M. Edouard Rod (born 1857) began as a disciple of M. Zola, but was soon, chiefly owing to the influence of foreign literature, led into the current of reaction. His work is widely different in tone from that of any of his contemporaries, and is impregnated with a rarer atmosphere. He is in the highest degree preoccupied by moral ideas and questions of conscience, yet he is capable at the same time, in *La Vie Privée de Michel Tessier* (1893) and *Le Ménage du Pasteur Naudié* (1898), of creating living characters, and of interesting us in their careers. If his work is lacking in the more salient qualities of brilliancy and colour, it is nevertheless admirable on account of the harmony of its proportions and the delicacy of touch which it manifests. The titles of his remaining works are *Le Sens de la Vie*, *Les Trois Cœurs*, *La Sacrifiée*, *Le Silence*, *Les Roches Blanches*, *Dernier Refuge Là-Haut*.

M. Paul Margueritte (born 1860) is another instance of a Naturalist converted. He began as a disciple of the Goncourts, and in 1887 signed a manifesto against M. Zola. The work, indisputably his masterpiece, to which he owed his celebrity is *La Force des Choses* (1891). His other works are *Jours d'épreuve* (1889), *Ma Grande* (1893), *La Tourmente* (1893), *Le Désastre* (1898), with its sequel *Les Tronçons du Glaive* (1900), a historical study of the war of 1870, written in collaboration with his brother. He is affiliated to the Goncourts by his nervous temperament, but no novelist of the present day has a more trenchant style, a greater precision of touch. In *La Force des Choses* and *Ma Grande* he has produced two human dramas remarkable for sincerity and truth, and for their poignant simplicity and pathos.

The work of J. H. Rosny (the name stands for two brothers who work in collaboration) has first and foremost the merit of originality. His conception of art is widely different from that of the Naturalistic school, and yet, although he began as a disciple of M. Zola, and later repudiated him, he cannot be said to belong to the reactionary movement. His work stands entirely apart from that of his contemporaries. Science forms his one preoccupation, and it positively overloads his work. His descriptive passages teem with allusions to chemistry, physical science, and natural history. His cult for science forms the basis of his work, the starting-point of his literary theories and of his moral ideas. His moral aim is to replace the Christian precepts of humility by a rational form of altruism, in which virtue is to be a means of developing superior beings to the fullest possible extent, and the effort of this morality is to tend towards the progressive amelioration of this life; his cult is that of "La bonne humanité." His early works, such as *Nell Horn*, in which he depicts scenes of London and Parisian life, and even *Vamireh* (1891), a prehistoric novel, betray the influence of the Naturalist school. *Daniel Valgraive* (1891), *L'Impérieuse Bonté* (1894), *L'Indomptable*, and *Renouveau*, *L'Autre Femme*, *Résurrection* are very different in character. The two first are inspired by the preoccupation of social and individual morality. Besides *Vamireh* he has written other prehistoric novels, *Erymah* and *Les Profondeurs de Kyamo.* His best work suffers from incoherence, from the neglect of composition, an indulgence in grotesque detail and barbarous verbal inventions, and a pedantic use of scientific phraseology. But all his work is redeemed by a certain greatness of soul, by the excellence of "sincerity and strength," by the enthusiasm rising from deep conviction, and by the largeness and nobility of his ideas; moreover, in spite of all its defects, his style has moments of simplicity, freshness, and majesty. His work resembles a rugged mountain on which we struggle over perilous steeps and through dark caverns, rewarded every now and then by intermittent glimpses of snowy splendours and dazzling horizons.

M. Marcel Prévost (born 1862) affords the greatest possible contrast to Rosny; his talent is vivacious, elegant, and insinuating; he has confined himself entirely to love stories, and moves on this ground with masterly ease, analysing the subtler shades with a delicate dexterity. He published *Le Scorpion* in 1887, *Mademoiselle Jauffre* in 1889. No wittier book appeared during the period 1880–1900 than the first series of his *Lettres de femmes* (1892). His particular deftness and cleverness found perhaps a larger scope in *Les Demi-Vierges* (1894); yet with all his grace and amenity he is a moralist, since in his love stories he strips passion of its poetry and leaves the bare materialism and vanity which lie beneath it; at the same time his attraction for what he affects to despise and condemn is clearly evident.

M. Paul Ernest Hervieu (born 1857) has of late years entirely devoted himself to the stage, but he made his reputation by two novels, *Peints par Eux Mêmes* (1893) and *L'Armature* (1895). The first of these two is ironical as to matter, and lucid and trenchant as to style; the second is a novel written with the purpose of showing that in modern society the only solid element is money, and that all other things, such as virtue, affection, &c., are but a brittle ornamentation. He proves himself an accomplished analyst in both these works, and he seems to delight in revealing the sore places which are hidden by the brilliant trappings of the world of fashion.

M. Maurice Barrès (born 1862) began by two books, *Sous l'œil des Barbares* and *Un homme libre*, which are devoted to the psychology of his own personality: in both he reveals himself as a writer of exquisite prose; but they suffer from the defect of being almost entirely unintelligible. In *Le Jardin de Bérénice* we find the same qualities, and with a considerable attenuation the same defect. In *Du Sang, de la Mort, et de la Volupté*, a work of singular inequality, the obscurity has entirely disappeared; impressions of certain landscapes and places are rendered with a wonderful delicacy, and the book abounds in passages of great beauty. *Les Déracinés* (1898) marks a fresh and a greater transformation. The book is a vehement protest against the dangers of individualism; unfortunately the interest awakened by its social theories is somewhat lessened by a want of cohesion in the construction. The book, however, is not only exceedingly interesting, but entirely human.

M. Anatole France (born 1844) has written novels, but can scarcely be called a novelist. He lacks the necessary qualities of invention and logical sequence; it is repugnant to his temperament to construct a plot; his novels follow his wayward fancy, and his characters talk more than they act. In *Le Lys Rouge* (1894) he attempts the psychological novel, but it differs from other works of the kind; for while it is perhaps inferior as a novel, it is far superior as a piece of literature; the characters, who are essentially alive, interest us more by what they say than by what they do. It is the deep philosophy and the liquid and inimitable style which interest and enchant us—that is to say, M. France himself, the showman more than the puppets. In 1897 M. France published the first volume of his *Histoire Contemporaine*, *L'Orme du Mail*, which has been followed by three other volumes, in which he invented a new form of novel, a novel without a plot, which enables him to study contemporary life from every side and aspect. Each volume of this series (*Le Mannequin d'Osier*, *L'Anneau d'Améthyste*, *Monsieur Bergeret à Paris*) is a masterpiece of satire and irony, and exhibits the cunning candour, the captivating grace and witchery which distinguish M. France's style.

A small group of novelists chose country life as their exclusive field of observation. Of these the most important are M. Ferdinand Fabre (1830–1898); M. Léon Cladel (born 1835), author of *Le Bouscassié*, *La Fête votive de Saint Bartholomée Porte-Glaive*, and *L'Homme de la Croix-aux-Bœufs*; M. Emile Pouvillon (born 1840), a writer of exquisite pastorals (*Césette*, *Jean de Jeanne*, and *Petites Âmes*); and M. André Theuriet (born 1833), author of *Sauvageonne*, *Les Mauvais Ménages*, and *Dans les Roses*, a delicate painter of provincial life and manner.

Among women authors, by far the most talented is the inimitable "Gyp" (Countess de Martel de Janville; born 1850), the modern Lucian, whose dialogues are unsurpassed for lightness of touch and sharpness of observation. Her masterpieces in this form remain *Autour du Mariage* (1883) and *Autour du Divorce* (1886), but she has also shown herself an accomplished novelist in *Le Mariage de Chiffon* (1894) and in *Bijou* (1896).

The most notable of the followers of "Gyp" in the line of light dialogue and sharp observation is Marie Anne de Bovet, author of *Roman de Femmes* (1895) and *Petites Rosseries* (1898).

M. René Bazin (born 1853), who belongs in reality to the old Idealist school, published *De toute son Âme* (1897). His best work is *La Terre qui meurt* (1899).

Criticism.—In the domain of criticism the period which begins in 1880 is still overshadowed by the great names of Renan, Taine, and in a lesser degree of Edmond Scherer (1815–1889). M. Sarcey continued from the year 1869 to 1900 to contribute his theatrical criticism to the newspaper *Le Temps* with unbroken regularity; but the true representatives of criticism during the period are MM. Brunetière, Anatole France, P. Bourget, and Jules Lemaître. M. Lemaître (born 1853) together with M. France (born 1844) were the initiators of the subjective Impressionist school of criticism, which must be traced immediately to the influence of Renan and ultimately to that of Montaigne. MM. France and Lemaître laid down the principle that impersonal and objective criticism did not exist, and that criticism was nothing else but the record of the adventures of the soul among masterpieces. The value of criticism of this kind varies with the value of the critic who practises it; in the case of MM. Lemaître and France it is hardly necessary to say that its value is consequently very great. M. Lemaître, who was for some time dramatic critic to the *Journal des Débats*, went over in that capacity to the *Revue des Deux Mondes* in 1895; in 1898 he deserted dramatic criticism altogether, and devoted himself to political work. Dramatic criticism was, in the case of M. Lemaître, a pretext for writing moral essays; and his collected articles on theatrical matters (published in ten volumes of *Impressions de Théâtre*) are in reality deeply interesting and subtle studies of contemporary society. His *Contemporains* (essays on writers who have become famous since 1870) have the same character. The impressions of books and plays which he gives to us with such apparent negligence have a philosophic value which results from the acuteness and subtlety of his intelligence and his incredible agility of mind; and his style has the supreme quality of perfect naturalness and ease, where all effort is either absent or concealed. Besides his critical work M. Lemaître has written plays (*Sérénus* and *Myrrha*) and two volumes of exquisitely graceful short stories. M. Anatole France's critical work is contained in the four volumes of *La Vie Littéraire*. These volumes form in reality a *Journal intime*—a sentimental journey through the world of books; they are distinguished by the same intensely personal and magically graceful style that characterizes M. France's work in another field.

M. Émile Faguet (born 1847), since 1876 professor at the Sorbonne, a disciple of Taine, has written four volumes on the four literary centuries of France, in which he reveals a great power of analysis. He succeeded M. Lemaître as dramatic critic to the *Journal des Débats*. He has also published two volumes of *Politiques et moralistes des XIXième siècle*.

M. René Doumic, the literary critic of the *Revue des Deux Mondes*, is a polemical writer, endowed with keen intelligence and an incisive style; he has already produced much brilliant work, notably four volumes of *Études sur la littérature Française*, 1896, 1897–1900. *Portraits d'Écrivains* and *Écrivains d'aujourdhui — Les Jeunes* (1895).

History.—From 1880 to the present day the three greatest names in French historical writing are Renan, Taine, and Fustel de Coulanges. The younger generation is divided into two schools: M. Thureau-Dangin remains faithful to classical traditions; M. Sorel is a disciple of Taine; the remaining historians seem to aim at a compromise between the two schools. The following is a list of the most important: Duc de Broglie (1821–1901)—*L'Église et l'Empire Romain au IVième siècle* (1856–66), *Le Secret du Roi* (1878), *Frédéric II. et Louis XV.* (1884), *Marie Thérèse Impératrice* (1888); Gaston Boissier (born 1823); Émile Ollivier (born 1825)—*Le 19 Janvier* (1869), *Le Ministère du 2 Janvier* (1875), *L'Église et l'État au Concile du Vatican* (1878), *l'Empire Libéral* (1894); Thureau-Dangin (born 1837) — *Un homme d'autrefois*, *L'histoire de la Monarchie de Juillet* (1886–92); Ernest Lavisse (born 1843)—*Études sur l'histoire de Prusse* (1879), *Vue Générale de l'histoire politique de l'Europe* (1890), *La Jeunesse du Grand Frédéric* (1891), *Le Grand Frédéric avant l'avènement* (1893); Albert Sorel (born 1842)—*Histoire diplomatique de la guerre Franco-Allemande* (1875), *La question d'Orient au XVIIIième siècle* (1877), *L'Europe et la Révolution Française* (1885–92); Henry Houssaye (born 1848)—*Histoire d'Alcibiade* (1873); *1814: Histoire de la campagne de France* (1888); *1815:* &c. (1893); *Waterloo* (1899); Gabriel Hanotaux (born 1853)—*Histoire de Richelieu* (1893–96); Albert Vandal (born 1853)—*L'alliance mise sous Napoleon* (1891–96).

Le Vicomte Melchior de Vogüé (born 1848) must be classed among historians, although he is at the same time an essayist and a philosopher. It was he who revealed the modern Russian novelists (Tolstoi, Tourgeneff, Dostoiewski) to the French public. His *Souvenirs et Visions*, *Regards historiques*, and *Devant le Siècle* contain brilliant studies of foreign literature, ancient and modern, historical studies, and criticisms of contemporary French literature. He has many points of resemblance to Chateaubriand, both in his imaginative power and his brilliant and poetic style.

Conclusion.—French literature in the later half of the 19th century could not boast of a constellation of poets such as those who were the pride and glory of the Romantic period; on the other hand, the balance is weighed down by two of the greatest men of genius that the century produced in Europe—Taine and Renan. Apart from his monumental historical achievement, M. Renan's incomparable style, with its unstudied grace, its inevitable perfection, its complete harmony between the idea and the expression, entitles him to the rank of the greatest prose writer of the century. There is nothing in this epoch, it is true, to equal the vast and many-stringed lyre of Victor Hugo, the lyrical passion of Musset, the seraphic organ-music of Lamartine, the great solemn echoes that fell from the ivory tower of Alfred de Vigny. Yet if we review the last half-century we can reckon three great poets—Baudelaire, Banville, and Leconte de Lisle; and in the work of Leconte de Lisle, and in that of his most brilliant disciple, M. de Heredia, we have examples of a lofty poetic vision, combined with an absolute perfection of technique—rhymes and verses which truly seem to be of gold. Besides these four prominent names there remain the delicate poetry of M. Sully Prudhomme, which follows more or less the traditional lines of French poetry, but joins to grace of diction an austere pensiveness, and the genius of Paul Verlaine, a lyric poet of the first order, who departs so far from the path of tradition that, since all things move in a circle, he can only be compared to the earliest French lyrists. In the poetry of Verlaine we are aware of a new note of pure lyricism without any admixture of rhetoric, a note that is like an "unbodied joy."

Turning to writers of fiction, if we embrace the period 1850–1900 in our review, the genius of Gustave Flaubert overshadows all other writers; if we confine ourselves to the Third Republic, we can count at least three writers of genius—Zola, Daudet, and Maupassant; and in addition to these, two whom it is impossible to classify in any definite category, so original and so personal is their exquisite art—M. Pierre Loti and M. Anatole France, who have both of them contributed invaluable jewels to the treasure-house of French literature.

In the region of criticism no period has ever been more fertile, and the historians of the early part of the century have found worthy successors in Fustel de Coulanges, Thureau-Dangin, and Albert Sorel.

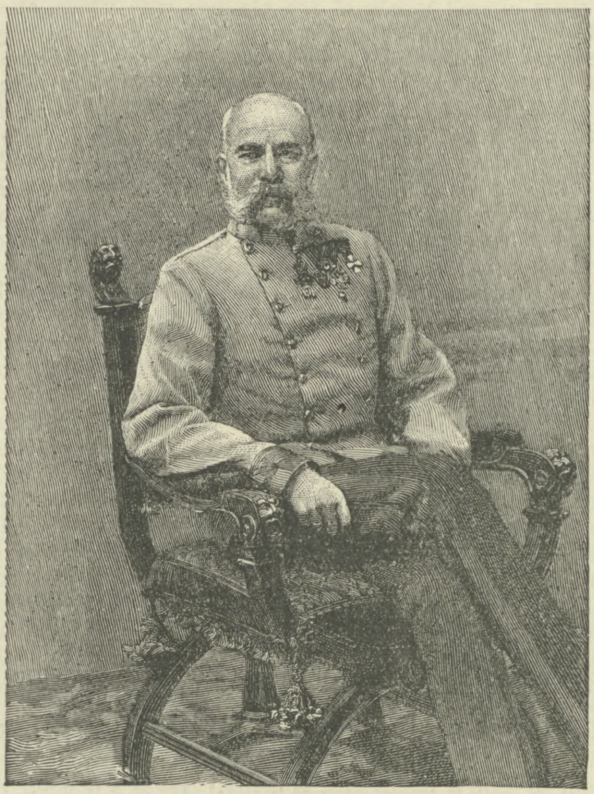
In the domain of the theatre we have had a renascence of poetical drama, of which M. Rostand is the most prominent exponent, and the appearance of a whole group of writers of subtle, delicate, and powerful dramas and comedies, such as Lemaître, Donnay, Hervieu, Porto-Riche, Lavedan, and François de Curel.

On the whole, the French literature of the second half of the 19th century can be said to rival in greatness and importance that of the first fifty years, and to claim a no less close examination from the comparative student of literature.

For French Drama and Art, see DRAMA and SCHOOLS OF PAINTING. (M. BA.)

France, Anatole (1844——), French critic, essayist, and novelist (whose real name is Jacques Anatole Thibault), was born in Paris on the 16th April 1844. His father was a bookseller, one of the last of the booksellers, if we are to believe the Goncourts, into whose establishment men came, not merely to order and buy, but to dip, and turn over pages, and discuss. M. France himself speaks of the pleasure with which, as a child, he used to listen to the nightly talks on literary subjects which took place in his father's shop. Nurtured in an atmosphere so essentially bookish, he turned naturally to literature. In 1868 his first work appeared, a study of Alfred de Vigny, a poet whom many lovers of French poetry regard with a quite peculiar affection. A volume of verse followed in 1873, *Les Poëmes dorés*, dedicated to Leconte de Lisle, and, as such a dedication suggests, an outcome of the "Parnassian" movement; and yet another volume of verse appeared in 1876, *Les Noces Corinthiennes.* But the poems in these volumes, though unmistakably the work of a man of great literary skill and cultured taste, are scarcely the poems of a man with whom verse is the highest form of expression. He was to find his richest vein in prose. And his prose is exquisite. He himself, avowing his preference for a simple, or seemingly simple, style as compared with the *artistic* style, vaunted by the Goncourts—a style compounded of neologisms and "rare" epithets, and startling forms of expression—observes: "A simple style is like white light. It is complex, but not to outward seeming. In language, a beautiful and desirable simplicity is but an appearance, and results only from the good order and sovereign economy of the various parts of speech." And thus one may say of M. France's own style that its beautiful translucency is the result of many qualities—felicity, grace, the harmonious grouping of words, a perfect measure. M. France is a sceptic. The essence of his philosophy, if a spirit so light, evanescent, elusive, can be said to have a philosophy, is doubt. He is a doubter in religion, metaphysics, morals, politics, æsthetics, science—a most genial and kindly doubter, and not at all without doubts even as to his own negative conclusions. Sometimes M. France's doubts are expressed in his own person — as in the *Jardin d'Épicure*, from which the above extracts are taken, or *Le Livre de mon Ami*, which may be accepted, perhaps, as partly autobiographical; sometimes, as in *La Rôtisserie de la Reine Pédauque*, and *Les Opinions de M. Jérôme Coignard*, or *L'Orme du Mail*, *Le Mannequin d'Osier*, and *L'Anneau d'Améthyste*, he entrusts the expression of his opinions, dramatically, to some fictitious character,—the Abbé Coignard, for instance, projecting, as it were, from the 18th century some very effective criticisms on the popular political theories of contemporary France—or the M. Bergeret of the three last-named novels, dealing in similar wise with some modern problems, and particularly, in *L'Anneau d'Améthyste*, with the humours and follies of the anti-Dreyfusards. All this makes a piquant combination. Nor should reference be omitted to works more distinctly of fancy, such as *Balthasar*, the story of one of the Magi, or *Thaïs*, the story of an actress and courtesan of Alexandria, whom a hermit converts, but with the loss of his own soul. Lightly as M. France bears his erudition, it is very real and extensive. As a critic—see the *Vie Littéraire*, reprinted mainly from *Le Temps*—he is graceful and appreciative. Academic in the best sense, he has found a place in the *Académie Française*, taking the seat vacated by Lesseps. He was received into that august body on the 24th December 1896. In the *affaire* Dreyfus he sided with M. Zola.

Francis Joseph I., Emperor of Austria, king of Bohemia, &c. &c., and apostolic king of Hungary (1830——), born 18th August 1830, was the eldest son of the Archduke Francis Charles, second son of the reigning emperor Francis I. His mother, the Archduchess Sophie, was daughter of Maximilian I., king of Bavaria. She was a woman of great ability and strong character,



The Emperor Francis Joseph I.
(*From a photograph by Carl Pietzner, Vienna.*)

and during the years which followed the death of the Emperor Francis was probably the most influential personage at the Austrian Court; for the Emperor Ferdinand, who succeeded in 1835, was physically and mentally incapable of performing the duties of his office; as he was childless, Francis Joseph was in the direct line of succession. During the disturbances of 1848 he spent some time in Italy, where, under Radetzky, at the battle of St Lucia, he had his first experience of warfare. At the end of that year, after the rising of Vienna and capture of the city by Windischgrätz, it was clearly desirable that there should be a more vigorous ruler at the head of the empire, and Ferdinand, now that the young archduke was of age, was able to carry out the abdication which he and his wife had long desired. All the preparations were made with the utmost secrecy; on 2nd December 1848, in the archiepiscopal palace at Olmütz, whither the Court had fled from Vienna, the emperor abdicated. His brother, the archduke, resigned his rights of succession to his son, and Francis Joseph was proclaimed emperor. Ferdinand retired to Prague, where he died in 1875. The new emperor was naturally during the first years of his reign completely in the hands of Prince Felix Schwarzenberg, to whom, with Windischgrätz and Radetzky, he owed it that Austria had emerged from the revolution apparently stronger than it had been before. The first task was to reduce Hungary to obedience, for the Magyars, who refused to acknowledge the act of 2nd December, at which they had not been represented, proclaimed a republic. In the war which followed the emperor himself took part, but it was not brought to a successful conclusion till the help of the Russians had been called in. The new reign began, therefore, under sinister omens, with the suppression of liberty in Italy, Hungary, and Germany. In 1853 a Hungarian named Lebenyi attempted to assassinate the emperor, and succeeded in inflicting a serious wound with a knife. With the death of Schwarzenberg in 1852 the personal government of the emperor really began, and with it that long series of experiments of which Austria has been the subject. Generally it may be said that throughout his long reign he has been the real ruler of his dominions; he has kept in his hands not only the appointment and dismissal of his ministers, but has himself directed their policy, and owing to the great knowledge of affairs, the unremitting diligence and clearness of apprehension, to which all who have transacted business with him have borne testimony, has been able to keep a very real control even of the details of government. The introduction of parliamentary government in 1866 necessarily made some change in his position, and so far as concerns Hungary he fully accepted the doctrine that ministers were responsible to parliament. In the other half of the empire this has not been possible (see the article on Austria), and the authority and influence of the emperor have been even increased by the contrast with the weaknesses and failures of the parliamentary system. The most noticeable features in his reign have been the repeated and sudden changes of policy, which, while they arise from the extreme difficulty of finding any system by which the empire can be governed, also are due to the personal idiosyncrasies of the emperor. First we have autocratic centralization under Bach; the personal influence of the emperor is seen in the conclusion of the Concordat with Rome, by which the work of Joseph II. was undone and the full power of the Papacy restored. The foreign policy of this period brought about the complete isolation of Austria, and the "ingratitude" towards Russia, as shown during the period of the Crimean War, which has become proverbial, caused a permanent estrangement between the two great Eastern empires and the imperial families. The system led inevitably to bankruptcy and ruin; the war of 1859, by bringing it to an end, saved Austria. After the first defeat Francis Joseph hastened to Italy; he commanded in person at Solferino, and by a meeting with Napoleon arranged the terms of the peace of Villafranca. The next six years, both in home and foreign policy, were marked by great vacillation. In order to meet the universal discontent and the financial difficulties constitutional government was introduced; a parliament was established in which all races of the empire were represented, and in place of centralized despotism was established Liberal centralization under Schmerling and the German Liberals. The opposition of the Magyars and Slavs continued, and the emperor had really withdrawn his confidence from Schmerling long before the Constitution was suspended in 1865 as a first step to a reconciliation with Hungary. In the complicated German affairs the emperor in vain sought for a minister on whose knowledge and advice he could depend. He was guided in turn by the inconsistent advice of Schmerling, Rechberg, Mensdorff, not to mention more obscure counsellors, and it is not surprising that Austria was repeatedly outmatched and outwitted by Prussia. In 1863, at the Fürsten Tag in Frankfurt, the emperor made an interesting attempt by his personal influence to solve the German question. The origin of the plan is still obscure. He invited all the German rulers to meet him in conference, and before them he laid a plan for the reform of the Confederation. The effect of the movement was immense; he seemed for a moment to have regained the position in Germany which his ancestors had held. He was welcomed to the ancient free city with enthusiasm. He himself presided at the discussions, and all the princes celebrated

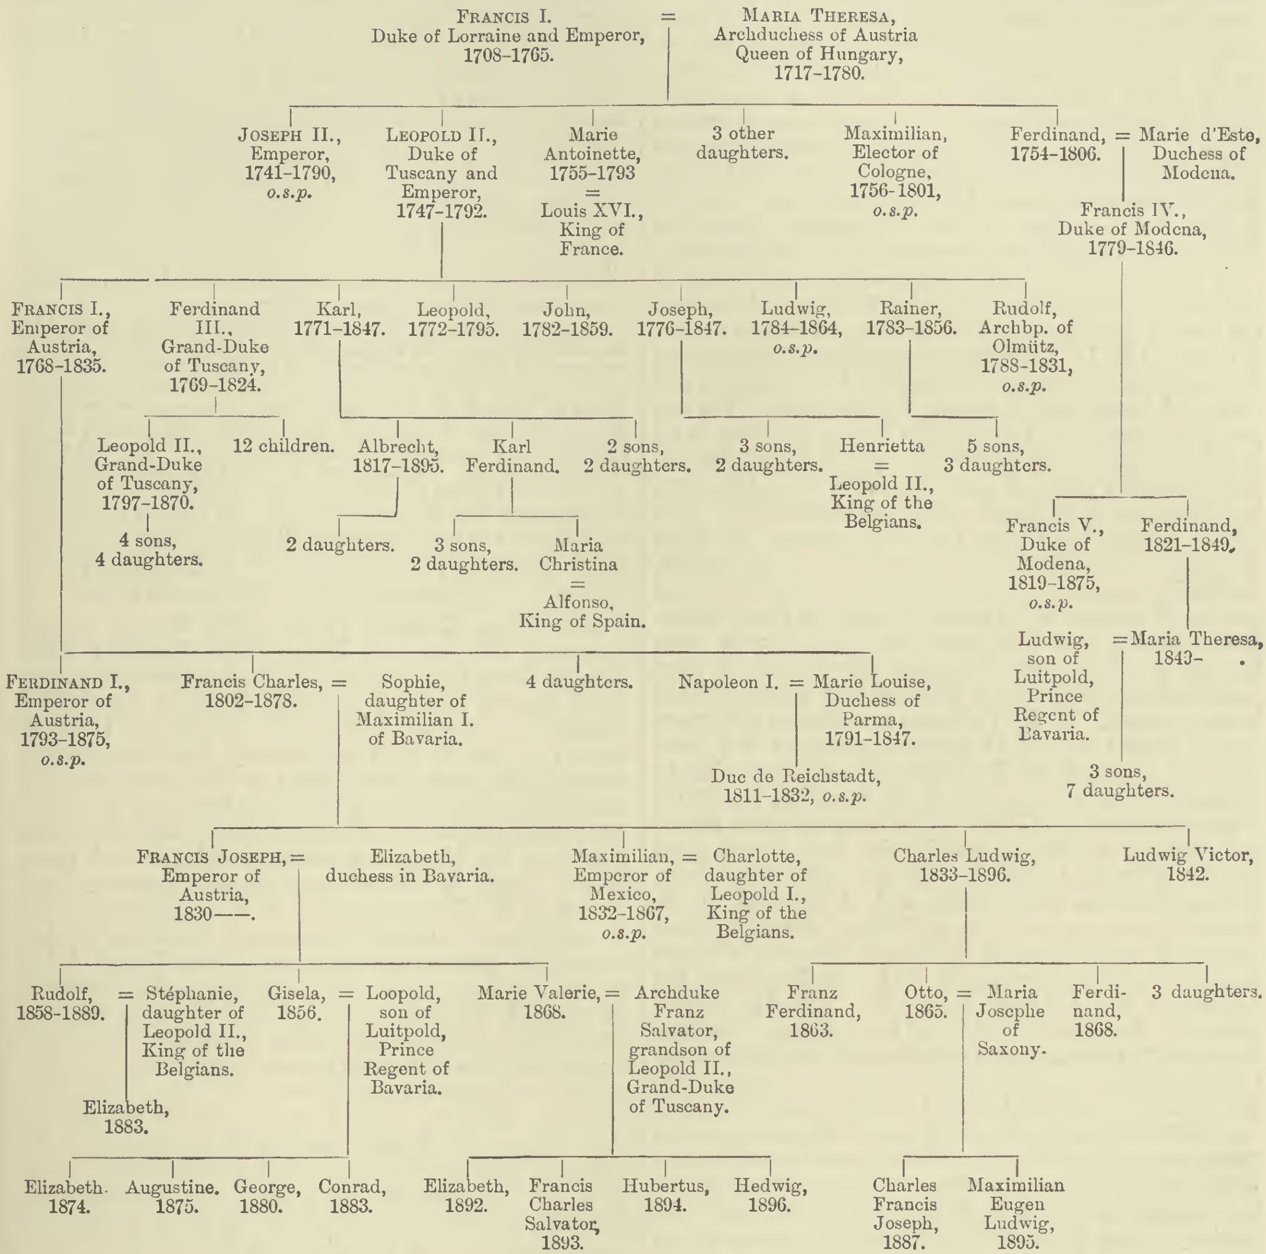


TABLE SHOWING THE DESCENT OF THE HABSBURG-LORRAINE DYNASTY.

the skill which he showed in the conduct of the debate; but the attempt failed, for the king of Prussia refused the invitation. The war with Prussia in 1866 was not of his seeking; he took no part in the campaign, but by a sudden resolution after the battle of Königgrätz telegraphed to Napoleon asking for his mediation, and offering him Venetia. The defeat made the reconciliation with Hungary, which the emperor had long desired, necessary. Deák was summoned to Vienna, and in a personal interview with the emperor explained the demands of the Magyars. At last the mistakes with which the reign was opened were repaired; Beust was appointed minister, and in 1867 the emperor and empress were solemnly crowned at Buda-Pest with the crown of St Stephen. (For the later history we must refer to the article on AUSTRIA-HUNGARY.) The influence of the emperor is to be seen first in the loyal adhesion to the constitutional system which he himself inaugurated. There is probably no other instance in history of a ruler, brought up as he was in the strictest school of absolute government, accepting without reserve the restrictions of parliamentary government, notwithstanding the great discouragement caused by the party struggles.

The emperor has also shown his desire to reconcile the Slavs to the crown as he did the Magyars; but though he has on more than one occasion held out hopes that he would be crowned king of Bohemia, the project has always been abandoned. In 1869 and 1870 he showed his prudence by refusing to be led into a war of revenge against Prussia, and in later years he fully accepted the reconciliation with Germany and Italy, the two Powers which were built up on the defeat of Austria—in this, as in internal affairs, refusing to allow prejudices, which would have been only natural for a man in his position, to influence his policy. He has therefore become one of the chief elements in the system on which the peace of Europe depends, just as in the government of his own dominions it is his personal influence which alone is able to maintain some authority over the parties and races, the discord of which threatens the disruption of the empire.

In his private life the emperor has been the victim of terrible catastrophes—his wife, his brother, and his only son having been destroyed by sudden and violent deaths. He married in 1854 ELIZABETH, daughter of Maximilian Joseph, duke in Bavaria, who belonged to the younger and non-royal branch of the house of Wittelsbach. The empress, who shared the remarkable beauty common to all her family, took little part in the public life of Austria. After the first years of married life she was seldom seen in Vienna, and spent much of her time in travelling. She built a castle of great beauty and magnificence, called the Achilleion, in the island of Corfu, where she often resided. In 1867 she accompanied the emperor to Buda-Pest, and took much interest in the reconciliation with the Magyars. She became a good Hungarian scholar, and spent much time in Hungary. An admirable horsewoman, in later years she repeatedly visited England and Ireland for the hunting season. In 1897 she was assassinated at Geneva by an Italian anarchist; previous attempts had been made on her and her husband's life during a visit to Trieste. There was one son of the marriage, the Crown Prince RUDOLPH (1857–1889). A man of much ability and promise, he was a good linguist, and showed great interest in natural history. He published two works, *Fifteen Days on the Danube*, and *A Journey in the East*, and also promoted the publication of an important illustrated work giving a full description of the whole Austro-Hungarian monarchy; he personally shared the labours of the editorial work. In 1881 he married Stéphanie, daughter of the king of the Belgians. On 30th January 1889 he committed suicide at Mayerling, a country house near Vienna. He left one daughter, Elizabeth, who was betrothed to Count Alfred Windischgrätz in 1901. In 1900 his widow, the Crown Princess Stéphanie, married Count Lonyay; by this she sacrificed her rank and position within the Austrian monarchy. Besides the crown prince the empress gave birth to three daughters, of whom two survive: Gisela (born 1857), who married a son of the prince regent of Bavaria; and Marie Valerie (born 1868), who married the Archduke Franz Salvator of Tuscany.

Owing to the composite nature of the Austro-Hungarian monarchy the person of the reigning monarch and all questions connected with the succession have a more fundamental importance than in other States, for it is by the dynasty alone that the empire is bound together. The rules of succession are determined by the Pragmatic Sanction and by the family code of the archducal house of Austria, by which, as in other German princely families, women are excluded from the succession so long as there are any male heirs. The table on page 309 shows the descent of the different branches of the family from the Emperor Francis and Maria Theresa, the founders of the present dynasty of Habsburg-Lorraine. In default of heirs-male of the present emperor the succession will go to his brother. The next brother, the Archduke Ferdinand, accepted the position of emperor of Mexico, and was shot by the Mexicans in 1867. The fourth brother is unmarried. The third brother, Karl Ludwig (died 1895), left three sons. The eldest, Franz Ferdinand, is therefore heir-presumptive. On the death of Francis V., last duke of Modena, without male issue, the emperor assumed the title of duke of Modena, and the Archduke Franz Ferdinand, who inherited the great wealth of the family of Este, assumed the style of archduke of Austria-Este. If he succeed to the empire the Este possessions will pass to his second brother. It will be remembered that the duchy of Modena was annexed to the kingdom of Italy in 1859, so that the family is no longer reigning. The title and possessions came into the house of Austria by the marriage of the Archduke Ferdinand with the heiress of the house of Este in 1777. It is Maria of Modena, the only daughter of the last duke of Modena (married to a son of the prince regent of Bavaria), who is regarded by some as the direct representative of the house of Stewart. In 1900 the Archduke Franz Ferdinand married the Countess Sophie Chotek, who received the title of princess of Hohenberg. As the countess is not of equal birth, the archduke, before the marriage took place, had to take an oath recognizing, that in virtue of the family code any children of the marriage would be incapable of succession. A large party in the Hungarian parliament contended, however, that the conception of a morganatic marriage was unknown in Hungary, and that therefore this was an arbitrary and illegal alteration in the law of succession. To meet this a special law was carried through the Hungarian Diet declaring the children excluded from the succession to the throne of Hungary.

The grand-duchy of Tuscany, which was originally acquired by the house of Lorraine in exchange for the duchy of Lorraine, which was annexed to France, was generally held by a younger branch of the family. The duchy was in 1859 annexed to the kingdom of Italy. A son of Leopold II., the last reigning duke, was the Archduke JOHANN NEPOMUCK SALVATOR (born 1852). He attained a high position in the Austrian army, and was the author of several works on military affairs. The opinions expressed in these accentuated differences which had arisen between him and the military authorities, especially the Archduke Albrecht. In 1887 he retired from active service; in 1889 he resigned all rights and titles which belonged to him as archduke, and under the name of JOHN ORTH assumed the command of a sailing-vessel. He was probably lost at sea during a voyage from Buenos Aires to Valparaiso in 1896.

Franck, César (1822–1890), French musical composer, was born at Liége, 10th December 1822. Though one of the most remarkable of modern composers, César Franck laboured for many years in comparative obscurity. After some preliminary studies at Liége he came to Paris in 1837 and entered the Conservatoire, obtaining the prize for the organ in 1841, after which he settled down in the French capital as teacher of the piano. His earliest compositions date from this period, and include four trios for piano and strings, besides several piano pieces. *Ruth*, a biblical cantata, was produced with success at the Conservatoire in 1846. An opera entitled *Le Valet de Ferme* was written about this time, but has never been performed. For many years Franck led a retired life, devoting himself to teaching and to his duties as organist, first at Saint-Jean-Saint-François, then at Ste Clotilde, where he acquired a great reputation as an improviser. He also wrote a mass, heard in 1861, and a quantity of motets, organ pieces, and other works of a religious character. Franck was appointed professor of the organ at the Paris Conservatoire in 1872, and the following year he was naturalized a Frenchman. Until then he was esteemed as a clever and conscientious musician, but he was now about to prove his title to something more. A revival of his early oratorio, *Ruth*, had brought his name again before the public, and this was followed by the production of *Rédemption*, a work for solo, chorus, and orchestra, given under the direction of M. Colonne on 10th April 1873. The serious character of the music and its unconventionality perhaps rather disconcerted the general public, but the work nevertheless made its mark, and Franck became the central figure of an enthusiastic circle of pupils and adherents whose devotion atoned for the comparative indifference of the masses. His creative power now manifested itself in a series of works of varied kinds, and the name of Franck began gradually to emerge from its obscurity. The following is an enumeration of his subsequent compositions:

Rebecca (1881), a biblical idyll for solo, chorus, and orchestra; *Les Béatitudes*, an oratorio composed between 1870 and 1880, perhaps his greatest work; the symphonic poems, *Les Éolides* (1876), *Le Chasseur Maudit* (1883), *Les Djinns* (1884), for piano and orchestra; *Psyche* (1888), for orchestra and chorus; symphonic variations for piano and orchestra (1885); symphony in D (1889); quintet for piano and strings (1880); sonata for piano and violin (1886); string quartet (1889); prelude, choral and fugue for piano (1884); prelude, aria and finale for piano (1889); various songs, notably "La Procession" and "Les Cloches du Soir." Franck also composed two four-act operas, *Hulda* and *Ghiselle*, both of which were produced at Monte Carlo after his death, which took place in Paris, 9th November 1890. The second of these was left by the master in an unfinished state, and the instrumentation was completed by several of his pupils. César Franck's influence on the younger French composers of the present has been very great. Yet it is impossible to accept him as a typical representative of French music. A Belgian by birth, he came of German stock, and heredity in this instance undoubtedly asserted itself. A more sincere, modest, self-respecting composer probably never existed. In the centre of the brilliant French capital he was able to lead a laborious existence consecrated to his threefold career of organist, teacher, and composer. He never sought to gain the suffrages of the public by unworthy concessions, but kept straight on his path, ever mindful of an ideal to be reached and never swerving therefrom. His compositions are not likely ever to obtain popularity in the widest sense of the word, but their great qualities of originality and nobility will cause them to be more and more prized by musicians. It may be said that several of the more prominent French composers of our day learned the practice of their art under César Franck. (A. He.)

Franeker, a Netherlands town, in the province of Friesland, 10 miles west of Leeuwarden, on the Harlingen-Leeuwarden railway. It is at the junction of many roads and waterways, and has a considerable market for agricultural produce, butter, cheese, and flax. It has also potteries and shipbuilding yards. Population (1900), 7114.

Frankfort, capital of Clinton county, Indiana, U.S.A., 40 miles from Indianapolis, at an altitude of 857 feet. It is at the intersection of the Chicago, Indianapolis, and Louisville, the Lake Erie and Western, the Toledo, St Louis and Kansas City, and the Vandalia railways. Population (1880), 2803; (1890), 5919; (1900), 7100, of whom 144 were foreign-born, and 90 negroes.

Frankfort, capital of Franklin county, Kentucky, U.S.A., and the capital of the State, on the Kentucky river, at an altitude of 560 feet. It has three railways, the Chesapeake and Ohio, the Louisville and Nashville, and the Frankfort and Cincinnati. Population (1880), 6958; (1890), 7892; (1900), 9487, of whom 266 were foreign-born, and 3316 negroes.

Frankfort-on-Main, a town of Prussia, province Hesse-Nassau, standing on the right bank of the Main, 24 miles above its confluence with the Rhine at Mainz. Since 1899 Frankfort has been the headquarters of the 18th German Army Corps. The restoration of the cathedral, begun in 1869, was finished in 1890. The church of St Leonhard was restored in 1882. The most noteworthy of the new churches are St Peter's (1893–95), in the North German Renaissance style, with a tower 256 feet high, standing north from the Zeil; Christ church (1883); and the Luther church (1894). A new synagogue was built in 1881. Several of the old houses incorporated in the Römer, and the Römer itself, were restored during the years 1888–98. The Judengasse, down to 1806 the sole Jews' quarter, has been pulled down, with the exception of the ancestral house of the Rothschild family, which has been restored and retains its ancient façade. The Thurn-und-Taxis Palace is incorporated with the imposing pile of the post-office, a new building of 1892–94, with a monument of the Emperor William I. (1895) in front of it. In the same quarter, *i.e.*, north of the Zeil, are the Exchange (1879), with a commercial museum, and the law courts (1884–89), in the German Renaissance style. The municipal library, which now contains some 215,000 volumes, was enlarged and rebuilt in 1891–93. The fine bridge, originally used by the Main-Neckar railway, has been given over to road traffic, and two new iron bridges at Gutleuthof and Niederrad carry the railway traffic from the south to the north bank of the Main, where all lines converge in a central station of the State railways. This station, which was built in 1883–88, and has replaced the three stations belonging to private companies which stood in juxtaposition on the Anlagen near the Mainzer Thor, lies some half-mile to the west. The intervening ground upon which the railway lines and buildings stood was sold for building sites, the sum thus obtained being more than sufficient to cover the cost of the majestic central station, which, in addition to spacious and handsome halls for passenger accommodation, has three glass-covered spans of 180 feet width each. The so-called Leinwand-Haus, a 14th-century building, reconstructed in 1892, contains a valuable historical museum and the town archives. Behind the Goethe-Haus was opened in 1897 the Goethe Museum, together with a library of some 20,000 volumes, representative of the Goethe period of German literature. There may also be mentioned the industrial art exhibition of the Polytechnic Association; two conservatories of music; Schopenhauer's house, on the Main side; monuments to Schopenhauer (1895), the Emperor William I. (1896), and Clemens Brentano; a commercial high school (1901) and a commercial museum; technical improvement, higher industrial, industrial art, commercial, and other schools; and a large number of banks. In 1891 the International Electro-Technical Exhibition was held here. Of recent years, Frankfort, or rather Sachsenhausen (on the left bank of the Main) and Bockenheim have developed considerable industrial activity, especially in publishing and printing, brewing, and the manufacture of quinine. Other sources of employment are the cutting of hair for making hats, the production of fancy goods, type, machinery, soap and perfumery, ready-made clothing, chemicals, electro-technical apparatus, and metal wares. Market-gardening is extensively carried on in the neighbourhood, and Frankfort itself is a seat of floriculture. Cider is extensively manufactured. Here is a trade arbitration court, for the settlement of disputes arising out of labour contracts. Since the completion of the canalization of the Main past the town the trade of Frankfort, especially the transit trade, has largely increased. A total of 4103 vessels of 1,560,700 tons entered and cleared together by river in 1898. Population (1885), 154,513; (1890), 179,985; (1895), 229,279; (1900), 288,489. In 1895 the town of Bockenheim was incorporated in Frankfort-on-Main. Old Frankfort life is described in Goethe's *Wahrheit und Dichtung* and in Heine's *Rabbi von Bacharach.* See also the series of plates entitled *Frankfurt, die freie Stadt, in Bauwerken und Strassenbildern*, by Reiffenstein (Frankfurt, 1894–98), and Dietz, *Frankfürter Bürgerbuch, geschichtliche Mitteilungen* (*ib.* 1896). (J. T. Be.)

