarchs, whose mere word could agitate the bourses and the chanceries of Europe, she had to pay for the prestige of her Emperor by a series of wars, the last of which ended with the invasion and the mutilation of the land. If the monotony of peace be of greater advantage to a country than the varying vicissitudes of war, it cannot be denied that the Third Republic compares favourably not only with the Second Empire, but with the age of Louis XIV., or with the epic and reconstructive period of the first Napoleon. It must, however, be said in justice to the Second Empire that its warlike career before its disastrous end was coincident with an epoch of national prosperity; while under the peaceful Third Republic France has lost her commercial supremacy on the Continent, though a considerable industrial development has taken place in Paris and in certain populous centres.

The Third Republic has not been fruitful in statesmen to raise the renown of the nation. Three chief causes may be suggested for this dearth. First, the failure of the parliamentary system to attract the best or even the second best men of the nation to take part in politics. Next, ministerial instability, which has prevented politicians from having the opportunity essential to developing their administrative powers. Third, the impersonal system of government, which has been carried to such an extent that not only have superior men been discouraged, but it has condemned its possessors to political ostracism, for fear lest their qualities should induce the people to hail a dictator. It was thus that Gambetta's career was cut short. Neither has the Republic produced much useful legislation. The French are not a parliamentary nation, and with their confused ideas on the separation of the powers they have never apprehended that the right function of a legislature is to legislate. The two chief reforms accomplished by the parliament of the Republic in the 19th century were the reorganization of public education and of the army. The development under the Republic of the educational system, already of high excellence in France, would have had better results had not the legislation on the subject been marked with sectarian animosity. The aim of the educational laws associated with the name of Jules Ferry was not only the elevation of the standard of public instruction, which they undoubtedly effected, but also the hindrance of the work of Roman Catholic schools and colleges. The anti-religious tendency of State education in France is exaggerated by its adversaries; yet the Ferry laws have never been accepted by the entire nation. A very large minority has refused the advantages offered to its children gratuitously in the primary schools, and for a modest price in the secondary establishments. So considerable is that minority that at the end of the 19th century the anti-clericals in parliament moved the Government to introduce legislation limiting the ecclesiastical teaching-orders, while they further demanded that education in a State school should be made an essential condition of public employment, civil or military. Thus the dawn of the new century was clouded with reviving controversies between secular and dogmatic education—which, based on the intolerant pretensions of the extreme Voltairean and Ultramontane schools of thought, have no counterpart in a land of many sects like England. Apart from this question, one disadvantage of the development of education in France is connected with the growth of centralized bureaucracy under the parliamentary Republic. A new generation of half-educated young men, disdaining manual toil, seek a career in petty official posts, which are often needlessly created for them at the cost of the taxpayer. From the same unsatisfactory class, unfitted for productive labour, come the journalists of mediocre talent who multiply in the land. A cheap and unlicensed press has become a national evil in France, since many of the most widely circulated organs of every political shade—socialist, anti-Semitic, clerical, and anti-clerical—are merely organs of violence and defamation, propagating in every corner of the territory the spirit of bitterness and dissension which is a deplorable feature of social life under the Third Republic.