Frankfort-on-Oder, a town of Prussia, on the Oder, 50 miles E.S.E. of Berlin, capital of the government district of Frankfurt, province of Brandenburg; a railway centre to Berlin, Breslau, Cüstrin, Posen, &c. There are Evangelical, Reformed, and Catholic churches; and among the schools are a higher grade girls', with a seminary for female teachers, and 9 Evangelical schools. A new stone bridge, 855 feet long, spanning the Oder, connects the town with the suburb of Damm. There is a monument of the Franco-German war (1882), and one to Prince Frederick Charles (1888). A workshop of the Lower-Silesian and Brandenburg railway employs over 800 workmen. Trade has suffered from the decline of the three fairs and the neighbourhood of Berlin. Population (1890), 55,738; (1900), 61,572.

Frankland, Sir Edward (1825–1899), English chemist, was born at Churchtown, near Lancaster, on 18th January 1825. After attending the grammar-school at Lancaster he studied chemistry, first in London and then in the laboratories of Liebig at Giessen and Bunsen at Marburg. From an early age he engaged in original research with great success, proving himself an experimentalist of exceptional brilliancy. Analytical problems, such as the isolation of certain organic radicals, attracted his attention to begin with, but he soon turned to synthetical studies, and he was only about twenty-five years of age when an investigation, doubtless suggested by the work of his master, Bunsen, on cacodyl, yielded the interesting discovery of the organo-metallic compounds which are formed by the direct combination of a metal with a positive organic radical. The theoretical deductions which he drew from the consideration of these bodies were even more interesting and important than the bodies themselves. Perceiving a molecular isonomy between them and the inorganic compounds of the metals from which they may be formed, he saw their true molecular type in the oxygen, sulphur, or chlorine compounds of those metals, from which he held them to be derived by the substitution of an organic group for the oxygen, sulphur, &c. In this way they enabled him to overthrow the theory of conjugate compounds, and they further led him in 1852 to publish the conception that the atoms of each elementary substance have a definite saturation capacity, so that they have only room, so to speak, for the attachment of a certain limited number of the atoms of other elements. The theory of valency thus founded has dominated the whole subsequent development of chemical doctrine, and forms the groundwork upon which the fabric of modern structural chemistry reposes. In applied chemistry Frankland's great work was in connexion with water-supply. Appointed a member of the second Royal Commission on the Pollution of Rivers in 1868, he was provided by the Government with a completely-equipped laboratory, in which, for a period of six years, he carried on the inquiries necessary for the purposes of that body, and was thus the means of bringing to light an enormous amount of valuable information respecting the contamination of rivers by sewage, trade-refuse, &c., and the purification of water for domestic use. In 1865, when he succeeded Hofmann at the Royal College of Chemistry, he undertook the duty of making monthly reports to the Registrar-General on the character of the water supplied to London, and these he continued down to the end of his life. At one time he was an unsparing critic of its quality, but in later years he became strongly convinced of its general excellence and wholesomeness. His analyses were both chemical and bacteriological, and his dissatisfaction with the processes in vogue for the former at the time of his appointment caused him to spend two years in devising new and more accurate methods. In 1859 he passed a night on the very top of Mont Blanc in company with Tyndall, of whom he was for some years a colleague at the Royal Institution, where he succeeded Faraday as professor of chemistry in 1863. One of the purposes of the expedition was to discover whether the rate of combustion of a candle varies with the density of the atmosphere in which it is burnt, a question which was answered in the negative. Other observations made by Frankland at the time formed the starting-point of a series of experiments which yielded far-reaching results. He noticed that at the summit the candle gave a very poor light, and was thereby led to investigate the effect produced on luminous flames by varying the pressure of the atmosphere in which they are burning. He found that pressure increases luminosity, so that hydrogen, for example, the flame of which in normal circumstances gives no light, burns with a luminous flame under a pressure of ten or twenty atmospheres, and the inference he drew was that the presence of solid particles is not the only factor that determines the light-giving power of a flame. Further, he showed that the spectrum of a dense ignited gas resembles that of an incandescent liquid or solid, and he traced a gradual change in the spectrum of an incandescent gas under increasing pressure, the sharp lines observable when it is extremely attenuated broadening out to nebulous bands as the pressure rises, till they merge in the continuous spectrum as the gas approaches a density comparable with that of the liquid state. An application of these results to solar physics in conjunction with Sir Norman Lockyer led to the view that at least the external layers, or photosphere, of the sun cannot consist of matter in the liquid or solid forms, but must be composed of gases or vapours. Frankland and Lockyer were also the discoverers of helium. In 1868 they noticed in the solar spectrum a bright yellow line which did not correspond to any substance then known, and which they therefore attributed to a hypothetical element, helium; this some thirty years afterwards was actually proved by Professor W. Ramsay to exist on this earth. Sir Edward Frankland died on 9th August 1899, while on a holiday in Norway.

A memorial lecture delivered by Professor H. E. Armstrong before the London Chemical Society on 31st October 1901 contained many personal details of Frankland's life, together with a full discussion of his scientific work. (H. M. R.)

Franklin, a town of Norfolk county, Massachusetts, U.S.A., with an area of 29 square miles of rolling surface. The principal village, which bears the same name as the town, is on the New England Railway. Population of the town (1880), 4051; (1890), 4831; (1900), 5017, of whom 1250 were foreign-born.

Franklin, a city of Merrimack county, New Hampshire, U.S.A., on the Merrimack river and on the Boston and Maine Railroad. It contains numerous small villages in which many minor manufactures are carried on. These villages are Franklin, Franklin Falls, Maplewood, Webster Place, Shaw Corner, and Lake City. Population of the town (1880), 3265; (1890), 4085; (1900), 5846, of whom 1323 were foreign-born.

Franklin, capital of Venango county, Pennsylvania, U.S.A., on the Allegheny river, at an altitude of 988 feet. Four railways intersect here, the Allegheny Valley, the Erie, the Lake Shore and Michigan Southern, and the Western New York and Pennsylvania. The city is well sewered, and paved with brick. Franklin is in the oil region, and owes its origin and prosperity to that mineral. Among its manufacturing establishments, those for the refining of petroleum are prominent. Population (1880), 5010; (1890), 6221; (1900), 7317, of whom 489 were foreign-born, and 264 negroes.

Franks, Sir Augustus Wollaston (1826–1897), English antiquary, was born on 20th March 1826, and was educated at Eton and at Trinity College, Cambridge. From his boyhood he evinced a strong predilection for antiquarian pursuits, and in 1851 was appointed assistant in the Antiquities Department of the British Museum, a line of life in general but little affected by young men endowed like Franks with ample private means. Here, and as Director of the Society of Antiquaries, which appointment he received in 1858, he made himself the first authority in England upon mediæval antiquities of all descriptions, upon porcelain, glass, the manufactures of savage nations, and in general upon all Oriental curiosities and works of art later than the Classical period. In 1866 the British and mediæval antiquities, with the ethnographical collections, were formed into a distinct department under his superintendence; and the Christy collection of ethnography in Victoria Street, London, prior to its amalgamation with the British Museum collections, was also under his care. He became a Vice-President and ultimately President of the Society of Antiquaries, and in 1878 declined the Principal Librarianship of the Museum. He retired on his seventieth birthday, 1896, and died on 21st May 1897. The British Museum has had officers as distinguished in their respective departments as Sir A. W. Franks, though none more so; but it was unique good fortune that almost the only officer it has ever had in a position greatly to enrich its collections from his own stores should also have been a man of rare munificence. Sir A. W. Franks's ample fortune was largely devoted to the collection of ceramics and precious objects of mediæval art, most of which became the property of the nation, either by donation in his lifetime or by bequest at his death. Although chiefly a mediæval antiquary, Franks was also an authority on classical art, especially Roman remains in Britain: he was also greatly interested in book-marks and playing-cards, of both of which he formed important collections. He edited Kemble's *Horæ Ferales*, and wrote numerous memoirs on archæological subjects. Perhaps his most important work of this class is the catalogue of his own collection of porcelain, which he permitted to be for a long time exhibited at the Bethnal Green Museum in the east of London. (R. G.)

Franz, Robert (1815–1892), German composer, was born at Halle, 28th June 1815. One of the most gifted of German song writers, he suffered in early life, as many musicians have suffered, from the hostility of his parents to a musical career. He was twenty years old when, his father's animosity conquered, he was allowed to live in Dessau to study organ-playing under Schneider. The two years of dry study under that famous teacher were advantageous chiefly in making him uncommonly intimate with the works of Bach and Handel, his knowledge of which he showed in his editions of the *Matthäus Passion*, *Magnificat*, ten cantatas, and of the *Messiah* and *L'Allegro*, though some of these editions have long been a subject of controversy among musicians. In 1843 he published his first book of songs, which ultimately was followed by some fifty more books, containing in all about 250 songs. At Halle, Franz filled various public offices, including those of organist to the city, conductor of the Sing-akademie and of the Symphony concerts, and he was also a royal music-director, and master of the music at the university. The first book of songs was warmly praised by Schumann and Liszt, the latter of whom wrote a lengthy review of it in Schumann's paper, *Die Neue Zeitschrift*, which later was published separately. Deafness had begun to make itself apparent as early as 1841, and Franz suffered also from a nervous disorder, which in 1868 compelled him to resign his offices. His future was then provided for by Liszt, Dr Joachim, Frau Magnus, and others, who gave him the receipts of a concert tour, amounting to some 100,000 marks. Franz died on 24th October 1892. On his seventieth birthday he published his first and only pianoforte piece. It is easy to find here and there among his songs gems that are hardly less brilliant than the best of Schumann's. Certainly no musician was ever more thoughtful and more painstaking. In addition to songs he wrote a setting for double choir of the 117th Psalm, and a four-part Kyrie; he also edited Astorga's *Stabat Mater* and Durante's *Magnificat*, and published an "open letter" to Hanslick on his methods of editing. (R. H. L.)

Franzensbad, or KAISER-FRANZENSBAD, a well-known Bohemian watering-place in the government district of Eger. It possesses besides an international hospital for poor patients and four large bathing establishments, Roman Catholic, Protestant, and Russian Churches, a synagogue, and a theatre. The mineral springs, used internally as well as externally, are twelve in number—saline, alkaline, and ferruginous—and one contains a considerable proportion of lithia salts. The so-called "moor-" or mud-baths, prepared from the peat of the Franzensbad marsh, which is rich in mineral substances, are an important part of the cure. Franzensbad is frequently resorted to for an after cure by patients from Marienbad and Karlsbad. There are over 8000 visitors during the season, and a considerable trade is done in mineral waters, &c. In 1890 the population (mostly German) was 2370; in 1900, 2330.

Franzensfeste, or FRANZENSVESTE, a strong Austrian fortress in the government district of Brixen, Tirol, on the road from the latter town to the Brenner Pass, at the entrance of the Pusterthal. It is situated on the right bank of the Eisack, about 9 miles north of Brixen, at the mouth of the narrow defile known as the "Brixener Klause," which is the junction of the roads from Botzen, Innsbruck, and the Pusterthal. It thus commands the Brenner road and railway and the entrance to the Puster Valley, with the railway to Villach, Klagenfurt, and Marburg. The latter line passes through the fortifications, crossing the Eisack by an iron bridge, 218 yards in length, and resting upon six granite piers. This bridge, together with the old wooden structure, the Ladritsch Brücke, is covered by the guns of the fort. Franzensveste station, about a mile north of the fortifications, has about 300 inhabitants.

For the strategic value of this fortress, and generally of the Austrian fortifications in Tirol, see articles by Lieut.-Col. Herman Frobenius in the *Archiv für die Artillerie- und Ingenieur-Officiere des deutschen Reichsheeres*, June–September 1895. The Austrian Field-Marshal Franz von Kuhn in his *Gebirgskrieg* (second edition, Vienna, 1878) draws many of his illustrations from Tirol, which he considers of incalculable value to the monarchy, not only in a war against Italy, but also in one with Germany.

Franz Josef Land, an arctic archipelago lying to the east of Spitsbergen and the north of Novaya Zemlya, extending northwards from about 80° N. lat. Petermann has expressed the opinion that Baffin may have sighted the west of Franz Josef Land in 1614, but the first actual discovery is due to Julius Payer, a lieutenant in the Austrian army, who was associated with Weyprecht in the second polar expedition fitted out by Count Wilczek on the ship *Tegetthof* in 1872. On 13th August 1873, the *Tegetthof* being then beset, high land was seen to the north-west. Later in the season Payer led expeditions to Hochstetter and Wilczek islands, and after a second winter in the ice-bound ship, a difficult journey was made northwards through Austria Sound, which was reported to separate two large masses of land, Wilczek Land on the east from Zichy Land on the west, to Cape Fligely, in 82° 5′ N. lat., where Rawlinson Sound branched away to the north-east. Cape Fligely was the highest latitude attained by Payer, and remained the highest attained in the Old World till 1895. Payer reported that from Cape Fligely, land (Rudolf Land) stretched north-east to a cape (Cape Sherard Osborn), and mountain ranges were visible to the north, indicating lands beyond the 83rd parallel, to which the names King Oscar Land and Petermann Land were given. In 1879 De Bruyne sighted high land in the Franz Josef Land region, but otherwise it remained untouched until Leigh Smith, in the yacht *Eira*, explored the whole southern coast from 42° to 54° E. long. in 1881 and 1882, discovering many islands and sounds, and ascertaining that the coast of Alexandra Land, in the extreme west, trended to north-west and north. In the face of almost insuperable difficulties, including the loss of his ship, Leigh Smith made botanical and zoological collections of great value, although he failed to reach high latitudes. After Leigh Smith comes another pause, and no further mention is made of Franz Josef Land till 1894. In that year Mr Alfred Harmsworth fitted out an expedition in the ship *Windward* under the leadership of Mr F. G. Jackson, with the object of establishing a permanent base from which systematic exploration should be carried on for successive years, and, if practicable, a journey should be made to the Pole. Mr Jackson and his party landed at "Elmwood," near Cape Flora, at the western extremity of Northbrook Island, on 7th September. After a preliminary reconnaissance to the north, which afterwards turned out to be vitally important, the summer of 1895 was spent in exploring the coast to the north-west by a boating expedition. This expedition visited many of the points seen by Leigh Smith, and discovered land, which it has been suggested may be the Gillies Land reported by the Dutch captain Gillies in 1707. In 1896 the Jackson-Harmsworth expedition worked northwards through an archipelago for about 70 miles, and reached Cape Richthofen, a promontory 700 feet high, whence an expanse of open water was seen to the northward, which received the name of Queen Victoria Sea. To the west, on the opposite side of a wide opening which was called the British Channel, appeared glacier-covered land, and an island lay to the northward. The island was probably the King Oscar Land of Payer. To north and north-east was the land which had been visited in the reconnaissance of the previous year, but beyond it a water-sky appeared in the supposed position of Petermann Land. Thus Zichy Land itself was resolved into a group of islands, and the outlying land sighted by Payer was found to be islands also. Meanwhile Nansen, on his southward journey, had approached Franz Josef Land from the north-east, finding only sea at the north end of Wilczek Land, and seeing nothing of Payer's Rawlinson Sound, or of the north end of Austria Sound. Nansen wintered near Cape Norway, only a few miles from the spot reached by Jackson in 1895. The general results of the two explorers agree in the conclusion that Franz Josef Land consists of an archipelago of small islands, which extends westwards to a distance as yet undetermined, but is probably connected by a continuous chain with Spitsbergen. Nansen had of course finally proved that a deep oceanic basin lies to the north. The *Windward* revisited "Elmwood" in 1896 and brought Nansen home, the work of the Jackson-Harmsworth expedition being continued for another year. As the non-existence of land to the north had been proved, the attempt to penetrate northwards was abandoned, and the last season was devoted to a survey and scientific examination of the archipelago, especially to the west; this was carried out by Jackson, Armitage, Koettlitz, Fisher, and Bruce. Further light was thrown on the relations of Franz Josef Land and Spitsbergen during 1897 by the discoveries of Captain Robertson of Dundee, and Wyche's Land was circumnavigated by Mr Arnold Pike and Sir Savile Crossley. The latter voyage was repeated in the following year by a German expedition under Dr Th. Lerner and Captain Rüdiger. In August 1898 an expedition under Mr Wellman, an American, landed at Cape Tegetthof. Beginning a northward journey with sledges at the end of the following winter, Wellman met with an accident which compelled him to return, but not before some exploration had been accomplished, and the eastern extension of the archipelago fairly well defined. In June 1899, H.R.H. the Duke of Abruzzi started from Christiania in his yacht, the *Stella Polare*, to make the first attempt to force a ship into the newly-discovered ocean north of Franz Josef Land. The *Stella Polare* succeeded in making her way through the British Channel to Crown Prince Rudolf Land, and wintered in Teplitz Bay, in 81° 33′ N. lat. The ship was nearly wrecked in the autumn, and the party had to spend most of the winter on shore, the Duke of Abruzzi suffering severely from frost-bite. In March 1900 a sledge party of thirteen, under Captain Cagni, started northwards. They found no trace of Petermann Land, but with great difficulty crossed the ice to 86° 33′ N. lat., 20 miles beyond Nansen's farthest, and 240 miles from the Pole. The party, with the exception of three, returned to the ship after an absence of 104 days, and the *Stella Polare* returned to Tromsö in September 1900. (H. N. D.)

Fraser, James (1818–1885), English bishop, was born at Prestbury, in Gloucestershire, on the 18th of August 1818. His father was of Scottish descent; his mother's family lived at Bilston, in Staffordshire, which occasioned him to receive his school education at Bridgnorth and Shrewsbury. At Oxford he gained a first-class and an Oriel fellowship, and was for some time tutor of the college, but did not take orders until 1846. He was successively rector of the livings of Cholderton, in Wiltshire, and of Ufton Nervet, in Berkshire; but his rise in life was owing to Hamilton, bishop of Salisbury's recommendation of him as an assistant commissioner of education. His report on the educational condition of thirteen poor-law unions, made in May 1859, is described by Mr Thomas Hughes as "a superb, almost a unique piece of work." In 1865 he was entrusted with a commission to report on the state of education in the United States and Canada, and his able performance of his mission brought him an offer of the bishopric of Calcutta, which he declined, but in January 1870 he accepted the see of Manchester. The task before him was an arduous one, for although his predecessor, Dr Prince Lee, had consecrated no fewer than 130 churches, the enormous population was still greatly in advance of the ecclesiastical machinery. Fraser worked with the utmost energy, and did even more for the Church by the liberality and geniality which earned him the title of "the bishop of all denominations." He was prominent in secular as well as religious works, interesting himself in every movement that promoted health, morality, or education; and especially serviceable as the friendly, unofficious counsellor of all classes. He was frequently invoked as an arbitrator in trade disputes, and was seldom absent from any important public gathering of a non-political nature. His theology was that of a liberal High Churchman, but his sympathies were exceedingly broad. His death, which occurred unexpectedly on the 22nd of October 1885, evoked the most earnest demonstrations of sorrow from all classes of society. A biography of him was written by Thomas Hughes, author of *Tom Brown's School-Days*. (R. G.)

Fraserburg, a town of Cape Colony, on the northern slope of the Nieuwveld range, near the sources of the Zak river, which, when flooded, flows northwards to the left bank of the Orange below Upington. Fraserburg is a thriving agricultural centre, and possesses some importance as the chief depôt for the distribution of supplies amongst the stock-breeders of the extensive Nieuwveld plains between Carnarvon and Calvinia. Population about 2000.

Fraserburgh, a police burgh and seaport of Aberdeenshire, Scotland, 47¼ miles north by east of Aberdeen by rail. The harbour has been enlarged at a total cost, up to 1898, of £315,000. There were 15 vessels of 3741 tons registered at the port at the end of 1898, and in that year 397 vessels of 63,195 tons entered, and 388 vessels of 61,844 tons cleared. Fraserburgh is the head of a fishery district (for statistics of district, see ABERDEENSHIRE). The value of the fish (mostly herrings) landed in 1899 was £200,504. Besides 161 other boats, there are now 10 steam trawlers. It has a public hall and a hospital. The Baptist church was built in 1880, and St Peter's Episcopal in 1891. There is an endowed academy. Population (1881), 6583; (1901), 8998.

Fraserville (formerly RIVIÈRE DU LOUP EN BAS), a town, railway station, and watering-place in Temiscouata county, Quebec, Canada, 107 miles (by water) north-east of Quebec, on the south shore of River St Lawrence, and at the mouth of the River du Loup. It contains a convent, boys' college, hospital, several mills, and a number of handsome villa residences. Population (1881), 2291; (1901), 4569.

Fraud, in its widest sense, is a term which has never been exhaustively defined by an English court of law, and for legal purposes probably cannot usefully be defined. But as denoting a cause of action for which damages can be recovered in civil proceedings it now has a clear and settled meaning. In actions in which damages are claimed for fraud, the difficulties and obscurities which commonly arise are due rather to the complexity of modern commerce and the ingenuity of modern swindlers than to any uncertainty or technicality in the modern law. To succeed in such an action, the person aggrieved must first prove a representation of fact, made either by words, by writing, or by conduct, which is in fact untrue. Mere concealment is not actionable unless it amounts not only to *suppressio veri*, but to *suggestio falsi*. An expression of opinion or of intention is not enough, unless it can be shown that the opinion was not really held, or that the intention was not really entertained, in which case it must be borne in mind, to use the phrase of Lord Bowen, that the state of a man's mind is as much a matter of fact as the state of his digestion. Next, it must be proved that the representation was made without any honest belief in its truth, that is, either with actual knowledge of its falsity or with a reckless disregard whether it is true or false. It was finally established, after much controversy, in the case of *Derry* v. *Peek* in 1889, that a merely negligent misstatement is not actionable, although the fact that a statement is made without reasonable grounds for believing it to be true may be strong evidence tending to show that it was made without honest belief in its truth. Further, the person aggrieved must prove that the offender made the representation with the intention that he should act on it, though not necessarily directly to him, and that he did in fact act in reliance on it. This principle excludes from the region of actionable fraud such "flourishing descriptions" as are common among auctioneers and house-agents, and also misrepresentations of a trifling and unimportant character. But the wrong-doer cannot escape the consequences of his own mis-statement by contending that the person who relied upon it ought not to have done so, and ought to have made further inquiries; by contending, in short, that by the exercise of more vigilance his own dishonesty might have been detected. Lastly, the complainant must prove that, as the direct consequence of the misrepresentation, he has suffered actual damage capable of pecuniary measurement.

As soon as the case of *Derry* v. *Peek* had established, as the general rule of law, that a merely negligent misstatement is not actionable, a statutory exception was made to the rule in the case of directors and promoters of companies who publish prospectuses and similar documents. By the Directors' Liability Act, 1890, such persons are liable for damage caused by untrue statements in such documents, unless they can prove that they had reasonable grounds for believing the statements to be true. It is also to be observed that, though damages cannot be recovered in an action for a misrepresentation made with an honest belief in its truth, still any person induced to enter into a contract by a misrepresentation, whether fraudulent or innocent, is entitled to avoid the contract and to obtain a declaration that it is not binding upon him. This is in accordance with the rule of equity, which since the Judicature Act prevails in all the courts. Whether the representation is fraudulent or innocent, the contract is not void, but voidable. The party misled must exercise his option to avoid the contract without delay, and before it has become impossible to restore the other party to the position in which he stood before the contract was made. If he is too late, he can only rely on his claim for damages, and in order to assert this claim it is necessary to prove that the misrepresentation was fraudulent. Fraud, in its wider sense of dishonest dealing, though not a distinct cause of action, is often material as preventing the acquisition of a right, for which good faith is a necessary condition. Also a combination or conspiracy by two or more persons to defraud gives rise to liabilities not at present very clearly or completely defined. (A. LL. D.)

Frederick Charles (1828–1885), Prussian prince, known as the "Red Prince" from the colour of his favourite Hussar uniform, was the eldest son of Prince Charles, brother of the Emperor William I. of Germany, his mother being a sister of the Empress Augusta. He was born in Berlin, 20th March 1828, and, like most princes of the House of Hohenzollern, was educated for the army. Chief amongst his various military tutors and governors was Major von Roon, afterwards Prussian minister for war, who attended him during the two years which he spent at the University of Bonn, 1846–48. In the latter year the prince entered the Foot Guards, and first saw active service under Marshal von Wrangel in the Schleswig–Holstein war. Shortly afterwards he attended his uncle, Prince William of Prussia, afterwards Emperor, in the campaign against the Free Companies of Baden. He was now a major of Hussars, having changed his branch of the service. He led a brilliant charge of about forty Hussars against the Polish legion at the battle of Wiesenthal, and received two wounds. Temporarily incapacitated for military duty, he devoted himself to the study of military works. The prince was appointed colonel of the First Dragoon Guards in 1852, and two years later was raised to the command of the First Guards Cavalry Brigade. In 1855 Frederick Charles visited Paris, where he closely studied the French military system, carefully noting its defects. He traced minutely the course of the Franco-Austrian war of 1859, and embodied his conclusions and strictures upon French tactics in a privately-published pamphlet. This pamphlet obtained a wider circulation than was intended, and gave rise to much indignation in France. Other military essays by the prince testified to his ability as a military critic. The prince became a general of cavalry, with the command of the Third Army Corps in 1861, and he commanded the Prussian corps forming the right wing of the allied army in 1864. It was he who had the credit of forcing the Danes to evacuate Schleswig, and also of leading the Prussians in the storming of the lines of Düppel. He acquired in this campaign the popular sobriquet of "Prinz Vorwärts." In the Austrian war of 1866 he commanded the First Army, numbering about 140,000 men. Entering Bohemia, he defeated the Austro-Saxon troops at Liebenau, Podol, and Gitschin. But his greatest generalship was displayed at the crowning battle of Königgrätz. The Austrians were commanded by the veteran Marshal Benedek, and the Prussians by their king, William I. Prince Frederick Charles halted at Kammeniz on 2nd July, and his troops commenced their march at midnight, the first shot being fired about 7·30 A.M. on 3rd July. It was alleged afterwards that the prince opened the engagement two hours sooner than commanded, in order that he might, if possible, win this decisive victory before the Crown Prince's army arrived. The attack became general at Königgrätz about ten o'clock, and a desperate struggle ensued, the result appearing uncertain until the Crown Prince and his force arrived at half-past twelve. When Chlum, which had been taken and lost seven times by the Prussians, was taken for the eighth time, the fate of the day was decided; and the retreat of the Austrians soon became a hasty and disastrous flight. The Austrians lost about 43,000, including 10,000 wounded and 13,000 unwounded prisoners; the Prussian loss was 10,000 men. When the war with France broke out in 1870, Prince Frederick Charles was appointed to the command of the Second Army. Again and again in the course of the campaign he gave evidence of his superior military abilities. He led his troops to victory in the great battles of Vionville and Gravelotte–St Privat, and compelled Marshal Bazaine to take refuge within the entrenchments of Metz. The prince then began a systematic blockade of the fortress, and after a siege of seventy days only, Bazaine surrendered with about 170,000 men. The prince was rewarded for this great feat by his elevation to the rank of field-marshal. From Metz the prince now hastened westwards to check the armies of D'Aurelle de Paladines and Chanzy in their attempts to raise the siege of Paris from the south. The series of battles which ensued, beginning with Beaune-la-Rolande, lasted almost uninterruptedly from the middle of November till the middle of January, when the French Army of the West was rendered impotent at the engagement of Le Mans. This was the prince's last action, for Paris capitulated immediately afterwards. After the Franco-German war Prince Frederick Charles was destined to see no further active service, the remainder of his life being spent in studying war, witnessing reviews, and farming his estates at Glienicke, near Potsdam. He made many efforts, some of which were successful, to reform and render more elastic the military system of the army. In appearance the prince was a model cavalry officer. He was strong and muscular in body, and active in his habits and pursuits. His private character was harsh and unamiable. In March 1879 his third daughter, Louise Margaret, was married to the Duke of Connaught. The prince died suddenly from apoplexy at his château of Glienicke on 15th June 1885.

(G. B. S.)

Frederick, capital of Frederick County, Maryland, U.S.A., in 39° 25′ N. and 77° 25′ W., in the broad and fertile valley of the Monocacy river, lying between the Catoctin Range and the Blue Ridge, at an altitude of 323 feet. It is on branches of the Baltimore and Ohio and the Pennsylvania railways. Population (1880), 8659; (1890), 8193; (1900), 9296, of whom 241 were foreign-born, and 1535 were negroes.

Frederick III. (1831–1888), King of Prussia and German Emperor, was born at Potsdam, 18th October 1831, being the eldest son of Prince William of Prussia, afterwards first German Emperor, and the Princess Augusta. He was carefully educated, and in 1849–50 studied at the University of Bonn. The next years were spent in military duties and in travels, in which he was accompanied by Moltke. In 1851 he visited England on the occasion of the Great Exhibition, and in 1855 became engaged to Victoria, Princess Royal of Great Britain, to whom he was married in London on 25th January 1858. On the death of his uncle in 1861 and the accession of his father, Prince Frederick William, as he was then always called, became Crown Prince of Prussia. His education, the influence of his mother, and perhaps still more that of his wife's father, the Prince Consort, had made him a strong Liberal, and he was much distressed at the course of events in Prussia after the appointment of Bismarck as Minister. He was urged by the Liberals to put himself into open opposition to the Government; this he refused to do, but he remonstrated privately with the King. In June 1863, however, he publicly dissociated himself from the Press Ordinances which had just been published. He ceased to attend meetings of the Council of State, and was much away from Berlin. The opposition of the Crown Prince to the Ministers was increased during the following year, for he was a warm friend of the Prince of Augustenburg, whose claims to Schleswig-Holstein Bismarck refused to support. During the war with Denmark he had his first military experience, being attached to the staff of Marshal von Wrangel; he performed valuable service in arranging the difficulties caused by the disputes between the Field-Marshal and the other officers, and was eventually given a control over him. After the war he continued to support the Prince of Augustenburg, and was strongly opposed to the war with Austria. During the campaign of 1866 he received the command of an army consisting of four army corps; he was assisted by General von Blumenthal, as Chief of the Staff, but took a very active part in directing the difficult operations by which his army fought its way through the mountains from Silesia to Bohemia, fighting four engagements in three days, and showed that he possessed genuine military capacity. In the decisive battle of Königgrätz the arrival of his army on the field of battle, after a march of nearly twenty miles, secured the victory. During the negotiations which ended the war he gave valuable assistance by persuading the King to accept Bismarck's policy as regards peace with Austria. From this time he was very anxious to see the King of Prussia unite the whole of Germany, with the title of Emperor, and was impatient of the caution with which Bismarck proceeded. In 1869 he paid a visit to Italy, and in the same year was present at the opening of the Suez Canal; on his way he visited the Holy Land.

He played a conspicuous part in the year 1870–71, being appointed to command the armies of the Southern States, General Blumenthal again being his Chief of the Staff; his troops won the victory of Wörth, took an important part in the battle of Sedan, and later in the siege of Paris. The popularity he won was of political service in preparing the way for the union of North and South Germany, and he was the foremost advocate of the Imperial idea at the Prussian Court. During the years that followed, little opportunity for political activity was open to him. He and the Crown Princess took a great interest in art and industry, especially in the Royal

Museums; and the excavations conducted at Olympia and Pergamon with such great results were chiefly due to him. The Crown Princess was a keen advocate of the higher education of women, and it was owing to her exertions that the Victoria Lyceum at Berlin (which was named after her) was founded. In 1878, when the Emperor was incapacitated by the shot of an assassin, the Prince acted for some months as Regent. His palace was the centre of all that was best in the literary and learned society of the capital. He publicly expressed his disapproval of the attacks on the Jews in 1878; and the coalition of Liberal parties founded in 1884 was popularly known as the "Crown Prince's party," but he scrupulously refrained from any act that might embarrass his father's Government. For many reasons the accession of the Prince was looked forward to with great hope by a large part of the nation. Unfortunately he was attacked by cancer in the throat; he spent the winter of 1887–88 at San Remo; in January 1888 the operation of tracheotomy had to be performed. On the death of his father, which took place on 9th March, he at once journeyed to Berlin; but his days were numbered, and he came to the throne only to die. In these circumstances his accession could not have the political importance which would otherwise have attached to it, though it was disfigured by a vicious outburst of party passion in which the names of the Emperor and the Empress were constantly misused. While the Liberals hoped the Emperor would use his power for some signal declaration of policy, the adherents of Bismarck did not scruple to make bitter attacks on the Empress. The Emperor's most important act was a severe reprimand addressed to Herr v. Putkamer, the reactionary Minister of the Interior, which caused his resignation; in the distribution of honours he chose many who belonged to classes and parties hitherto excluded from Court favour. A serious difference of opinion with the Chancellor regarding the proposal for a marriage between Prince Alexander of Battenberg and the Princess Victoria of Prussia was arranged by the intervention of Queen Victoria, who visited Berlin to see her dying son-in-law. He expired at Potsdam on 15th June 1888, after a reign of ninety-nine days.

After the Emperor's death Professor Geffcken, a personal friend, published in the *Deutsche Rundschau* extracts from the Diary of the Crown Prince containing passages which illustrated his differences with Bismarck during the war of 1870. The object was to injure Bismarck's reputation, and a very unseemly dispute ensued. Bismarck at first, in a letter addressed to the new Emperor, denied the authenticity of the extracts on the ground that they were unworthy of the Crown Prince. Geffcken was then arrested and imprisoned. He had undoubtedly showed that he was an injudicious friend, for the Diary proved that the Prince, in his enthusiasm for German unity, had allowed himself to consider projects which would have seriously compromised the relations of Prussia and Bavaria. The treatment of the Crown Prince's illness also gave rise to an acrimonious controversy. It arose from the fact that as early as May 1887 the German physicians recognized the presence of cancer in the throat, but Sir Morell Mackenzie, the English specialist who was also consulted, disputed the correctness of this diagnosis, and advised that the operation for removal of the larynx, which they had recommended, should not be undertaken. His advice was followed, and the differences between the medical men were made the occasion for a considerable display of national and political animosity.

The Empress VICTORIA, who, after the death of her husband, was known as the Empress Frederick, died on the 5th of August 1901 at the Castle of Friedrichskron, Cronberg, near Homburg v. d. H., where she spent her last years. Of the Emperor's children two, Prince Sigismund (1864–66) and Prince Waldemar (1869–79), died in childhood. He left two sons, William (*q.v.*), who succeeded him, and Henry, who adopted a naval career. Of his daughters, the Princess Charlotte was married to the Hereditary Prince of Meiningen; the Princess Victoria to Prince Adolf of Schaumburg-Lippe; the Princess Sophie to the Duke of Sparta, Crown Prince of Greece; and Princess Margaretha to Prince Friedrich Karl of Hesse.

(J. W. HE.)

Fredericksburg, a city of Virginia, U.S.A., in 38° 18′ N. and 77° 27′ W., on the Rappahannock river, at the head of navigation and tide. Though situated within the limits of Spottsylvania County, and containing the court house, it is independent of the county government. It is regularly built, on a succession of benches rising from the river. It is divided into two wards, Upper and Lower, and is on the Potomac, Fredericksburg, and Piedmont, and the Richmond, Fredericksburg, and Potomac railways. It was the scene of one of the severest battles of the Civil War. General Burnside, in command of the Union forces, attempted to storm the Confederate defences on the banks on which the city is built, but after repeated charges, in which his troops were decimated, he was forced to withdraw. Fredericksburg College had, in 1899, 12 instructors and 114 students. Population (1880), 5010; (1890), 4528; (1900), 5068.

Fredericton, the capital of New Brunswick, on the St John river, 84 miles from its mouth. Among recent improvements are the new parliament buildings, the post-office, the normal school, a neat and well-kept park, and the two bridges, passenger and railway, which unite the city with the towns of St Marys and Gibson on the east side of the river. In 1899–1900 exports were valued at $151,334, imports at $419,441. Population (1891), 6502; (1900), 7000.

Frederikshavn, a seaport of Denmark, county Hjörring, on the Cattegat, 25 miles south of the Skaw, and 50 miles by rail north-north-east from Aalborg. Originally it was a fishing station, known as FLADSTRAND, but it is now a harbour of refuge (1882–91) for the Cattegat. It is also a fishing centre, especially for plaice, and sends fishing boats to Iceland and to the oyster grounds of the North Sea. In 1899 the port was entered by 1311 vessels of 167,704 tons, and cleared by 1215 of 166,868 tons, the chief exports being fish, butter, cattle, and bacon; and the chief imports, coal and butter (this last in transport). Population (1880), 2891; (1900), 6338.

Fredrikshald, a seaport town of Norway, county Smaalenene, close to the Swedish frontier, 85 miles south-south-east of Christiania by rail. It is one of the principal ports of the kingdom for the export of timber. The total trade in 1897 was valued at £627,300 (£344,000 in 1887). Marble of very fine quality and grain is extensively quarried and exported for architectural ornamentation and for furniture-making. Wood-pulp is also exported. The industries embrace granite quarries, wood-pulp factories, and factories for sugar, tobacco, curtains, travelling-bags, boots, &c. Population (1875), 9792; (1900), 11,936.

Fredrikstad, a rapidly-growing seaport and manufacturing town of Norway, standing at the mouth of the Glommen, 59 miles by rail south by east of Christiania. The new town, on the right bank, is the centre of the timber export trade, this place being the principal port in Norway for the export of pit-props, planed boards, and other varieties of timber. In the closing years of the 19th century there was an extraordinary development in the making of red bricks, owing to the great expansion of Christiania, Gothenburg, and other towns. In 1899 the total output of bricks was 150 millions, as compared with 50 millions in 1896. Granite is hewn to a great extent and exported. Besides the large number of saw and planing mills, there are shipbuilding yards, engine and boiler works, cotton and woollen mills, and factories for acetic acid and naphtha. The total trade of the port was valued at £996,000 in 1897. The harbour, which can be entered by vessels drawing 14 ft., is kept open in winter by an ice-breaker. In 1899 the port owned a mercantile fleet of 176 vessels of 54,150 tons. In the vicinity is the much-frequented seaside resort of Hankö. Population (1875), 9616; (1900), 14,573.

Free Church Federation.—In the *Methodist Times* of 20th February 1890 Dr Guinness Rogers suggested that there should be a Nonconformist Church Congress as well as an Anglican Church Congress. The first was held in Manchester on 7th November 1892. In the following year it was resolved that the basis of representation should be neither personal (as in the Anglican Church Congress) nor denominational, but territorial. England and Wales have since been completely covered with a network of Local Councils, each of which elects its due proportion of representatives to the National gathering. This territorial arrangement eliminated all sectarian distinctions, and also the possibility of committing the different Churches as such to any particular policy. The representatives of the Local Councils attend not as Denominationalists, but as Evangelical Free Churchmen. The name of the organization was changed from Congress to National Council as soon as the Assembly ceased to be a fortuitous concourse of atoms, and consisted of duly appointed representatives from the Local Councils of every part of England. The Local Councils consist of representatives of the Congregational and Baptist Churches, the Methodist Churches, the Presbyterian Church of England, the Free Episcopal Churches, the Society of Friends, and such other Evangelical Churches as the National Council may at any time admit. The constitution states the following as the objects of the National Council: (*a*) To facilitate fraternal intercourse and co-operation among the Evangelical Free Churches; (*b*) to assist in the organization of Local Councils; (*c*) to encourage devotional fellowship and mutual counsel concerning the spiritual life and religious activities of the Churches; (*d*) to advocate the New Testament doctrine of the Church, and to defend the rights of the associated Churches; (*e*) to promote the application of the law of Christ in every relation of human life.

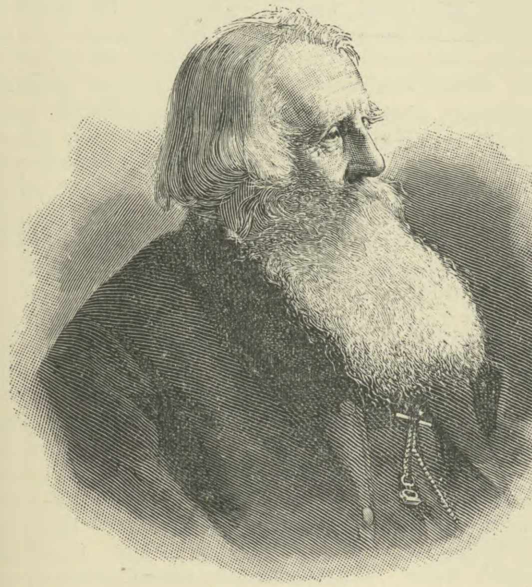
A striking feature of this movement is the adoption of the parochial system for the purpose of local work. Each of the associated Churches is requested to look after a parish, not of course with any attempt to exclude other Churches, but as having a special responsibility for those in that area who are not already connected with some existing Church. In the great cities, especially in London and in the counties, Local Councils are formed into Federations, which are intermediate between them and the National Council. The Local Councils do what is possible to prevent overlapping and excessive competition between the Churches. Large circulating libraries are already established for the benefit of ministers in villages and country districts. A considerable literature has sprung into existence, consisting of numerous periodicals, hymn-books for special occasions, and works of different kinds explaining the history and ideals of the Evangelical Free Churches. These can be obtained from the organizing secretary at the Memorial Hall, Farringdon Street, London, E.C. The primary object of the whole organization is to reach the masses of the people who are not yet attached to any Church. The Churches represented in the National Council have 9005 separated or ordained ministers, 50,729 local preachers, 388,160 Sunday-school teachers, 3,350,224 Sunday scholars, 1,911,924 communicants, and sitting accommodation in their sanctuaries for 7,993,708.

The most remarkable manifestation of this unprecedented reunion is the fact that a committee of the associated Churches has already prepared and published a Catechism expressing the positive and fundamental agreement of all the Evangelical Free Churches on the essential doctrines of Christianity. An account of the origin of this Catechism, together with the names of the theologians of all Churches who took part in its preparation, will be found in the prefatory note to the Catechism. A fuller history of its origin and its striking features was published in the *Contemporary Review* of January 1899. The Catechism represents substantially the creed of not less than 80,000,000 Protestants. It has been widely circulated throughout Great Britain, in British colonies, and the United States of America. It has also been translated into Welsh, French, and Italian. This movement has spread to all parts of Australia, New Zealand, South Africa, Jamaica, the United States of America, and India. It is perhaps necessary to add that it differs essentially from the Evangelical Alliance, inasmuch as its unit is not an individual, private Christian, but a definitely organized and visible Church. The essential doctrine of the movement is a particular doctrine of churchmanship which, as explained in the Catechism, regards the Lord Jesus Christ as the sole and Divine Head of every branch of the Holy Catholic Church throughout the world. For this reason those who do not accept the deity of Christ are necessarily excluded from the National Council and its local constituent councils. (H. P. H.)

Freeland, a borough of Luzerne county, Pennsylvania, U.S.A., in the anthracite coal region, on the Lehigh Valley Railway. It is a supply- and shipping-point for the coal mines in the neighbourhood. Population (1890), 1730; (1900), 5254, of whom 1339 were foreign-born.

Freeman, Edward Augustus (1823–1892), English historian, was born at Harborne, Staffordshire, on 2nd August 1823. He lost both his parents in infancy, was brought up by a grandmother, and was educated at private schools and by a private tutor. He was a studious and precocious boy, more interested in religious matters, history, and foreign politics than in boyish things. He obtained a scholarship at Trinity College, Oxford, and a second class in the degree examination, and was elected fellow of his college (1845). While at Oxford he was much influenced by the High Church movement, and thought seriously of taking orders, but abandoned the idea. He married the daughter of his former tutor, the Rev. R. Gutch, in 1847, and entered on a life of study. Ecclesiastical architecture attracted him strongly. He visited many churches and began a practice, which he pursued throughout his life, of making drawings of buildings on the spot and afterwards tracing them over in ink. His first book, save for his share in a volume of English verse, was *A History of Architecture* (1849). Though he had not then seen any buildings outside England, it contains a good sketch of the development of the art. It is full of youthful enthusiasm and is written in florid language. After some changes of residence he bought a house called Somerleaze, near Wells, Somerset, and settled there in 1860. His life was one of strenuous literary work. He wrote many books, and countless articles for reviews, newspapers, and other publications, and was a constant contributor to the *Saturday Review* until 1878, when he ceased to write for it for political reasons. His *Saturday*

Review articles corrected many errors and raised the level of historical knowledge among the educated classes, but as a reviewer he was apt to forget that a book may have blemishes and yet be praiseworthy. For some years he was an active county magistrate. He was deeply interested in politics, was a follower of Mr Gladstone, and approved the Home Rule Bill of 1886, but objected to the later proposal to retain the Irish members at Westminster. To be returned to Parliament was one of his few ambitions, and in 1868 he unsuccessfully contested Mid-Somerset. Foreign rather than domestic politics had the first place with him. Historical and religious sentiment combined with his detestation of all that was tyrannical to inspire him with hatred of the Turk and sympathy with the smaller and subject nationalities of Eastern Europe. He took a prominent part in the agitation which followed "the Bulgarian atrocities"; his speeches were intemperate, and he was accused of uttering the words "Perish India!" at a public meeting in 1876. This, however, was a misrepresentation of his



EDWARD AUGUSTUS FREEMAN.
(*From a photo. by Elliott and Fry.*)

words. He was made a knight commander of the order of the Saviour by the king of Greece, and also received an order from the prince of Montenegro.

Freeman advanced the study of history in England in two special directions, by insistence on the unity of history, and by teaching the importance and right use of original authorities. History is not, he urges, to be divided "by a middle wall of partition" into ancient and modern, nor broken into fragments as though the history of each nation stood apart. It is more than a collection of narratives; it is a science, "the science of man in his political character." The historical student, then, cannot afford to be indifferent to any part of the record of man's political being; but as his abilities for study are limited, he will, while reckoning all history to be within his range, have his own special range within which he will master every detail (*Rede Lecture*). Freeman's range included Greek, Roman, and the earlier part of English history, together with some portions of foreign mediæval history, and he had a scholarly though general knowledge of the rest of the history of the European world. He regarded the abiding life of Rome as "the central truth of European history," the bond of its unity, and he undertook his *History of Sicily* (1891–94) partly because it illustrated this unity. Further, he urges that all historical study is valueless which does not take in a knowledge of original authorities, and he teaches both by example and precept what authorities should be thus described, and how they are to be weighed and used. He did not use manuscript authorities, simply because he had no need to do so. All the authorities which he needed were already in print, and his books would not have been better if he had disinterred a few more facts from unprinted sources.

His reputation as a historian will chiefly rest on his *History of the Norman Conquest* (1867–76), his longest completed book. In common with his works generally, it is distinguished by exhaustiveness of treatment and research, critical ability, a remarkable degree of accuracy, and a certain insight into the past which he gained from his practical experience of men and institutions. He is almost exclusively a political historian. His saying that "history is past politics and politics are present history" is significant of this limitation of his work, which left on one side subjects of the deepest interest in a nation's life. In dealing with constitutional matters he sometimes attaches too much weight to words and formal aspects. This gives certain of his arguments an air of pedantry, and seems to lead him to find evidences of continuity in institutions which in reality and spirit were different from what they once had been. As a rule his estimates of character are remarkably able. It is true that he is sometimes swayed by prejudice, but this is the common lot of great historians; they cannot altogether avoid sharing in the feelings of the past, for they live in it, and Freeman did so to an extraordinary degree. Yet if he judges too favourably the leaders of the national party in England on the eve of the Norman Conquest, that is a small matter to set against the insight which he exhibits in writing of Aratus, Sulla, Nicias, William the Conqueror, Thomas of Canterbury, Frederick the Second, and many more. In width of view, thoroughness of investigation, and honesty of purpose he is unsurpassed by any historian. He never conceals or wilfully misrepresents anything, and he reckoned no labour too great which might help him to draw a truthful picture of the past. When a place had any important connexion with his work he invariably visited it. He travelled much, always to gain knowledge, and generally to complete his historical equipment. His collected articles and essays on places of historical interest are perhaps the most pleasing of his writings, but they deal exclusively with historical associations and architectural features. The quantity of work which he turned out is enormous, for the fifteen large volumes which contain his *Norman Conquest*, his unfinished *History of Sicily*, his *William Rufus* (1882), and his *Essays* (1872–79), and the crowd of his smaller books, are matched in amount by his uncollected contributions to periodicals. In respect of matter his historical work is uniformly excellent. In respect of form and style the case is different. Though his sentences themselves are not wordy, he is extremely diffuse in treatment, habitually repeating an idea in successive sentences of much the same import. While this habit was doubtless aggravated by the amount of his journalistic work, it seems originally to have sprung from what may be called a professorial spirit, which occasionally appears in the tone of his remarks. He was anxious to make sure that his readers would understand his exact meaning, and to guard them against all possible misconceptions. His lengthy explanations are the more grievous because he insists on the same points in several of his books. His prolixity was increased by his unwillingness, when writing without prescribed limits, to leave out any detail, however unimportant. His passion for details not only swelled his volumes to a portentous size, but was fatal to artistic construction. The length of his books has hindered their usefulness. They were written for the public at large, but few save professed students, who can admire and value his exhaustiveness, will read the many hundreds of pages which he devotes to a short period of history. In some of his smaller books, however, he shows great powers of condensation and arrangement, and writes tersely enough. His style is correct, lucid, and virile, but generally nothing more, and his endeavour to use as far as possible only words of Teutonic origin limited his vocabulary and makes his sentences rather monotonous. While Froude often strayed away from his authorities, Freeman kept his authorities always before his eyes, and his narrative is sometimes little more than a translation of their words. Accordingly, while it has nothing of Froude's carelessness and inaccuracy, it has nothing of his charm of style. Yet now and again he rises to the level of some heroic event, and parts of his chapter on the "Campaign of Hastings" and of his record of the wars of Syracuse and Athens, his reflexions on the visit of Basil the Second to the church of the Virgin on the Acropolis, and some other passages in his books, are fine pieces of eloquent writing.

The high quality of Freeman's work was acknowledged by all competent judges. He was made D.C.L. of Oxford and LL.D. of Cambridge *honoris causâ*, and when he visited the United States on a lecturing tour was warmly received at various places of learning. He served on the royal commission on ecclesiastical courts appointed in 1881. In 1884 he was appointed regius professor of modern history at Oxford. His lectures were thinly attended, for he did not care to adapt them to the requirements of the university examinations, and he was not perhaps well fitted to teach young men. But he exercised a wholesome influence over the more earnest students of history among the resident graduates. From 1886 he was forced by ill-health to spend much of his time abroad, and he died of small-pox at Alicante on 16th March 1892, while on a tour in Spain. Freeman had a strongly marked personality. Though impatient in temper and occasionally rude, he was tender-hearted and generous. His rudeness to strangers was partly caused by shyness and partly by a childlike inability to conceal his feelings. Eminently truthful, he could not understand that some verbal insincerities are necessary to social life. He had a peculiar faculty for friendship and his friends always found him sympathetic and affectionate. In their society he would talk well and showed a keen sense of humour. He considered it his duty to expose careless and ignorant writers and certainly enjoyed doing so; but, merciless as his attacks were, they were not the outcome of personal spite. He worked hard and methodically, often had several pieces of work in hand, and kept a daily record of the time which he devoted to each of them. His tastes were curiously limited. No art interested him except architecture, which he studied throughout his life; and he cared little for literature which was not either historical or political. In later life he ceased to hold the theological opinions of his youth, but remained a devout churchman.

Freeport, capital of Stephenson county, Illinois, U.S.A., on the Pecatonica river, at an altitude of 760 feet. It has a level site, and its plan is fairly regular. Three railways, the Chicago and North-Western, the Chicago, Milwaukee, and St Paul, and the Illinois Central intersect here. Population (1880), 8516; (1890), 10,189; (1900), 13,258, of whom 2264 were foreign-born.

Free Ports, strictly speaking, are localities where no customs duties are levied, and where no customs supervision exists. In these ports (subject to payment for specific services rendered, wharfage, storage, &c., and to the observance of local police and sanitary regulations) ships load and unload, cargoes are deposited and handled, industries are exercised, manufactures are carried on, goods are bought and sold, without any action on the part of fiscal authorities. Ports are likewise designated "free" where a space or zone exists within which commercial operations are conducted without payment of import or export duty, and without active interference on the part of customs authorities. The French and German designations for these two descriptions of ports are—for the former "La ville franche," "Freihafen"; for the latter "Le port franc," "Freibezirk" or "Freilager." The English phrase free port applies to both.[1] The leading conditions under which free ports in Europe derived their origin were as follows:—(1) When public order became re-established during the Middle Ages, trading centres were gradually formed. Marts for the exchange and purchase of goods arose in different localities. Many Italian settlements, constituting free zones, were established in the Levant. The Hanseatic towns arose in the 12th century. Great fairs became recognized—the Leipzig charter was granted in 1268. These localities were free as regards customs duties, although dues of the nature of octroi charges were often levied. (2) Until the 19th century European states were numerous, and often of small size. Accordingly uniform customs tariffs of wide application did not exist. Uniform rates of duty were fixed in England by the Subsidy Act of 1660. In France, before the Revolution (besides the free ports) Alsace and the Lorraine Bishoprics were in trade matters treated as foreign countries. The unification of the German customs tariff began in 1834 with the Steuerverein and the Zollverein. The Spanish fiscal system did not include the Basque provinces until about 1850. The uniform Italian tariff dates from 1861. Thus until very recent times on the Continent free ports were compatible with the fiscal policy and practice of different countries. (3) Along the Mediterranean coast, up to the 19th century, convenient shelter was needed from corsairs. In other Continental countries the prevalent colonial and mercantile policy sought to create trans-oceanic trade. Free ports were advantageous from all these points of view.

In following the history of these harbours in Europe, it is to be observed that in Great Britain free ports have never existed. In 1552 it was contemplated to place Hull and Southampton on this footing but the design was abandoned. Subsequently the bonding and not the free port system was adopted in the United Kingdom.

Austria-Hungary.—Fiume and Trieste were respectively free ports during the periods 1722–1893 and 1719–1893.

Belgium.—The Emperor Joseph II. during his visit to the Austrian Netherlands in June 1781 endeavoured to create a direct trade between that country and India. Ostend was made a free port, and large bonding facilities were afforded at Bruges, Brussels, Ghent, and Louvain. In 1796, however, the revolutionary government abolished the Ostend privileges.

Denmark.—In November 1894 an area of about 150 acres at Copenhagen was opened as a free port, and great facilities are afforded for shipping and commercial operations in order that the Baltic trade may centre there.

France.—Marseilles was a free port in the Middle Ages, and so was Dunkirk when it formed part of Flanders. In 1669 these privileges were confirmed, and extended to Bayonne. In 1784 there was a fresh confirmation, and Lorient and St Jean de Luz were included in the *ordonnance.* The National Assembly in 1790 maintained this policy, and created free ports in the French West Indies. In 1795, however, all such privileges were abolished, but large bonding facilities were allowed at Marseilles to favour the Levant trade.

[1] In China at the present time (1902) certain ports are designated "free and open." This phrase means that the ports in question are (1) open to foreign trade, and (2) that vessels engaged in over-sea voyages may freely resort there. Exemption from payment of customs duties is not implied, which is a matter distinct from the permission granted under treaty engagements to foreign vessels to carry cargoes to and from the "treaty ports."

The government of Louis XVIII. in 1814 restored, and in 1817 again revoked, the free port privileges of Marseilles. There are now no free ports in France or in French possessions; the bonding system is in force.

Germany.—Bremen, Hamburg, and Lübeck were reconstituted free towns and ports under the treaties of 1814–15. Certain minor ports, and several landing stages on the Rhine and the Neckar, were also designated free. As the Zollverein policy became accepted throughout Germany, previous privileges were gradually lessened, and since 1888 only Hamburg remains a free port. There an area of about 2200 acres is exempt from customs duties and control, and is largely used for shipping and commercial purposes. Brake, Bremen, Bremerhaven, Cuxhaven, Geestemünde, and Lübeck are now "Freibezirke," and in 1899 free areas were opened under similar conditions at Neufahrwasser (the entrance to Danzig) and at Stettin. Heligoland is outside the Zollverein—practically a foreign country.

In *Italy* free ports were numerous and important, and possessed privileges which varied at different dates. They were—Ancona, during the period 1696–1868; Brindisi, 1845–62; Leghorn (in the 17th and 18th centuries a very important Mediterranean harbour), 1675–1867; Messina, 1695–1879; Senigallia, 1821–68, during the month of the local fair. Venice possessed warehouses, equivalent to bonded stores, for German and Turkish trade during the Republic, and was a free port 1851–73. Genoa was a free port in the time of the Republic and under the French Empire, and was continued as such by the treaties of 1814–15. The free port was, however, changed into a "deposito franco" by a law passed in 1865 and only storing privileges now remain.

Rumania.—Braila, Galatz, and Kustenji were free ports (for a period of about forty years) up to 1883, when bonded warehouses were established by the Rumanian Government.

Russia.—Archangel was a free port, at least for English goods, from 1553 to 1648. During this period English products were admitted into Russia *viâ* Archangel without any customs payment for internal consumption, and also in transit to Persia. The Tsar Alexis revoked this grant on the execution of Charles I. Free ports were opened in 1895 at Kola, in Russian Lapland, and in 1899 at Dalny, adjoining Port Arthur.

The number of free ports outside Europe has also lessened. The administrative policy of European countries has been gradually adopted in other parts of the world, and customs duties have become almost universal, conjoined with bonding and transhipment facilities. In British colonies and possessions, under an Act of Parliament passed in 1766, and repealed in 1867, two ports in Dominica and four in Jamaica were free. Malacca, Penang, and Singapore had been free ports since 1824, and Hong Kong since 1842. Zanzibar was a free port during 1892–99. Aden, Gibraltar, St Helena, and St Thomas (West Indies) are sometimes designated free ports. A few duties are, however, levied, which are really octroi rather than customs charges. These places are mainly stations for coaling and awaiting orders.

Some harbours in the Netherlands East Indies were free ports between 1829–99; but these privileges were withdrawn by laws passed in 1898–99, in order to establish uniformity of customs administration. Harbours where custom houses are not maintained will be practically closed to foreign trade, though the governor-general may in special circumstances vary the application of the new regulations.

Macao has been a free port since 1845. Portugal has no other harbour of this character.

The American Republics have adopted the bonding system. In 1896 a free wharf was opened at New Orleans in imitation of the recent European plan. Livingstone (Guatemala) was a free port during the period 1882–88.

The privileges enjoyed under the old free port system benefited the towns and districts where they existed; and their abolition has been, locally, injurious. These places were, however, "foreign" to their own country, and their inland intercourse was restricted by the duties levied on their products, and by the precautions adopted to prevent evasion of these charges. With fiscal usages involving preferential and deferential treatment of goods and places, the drawbacks thus arising did not attract serious attention. Under the limited means of communication within and beyond the country, in former times, these conveniences were not much felt. But when finance departments became more completely organized, the free port system fell out of favour with fiscal authorities: it afforded opportunities for smuggling, and impeded uniformity of action and practice. It became, in fact, out of harmony with the administrative and financial policy of later times. Bonding and entrepôt facilities, on a scale commensurate with local needs, now satisfy trade requirements. In countries where high customs duties are levied, and where fiscal regulations are minute and rigid, if an extension of foreign trade is desired, and the competition which it involves is a national aim, special facilities must be granted for this purpose. In these circumstances a free zone sufficiently large to admit of commercial operations and transhipments on a scale which will fulfil these conditions (watched but not interfered with by the customs) becomes indispensable. The German Government have, as we have seen, maintained a free zone of this nature at Hamburg. And when the free port at Copenhagen was opened, counter measures were adopted at Danzig and Stettin. An agitation has arisen in France to provide at certain ports free zones similar to those at Copenhagen and Hamburg, and to open free ports in French possessions. Resolutions to this effect were brought before the Chamber of Deputies in March 1899, and were referred to the Commission de Commerce et de l'Industrie: the ultimate action of the Legislature and Government is doubtful. Colonial free ports, such as Hong Kong and Singapore, do not interfere with the uniformity of the home customs and excise policy. These two harbours in particular have become great shipping resorts and distributing centres. The policy which led to their establishment as free ports has certainly promoted British commercial interests. (C. M. K*.)

Freetown. See SIERRA LEONE.

Freiberg, a town of Germany, 2 miles west of the Freiberger Mulde, 19 miles by rail south-west of the town and in the circle of Dresden, kingdom of Saxony. There are 5 Protestant churches and 1 Catholic church. The library of the Academy of Mines has now upwards of 36,000 volumes, besides MSS. and maps; and, in addition to a gymnasium and a *real* school, there are a commercial, a mining, a tanning, and an agricultural school. Population (1890), 28,955; (1900), 30,176.

Freiburg IN THE BREISGAU, a town and archiepiscopal see of Germany, grand-duchy of Baden, at the west foot of the Black Forest, 38 miles by rail north-north-east from Basel. A characteristic feature of the town is its numerous fountains. Another conspicuous ornament is the monument (1876) which commemorates the 14th (German) Army Corps and General von Werder for the part they took in the war of 1870–71. In 1900 the university was attended by 1766 students, and had 119 professors. The town possesses further the church of St Martin's (13th century, restored in 1880–81), a synagogue (1871), a museum, the corn market (1876), a theological seminary, a technical, an agricultural, and a commercial school. Population (1885), 42,596; (1900), 61,513.

Freiburg, or FRIBOURG, one of the Swiss cantons, with an area of 644 square miles, of which 78 square miles may be regarded as "unproductive." Of the rest, 113 square miles are covered by forests, and rather over $\frac{3}{4}$ square mile by vineyards. There are 281 communes in the canton, distributed over seven districts. The district of Sarine in 1900 numbered 33,052 inhabitants, that of the Singine or Sense had 18,800, that of the Gruyère had 22,936, that of the Lake had 15,440, that of the Glâne had 14,298, that of the Broye (capital, Estavayer or Stäffis) had 14,780, and that of the Veveyse had 8413. Besides the railway westwards from Freiburg to Estavayer past Payerne, there is another running northwards from Freiburg to Morat (Murten), while steamers ply on the Lake of Morat. One of the most interesting and most curious points relating to the canton is that the linguistic frontier between French and German not merely passes through it from north to south, but actually passes through its capital, Freiburg. In 1888 the population of the canton was 119,155, of whom 100,067 were Roman Catholics, 18,925 were Protestants, and 125 Jews. In 1900 the total population was 127,719, of whom 87,541 were French-speaking folk, while 38,759 spoke German. The cantonal constitution of 1857 still prevails, having been modified in only a very few minor respects since that date. It is remarkable as containing none of the modern devices (referendum, initiative, proportional representation), save the right of "initiative" of 6000 citizens to demand a revision of the cantonal constitution. In 1897 the state revenue of the canton was 3,544,222 francs (a rise of 12½ per cent. since 1885), and the state expenditure 3,475,083 francs (also a rise of 12½ per cent. since 1885), but in 1898 there was a deficit of 5910 francs. In 1897 the public debt was 38,803,500 francs, the largest cantonal debt in Switzerland, save in the case of Bern.

See Daguet. *Histoire de la Ville et Seigneurie de Fribourg* (to 1481), 1889.—Dellion. *Dictionnaire historique-statistique des paroisses Catholiques du Canton de F.*, 6 vols. Fribourg, 1884–88. —Heyck. *Geschichte d. Herzoge von Zähringen.* Freiburg i/B. 1891.—Kuenlin. *Der Kant. Freiburg.* St Gallen and Bern, 1834.—Zimmerli. *Die Deutsch-Französische Sprachgrenze in d. Schweiz*, vol. ii. 1895. (W. A. B. C.)

Freiburg, or Fribourg, capital of the above canton, on the railway between Bern (20 miles distant) and Lausanne (41 miles distant). Since 1663 the bishop of Lausanne has resided in Freiburg. The cantonal museum contains many antiquities, and also the paintings and statuary left to the town in 1879 by "Marcello," the artistic *nom de guerre* of the Duchess Adela Colonna, a member of the Fribourg family of d'Affry. In 1889 a Romanist University was founded in Freiburg; during the winter of 1899–1900 it was attended by 373 students. The span of M. Chaley's bridge is 808 feet, and two more wire cables (with 2238 strands) were added in 1880–81. It is 167 feet in height, but the Gotteron bridge is 246 feet high. The Grandfey viaduct is 249 feet high. In 1900 the population was 15,773.

Freienwalde, a town of Prussia, on the Oder, 28 miles north-east of Berlin; capital of the circle of Ober-Barnim, government district of Potsdam, province of Brandenburg; on the Frankfurt–Angermünde railway. Medicinal springs in the neighbourhood make it a favourite summer watering-place for the people of Berlin. A new tower commands a fine view of the Oderbruch. There are water-glass and brick works. Population (1890), 7259; (1900), 7989.

Freising, a town of Bavaria, Germany, district Upper Bavaria, on the Isar, 16 miles by rail north-north-east of Munich. The former Benedictine abbey (725–1803) of Weihenstephan is the seat of a royal model farm and brewery, with agricultural, horticultural, and brewing school, and an agricultural museum. Population (1885), 9125; (1900), 10,090.

Fremantle, town and chief port of West Australia, at the mouth of the Swan river, 12 miles south-west from Perth, with which it is connected by rail and cargo steamers. There are a town hall, handsome Episcopal church, and various other public buildings, and a recreation ground. The harbour is not naturally a good one, but improvements have been effected, including the construction of two moles. Fremantle is the western terminus of the Eastern Railway. The mean temperature for the year is 63·2° F.; for January, 73·4°; for July, 55·0°. Population (1881), 3641; (1900) (with suburbs), 20,359.

Frémont, John Charles (1813–1890), American explorer and politician, was born in Savannah, Ga., 21st January 1813. His father, a native of France, died when he was yet a boy, and his mother, a Virginian, removed to Charleston, S.C. He had a taste for mathematics, but was otherwise far from being a hard-working student; he was even expelled from Charleston College. Subsequently, however, he was given a degree, and passed an examination for a professorship in the United States navy; but he declined this appointment to give his attention to civil engineering in connexion with railways. In the spring of 1838 he became assistant to the French explorer Nicollet, whom the War Department employed to make a map of the country extending from the upper waters of the Missouri river to the British boundary line. Frémont showed great talent as an explorer in the five important expeditions he made in the north-west. The object of the first expedition was to obtain accurate knowledge as to the character of the territories of Nebraska and Wyoming, and especially of South Pass, the opening through the mountains on the way to Oregon (1842). The purpose of the second expedition (1843–44) was to explore the possible lines of communication between Missouri, Nebraska, Wyoming, Utah, Idaho, and Oregon, and find a way by land from the lower Columbia river to the Bay of San Francisco. The third expedition, begun in 1845, was designed to explore the great basin and the coast regions of California and Oregon, but it was changed by events connected with the Mexican war into a military and political conquest. From Oregon Frémont went to the Mexican province of California, and collected under his standard the scattered settlers who sided with the Americans in opposition to the Mexicans in the war then in progress. In less than thirty days he won the territory from the Mexicans, and, on 4th July 1846, was chosen its governor. A few months later Mexican authority was withdrawn, and California thenceforth belonged to the United States. In 1848, Frémont undertook at his own expense to discover a passage to California *viâ* the headwaters of the Rio Grande, along a route subsequently followed by the Southern Pacific railway. His fifth and last expedition, begun in 1853, was for the purpose of finding the best route for a national railway from the Mississippi valley to the Pacific Ocean. When, in 1850, California was admitted as a state, Frémont became one of her first two senators. But as he drew the short term he had only three weeks of service in the United States Senate, and he failed to obtain re-election on account of his anti-slavery opinions. In 1856, the newly-formed Republican party was in search of a popular anti-slavery man as candidate for the Presidency, and Frémont, then only forty-three years old, was nominated by both the Republicans and the National Americans. It was still too soon, however, for an anti-slavery policy to win the confidence of a majority of the voters, and he was defeated by Buchanan. Frémont was in Europe when the Civil War began. He purchased for the Federal Government a large supply of arms from France, and was appointed major-general in the regular army, with headquarters in St Louis. His military training had not been sufficient to fit him for so high a command. He declared martial law, arrested secessionists and muzzled the opposition press; but as he lacked system and executive ability his affairs soon became badly involved and he was subjected to damaging criticism. In August 1861, he announced his intention to emancipate the slaves of all Missourians in rebellion against the United States; but as this announcement was in advance of public opinion, President Lincoln decided to annul it. In November 1861 Frémont was removed on account of the alleged extravagance and inefficiency of his management of military affairs. In compliance with popular sympathy he was placed in command of the mountain district south of the Ohio river, but his operations against "Stonewall" Jackson were not sufficiently successful to inspire confidence. In June 1862, his corps was incorporated in the Army of Virginia, and he asked to be relieved from service under its commander, General Pope. Thenceforth he held no command. Frémont's picturesque career and his anti-slavery ideas made him a favourite of the Republicans, who were discontented with Lincoln's administration, and, in May 1864, he was nominated as their candidate for the Presidency, but he withdrew, lest his opposition to Lincoln might result in the election of a Democrat. After the war he was interested in the plan for a trans-continental railway between Norfolk, Va., and San Francisco, which proved to be a very unsuccessful financial enterprise. From 1878 to 1881 he was governor of the territory of Arizona. In his last years Congress authorized the President to appoint him major-general and placed him on the retired list. He died in New York on the 13th of July 1890. A volume of his memoirs, covering only the earlier part of his life, was published in 1886.

Fremont, capital of Dodge county, Nebraska, U.S.A., in 41° 26′ N. and 96° 30′ W., on the north bank of the Platte river, at an altitude of 1200 feet. It is on three railways, the Union Pacific (main line), the Fremont, Elkhorn, and Missouri Valley, and the Sioux City and Pacific. It is regularly laid out, has a good water supply and sewerage, and has stock-yards, packing-houses, and some manufactures. Population (1880), 3013; (1890), 6747; (1900), 7241, of whom 1303 were foreign-born.

Fremont, capital of Sandusky county, Ohio, U.S.A., on the Sandusky river, at an altitude of 630 feet. It is on three important railways, the Lake Shore and Michigan Southern, the Lake Erie and Western, and the Wheeling and Lake Erie. Both petroleum and natural gas are obtained in the neighbourhood. Population (1880), 8446; (1890), 7141; (1900), 8439, of whom 1074 were foreign-born, and 137 negroes.

French Congo.—The French colony in Equatorial Africa described by the name of French Congo has a coast-line along the Atlantic extending from 1° N. lat. to 5° S. lat., and stretching inland up to the 10th northern parallel, where it joins on to the French sphere of influence around Lake Chad. As defined by various conventions (see *History*), the limits of this possession are as follows:—Inland from the Muni estuary, which is the northern extremity on the coast, the boundary marches with that of the Spanish settlements, first east to about 11° 30′ E. long., and then north to the frontier of the German colony of Cameroon, in 2° N. lat., with which it runs east to the 16th meridian, and then north as far as the French Congo extends. Inland from the Lueme estuary, which is the southern limit on the coast, the boundary coincides first with that of the disconnected Portuguese territory of Kabinda, and then with that of the Congo Free State, running north-east and east along the Congo, the Ubangi, and the Mbomu. Near the parallel of 5° N. lat., to the south of the Sultanate of Tambura, the boundary turns northwards, and thence skirts the territories of Bahr el Ghazal and Fertit to the 10th parallel.

Physical Features.—The principal variations in the coast-line are Cape St John, the Bay of Corisco, the estuary of the Gaboon, Cape Lopez, the mouths of the Ogowe, the Bay of Mayumba, the roadstead of Loango, and the Pointe Noire. The coast region is low and marshy. Behind there is a ridge which rises from 3000 to 4500 feet, called the Crystal Mountains, then a plateau with an elevation varying from 1500 to 2800 feet, cleft with deep river-valleys, the walls of which are friable, almost vertical, and in some places 760 feet high. The coast rivers flowing into the Atlantic cross four terraces. On the higher portion of the plateau their course is over bare sand; on the second terrace, from 1200 to 2000 feet high, it is over wide grassy tracts; then, for 100 miles, the course passes through virgin forest, and, lastly, crosses the shore region, which is about 10 miles broad. The river-courses of French Equatorial Africa thus, in some respects, resemble those of Scandinavia. With rare exceptions, they are not navigable. On the north, the Rio Campo, 80 miles long, is unimportant. The San Benito or Eyo, visited by Crampel in 1889, probably descends from Cameroon. The Muni, which runs to the south of Cape St John, is under 40 miles in length. The Gaboon is rather a bay than an estuary; it is about 10 miles wide and receives the Como and the Rembo. The Ogowe rises near 2° 40′ S. lat., half-way between the coast and the Congo; first flowing in a north-westerly direction, forming numerous rapids and receiving the Passa, which waters Franceville, and the Nkoni, it then bends westwards, receives on the north the Ivindo, waters Lopé and N'Jolé near its confluence with the Okano, and thence, after being increased by the Ngunie, flows southwards. After issuing from the mountains it becomes wider for several miles, being fed by the lagoons Anengé and Zonengué, and divides into several arms round Cape Lopez. It is navigable from its mouth to N'Jolé, a distance of 235 miles. Its whole length is at least 750 miles. Other rivers are the Nyanga, 120 miles long, and the Kwilu. The latter, 320 miles in length, is formed by the Kiasi and the Luété; it has a very winding course, flowing by turns from north to south, from east to west, from south to north-west, and from north to south-west. It is encumbered with rocks and eddies, and is navigable only over 38 miles, and for five months in the year. 450 miles of the Congo are comprised within the boundary-line. The most important French post on the river is Brazzaville, situated at the lower end of the reach called Stanley Pool. The Ubangi receives from French territory the Ibenga and the Kemo.

Fauna and Flora.—The fauna includes the gorilla, the chimpanzee, the elephant, the hippopotamus, the alligator, and numerous serpents. There are few domestic animals, except fowls. As to the flora, it is remarkable for its splendour and variety. The forests contain bamboo, ebony, sandal-wood, baobab, caoutchouc, the castor plant, earth-nuts, &c.

Climate.—The climate is everywhere very warm, and dangerous for Europeans. On the coast four seasons are distinguished: the dry season (15th May to 15th September), the rainy season (15th September to 15th January), then a second dry season (15th January to 1st March), and a second rainy season (1st March to 1st May). The rainfall at Libreville is about 8 feet.

History of Occupation.—France acquired the estuary of the Gaboon in 1841–44, by agreement with native chiefs, to serve as a re-victualling station for vessels appointed to watch the coast. In 1849 Libreville was founded by a convoy of slaves taken from a slave-ship. In 1862 Cape Lopez was ceded to France, and the colony extended along the coast, nominally to the length of 200 miles. In the meantime the exploration of the interior had been begun. Du Chaillu penetrated (1856–65) to the south of the Ogowe; Walker, an Englishman, explored the Ngunie, an affluent of the Ogowe, in 1866. In 1872–1875 Marche and Compiègne examined the same river as far as the mouth of the Ivindo. In 1875 de Brazza began his travels, ascending in 1876–78 the Ogowe for more than 400 miles, and thence striking across to the Congo, which Stanley had just revealed. In a second journey (1879–82) he founded Brazzaville and explored the Kwilu, at the same time carrying on negotiations with the King of the Batéké. Loango was occupied in 1883. In the same year de Brazza set out at the head of the West African Expedition, and in the course of two years acquired new territories for France. The convention of February 1885 determined the frontier of the Congo Free State (then the International Association); boundary agreements were made with Germany (December 1885) and Portugal (May 1886); the zones of the north and south were delimited; and an arrangement with the Congo Free State in 1887 settled difficulties relating to the Ubangi, France abandoning the preferential rights which she had received in 1884. By creating the posts of Bangi (1890), Wesso, and Abira (1891), France extended her influence along the Ubangi and the Sanga. But at the same time the Belgians passed the parallel of 4° N. lat.—which, after the compromise of 1887, France had regarded as the southern boundary of her possessions—and, occupying the Sultanate of Bangasso, pushed on as far as 9° N. lat. The dispute which thus arose was only settled in 1894 after the Anglo-Congolese Convention of May 12 of that year, against which both the German and the French Governments protested. By a compromise of August 14, the boundary was definitely drawn and, in accordance with this pact, which put the frontier back to about 4° N. lat., France from 1895 to 1897 took possession of the Upper Ubangi, with Bangasso, Rafai, and Semio. Then began the French encroachment on the Bahr el Ghazal; the Marchand Expedition, despatched to the support of M. Liotard, the Lieutenant-Governor of the Upper Ubangi, reached Tambura in July 1897, and Fashoda in July 1898. A dispute with Great Britain arose, and it was decided that the expedition should evacuate Fashoda. The convention of 21st March 1899 finally terminated the dispute. Thus, after the Franco-Spanish Treaty of June 1900, settling the limits of the Spanish territory on the coast, the boundaries of the French Congo on all its frontiers were determined.

The important places are Libreville, with 3000 inhabitants; Bangi, on the Ubangi; Brazzaville, on the Congo, which, with the advent of the *concessionaires* (see below), has made rapid strides forward; Buensa; Franceville, near the Ogowe; Loango, a port much frequented; and N'Jolé, on the Ogowe.

Area and Population.—The area has been estimated at about 550,000 square miles. The population can be even less accurately determined, no kind of census whatever being yet possible. Perhaps 8,000,000 is the nearest approach to the right number. The natives belong either to a negro race (Loanga Batéké, Bubargi) or to a race crossed with red blood (Paheeni). The French Congo is now administered by a governor-general, assisted by a council composed of three official and three civilian members. He bears the title of *Commissaire-Général*, and has under his orders a lieutenant-governor for the Congo Proper, and another for the Upper Ubangi. A Government Commissioner is appointed for the Shari region. The seat of government is at Libreville. There is a tribunal of first instance, a paymaster-general, a vicar-apostolic, and a commandant for the naval station. It was only in 1889 that it became necessary for even the chief officials for the administration of justice to be legal magistrates. The budget for 1901 balanced at £225,000. In the estimated receipts France figured for £83,000, indirect contributions for £55,000, and returns from the concessions for £23,500. Of the estimated expenditure £55,000 was for administration, £66,000 for the occupation of the Shari.

For the exploitation of the colony the system has been adopted of farming out large areas to different companies. The terms of land tenure, &c., are mainly regulated by decrees of March 1899. Concessionaires are bound to pay rent, to provide security, and to contribute to the customs stations. Up to 1st September 1899, 37 concessions had been made, and it was estimated that 35 of these covered an area of nearly 240,000 square miles, the grants varying from 425 square miles to 54,000 square miles.

The natives cultivate manioc, which is their principal food. Rubber and ivory are as yet the only outstanding sources of wealth. In 1898, out of a total value of exports of £227,800, the former stood for £91,000 and the latter for £61,500. Other considerable exports are timber and palm-tree products. Warnings have been heard that the supply of ivory is likely to run out if the present abusive manner of collecting it be persisted in. On the other hand, the cultivation of the coffee and cacao plants is spreading; on 1st January 1899 there were 300,000 of the former and 200,000 of the latter. The cultivation of vanilla is also receiving considerable attention, and the rearing of zebras may yield good results. France obtained only £60,000 of the exports. Great Britain was the best customer, taking two-thirds of the rubber and more ivory than either France or Germany, which has the next largest share in the trade. The imports in 1898 were valued at £193,750, of which France only sent £51,300. Textiles figured in the total for £76,000. No other import approached this figure; the chief were hardware, intoxicants, and arms. In 1899 a committee was revived at Libreville by decree to watch over and advise upon all points connected with the economic development of the colony. The improvement of the country has already begun, and the plantations on the coast, as well as the factories on the Sanga and the Ubangi, are becoming profitable; but satisfactory results will only be attained when transport is facilitated, and the produce of the interior, including ivory, gold, copper, and iron, can be easily conveyed to the coast. It should be observed that no imports are chargeable on foreign merchandise conveyed inland, either in the basins of the Congo and Kwilu, in virtue of the Berlin Act of 1885, or in that of the Shari, in virtue of the Anglo-French Convention of 1899. Though internal communications are not organized, the utilization of the valleys of the Ogowe and the Kwilu has for several years been under consideration, and a survey for a railway between the Gaboon and the Sanga was made in 1899. In the meantime, produce from Brazzaville can be sent by the Belgian railway, which passes round the falls of the Congo and rejoins the river at Matadi, where it is navigable. A telegraph line from Loango to Brazzaville is being constructed. There is telegraphic communication with Europe by a British submarine cable, and steamship communication between Libreville and Marseilles, Bordeaux, Liverpool, and Hamburg. The port of Libreville should be improved and made accessible to the largest vessels.

(P. L.)

Frere, Sir Henry Bartle Edward (1815–1884), British administrator, born at Clydach, in Brecknockshire, on 29th March 1815, was the son of Edward Frere, a member of an old east county family, and a nephew of John Hookham Frere, of *Anti-Jacobin* and *Aristophanes* fame. After leaving Haileybury, Bartle Frere was appointed a writer in the Bombay Civil Service in 1834, and went out to India by the then unfamiliar overland route. Having passed his examination in the native languages, he was appointed assistant collector at Poona in 1835. There he did valuable work in checking the extortion of the native officials, gained the confidence both of the people and of his superiors, and was in 1842 chosen as private secretary to Sir George Arthur, governor of Bombay. Two years later he became political resident at the court of the Rajah of Sattara, where he did much to benefit the country by the development of its communications. On the Rajah's death in 1848 he administered the province both before and after its formal annexation in 1849. In 1850 he was appointed chief commissioner of Sind, and took ample advantage of the opportunities afforded him of developing the province. He pensioned off the dispossessed amirs, improved the harbour at Karáchi, where he also established municipal buildings, a museum, and barracks, instituted fairs, multiplied roads, canals, and schools. Returning to India in 1857 after a well-earned rest, Frere was greeted at Karáchi with news of the mutiny. His rule had been so successful that he felt he could answer for the internal peace of his province. He therefore sent his only European regiment to Mooltan, thus securing that strong fortress against the rebels, and sent further detachments to aid Sir John Lawrence in the Punjab. The 178 British soldiers who remained in Sind proved sufficient to extinguish such insignificant outbreaks as occurred. His services were fully recognized by the Indian authorities, and he received the thanks of both houses of Parliament, and was made K.C.B. He became a member of the Viceroy's council in 1859, and was especially serviceable in financial matters. In 1862 he was appointed governor of Bombay, where he effected great improvements, such as the demolition of the old ramparts, and the erection of handsome public offices upon a portion of the space, the inauguration of the university buildings, and the improvement of the harbour. He established the Deccan College at Poona, as well as a college for instructing natives in civil engineering. The prosperity—due to the American civil war—which rendered these developments possible brought in its train a speculative mania, which led eventually to the disastrous failure of the Bombay Bank (1866), an affair in which, from neglecting to exercise such means of control as he possessed, Frere incurred severe and not wholly undeserved censure. In 1867 he returned to England, was made G.C.S.I., and received honorary degrees from Oxford and Cambridge; he was also appointed a member of the Indian Council. In 1872 he was sent by the Foreign Office to Zanzibar to negotiate a treaty with the sultan, Sayyid Burghash, for the suppression of the slave traffic. In 1875 he accompanied the Prince of Wales to Egypt and India. The tour was beyond expectation successful, and to Frere, from Queen Victoria downwards, came acknowledgments of the service he had rendered in piloting the expedition. He was asked by Lord Beaconsfield to choose between being made a baronet or G.C.B. He chose the former, but the Queen bestowed both honours upon him. But the greatest service that Frere undertook on behalf of his country was to be attempted not in Asia, but in Africa. Sir Bartle landed at Cape Town as High Commissioner of South Africa on 31st March 1877. He had been chosen by Lord Carnarvon in the previous October as the statesman most capable of carrying his scheme of confederation into effect, and within two years it was hoped that he would be the first governor of the South African Dominion. He went out in harmony with the aims and enthusiasm of his chief, "hoping to crown by one great constructive effort the work of a bright and noble life."

Discord or a policy of blind drifting seemed to be the alternatives presented to Frere upon his arrival. He chose the former as the less dangerous, and the first year of his sway was marked by a Kaffir war on the one hand and by a rupture with the Cape (Molteno – Merriman) ministry on the other. The Transkei Kaffirs were subjugated early in 1878 by General Thesiger and a small force of regular and colonial troops. The constitutional difficulty was solved by Frere dismissing his obstructive cabinet and entrusting the formation of a ministry to Mr Gordon Sprigg. Frere emerged successfully from a year of crisis, but the advantage was more than counterbalanced by the resignation of Lord Carnarvon early in 1878, at a time when Frere required the steadiest and most unflinching support. He had reached the conclusion that there was a widespread insurgent spirit pervading the natives, which it was necessary to put down, and that it should be suppressed speedily and once for all by the direct action of the imperial power—not merely scotched by setting Boer against Zulu or Kaffir against Fingo. He became aware that this insurgent spirit had its focus and strength in the celibate military organization of Cetywayo and in the prestige which impunity for the outrages he had committed had gained for the Zulu king in the native mind. That organization and that evil prestige must be put an end to, if possible by moral pressure, but otherwise by force. Frere reiterated these views to the Colonial Office, where they found a general acceptance. When, however, in view of a series of outrages upon the Natal border (not so much serious in themselves as indicating a feeling of contempt and defiance), Frere undertook the responsibility of forwarding an ultimatum to the Zulu chief in November 1878, the Home Government abruptly discovered that a native war in South Africa was inopportune, and raised difficulties about reinforcements. Having entrusted into Lord Chelmsford's hands the enforcement of the British demands, Frere's immediate responsibility ceased. On 10th January 1879 the British troops crossed the Tugela, and fourteen days later the disaster of Isandhlwana was reported; and Frere, attacked and censured in the House of Commons, was but feebly defended by the Government. Lord Beaconsfield, it appears, supported Frere; the majority of the cabinet were inclined to recall him. The result was the unsatisfactory compromise by which he was censured and begged to stay on. Frere wrote an elaborate justification of his conduct, which was adversely commented on by the Colonial Secretary (Sir M. Hicks-Beach), who "did not see why Frere should take notice of attacks; and as to the war, all African wars had been unpopular." Frere's rejoinder was that no other sufficient answer had been made to his critics, and that he wished to place one on record. "Few may now agree with my view as to the necessity of the suppression of the Zulu rebellion. Few, I fear, in this generation. But unless my countrymen are much changed, they will some day do me justice. I shall not leave a name to be permanently dishonoured." The Government had some excuse for irritation, but the disaster at Isandhlwana ought to have been visited upon the military authorities and not upon Frere.