The reorganization of the army may be looked upon with more satisfaction. In spite of the excesses of militarism the French army is an admirable institution. The whole manhood of France passes through its ranks. The period of self-denying discipline imposed upon Frenchmen of all classes after the close of their school-days, which are more laboriously employed than those of the youth of England, has produced a new nation. Compulsory military service is accepted, not with enthusiasm, but without murmuring. The working of the system in France, from the point of view of national life, seems to be not less satisfactory than in Germany, and thus to encourage nations which need, but dread, conscription. The composition of the French army, recruited from every social class, has had much to do with the place it has taken in the heart and imagination of the people, similar to that which monarchical tradition occupies in certain other countries. Thus in a land where all the regimes of a century have been only temporary expedients, it is looked upon as a permanent institution handed down from a historical past and superior to party rivalries. This explains the attitude of the nation towards the assailants of the army, even where the latter have had some show of justice in their attacks. The severe training which all Frenchmen have to undergo, in boyhood at school and on the threshold of life in the army, has a two-sided effect. A minority of the nation considers that it has been so hard worked in youth that it is justified in making no further effort in manhood. In the rich reactionary upper class this feeling takes the form of lives wasted in frivolity. The men of the middle class who have this disposition swell the crowd of State-paid functionaries or take to journalism or to politics. But the great masses of the nation, frugal and industrious by instinct, unconsciously profit from their years of early discipline, in which their natural habits of good order and diligence are developed. The women of France are no less hard-working than the men, and it was the quiet workers of both sexes, of the great class which abstains from politics, who paid the war indemnity to Germany in the first days of the Republic. It is their labours which have since counterbalanced the improvident finance of the politicians. Without these qualities, to which are due the industrial enterprises and the artistic creations of the last generation of the 19th century, France would not have remained in the front rank of nations. The political future of the land was never more uncertain than at the opening of the 20th century; but France contains two elements of stability which seem likely to survive all vicissitudes. On the one hand there are the industry and frugality of the people, which, though menaced by the scourge of intemperance, are still unequalled in Europe. On the other hand is the system of administration constructed by Napoleon, which, though incompatible with parliamentary government, may perhaps survive it, as it seems essential to the orderly existence of France, having survived all the changes of regime of a century. (J. E. C. B.)

4. Literature since 1880.

The salient feature of the history of French literature from 1880 to 1900 is the progress of a reaction against what was somewhat inaccurately called the Realistic school. The Romantic school was paramount during the first half of the 19th century, and it was not until after 1850 that the Naturalistic movement prevailed. This movement derived its origin from the naturalist philosophy, which developed in France under two different forms:—(1) The simple theory of sensation of Condillac; (2) the Positivism of Comte. From the first we get the sensuous realism of Gautier and Flaubert; from the second the naturalism of M. Zola. Gautier develops the theory of "art for art's sake" in his Preface to *Mademoiselle de Maupin*, which was the manifesto of a school represented by Gautier, Flaubert, Bouilhet, and, with certain modifications, by Leconte de Lisle, Théodore de Banville, and the Goncourts. In the period here under consideration the representatives of this school are the "Parnassian" poets; among the novelists, the Goncourts alone, and they only in a modified degree, belong to this category.

The watchword of the Utilitarian school was "Art for Utility's sake," and its philosophy was that propounded by Auguste Comte in 1830 and popularized by Taine. The doctrine that science, based on the only trustworthy data, those of the senses, should be the sole guide of the human mind was adopted by M. Zola and his disciples. The aim of the school was to do away with all convention; to institute a searching and exhaustive inquiry into human nature; to discover the human "document"; to present what they termed a "slice of life" without beginning or end, the personality of the author being eliminated. These theories, however, were never rigidly practised by their propounders. M. Zola himself admitted that "the realistic novel was a corner of nature seen through a temperament." Not only were the leaders of the school forced to relax the severity of their precepts, but it soon became apparent that the term was in reality a misnomer, and that in many cases the theories of the school were merely confuted by the practice of its disciples. For if Defoe, Lesage, and Tolstoi are realists in the true sense of the word, then assuredly is M. Zola something different. So far from seeing life "steadily" and seeing it "whole," as Matthew Arnold inculcated, Zola confines himself to the study of the baser and the brutal elements in man and nature while he eliminates the soul; moreover, he saw the elements to which he confined himself through the distorting glass of a pessimistic and imaginative temperament, so that he evokes monstrous and monotonous visions for us, phantasmagorias of ugliness and crime, sordid and sombre panoramas which are impressive from their very size and from the violence and heaviness with which the coarse colours are laid on the canvas. His work, however, is not lacking in an element of grandeur; thus we get the epic of the train, the mine, the shop, and the battlefield, but never truly realistic studies of contemporary life.

The Realistic school may be said, therefore, to have merely succeeded in substituting one convention for another; but this is only true so far as concerns the theories of the school and those authors who slavishly adhered to it. Maupassant, for instance, who belongs to the Realistic school, was a true Realist, not because he adopted any particular theories, but because he was enabled by his temperament to look on life with penetrating eyes, and by his talent to depict what he saw with unsurpassed vividness. But both by his clearness of vision and by the lucidity, the purity, and the masculine directness of his style he was a classic; and this, as we have already said, is the case of all true Realists such as Defoe and Lesage.

The Realistic school did not fail to produce in its turn a reaction and a revolt against its conventions. Authors who have since attained to the fulness of their powers, such as MM. Brunetière, Lemaître, Bourget, and Anatole France, protested against the conventions of the Realistic school and strove to counteract its influence. It is this counter-movement which has continued up to the present day. Another important factor in the origin of the new phase has been the influence of foreign literatures. The novels of George Eliot, Tolstoi, and Tourgeneff exercised a wide influence in France, and helped to reveal the limited range of the French Naturalist school; for in these foreign novels Nature was depicted in her entirety and not only in her baser aspects. At the same time a revolt arose against the aridity of the Realists, against their inability to look beyond the objects and facts within their immediate ken, and their total elimination of the life of the soul and the region of ideas. This tendency gave birth to a renascence of idealism. In 1889 M. Bourget wrote in the preface to his novel *Le Disciple*, after quoting Littré's well-known saying respecting the ocean of the unknown and the comparatively infinitesimal results of science: "A ceux qui te diront que derrière cet océan il y a le vide, l'abîme du noir et de la mort, aie le courage de répondre, vous ne le savez pas. Et puisque tu sais, puisque tu éprouves qu'une âme est en toi, travaille à ce que cette âme ne meure pas en toi avant toi-même." The younger generation turned once more to the region of ideas, and the tendency of French literature from 1889 up to the present day has been termed Idealist. Again, just as M. Taine's theories were adopted in a distorted form by the Naturalistic school, the philosophy of M. Renan was an important factor in the origin of the new tendency. But since no movement ever stops halfway, but continues naturally until it reaches its extreme limit, this tendency went farther than M. Renan's idealism, and passed on into mysticism; though this movement, as we look at it now, seems to be split up into singularly various elements, for together with the existence of symbolism and mysticism, incredulity and sensualism have survived, and a brutally cynical element has appeared which has been christened "*rosserie*." Doubtless it may be argued that the idealism of the new generation is skin-deep, that it is mystical without being Christian; it is at the same time probable that when we can look back upon the present period from a standpoint which will enable us to see it in its true perspective and proportion, the whole movement will seem to have been fairly named idealistic. Amidst the restlessness, the mobility, the shifting phases of this generation in France—the sudden and shortlived enthusiasms, at one time for Norwegian and other Northern literatures, at another for Neo-Hellenism and a Latin Renascence—there is perhaps a definite trend towards Faith in the largest sense of the word, towards an imperious necessity of believing, to which the thirst of knowledge is subordinated; and this movement, while to some critics it may have the appearance of being retrograde and reactionary, is perhaps in reality a renascence of the national genius of France, another example of the elasticity of the French temperament. On the one hand we have a young school who feel this necessity of faith in the largest sense; on the other hand we have writers like M. Bourget and M. Brunetière appearing as the plain, outspoken champions of catholicism; writers like MM. Lemaître and Barrès appearing as the prophets of national energy. Again, in works such as *Pour la Couronne* by M. Coppée, and M. Rostand's *Cyrano de Bergerac*, we have a renascence of another kind—a return from the complicated minstrelsy of intimate rhythms and obscure suggestions practised in later years by Symbolists (which has proved to be productive of some beautiful music and much unintelligible discord), to the simpler and more commonplace song of an earlier day. It is a message that we have heard before; but it is precisely this message, old and eternally new, which we demand of the poets at perennially recurring intervals, when man is momentarily wearied of writers whose sole aim is to lay stress on the burden of existence and to point out the ugliness of the world.

Poets.—The progress of French poetry from 1880 onwards can be divided into two main branches:—(1) The successors of the Parnassians who maintained the Parnassian tradition; (2) the Symbolists, decadents, &c. Besides these two branches there is a group of poets who, although contemporary with the Parnassians, scarcely belong to them—we will designate these as the Provincial and Rustic poets, although they do not all hail from the provinces or exclusively confine themselves to pastoral themes; and finally, there are those contemporary poets of the present day who cannot yet be classified in any definite manner, since they represent widely varying tendencies and currents.