The Zulu trouble and the disaffection that was brewing in the Transvaal reacted upon each other in the most disastrous manner. Frere had borne no part in the actual annexation of the Transvaal, which was announced by Sir Theophilus Shepstone a few days after the High Commissioner's arrival at Cape Town. The delay of Shepstone to give the country a constitution gave a pretext to the malcontent Boers, a rapidly increasing minority, while the reverse at Isandhlwana had lowered British prestige. Owing to the Kaffir and Zulu wars Sir Bartle had hitherto been unable to give his undivided attention to the state of things in the Transvaal. Much had been effected since the annexation by Shepstone and his successor, Owen Lanyon: debts paid, credit restored, the Zulu trouble rolled away. At the same time the grievances of the Boers were genuine. An autocratic régime had been set up, while no signs were forthcoming of the free constitution promised by Shepstone. In April 1879 Sir Bartle was at last able to visit the Transvaal, and the conviction was forced upon him that the government had been unsatisfactory in many ways. The country was very unsettled. A large camp, numbering 4000 disaffected Boers, had been formed near Pretoria, and they were terrorizing the country. Frere visited them unarmed and practically alone. Even yet all might have been well, for he won the Boers' respect and liking. On the condition that the Boers dispersed, Frere undertook to represent their complaints to the British Government, and to urge the fulfilment of the promises that had been made to them. They parted with mutual good feeling, and the Boers did eventually disperse—on the very day upon which Frere received the telegram announcing the Government's censure. He returned to Cape Town, and his journey back was in the nature of a triumph. But bad news awaited him at Government House. On 1st June 1879 the Prince Imperial had met his death in Zululand, and a few hours later Frere heard that the High Commissionership, with the care of affairs in the Transvaal and Zululand, had been transferred from him to Sir Garnet Wolseley. When Mr Gladstone's ministry came into office in the spring of 1880, Lord Kimberley had no intention of recalling Frere. In June, however, a section of the Liberal party memorialized Mr Gladstone to remove him, and the Prime Minister weakly complied (1st August 1880). Upon his return Frere replied to the charges relating to his conduct respecting Afghanistan as well as South Africa, previously preferred in Mr Gladstone's Midlothian speeches, and was preparing a fuller vindication when he died at Wimbledon from the effect of a severe chill, 29th May 1884. He was buried in St Paul's, and in 1888 a statue of Frere upon the Thames Embankment was unveiled by the prince of Wales. His *Life and Correspondence*, by John Martineau, was published in 1895. Frere himself edited the works of his uncle, Hookham Frere, and the popular story-book, *Old Deccan Days*, written by his daughter, Mary Frere. He was three times president of the Royal Asiatic Society. (T. SE.)

Frère-Orban, Hubert Joseph Walther (1812–1896), Belgian statesman, was born at Liège on 24th April 1812. His family name was Frère, to which on his marriage he added his wife's name of Orban. After studying law in Paris, he practised as a barrister at Liège, took a prominent part in the Liberal movement, and in June 1847 was returned to the Chamber as member for Liège. In August of the same year he was appointed Minister of Public Works in the Rogier Cabinet, and from 1848 to 1852 was Minister of Finance. He founded the Banque Nationale and the Caisse d'Épargne, abolished the newspaper tax, reduced the postage, and modified the customs duties as a preliminary to a decided free-trade policy. The Liberalism of the Cabinet, in which Frère-Orban exercised an influence hardly inferior to that of Rogier, was, however, distasteful to Napoleon III. Frère-Orban, to facilitate the negotiations for a new commercial treaty, conceded to France a law of copyright, which proved highly unpopular in Belgium, and he resigned office, soon followed by the rest of the Cabinet. His work *La Mainmorte et la charité* (1854–57), published under the pseudonym of Jean van Damme, contributed greatly to restore his party to power in 1857, when he again became Minister of Finance. He now embodied his free-trade principles in commercial treaties with England and France, and abolished the *octroi* duties and the tolls on the national roads. He resigned in 1861 on the gold question, but soon resumed office, and in 1868 succeeded Rogier as Prime Minister. In 1869 he defeated the attempt of France to gain control of the Luxembourg railways, but, despite this service to his country, fell from power at the elections of 1870. He returned to office in 1878 as President of the Council and Foreign Minister. He provoked the bitter opposition of the Clerical party by his law of 1879 establishing secular primary education, and in 1880 went so far as to break off diplomatic relations with the Vatican. He next found himself at variance with the Radicals, whose leader, Janson, moved the introduction of universal suffrage. Frère-Orban, while rejecting the proposal, conceded an extension of the franchise (1883); but the hostility of the Radicals, and the discontent caused by a financial crisis, overthrew the Government at the elections of 1884. Frère-Orban continued to take an active part in politics as leader of the Liberal opposition till 1894, when he failed to secure re-election. He died at Brussels on 2nd January 1896. Besides the work above mentioned, he published *La Question monétaire* (1874); *La Question monétaire en Belgique* in 1889; *Échange de vues entre MM. Frère-Orban et E. de Laveleye* (1890); and *La Révision constitutionnelle en Belgique et ses conséquences* (1894). He was also the author of numerous pamphlets, among which may be mentioned his last work, *La Situation présente* (1895). (E. SY.)

Freshwater, a seaside resort and railway station, in the Isle of Wight parliamentary division of Hampshire, England, 9½ miles west of Newport. The parish contains Farringford House, for some time the home of Lord Tennyson the poet, to whom there is a memorial tablet in All Saints' church. Area of parish, 4836 acres. Population about 3000.

Fresno, capital of Fresno county, California, U.S.A., in the San Joaquin Valley, at an altitude of 290 feet. It is surrounded by a rich farming region, which produces especially grain and fruit. One of the most extensive irrigation systems of the West is in operation in the neighbouring country. The city has a regular plan and an excellent water supply and sewerage. It is on the Southern Pacific and the Atchison, Topeka, and Santa Fé railways. Population (1880), 1112; (1890), 10,818; (1900), 12,470, of whom 3299 were foreign-born, and 1573 were coloured, including 291 negroes.

Freycinet, Charles Louis de Saulces de (1828——), French statesman, was born at Foix on 14th November 1828. He was educated at the Ecole Polytechnique, and entered the Government service as a mining engineer. In 1858 he was appointed traffic manager to the Compagnie de chemins de fer du Midi, a post in which he gave proof of his remarkable talent for organization, and in 1862 returned to the engineering service (in which he attained in 1886 the rank of Inspector-General). He was sent on a number of special scientific missions, among which may be mentioned one to England, on which he wrote a notable *Mémoire sur le travail des femmes et des enfants dans les manufactures de l'Angleterre* (1867). On the establishment of the Third Republic in September 1870, he offered his services to Gambetta, was appointed Prefect of the Department of Tarn-et-Garonne, and in October became chief of the military cabinet. It was mainly his powers of organization that enabled Gambetta to raise army after army to oppose the invading Germans. He showed himself a strategist of no mean order; but the policy of dictating operations to the generals in the field was not attended with happy results. The friction between him and General Aurelle de Paladines resulted in the loss of the advantage temporarily gained at Orleans, and he was responsible for the campaign in the east, which ended in the destruction of Bourbaki's army. In 1871 he published a defence of his administration under the title of *La Guerre en province pendant le siège de Paris.* He entered the Senate in 1876 as a follower of Gambetta, and in December 1877 became Minister of Public Works in the Dufaure Cabinet. He carried a great scheme for the gradual acquisition of the railways by the State and the construction of new lines at a cost of three milliards, and for the development of the canal system at a further cost of one milliard. He retained his post in the Ministry of M. Waddington, whom he succeeded in December 1879 as President of the Council and Minister for Foreign Affairs. He passed an amnesty for the Communists, but in attempting to steer a middle course on the question of the religious Associations, lost the support of Gambetta, and resigned in September 1880. In January 1882 he again became President of the Council and Minister for Foreign Affairs. His refusal to join England in the bombardment of Alexandria was the death-knell of French influence in Egypt. He attempted to compromise by occupying the Isthmus of Suez, but the vote of credit was rejected in the Chamber by 417 votes to 75, and the Ministry resigned. He returned to office in April 1885 as Foreign Minister in the Brisson Cabinet, and retained that post when, in January 1886, he succeeded to the Premiership. He came into power with an ambitious programme of internal reform; but except that he settled the question of the exiled Pretenders, his successes were won chiefly in the sphere of colonial extension. In spite of his unrivalled skill as a parliamentary tactician, he failed to keep his party together, and was defeated on 3rd December 1886. In the following year, after two unsuccessful attempts to construct new Ministries, he stood for the Presidency of the Republic; but the Radicals, to whom his opportunism was distasteful, turned the scale against him by transferring their votes to M. Sadi Carnot. In April 1888 he became Minister of War in the Floquet Cabinet—the first civilian since 1848 to hold that office. His services to France in this capacity were the crowning achievement of his life, and he enjoyed the conspicuous honour of holding his office without a break for five years through as many successive administrations—those of Floquet and Tirard, his own fourth ministry (March 1890–February 1892), and the Loubet and Ribot ministries. To him were due the introduction of the three-years' service and the establishment of a general staff, a supreme council of war, and the army commands. His Premiership was marked by heated debates on the clerical question, and it was a hostile vote on his Bill against the religious Associations that caused the fall of his Cabinet. He failed to clear himself entirely of complicity in the Panama scandals, and in January 1893 resigned the Ministry of War. In November 1898 he once more became Minister of War in the Dupuy Cabinet, but resigned office on 6th May 1899. He has published, besides the works already mentioned, *Traité de mécanique rationelle* (1858); *De l'Analyse infinitésimale* (1860, revised ed. 1881); *Des Pentes économiques en chemin de fer* (1861); *Emploi des eaux d'égout en agriculture* (1869); *Principes de l'assainissement des villes* and *Traité d'assainissement industriel* (1870); *Essai sur la philosophie des sciences* (1896); besides some remarkable "Pensées" contributed to the *Contemporain* under the pseudonym of "Alceste." In 1890 he was elected to the French Academy in succession to Émile Augier.

Freytag, Gustav (1816–1895), German novelist, was born at Kreuzburg, in Silesia, 13th July 1816. He was educated at the universities of Breslau and Berlin, and, settling in the former city, gave lessons in the university as a private tutor, but devoted his principal attention to writing for the stage, without, however, attaining any very prominent position until in after years (1854) he produced his comedy, *Die Journalisten.* In 1847 he migrated to Berlin, and in the following year of revolution founded at Dresden, in conjunction with Julian Schmidt, *Die Grenzboten*, a monthly periodical which immediately took rank as the exponent of sane and strenuous Liberalism in politics, and was equally distinguished by the general soundness of its criticism. Freytag helped to conduct it until 1861, and again from 1867 till 1870, when for a short time he edited the new periodical, *Im Neuen Reich.* His literary fame was made universal by the publication in 1855 of his novel, *Soll und Haben* (*Debit and Credit*), which was translated into almost all the languages of Europe. It is certainly the best German novel of its day, impressive by its sturdy but unexaggerated realism, and in many parts highly humorous. Its main purpose is the recommendation of the German middle class as the soundest element in the country, but it also has a more directly patriotic intention in the contrast which it draws between the homely virtues of the Teuton and the shiftlessness of the Pole and the rapacity of the Jew. As a Silesian, Freytag had no great love for his Slavonic neighbours, and being a native of a province which owed everything to Prussia, he was naturally an earnest champion of Prussian hegemony over Germany. His powerful advocacy of this idea in his *Grenzboten* gained him the friendship of the Duke of Saxe-Coburg-Gotha, who took him with him in the French campaign of 1870. Before this he had published (1864) another novel, *Die Verlorne Handschrift* (*The Lost Manuscript*), founded on a supposed discovery of the lost history of Tacitus, and dealing in some measure with the inner life of the University of Leipzig. It obtained considerable success, but was less celebrated than *Debit and Credit.* Between 1859 and 1867 he published in five volumes *Bilder aus der deutschen Vergangenheit* (*Pictures from the German Past*), a most valuable work, full of delightful and instructive collections of essays illustrating the history and manners of old Germany. In 1872 he began a work with a similar patriotic purpose, *Die Ahnen* (*The Ancestors*), designed to unfold German history in a series of romances. These continued to appear until 1880, but were not very successful. The author's aversion from the Slavonic race is again noticeable. In 1887 Freytag published his *Autobiography*, more distinguished by elegance of style than by copiousness of information, and died, full of years and honours, at Wiesbaden, 30th April 1895. Among his other works of importance may be noticed his essays, chiefly reprinted from the *Grenzboten*, an esteemed work on the technique of the drama, and an excellent biography of the Baden statesman Karl Mathy. Freytag had all the qualities most characteristic of a German of the practical type, and his great success in literature and life was largely owing to the fidelity with which he represented his nation. (R. G.)

Friedek, a town in Austrian Silesia, on the Ostrawitza, a tributary of the Oder. It has a château of the late Archduke Albrecht of Austria, who was the proprietor of the two large smelting works in the vicinity; and there is a very old parish church. It has also a considerable textile industry. Friedek, with the Moravian town of Mistek, on the opposite side of the river, forms the station Friedek-Mistek, on the Kaiser Ferdinands Nordbahn.

Population (1890), 7374; (1900), 9023, estimated to be two-thirds Czech, one-third German and Polish.

Friedrichroda, a favourite summer resort in the grand-duchy of Coburg-Gotha, Germany, at the north foot of the Thuringian Forest, 13 miles by rail south-west from Gotha. It is surrounded by fir-clad hills and possesses numerous handsome villa residences. There are a *kurhaus*, a sanatorium, and the ducal hunting castle of Reinhardsbrunn, built out of the ruins of a Benedictine monastery (1089–1525) in 1827–35. The people bleach linen on a very extensive scale and manufacture toys. Population (1900), 4397.

Friedrichshafen, a town, lake-port, summer resort, and bathing-place of Würtemberg, Germany, on the east shore of the Lake of Constance. It consists of the former imperial town of Buchhorn (dating from 837) and the monastery and village of Hofen (dating from 1050), united in 1824–30. The principal building is the royal castle (summer residence), to which is attached the Evangelical parish church. A hydropathic, whey cure, baths, &c., attract visitors in summer. There are also here the natural history and antiquarian collections of the Lake Constance Association. Population (1900), 4627.

Friendly Societies.—*United Kingdom.*—The Friendly Societies Act, 1875, and the several Acts amending it, are still, in effect, the law by which these societies are regulated, though in form they have been replaced by two consolidating Acts, viz., the Friendly Societies Act, 1896, and the Collecting Societies and Industrial Assurance Companies Act, 1896. All that is necessary in the present article, therefore, is to state the purport of the amendments made since 1876, and to trace to the present time the results of the working of the Act of 1875. That Act, in continuation of an enactment which first appeared in a statute passed in 1829, required every registered society to make quinquennial returns of the sickness and mortality experienced by its members. By the year 1880 ten periods of five years had been completed, and at the end of each of them a number of returns had been received. Some of these had been tabulated by actuaries, the latest tabulation being of those for the five years ending 1855. There remained untabulated five complete sets of returns for the five subsequent quinquennial periods. It was resolved that these should be tabulated once for all, and it was considered that they would afford sufficient material for the construction of tables of sickness and mortality that might be adopted for the future as standard tables for friendly societies; and that it would be inexpedient to impose any longer on the societies the burden of making such returns. This requirement of the Act was accordingly repealed in 1882. The result of the tabulation appeared in 1896, in a blue book of 1367 folio pages, containing tables based upon the experience of nearly four and a half million years of life. These tables show generally, as compared with previous observations, an increased liability to sickness. With regard to the procedure of the registrars some amendments of the law have been made. An appeal to the Chief Registrar in the case of the refusal of an assistant registrar to register a society or an amendment of rules, and in the case of suspension or cancelling of registry, is interposed before appeal is to be made to the High Court. The grounds upon which registry under a particular name may be refused are extended to include the opinion of the registrar, that the name is likely to deceive the members or the public as to the nature of the society, and not merely as to its identity. Authority is given to the Chief Registrar to direct the expense of an inspection or special meeting to be defrayed by the members or officers, or former members or officers, of a society, if he does not think they should be defrayed either by the applicants or out of the society's funds. He is also empowered, with the approval of the Treasury, to exempt any friendly society from the provisions of the Collecting Societies Act if he considers it to be one to which those provisions ought not to apply. Every society registered after 1895, to which these provisions do apply, is to use the words "Collecting Society" as the last words of its name.

The law as to the membership of infants has been altered twice. The Act of 1875 allowed existing societies to continue any rule or practice of admitting children as members that was in force at its passing, and prohibited membership under sixteen years of age in any other case, except the case of a juvenile society composed wholly of members under that age. The Treasury made special regulations for the registry of such juvenile societies. In 1887 the maximum age of their members was extended to twenty-one. In 1895 it was enacted that no society should have any members under one year of age, whether authorized by an existing rule or not; and that every society should be entitled to make a rule admitting members at any age over one year. The Treasury, upon this enactment coming into operation, rescinded its regulations for the registry of juvenile societies; and though it is still the practice to submit for registry societies wholly composed of persons under twenty-one, these societies in no way differ from other societies, except in the circumstance that they are obliged to seek officers and a committee of management from outside, as no member of the committee of any society can be under twenty-one years of age. In order to promote the discontinuance of this anomalous proceeding of creating societies under the Friendly Societies Act, which, by the conditions of their existence, are unable to be self-governing, the Act provides an easy method of amalgamating juvenile societies and ordinary societies or branches, or of distributing the members and the funds of a juvenile society among a number of branches. The liability of schoolboys and young working lads to sickness is small, and these societies frequently accumulate funds, which, as their membership is temporary, remain unclaimed and are sometimes misapplied.

The affiliated orders have strengthened their position; most of the lodges existing before 1875 have converted themselves into registered branches. The requirement that for that purpose a vote of three-fourths should be necessary was altered in 1895 to a bare majority vote. The provisions as to settlement of disputes were extended in 1885 to every description of dispute between branches and the central body, and in 1895 it was provided that the forty days after which a member may apply to the court to settle a dispute where the society fails to do so, shall not begin to run until application has been made in succession to all the tribunals created by the order for the purpose. In 1887 it was enacted that no body which had been a registered branch should be registered as a separate society except upon production of a certificate from the order that it had seceded or been expelled; and in 1895 it was further enacted that no such body should, after secession or expulsion, use any name or number implying that it is still a branch of the order. The orders generally, especially the greater ones, have carefully supervised the valuations of their branches, and have urged and, as far as circumstances have rendered it practicable, have enforced upon the branches measures for diminishing the deficiencies which the valuations have disclosed. They have organized plans by which branches disposed to make an effort to help themselves in this matter may be assisted out of a central fund.

The establishment of the National Conference of Friendly

Societies by the orders and a few other societies has been of great service in obtaining some of these improvements in the law, and in enabling the societies strongly to represent to the Government and the Legislature any grievance entertained by them. A complaint that membership of a shop club was made by certain employers a condition of employment, and that the rules of the club required the members to withdraw from other societies, led to the appointment of a departmental committee, who recommended that such a condition of employment should be made illegal, except in certain cases, and that in every case it should be illegal to make the withdrawal from a society a condition of employment.

The practice among societies of combining together to obtain medical attendance and medicine for their members by the formation of medical associations has increased. In 1895 trade unions were enabled to join in such associations, and it was provided that a contributing society or union should not withdraw from an association except upon three months' notice. The working of these associations has been viewed with dissatisfaction by members of the medical profession, and it has been suggested that a board of conciliation should be formed consisting of representatives of the Conference of Friendly Societies and of an equal number of medical men. One of the most important organic reforms introduced by the Act of 1875 was the requirement from every society of a valuation of its assets and liabilities once in every five years. No comparison of the aggregates of the valuations that have been completed since the passing of the Act could be made, or if made, would be of any service, inasmuch as the elements on which they depend are extremely variable; but a consideration of the successive valuations of individual societies strongly confirms the conclusion that "nothing is more elastic than the contract made by a friendly society with its members; no error more easy of remedy if found out in time than one existing in the original terms of such a contract."

The following figures are derived from returns of registered societies and branches of registered societies to 31st December 1899:—

	Number of Members.	Amount of Funds.
		£
7,090 Ordinary Friendly Societies	2,807,823	13,747,273
19,340 Branches of Registered Orders	2,409,438	19,004,596
45 Collecting Friendly Societies	5,922,615	5,207,686
86 Medical Societies	298,691	70,027
70 Benevolent Societies	18,363	286,141
632 Working Men's Clubs	175,469	209,041
465 Specially Authorized Societies	114,307	956,256
55 Cattle Insurance Societies	3,424	6,599
27,783 Societies and Branches	11,750,130	39,487,619

(E. W. B.)

United States.—Under the title of Fraternal Societies are included in the United States what are known in England as friendly societies, having some basis of mutual help to members, mutual insurance associations, and benefit associations of all kinds. There are various classes and a great variety of forms of fraternal associations. It is therefore difficult to give a concrete historical statement of their origin and growth; but, dealing with those having benefit features for the payment of certain amounts in case of sickness, accident, or death, it is found that their history in the United States is practically within the last half of the 19th century. The more important of the older organizations are the Improved Order of Red Men, founded in 1771 and re-organized in 1834; Ancient Order of Foresters, 1836; Ancient Order of Hibernians of America, 1836; United Ancient Order of Druids, 1839; Independent Order of Rechabites, 1842; Independent Order of B'nai B'rith, founded in 1843; Order of the United American Mechanics, 1845; Independent Order of Free Sons of Israel, 1849; Junior Order of United American Mechanics, 1853. A very large proportion, probably more than one-half, of the societies which have secret organizations pay benefits in case of sickness, accident, disability, and funeral expenses in case of death. This class of societies grew out of the English friendly societies, and have Masonic characteristics. The Freemasons and other secret societies, while not all having benefit features in their distinctive organizations, have auxiliary societies with such features. There is also a class of secret societies, based largely on Masonic usages, that have for their principal object the payment of benefits in some form. These are the Odd-Fellows, the Knights of Pythias, the Knights of Honour, the Royal Arcanum, and some others. Many trade unions have now adopted benefit features, especially the Typographical Union, while many subordinate unions and great publishing houses have mutual relief associations purely of a local character, and some of the more important newspapers have such mutual relief or benefit societies. The New York trade unions, taken as a whole, have paid out large sums of money in benefits where members have been out of work, or are sick, or are on strike, or have died. The total paid in a recent year for all these benefits was over $500,000.

Membership.

It is impossible to give the membership of all the fraternal associations in the United States; but according to the latest lists, including Odd-Fellows, Freemasons, purely benefit associations, and all the class of the larger fraternal organizations, the membership is nearly 5,500,000. Among the more important, so far as membership is concerned, are the Knights of Pythias, with a membership of nearly 500,000; the Odd-Fellows, with nearly 1,000,000; the Modern Woodmen of America, with nearly 450,000; the Ancient Order of United Workmen, with nearly 400,000; Improved Order of Red Men, with about 215,000; Royal Arcanum, with over 190,000; Knights of the Maccabees, with about 190,000; Junior Order of United American Mechanics, with nearly 184,000; Foresters of America, with 155,000; Independent Order of Foresters, with 150,000, &c. These and other organizations pay out a vast amount of money every year in the various forms of benefits. At the present time the sum is probably over $40,000,000, while the aggregate paid out by them since their organization would reach very nearly $500,000,000.

Assessment Insurance.

Since about the year 1870 a new form of benefit organization has come into existence. This is a life insurance based on the assessment plan, assessments being levied whenever a member dies; or, as more recently, regular assessments being made in advance of death, as post-mortem assessments have proved a fallacious method of securing the means of paying death benefits. The importance of this class of insurance is shown by a comparative statement. On the 1st January 1899 the number of policies in force under regular level premium companies was 11,218,330, the amount of insurance carried by them being $6,825,037,770. The assessment companies and orders, including industrial insurance, had a membership the year before of 4,039,062, while the amount of insurance in force under them was $7,799,428,000. There are about 200 mutual benefit insurance companies or associations in the United States conducted on the "lodge system"; that is to say, they have regular meetings for social purposes and for general improvement, and in their work there is found the mysticism, forms, and ceremonies which belong to secret societies generally. These elements have proved a very strong force in keeping this class of associations fairly intact. The "work" of the lodges in the initiation of members and their passing through various degrees is attractive to many people, and in small places, remote from the amusements of the city, these lodges constitute a resort where members can give play to their various talents. In most of them the features of the Masonic ritual are prominent. The amount of insurance which a single member can carry in such associations is small. In the Knights of Honour, one of the first of this class, policies ranging from $500 to $2000 are granted. In the Royal Arcanum the maximum is $3000. This form of insurance may be called co-operative, and has many elements which make the organizations practising it stronger than the ordinary assessment insurance companies having no stated meetings of members. These co-operative insurance societies are organized on the federal plan—as the Knights of Honour, for instance—having local assemblies, where the lodge room element is in force; state organizations, to which the local bodies send delegates, and the national organization, which conducts all the insurance business through its executive officers. The local societies pay a certain given amount towards the support of the state and national offices, and while originally they paid death assessments, as called for, they now pay regular monthly assessments, in order to avoid the weakness of the post-mortem assessment. The difficulty which these organizations have in conducting the insurance business is in keeping the average age of membership at a low point, for with an increase in the average the assessments increase, and many such organizations have had great trouble to convince younger members that their assessments should be increased to make up for the heavy losses among the older members. The experience of these purely insurance associations has not been sufficient yet to demonstrate their absolute soundness or desirability, but they have enabled a large number of persons of limited means to carry insurance at a very low rate. They have not materially interfered with regular level premium insurance enterprises, for they have stimulated the people to understand the benefits of insurance, and have really been an educational force in this direction.

A modern method of benefit association is found in the railway relief departments of some of the large railway corporations.

Railway Relief Departments.

These departments are organized upon a different plan from the benefit features of labour organizations and secret societies, providing the members not only with payments on account of death, but also with assistance of definite amounts in case of sickness or accident, the railway companies contributing to the funds, partly from philanthropic and partly from financial motives. The principal railway companies in the United States which have established these relief departments are the Pennsylvania, the Philadelphia and Reading, the Baltimore and Ohio, the Chicago, Burlington and Quincy, and the Plant System. The membership of these railway relief departments includes over one-eighth of all the railway employés in the United States, and on the various lines the number enrolled in them varies from 55 to 65 per cent. The Baltimore and Ohio, which organized its department in 1880, paid out a very large amount of money, up to 30th June 1896 the sum being nearly $5,000,000. The Pennsylvania line has paid out a like sum. In one fiscal year this railway paid out nearly $800,000, 18·27 per cent. being paid by the company; the Pennsylvania lines west distributed over $300,000, nearly 18 per cent. being paid by the company. The Baltimore and Ohio paid over $434,000, of which nearly 16 per cent. was paid by the company. The balance of the payments was made by the members of the associations through a mutual insurance plan. These data indicate the volume of business of railway relief associations. The relief department benefits the employés, the railways, and the public, because it is based upon the sound principle that the "interests and welfare of labour, capital, and society are common and harmonious, and can be promoted more by co-operation of effort than by antagonism and strife."

The railway employés support one-twentieth of the entire population, and most of their associations maintain organizations to provide their members with relief and insurance. The Brotherhood of Locomotive Engineers, the Order of Railway Conductors of America, the Brotherhood of Locomotive Firemen, the Brotherhood of Railway Trainmen, the Brotherhood of Railway Trackmen, the Switchmen's Union, the Brotherhood of Railway Carmen, and the Order of Railway Telegraphers, all have relief and benefit features. The oldest and largest of these is the International Brotherhood of Locomotive Engineers, founded at Detroit in August 1863. Like other labour organizations of the higher class of workmen, the objects of the brotherhoods of railway employés are partly social and partly educational, but in addition to these great purposes they seek to protect their members through relief and benefit features. Of course the relief departments of the railway companies are competitors of the relief and insurance features of the railway employés' Orders, but both methods of providing assistance have proved successful and beneficial.

Frisian Islands, the chain which stretches from the Zuider Zee eastwards and northwards as far as Jutland, fringing the coasts of Holland, Hanover (East Friesland), Oldenburg, Schleswig, and Holstein. The term is, strictly speaking, ethnographical. The chain is divided into three groups:—(1) the West Frisian, (2) the East Frisian, and (3) the North Frisian. The first group embraces Texel or Tessel (44,050 acres; 6000 pop.), Vlieland (12,220 acres; 700 pop.), Terschelling (25,765 acres; 3750 pop.), Ameland (14,360 acres; 2250 pop.), Schiermonnikoog (12,100 acres; 900 pop.), Boschplaat, and Rottum or Rottummeroog (640 acres; 400 pop.). With the exception of Wangeroog, which belongs to the grand-duchy of Oldenburg, the East Frisian islands belong to Prussia (*i.e.*, Hanover). They comprise Borkum ($2\frac{1}{2}$ miles by 5; 1350 pop.), Memmert; Juist ($2\frac{1}{4}$ sq. miles; 200 pop.), Norderney ($5\frac{1}{2}$ sq. miles; 3500 pop.), Baltrum (120 pop.), Langeoog (8 miles by 1; 250 pop.), Spiekeroog (4 sq. miles; 250 pop.), and Wangeroog (4 miles by $\frac{1}{2}$ mile; 100 pop.). All these islands are visited for sea-bathing in summer. Norderney, which inspired Heine's *Nordseebilder*, and Borkum are visited annually, the one by 24,000 and the other by 14,000 persons, and have been in repute since the beginning of the 19th century. In the beginning of the 18th century Wangeroog was eight times its present area. Borkum and Juist are two surviving fragments of the original island of Borkum (380 sq. miles), which was rent asunder by the sea in 1170. The North Frisian group embraces the islands of Nordstrand ($17\frac{1}{4}$ sq. miles; 2300 pop.), Pellworm ($16\frac{1}{4}$ sq. miles; 2000 pop.), Amrum ($10\frac{1}{2}$ sq. miles; 670 pop.), Föhr (32 sq. miles; 4500 pop.), Sylt (38 sq. miles; 4000 pop.), Röm (16 sq. miles; 1150 pop.), Fanö (21 sq. miles; 3000 pop.), and Heligoland ($\frac{1}{4}$ sq. mile; 2300 pop.). Except Fanö, all these belong to Prussia (province Schleswig-Holstein). Sylt (Westerland) is one of the most fashionable seaside resorts of Germany. Heligoland was anciently the holy island of the Frisian race. In the North Frisian group there is also a number of smaller islands called *halligen*, and rising generally only a few feet above the level of the sea, and crowned each by a single house standing on an artificial mound and surrounded by a dyke or embankment.[1]

The chain of the Frisian Islands, which lies 3 to 20 miles from the existing coastline, marks the outer fringe of the former continental coastline, and is separated from the firm land of the existing continent by shallows, known as *wadden* or *watten*,[2] answering to the *maria vadosa* of the Romans. Notwithstanding the artificial protection which is afforded these islands by earthen embankments, backed by stones and timber, and matted together with long tenacious grass, they are slowly but surely crumbling away under the persistent attacks of storm and flood. But the efforts of man are from time to time stimulated afresh. For instance, in 1873 a strong causeway was built from Ameland to Holwerd on the mainland with the view of promoting the warping of the *wadden*. In 1896 the Prussian Government voted £66,000 for the protection of the North Frisian *halligen*. About the year 1250 the area of the North Frisian islands was estimated at 1065 sq. miles; by 1850 this had diminished to only 105 sq. miles. The island of Nordstrand has been exceptionally severely visited by storms and inundations, having suffered terribly in 1300, in 1436, and in 1634. But since the 16th century the low-lying sea-

"Coming of Age in the Olden Time." By W. P. Frith, R.A.

marshes of the continent adjacent to the *wadden* and *watten* have been intermittently but effectually enclosed and drained. For instance, some 66,600 acres have been thus reclaimed to the north of the Ij in Holland; between 1545 and 1877 some 64,850 acres were reclaimed around the Dollart; and in Dithmarsch accretions were made amounting to 14,600 acres between 1579 and 1873. The view that the Dollart and similar indentations of this coast were formed by violent cataclysms is now abandoned by the modern school of Dutch and continental geographers in favour of the theory that their formation has been gradual, and has resulted more from the permanent subsidence of the coast, assisted more or less by sea-floods and the neglect of the embankments. The lands occupied by the Frisians originally extended across what is now the northern part of the Zuider Zee into the present province of North Holland, the eastern peninsula of which is indeed called West Friesland. The inhabitants of these islands support themselves by seafaring (they make excellent sailors), pilotage, grazing of cattle and sheep, fishing, and a little agriculture. Dr D. F. Buitenrust Hettema is editing a *Fryske Bybleteek* (Utrecht, 1895, &c.), a series of reprints of Middle Frisian literary works of the 16th, 17th, and 18th centuries.

Frith, William Powell (1819——), English painter, was born at Aldfield, in Yorkshire, on 9th January 1819. His parents moved in 1826 to Harrogate, where his father became landlord of the Dragon Inn, and it was then that the boy began his general education at a school at Knaresborough. Later he went for about two years to a school at St Margaret's, near Dover, where he was placed specially under the direction of the drawing-master, as a step towards his preparation for the profession which his father had decided on as the one that he wished him to adopt. In 1835 he was entered as a student in the well-known art school kept by Henry Sass in Bloomsbury, from which he passed after two years to the Royal Academy schools. His first independent experience was gained in 1839, when he went about for some months in Lincolnshire executing several commissions for portraits; but he soon began to attempt compositions, and in 1840 his first picture, "Malvolio, cross-gartered before the Countess Olivia," appeared at the Royal Academy. During the next few years he produced several notable paintings, among them "Squire Thornhill relating his town adventures to the Vicar's family," and "The Village Pastor," which established his reputation as one of the most promising of the younger men of that time. This last work was exhibited in 1845, and in the autumn of that year he was elected an Associate of the Royal Academy. His promotion to the rank of Academician followed in 1853, when he was chosen to fill the vacancy caused by Turner's death. The chief pictures painted by him during his tenure of Associateship were: "An English Merry-making in the Olden Time," "Old Woman accused of Witchcraft," "The Coming of Age," "Sancho and Don Quixote," "Hogarth before the Governor of Calais," and the "Scene from Goldsmith's 'Good-natured Man,'" which was commissioned in 1850 by Mr Sheepshanks, and bequeathed by him to the South Kensington Museum. Then came a succession of large compositions, which gained for the artist an extraordinary popularity. "Life at the Seaside," better known as "Ramsgate Sands," was exhibited in 1854, and was bought by Queen Victoria; "The Derby Day," in 1858; "Claude Duval," in 1860; "The Railway Station," in 1862; "The Marriage of the Prince of Wales," painted for Queen Victoria, in 1865; "The Last Sunday of Charles II," in 1867; "The Salon d'Or," in 1871; "The Road to Ruin," a series, in 1878; a similar series, "The Race for Wealth," shown at a gallery in King Street, St James's, in 1880; "The Private View," in 1883; and "John Knox at Holyrood," in 1886. The artist has also painted a considerable number of portraits of well-known people. In 1889 he became an Honorary Retired Academician. His "Derby Day" is now in the National Gallery of British Art. In his youth, in common with the men by whom he was surrounded, he had leanings towards romance, and he scored many successes as a painter of imaginative subjects. In these he proved himself to be possessed of exceptional qualities as a colourist and manipulator, qualities that promised to earn for him a secure place among the best executants of the British School. But in his middle period he chose a fresh direction. Fascinated by the welcome which the public gave to his first attempts to illustrate the life of his own times, he undertook a considerable series of large canvases, in which he commented on the manners and morals of society as he found it. He became a pictorial preacher, a painter who moralized about the everyday incidents of modern existence; and he sacrificed some of his technical variety. There remained, however, in all his later work a remarkable sense of characterization, and an appreciation of dramatic effect more than ordinarily acute.

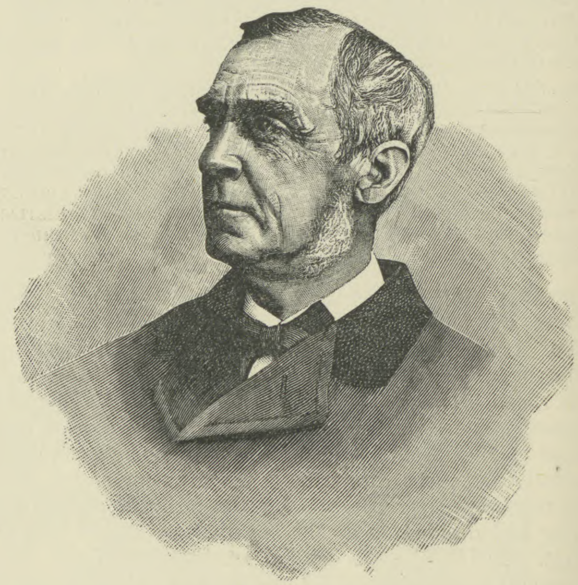
Frohschammer, Jakob (1821–1893), German theologian and philosopher, was born at Illkofen, near Ratisbon, on 6th January 1821. Destined by his parents for the Roman Catholic priesthood, he studied theology at Munich, but felt an ever-growing attraction to philosophy. Nevertheless, after much hesitation, he took what he himself calls the most mistaken step of his life, and in 1847 entered the priesthood. His keenly logical intellect, and his impatience of authority where it clashed with his own convictions, quite unfitted him for that unquestioning obedience to his superiors which the Church demanded. It was only after open defiance of the bishop of Ratisbon that he obtained permission to continue his studies at Munich. He at first devoted himself more especially to the study of the history of dogma, and in 1850 published his *Beiträge zur Kirchengeschichte*, which was placed on the Index Expurgatorius. But he felt that his real vocation was philosophy, and after holding for a short time an extraordinary professorship of theology, he became professor of philosophy in 1855. This appointment he owed chiefly to his work, *Ueber den Ursprung der menschlichen Seelen* (1854), in which he maintained that the human soul was not implanted by a special creative act in each case, but was the result of a secondary creative act on the part of the parents: that soul as well as body, therefore, was subject to the laws of heredity. This was supplemented in 1855 by the controversial *Menschenseele und Physiologie*. Undeterred by the offence which these works gave to his ecclesiastical superiors, he published in 1858 the *Einleitung in die Philosophie und Grundriss der Metaphysik*, in which he assailed the doctrine of Thomas Aquinas, that philosophy was the handmaid of theology. In 1861 appeared *Ueber die Aufgabe der Naturphilosophie und ihr Verhältniss zur Naturwissenschaft*, which was, he declared, directed against the purely mechanical conception of the universe, and affirmed the necessity of a creative Power. In the same year he published *Ueber die Freiheit der Wissenschaft*, in which he maintained the independence of science, whose goal was truth, against authority, and reproached the excessive respect for the latter in the Roman Church with the insignificant part played by the German Catholics in literature and philosophy. He was denounced by the pope himself in an apostolic brief of

11th December 1862, and students of theology were forbidden to attend his lectures. Public opinion was now keenly excited; he received an ovation from the Munich students, and the king, to whom he owed his appointment, remained staunch to him. A conference of Catholic *savants* was held in 1863 under the presidency of Döllinger, and decided that authority must be supreme in the Church. When, however, Döllinger and his school in their turn started the Old Catholic movement, Frohschammer refused to associate himself with their cause, holding that they did not go far enough, and that their declaration of 1863 had cut the ground from under their feet. Meanwhile he had, in 1862, founded the *Athenäum* as the organ of Liberal Catholicism. For this he wrote the first adequate account in German of the Darwinian theory of natural selection, and drew a warm letter of appreciation from Darwin himself. Excommunicated in 1871, he replied with three articles, which were reproduced in thousands as pamphlets in the chief European languages—*Der Fels Petri in Rom* (1873), *Der Primat Petri und des Papstes* (1875), and *Das Christenthum Christi und das Christenthum des Papstes* (1876). His later years were occupied with a series of philosophical works, of which the most important were *Die Phantasie als Grundprincip des Weltprocesses* (1877), *Ueber die Genesis der Menschheit und deren geistige Entwicklung in Religion, Sittlichkeit und Sprache* (1883), and *Ueber die Organisation und Cultur der menschlichen Gesellschaft* (1885). His system is based on the unifying principle of imagination ("Phantasie"), which he extends to the objective creative force of Nature, as well as to the subjective mental phenomena to which the term is usually confined. He died at Bad Kreuth in the Bavarian Highlands on 14th June 1893.

Frohschammer's works, in addition to those already mentioned, include: *Beleuchtung der Encyklika* (anonymous, 1865); *Das Christenthum und die moderne Naturwissenschaft* (1868); *Das Recht der eigenen Ueberzeugung, Die politische Bedeutung der Unfehlbarkeit des Papstes und der Kirche*, and *Zur Würdigung der Unfehlbarkeit des Papstes und der Kirche* (1869); *Die Unfehlbarkeit des Papstes* (addressed to the archbishop of Munich—Freising, 1871), *Ueber die religiösen und kirchenpolitischen Fragen der Gegenwart. Gesammelte Abhandlungen* (1875); *Die wahre Bedeutung des Kulturkampfes* (1878); *Monaden und Weltphantasie* and *Ueber die Bedeutung der Einbildungskraft in der Philosophie Kant's und Spinoza's* (1879); *Ueber die Principien der Aristotelischen Philosophie und die Bedeutung der Phantasie in derselben* (1881); *Die Philosophie als Idealwissenschaft und System* (1884); *Die Philosophie des Thomas von Aquino kritisch gewürdigt* (1889); *Ueber das Mysterium Magnum des Daseins* (1891); *System der Philosophie im Umriss* (1892 *et seq.*); *Briefe von und über J. Frohschammer herausgegeben von B. Münz* (1897); *J. Frohschammer's philosophisches System im Grundriss, nach Frohschammer's Vorlesungen herausgegeben von A. Attensperger* (1899). In 1888 he published a brief autobiography. For his philosophy consult F. Friedrich and B. Münz. (H. Sy.)

Frome (or Frome Selwood), a market-town in the Frome parliamentary division (since 1885) of Somersetshire, England, 11 miles south of Bath by rail. There are in all five parish or district churches, a Roman Catholic church, and various Nonconformist chapels. A recreation ground was provided in 1888. Public offices and a Church of England home for boys have been erected; there is a cottage hospital. Area of urban district, 731 acres; population (1881), 9377; (1891), 9613. Area of township, 7614 acres; population (1881), 11,304; (1901), 11,055. There is a parish of Frome.

Froude, James Anthony (1818–1894), English historian, son of R. H. Froude, archdeacon of Totnes, was born at Darlington, Devon, on 23rd April 1818. He was educated at Westminster and Oriel College, Oxford, then the centre of the ecclesiastical revival. He obtained a second class and the chancellor's English essay prize, and was elected a fellow of Exeter College (1842). Though not so conspicuous in the High Church movement at Oxford as his elder brother, Richard Hurrell Froude, he was one of its prominent adherents, and helped J. H. Newman, afterwards cardinal, in his *Lives of the English Saints*. He was ordained deacon in 1844. Soon afterwards his religious opinions began to change, he grew dissatisfied with the views of the High Church party, and came under the influence of Carlyle's teaching. Signs of this change first appeared publicly in his *Shadows of the Clouds*, a volume containing two stories of a religious sort, which he published in 1847 under the pseudonym of "Zeta," and his complete desertion of his party was declared



J. A. Froude.
(*From a photo. by Elliott and Fry.*)

a year later in his *Nemesis of Faith*, of which the earlier part seems to be autobiographical. He resigned his fellowship at Oxford, and mainly at least supported himself by writing, contributing largely to *Fraser's Magazine* and the *Westminster Review*. The excellence of his style was soon generally recognized. The first two volumes of his *History of England from the Fall of Wolsey to the Defeat of the Spanish Armada* appeared in 1856, and the work was completed in 1870. As a historian he is chiefly remarkable for literary excellence, for the art with which he represents his conception of the past. He condemns a scientific treatment of history and disregards its philosophy. He held that its office was simply to record human actions and that it should be written as a drama. Accordingly he gives prominence to the personal element in history. His presentations of character and motives, whether truthful or not, are undeniably fine; but his doctrine that there should be "no theorizing" about history tended to narrow his survey, and consequently he sometimes, as in his remarks on the foreign policy of Elizabeth, seems to misapprehend the tendencies of a period on which he is writing.