The Parnassian school was founded by MM. L. Xavier de Ricard (born 1843) and Catulle Mendès, who chose as their tetrarchs and judges Théophile Gautier, Leconte de Lisle, Baudelaire, and Banville. The *Parnasse contemporain*, an anthology of new poetry, was published in instalments. The first appeared on 2nd March 1866, the eighteenth and last in June of the same year. There were thirty-seven contributors, of whom the most important were Gautier, Banville, Heredia, Vacquerie, Baudelaire, Sully Prudhomme. A second *Parnasse* was published in 1871, a third in 1876. Finally M. Lemerre published a complete anthology in four volumes. Among the members of this brilliant group none was more richly gifted by nature than M. Catulle Mendès (born 1841). The fairies of literature seem all to have attended his baptism and, each one conferred on him her particular gift; no wicked fairy was there to confer some saving flaw, some great defect productive of a correspondingly predominant quality—"Master of all styles, he is supreme in none." With Mr Swinburne's power of assimilation, he lacks Mr Swinburne's lyrical genius; his talent is always under perfect control; he rides Pegasus so well, with such consummate mastery and ease, that the horse cannot ever escape from the earth and soar into the heavens. His poetry (and he is not only a poet, but a novelist and a writer of short stories) is in turn realistic, romantic, neo-Hellenic, heroic in the vein of Victor Hugo and lyrical in the manner of Heine, appearing under the titles of *Philoméla*, *Soirs Moroses*, *Pantéleia*, *Contes épiques*, *Intermède*. It is his extreme versatility and power of assimilation which have perhaps prevented him from attaining to greatness or to supreme excellence in any one line; his poems give one the impression of exquisitely manufactured imitations; parodies in earnest, what the French call *pastiches*. The work of M. Sully Prudhomme (born 1839) bears far more resemblance to that of Lamartine than to that of Leconte de Lisle and his disciples. He might be called a French Matthew Arnold; his poems have the same charm and dignity, the same accent of stoical resignation, the same pensive note of melancholy as of an ivory lyre; but although his work is philosophical, he is a poet who thinks and not a philosopher who turns to rhyme for recreation.

M. François Coppée (born 1842) furnishes a signal example of the influence of Realism on French poetry; he has proved to be the most popular of the Parnassians; no sharper contrast could be found to his sentimental realism, his choice of familiar themes and humble subject-matter, than the spirit which inspires the verse of J. M. de Heredia (born 1842), the artificer of sonnets which are unequalled not only for the sweetness of their versification and for the metrical perfection which they exhibit, but also for the wide range of vision which is evoked by their disciplined utterance.

Less celebrated than most of the Parnassians, but equal almost to the greatest in accomplishment, André Lemoyne (born 1822) is the poet of landscape. His poems remind us of the painting of Corot. He produces delicate and musical pieces, impregnated with a particular atmosphere, which have a charm not unlike that of Collins's *Ode to Evening*. Side by side with Lemoyne, André Theuriet (born 1833), the author of the graceful *Chemin des Bois*, deserves to be mentioned. M. Léon Dierx (born 1838), elected at the death of Mallarmé to be "Prince of Poets," has published but little. His verse, which is above all things artistic, and masterly in technique, is essentially characteristic and representative of the true Parnassian school. His *Lèvres closes* was published in 1868.

Guy de Maupassant, Anatole France, and Alphonse Daudet all began their literary careers by a short sojourn among the Parnassians. Another teller of tales—and tales as little edifying as it is possible to find—who was endowed with true lyrical and imaginative gifts, is Armand Silvestre (1837–1901), the poet of *La Chanson des heures* (1878), *Ailes d'or* (1880), *Le Chemin des étoiles* (1885). His poems are pervaded by a vague pantheism, and seem to be woven out of a rainbow haze of dreams, their chief merit lying in the way in which they seem to flower in an endless succession of monotonous and sumptuous images. The list of Parnassians would be incomplete without mentioning Jean Cazalis (born 1840), M. Albert Mérat (born 1840), and M. Fréderic Plessis (born 1851), the classic poet of *La Lampe d'Argile*.

The influence of the Realistic school, which was at its height in 1880, can be traced in all the productions of this Parnassian school, for while their poetry escaped from the contagion of ugliness and brutality, it was none the less objective in character, and chose for its themes, as the case might be, detailed landscapes, historical scenes accurately reproduced, or realistic studies of modern life. The attention to detail and concision of style which were sought after and attained, left little to individual interpretation. A reactionary movement, such as that which arose against the novel, appeared here also, and hence the Symbolist school came into being, which aimed at greater freedom, a less strict prosody, and a more musical poetry. But it must be borne in mind that this Symbolist movement was a revolt against the precepts of the Parnassians and the legacy of the Romantic school, and it can only be called a reaction against naturalism, in so far as the influence of naturalism is to be traced in the poetry of the Parnassians. The Parnassians had borrowed from the plastic arts; the Symbolists aimed at the vagueness, mystery, suggestiveness of music, *de la musique avant toute chose*. The high priests of this movement were Paul Verlaine (1844–1896), remarkable much less for his theories than for his exquisite practice, in which he showed himself a lyric poet of the first order, comparable with Shelley and Heine, and not without certain affinities to the earliest French singers, such as Charles d'Orléans; and Stéphane Mallarmé (1842–1898) perhaps less remarkable for his practice than for his theory. He not only advocated vagueness of music and of sound, but mistiness of imagery and of sense—in fact, obscurity. Then followed a riot of rebellious rhymers, for whom sense capitulated unconditionally to sound and sensibility. M. Vielé-Griffin (born 1864) and M. Gustave Kahn (born 1859) gave us *vers libres* which, but for their typographical arrangement, are indistinguishable from prose. Indeed, the extreme limit of this school is reached in the *ballades* of M. Paul Fort (born 1872), which are actually printed as prose. In the verse of these disciples of the Symbolist school rhyme is often reduced to assonance, and poetry tends to become less and less subject to any exterior discipline; it is made instead to depend upon an intimate rhythm, which varies with every different poet, the result, should the poet have a sensitive ear, being often in the highest degree musical. Verlaine and Mallarmé can only be said to have exercised a pernicious influence on the least gifted of their disciples, and in many ways their influence was wholly beneficent. The tyranny of the rhyme was broken, prosody became more supple, and a freer rhythm was introduced. The phase must by no means be considered an abnormal one. In the Symbolist movement French poetry reverted more or less to what it was in 1820, to the suggestive imagery and musical vagueness of Lamartine. French poetry at that epoch was moving naturally towards the ideal of the Symbolists, when it was deflected from its course by the appearance of Victor Hugo, who fashioned a new instrument for lyrical poetry to suit his visionary genius and his command of magnificent rhetoric; and the instrument subsisted and was played upon by generations of more and more dexterous artists, until the Symbolists shattered it.

By far the most gifted of the disciples of the Symbolist school is M. Henri de Regnier (born 1864), the singer of *Lendemains* (1886), *Aréthuse* (1895), and *Les Jeux rustiques et divins* (1897). We find in his work a harmonious combination of old traditions and modern innovations. He has adopted and practised the precept of André Chénier—

> "Sur des pensers nouveaux faisons des vers antiques,"

and his work, especially his latest volume, testifies more perhaps to the influence of André Chénier than to that of contemporary writers; it is, nevertheless, stamped with originality. He takes ancient myths and interprets them anew, using mythological symbols as a vehicle for the expression of modern ideas; he is symbolical without being obscure. He is particularly successful in the choice of an imagery which has a kind of subdued splendour that harmonizes well with the grave music of his dreams; throughout his poetry there is a vein of impassioned meditation, suggestive, dreamy, and melodious. The melancholy note of his song and the sumptuousness of his imagery remind one of poems such as Mr Swinburne's *Triumph of Time*. He presents affinities to Mr Swinburne and also to Keats, especially to the early poems of Keats, such as the Bacchic song in Canto IV. of *Endymion*. His poems abound with extremely beautiful lines, and *Les Médailles d'Argile* (1900) showed a great advance on his earlier works, and contained the promise of still finer performance.

M. Albert Samain (1859–1900) was also a dreamer; he had an exquisite sense for half tones, subtle shades, elusive scents and fugitive murmurs, and he rendered the same in musically murmured verse. M. Francis Vielé-Griffin is the boldest among the initiators of the new movement, and his poetry breaks away from all traditions; but his work, which is not without charm of melody, is almost entirely unintelligible and incoherent. The disciples of the Symbolist school have given most of their work to the world through the medium of a Review entitled *Le Mercure de France.* The principal contributors to this periodical are MM. Robert de Souza, Francis Jammes (born 1868), Laurent Tailhade (born 1854—author of *Jardin des rêves,* 1880), and M. Jean Moréas (born 1856), the poet of various volumes from *Les Syrtes* of 1884 to *Les Stances* of 1901.