Froude was not a historical scholar and his work is often marred by prejudice and incorrect statements. He wrote with a purpose. The keynote of his *History* is contained in his assertion that the Reformation was "the root and source of the expansive force which has spread the Anglo-Saxon race over the globe." Hence he overpraises Henry VIII. and others who forwarded the movement, and speaks too harshly of some of its opponents. So too, in his *English in Ireland* (1871–74), which was written to show the futility of attempts to conciliate the Irish, he aggravates all that can be said against the Irish, and touches too lightly on atrocities on the part of the English. A strong anti-clerical prejudice is manifest in his historical work generally, and is doubtless the result of the change in his views on Church matters and his abandonment of the clerical profession. Carlyle's influence on him may be traced both in his admiration for strong rulers and strong government, which sometimes led him to write as though tyranny and brutality were excusable, and in his independent treatment of character. His rehabilitation of Henry VIII. was a useful protest against the idea that the king was a mere sanguinary profligate, but his representation of him as the self-denying minister of his people's will is erroneous, and is founded on the false theory that the preambles of the Acts of Henry's Parliaments represented the opinions of the educated laymen of England. As an advocate he occasionally forgets that sobriety of judgment and expression become a historian. He was not a judge of evidence, and seems to have been unwilling to admit the force of any argument or the authority of any statement which militated against his case. In his *Divorce of Catherine of Aragon* (1891) he made an unfortunate attempt to show that certain fresh evidence on the subject, brought forward by Dr Gairdner, Dr Friedmann, and others, was not inconsistent with the views which he had expressed in his *History* nearly forty years before. No attempt at thoroughness of investigation appears in any of his books. The manuscript treasures of Hatfield were opened to him, but he is said to have been content with a single day's examination of them; and though he visited Simancas, his work there must have been careless. His *Life of Cæsar* (1879), a glorification of Imperialism, betrays an imperfect acquaintance with the life and writings of Cicero; and of his two pleasant books of travel, *The English in the West Indies* (1888) shows that he made little effort to master his subject, and *Oceana* (1886), the record of a tour in Australia and New Zealand, among a multitude of other blunders, notes the prosperity of the working-classes in Adelaide at the date of his visit, when, in fact, owing to a failure in the wheat-crop, hundreds were then living on charity. He was constitutionally inaccurate, and seems to have been unable to represent the exact sense of a document which lay before him, or even to copy from it correctly. Historical scholars ridiculed his mistakes, and Freeman, the most violent of his critics, never let slip a chance of hitting at him in the *Saturday Review*. Froude's temperament was sensitive, and he suffered from these attacks, which were in truth far too savage in tone. The literary quarrel between him and Freeman excited general interest when it blazed out in a series of articles which Freeman wrote in the *Contemporary Review* (1878–79) on his *Short Study* of Thomas Becket.

Yet, notwithstanding its defects, Froude's *History* is a great achievement; it presents an important and powerful account of the Reformation period in England, and lays before us a picture of the past magnificently conceived, and painted in colours which will never lose their freshness and beauty. As with Froude's work generally, its literary merit is remarkable; it is a well-balanced and orderly narrative, coherent in design and symmetrical in execution. Though it is perhaps needlessly long, the thread of the story is never lost amid a crowd of details; every incident is made subordinate to the general idea, appears in its appropriate place, and contributes its share to the perfection of the whole. The excellence of its form is matched by the beauty of its style, for Froude was a master of English prose. The most notable characteristic of his style is its graceful simplicity; it is never affected or laboured; his sentences are short and easy, and follow one another naturally. He is always lucid. He was never in doubt as to his own meaning, and never at a loss for the most appropriate words in which to express it. Simple as his language is, it is dignified and worthy of its subject. Nowhere perhaps does his style appear to more advantage than in his four series of essays entitled *Short Studies on Great Subjects* (1867–82), for it is seen there unfettered by the obligations of narrative. Yet his narrative is admirably told. For the most part flowing easily along, it rises on fit occasions to splendour, picturesque beauty, or pathos. Few more brilliant pieces of historical writing exist than his description of the coronation procession of Anne Boleyn through the streets of London, few more full of picturesque power than that in which he relates how the spire of St Paul's was struck by lightning; and to have once read is to remember for ever the touching and stately words in which he compares the monks of the London Charterhouse preparing for death with the Spartans at Thermopylæ. Proofs of his power in the sustained narration of stirring events are abundant; his treatment of the Pilgrimage of Grace, of the sea fight at St Helens and the repulse of the French invasion, and of the murder of Rizzio, are among the most conspicuous examples of it. Nor is he less successful when recording pathetic events, for his stories of certain martyrdoms, and of the execution of Mary Queen of Scots, are told with exquisite feeling and in language of well-restrained emotion. And his characters are alive. We may not always agree with his portraiture, but the men and women whom he saw exist for us instinct with the life with which he endows them and animated by the motives which he attributes to them. His successes must be set against his failures. At the least he wrote a great history, one which can never be disregarded by future writers on his period, be their opinions what they may; which attracts and delights a multitude of readers, and is a splendid example of literary form and grace in historical composition.

The merits of his work met with full recognition. Each instalment of his *History*, in common with almost everything which he wrote, was widely read, and in spite of some adverse criticisms was received with eager applause. In 1868 he was elected Rector of St Andrews University, defeating Disraeli by a majority of fourteen. He was warmly welcomed in the United States, which he visited in 1872, giving lectures in various places. On the death of his adversary Freeman in 1892, he was appointed, on the recommendation of Lord Salisbury, to succeed him as regius professor of modern history at Oxford. Except to a few Oxford men, who considered that historical scholarship should have been held to be a necessary qualification for the office, his appointment gave general satisfaction. His lectures on Erasmus and other 16th-century subjects were largely attended. With some allowance for the purpose for which they were originally written, they present much the same characteristics as his earlier historical books. His health gave way in the summer of 1894, and he died on 20th October of that year, at the age of seventy-six. His long life was full of literary work. Besides his labours as an author, he was for fourteen years editor of *Fraser's Magazine*. He was one of Carlyle's literary executors, and brought some sharp criticism upon himself by publishing Carlyle's *Reminiscences* and the *Memorials of Jane Welsh Carlyle*, for they exhibited the domestic life and character of his old friend in an unpleasant light. Carlyle had given the manuscripts to him, telling him that he might publish them if he thought it well to do so, and at the close of his life agreed to their publication. Froude therefore declared that in giving them to the world he was carrying out his friend's wish by enabling him to make a posthumous confession of his faults. But Carlyle did not intend that they should be published without "fit editing," and said so in a passage which Froude omitted to print. Besides publishing these manuscripts, he wrote a *Life of Carlyle.* His earlier study of Irish history afforded him suggestions for a historical novel entitled *The Two Chiefs of Dunboy* (1889). In spite of one or two stirring scenes, it is a tedious book; it lacks the necessary elements of romance, and its personages are little more than machines for the enunciation of the author's opinions and sentiments. Though Froude had some intimate friends, he was generally reserved. When he cared to please, his manners and conversation were charming. Those who knew him well formed a high estimate of his ability in practical affairs. In 1874 Lord Carnarvon, then colonial secretary, sent him to South Africa on a mission of inquiry, and in 1875 to Cape Town as a member of a proposed conference; but his speeches there were rather injudicious, and his mission was a failure. He was twice married. His first wife, a daughter of Mr Pascoe Grenfell, died in 1860; his second, a daughter of Mr John Warre, M.P. for Taunton, died in 1886. (W. Hu.)

FRUIT AND FLOWER FARMING.

Imports of Fresh Fruit.

The quantities of apples, pears, plums, cherries, and grapes imported in the raw condition into the United Kingdom in each year, 1892 to 1901, are shown in Table I. Previous to 1892 apples only were separately enumerated. Up to 1899 inclusive the quantities were given in bushels, but in 1900 a change was made to hundredweights. This renders the quantities in that and subsequent years not directly comparable with those in earlier years, but the comparison of the values, which are also given in the table, continues to hold good. In some years the value of imported apples exceeds the aggregate value of the pears, plums, cherries, and grapes imported. The extreme values for apples shown in the table are £844,000 in 1893 and £1,582,000 in 1896. Grapes rank next to apples in point of value, and over the ten years the amount ranged between £394,000 in 1892 and £695,000 in 1901. On the average, the annual outlay on imported plums is slightly in excess of that on pears. The extremes shown are £166,000 in 1895 and £498,000 in 1897. In the case of pears, the smallest outlay tabulated is £167,000 in 1895, whilst the largest is £411,000 in 1894. The amounts expended upon imported cherries varied between £96,000 in 1895 and £308,000 in 1900. In 1900 apricots and peaches, imported raw, previously included with raw plums, were for the first time separately enumerated, the import into the United Kingdom for that year amounting to 13,689 cwt., valued at £25,846; in 1901 the quantity was 13,463 cwt., and the value £32,350. In 1900, also, currants, gooseberries, and strawberries, hitherto included in unenumerated raw fruit, were likewise for the first time separately returned. Of raw currants the import was 64,462 cwt., valued at £87,170; of raw gooseberries 26,045 cwt., valued at £14,626; and of raw strawberries 52,225 cwt., valued at £85,949. In 1901 the quantities and values were respectively—currants, 70,402 cwt., £75,308; gooseberries, 21,735 cwt., £11,420; strawberries, 38,604 cwt., £51,290. Up to 1899 the imports of tomatoes were included amongst unenumerated raw vegetables, so that the quantity was not separately ascertainable. For 1900 the import of tomatoes was 833,032 cwt., valued at £792,339, which is equivalent to a fraction under $2\frac{1}{2}$d. per lb. For 1901 the quantity was 793,991 cwt., and the value £734,051.

Table I.—Imports of raw apples, pears, plums, cherries, and grapes into the United Kingdom, 1892 to 1901. Quantities in thousands of bushels (thousands of cwt. in 1900 and 1901), values in thousands of pounds sterling.

Year.	Apples.	Pears.	Plums.	Cherries.	Grapes.
	Quantities.				
1892	4515	637	413	217	762
1893	3460	915	777	346	979
1894	4969	1310	777	311	833
1895	3292	407	401	196	865
1896	6177	483	560	219	883
1897	4200	1052	1044	312	994
1898	3459	492	922	402	1136
1899	3861	572	558	281	1158
1900	2129 [a]	477 [a]	423 [a]	243 [a]	593 [a]
1901	1830 [a]	349 [a]	264 [a]	213 [a]	680 [a]
	Values.				
1892	1354	297	200	135	394
1893	844	347	332	195	530
1894	1389	411	302	167	470
1895	960	167	166	96	487
1896	1582	207	242	106	443
1897	1187	378	498	178	495
1898	1108	222	435	231	550
1899	1186	266	294	154	588
1900	1225	367	393	308	595
1901	1183	296	244	214	695

[a] Thousands of cwt.

In 1900 the outlay of the United Kingdom upon imported raw fruits, such as can easily be produced at home, was £2,708,512, made up as follows:—

Apples . . .	£1,224,655	Currants . . .	£87,170
Grapes . . .	595,000	Strawberries . .	85,949
Pears . . .	366,871	Apricots and peaches	25,846
Cherries . .	308,395	Gooseberries . .	14,626

In addition, £289,752 was spent upon "unenumerated" raw fruit, and £602,130 on nuts other than almonds "used as fruit," which would include walnuts and filberts, both produced at home. It is certain, therefore, that the expenditure on imported fruits, such as are grown within the limits of the United Kingdom, exceeds three millions sterling per annum. The remainder of the outlay on imported fruit in 1900, amounting to £3,660,419, was made up of £2,120,789 for oranges, £420,857 for lemons, £548,956 for bananas, and £569,817 for almond-nuts; these cannot be grown on an industrial scale in the British Isles.

In 1901 the total expenditure on raw fruit imported into the United Kingdom was £7,623,500, the largest items being £2,119,726 for oranges, £1,182,798 for apples, £1,090,477 for almonds and other nuts used as fruit, £875,542 for bananas, and £694,942 for grapes.

Acreages of Orchards and Small Fruit Plantations.

The Board of Agriculture returns concerning the orchard areas of Great Britain show a continuous expansion year by year from 199,178 acres in 1888 to 234,660 acres in 1901, as will be learnt from Table II. There is, it is

Table II.—Extent of Orchards in Great Britain in each year, 1887 to 1901.

Year.	Acres.	Year.	Acres.	Year.	Acres.
1887	202,234	1892	208,950	1897	224,116
1888	199,178	1893	211,664	1898	226,059
1889	199,897	1894	214,187	1899	228,603
1890	202,305	1895	218,428	1900	232,129
1891	209,996	1896	221,254	1901	234,660

true, an exception in 1892, but the decline in that year is explained by the circumstance that since 1891 the agricultural returns have been collected only from holdings of more than one acre, whereas they were previously obtained from all holdings of a quarter of an acre or more. As there are many holdings of less than an acre in extent upon which fruit is grown, and as fruit is largely raised also in suburban and other gardens which do not come into the returns, it may be taken for granted that the actual extent of land devoted to fruit culture exceeds that which is indicated by the official figures. Table III. shows that

Table III.—Areas under Orchards in England, Wales, and Scotland, in each year, 1896 to 1901,—Acres.

Year.	England.	Wales.	Scotland.	Great Britain.
1896	215,642	3677	1935	221,254
1897	218,261	3707	2148	224,116
1898	220,220	3690	2149	226,059
1899	222,712	3666	2225	228,603
1900	226,164	3695	2270	232,129
1901	228,580	3767	2313	234 660

the expansion of the orchard area of Great Britain is mainly confined to England, for it is almost at a standstill in Wales, and only increases slowly in Scotland. The acreage officially returned as under orchards is that of arable or grass land which is also used for fruit trees of any kind. Conditions of soil and climate determine the irregular distribution of orchards in Great Britain. The dozen counties which possess the largest extent of orchard land all lie in the south or west of the island. According to the returns for 1901, they are the following :—

County.	Acres.	County	Acres.	County.	Acres.
Kent .	27,175	Worcester	21,414	Salop .	4758
Devon .	27,161	Gloucester	19,806	Dorset .	4459
Hereford	26,987	Cornwall .	5,252	Monmouth	4027
Somerset	24,929	Middlesex	4,974	Wilts .	3774

Leaving out of consideration the county of Kent, which grows a greater variety of fruit than any of the others, the counties of Devon, Hereford, Somerset, Worcester, and Gloucester have an aggregate orchard area of 120,297 acres. These five counties of the west and south-west of England—constituting in one continuous area what is essentially the cider country of Great Britain—embrace therefore rather more than half of the entire orchard area of the island. Eight English counties have less than 1000 acres each of orchards, namely, the small counties of Bedford, Huntingdon, and London, and the northern counties of Cumberland, Westmorland, Northumberland, Durham, and the East Riding of York. Rutland has less than 100 acres. The largest orchard areas in Wales are in the two counties adjoining Hereford—Brecon with 1185 acres, and Radnor with 723 acres; at the other extreme is Anglesey, with an orchard area of only 41 acres. Of the Scottish counties, Lanark takes the lead with 771 acres, Perth and Haddington following with 566 and 126 acres respectively. Ayr, according to the 1901 returns, is the only other county possessing 100 acres or more of orchards, whilst Kincardine, Orkney, Shetland, and Wigtown return no orchard area, and Banff, Bute, Kinross, Nairn, Peebles, and Sutherland return less than 10 acres each. It may be added that in 1901 Jersey returned 1027 acres of orchards; Guernsey, &c., 209 acres; and the Isle of Man 307 acres.

Outside the cider counties proper of England, the counties in which orchards for commercial fruit-growing have increased considerably in recent years include Berks, Buckingham, Cambridge, Essex, Lincoln, Middlesex, Monmouth, Norfolk, Oxford, Salop, Sussex, Warwick, and Wilts. Apples are the principal fruit grown in the western and south-western counties, pears also being fairly common. In parts of Gloucestershire, however, and in the Evesham and Pershore districts of Worcestershire, plum orchards predominate. Plums are likewise largely grown in Cambridgeshire and the neighbouring counties. Large quantities of apples, plums, damsons, cherries, and pears are grown for the market in Kent and Middlesex, whilst in many counties damsons are cultivated around fruit plantations to shelter the latter from the wind.

Of small fruit (currants, gooseberries, strawberries, raspberries, &c.) no return was made of the acreage previous to 1888, in which year it was given as 36,724 acres for Great Britain. In 1889 it rose to 41,933 acres. The areas in subsequent years are shown in Table IV. It

Table IV.—Areas of Small Fruit in Great Britain in each year, 1890 to 1901.

Year.	Acres.	Year.	Acres.	Year.	Acres.
1890	46,234	1894	68,415	1898	69,753
1891	58,704	1895	74,547	1899	71,526
1892	62,148	1896	76,245	1900	73,780
1893	65,487	1897	69,792	1901	74,999

will be observed that, owing to corrections made in the enumeration in 1897, a considerable reduction in the area is recorded for that year, and presumably the error then discovered existed in all the preceding returns. Despite this, however, the area of 74,999 acres in 1901 is double that of 1888, and there has undoubtedly been a considerable expansion, rather than a contraction, of small fruit plantations since 1896. The acreage of small fruit in Great Britain is about one-third that of the orchards. As may be seen in Table V., it is mainly confined to

Table V.—Areas under Small Fruit in England, Wales, and Scotland in 1898, 1899, 1900, and 1901,—Acres.

Year.	England.	Wales.	Scotland.	Great Britain.
1898	63,438	1044	5271	69,753
1899	64,867	1106	5553	71,526
1900	66,749	1109	5922	73,780
1901	67,828	1092	6079	74,999

England, though Scotland has a much larger acreage of small fruit than of orchards. Fully one-third of the area of small fruit in England belongs to Kent alone, that county having returned 22,778 acres in 1901. Middlesex ranks next with 4524 acres, followed by Worcestershire with 3851 acres, Cambridge with 3740 acres, Norfolk with 3342 acres, Hants with 2382 acres, and Essex with 1983 acres. The largest county area of small fruit in Wales is 622 acres in Denbighshire, and in Scotland 2174 acres in Lanarkshire, followed by 348 acres in Haddingtonshire. The only counties in Great Britain which make no return under the head of small fruit are Orkney, Shetland, and Sutherland. It is hardly necessary to say that considerable areas of small fruit, in kitchen gardens and elsewhere, find no place in the official returns, which, however, include small fruit grown between and under orchard trees.

Gooseberries are largely grown in most small fruit districts. Currants are less widely cultivated, but the red currant is more extensively grown than the black, the latter having suffered seriously from the ravages of the black currant mite. Kent is the great centre for raspberries and for strawberries, though, in addition, the latter fruit is largely grown in Middlesex, South Hants, Norfolk, and other counties.

There are no official returns as to the acreage devoted to orchard cultivation in Ireland. The figures relating to small fruit, moreover, extend back only to 1899, when the area under this head was returned as 4809 acres, which became 4359 acres in 1900 and 4877 acres in 1901. In most parts of the country there are districts favourable to the culture of small fruits, such as strawberries, raspberries, gooseberries, and currants, and of top fruits, such as apples, pears, plums, and damsons. The only localities largely identified (in 1900) with fruit culture as an industry were the Drogheda district and the Armagh district. In the former all the varieties named are grown except strawberries, the speciality being raspberries, which are marketed in Dublin, Belfast, and Liverpool. In the Armagh district, again, all the varieties named are grown, but in this case strawberries are the speciality, the markets utilized being Richhill, Belfast, and those in Scotland. In the Drogheda district the grower bears the cost of picking, packing, and shipping, but he cannot estimate his net returns until his fruit is on the market. Around Armagh the Scottish system prevails—that is, the fruit is sold while growing, the buyer being responsible for the picking and marketing.

Fruit-Growing in Kent.

As by far the largest fruit-growing county in England, Kent may appropriately be dealt with first. For centuries that county has been famous for its fruit, and appears to have been the centre for the distribution of trees and grafts throughout the country. The cultivation of fruit land upon farms in many parts of Kent has always been an important feature in its agriculture. The most recent description of this noteworthy characteristic of Kentish farming is contained in a comprehensive paper on the agriculture of Kent by Mr Charles Whitehead,[1] whose remarks, with various additions and modifications, are here reproduced :—

Where the conditions are favourable, especially in East and Mid Kent, there is a considerable acreage of fruit land attached to each farm, planted with cherry, apple, pear, plum, and damson trees, and with bush fruits, or soft fruits as they are sometimes called, including gooseberries, currants, raspberries, either with or without standard trees, and strawberries, and filberts and cob-nuts in Mid Kent. This acreage has largely increased, and will no doubt continue to increase, as, on the whole, fruit-growing has been profitable, and has materially benefited those fortunate enough to have fruit land on their farms. There are also cultivators who grow nothing but fruit. These are principally in the district of East Kent, between Rochester and Canterbury, and in the district of Mid Kent near London, and they manage their fruit land, as a rule, better than farmers, as they give their undivided attention to it and have more technical knowledge. But there has been great improvement of late in the management of fruit land, especially of cherry and apple orchards, the grass of which is fed off by animals having corn or cake, or the land is well manured. Apple trees are grease-banded and sprayed systematically by advanced fruit-growers, to prevent or check the attacks of destructive insects. Far more attention is being paid to the selection of varieties of apples and pears having colour, size, flavour, keeping qualities, and other attributes to meet the tastes of the public, and to compete with the beautiful fruit that comes from the United States and Canada.

Of the various kinds of apples at present grown in Kent mention should be made of Mr Gladstone, Beauty of Bath, Devonshire Quarrenden, Lady Sudely, Yellow Ingestre, and Worcester Pearmain. These are dessert apples coming to pick in August and September, and not stored. For storing, King of the Pippins, Cox's Orange Pippin (the best dessert apple in existence), Cox's Pomona, Duchess, Favourite, Gascoyne's Scarlet Seedling, Court Pendu Plat, Baumann's Red Reinette, Allington Pippin, Duke of Devonshire, and Blenheim Orange. Among kitchen apples for selling straight from the trees the most usually planted are Lord Grosvenor, Lord Suffield, Keswick Codlin, Early Julian, Eclinville Seedling, Pott's Seedling, Early Rivers, Grenadier, Golden Spire, Stirling Castle, and Domino. For storing, the cooking sorts favoured now are Stone's or Loddington, Warner's King, Wellington, Lord Derby, Queen Caroline, Tower of Glamis, Winter Queening, Lucombe's Seedling, Bismarck, Bramley's Seedling, Golden Noble, and Lane's Prince Albert. Almost all these will flourish equally as standards, pyramids, and bushes. Among pears are Hessle, Clapp's Favourite, William's Bon Chrétien, Beurré de Capiaumont, Fertility, Beurré Riche, Chissel, Beurré Clairgeau, Louise Bonne of Jersey, Doyenne du Comice, and Vicar of Winkfield. Among plums, Rivers's Early Prolific, Czar, Belgian Purple, Black Diamond, Kentish Bush Plum, Pond's Seedling, Magnum Bonum, and Victoria are mainly cultivated. The damson known as Farleigh Prolific, or Crittenden's, is most extensively grown throughout the county, and usually yields large crops, which make good prices. As a case in point, purchasers were offering to contract for quantities of this damson at £20 per ton in May of 1899, as the prospects of the yield were unsatisfactory. On the other hand, in one year recently, when the crop was abnormally abundant, some of the fruit barely paid the expenses of sending to market. The varieties of cherries most frequently grown are Governor Wood, Knight's Early Black, Frogmore Blackheart, Black Eagle, Waterloo, Amberheart, Bigarreau, Napoleon Bigarreau, and Turk. A variety of cherry known as the Kentish cherry, of a light red colour and fine subacid flavour, is much grown in Kent for drying and cooking purposes. Another cherry, similar in colour and quality, which comes rather late, known as the Flemish, is also extensively cultivated, as well as the very dark red large Morella, used for making cherry brandy. These three varieties are grown extensively as pyramids, and the last-named also on walls and sides of buildings. Sometimes the cherry crop is sold by auction to dealers, who pick, pack, and consign the fruit to market. Large prices are often made, as much as £80 per acre being not uncommon. The crop on a large cherry orchard in Mid Kent has been sold for more than £100 per acre.

Where old standard trees have been long neglected and have become overgrown by mosses and lichens, the attempts made to improve them seldom succeed. The introduction of bush fruit trees dwarfed by grafting on the Paradise stock has been of much advantage to fruit cultivators, as they come into bearing in two or three years, and are more easily cultivated, pruned, sprayed, and picked than standards. Many plantations of these bush trees have been formed in Kent of apples, pears, and plums. Half standards and pyramids have also been planted of these fruits, as well as of cherries. Fruit bushes of gooseberries and currants, and of raspberry canes, have been planted to a great extent in many parts of the East and Mid divisions of Kent, but not much in the Weald, where apples are principally grown. Sometimes fruit bushes are put in alternate rows with bush trees of apple, pear, plum, and damson, or other standards, or they are planted by themselves. The distances apart for planting are generally for cherry and apple trees on grass 30 feet by 30 feet; for standard apples and pear trees from 20 feet to 24 feet upon arable land, with bush fruit, as gooseberries and currants, under them. These are set 6 feet by 6 feet apart, and 5 feet by 2 feet for raspberries, and strawberries 2 feet 6 inches to 3 feet by 1 foot 6 inches to 1 foot 3 inches apart. On some fruit farms bush or dwarf trees—apples, pears, plums—are planted alone, at distances varying from 8 feet to 10 feet apart, giving from 485 to 680 bush trees per acre, nothing being grown between them except perhaps strawberries or vegetables during the first two or three years. It is believed that this is the best way of ensuring fruit of high quality and colour. Another arrangement consists in putting standard apple or pear trees 30 feet apart (48 trees per acre), and setting bush trees of apples or pears 15 feet apart between them; these latter come quickly into bearing, and are removed when the standards are fully grown. Occasionally gooseberry or currant bushes, or raspberry canes or strawberry plants, are set between the bush trees, and taken away directly they interfere with the growth of these. Half standard apple or plum trees are set triangularly 15 feet apart, and strawberry plants at a distance of 1½ foot from plant to plant and 2½ feet from row to row. Or currant or gooseberry bushes are set between the half standards, and strawberry plants between these.

These systems involve high farming. The manures used are London manure, where hops are not grown, and bone meal, superphosphate, rags, shoddy, wool-waste, fish refuse, nitrate of soda, kainit, and sulphate of ammonia. Where hops are grown the London manure is wanted for them. Fruit plantations are always dug by hand with the Kent spud. Fruit land is never ploughed, as in the United States and Canada. The soil is levelled down with the "Canterbury" hoe, and then the plantations are kept free from weeds with the ordinary or "plate" hoe. The best fruit farmers spray fruit trees regularly in the early spring, and continue until the blossoms come out, with quassia and soft soap and paraffin emulsions, and a very few with Paris green only, where there is no under fruit, in order to prevent and check the constant attacks of the various caterpillars and other insect pests. This is a costly and laborious process, but it pays well, as a rule. The fallacy that fruit trees on grass land require no manure, and that the grass may be allowed to grow up to their trunks without any harm, is exploding, and many fruit farmers are well

[1] *Jour. Roy. Agric. Soc.*, 1899.

manuring their grass orchards and removing the grass for some distance round the stems, particularly where the trees are young.

Strawberries are produced in enormous quantities in the northern part of the Mid Kent district round the Crays, and from thence to Orpington; also near Sandwich, and to some extent near Maidstone. Raspberry canes have been extensively put in during the last few years, and in some seasons yield good profits. There is a very great and growing demand for all soft fruits for jam-making, and prices are fairly good, taking an average of years, notwithstanding the heavy importations from France, Belgium, Holland, Spain, and Italy. The extraordinary increase in the national demand for jam and other fruit preserves has been of great benefit to Kent fruit producers. The cheapness of duty-free sugar, as compared with sugar paying duty in the United States and other large fruit-producing countries, afforded one of the very few advantages possessed by British cultivators, but the re-imposition of the sugar duty in the United Kingdom in 1901 has modified the position in this respect. Jam factories were established in several parts of Kent about 1889 or 1890, but most of them collapsed either from want of capital or from bad management. There are still a few remaining, principally in connexion with large fruit farms. One of these is at Swanley, whose energetic owners farm nearly 2000 acres of fruit land in Kent. The fruit grown by them that will not make satisfactory prices in a fresh raw state is made into jam, or if time presses it is first made into pulp, and kept until the opportunity comes for making it into jam. In this factory there are fifteen steam-jacketed vats in one row, and six others for candied peel. A season's output on a recent occasion comprised about 3500 tons of jam, 850 tons of candied peel, and 750 gross (108,000 bottles) of bottled fruit. A great deal of the fruit preserved is purchased, whilst much of that grown on the farms is sold. A strigging machine is employed, which does as much work as fifty women in taking currants off their strigs or stalks. Black currant pulp is stored in casks till winter, when there is time to convert it into jam. Strawberries cannot be pulped to advantage, but it is otherwise with raspberries, the pulp of which is largely made. Apricots for jam are obtained chiefly from France and Spain. There is another flourishing factory near Sittingbourne worked on the same lines. It is very advantageous to fruit farmers to have jam factories in connexion with their farms, or to have them near, as they can thoroughly grade their fruit, and send only the best to market, thus ensuring a high reputation for its quality. Carriage is saved, which is a serious charge, though railway rates from Kent to the great manufacturing towns and to Scotland are very much less proportionally than those to London, and consequently Kent growers send increasing quantities to these distant markets, where prices are better, not being so directly interfered with by imported fruit, which generally finds its way to London.

Kentish fruit-growers are becoming more particular in picking, grading, packing, and storing fruit, as well as in marketing it. A larger quantity of fruit is now carefully stored, and sent to selected markets as it ripens, or when there is an ascertained demand, as it is found that if it is consigned to market direct from the trees there must frequently be forced sales and competition with foreign fruit that is fully matured and in good order. It was customary formerly for Kentish growers to consign all their fruit to the London markets; now a good deal of it is sent to Manchester, Birmingham, Liverpool, Sheffield, Newcastle, and other large cities. Some is sent even to Edinburgh. Many large growers send no fruit to London now. It is by no means uncommon for growers to sell their fruit crops on the trees or bushes by auction or private treaty, or to contract to supply a stipulated quantity of specified fruit, say of currants, raspberries, or strawberries, to jam manufacturers. There is a considerable quantity of fruit, such as grapes, peaches, nectarines, grown under glass, and this kind of culture tends to increase.

Filberts and cob-nuts are a special product of Kent, in the neighbourhood of Maidstone principally, and upon the Ragstone soils, certain conditions of soil and situation being essential for their profitable production. A part of the filbert and cob-nut crop is picked green in September, as they do well for dessert, though their kernels are not large or firm, and it pays to sell them green, as they weigh more heavily. One grower in Mid Kent has 100 acres of nuts, and has grown 100 tons in a good year. The average price of late years has been about 5d. per lb, which would make the gross return of the 100 acres amount to £4660. Kentish filberts have long been proverbial for their excellence. Cobs are larger and look better for dessert, though their flavour is not so fine. They are better croppers, and are now usually planted. This cultivation is not much extending, as it is very long before the trees come into full bearing. The London market is supplied entirely with these nuts from Kent, and there is some demand in America for them. Filbert and cob trees are most closely pruned. All the year's growth is cut away except the very finest young wood, which the trained eye of the tree-cutter sees at a glance is blossom-bearing. The trees are kept from 5½ to 7 feet high upon stems from 1½ to 2 feet high, and are trained so as to form a cup of from 7 to 8 feet in diameter.

There seems no reason to expect any decrease in the acreage of fruit land in Kent, and if the improvement in the selection of varieties and in the general management continues it will yet pay. A hundred years ago every one was grubbing fruit land in order that hops might be planted, and for this many acres of splendid cherry orchards were sacrificed. Now the disposition is to grub hop plants and substitute cherry trees.

Fruit-Growing in other Districts.

The large fruit plantations in the vicinity of the metropolis are to be found mostly in the valley of the Thames above London, around such centres as Richmond, Hounslow, Cranford, and Southall. All varieties of orchard trees and small fruit are grown in these districts, the nearness of which to the metropolitan fruit market at Covent Garden is of course an advantage. Some of the orchards are old, and are not managed on modern principles. They contain, moreover, varieties of fruit many of which are out of date and would not be employed in establishing new plantations. In the better-managed grounds the antiquated varieties have been removed, and their places taken by newer and more approved types. In addition to apples, pears, plums, damsons, cherries, and quinces as top fruit, currants, gooseberries, and raspberries are grown as bottom fruit. Strawberries are extensively grown in some of the localities, and occasionally outdoor tomatoes are ripened and marketed.

Fruit is extensively grown in Cambridgeshire and adjacent counties in the east of England. A leading centre is Cottenham, where the Lower Greensand crops out and furnishes one of the best of soils for fruit-culture. In Cottenham about a thousand acres are devoted to fruit, and nearly the same acreage to asparagus, which is, however, giving place to fruit. Plums and gooseberries are the most largely grown, apples, currants, and raspberries following. Of varieties of plums the Victoria is first in favour, and then Rivers's Early Prolific, Tsar, and Gisborne. London is the chief market, as it receives about half the fruit sent away, whilst a considerable quantity goes to Manchester, and some is sent to a neighbouring jam factory at Histon, where also a moderate acreage of fruit is grown. Another fruit-growing centre in Cambridgeshire is at Willingham, where—besides plums, gooseberries, and raspberries—outdoor tomatoes are a feature. Greengages are largely grown near Cambridge. Wisbech is the centre of an extensive fruit district, situated partly in Cambridgeshire and partly in Norfolk. Gooseberries, strawberries, and raspberries are largely grown, and as many as 80 tons of the first-named fruit have been sent away from Wisbech station in a single day. In the fruit-growing localities of Huntingdonshire plums and gooseberries are the most extensively grown, but apples, pears, greengages, cherries, currants, strawberries, and raspberries are also cultivated. As illustrating variations in price, it may be mentioned that about the year 1880 the lowest price for gooseberries was £10 per ton, whereas it has since been down to £4. Huntingdonshire fruit is sent chiefly to Yorkshire, Scotland, and South Wales, but railway freights are high.

Essex affords a good example of successful fruit-farming at Tiptree Heath, near Kelvedon, where under one management about 260 acres out of a total of 360 are under fruit. The soil, a stiff loam, grows strawberries to perfection, and 165 acres are allotted to this fruit. The other principal crops are 43 acres of raspberries and 30 acres of black currants, besides which there are small areas of red currants, gooseberries, plums, damsons, greengages, cherries, apples, quinces, and blackberries. The variety of strawberry known as the Small

Scarlet is a speciality here, and it occupies 55 acres, as it makes the best of jam. The Paxton, Royal Sovereign, and Noble varieties are also grown. Strawberries stand for six or seven years on this farm, and begin to yield well when two years old. A jam factory is worked in conjunction with the fruit farm. Pulp is not made except when there is a glut of fruit. Perishable fruit intended for whole-fruit preserves is never held over after it is gathered. The picking of strawberries begins at 4 A.M., and the first lot is made into jam by 6 A.M.

Hampshire, like Cambridgeshire and Norfolk, is one of the few counties in which the area of small fruit exceeds that of orchards, the former in 1901 being returned at 2382 acres, and the latter at 2078 acres. Compared with a dozen years previously, the acreage of small fruit has trebled. This is largely due to the extension of strawberry culture in the Southampton district, where the industry is in the hands of many small growers, few of whom cultivate more than 20 acres each. Sarisbury and Botley are the leading parishes in which the business is carried on. Most of the strawberry holdings are from half an acre to 5 acres in extent, a few are from 5 to 10 acres, fewer still from 10 to 20 acres, and only half-a-dozen over that limit. Runners from one-year plants are used for planting, being found more fruitful than those from older plants. Peat moss manure from London stables is much used, but artificial manures are also employed with good results. Shortly after flowering the plants are bedded down with straw at the rate of about 25 cwt. per acre. Picking begins some ten days earlier than in Kent, at a date between 1st June and 15th June. The first week's gathering is sent mostly to London, but subsequently the greater part of the fruit goes to the Midlands and to Scotland and Ireland.

In recent years fruit-growing has much increased in South Worcestershire, in the vicinity of Evesham and Pershore. Hand-lights are freely used in the market gardens of this district for the protection of cucumbers and vegetable marrows, besides which tomatoes are extensively grown out of doors. The egg plum and the Worcester damson are the chief fruit crops, apples and cherries ranking next, pears being grown to only a moderate extent. In a prolific season a single tree of the Damascene or Worcester damson will yield from 400 to 500 ℔ of fruit. There is a tendency to grow plum trees in the bush shape, as they are less liable than standards to injury from wind. The manures used include soot, fish guano, blood manure, and phosphates—basic slag amongst the last named. In the Pershore district, where there is a jam factory, plums are the chief tree fruit, whilst most of the orchard apples and pears are grown for cider and perry. Gooseberries are a feature, as are also red and black currants and a few white, but raspberries and strawberries are little grown, and cherries much less than formerly. The soil, a strong or medium loam of fair depth, resting on clay, is so well adapted to plums that trees live for fifty years. In order to check the ravages of the winter moth, plum and apple trees are grease-banded at the beginning of October and again at the end of March. The trees are also sprayed when necessary with insecticidal solutions. Pruning is done in the autumn. An approved distance apart at which to grow plum trees is 12 feet by 12 feet. In the Earl of Coventry's fruit plantation, 40 acres in extent, at Croome Court, plums and apples are planted alternately, the bottom fruit being black currants, which are less liable to injury from birds than are red currants or gooseberries. Details concerning the methods of cultivation of fruit and flowers in various parts of England, the varieties commonly grown, the expenditure involved, and allied matters, will be found in Mr W. E. Bear's papers in the *Journal of the Royal Agricultural Society* in 1898 and 1899.

The Woburn Experimental Fruit Farm.

The establishment in 1894 of the experimental fruit farm at Ridgmont, near Woburn, Beds, is likely to exercise a healthy influence upon the progress and development of fruit-farming in England. The farm was founded, and is carried on, by the public-spirited enterprise of the Duke of Bedford and Mr Spencer U. Pickering, the latter acting as director. The main object of the experimental station is "to ascertain facts relative to the culture of fruit, and to increase our knowledge of, and to improve our practice in, this industry." The farm is 20 acres in extent, and occupies a field which up to June 1894 had been used as arable land for the ordinary rotation of farm crops. The soil is a sandy loam 9 or 10 inches deep, resting on a bed of Oxford Clay. Although it contains a large proportion of sand, the land would generally be termed very heavy, and the water often used to stand on it in places for weeks together in a wet season. The tillage to which the ground was subjected for the purposes of the fruit farm much improved its character, and in dry weather it presents as good a tilth as could be desired. Chemical analyses of the soil from different parts of the field show such wide differences that it is admitted to be by no means an ideal one for experimental purposes. Without entering upon further details, it may be useful to give a summary of the chief results hitherto obtained.

Apples have been grown and treated in a variety of ways, but of the different methods of treatment careless planting, coupled with subsequent neglect, has given the most adverse results, the crop of fruit being not 5 per cent. of that from trees grown normally. Of the separate deleterious items constituting total neglect, by far the most effective was the growth of weeds on the surface; careless planting, absence of manure, and the omission of trenching all had comparatively little influence on the results. A set of trees that had been carelessly planted and neglected, but subsequently tended in the early part of 1896, were in the autumn of that year only 10 per cent. behind their normally-treated neighbours, thus demonstrating that the response to proper attention is prompt. The growth of grass around young apple trees produced a very striking effect, the injury being much greater than that due to weeds. It is possible, however, that in wet years the ill effects of both grass and weeds would be less than in dry seasons. Nevertheless, the grass-grown trees, after five years, were scarcely bigger than when planted, and the actual increase in weight which they showed during that time was about eighteen times smaller than in the case of similar trees in tilled ground. It is believed that one of the main causes of the ill effects is the large increase in the evaporation of water from the soil which is known to be produced by grass, the trees being thereby made to suffer from drought, with constant deprivation of other nourishment as well. That grass growing round young apple trees is deleterious was a circumstance known to many horticulturists, but the extent to which it interferes with the development of the trees had never before been realized. Thousands of pounds are annually thrown away in England through want of knowledge of this fact. Yet trees will flourish in grass under certain conditions, and there were signs that those on the farm were in 1900 beginning to get over the baneful influence of the grass. Whether the dominant factor is the age (or size) of the tree is being investigated by grassing over trees which have hitherto been in the open ground, and so far (1901), the results appear to indicate that the grass is as deleterious to the older trees as it was to the younger ones. Again, it appears to have been demonstrated that young apple trees, at all events in certain soils, require but little or no manure in the early stages of their existence, so that in this case also large sums must be annually wasted upon manurial dressings which produce no effects. The experiments have dealt with dwarf trees of Bramley, Cox, and Potts, six trees of each variety constituting one investigation. Some of the experiments were repeated with Stirling Castle, and others with standard trees of Bramley, Cox, and Lane's Prince Albert. All were planted in 1894–95, the dwarfs being then three years old and the standards four. In each experiment the "normal" treatment is altered in some one particular, this normal treatment consisting of planting the trees carefully in trenched ground, and subsequently keeping the surface clean; cutting back after planting, pruning moderately in autumn, and shortening the growths when it appeared necessary in summer; giving in autumn a dressing of mixed mineral manures, and in February one of nitrate of soda, this dressing being probably equivalent to one of 12 tons of dung per acre. In the experiments on branch treatment, the bad effects of omitting to cut the trees back on planting, or to prune them subsequently, is evident chiefly in the straggling and bad shape of the resulting trees, but such trees also are not so vigorous as they should be. The quantity of fruit borne, however, is in excess of the average. The check on the vigour and growth of a tree by cutting or injuring its roots is in marked contrast with the effects of a similar interference with the branches. Trees which had been root-pruned each year were in 1898 little more than half as big as the normal trees, whilst those root-pruned every second year were about two-thirds as big as the normal. The crops borne by these trees were nevertheless heavy in proportion to the size of the trees. Such frequent root-pruning is not, of course, a practice which should be adopted. It was found that trees which had been carefully lifted every other year and replanted at once experienced no ill effects from the operation; but in a case where the trees after being lifted had been left in a shed for three days before replanting—which would reproduce to a certain extent the conditions experienced when trees are sent out from a nursery—material injury was suffered, these trees after four years being 28 per cent. smaller than similar ones which had not been replanted. Sets of trees planted respectively in November, January, and March have, on the whole, shown nothing in favour of any of these different times for planting purposes. Some doubt is thrown on the accepted view that there is a tendency, at any rate with young apple and pear trees, to fruit in alternate seasons.

Strawberries of eighty-five different varieties have been experimented with, each variety being represented in 1900 by plants of five different ages, from one to five years. In 1896 and 1898 the crops of fruit were about twice as heavy as in 1897 and 1899, but it has not been found possible to correlate these variations with the meteorological records of the several seasons. Taking the average of all the varieties, the relative weights of crop per plant, when these are compared with the two-year-old plants in the same season, are, for the five ages of one to five years, 31, 100, 122, 121, and 134, apparently showing that the bearing power increases rapidly up to two years, less rapidly up to three years, after which age it remains practically constant. The relative average size of the berries shows a deterioration with the age of the plant. The comparative sizes from plants of one to five years old were 115, 100, 96, 91, and 82 respectively. If the money value of the crop is taken to be directly dependent on its total weight, and also on the size of the fruits, the relative values of the crop for the different ages would be 34, 100, 117, 111, and 110, so that, on the Ridgmont ground, strawberry plants could be profitably retained up to five years, and probably longer. As regards what may be termed the order of merit of different varieties of strawberries, it appears that even small differences in position and treatment cause large variations, not only in the features of the crop generally, but also in the relative behaviour of the different varieties. The relative cropping power of the varieties under apparently similar conditions may often be expressed by a number five or tenfold as great in one case as in the other. A comparison of the relative behaviour of the same varieties in different seasons is attended by similar variations. The varying sensitiveness of different varieties of strawberry plants to small and undefinable differences in circumstances is indeed one of the most important facts brought to light in the experiments. Manurial experiments upon strawberries, as well as upon raspberries, gooseberries, black, red, and white currants, are not sufficiently advanced to permit the establishment of conclusions of practical value.

The Flower-Growing Industry.

During the last two or three decades of the 19th century a very marked increase in flower production occurred in England. Notably was this the case in the neighbourhood of London, where, within a radius of 15 or 20 miles, the fruit crops, which had largely taken the place of garden vegetables, were themselves ousted in turn to satisfy the increasing demand for land for flower cultivation. No flower has entered more largely into the development of the industry than the narcissus or daffodil, of which there are now some 600 varieties, fully one-fourth of these being worth cultivating. On some flower farms a dozen or more acres are devoted to narcissi alone, the production of bulbs for sale as well as of flowers for market being the object of the growers.

In the London district the country in the Thames valley, west of the metropolis, is as largely occupied by flower farms as it is by fruit farms—in fact, the cultivation of flowers is commonly associated with that of fruit. In the vicinity of Richmond narcissi are extensively grown, as they also are more to the west in the Long Ditton district, and likewise around Twickenham. Roses come more into evidence in the neighbourhood of Hounslow, Cranford, and Ealing, and in some gardens daffodils and roses occupy alternate rows. South of London is the Mitcham country, long noted for its production of lavender. The incessant growth of the lavender plant upon the same land, however, has led to the decline of this industry, which has been largely transferred to districts in the counties of Bedford, Essex, and Hertford. At Mitcham, nevertheless, mixed flowers are very largely grown for the supply of the metropolis, and one farm alone has nearly 100 acres under flowers and glass-houses. Chrysanthemums, asters, Iceland poppies, gaillardias, pansies, calceolarias, geraniums, and other plants are cultivated in immense quantities. At Swanley and Eynsford, in Kent, flowers are extensively cultivated in association with fruit and vegetables. Narcissi, chrysanthemums, violets, carnations, campanulas, roses, pansies, irises, sweet peas, and many other flowers are here raised, and disposed of in the form both of cut flowers and of plants.

The Scilly Isles are important as providing the main source of supply of flowers to the English markets in the early months of the year. This trade arose almost by accident, for it was about the year 1870 that a box of narcissi sent to Covent Garden Market, London, realized £1; and the knowledge of this fact getting abroad, the farmers of the isles began collecting wild bulbs from the fields in order to cultivate them and increase their stocks. Some ten years, however, elapsed before the industry promised to become remunerative. In 1885 a Bulb and Flower Association was established to promote the industrial growth of flowers. The exports of flowers in that year reached 65 tons, and they steadily increased until 1893, when they amounted to 450 tons. A slight decline followed, but in 1896 the quantity exported was no less than 514 tons. This would represent upwards of $3\frac{1}{2}$ million bunches of flowers, chiefly narcissi and anemones. Rather more than 500 acres are devoted to flower-growing in the isles, by far the greater part of this area being assigned to narcissi, whilst anemones, gladioli, marguerites, arum lilies, Spanish irises, pinks, and wallflowers are cultivated on a much smaller scale. The great advantage enjoyed by the Scilly flower-growers is earliness of production, due to climatic causes; the soil, moreover, is well suited to flower culture, and there is an abundance of sunshine. The long journey to London is somewhat of a drawback, in regard to both time and freight, but the earliness of the flowers more than compensates for this. Open-air narcissi are usually ready at the beginning of January, and the supply is maintained in different varieties up to the middle or end of May. The narcissus bulbs are usually planted in October, 4 inches by 3 inches apart for the smaller sorts and 6 inches by 4 to 6 inches for the larger. A compost of farmyard manure, seaweed, earth, and road scrapings is the usual dressing, but nitrate of soda, guano, and bones are also occasionally employed. A better plan, perhaps, is to manure heavily the previous crop, frequently potatoes, no direct manuring then being needed for the bulbs, these not being left in the ground more than two or three years. The expenses of cultivation are heavy, the cost of bulbs alone—of which it requires nearly a quarter of a million of the smaller varieties, or half as many of the largest, to plant an acre—being considerable. The polyanthus varieties of narcissus are likely to continue the most remunerative to the flower-growers of Scilly, as they flourish better in these isles than on the mainland.

In the district around the Wash, in the vicinity of such towns as Wisbech, Spalding, and Boston, the industrial culture of bulbs and flowers underwent great expansion in the period between 1880 and 1900. At Wisbech one concern alone has a farm of some 900 acres, devoted chiefly to flowers and fruit, the soil being a deep fine alluvium. Roses are grown here, one field containing upwards of 100,000 trees. Nearly 20 acres are devoted to narcissi, which are grown for the bulbs and also, together with tulips, for cut flowers. Carnations are cultivated both in the field and in pots. Cut flowers are sent out in large quantities, neatly and effectively packed, the parcel post being mainly employed as a means of distribution. In the neighbourhood of Spalding crocuses and snowdrops are less extensively grown than used to be the case. On one farm, however, upwards of 20 acres are devoted to narcissi alone, whilst gladioli, lilies, and irises are grown on a smaller scale. Around Boston narcissi are also extensively grown for the market, both bulbs and cut blooms being sold. The bulbs are planted 3 inches apart in rows, the latter being 9 inches apart, and are allowed to stand from two to four years.

The imports of fresh flowers into the United Kingdom were not separately shown prior to 1900. In that year, however, their value amounted to £200,585, and in 1901 to £225,011. From the monthly totals quoted in Table VI. it would appear that the trade sinks to its minimum dimensions in the four months July to October inclusive,

Table VI.—Values of Fresh Flowers imported into the United Kingdom in each month of 1900 and 1901

Month.	1900.	1901.
January	£27,991	£26,521
February	24,888	25,525
March	34,693	45,655
April	40,256	45,848
May	22,506	22,586
June	12,245	11,433
July	2,305	2,523
August	821	1,252
September	632	478
October	3,962	4,026
November	11,671	17,173
December	18,615	21,991
Total	£200,585	£225,011

and that after September the business continually expands—excepting in February, for the shortness of which month allowance must be made—up to April, subsequent to which contraction again sets in. About one-half of the trade belongs practically to the three months of February, March, and April.

Hothouse Culture of Fruit and Flowers.

The cultivation of fruit and flowers under glass has increased enormously since about the year 1880, especially in the neighbourhood of London, where large sums of money have been sunk in the erection and equipment of hothouses. In the parish of Cheshunt, Herts, alone there are upwards of 130 acres covered with glass, and between that place on the north and London on the south extensive areas of land are similarly utilized. At Erith, Swanley, and other places in Kent, as also at Worthing, in Sussex, glass-house culture has much extended. A careful estimate puts the area of industrial hothouses in England at about 1200 acres, representing a tenfold increase within the space of thirty years. The leading products are grapes, tomatoes, and cucumbers, the last-named two being true fruits from the botanist's point of view, though commercially included with vegetables. Peaches, nectarines, and strawberries are largely grown under glass, and, in private hothouses—from which the produce is used mainly for household consumption, and which are not taken into consideration here—pineapples, figs, and other fruit. Conservative estimates indicate the average annual yield of hothouse grapes to be about 12 tons per acre, and of tomatoes 20 tons. The greater part of the space in the hothouses is assigned to fruit, but whilst some houses are devoted exclusively to flowers, in others, where fruit is the main object, flowers are forced in considerable quantities in winter and early spring. The flowers grown under glass include tulips, hyacinths, primulas, cyclamens, spiræas, mignonettes, fuchsias, calceolarias, lilies, geraniums, roses, chrysanthemums, and many others. There is an increasing demand for foliage hothouse plants, such as ferns, palms, crotons, aspidistras, and solanums. Tomatoes are grown largely in vineries and in cucumber-houses, as also in houses exclusively occupied by them, in which case two and sometimes three crops can be gathered in the year. In the Channel Islands, where potatoes grown under glass are lifted in April and May, in order to secure the high prices of the early markets, tomato seedlings are planted out from boxes into the ground as quickly as the potatoes are removed, the tomato planter working only a few rows behind the potato digger. The trade in imported tomatoes is so considerable that home growers are well justified in their endeavours to meet the demand more fully with native produce, whether raised under glass or in the open. Tomatoes were not separately enumerated in the imports previous to 1900. It has already been stated that in 1900 the raw tomatoes imported amounted to 833,032 cwt., valued at £792,339, and in 1901 to 793,991 cwt., valued at £734,051. From the monthly quantities given in Table VII., it would appear that the imports are largest

TABLE VII.—Quantities of Tomatoes imported into the United Kingdom in each month of 1900 and 1901.

Month.	1900.	1901.
	Cwt.	Cwt.
January	27,496	37,768
February	38,420	36,310
March	46,888	49,576
April	44,746	57,007
May	47,199	33,590
June	123,032	100,738
July	160,303	186,535
August	115,152	132,786
September	91,468	75,412
October	66,061	37,490
November	36,906	20,924
December	35,361	25,855
Total	833,032	793,991
Value	£792,339	£734,051

in June, July, and August, about one-half of the year's total arriving during those three months. It is too early in June and July for home-grown outdoor tomatoes to enter into competition with the imported product, but home-grown hothouse tomatoes should be qualified to challenge this trade.

Prospects of the Fruit and Flower-Growing Industries.

As regards open-air fruit-growing, the outlook for new ventures is perhaps brighter than in the hothouse industry, not—as Mr Bear has pointed out—because the area of fruit land in England is too small, but because the level of efficiency, from the selection of varieties to the packing and marketing of the produce, is very much lower in the former than in the latter branch of enterprise. In other words, whereas the practice of the majority of hothouse nurserymen is so skilled, so up-to-date, and so entirely under high pressure that a new competitor, however well trained, will find it difficult to rise above mediocrity, the converse is true of open-air fruit-growers. Many, and an increasing proportion, of the latter are thoroughly efficient in all branches of their business, and are in possession of plantations of the best market varieties of fruit, well cultivated, pruned, and otherwise managed. But the extent of fruit plantations completely up to the mark in relation to varieties and treatment of trees and bushes, and in connexion with which the packing and marketing of the produce are equally satisfactory, is small in proportion to the total fruit area of the country. Information concerning the best treatment of fruit trees has spread widely in recent years, and old plantations, as a rule, suffer from the neglect or errors of the past, however skilful their present holders may be. Although the majority of professional market fruit-growers may be well up to the standard in skill, there are numerous contributors to the fruit supply who are either ignorant of the best methods of cultivation and marketing, or careless in their application. The bad condition of the great majority of farm orchards is notorious, and many landowners, farmers, and amateur gardeners who have planted fruit on a more or less extensive scale have mismanaged their undertakings. For these reasons new growers of open-air fruit for market have opportunities of succeeding by means of superiority to the majority of those with whom they will compete, provided that they possess the requisite knowledge, energy, and capital. It has been asserted on sound authority that there is no chance of success for fruit-growers except in districts favourable as regards soil, climate, and nearness to a railway or a good market; and, even under these conditions, only for men who have had experience in the industry and are prepared to devote their unremitting attention to it. Most important is it to a beginner that he should ascertain the varieties of fruit that flourish best in his particular district. Certain kinds seem to do well or fairly well in all parts of the country; others, whilst heavy croppers in some localities, are often unsatisfactory in others.

As has been intimated, there is probably in England less room for expansion of fruit culture under glass than in the open. The large increase of glass-houses in recent years appears to have brought the supply of hothouse produce, even at greatly reduced prices, at least up to the level of the demand; and as most nurserymen continue to extend their expanse of glass, the prospect for new competitors is not a bright one. Moreover, the vast scale upon which some of the growers conduct the hothouse industry puts small producers at a great disadvantage, not only because the extensive producers can grow grapes and other fruit more economically than small growers—with the possible exception of those who do all or nearly all their own work—but also, and still more, because the former have greater advantages in transporting and marketing their fruit. There has, in recent years, been a much greater fall in the prices of hothouse than of open-air fruit, especially under the existing system of distribution, which involves the payment by consumers of 50 to 100 per cent. more in prices than growers receive. The best openings for new nurseries are probably, not where they are now to be found in large groups, and especially not in the neighbourhood of London, but in suitable spots near the great centres of population in the Midlands and the North, or big towns elsewhere not already well supplied with nurseries. By such a selection of a locality the beginner may build up a retail trade in hothouse fruit, or at least a trade with local fruiterers and grocers, thus avoiding railway charges and salesmen's commissions to a great extent, though it may often be advantageous to send certain kinds of produce to a distant market. Above all, a man who has no knowledge of the hothouse industry should avoid embarking his capital in it, trusting himself in the hands of a foreman, as experience shows that such a venture usually leads to disaster. Some years of training in different nurseries are desirable for any young man who is desirous of becoming a grower of hothouse fruit.

There can be no doubt that flower-growing is greatly extending in England, and that competition among home growers is becoming more severe. Foreign supplies of flowers have increased, but not nearly as greatly in proportion as home supplies, and it seems clear that home growers have gained ground in relation to their foreign rivals, except with respect to flowers for the growth of which foreigners have extraordinary natural advantages. There seems some danger of the home culture of the narcissus being over-done, and the chrysanthemum appears to be produced in excess of the demand. Again, in the production of violets, the warm and sunny South of France has an advantage not possessed by England, whilst Holland, likewise for climatic reasons, maintains her hold upon the hyacinth and tulip trade. Whether the production of flowers as a whole is gaining ground upon the demand or not is a difficult question to answer. It is true that the prices of flowers have fallen generally; but production, at any rate under glass, has been cheapened, and if a fair profit can be obtained, the fall in prices, without which the existing consumption of flowers would be impossible, does not necessarily imply over-production. There is some difference of opinion among growers upon this point; but nearly all agree that profits are now so small that production on a large scale is necessary to provide a fair income. Industrial flower-growing affords such a wide scope for the exercise of superior skill, industry, and alertness, that it is not surprising to find some who are engaged in it doing remarkably well to all appearance, while others are struggling on and hardly paying their way. That a man with only a little capital, starting in a small way, has many disadvantages is certain; also that his chance of saving money and extending his business quickly is much smaller than it was. To the casual looker-on, who knows nothing of the drudgery of the industry, flower-growing seems a delightful method of getting a living. That it is an entrancing pursuit there is no doubt; but it is equally true that it is a very arduous one, requiring careful forethought, ceaseless attention, and abundant energy. Fortunately for those who might be tempted, without any knowledge of the industry, to embark capital in it, flower-growing, if at all comprehensive in scope, so obviously requires a varied and extensive technical knowledge, that any one can see that a thorough training is necessary to a man who intends to adopt it as a business, especially if hothouse flowers are to be produced.

The market for fruit, and more especially for flowers, is a fickle one, and there is nearly always some uncertainty as to the course of prices. The perishable nature of soft fruit and cut flowers renders the markets very sensitive to anything in the nature of a glut, the occurrence of which is usually attended with disastrous results to producers. Foreign competition, moreover, has constantly to be faced, and it is likely to increase rather than diminish. French growers have a great advantage over the open-air cultivators of England, for the climate enables them to get their produce into the markets early in the season, when the highest prices are obtainable. The geographical advantage which France enjoys in being so near to England is likely, however, to be considerably discounted by the increasing facilities for cold storage in transit, both by rail and sea. The development of such facilities will permit of the retail sale in England of luscious fruit as fresh and attractive as when it was gathered beneath the sunny skies of California. In the case of flowers, fashion is an element not to be ignored. Flowers much in request in one season may meet with very little demand in another, and it is difficult for the producer to anticipate the changes which caprice may dictate. Even for the same kind of flower the requirements are very uncertain, and the white chrysanthemum which is all the rage in one season may be discarded in favour of chrysanthemums of another colour in the next. The sale of fresh flowers for church decoration at Easter has reached enormous dimensions. The irregularity in the date of the festival, however, causes inconvenience to growers. If it falls very early the great bulk of suitable flowers may not be sufficiently forward for sale, whilst a late Easter may find the season too far advanced. The trade in cut flowers, therefore, is generally attended by uncertainty, and often by anxiety. (W. Fr.)

Fryxell, Anders (1795–1881), Swedish historian, was born at Hesselskog, Dalsland, Sweden, on the 7th of February 1795. He was educated at Upsala, took holy orders in 1820, was made a doctor of philosophy in 1821, and in 1823 began to publish the great work of his life, the *Stories from Swedish History.* He did not bring this labour to a close until, fifty-six years later, he published the forty-sixth and crowning volume of his vast enterprise. Fryxell, as a historian, appealed to every class by the picturesqueness of his style and the breadth of his research; he had the gift of awakening to an extraordinary degree the national sense in his readers. In 1824 he published his *Swedish Grammar*, which was long without a rival. In 1833 he received the title of professor, and in 1835 he was appointed to the incumbency of Sunne, in the diocese of Karlstad, where he resided for the remainder of his life. In 1840 he was elected to the Sweden Academy in succession to the poet Wallin (1779–1839). In 1847 Fryxell received from his bishop permission to withdraw from all the services of the Church, that he might devote himself without interruption to historical investigation. Among his numerous minor writings are prominent his *Characteristics of Sweden between 1592 and 1600* (1830), his *Origins of the Inaccuracy with which the History of Sweden in Catholic Times has been Treated* (1847), and his *Contributions to the Literary History of Sweden.* It is now beginning to be seen that the abundant labours of Fryxell were rather of a popular than of a scientific order, and although their influence during his lifetime was unbounded, it is only fair to later and exacter historians to admit that they threaten to become obsolete in more than one direction. On the 21st of March 1881 Anders Fryxell died at Stockholm, and in 1884 his daughter Eva Fryxell (born 1829) published from his MS. an interesting *History of My History*, which was really a literary autobiography and displays the persistency and tirelessness of his industry. (E. G.)

Fuente Ovejuna, a town of Spain, in the province of Cordoba, on a hill near the western limits of the province, in a well-irrigated district. Population about 10,000. Cattle are largely reared in the neighbourhood, which also contains argentiferous lead mines and stone quarries. The local industries are tanning, and the manufacture of soap, flour, and preserved meat. There is trade in wheat, wine, pod-fruit, and honey. The parish church is an old palace of the Knights of Calatrava. There are several other churches—one, the Assumption, with three fine naves and altars. Many ruins still stand on the hills around the town.

Fuenterrabia, an ancient town of Spain, on the French frontier, near the Bay of Biscay. It has begun to revive from the decay into which it had fallen, having become a summer resort for people from the interior of Spain. Hotels and villas have been built in the new part of the town that has sprung up outside the picturesque walled fortress, and there is quite a contrast between the part inside the heavy, half-ruined ramparts, with its narrow, steep streets and curious gable-roofed houses, its fine old church and castle, and its massive town hall, and the new suburbs and fishermen's quarter facing the estuary of the Bidassoa. Many local industries are thriving on the outskirts of the town; rope and net manufactures, flour mills, saw mills, mining railways, paper mills. The population, which is rapidly growing, is over 5000.

Fugue, an exacting and highly organized musical form. It originated in the abundant canonic imitations of early vocal writers, advanced with the growth of instrumental music (chiefly at the hands of famous organists) during the 17th century, and reached a perfection in the works of Bach (1685–1750) which no subsequent writer has surpassed. Fugue is written for two or more parts, and may be vocal or instrumental. Its chief characteristic lies in the equal interest of all its voices. In other great forms—*symphony*, *sonata*, and notably *song*—one voice is usually important while others are subservient, but in fugue all are equally important; and since average listeners only attend with ease to one prominent part, commonly called the tune, fugue is associated with erudition and mental effort, and often dissociated from emotional power, which, however, it can possess to a stupendous degree. Fugue is akin to Canon (see MUSIC, *Ency. Brit.*, vol. xvii. p. 82); Albrechtsberger—Beethoven's master, and an authority—even defines canon as "a kind of fugue." But fugue, inferior in its first loose forms, gradually gained upon the older form in artifice and restraint, and far surpassed it in freedom, magnitude, and expressiveness.

The chief parts of a fugue are:—*Exposition*, which begins with the entry of the subject and ends when all the voices have stated it; *Counter-exposition* (optional), in which the subject is sometimes restated, somewhat differently, but without further modulation; *Episode*, of which several are possible in one fugue, and in which (under a rather misleading name) fragments of the subject or subsidiary subjects are developed to afford both contrast and illumination; *Stretto*, in which interest is heightened by such rapid recurrences of the subject that the successive statements overlap; *Stretto maestrale*, a rare and difficult stretto, in which all voices, entering closely, still preserve the subject unaltered; and *Pedal*, in which the dominant or other note is persistently held through intricate melodic or harmonic devices. (For origin, see Faburden in MUSIC, vol. xvii. p. 81). Such a note, acting as guide to the mind, justifies the greatest complexities while it establishes key; hence its place of importance near the end of a fugue. Other devices common to both fugue and canon are:—*Augmentation*, the doubling in duration of every note in the subject; *diminution*, the reverse process; *inversion*, in which the direction—up or down—of each interval in the subject is reversed. These devices together give endless, even bewildering, varieties of treatment.

The first statement of the theme is technically the *subject;* the second is called *answer*, and is either an exact or modified transposition of the subject into the dominant key. Strict rules (to preserve a perfect tonic and dominant balance) govern this point, and a fugue is styled *real* or *tonal* accordingly. The melody which accompanies the answer is called *counter-subject;* theoretically important, it is sometimes ignored; and a real secondary or companion subject appears later to usurp its place. When the counter-subject is actually sounded with the subject itself, and acquires equal importance, the fugue is called a *double fugue*, or *fugue with two subjects.* In a most effective variety of double fugue, two subjects receive separate expositions, to be ultimately combined.

The historic connexion of fugue with the development of harmonic resource is shown with striking clearness in the greatest collection of fugues, known as Bach's "Forty-eight" (*Wohltemperirte Klavier*). These were written to establish equal right of existence for all keys. This fact and the one-fold nature of fugue form caused Bach, with his unerring instinct and great power, to organize and widen the key kingdom of each degree of the scale. He did this so well that his successors, in developing the superior forms of sonata and symphony, found their key heritage too rich; and only in recent times have composers risen, and that with difficulty, to the intellectual height of the simpler form, perfected nearly two centuries ago. (H. W. D.)

Fukui, a town in the province of Echizen, Nippon, Japan, near the west coast, some miles north by east of Wakasa Bay. It lies in a volcanic district much exposed to earthquakes, and suffered severely during the disturbances of 1891–92, when a chasm over 40 miles long was opened across the Neo valley from Fukui to Katabira. But Fukui has since revived, and is now in a flourishing condition, with several local industries, and a population which increased from 37,000 in 1884 to 42,000 in 1898.

Fukuoka, a town on the north-west coast of the island of Kiushiu, Japan, about 60 miles north by east of Nagasaki. With Hakata, on the opposite side of a small coast stream, it forms a large centre of population, with an increasing export trade and several local industries. Of these the most important is silk-weaving, and Hakata especially is noted for its durable silk fabrics. Fukuoka was formerly the residence of the powerful daimio of Chikuzen, and played a conspicuous part in the mediæval history of Japan; the renowned temple of Yeiyas in the district was destroyed by fire during the revolution of 1868. Population (1892), 55,000; (1898), 66,000. There are several other places of this name in Japan, the most important being FUKUOKA in the province of Mutsu, North Nippon, a railway station on the main line from Tôkyô to Aimori Ura Bay. Population (1900) about 5000.

Fulahs. See NIGERIA.

Fulda, a town and episcopal see of Prussia, province Hesse-Nassau, situated between the Rhön and the Vogel mountains, 69 miles by rail north-east from Frankfort-on-Main. The present cathedral dates from 1704–12, and stands on the site of the former abbey churches, for the first three were all burnt (in 937, 1286, and 1398), and the fourth was pulled down to make room for the existing structure. The interior, which was restored in 1895–96, contains the tomb of St Boniface, the Apostle of the Frisians, and a statue of Charlemagne. The former Benedictine monastery is now used as a theological seminary. The former episcopal palace was built in 1710–13, and now serves municipal purposes. There are several interesting churches, including the round church of St Michael's (822, restored in 1853); the parish church (1770–75), and the church of St Severus (15th century, restored in 1899). Amongst the secular buildings and institutions may be mentioned the library, the episcopal residence, town hall, post office, museum of antiquities, house of the Sisters of Mercy (1884), and monument of the war of 1870–71. There are a couple of seminaries and a school of military music. The town, as distinguished from the abbey, dates from 1208. It is a stronghold of the Ultramontane movement in Germany. Population (1885), 12,284; (1900), 16,903.

Fulham, a metropolitan borough in the county of London, Middlesex, situated on the Thames, 5½ miles south-west of St Paul's, and opposite Putney, with which it is connected by a stone bridge of five arches in place of the old bridge closed in 1886. The new bridge was erected on the site of the aqueduct of the Chelsea Waterworks Company between the years 1882 and 1886. Water mains are laid under the footways of the new bridge to obviate the necessity for a separate aqueduct. Fulham and Hammersmith formed one parish down to 1834, in which year the hamlet of Hammersmith was created a district and separate parish. The streets of Fulham have been largely rebuilt, and the market gardens and open spaces, for which the place was once famous, have been mostly built upon. There is no record of the first erection of a parish church, but the first known rector was appointed in 1242, and probably a church existed a century before this. The earliest portion of the church, which was demolished in 1880–81, did not date farther back than the 15th century. The new church, built from the designs of the late Sir Arthur Blomfield, was consecrated in 1881. The fine old monuments have been preserved and placed in the new church. The Manor House or Fulham Palace is the oldest building in the parish, but much of it has been rebuilt at various times. The oldest portion of the building is the western quadrangle, built by Bishop Fitzjames (1506–22). The Manor of Fulham is said to have been given to Bishop Erkenwald about the year 691 for himself and his successors in the see of London, and Holinshed relates that the bishop of London was lodging in his manor place in 1141, when Geoffrey de Mandeville, riding out from the Tower, took him prisoner. The parliamentary division of Fulham is conterminous with the metropolitan borough. Population (1881), 42,900; (1891), 91,790; (1901), 137,289. An exhaustive history of the parish by C. J. Fèret was published in 1900, entitled *Fulham, Old and New* (3 vols. 4to).

Fulton, capital of Callaway county, Missouri, U.S.A., in 38° 51′ N. and 91° 56′ W., on the Chicago and Alton Railroad. Its site is hilly and its plan somewhat irregular. It has an excellent water-supply from deep wells. Westminster College, situated here, is a Presbyterian institution, founded in 1853. In 1899 it had 10 instructors and 99 students. The Synodical Female College, founded in 1872, is of the same denomination, and had, in 1899, 11 instructors and 104 students. Population (1880), 2409; (1890), 4314; (1900), 4883, of whom 244 were foreign-born and 1167 negroes.

Fumay, a town in the arrondissement of Rocroi, department of Ardennes, France, north of Mézières by rail, on the river Meuse. There are valuable subterranean slate workings, whence slate was quarried as early as the 12th century. The blocks detached are of immense size, 50 to 80 feet and even more in length, and 3 to 6 feet in thickness. They are afterwards cut up into sizes suitable for roofings. There are also important engineering works and forges, one establishment employing 300 workmen. Population (1891), 4869; (1901), 5667.

Functions, Analytic.—Roughly speaking, the first principles of the theory of analytical functions may be developed either after Cauchy or after Weierstrass. The present article attempts to show the character and applications of the latter or strictly elementary theory. To this end space is saved by the omission of details in regard to which information is easily accessible in the English authorities cited on p. 544.

Every variable which enters is capable of the complex form $\xi + i\eta$, where ξ and η are real and $i = \sqrt{-1}$, and can be represented by a point whose rectangular cartesian co-ordinates are ξ and η; the positive square root $(\xi^2 + \eta^2)^{\frac{1}{2}}$ is called the modulus or absolute value of the quantity, and often written $|\xi + i\eta|$; denoting it by r, the angle determined by $\xi = r\cos\theta$, $\eta = r\sin\theta$ is called the phase or argument of the quantity, and, without further convention, is ambiguous by additive integral multiples of 2π. A series of positive integral powers of a complex quantity x, shortly called a power series, which converges for a value c of x, converges both absolutely and uniformly for all values of x whose modulus is less than $|c|$; the region within which the series is intelligible is, therefore, that which is interior to a certain circle, called the circle of convergence; within this circle the series can be differentiated any finite number of times, two series can be multiplied together, &c. If M be a real quantity not exceeded by the modulus of the sum of the series for any value of x whose modulus $|x| = r$ is less than the radius of convergence, the coefficient a_m of the term $a_m x^m$ of the series is in absolute value less than or equal to Mr^{-m}. The series may vanish to order r at $x = 0$, in which case the lowest power of x which enters is x^r; but every other point for which the series vanishes must be at a finite distance from $x = 0$. Thus if two power series in x are equal to one another for an infinite number of values of x lying near $x = 0$, and having this as their *point of condensation*, or *limiting point*, they must agree term by term; this is the so-called principle of indeterminate coefficients. A power series may have an infinite number of zeros, that is, points for which it vanishes, lying within its circle of convergence, but the point of condensation of these zeros cannot lie actually within the circumference of convergence; and any two of its zeros are at finite distance from one another. If $f_i(x)$ be one of an infinite number of series of positive and negative integral powers of x, all convergent for $r < |x| < R$, and the sum $\sum_{i=1}^{\infty} f_i(x)$ be, for $|x| = c$, where $r < c < R$, uniformly convergent in regard to the phase of x, then this sum can be legitimately arranged according to powers of x, the coefficient of any power being the sum of the infinite number of corresponding coefficients in the various series $f_i(x)$. This last result may be called Weierstrass's double series theorem, and compared with the following: if for $i = 1, 2, \ldots \infty$, the infinite series $\sum_{j=1}^{\infty} u_{ij}$ be absolutely convergent, the sum of the moduli of its terms being U_i, and if the sum $\sum_{i=1}^{\infty} U_i$ be convergent, then each of the series $\sum_{i=1}^{\infty} u_{ik}$ is convergent, and their sum $\sum_{k=1}^{\infty}\sum_{i=1}^{\infty} u_{ik}$ is the same as $\sum_{i=1}^{\infty}\sum_{k=1}^{\infty} u_{ik}$. When a real quantity can assume values exceeding by as little as desired a specified value K, but cannot be less than K, we speak of K as the *lower outside value*, or *limiting value*, of the quantity; then a real continuous quantity necessarily arrives actually at its lower outside value, as well as its upper outside value. This fact requires mention; it can be applied, for instance, to show that if an infinite series of rational functions of x converge uniformly in the neighbourhood of every point of a finite and connected region, then it converges uniformly over the whole of that region, namely, the least number of terms which must be suppressed that the absolute value of those following may be less than an assigned ϵ can be taken to be the same for the whole region.

Notion of a Monogenic Analytic Function.—Denote by $f(x)$ the value represented within its circle of convergence C, whose centre is c, by a power series $\Sigma a_m(x-a)^m$; let R be the radius of the circle, and c_1 a point within the circle at distance D from its centre c. A circle Γ, of radius R–D, described with c_1 as centre will lie entirely within C, except at the point of contact. For values of x within Γ the series $f(x)$ can be rearranged in powers of $x - c_1$, and will take the form $f_1(x) = \sum_{n=0}^{\infty} \frac{(x-c_1)^n}{n!} f^{(n)}(c_1)$, where $f^{(n)}(c_1)$ is the value at c_1 of the nth differential coefficient of $f(x)$. The possibility of this rearrangement, namely, the fact that within Γ the series $f_1(x)$ is equal to $f(x)$, follows from Weierstrass's double series theorem. Two alternatives are now possible—either the radius of the circle of convergence C_1 of the series $f_1(x)$ is precisely R–D, or it is greater than R–D. Suppose that it is greater. Then it can be shown that for *all* points of C_1 which lie within C, including those points which lie outside Γ, the value represented by $f_1(x)$ is equal to that represented by $f(x)$. In this case we say that the value represented by $f_1(x)$ for points outside C, or upon the circumference of C, is a *continuation* of $f(x)$. It can then be shown, in part justification of this definition, that if, with a point c_2 internal to C, as centre, we similarly construct a series $f_2(x)$, in $x - c_2$, with a circle of convergence C_2 extending beyond C, and these two circles C_1, C_2 have a common region both within and without C, then the values $f_1(x), f_2(x)$ agree in the common region of C_1 and C_2 lying outside C. It is clear that having once *continued* the function $f(x)$ beyond the circle C, it may be possible to continue it beyond the circle C_1, the series $f_1(x)$ being used as basis. We may then at once make the statement: *It is the aggregate of all such possible continuations which we regard as constituting a monogenic analytical function;* the word *monogenic* having reference to the fact that the various series, in $x-c$, $x-c_1$, $x-c_{11}$,..., which represent the function in different parts of the plane, have a single origin, namely, the series $f(x)$, and *all the properties of the function being virtually contained in this one series;* the word *analytical* having reference to the possibility of obtaining the value of the function in all the region of its existence by the well-defined analytical operation of summing a power series. But the statement is not yet complete. It is convenient to regard all the points of the plane for which x is of infinite modulus, which are all given by the single equation $x^{-1}=0$, as constituting one point, and to regard a series of ascending positive integral powers of x^{-1} as similar to a power series in a quantity $x-c$. Such a series will have a region of convergence given by an equation $|x^{-1}|<R$, consisting therefore of points lying *outside* a circle of finite radius whose centre is the point $x=0$; and such a series may represent a continuation of a function given by a power series in $x-c$ when the regions of the two series have a common part at every point of which the values represented by them agree. *The previous statement of what is meant by a monogenic analytic function requires then to be completed by the convention that by a derived series in* $x-a$, *when* a *is infinite, shall be understood a series of positive integral ascending powers of* x^{-1}. In general it will be sufficient to speak of a function, or of an analytic function, the monogenic character being understood. It is obvious, however, that the definition can in the first instance be accepted only as a limitation of the class of functions to be investigated and not as an analysis of the word function as commonly used to cover any sort of numerical dependence. As a fact it is in the establishment of the confidence that the limitation is not too narrow for practical applications that the development of the later theory marks so great an advance. But the reader should consult the earlier parts of Lagrange's *Théorie des Fonctions Analytiques*, and *Leçons sur le Calcul des Fonctions* (1806).

We return, however, to further consideration of the series $f(x)$, in $x-c$, with circle of convergence C. When we rewrite this series in the form $f_1(x)$, in powers of $(x-c_1)$, it is not possible that for every point c_1, interior to C, the circle of convergence, C_1, of $f_1(x)$, should extend beyond the circle C. If for all points a_1 interior to a circle H within which a series $\phi(x)$, in $x-a$, converges, the lower outside value of the radii of convergence of the derived series $\phi_1(x)$ in $x-a_1$ be a finite quantity D other than zero, then the true radius of convergence of the series $\phi(x)$ can be shown to be greater by D than the radius of the circle H. Hence it follows that there is at least one point upon the circumference of the circle of convergence C of the series $f(x)$ *such that as* c_1 *is taken nearer and nearer to this point the radius of convergence of the derived series* $f_1(x)$, *in* $x-c_1$, *approaches indefinitely to zero.* Such a point is called a *singular* point of the function under consideration; *at* it the function, strictly speaking, is undefined. It may happen that such a singular point is found in every arc of the circumference of convergence, however small the arc. An example is given by either of the series $\sum_{n=1}^{\infty} x^{u_n}$, where $u_n=n!$, or $u_n=n^2$. In such a case the function, so to say, *dies out* on the circumference, and, as a *monogenic* function, cannot be continued over the circumference. But in the more common case, when the original circumference of convergence is not the complete boundary of the region of existence of the function, it is still true that this region has a boundary, that is, cannot consist of all points of the plane (the point $x^{-1}=0$ being counted in, as explained above). For if there be an assignable radius for the circle of convergence of a power series there is, as remarked above, necessarily one singular point upon its circumference; while if the radius of convergence is unlimited it is still true that the point $x^{-1}=0$ cannot be regarded as lying within the circle, since this would involve the obvious impossibility of identity in value, for $x=\infty$, of a power series in x^{-1} with a power series in a quantity $x-c$, wherein c is finite. Thus the singular points of a function constitute the boundary of its region of existence. We consider the possible character of these singular points to some further extent in the next paragraph; in regard to the continuation and the monogenic character of a function the further remarks may be added here. Any rational relation connecting the values of power series, which have a common region of convergence, also connects the values of the series formed by any possible continuation of these series, and therefore may be regarded as a relation connecting the monogenic functions to which they give rise; a series which is not a power series may represent, for different regions, different monogenic functions, as is shown, for instance, by the series $\sum_{n=1}^{\infty}(x^{2n}-x^{-2n})^{-1}$, which for $|x|<1$ represents $x(x-x^{-1})^{-1}$, and for $|x|>1$ represents $x^{-1}(x-x^{-1})^{-1}$.

Single-valued Functions.—It follows from the definition of singular points which has been given, that if a power series be continued from a point A to a point B by two different paths enclosing a region containing no singular points, the values thus obtained at B will be the same. A function which by all continuations within a certain region always takes the same value at any point, is called single-valued in that region; for instance the series $\sum_{n=1}^{\infty}\frac{x^n}{n}$ gives a single-valued function in any closed region which does not surround either of the points $x=1$, $x^{-1}=0$. We consider now briefly functions which are single-valued in the whole plane of x. For such a function $f(x)$ we divide the singular points into two categories: firstly, those which are not singular points of the inverse $1/f(x)$, which we call *poles;* secondly, those which are singular points of $1/f(x)$, which we call *essential singularities.* By the definition of a singular point, every point which is not singular is the centre of a circle of finite, though possibly very small radius, within which there is no singular point; hence if $x=c$ be a pole, $1/f(x)$ must be capable of being represented near this point by a power series in $x-c$, necessarily of the form $(x-c)^m\phi$, where ϕ is a power series in $x-c$ which does not vanish for $x=c$; thus $(x-c)^m f(x)$ must, near $x=c$, be capable of being represented by a power series in $x-c$ not vanishing for $x=c$. The positive integer m is >0 since otherwise $x=c$ would not be a singular point; thus as we approach a pole, by whatever path, the function always increases indefinitely in absolute value, so that no ambiguity would arise by agreeing to consider the function as having the definite value infinity at the pole; moreover, the pole can be made the centre of a circle of finite, if small, radius, within which the function has no other singular point; so that also, in cases where the boundary of the region of existence of the function contains a curve upon every arc of which, however small, there are singular points, no pole of the function can be upon this curve. For such reasons the pole is also called an *unessential* singularity. Replacing $x-c$ by x^{-1} similar remarks apply to the consideration of the case in which $x^{-1}=0$ is a pole. The category of essential singularities, on the other hand, includes very various possibilities. In all cases, if A be a finite constant, the essential singularity c of the function $f(x)$ is easily seen to be an essential singularity both of $f(x)-\mathrm{A}$ and of $1/f(x)$. If it be possible to make c the centre of a circle of not zero radius, within which c is the only singularity of $f(x)$, then within this circle, except at c, the function can be represented as a series $\sum_{n=-\infty}^{\infty} a_n(x-c)^n$, wherein the number of negative terms is infinite (see below, *Laurent's* theorem), and the coefficient a_{-m} is in absolute value less than $\mathrm{M}\,|(x-c)^m|$, where M is the greatest modulus of the function for the value of $|x-c|$. Thence it follows that the function increases indefinitely as x approaches c by a suitable path. If every circle whose centre is c, however small, contains poles of $f(x)$, but no other singularities, the same conclusion follows. In either case c is an essential singularity of the function $1/[f(x)-\mathrm{A}]$, and is the centre of a circle within which no other essential singularities of this function are found; thus this function increases indefinitely as we approach c by a suitable path, and therefore the function $f(x)$ approaches indefinitely to the arbitrary value A as we approach c by a suitable path. Both results may be included in the statement that near an essential singularity which is isolated from other essential singularities, points can be found at which the function differs as little as desired from any assigned value, or is greater than any assigned value. In fact it can be proved that there are in general points near $x=c$, at which the function is actually equal to any assigned value, two values, at most, being excepted. For instance, the function $e^{\frac{1}{x-c}}$ approaches as near as we please to any assigned value for values of x near c, and becomes equal to any assigned value other than the two 0 and ∞. But when the essential singularity is not finitely distant from other essential singularities, as for instance is the case of the essential singularities of the function $\sum_{n=1}^{\infty} x^{n^2}$, the matter is still more difficult. Thus the function $x+\sum_{n=1}^{\infty} x^{a^n+2}/(a^n+1)(a^n+2)$, where a is a positive integer greater than unity, has essential singularities in every arc of the circle $|x|=1$, however small, though the series converges for every point on this circle.

A function whose only singularities are poles is easily proved to be a rational function; if it have one or more essential singularities it is called *transcendental;* a function which has no singularity for finite values of x is called an *integral* function, and can then be either rational or transcendental. For a rational integral function $f(x)$ a finite R can be assigned, such that for every $|x|>\mathrm{R}$, the function is in absolute value greater than an assigned value M; thus $f(x)$ must vanish for finite values of x, since otherwise $1/f(x)$ can easily be shown to be also a rational integral function, whereas in fact $1/f(x)$ diminishes indefinitely as $|x|$ increases sufficiently. For a transcendental integral function there are, as follows from the remarks above, points among those for which $|x|$ is greater than an assigned R, at which the function differs as little as desired from any assigned value, or is greater than any assigned value.