Alongside of, and contemporary with, the Parnassians, there flourished what we have called the Provincial poets. Of these the most important are M. Jules Breton (born 1827), author of *Les Champs et la Mer;* M. Charles de Pomairols, a disciple of Lamartine (of whom he has given us a fine study); and Alfred de Vigny, whose work has some of the gravity and elevation of his masters. M. Gabriel Vicaire (1848–1900), native of Bresse, published his *Émaux Bressans* in 1884, a volume of fresh and delightful and spontaneous lyrics. The Provence produced M. Jean Aicard (born 1848). Finally, in Paris itself we find M. Déroulède, the French Körner, the patriotic singer of *Chants du Soldat* (born 1846); and M. Richepin (born 1849), author of *La Chanson des Gueux, Les Caresses, Les Blasphèmes, La Mer,* and several dramas in verse—*Nana-Sahib, Par le Glaive,* and *Le Flibustier.* M. Richepin is one of the most interesting and curious figures in contemporary French poetry; romantic by temperament, he had made no attempt to modify his proclivities; his dramas might almost have been written in 1830. In *La Chanson des Gueux* he celebrated the tramps and beggars of Paris; in *Les Caresses* he is frankly pagan and sensual, and in these poems as well as in *Les Blasphèmes* he reminds one of the more extravagant excesses of Mr Swinburne's early work. For sheer virtuosity and skill in versification he can hold his own not only with all his contemporaries, but with the most accomplished French rhymers of the past; his verse has the quality of vigour, sonority, and colour in the highest degree. Like Mr Swinburne, M. Richepin is a scholar, and his erudition is a little too evident; in his violence and extravagancies there is the same suspicion of insincerity and rhetoric that we find in the more violent poems of Mr Swinburne, and he never attains to Mr Swinburne's purely poetic inspiration. He remains an astonishing versifier rather than a great poet.

We now come to the representative poets of the present day. One of the most notable is certainly M. Maurice Bouchor (born 1865), author of *Les Symboles* (1888); his poetry has a note of high seriousness and religious feeling. Deserving of mention are M. Georges Leygues, author of *Le Coffret Brisé* (1882); M. Edmond Haraucourt, a brilliant disciple of Leconte de Lisle, author of *L'Âme Nue* (1885); M. Jean Rameau, author of *Le Chemin des Étoiles* (1888); M. André Rivoire's poems in the *Revue de Paris* have attracted attention. The poems of the Vicomte de Borelli, author of *Rana* and *Alain Chartier,* performed at the Comédie Française (1889), are particularly interesting as being the work not of a professional man of letters, but of a soldier.

The poetry of M. Edmond Rostand (born 1864) is looked upon with scorn by the contributors to the *Mercure de France,* and, partly perhaps because it so instantaneously and emphatically won the suffrages of the great public, older critics have been chary in their appreciation. Doubtless M. Rostand is first and foremost a dramatist, and his poetry is better heard than read: but although it is neither the poetry of the Parnassians (to which it stands in the same relation that the poetry of Mr Kipling holds to the poetry of Tennyson), nor of the Symbolists, yet poetry of a kind it is, brilliant, witty, full of fancy, fertile—too fertile, perhaps—in invention; it assimilates the character of French poetry of many epochs. M. Rostand is an astounding juggler rather than a supreme artist in words; and although it would be unjust to accuse him of a fatal fluency—for while everything that he touches turns into poetry, the result is gold and not tinsel—yet this marvellous facility has the danger of turning him from the main road along which he determines to travel, into byways of attractive episodes, or of causing him to forget in ingenious detail the main architectural design of his fabric. As far as largeness of aim and design are concerned, his most important work so far has been *L'Aiglon,* but it cannot be said to be on the whole so satisfactory as *Cyrano de Bergerac,* which contains what is without doubt the best verse he has so far given us. M. Rostand's qualities and defects are equally well displayed, if on a smaller scale, in his earlier plays—*Les Romanesques, La Princesse Lointaine,* and *La Samaritaine.*