Existence and Methods of Representation of Single-valued Functions of given Description.—As soon as any considerable number of descriptive properties of single-valued monogenic analytic functions have been deduced, the question naturally arises how far such properties suffice to identify the functions; with which is connected the further question of obtaining representations having a more extended validity than usually possessed by a power series. We mention the following theorems (1) *Laurent's Theorem.*—If the annular region between the circles $|x-c|=r$, $|x-c|=\mathrm{R}$ lie entirely within the region of existence of a (single-valued monogenic analytic) function, there exists a series, $\sum_{n=-\infty}^{\infty} \mathrm{A}_n(x-c)^n$, valid, and giving the value of the function, for all the points of this region. By definition the function is *developable* (or *holomorphic*), that is, of the form $\sum_{n=0}^{\infty} \mathrm{B}_n(x-a)^n$, about every point a in its region of existence. (2) *Weierstrass's Factor Theorem.*—If $a_1, a_2, a_3,\dots$ be an enumerable aggregate of points with $x=\infty$ as point of condensation, there exists an integral function vanishing to the first order in these and only these points, and expressible by the infinite product $\prod_{n=1}^{\infty}\left[\left(1-\frac{x}{a_n}\right)e^{\phi_n}\right]$, where ϕ_n is a polynomial consisting of a number, at most n, but often fewer, of terms of the series $\frac{x}{a_n}+\frac{x^2}{2a^2_n}+\frac{x^3}{3a^3_n}+\dots$ Conversely an integral function vanishing in $a_1, a_2,\dots$ can be expressed in the form $e^{\phi}\prod_{n=1}^{\infty}\left[\left(1-\frac{x}{a_n}\right)e^{\phi_n}\right]^{r_n}$, where r_n is a positive integer and ϕ is an integral function. Familiar examples are the gamma function $1/\Gamma(1+x)=e^{Cx}\prod_{n=1}^{\infty}\left[\left(1+\frac{x}{n}\right)e^{-\frac{x}{n}}\right]$ and the elliptic sigma function (see below, Elliptic Functions) $\sigma(u)=u\prod\left[\left(1-\frac{u}{\Omega}\right)e^{\frac{u}{\Omega}+\frac{u^2}{2\Omega^2}}\right]$, where $\Omega=2mw+2m'w'$, and the product extends to all integral values of m and m' other than the one combination $m=m'=0$. It is necessary that w'/w should not be real. (3) *Mittag-Leffler's Theorem.*—If $a_1, a_2, a_3,\dots$ be an enumerable aggregate of points with $x=\infty$ as point of condensation, and $f_1(x), f_2(x), f_3(x),\dots$ be a corresponding set of rational functions of which $f_n(x)$ is infinite only at a_n, and, when n is finite, vanishes for $x=\infty$, it is possible to construct a function $\mathsf{F}(x)$ infinite only at $a_1, a_2, a_3,\dots$ and such that in the neighbourhood of a_n the difference $\mathsf{F}(x)-f_n(x)$ remains finite. And a generalization can be made to the case when the functions $f_1(x), f_2(x),\dots$ are not rational, and the point of condensation of the points $a_1, a_2,\dots$ is not at infinity. A familiar example is furnished by the trigonometrical function cot $x\pi$ for which the points $a_1, a_2,\dots$ are the points $x=m$, and the functions $f_1(x), f_2(x),\dots$ are of the form $(x-m)^{-1}+m^{-1}$, where m is a positive or negative integer. (4) The consideration of methods of representation by means of an infinite series of polynomials is too large for the present occasion; Runge has proved that given any connected region, a function can be constructed having this as its region of existence; more recently Mittag-Leffler has announced a method of representing a given function over the whole of its region of existence by means of a single series. *Miscellaneous.*—From many general results that must be omitted here, the following may be selected for bare reference: (1) The theorem of Picard as to the values assumed, in its whole region of existence, by a single-valued integral function, or as to the values actually assumed by a function near an isolated essential singularity (see below under *Elliptic Functions*). (2) The investigations of Darboux, Poincaré, Hadamard, Fabry, Borel, and others, as to the positions of the zero and singular points of a function whose value is to be determined from one given Taylor expansion. (3) The theorem of Poincaré as to the possibility of representing any multiple-valued analytic function by means of single-valued functions.

Algebraic Functions.—Having explained the notion of a monogenic analytical function, and considered its fundamental properties, it becomes proper to inquire as to the scope of the notion. The most natural ways in which a function can enter are perhaps as defined by algebraic equations and as defined by differential equations. Of these the latter belong to another article (DIFFERENTIAL EQUATIONS). Here we consider briefly the properties that arise when y is determined from x by an equation $f(y, x)=0$, wherein f denotes a polynomial rational and integral in both x and y, which is incapable of being written as a product of other polynomials of the same rational form. It can be shown that in the neighbourhood of any finite value of x, say $x=a$, exception being made (1) of those for which the coefficient of the highest power of y in $f(y, x)$ vanishes, (2) of those for which the equations $f(y, x)=0$, $\frac{\delta f}{\delta y}=0$ are consistent, every value of y for which $f(y, x)=0$ is expressible by a power series in $x-a$. But in order to meet the case of all values of x it is desirable to proceed in the first instance somewhat differently. It can be shown that if a, b, be any finite values of x, y for which $f(b, a)=0$, all corresponding values of x, y which satisfy the equation $f(y, x)=0$, and are sufficiently nearly equal to a, b, can be expressed by a pair of power series in a parameter t of the form $x=a+P(t)$, $y=b+Q(t)$, or by a finite number of such pairs, where $P(t)$, $Q(t)$ vanish for $t=0$, the series being such as to give only one value of t within the region of convergence corresponding to specified values of x and y; and that this is equally true for all infinite values of x or y, or both, which arise by a limiting process as satisfying the equation $f(y, x)=0$, provided only it be understood that in such a case $x-a$ or $y-b$ or both shall be replaced respectively by x^{-1} and y^{-1}. And further, if such a pair of simultaneous series be called an *element*, that only a finite number of elements is necessary to exhaust all simultaneous values of x, y satisfying the equation $f(y, x)=0$, *while every element may be regarded as derived from any one element by a succession of continuations expressed by equations of the form* $t=c+c_1\tau+c_2\tau^2+\ldots$, whereby the so-called infinitesimal t of one element is (reversibly) related to the infinitesimal τ of a derived element. The values of x, y which arise by putting $t=0$ in an element, constitute what may be called the centre of the element; but, inasmuch as there may be several different elements which have the same centre, it is desirable not to consider the centre apart from the element with which it arises. So considered the centre is called a place. The aggregate of all such places constitutes a *monogenic algebraic construct* (or *configuration*, or *surface*). This is then to be regarded as a generalization of the infinite plane considered in dealing with functions of a single variable x, and we are to consider functions which are single-valued upon this construct. The notion of monogenic construct is wider than that of a monogenic function, by the inclusion of the exceptional values of x and y referred to above; it appears from what has been stated that y is a multiple-valued monogenic function of x, whose region of existence is bounded by the exceptional values of x. An analytic function upon the construct is one whose value for the neighbourhood of any values of x, y which belong thereto and to the region of existence of the function, is given by a power series in the infinitesimal t; a pole of such a function requires a series of integral powers of t, in which the number of negative powers is finite. Then a single-valued analytic function, whose only singularities are poles, can be shown to be expressible as a rational function of x and y; while conversely a rational function (of x and y) is clearly a single-valued analytic function upon the construct having as singularities only poles. When such a function R has a pole for $x=a$, $y=b$, and r is the smallest possible integer for which t^rR is finite, t being the infinitesimal at (a, b), then R is said to become infinite to order r; similarly if R be equal to C at $x=a$, $y=b$, and r is the greatest positive integer for which $(R-C)\,t^{-r}$ is finite, then R is said to become r times equal to C. With this language we have the theorem that R becomes equal to every assignable value, finite or infinite, and this the same number of times for every value. This number is called the *order* of R. There is a lower limit to the number of poles of arbitrary position, for which there exists a rational function infinite to the first order at each; if this number be $p+1$, the number p is called the *class* of the algebraic construct, and is of fundamental importance in the developments, ramifying into all branches of mathematics, of the theory of an algebraic construct. Historically these developments centre round the theorem of integral calculus known as *Abel's theorem.* If, for the algebraic construct, R be a rational function, the integral $\int R dx$ can, in general, be evaluated in terms of algebraic and logarithmic functions only when the algebraic construct is of class zero, in which case x and y can be expressed as rational functions of a single parameter. When the construct is of class unity the integral can be expressed in terms of elliptic functions (see below). In general we have, however, this theorem; let $x_1, x_2, \ldots x_k$ denote the places where any other rational function than R, say Z, vanishes and $c_1, \ldots c_k$ the places where Z is infinite, to the first order; then the sum of k like integrals, $\sum_{r=1}^{k}\int_{c_r}^{x_r} R dx$, has a calculable value which we express by $\left[\left(R\frac{dx}{dt}\right)\log Z\right]_{t^{-1}}$, where the meaning is that in the neighbourhood of any place where the integral $\int R dx$ becomes infinite we are to substitute for x, y in $R\frac{dx}{dt}\log Z$ their values in terms of the infinitesimal t at the place and determine, in the expansion in ascending powers of t, the coefficient of t^{-1}, and then form the sum of all these coefficients, the number of which is always finite. This theorem can be proved by means of the following lemma: if K be any rational function on the construct the sum of the coefficients of t^{-1} in the various expansions of $K\frac{dx}{dt}$ at the places where the integral $\int K dx$ becomes infinite, is zero; this lemma we may express by $\left[K\frac{dx}{dt}\right]_{t^{-1}}=0$; it is easily deduced from the corresponding theorem for rational functions of one variable. Abel's theorem leads to the study of single-valued analytic functions of several variables with systems of simultaneous periods, which, apart from their intrinsic interest, are of importance as affording clues for the elucidation of the many initial difficulties presenting themselves in regard to functions of more than one variable. On the other hand, the attempt to resolve an algebraical construct, whose class is greater than unity, in terms of single-valued functions of one variable, leads to the discussion of certain functions, with an infinite number of essential singularities, which are unaltered by a set of linear substitutions of the variable forming an infinite discontinuous group. Of such developments, already of vast extent, only the barest mention can be made here.

Elliptic Functions.—If w, w' be two fixed quantities whose ratio is not real, $\Omega=2mw+2m'w'$, it can be shown that the doubly infinite sum $u^{-2}+\Sigma[(u+\Omega)^{-2}-\Omega^{-2}]$, extending to all positive and negative integer values of m and m' other than the one pair $m=m'=0$, is both absolutely and uniformly convergent for all finite values of u other than the values $u=-\Omega$, and represents a single-valued monogenic analytical function; it is generally denoted by $p(u)$. It is *doubly periodic*, satisfying the equations $p(u+2w)=pu$, $p(u+2w')=pu$, and therefore also the equations $p(u+2mw+2m'w')=p(u)$. Thus all the values of which it is susceptible arise for values of u expressed by $u=2xw+2x'w'$, wherein x, x' are real quantities such that $0 \leqslant x<1$, $0 \leqslant x'<1$. Within this range of values, constituting what is known as the parallelogram of periods, the function has no singular point save the pole of the second order at $u=0$, and it takes every assignable value for just two values of u (which may coincide). It is therefore said to be a doubly periodic function of the second order, its differential coefficient, $p'(u)$, whose square is equal to $4[pu-pw][pu-pw'][pu+pw+pw']$, being of the third order. As a rational function of these two functions, $pu, p'u$, every single-valued analytic function of u, having the periods $2w, 2w'$ and having no other singularities than poles, can be represented. In particular $p(u+v)$ can be represented rationally by $pu, pv, p'u, p'v$. Moreover, every single-valued analytic function of u which is periodic, is necessarily either singly periodic, and can then be represented by trigonometric functions, or is doubly periodic. The function pu is the negative of the second differential coefficient of the logarithm of the integral function $\sigma(u)$ which is given by the doubly infinite product $\sigma(u)=u\,\Pi'\left[\left((1-\frac{u}{\Omega}\right)e^{\frac{u}{\Omega}+\frac{u^2}{2\Omega^2}}\right]$, where Ω has the same meaning as before; this function is not periodic, but satisfies such equations as $\sigma(u+2w)=-e^{2\eta(u+w)}\sigma(u)$, $\sigma(u+2w')=e^{-2\eta'(u+w')}\sigma(u)$, where η, η' are constants such that $\eta w'-\eta' w=\frac{i\pi}{2}$ or $-\frac{i\pi}{2}$, according as the real part of $\frac{w'}{iw}$ is positive or negative; we have, in fact, for all values of u and v, the relation $\sigma^2(u)\sigma^2(v)[p(v)-p(u)]=\sigma(u+v)\sigma(u-v)$; this relation shows, moreover, that each of the functions $p(u)-p(w)$, $p(u)-p(w')$, $p(u)-p(w+w')$, is the square of a single-valued function, as also appears from the fact that each has a double pole, at $u=0$, and each a double zero, respectively at $u=w$, $u=w'$, $u=w+w'$. It is as the ratio of the square roots of these functions that the Jacobi elliptic functions, *snu, cnu, dnu*, most naturally arise. But, taking for instance $\phi(u)=\sqrt{pu-pw}$, the sign for all values of u being given by the prescription that the sign for small real positive values of u shall be positive, this function satisfies the equations $\phi(u+2w)=\phi(u)$, $\phi(u+2w')=-\phi(u)$, and has the periods $2w$ and $4w'$; it can therefore be rationally expressed by the functions $p_1(u), p'_1(u)$, formed from the periods $2w, 4w'$ as pu, pu' were formed from $2w, 2w'$; in fact it is equal to $\frac{1}{2}p'_1(u)\div[p_1(2w')-p_1(u)]$. The function pu is easily seen, from the series which represents it, to be unaltered if $2w, 2w'$ be replaced by $2\omega=2pw+2p'w'$, $2\omega'=2qw+2q'w'$, where p, q, p', q' are any integers for which $pq'-p'q=\pm 1$; it is, moreover, a homogeneous function of degree -2 in the three quantities u, w, w'; more generally if $2\omega=2pw+2p'w'$, $2\omega'=2qw+2q'w'$, where p, q, p', q' are integers such that $pq'-p'q=r$, and $p_1(u)$ denote the function formed with $2\omega, 2\omega'$ as periods, we have pu equal to the sum of $p_1(u)$ and $r-1$ terms of the form $p_1\left(u+\frac{2\omega k+2\omega' k'}{r}\right)-p_1\left(\frac{2\omega k+2\omega' k'}{r}\right)$, where k, k' are integers for which $pk+qk'$ and $p'k+q'k'$ are divisible by r. It can be proved that every pair of formulæ $2\omega=2pw+2p'w'$, $2\omega'=2qw+2q'\omega'$, in which p, q, p', q' are such integers that $pq'-p'q=1$ can be derived by repetition of the two pairs given by $(\omega=-w', \omega'=w)$, $(\omega=w, \omega'=w+w')$; these give respectively $-p\omega'/p\omega=-pw/pw'$, and $-p\omega'/p\omega=1+pw'/pw$; or, if $h=-pw'/pw$, they change h respectively into $1/h$ and $1-h$; thus by all substitutions $2\omega=2pw+2p'w'$, $2\omega'=2qw+2qw'$, in which $pq'-p'q=1$, the function h can only take the six values $h, 1/h, 1-h, 1/(1-h)$, $h/(h-1)$, $(h-1)/h$, which are the roots of an equation $(1-\theta+\theta^2)^3/\theta^2(1-\theta)^2=(1-h+h^2)^3/h^2(1-h)^2$. Thus the function $z(\tau)=\frac{4}{27}(p^2w+pwpw'+p^2w')^3/p^2wp^2w'(pw+pw')^2$, which is clearly a single-valued function of the ratio $\tau=w'/w$, is unaltered by any transformation $\tau'=(q+q'\tau)/(p+p'\tau)$, in which p, q, p', q' are integers for which $pq'-p'q=1$. If the imaginary part of $\tau(=\rho+i\sigma)$ be positive, the imaginary part of τ', being equal to $i\sigma(pq'-p'q)\div[(p+p'\rho)^2+p'^2\sigma^2]$, is also positive; it can be shown that the upper half of the infinite plane of τ can be divided into regions, all bounded by arcs of circles (or straight lines), such that every point of any region other than the so-called fundamental region can be obtained from a definite point of the fundamental region by a definite one of the transformations, that is, as remarked above, by a definite combination of the two primary transformations $\tau'=-1/\tau$, $\tau'=1+\tau$, while every such transformation leads from any point of the fundamental region to a corresponding point of a different region. If $\tau=\xi+i\eta$, the fundamental region can be taken to be the region for which $-\frac{1}{2}<\xi<\frac{1}{2}$ and $\xi^2+\eta^2>1$, together with the points, on the curves limiting this region, for which ξ is negative. Upon the infinite half plane the function $z(\tau)$ is a single-valued monogenic analytical function whose only essential singularities are those arising, by the transformations, from $\tau=\infty$, therefore given by all real rational values of τ; the equation $z(\tau')=z(\tau)$ can be shown to require a relation of the form $\tau'=(q+q'\tau)/(p+p'\tau)$, and the function $z(\tau)$ takes every value just once within the fundamental and therefore within every other region. Putting $J(\tau)=\frac{z(\tau)}{z(\tau)-1}=4(p^2w+pwpw'+p^2w')^3 \div(pw-pw')^2(pw+2pw')^2(2pw+pw')^2$ the function $J(\tau)$ is equal to 0 for $\tau=e^{\frac{2\pi i}{3}}$, is equal to 1 for $\tau=i$, and has an essential singularity for $\tau=\infty$; the inverse function $\tau(J)$ is infinitely valued, has branch places with connexion of three values for $J=0$, the circuit of the branch place leading to a linear substitution of period three (such as $\tau'=-(1+\tau)^{-1}$), branch places with connexion of two values for $J=1$, the circuit of the branch place leading to a linear substitution of period two (such as $\tau'=-1/\tau$), and a branch place with connexion of all values for $J=\infty$, the circuit leading to a non-periodic linear substitution (such as $\tau'=1+\tau$); these are the only singularities of the function $\tau(J)$. Each of the functions $\sqrt[3]{J(\tau)}$, $\sqrt{J(\tau)-1}$, $\sqrt[8]{-\frac{pw+2pw'}{pw-pw'}}$, $\sqrt[8]{\frac{2pw+pw'}{pw-pw'}}$, $\sqrt[24]{-\frac{(pw+2pw')(2pw+pw')}{(pw-pw')^2}}$ besides others, is a single-valued function of τ, being expressible without ambiguity in terms of the single function $\eta(\tau)=e^{\frac{i\pi\tau}{12}}\prod_{n=1}^{\infty}(1-e^{2i\pi n\tau})=e^{\frac{i\pi\tau}{12}}\sum_{n=-\infty}^{\infty}(-1)^m e^{(3m^2+m)i\pi\tau}$; these functions are not, however, unaltered by all the linear substitutions; we have in fact $\eta\left(-\frac{1}{\tau}\right)=\sqrt{-i\tau}\,\eta(\tau)$, $\eta(1+\tau)=e^{\frac{i\pi}{12}}\eta(\tau)$. A more general theorem below.

The aggregate of the substitutions $\tau'=(q+q'\tau)/(p+p'\tau)$, wherein p, q, p', q' are integers for which $pq'-p'q=1$, constitutes a *group* (*q.v.*); the function $J(\tau)$, unaltered by all the substitutions of this group, is called a *modular function.* More generally a function unaltered by all the substitutions of any group of linear transformations is called an *automorphic function*; of such functions doubly-periodic functions are a particular case, being unaltered by the transformations of the group arising by repetition and combination of the two transformations

$u'=u+2w$, $u'=u+2w'$. In the case of a single-valued analytic doubly-periodic function which has no essential singularity for finite values of the argument u, we have the three fundamental properties: (1) That if the coefficient of the first negative power of $u-a$ in the expansion of the function for the neighbourhood of the pole a be called the residue of the function for this pole, the sum of the residues of the function at all its poles within any one parallelogram of periods is zero; (2) That the function takes any specified value A, within the parallelogram, a number of times equal to the aggregate order of its poles, this number being not less than 2; this minimum is reached for the function $p(u)$; (3) That the sum of the values of u for which the function takes the value A, can differ from the sum of the values of u for which the function takes any other value B, only by an expression of the form $2mw+2m'w'$, where m, m' are integers. Analogous properties hold for automorphic functions; but space prevents further explanation. The elliptic functions pu, $p'u$ enable us to represent the cubic curve $y^2=4x^3-g_2x-g_3$, in the form $x=p(u)$, $y=p'(u)$, by means of single-valued functions; and a similar representation, by these functions, can be made of any algebraic construct of class unity. In accordance with a theorem of Poincaré, automorphic functions can be constructed whereby a given algebraic construct of any class may be similarly represented by single-valued functions, in a form valid for all places of the construct.

The modular function $J(\tau)$ considered above, unaltered by the group of linear substitutions $\tau'=(q'\tau+q)/(p'\tau+p)$, where p, q, p', q' are any integers for $pq'-p'q=1$, may be regarded as the independent variable of a differential equation (*q.v.*) of the third order of the form $s'''/s'-\frac{3}{2}(s''/s')^2=\frac{1}{2}(1-\alpha^2)(x-1)^{-2}+\frac{1}{2}(1-\beta^2)x^{-2}+\frac{1}{2}(\alpha^2+\beta^2-\gamma^2-1)x^{-1}(x-1)^{-1}$, of which the dependent variable s is equal to τ. A function satisfying this equation being denoted by $s(\alpha, \beta, \gamma, x)$, we have in fact $\tau=s(\frac{1}{2}, \frac{1}{3}, 0, J)$. Putting $\lambda=(2pw'+pw)/(pw'-pw)$, we similarly have $\tau=s(0,0,0,\lambda)$, and λ is a single-valued function of τ, unaltered only by the (self-conjugate) subgroup of modular substitutions in which the coefficients q and p' are even integers, and therefore p and q' odd integers; the fundamental region for this subgroup, if $\tau=\xi+i\eta$, may be taken to be given by $-1<\xi<1$, $(\xi+\frac{1}{2})^2+\eta^2>\frac{1}{4}$, $(\xi-\frac{1}{2})^2+\eta^2>\frac{1}{4}$, and may be divided into six regions which are equivalent to one another by the substitutions of the general modular group. Within this fundamental region λ takes every value just once, except the values 0, 1, ∞, which can arise only at the angular points ($\tau=0$, ∞, -1 and the equivalent point $\tau=1$); these being essential singularities for the function λ. For $\lambda(\tau)$, as for $J(\tau)$, the region of existence is the upper half plane, every short length of the axis $\eta=0$ containing essential singularities.

As bare illustrations of the utility of the function $\tau=s(0, 0, 0, \lambda)$ we refer to the proof of the theorem: (i.) If a single-valued analytic monogenic integral function $\phi(x)$ do not take the values 0 and 1 for finite values of x, then it is a constant; for in that case the function $s[0, 0, 0, \phi(x)]$ is a single-valued analytic monogenic integral function; and it is impossible that the imaginary part of such a function should not become negative, as is the case of $s(0, 0, 0, \lambda)$ for all values of λ. Hence it follows that for a single-valued monogenic analytic function $F(x)$ which has $x=\infty$ as an isolated essential singularity and no other essential singularity, there cannot be three values a, b, c which the function does not assume for finite values of x; for by taking proper linear function of the function we could then obtain a single-valued analytic monogenic function not taking the values 0, 1, ∞ for finite values of x. It can further be shown, by using the function $s(\frac{1}{2}, \frac{1}{3}, 0, J)$, that if there be three values a, b, c which the function does not assume for an infinite number of finite values of x, then $F(x)$ must be a rational function; (ii.) Any function $s(\alpha, \beta, \gamma, x)$ is a single-valued function of $\tau=s(0, 0, 0, x)$; for putting $\tau'=\frac{\tau-i}{\tau+i}$, the values of τ' which correspond to the singular points $x=0$, 1, ∞ of $s(\alpha, \beta, \gamma, x)$, though infinite in number, all lie on the circumference of a circle, $|\tau'|=1$, within which $s(\alpha, \beta, \gamma, x)$ is expressible in the form $\sum_{n=0}^{\infty} a_n \tau'^n$. The same for any function whose only singularities are branch places at $x=0$, $x=1$, $x=\infty$.

Functions of Several Variables.—In order to appreciate the power of Weierstrass's methods it is necessary to study their application to the case of functions of more than one independent variable, for which the Cauchy methods are mostly inapplicable. The region of existence of a monogenic analytical function is as in the simpler case to be defined by a succession of power series; the singular points are either essential or unessential, but there are two sorts of unessential singularities of which only one sort can be called poles. To define an unessential singularity it is necessary to premise that if a power series in the variables x, $x_1,\dots x_n$ vanish at a point $x=0$, $x_1=0,\dots x_n=0$ it is possible to write the series in the form $(x^k+u_1x^{k-1}+\dots+u_k)E$, where $u_1,\dots u_k$ are power series in $x_1,\dots x_n$, all vanishing at $x_1=0,\dots x_n=0$, and E is a power series in x, $x_1,\dots x_n$ not vanishing at $x=0$, $x_1=0,\dots x_n=0$; from this it is possible, given two power series both vanishing at $x=0$, $x_1=0,\dots x_n=0$, to distinguish between the two cases when: (1) The two series have a common factor in the form of a power series vanishing at $x=0$, $x_1=0,\dots x_n\dots 0$; (2) The two series have no such common factor. Now as we approach to a singular point of a function of several variables, and consequently the range of convergence of the derived power series representing the function diminishes without limit, there may exist a power series ϕ, with centre at the singular point, such that for the product of the function F, and the series ϕ, the point is an ordinary point; then the function can be represented in the neighbourhood of the point as the quotient, $F=\psi/\phi$, of two power series, and the point is said to be an unessential singularity. If now any factor, in the form of a power series vanishing at the point, which is common to ψ and ϕ, be divided out, the reduced quotient $F=\psi_1/\phi_1$ will still be such that ϕ_1 vanishes at the point, or the point would be an ordinary point for the function; if then ψ_1 does not vanish at the point, the function F has the value ∞ at the point by whatever path the point is approached, and the point is one which is an ordinary point for $1/F$; this may be called a pole; if, however, ψ_1 also vanish at the point the limiting value of the function F as the singular point is approached is entirely indeterminate and depends on the path of approach. For a function of two complex variables such points of indetermination are generally discrete; for a function of p variables they form a continuum of $2p-4$ dimensions; and the existence of such points constitutes one of the main difficulties of the theory. There exist, however, proofs of the two following propositions, which generalize results for functions of one variable: (1) If a single-valued analytical monogenic function of p variables have no essential singularity, either for finite values of the variables, or at infinity, then it is a rational function of the variables; (2) If a function known to exist, and to be single-valued, be further known to be expressible in the neighbourhood of every *finite* point as a quotient of two power series with a presumably limited range of convergence, then the function can be expressed as a quotient of two integral functions, that is, as a quotient of two power series converging for all finite values of the variables; and this in such a way that these integral functions have no common zero other than the points of the $(2p-4)$-fold over which the function is essentially indeterminate.

The monogenic analytical single-valued functions of several variables other than the algebraic functions in regard to which most definite results have been obtained are those possessing sets of simultaneous periods, and having no essential singularities for finite values of the variables; if $a_1, \ldots a_p$ be such a set of periods the property is $\phi(x_1+a_1, \ldots x_p+a_p) = \phi(x_1, \ldots x_p)$; the greatest possible number of such sets of simultaneous periods is $2p$, but not every $2p$ sets of p quantities can be the periods of such a function; it is necessary, on the contrary, that the $2p^2$ quantities should be connected by $2p^2 - \frac{1}{2}p(p+1)$ relations of a certain form. The main general result for such periodic functions is that, of functions having the same periods, all can be expressed rationally in terms of $(p+1)$ functions chosen of suitable generality, these $(p+1)$ functions being themselves connected by a rational relation. So far as is known two main methods are available for the proof of these statements: (1) When by the general theorem quoted above, the periodic function is expressed as a quotient of two integral functions, these are found to be quasi-periodic, having a property expressed by $\Theta(x_1-a_1, \ldots x_p-a_p) = e^u\Theta(x_1, \ldots x_p)$ where u is a linear function of the variables; these can therefore be expanded, by a theorem not difficult to prove, which is the generalization of Laurent's theorem, in integral powers of quantities $e^{\lambda_1 x_1}, \ldots e^{\lambda_p x_p}$ (wherein $\lambda_1, \ldots \lambda_p$ are constants). On the basis of this expansion the properties of the functions can be developed; (2) Another method of proof is obtained by directly connecting the periodic functions with an algebraic construct and utilizing the methods (of contour integration, &c.) used with such success by Riemann in his investigations in regard to Abelian functions. It is, in fact, as Abelian functions that periodic functions of several variables first arise, being introduced to express the solution of the inversion problem, suggested by Abel's theorem, which generalizes the inversion of the elliptic integral from which elliptic functions take their origin; the quasi-periodic integral functions, denoted above by Θ, by which the periodic functions can be expressed, forming an important part of the development. And, as in the case of one variable, the theory is intimately related to that of *automorphic functions*, that is, of functions of several variables unaltered by groups of linear substitutions of the variables.

Functions of Real Variables.—

The idea of functional dependence came into Mathematics from analytical geometry; mathematical analysis as founded, and as at first developed, was based on geometrical intuition; a *function* was some variable length connected with a curve; an *irrational number* was the ratio of two incommeasurable geometric magnitudes; approach to a *limit* meant tending continually towards it; none of these essential notions—number, limit, function—was precisely defined. Modern analysis, on the other hand, is throughout arithmetical; all the essential notions are defined arithmetically; the arithmetic even on which analysis rests has been reformulated in such a way as to sever the notion of number from that of magnitude. It is the object of this article to give some account of the Theory of Functions of Real Variables as it has been remodelled in the process of complete arithmetization. Notations and ideas which have been sufficiently explained in the articles Infinitesimal Calculus (*Ency. Brit.* 9th ed. vol. xiii.) and Function (vol. ix.), will be utilized without further discussion. Limitations of space prevent the presentation of proofs of theorems.

The landmarks of the theory are the introduction of the system of ordinal numbers and the establishment of the *continuum* of real numbers; the definition of the domain of a variable or a system of variables by means of the theory of Aggregates[1]; the general principle of convergence to a limit; the definition of functional dependence; the establishment of the notions of continuity, differentiability, and integrability of functions; the representation of functions by means of the results of limiting processes; the conduct of operations on functions so represented. The systematic arithmetical development of the theory is mainly due to Weierstrass.

1. *The Continuum of Real Numbers.*—The capacity of numbers to answer questions of how many and how much, in other words to express the results of operations of counting and measuring, may be regarded as a secondary property derived from the more fundamental one of expressing order. The fact that a formally complete theory of Arithmetic can be based on the notion of order only was pointed out by Dedekind. According to this theory, a natural number is a mark which serves to specify the place of an object in a series or "progression" (see Number), and the essential fact of the theory is the possibility of referring the objects in one series to the objects in another series one by one. Natural numbers form a series with a definite order, and the expressions "greater than" and "less than" mean "more advanced" and "less advanced" in this order. Rational fractions are introduced by means of pairs of natural numbers which obey certain defined laws of operation, and for these also the order is defined.

[1] The term "Theory of Aggregates" is here used as the equivalent of the German "Mengenlehre" and the French "théorie des ensembles."

Negative numbers are introduced in a similar way. The whole system of rational numbers thus constructed has a definite order. The meanings to be attached to addition, subtraction, multiplication, and division, the commutative, associative, and distributive laws of operation, can all be based on the notion of order and the possibility of one-to-one correspondences. The formal system thus developed can be applied to express the results of counting and measuring. Irrational numbers are introduced by means of "cuts" (see NUMBER). An irrational number is the mark of a cut which separates all rational numbers into two classes, the inferior class having no greatest number, and the superior class no least number. The whole system of rational and irrational numbers possesses a definite order, and forms a *continuum*. In fact the notion of a one-dimensional continuum first becomes precise in virtue of the establishment of this system.

2. *Measurement.*—It will be sufficient to consider here the measurement of one kind of concrete quantity, viz., the length of a segment of a straight line (produced indefinitely). We choose any other segment of the line, and mark its ends with the numbers 0 and 1; then we lay off on the straight line a series of segments with contiguous ends each equal to this "unit" segment, and mark their ends with the numbers 1 and 2, 2 and 3, . . . the points marked 1, or 2, . . . being the same for consecutive segments; on the other side of the point marked 0 we lay off segments in the same way as before, and mark their ends with the numbers 0 and -1, -1 and -2. . . . The first requisite for the measurement is the possibility of equal segments; the test of equality of length is congruence. The second requisite for the measurement is that, when the process above described is carried far enough, any point of the line chosen in advance should be found either within a marked segment or at an end of such a segment; this is the "axiom of Archimedes." We now divide the segment between m and $m+1$, where m may be zero or any positive or negative integer, into q equal segments, and mark their extremities in order with the numbers

$$m, \frac{qm+1}{q}, \frac{qm+2}{q}, \ldots \frac{qm+q-1}{q}, m+1,$$

each fraction being reduced to its lowest terms, and we do the same with any other marked segment and with any other integer in place of q. Thus certain points of the line will be marked with rational numbers, and the correspondence between the points and the numbers has these properties—(1) the order of the points is the same as that of the numbers; (2) the difference of the numbers marking two points is the same as the difference of the numbers marking two other points when the distance between the first two is the same as the distance between the second two. The points which can be marked by carrying this process far enough are called rational points. There are points of the line which are not rational points, and the above method of marking the points is completed by marking such points with irrational numbers; each point of the line may be regarded as effecting a "cut" in the system of rational points, to which there corresponds a definite cut in the system of rational numbers; if the point is not a rational point it is marked with the irrational number defined by this cut. By this process any chosen point of the line will be marked by a definite number, rational or irrational, and the correspondence between the points and the numbers has the above properties (1) and (2). That, after choice of any irrational number, one point of the line can be found which must, in carrying out the above process, be marked with that number, is a geometrical axiom first recognized as necessary by Dedekind and G. Cantor; in accordance with this axiom the process effects a one-to-one correspondence of real numbers and points of a straight line, and the length of any segment is measured with reference to the chosen unit segment, by the difference of the numbers that correspond to its ends. On account of this correspondence a real number is frequently referred to as a "point."

3. *Domain of a Variable.*—The notion of an "aggregate" or "manifold" in general underlies the system of ordinal numbers (see NUMBER). An aggregate is said to be "infinite" when it is possible to effect a one-to-one correspondence of all its elements with some of its elements. Thus the aggregates of positive integers and of points on a straight line are infinite aggregates. An aggregate whose elements are real numbers is said to "extend to infinite values" if, after any number N, however great, has been specified, it is possible to find in the aggregate numbers which exceed N in absolute value; such an aggregate is always infinite. The "neighbourhood of a number (or point) a for a positive number h" is the aggregate of all numbers (or points) x for which the absolute value of $x-a$, denoted by $|x-a|$, does not exceed h. The idea of a "variable" is that of a number to which we may assign at pleasure any of the values which constitute a definite aggregate, called the "domain" of the variable. This domain may be an "interval," *i.e.*, it may consist of two terminal numbers, all the numbers between them and no others; when the domain of a variable number is an interval the number is said to be "continuously variable," when the domain consists of all real numbers the variable is said to be "unrestricted." A domain which consists of all real numbers which are greater than some fixed number will be described as an "interval unlimited towards the right"; similarly we may have an "interval unlimited towards the left."

4. *Domain of a Set of Variables.*—The numerical continuum of n dimensions (C_n) is the aggregate that is arrived at by attributing simultaneous values to each of n variables $x_1, x_2, \ldots x_n$, these values being any real numbers. The elements of such an aggregate are called "points," and the numbers $x_1, x_2, \ldots x_n$ the "co-ordinates" of a point. Denoting in general the points $(x_1, x_2, \ldots x_n)$ and $(x'_1, x'_2 \ldots x'_n)$ by x and x', the sum of the differences $|x_1-x'_1| + |x_2-x'_2| + \ldots + |x_n-x'_n|$ may be denoted by $|x-x'|$ and called the "difference of the two points." We can in various ways choose out of the continuum an aggregate of points, which may be an infinite aggregate, and any such aggregate can be the "domain" of a "variable point." The domain is said to "extend to an infinite distance" if, after any number N, however great, has been specified, it is possible to find in the domain points of which one or more co-ordinates exceed N in absolute value. The "neighbourhood" of a point a for a (positive) number h is the aggregate constituted of all the points x, which are such that the "difference" denoted by $|x-a| \leqslant h$. If an infinite aggregate of points does not extend to an infinite distance, there must be at least one point a, which has the property that the points of the aggregate which are in the neighbourhood of a for any number h, however small, themselves constitute an infinite aggregate, and then the point a is called a "limiting point" of the aggregate; it may or may not be a point of the aggregate. An aggregate of points is "perfect" when all its points are limiting points of it, and all its limiting points are points of it; it is "connected" when, after taking any two points a, b of it, and choosing any positive number ϵ, however small, a number m and points $x', x'', \ldots x^{(m)}$ of the aggregate can be found so that all the differences denoted by $|x'-a|$,

$|x''-x'|, \ldots |b-x^{(m)}|$ are less than ϵ. A perfect connected aggregate is a *continuum*. This is G. Cantor's definition.

The definition of a continuum in C_n leaves open the question of the number of dimensions of the continuum, and a further explanation is necessary in order to define arithmetically what is meant by a "homogeneous part" H_n of C_n. Such a part would correspond to an interval in C_1, or to an area bounded by a simple closed contour in C_2; and, besides being perfect and connected, it would have the following properties: (1) There are points of C_n which are not points of H_n; these form a complementary aggregate H'_n. (2) There are points "within" H_n; this means that for any such point there is a neighbourhood consisting exclusively of points of H_n. (3) The points of H_n which do not lie "within" H_n are limiting points of H'_n; they are not points of H'_n, but the neighbourhood of any such point for any number h, however small, contains points within H_n and points of H'_n; the aggregate of these points is called the "boundary" of H_n. (4) When any two points a, b within H_n are taken, it is possible to find a number ϵ and a corresponding number m, and to choose points $x', x'', \ldots x^{(m)}$, so that the neighbourhood of a for ϵ contains x', and consists exclusively of points within H_n, and similarly for x' and x'', x'' and x''', . . . $x^{(m)}$ and b. Condition (3) would exclude such an aggregate as that of the points within and upon two circles external to each other and a line joining a point on one to a point on the other, and condition (4) would exclude such an aggregate as that of the points within and upon two circles which touch externally.

5. *General Notion of Functionality.*—The idea of a function was at first geometrical; the function was regarded as given graphically; nevertheless arithmetical notions were almost from the first associated with geometrical ones, the curve which represents the function being determined by an equation. Among early writers on analysis we find the use of the word "function" in the sense of a power or some other analytical expression; and the two notions (1) that which is determined by a curve supposed drawn, and (2) that which is determined by an analytical expression supposed written down, were not for a long time clearly distinguished. It was for this reason that Fourier's discovery that a single analytical expression is capable of representing (in different parts of an interval) what would in his time have been called different functions so profoundly struck mathematicians (§ 22). The analysts who, in the middle of the 19th century, occupied themselves with the theory of the convergence of Fourier's series were led to impose a restriction on the character of a function in order that it should admit of such representation, and thus the door was opened for the introduction of the general notion of functional dependence. This notion may be expressed as follows: We have a variable number, y, and a variable number or system of such numbers, x, a domain of the variable or variables x, and a rule for assigning one or more definite values to y when x is any point in the domain; then y is said to be a "function" of the variable or variables, and these are called the "argument" of the function. According to this notion a function is, as it were, an indefinitely extended table, like a table of logarithms; to each point in the domain of the argument there correspond values for the function, but it remains arbitrary what values the function is to have at any such point. For the definition of any particular function two things are requisite: (1) a statement of the values of the variable, or of the aggregate of variable points, to which values of the function are to be made to correspond, *i.e.*, of the "domain of the argument"; (2) a rule for assigning the value or values of the function that correspond to any point in this domain. We may refer to the second of these two essentials as "the rule of calculation." The relation of functions to analytical expressions may then be stated in the form that the rule of calculation is: "Give the function the value of the expression at any point at which the expression has a determinate value," or again more generally, "Give the function the value of the expression at all points of a definite aggregate included in the domain of the argument." The former of these is the rule of those among the earlier analysts who regarded an analytical expression and a function as the same thing, and their usage may be retained without causing confusion and with the advantage of brevity, the analytical expression serving to specify the domain of the argument as well as the rule of calculation, *e.g.*, we may speak of "the function $1/x$." But in complicated cases separate statements of the domain of the argument and the rule of calculation cannot be dispensed with. In general, when the rule of calculation is determined as above by an analytical expression at any aggregate of points, the function is said to be "represented" by the expression at those points.

When the rule of calculation assigns a single definite value for a function at each point in the domain of the argument the function is "uniform" or "one-valued." In what follows it is to be understood that all the functions considered are one-valued, and the values assigned by the rule of calculation real.

In the most important cases the domain of the argument of a function of one variable is an interval, and that of a function of n variables is a homogeneous part of the numerical continuum of n dimensions, with the possible exception of isolated points.

6. *Limits.*—Let $f(x)$ be a function of a variable point x, representing a value of one variable number, or simultaneous values of n variable numbers, and let a be a point such that there are points of the domain of the argument x in the neighbourhood of a for any number h however small. If there is a number L which has the property that, after any positive number ϵ, however small, has been specified, it is possible to find a positive number h, so that $|L-f(x)|<\epsilon$ for all points x of the domain (other than a) for which $|x-a|<h$, then L is the limit of $f(x)$ at the point a. The condition for the existence of L is that, after the positive number ϵ has been specified, it must be possible to find a positive number h, so that $|f(x')-f(x)|<\epsilon$ for all points x and x' of the domain (other than a) for which $|x-a|<h$ and $|x'-a|<h$.

If $f(x)$ is a function of one variable x in a domain which extends to infinite values, and if, after ϵ has been specified, it is possible to find a number N, so that $|f(x')-f(x)|<\epsilon$ for all values of x and x' which are in the domain and exceed N, then there is a number L which has the property that $|f(x)-L|<\epsilon$ for all such values of x. In this case $f(x)$ has a limit L at $x=\infty$. In like manner $f(x)$ may have a limit at $x=-\infty$. This statement includes the case where the domain of the argument consists exclusively of positive integers. The values of the function then form a "sequence," $u_1, u_2, \ldots u_n, \ldots$, and this sequence can have a limit at $n=\infty$.

In the case of a function of n variables in a domain which extends to an infinite distance, there is a limit at an infinite distance if, after ϵ has been specified, a number N can be found, so that $|f(x')-f(x)|<\epsilon$ for all points x and x' of the domain which have one or more coordinates exceeding N in absolute value.

The principle common to the above definitions and theorems is called, after P. du Bois Reymond, "the general principle of convergence to a limit."

A function which has not a limit at a point a may be such that, if a certain aggregate of points is chosen out of the domain of the argument, and the points x in the neighbourhood of a are restricted to belong to this aggregate, then the function has a limit at a. For example $\sin(1/x)$ has limit zero at 0 if x is restricted to the aggregate $1/\pi$, $1/2\pi$, . . . $1/n\pi$, . . . or to the aggregate $1/2\pi$, $2/5\pi$, . . . $n/(n^2+1)\pi$, . . ., but if x takes all values in the neighbourhood of 0, $\sin(1/x)$ has not a limit at 0. Again, in the case of a function of one variable, there may be a limit at a if the points x in the neighbourhood of a are restricted by the condition that $x-a$ is positive; then we have a "limit on the right" at a; similarly we may have a "limit on the left" at a point; in the case of a function of several variables we may have a limit for approach to a point by a particular path. Any such limit is described as a "limit for a restricted domain."

The limit L of $f(x)$ at a stands in no necessary relation to the value of $f(x)$ at a. If the point a is in the domain of the argument, the value of $f(x)$ at a is assigned by the rule of calculation, and may be different from L. In case $f(a)=L$ the limit is said to be "attained." If the point a is not in the domain of the argument, there is no value for $f(x)$ at a. In the case where $f(x)$ is defined for all points in an interval (or in a domain H_n [§ 4]), containing a, except the point a, and has a limit L at a, we may arbitrarily annex the point a to the domain of the argument and assign to $f(a)$ the value L; the function is then said to be "extrinsically defined." The so-called "indeterminate forms" (INFINITESIMAL CALCULUS, *Ency. Brit.* vol. xiii. p. 21) are examples.

7. *Superior and Inferior Limits; Infinities.*—The value of a function at every point in the domain of its argument is finite, since, by definition, the value can be assigned, but this does not necessarily imply that there is a number N which exceeds all the values (or is less than all the values). It may happen that however great a number N we take there are among the values of the function numbers which exceed N (or are less than $-N$).