Novelists.—Among the novelists of the later half of the 19th century, the only two of importance who may be said to belong to the Idealistic, if not to the Romantic, school are Octave Feuillet (1821–1890) and Victor Cherbuliez (1829–1899). Whatever charges of artificiality or sentimentality may be brought against the work of Feuillet, his novels are likely to survive, owing to the perfection of their construction and the purity and grace of their style. Cherbuliez, who to a greater degree than Feuillet held aloof from the tendencies of the contemporary novel, was perhaps more of a moralist and a humorist than a novelist. His ingenious and complicated stories, although they do not fail to entertain us, betray inexperience of life, and they justify Maupassant's criticism that Cherbuliez did not deserve to be called an Idealist merely because his observation of life happened to be inaccurate. His best novels are *Un Cheval de Phidias, Le Prince Vitale,* and *Le Grand Œuvre.*

Towards the year 1880 the Naturalist movement had reached its zenith, and the inevitable reaction did not fail to set in. But before dealing with it, it will be well to consider the work of the Naturalists as it existed in 1880. It can be divided into two branches—on the one hand, the Impressionists, whose object it was to interpret nature, and to whom the impressions received from nature were a means of expressing their personality; and on the other the Naturalists proper, whose aim was to achieve absolute and objective reality, and whose failure to do so was productive of so many curious and interesting results. To the Impressionists belong the two Goncourts, the most literary of all French writers of the century, whose work may be summed up in one word, *nervosity,* and who, in their determination to render the vibration of their impressions, dared any discord; Alphonse Daudet; and Pierre Loti, who in reality belongs to a class all by himself, since he is not a novelist at all, but a poet and a painter in words. To the Naturalistic school proper belong M. Zola, whose *L'Assommoir* appeared in 1887; and Guy de Maupassant, whose masterpiece, *Boule de Suif,* appeared in 1880.

J. K. Huysmans (born 1848) began as a Naturalist, and in his work we see more strikingly manifested than elsewhere not only the tendencies of the Naturalist school and the reaction they produced, but the extreme limit of this reaction; in fact, the transition from naturalism to mysticism. Huysmans' first books appeared in 1878–79, *À Rebours* in 1884, *Là-Bas* in 1891. In his early stories, *Marthe* (1876), *Les Sœurs Vatard* (1879), *Sac au Dos*

(1880), the hideousness of hideous things is depicted with Flemish minuteness; the world seems to reek in his nostrils; he goes out of his way to choose the most repulsive subjects, and seems to enjoy a bitter satisfaction in dwelling on the most sordid aspects of his loathsome vision. The extreme sensibility of his temperament, however, led him farther; his pessimism reaches its lowest degree in a study of Satanism in *Là-Bas*, and from blasphemy to belief the transition is a natural one, since in order to blaspheme it is necessary first to believe. Disgusted with himself and the horror of his life, the author of *Là-Bas* seeks refuge in a Trappist convent. We then get an account of this experience in *En Route* (1895). This is by far his most interesting and important work, remarkable for the absence of all literary catholicism such as that affected by Baudelaire, for the poignant sincerity with which his moral crisis is depicted, and for the sheer beauty of many scenes and passages. *La Cathédrale* (1898) consists almost entirely of a description of the Cathedral of Chartres.

The reactionary movement which is illustrated by the career of Huysmans was headed by M. Paul Bourget (born 1852), who deserves the credit of reinstating psychology in the position from which it had been ousted by the physiology of the Naturalists. In his critical essays M. Bourget attempts to discover and to define the fundamental moral idea forming the basis of the work of the writers whom he studies, in his novels his aim is to analyse the soul of man. He chose for his field of observation the fashionable world of Paris, and consequently he is the psychologist and novelist of Society. The chief excellence of his work, and at the same time its cardinal defect, lies in his system of explanation. His characters do not reveal themselves to the reader by their acts and words, the author explains them to us himself. If we eliminate the dissertations from his novels, we are left with "novelette" plots of the most commonplace description; on the other hand, it is precisely in dissertations that his great talents are manifest, when the subject of the book is purely an analytic study which admits of dissertation.