If a number can be found which is greater than every value of the function, then either (α) there is one value of the function which exceeds all the others, or (β) there is a number S which exceeds every value of the function but is such that, however small a positive number ϵ we take, there are values of the function which exceed $S-\epsilon$. In case (α) the function has a greatest value; in case (β) the function has a superior limit S, and then there must be a point a which has the property that there are points of the domain of the argument, in the neighbourhood of a for any h, at which the values of the function differ from S by less than ϵ. Thus S is the limit of the function at a, either for the domain of the argument or for some more restricted domain. If a is in the domain of the argument, and if, after omission of a, there is a superior limit S which is in this way the limit of the function at a, if further $f(a)=S$, then S is the greatest value of the function; in this case the greatest value is a limit (at any rate for a restricted domain) which is attained; it may be called a "superior limit which is attained." In like manner we may have a "smallest value" or an "inferior limit," and a smallest value may be an "inferior limit which is attained."

All that has been said here may be adapted to the description of greatest values, superior limits, &c., of a function in a restricted domain contained in the domain of the argument. In particular, the domain of the argument may contain an interval (or a domain H_n [§ 4]), and therein the function may have a superior limit, or an inferior limit, which is attained; such a limit is a *maximum* value or a *minimum* value of the function.

Again, if, after any number N, however great, has been specified, it is possible to find points of the domain of the argument at which the value of the function exceeds N, the values of the function are said to have an "infinite superior limit," and then there must be a point a which has the property that there are points of the domain, in the neighbourhood of a for any h, at which the value of the function exceeds N. If the point a is in the domain of the argument the function is said to "tend to become infinite" at a; it has of course a finite value at a. If the point a is not in the domain of the argument the function is said to "become infinite" at a; it has of course no value at a. In like manner we may have a (negatively) infinite inferior limit. Again, after any number N, however great, has been specified and a number h found, so that all the values of the function, at points in the neighbourhood of a for h, exceed N in absolute value, all these values may have the same sign; the function is then said to become, or to tend to become, "determinately (positively or negatively) infinite"; otherwise it is said to become, or to tend to become, "indeterminately infinite."

All the infinities that occur in the Theory of Functions of Real Variables are of the nature of variable finite numbers, with the single exception of the infinity of an infinite aggregate. The latter is described as an "actual infinity," the former as "improper infinities." There is no "actual infinitely small" corresponding to the actual infinity. The only "infinitely small" is zero. All "infinite values" are of the nature of superior and inferior limits which are not attained.

8. *Increasing and Decreasing Functions.*—A function $f(x)$ of one variable x, defined in the interval between a and b, is "increasing throughout the interval" if, whenever x and x' are two numbers in the interval and $x'>x$, then $f(x')>f(x)$; the function "never decreases throughout the interval" if, x' and x being as before, $f(x')\geqslant f(x)$ Similarly for decreasing functions, and for functions which never increase throughout an interval. A function which never increases or never diminishes throughout an interval is said to be "monotonous throughout" the interval. Taking in the above definition $b>a$, the definition may apply to a function under the restriction that x' is not b and x is not a; such a function is "monotonous within" the interval. In this case we have the theorem that the function (if it never decreases) has a limit on the left at b and a limit on the right at a, and these are the superior and inferior limits of its values at all points within the interval (the ends excluded); the like holds *mutatis mutandis* if the function never increases. If the function is monotonous throughout the interval, $f(b)$ is the greatest (or least) value of $f(x)$ in the interval; and if $f(b)$ is the limit of $f(x)$ on the left at b, such a greatest (or least) value is an example of a superior (or inferior) limit which is attained. In these cases the function tends continually to its limit.

These theorems and definitions can be extended, with obvious modifications, to the cases of a domain which is not an interval, or extends to infinite values. By means of them we arrive at sufficient, but not necessary, criteria for the existence of a limit; and these are frequently easier to apply than the general principle of convergence to a limit, of which principle they are particular cases.

9. *Continuity of Functions.*—A function $f(x)$ of one variable x is said to be "continuous" at a point a if (1) $f(x)$ is defined in an interval containing a, (2) $f(x)$ has a limit[1] at a, (3) $f(a)$ is equal to this limit. If $f(x)$ has a limit on the left at a and $f(a)$ is equal to this limit, the function is said to be "continuous to the left" at a; similarly the function may be "continuous to the right" at a.

[1] It must be a limit for continuous variation, not for a restricted domain.

A function is said to be "continuous throughout an interval" when it is continuous at every point of the interval. This implies continuity to the right at the smaller end-value and continuity to the left at the greater end-value. When these conditions at the ends are not satisfied the function is said to be continuous "within" the interval. By a "continuous function" of one variable we always mean a function which is continuous throughout an interval.

The principal properties of a continuous function are:

(1) The function is practically constant throughout sufficiently small intervals; this means that, after any point a of the interval has been chosen, and any positive number ϵ, however small, has been specified, it is possible to find a number h, so that the difference between any two values of the function in the interval between $a-h$ and $a+h$ is less than ϵ. There is an obvious modification if a is an end-point of the interval.

(2) The continuity of the function is "uniform"; this means that the number h which corresponds to any ϵ as in (1) may be the same at all points of the interval, or, in other words, that the numbers h which correspond to ϵ for different values of a have a positive inferior limit.

(3) The function has a greatest value and a least value in the interval, and these are superior and inferior limits which are attained.

(4) There is at least one point of the interval at which the function takes any value between its greatest and least values in the interval.

(5) If the interval is unlimited towards the right (or towards the left), the function has a limit at ∞ (or at $-\infty$).

10. *Discontinuity of Functions.*—The discontinuities of a function of one variable, defined in an interval with the possible exception of isolated points, may be classified as follows:

(1) The function may become infinite, or tend to become infinite, at a point.

(2) The function may be undefined at a point.

(3) The function may have a limit on the left and a limit on the right at the same point; these may be different from each other, and at least one of them must be different from the value of the function at the point.

(4) The function may have no limit at a point, or no limit on the left, or no limit on the right, at a point.

In case a function $f(x)$, defined as above, has no limit at a point a, there are four limiting values which come into consideration. Taking any positive number h, the values of the function at points between a and $a+h$ (a excluded) have a superior limit (or a greatest value), and an inferior limit (or a least value); further, as h decreases, the former never increases and the latter never decreases; accordingly each of them tends to a limit. We have in this way two limits on the right—the inferior limit of the superior limits in diminishing neighbourhoods, and the superior limit of the inferior limits in diminishing neighbourhoods. These are denoted by $\overline{f(a+0)}$ and $\underline{f(a+0)}$, and they are called the "limits of indefiniteness" on the right. Similar limits on the left are denoted by $\overline{f(a-0)}$ and $\underline{f(a-0)}$. Unless $f(x)$ becomes, or tends to become, infinite at a, all these must exist, any two of them may be equal, and at least one of them must be different from $f(a)$, if $f(a)$ exists. If the first two are equal, there is a limit on the right denoted by $f(a+0)$; if the second two are equal, there is a limit on the left denoted by $f(a-0)$. In case the function becomes, or tends to become, infinite at a, one or more of these limits is infinite in the sense explained in § 7; and now it is to be noted that, *e.g.*, the superior limit of the inferior limits in diminishing neighbourhoods on the right of a may be negatively infinite; this happens if, after any number N, however great, has been specified, it is possible to find a positive number h, so that all the values of the function in the interval between a and $a+h$ (a excluded) are less than $-N$; in such a case $f(x)$ tends to become negatively infinite when x decreases towards a; other modes of tending to infinite limits may be described in similar terms.

11. *Oscillation of Functions.*—The difference between the greatest and least of the numbers $f(a)$, $\overline{f(a+0)}$, $\underline{f(a+0)}$, $\overline{f(a-0)}$, $\underline{f(a-0)}$, when they are all finite, is called the "oscillation" of the function $f(x)$ at the point a. This difference is the limit for $h=0$ of the difference between the superior and inferior limits of the values of the function at points in the interval between $a-h$ and $a+h$. The corresponding difference for points in a finite interval is called the "oscillation of the function in the interval." When any of the four limits of indefiniteness is infinite the oscillation is infinite in the sense explained in § 7.

For the further classification of functions we divide the domain of the argument into partial intervals by means of points between the end-points. Suppose that the domain is the interval between a and b. Let intermediate points $x_1, x_2, \ldots x_{n-1}$, be taken so that $b>x_{n-1}>x_{n-2}\ldots>x_1>a$. We may devise a rule by which, as n increases indefinitely, all the differences $b-x_{n-1}, x_{n-1}-x_{n-2}, \ldots x_1-a$ tend to zero as a limit. The interval is then said to be divided into "indefinitely small partial intervals."

A function defined in an interval with the possible exception of isolated points may be such that the interval can be divided into a set of finite partial intervals within each of which the function is monotonous (§ 8). When this is the case the sum of the oscillations of the function in those partial intervals is finite, provided the function does not tend to become infinite. Further, in such a case the sum of the oscillations will remain below a fixed number for any mode of dividing the interval into indefinitely small partial intervals. A class of functions may be defined by the condition that the sum of the oscillations has this property, and such functions are said to have "restricted oscillation." It can be proved that any function with restricted oscillation is capable of being expressed as the sum of two monotonous functions, of which one never increases and the other never diminishes throughout the interval. Such a function has a limit on the right and a limit on the left at every point of the interval. This class of functions includes all those which have a finite number of maxima and minima in a finite interval, and some which have an infinite number. It is to be noted that the class does not include all continuous functions.

12. *Differentiable Function.*—The idea of the differentiation of a continuous function is that of a process for measuring the rate of growth; the increment of the function is compared with the increment of the variable. If $f(x)$ is defined in an interval containing the point a, and $a-k$ and $a+k$ are points of the interval, the expression

$$\frac{f(a+h)-f(a)}{h} \quad (1)$$

represents a function of h, which we may call $\phi(h)$, defined at all points of an interval for h between $-k$ and k except the point 0. Thus the four limits $\overline{\phi(+0)}$, $\underline{\phi(+0)}$, $\overline{\phi(-0)}$, $\underline{\phi(-0)}$ exist, and two or more of them may be equal. When the first two are equal either of them is the "progressive differential coefficient" of $f(x)$ at the point a; when the last two are equal either of them is the "regressive differential coefficient" of $f(x)$ at a; when all four are equal the function is said to be "differentiable" at a, and either of them is the "differential coefficient" of $f(x)$ at a, or the "first derived function" of $f(x)$ at a. In this case $\phi(h)$ has a definite limit at $h=0$, or is determinately infinite at $h=0$ (§ 7). The four limits here in question are called, after Dini, the "four derivates" of $f(x)$ at a. In accordance with the notation for derived functions they may be denoted by

$$\overline{f'_+(a)},\ \underline{f'_+(a)},\ \overline{f'_-(a)},\ \underline{f'_-(a)}.$$

A function which has a finite differential coefficient at all points of an interval is continuous throughout the interval, but if the differential coefficient becomes infinite at a point of the interval the function may or may not be continuous throughout the interval; on the other hand a function may be continuous without being differentiable. This result, comparable in importance, from the present point of view, with the discovery of Fourier's theorem, is due to Riemann; but the failure of an attempt made by Ampère to prove that every continuous function must be differentiable may be regarded as the first step in the theory. Examples of analytical expressions which represent continuous functions that are not differentiable have been given by Riemann, Weierstrass, Darboux, and Dini.

13. *Properties of Derived Functions.*—In regard to the first derived function we have the "theorem of intermediate value": if $f'(x)$ is continuous throughout the interval between a and b, there is a value of x in the interval for which

$$f'(x)=\frac{f(b)-f(a)}{b-a}, \qquad \text{(i.)}$$

or, in the usual notation, there is a number θ between 0 and 1 which has the property that

$$f(b)=f(a)+(b-a)f'\{a+\theta(b-a)\}.$$

This theorem lies at the foundation of the Differential Calculus and of all its applications.

The formation of second and higher differential coefficients need not be dwelt upon here, but it is to be observed that, when $f''(x)$ exists, we have the relation

$$f''(x)=\underset{h=0}{L_t}\frac{f(x+h)-2f(x)+f(x-h)}{h^2}; \qquad \text{(ii.)}$$

on the other hand the limit expressed by the right-hand member of (ii.) may exist although $f''(x)$ does not exist. The same remark applies to the relation

$$f^{(n)}(x)=\underset{h=0}{L_t}h^{-n}\Big[f(x+nh)-nf\{x+(n-1)h\}$$
$$+\frac{n(n-1)}{2\,!}f\{x+(n-2)h\}-\cdots+(-)^n f(x)\Big]. \qquad \text{(iii.)}$$

We have the important results (1) that, when $f'(x)$ vanishes throughout an interval, $f(x)$ is constant throughout the interval; (2) when either $f''(x)$ or the right-hand member of (ii.) can be proved to vanish throughout an interval, $f(x)$ will be proved to be a linear function of x in the interval.

14. *Analytic Function.*—The theorem of intermediate value may be generalized. If $f(x)$ and its first n differential coefficients are continuous in the interval between a and $a+h$, then

$$f(a+h)=f(a)+hf'(a)+\frac{h^2}{2!}f''(a)+\dots$$
$$+\frac{(h^{n-1}}{(n-1)!}f^{(n-1)}(a)+R_n,$$

where R_n may have various forms, some of which have been given in the article INFINITESIMAL CALCULUS, *Ency. Brit.* vol. xiii. pp. 19 and 41. This result is known as "Taylor's theorem."

When Taylor's theorem leads to a representation of the function by means of an infinite series, the function is said to be "analytic" (cf. § 20).

15. *Ordinary Function.*—The idea of a curve representing a continuous function in an interval is that of a line which has the following properties: (1) the co-ordinates of a point of the curve are a value x of the argument and the corresponding value y of the function; (2) at every point the curve has a definite tangent; (3) the interval can be divided into a finite number of partial intervals within each of which the function is monotonous; (4) the property of monotony within partial intervals is retained after interchange of the axes of co-ordinates x and y. According to condition (2) y is a continuous and differentiable function of x, but this condition does not include conditions (3) and (4): there are continuous partially monotonous functions which are not differentiable, there are continuous differentiable functions which are not monotonous in any interval however small; and there are continuous, differentiable, and monotonous functions which do not satisfy condition (4) (cf. § 23). A function which can be represented by a curve, in the sense explained above, is said to be "ordinary," and the curve is called the "graph" of the function. All analytic functions are ordinary, but not all ordinary functions are analytic.

16. *Integrable Function.*—The idea of integration is twofold. We may seek the function which has a given function as its differential coefficient, or we may generalize the question of finding the area of a curve. The first inquiry leads directly to the indefinite integral, the second directly to the definite integral. Following the second method we define "the definite integral of the function $f(x)$ through the interval between a and b" to be the limit of the sum

$$\sum_1^n f(x'_r)(x_r-x_{r-1})$$

when the interval is divided into ultimately indefinitely small partial intervals by points $x_1, x_2, \dots x_{n-1}$; here x'_r denotes any point in the rth partial interval, x_0 is put for a, and x_n for b. It can be shown that the limit in question is finite and independent of the mode of division into partial intervals and of the choice of the points such as x'_r, provided (1) the function is defined for all points of the interval, and does not tend to become infinite at any of them; (2) for any one mode of division of the interval into ultimately indefinitely small partial intervals, the sum of the products of the oscillation of the function in each partial interval and the difference of the end-values of that partial interval has limit zero when n is increased indefinitely. When these conditions are satisfied the function is said to be "integrable" in the interval. The numbers a and b which limit the interval are usually called the "lower and upper limits." We shall call them the "nearer and further end-values."

We have the following theorems:—

(1) Any continuous function is integrable.

(2) Any function with restricted oscillation is integrable.

(3) A discontinuous function is integrable if it does not tend to become infinite, and if the points at which the oscillation of the function exceeds a given number σ, however small, can be enclosed in partial intervals[1] the sum of whose breadths can be diminished indefinitely.

(4) The sum or product of two integrable functions is integrable.

As regards integrable functions we have the following theorems:—

(1) If S and I are the superior and inferior limits (or greatest and least values) of $f(x)$ in the interval between a and b, $\int_a^b f(x)dx$ is intermediate between $S(b-a)$ and $I(b-a)$.

[1] These partial intervals must be a set chosen out of some complete set obtained by the process used in the definition of integration.

(2) The integral is a continuous function of each of the end-values.

(3) Taking the further end-value b as variable, and writing $\int_a^x f(x)dx = F(x)$, if $f(x)$ is continuous at b, $F(x)$ is differentiable at b, and $F'(b) = f(b)$.

(4) In case $f(x)$ is continuous throughout the interval $F(x)$ is continuous and differentiable throughout the interval, and $F'(x) = f(x)$ throughout the interval.

(5) In case $f'(x)$ is continuous throughout the interval between a and b,

$$\int_a^b f'(x)dx = f(b) - f(a).$$

(6) In case $f(x)$ is discontinuous at one or more points of the interval between a and b, in which it is integrable,

$$\int_a^x f(x)dx$$

is a function of x, of which the four derivates at any point of the interval are equal to the limits of indefiniteness of $f(x)$ at the point.

(7) It may be that there exist functions which are differentiable throughout an interval in which their differential coefficients are not integrable; if, however, $F(x)$ is a function whose differential coefficient, $F'(x)$, is integrable in an interval, then

$$F(x) = \int_a^x F'(x)dx + \text{const.},$$

where a is a fixed point, and x a variable point, of the interval. Similarly, if any one of the four derivates of a function is integrable in an interval, all are integrable, and the integral of either differs from the original function by a constant only.

The theorems (4), (6), (7) show that there is some discrepancy between the indefinite integral considered as the function which has a given function as its differential coefficient, and as a definite integral with a variable end-value.

We have also two theorems concerning the integral of the product of two integrable functions $f(x)$ and $\phi(x)$; these are known as "the first and second theorems of the mean." The first theorem of the mean is that, if $\phi(x)$ is one-signed throughout the interval between a and b, there is a number M intermediate between the superior and inferior limits, or greatest and least values, of $f(x)$ in the interval, which has the property expressed by the equation

$$M\int_a^b \phi(x)dx = \int_a^b f(x)\phi(x)dx.$$

The second theorem of the mean is that, if $f(x)$ is monotonous throughout the interval, there is a number ξ between a and b which has the property expressed by the equation

$$\int_a^b f(x)\phi(x)dx = f(a)\int_a^\xi \phi(x)dx + f(b)\int_\xi^b \phi(x)dx.$$

(Cf. the article FOURIER'S SERIES.)

17. *Improper Definite Integrals.*—We may extend the idea of integration to cases of functions which are not defined at some point, or which tend to become infinite in the neighbourhood of some point, and to cases where the domain of the argument extends to infinite values. If c is a point in the interval between a and b at which $f(x)$ is not defined, we impose a restriction on the points x'_r of the definition: none of them is to be the point c. This comes to the same thing as defining $\int_a^b f(x)dx$ to be

$$\underset{\epsilon=0}{L_t}\int_a^{c-\epsilon} f(x)dx + \underset{\epsilon'=0}{L_t}\int_{c+\epsilon'}^b f(x)dx, \qquad (1)$$

where, to fix ideas, b is taken $> a$, and ϵ and ϵ' are positive. The same definition applies to the case where $f(x)$ becomes infinite, or tends to become infinite, at c, provided both the limits exist. This definition may be otherwise expressed by saying that a partial interval containing the point c is omitted from the interval of integration, and a limit taken by diminishing the breadth of this partial interval indefinitely; in this form it applies to the cases where c is a or b.

Again, when the interval of integration is unlimited to the right, or extends to positively infinite values, we have as a definition

$$\int_a^\infty f(x)dx = \underset{h=\infty}{L_t}\int_a^h f(x)dx,$$

provided this limit exists. Similar definitions apply to

$$\int_a^{-\infty} f(x)dx, \text{ and to } \int_{-\infty}^\infty f(x)dx.$$

All such definite integrals as the above are said to be "improper," for example $\int_0^\infty \frac{\sin x}{x}dx$ is improper in two ways. It means

$$\underset{h=\infty}{L_t}\ \underset{\epsilon=0}{L_t}\int_\epsilon^h \frac{\sin x}{x}dx,$$

in which the positive number ϵ is first diminished indefinitely, and the positive number h is afterwards increased indefinitely.

The "theorems of the mean" (§ 16) require modification when the integrals are improper (cf. the article FOURIER'S SERIES).

When the improper definite integral of a function which becomes, or tends to become, infinite, exists, the integral is said to be "convergent." If $f(x)$ tends to become infinite at a point c in the interval between a and b, and the expression (1) does not exist, then the expression $\int_a^b f(x)dx$, which has no value, is called a "divergent integral," and it may happen that there is a definite value for

$$L_t\left\{\int_a^{c-\epsilon} f(x)dx + \int_{c+\epsilon'}^b f(x)dx\right\}$$

provided that ϵ and ϵ' are connected by a definite relation, and both, remaining positive, tend to limit zero. The value of the above limit is then called a "principal value" of the divergent integral. Cauchy's principal value is obtained by making $\epsilon' = \epsilon$, *i.e.*, by taking the omitted interval so that the infinity is at its middle point. A divergent integral which has one or more principal values is sometimes described as "semi-convergent."

18. *Functions of several Variables.*—We have already explained what is meant by the domain of the argument and the rule of calculation of a function of several independent variables, by the limit of such a function at a point, by a function extrinsically defined or tending to become infinite. We shall now suppose that the domain of the argument is a homogeneous part of the numerical

continuum of n dimensions, with the possible exception of isolated points. The definition of a continuous function admits of immediate extension to functions of several variables, but then it is to be noted that a function of n variables may be a continuous function of each set of r variables $(r < n)$ when the rest are kept constant, without being a continuous function of the n variables; more generally the function may be continuous in a restricted domain. The definition of partial differentiation presents no difficulty. The extension of the theorem of intermediate value (§ 13) leads to the theorem of the total differential; for two variables x, y the theorem is that there exist numbers θ and η between 0 and 1, for which

$$f(a+h,\ b+k)-f(a,\ b)=hf_x(a+\theta h,\ b+k)+kf_y(a,\ b+\eta k),$$

provided that the function $f(x, y)$ has continuous partial differential coefficients, $f_x(x, y)$ and $f_y(x, y)$, at all points with a x in the interval between a and $a+h$, and a y in the interval between b and $b+k$. In regard to higher differential coefficients the theorem expressed by $\frac{\partial}{\partial x}\frac{\partial f}{\partial y}=\frac{\partial}{\partial y}\frac{\partial f}{\partial x}$ holds, provided one of the first partial differential coefficients, say $\frac{\partial f}{\partial x}$, and also the corresponding second partial differential coefficient, $\frac{\partial}{\partial y}\frac{\partial f}{\partial x}$, are continuous at the point (x, y). Taylor's theorem, with a remainder after n terms, can be extended to a function of several variables, provided all the partial differential coefficients up to the nth order inclusive are continuous.

With a view to the establishment of the notion of integration through a domain, we must define the "extent" of the domain. Take first a domain consisting of the point a and all the points x for which $| x-a | \leqq \frac{1}{2}h$, where h is a chosen positive number; the extent of this domain is h^n, n being the number of variables; such a domain may be described as "square," and the number h may be called its "breadth"; it is a homogeneous part of the numerical continuum of n dimensions, and its boundary consists of all the points for which $| x-a | = \frac{1}{2}h$. Now the points of any domain, which does not extend to an infinite distance, may be assigned to a finite number m of square domains of finite breadths, so that every point of the domain is either within one of these square domains or on its boundary, and so that no point is within two of the square domains; also we may devise a rule by which, as the number m increases indefinitely, the breadths of all the square domains are diminished indefinitely. When this process is applied to a homogeneous part, H of the numerical continuum C_n, then, at any stage of the process, there will be some square domains of which all the points belong to H, and there will generally be others of which some, but not all, of the points belong to H. As the number m is increased indefinitely the sums of the extents of both these categories of square domains will tend to definite limits, which cannot be negative; when the second of these limits is zero the domain H is said to be "measurable," and the first of these limits is its "extent"; it is independent of the rule adopted for constructing the square domains and contracting their breadths. The notion thus introduced may be adapted by suitable modifications to continua of lower dimensions in C_n.

The integral of a function $f(x)$ through a measurable domain H, which is a homogeneous part of the numerical continuum of n dimensions, is defined in just the same way as the integral through an interval, the extent of a square domain taking the place of the difference of the end-values of a partial interval; and the condition of integrability takes the same form as in the simple case. In particular, the condition is satisfied when the function is continuous throughout the domain. The definition of an integral through a domain may be adapted to any domain of measurable extent. The extensions to "improper" definite integrals may be made in the same way as for a function of one variable; in the particular case of a function which tends to become infinite at a point in the domain of integration, the point is enclosed in a partial domain which is omitted from the integration, and a limit is taken when the extent of the omitted partial domain is diminished indefinitely; a divergent integral may have different (principal) values for different modes of contracting the extent of the omitted partial domain. In applications to mathematical physics great importance attaches to convergent integrals and to principal values of divergent integrals. Delicate questions arise as to the possibility of representing the integral of a function of n variables through a domain H_n, as a multiple integral, of evaluating it by successive integrations with respect to the variables one at a time, and of interchanging the order of such integrations. These questions have been discussed very completely by C. Jordan, and we may quote the result that all the transformations in question are valid when the function is continuous throughout the domain. The same investigations may be applied to answer the questions of the validity of differentiation and integration of an integral with respect to a parameter by performing the like processes on the subject of integration. Taking for simplicity the case of a function of one variable x integrated in the interval between a and b, the parameter being allowed to vary in an interval containing the value α, the process of differentiation under the sign of integration certainly succeeds for α, if the function of x involving the parameter α becomes a function of x and y which is continuous in a domain consisting of all points (x, y) for which x lies between a and b, and y lies between $\alpha+k$ and $\alpha-k$, where k may be as small as we please. The corresponding theorem for integration under the sign of integration can be stated without difficulty. The condition of continuity in the domain of the increased number of variables is sufficient though it is not necessary. When the domain extends to an infinite distance additional conditions, restricting the manner of approach of the function to zero at infinite distances, are requisite for the validity of the processes.

19. *Representation of Functions in general: Series.*—Rational functions are represented by rational algebraic expressions. Some, but not all, implicit algebraic functions which are not rational can be represented rationally in terms of fractional powers of rational algebraic expressions. For the representation of all other one-valued functions of a real variable recourse must be had to limiting processes. We may have functions represented by infinite series, infinite products, definite integrals, or by limits of rational functions of two or more variables in a domain in which all but one of them vary. As an example of the last-named method

$$\underset{y=\infty}{Lt}\ \frac{xy}{x^2y+1}$$

represents a function of x, which vanishes at $x=0$, and at all other points has the value of $1/x$. The two definitions of the Γ function as a definite integral and as an infinite product may serve as examples of the representation of functions by such means. In another method, elaborated by T. Brodén, a continuous function is arrived at graphically, by beginning with a function having a graph in the form of a polygon, and interpolating additional angular points in an ordered sequence without limit. But much the most important method is that of series. From a sequence of numbers a_r, $(r=0, 1, \ldots)$ we may form a new sequence s_n, $(n=0, 1, \ldots)$ by the rule $s_n=\sum_{r=0}^{n} a_r$. If the new sequence has a limit s at $n=\infty$ (§ 6), the "infinite series of numbers" $\sum_{r=0}^{\infty} a_r$ "converges," and s is its "sum." If the series $\sum_{r=0}^{\infty} | a_r |$ also converges, the series $\sum_{r=0}^{\infty} a_r$ is said to converge "absolutely"; otherwise its convergence is "conditional." The importance of this distinction lies in the fact that the sum of an absolutely convergent series is independent of the order of its terms, but this is not the case for a conditionally convergent series (cf. the article SERIES, *Ency. Brit.* vol. xxi.). The numbers a_r may be the values at a point a of an infinite aggregate of functions of a variable x, represented in a domain containing a by analytical expressions $f_r(x)$, $(r=0, 1, \ldots)$. The analytical expression $f_0(x)+f_1(x)+\ldots$ is then called an "infinite series of functions," and the aggregate of the points a at which it converges form the "domain of convergence." The expression represents a function in this domain.

20. *Power Series.*—Taylor's theorem leads in certain cases to a representation of a function by an infinite series. We have under certain conditions (§ 14)

$$f(x)=f(a)+\sum_{r=1}^{n-1}\frac{(x-a)^r}{r!}f^{(r)}(a)+R_n;$$

and this becomes

$$f(x)=f(a)+\sum_{r=1}^{\infty}\frac{(x-a)^r}{r!}f^{(r)}(a), \qquad (1)$$

provided that (α) a positive number k can be found so that at all points in the interval between a and $a+k$ (except these points) $f(x)$ has continuous differential coefficients of all finite orders, and at a has progressive differential coefficients of all finite orders; (β) Cauchy's form of the remainder $\frac{(x-a)^n}{(n-1)!}(1-\theta)^{n-1}f^{(n)}\{a+\theta(x-a)\}$ has the limit zero when n increases indefinitely, for all values of θ between 0 and 1, and for all values of x in the interval between a and $a+k$, except possibly $a+k$. When these conditions are satisfied, the series (1) represents the function at all points of the interval between a and $a+k$, except possibly $a+k$, and the function is "analytic" (§ 14) in this domain. Obvious modifications admit of extension to an interval between a and $a-k$, or between $a-k$ and $a+k$. When a series of the form (1) represents a function it is called "the Taylor's series for the function."

Taylor's series is a power series, *i.e.*, a series of the form

$$\sum_{n=0}^{\infty} a_n(x-a)^n.$$

As regards power series we have the following theorems:

(1) If the power series converges at any point except a there is a number k which has the property that the series converges absolutely in the interval between $a-k$ and $a+k$, with the possible exception of one or both end-points.

(2) The power series represents a continuous function in its domain of convergence (the end-points may have to be excluded).

(3) This function is analytic in the domain, and the power series representing it is the Taylor's series for the function.

The theory of power series has been developed chiefly from the point of view of the theory of functions of complex variables.

21. *Uniform Convergence.*—We shall suppose that the domain of convergence of an infinite series of functions is an interval with the possible exception of isolated points. Let $f(x)$ be the sum of the series at any point x of the domain, and $f_n(x)$ the sum of the first $n+1$ terms. The condition of convergence at a point a is that, after any positive number ϵ, however small, has been specified, it must be possible to find a number n so that $| f_m(a)-f_p(a) | < \epsilon$ for all values of m and p which exceed n, and the sum, $f(a)$, is the limit of the sequence of numbers $f_n(a)$ at $n=\infty$. The convergence is said to be "uniform" in an interval if, after specification of ϵ, the same number n suffices at all points of the interval to make $| f(x)-f_m(x) | < \epsilon$ for all values of m which exceed n. The numbers n corresponding to any ϵ are all finite, but, when ϵ is less than some fixed finite number, they may have an infinite superior limit (§ 7); when this is the case there must be at least one point, α, of the interval which has the property that, whatever number N we take, ϵ can be taken so small that, at some point in the neighbourhood of α, n must be taken $>N$ to make $| f(x)-f_m(x) | < \epsilon$ when $m>n$; then the series does not converge uniformly in the neighbourhood of α. This distinction may be otherwise expressed thus:—Choose a first and ϵ afterwards, then the number n is finite; choose ϵ first and allow a to vary, then the number n becomes a function of a, which may tend to become infinite, or may remain below a fixed number; if such a fixed number exists, however small ϵ may be, the convergence is uniform.

As regards series whose terms represent continuous functions we have the following theorems:

(1) If the series converges uniformly in an interval it represents a function which is continuous throughout the interval.

(2) If the series represents a function which is discontinuous in an interval it cannot converge uniformly in the interval.

(3) A series which does not converge uniformly in an interval may nevertheless represent a function which is continuous throughout the interval.

(4) A power series converges uniformly in any interval contained within its domain of convergence, the end-points being excluded.

(5) If $\sum_{r=0}^{\infty} f_r(x)=f(x)$ converges uniformly in the interval between a and b

$$\int_a^b f(x)dx=\sum_{r=0}^{\infty}\int_a^b f_r(x)dx,$$

or a series which converges uniformly may be integrated term by term.

(6) If $\sum_{r=0}^{\infty} f'_r(x)$ converges uniformly in an interval, then $\sum_{r=0}^{\infty} f_r(x)$ converges in the interval, and represents a continuous differentiable function, $\phi(x)$; in fact we have

$$\phi'(x)=\sum_{r=0}^{\infty} f'_r(x),$$

or a series can be differentiated term by term if the series of derived functions converges uniformly.

A series whose terms represent functions which are not continuous throughout an interval may converge uniformly in the interval. If $\sum_{r=0}^{\infty} f_r(x), =f(x)$, is such a series, and if all the functions $f_r(x)$ have limits at a, then $f(x)$ has a limit at a, which is $\sum_{r=0}^{\infty} \underset{x=a}{Lt} f_r(x)$. A similar theorem holds for limits on the left or on the right.

22. *Fourier's Series.*—An extensive class of functions admit of being represented by series of the form

$$a_0+\sum_{n=1}^{\infty}\left(a_n\cos\frac{n\pi x}{c}+b_n\sin\frac{n\pi x}{c}\right), \qquad \text{(i.)}$$

and the rule for determining the coefficients a_n, b_n of such a series, in order that it may represent a given function

$f(x)$ in the interval between $-c$ and c, was given by Fourier, viz., we have

$$a_0 = \frac{1}{2c}\int_{-c}^{c} f(x)dx, \quad a_n = \frac{1}{c}\int_{-c}^{c} f(x)\cos\frac{n\pi x}{c}dx,$$

$$b_n = \frac{1}{c}\int_{-c}^{c} f(x)\sin\frac{n\pi x}{c}dx.$$

The interval between $-c$ and c may be called the "periodic interval," and we may replace it by any other interval, *e.g.*, that between 0 and 1, without any restriction of generality. When this is done the sum of the series takes the form

$$\underset{n=\infty}{Lt}\int_0^1 \sum_{r=-n}^{r=n} f(z)\cos\{2r\pi(z-x)\}dz,$$

and this is

$$\underset{n=\infty}{Lt}\int_0^1 f(z)\frac{\sin\{(2n+1)(z-x)\pi\}}{\sin\{(z-x)\pi\}}dz. \qquad \text{(ii.)}$$

Fourier's theorem is that, if the periodic interval can be divided into a finite number of partial intervals within each of which the function is ordinary (§ 15), the series represents the function within each of those partial intervals. In Fourier's time a function of this character was regarded as completely arbitrary. By a discussion of the integral (ii.) based on the Second Theorem of the Mean (§ 16) it can be shown that, if $f(x)$ has restricted oscillation in the interval (§ 11), the sum of the series is equal to $\frac{1}{2}\{f(x+0)+f(x-0)\}$ at any point x within the interval, and that it is equal to $\frac{1}{2}\{f(+0)+f(1-0)\}$ at each end of the interval. (See the article FOURIER'S SERIES.) It therefore represents the function at any point of the periodic interval at which the function is continuous (except possibly the end-points), and has a definite value at each point of discontinuity. The condition of restricted oscillation includes all the functions contemplated in the statement of the theorem and others. Further, it can be shown that, in any partial interval throughout which $f(x)$ is continuous, the series converges uniformly, and that no series of the form (i.), with coefficients other than those determined by Fourier's rule, can represent the function at all points, except points of discontinuity, in the same periodic interval. The result can be extended to a function $f(x)$ which tends to become infinite at a finite number of points α of the interval, provided (1) $f(x)$ tends to become determinately infinite at each of the points α, (2) the improper definite integral of $f(x)$ through the interval is convergent, (3) $f(x)$ has not an infinite number of discontinuities or of maxima or minima in the interval.

23. *Representation of Continuous Functions by Series.*—If the series for $f(x)$ formed by Fourier's rule converges at the point a of the periodic interval, and if $f(x)$ is continuous at a, the sum of the series is $f(a)$; but it has been proved by P. du Bois Reymond that the function may be continuous at a, and yet the series formed by Fourier's rule may be divergent at a. Thus some continuous functions do not admit of representation by Fourier's series. All continuous functions, however, admit of being represented with arbitrarily close approximation in either of two forms, which may be described as "terminated Fourier's series" and "terminated power series," according to the two following theorems:—

(1) If $f(x)$ is continuous throughout the interval between 0 and 2π, and if any positive number ϵ however small is specified, it is possible to find an integer n, so that the difference between the value of $f(x)$ and the sum of the first n terms of the series for $f(x)$, formed by Fourier's rule with periodic interval from 0 to 2π, shall be less than ϵ at all points of the interval. This result can be extended to a function which is continuous in any given interval.

(2) If $f(x)$ is continuous throughout an interval, and any positive number ϵ however small is specified, it is possible to find an integer n and a polynomial in x of the nth degree, so that the difference between the value of $f(x)$ and the value of the polynomial shall be less than ϵ at all points of the interval.

Expansions in series of the kinds described in the above theorems (1) and (2) are called "asymptotic expansions." Suppose that $f_0(x)+f_1(x)+\dots$ is an infinite series of functions which does not converge in a certain domain; it may happen that, after any number ϵ, however small, is specified, an integer n can be found so that, at any point a of the domain, $|f(a)-\sum_{r=0}^{n} f_r(a)|<\epsilon$; but it will also happen that, after any number N, however great, is specified, an integer $n'(>n)$ can be found so that $|\sum_{r=0}^{m} f_r(a)|>\text{N}$ for all values of m which exceed n'. The divergent series $f_0(x)+f_1(x)+\dots$ is then an asymptotic expansion for the function $f(x)$.

Again it can be proved that, if $f(x)$ is continuous throughout a given interval, polynomials in x of finite degrees can be found, so as to form an infinite series of polynomials whose sum is equal to $f(x)$ at all points of the interval. Methods of representation of continuous functions by infinite series of rational fractional functions have also been devised.

Particular interest attaches to continuous functions which are not differentiable. Weierstrass gave as an example the function represented by the series $\sum_{n=0}^{\infty} a^n\cos(b^n x\pi)$, where a is positive and less than unity, and b is an odd integer exceeding $(1+\frac{3}{2}\pi)/a$. It can be shown that this series is uniformly convergent in every interval, and that the continuous function $f(x)$ represented by it has the property that there is, in the neighbourhood of any point x_0, an infinite aggregate of points x', having x_0 as a limiting point, for which $\{f(x')-f(x_0)\}/(x'-x_0)$ tends to become infinite with one sign when $x'-x_0$ approaches zero through positive values, and infinite with the opposite sign when $x'-x_0$ approaches zero through negative values. Accordingly the function is not differentiable at any point. The definite integral of such a function $f(x)$ through the interval between a fixed point and a variable point x, is a continuous differentiable function $F(x)$, for which $F'(x)=f(x)$; and, if $f(x)$ is one-signed throughout any interval, $F(x)$ is monotonous throughout that interval, but yet $F(x)$ cannot be represented by a curve; in any interval, however small, the tangent would have to take the same direction for infinitely many points, and yet there is no interval in which the tangent has everywhere the same direction. Further, it can be shown that all functions which are everywhere continuous and nowhere differentiable are capable of representation by series of the form $\Sigma a_n\phi_n(x)$, where Σa_n is an absolutely convergent series of numbers, and $\phi_n(x)$ is an analytic function whose absolute value never exceeds unity.

24. *Interchange of Limiting Operations.*—When we require to perform any limiting operation upon a function which is itself represented by the result of a limiting process, the question of the possibility of interchanging the order of the two processes always arises. In the more elementary problems of analysis it usually happens that such an interchange is possible; but in general it is not possible, or, in other words, the performance of the two processes in different orders may lead to two different results, or the performance of them in one of the two orders may lead to no result. The fact that the inter-

change is possible under suitable restrictions for a particular class of cases is a theorem to be proved. Among examples of such interchanges we have the differentiation and integration of an infinite series term by term (§ 21), and the differentiation and integration of a definite integral with respect to a parameter by performing the like processes upon the subject of integration (§ 18). As a last example we may take the limit of the sum of an infinite series of functions at a point in the domain of convergence. Suppose that the series $\sum_{r=0}^{\infty} f_r(x)$ represents a function $f(x)$ in an interval containing a point a, and that each of the functions $f_r(x)$ has a limit at a. If we first put $x=a$, and then sum the series, we have the value $f(a)$; if we first sum the series for any x, and afterwards take the limit of the sum at $x=a$, we have the limit of $f(x)$ at a; if we first replace each function $f_r(x)$ by its limit at a, and then sum the series, we may arrive at a value different from either of the foregoing. If the function $f(x)$ is continuous at a, the first and second results are equal; if the functions $f_r(x)$ are all continuous at a, the first and third results are equal; if the series is uniformly convergent, the second and third results are equal. This last case is an example of the interchange of the order of two limiting operations, and a sufficient, though not always a necessary, condition, for the validity of such an interchange will usually be found in some suitable extension of the idea of uniform convergence.

Fundy, Bay of, an inlet of the North Atlantic, separating New Brunswick from Nova Scotia. It is 145 miles long, 48 miles wide at the mouth and gradually narrows towards the head. It is remarkable for the great rise and fall of the tide, which at the head of the bay is about 55 feet. At spring tides the water in the Bay of Fundy is 19 feet higher than it is in Bay Verte, in Northumberland Strait, only 15 miles distant. Large areas of fertile marshes are situated at the head of the bay, and the remains of a submerged forest show that the land has subsided in the latest geological period at least 40 feet.

Fünfhaus, formerly a suburb of Vienna, but, since 1891, incorporated with the Austrian capital, of which it forms the 15th Ward. In 1890 the population was 44,162; in 1900, 45,371.

FUNGI.

FUNGI in the broad sense include all the lower cellular Cryptogams devoid of chlorophyll, which arise from spores, and the thallus of which is either unicellular or composed of branched or unbranched tubes or cell-filaments, with apical growth (hyphæ), or of more or less complex wefted sheets or tissue-like masses of such (mycelium). The latter may in certain cases attain large dimensions, and even undergo cell-divisions in their interior, resulting in the development of true tissues. The spores, which may be uni- or multi-cellular, are either abstricted free from the ends of hyphæ (acrogenous), or formed from segments in their course (*Chlamydospores*), or from protoplasm in their interior (endogenous). The want of chlorophyll restricts their mode of life—which is rarely aquatic—since they are therefore unable to decompose the carbon dioxide of the atmosphere, and renders them dependent on other plants or (rarely) animals for their carbonaceous food-materials. These they obtain usually in the form of carbohydrates from the dead remains of other organisms, or in this or other forms from the living cells of their hosts; in the former case they are termed *Saprophytes*, in the latter *Parasites*. While some moulds (*Penicillium*, *Aspergillus*) can utilize almost any organic food-materials, other Fungi are more restricted in their choice—*e.g.*, insect-parasites, horn- and feather-destroying Fungi, and parasites generally. It was formerly the custom to include with the Fungi the Schizomycetes or Bacteria, and the Myxomycetes or Mycetozoa; but the peculiar mode of growth and division, the cilia, spores, and other peculiarities of the former, and the emission of naked amœboid masses of protoplasm, which creep and fuse to streaming plasmodia, with special modes of nutrition and spore-formation of the latter, have led to their separation as groups of organisms independent of the true Fungi. On the other hand, Lichens, previously regarded as autonomous plants, are now known to be dual organisms—Fungi symbiotic with Algæ.

The number of species in 1889 was estimated by Saccardo at about 32,000, but of these 8500 were so-called *Fungi imperfecti*—*i.e.*, forms of which we only know certain stages, such as conidia, pycnidia, &c., and which there are reasons for regarding as merely the corresponding stages of higher forms. Saccardo also included about 400 species of Myxomycetes and 650 of Schizomycetes. Allowing for these and for the cases, undoubtedly not few, where one and the same fungus has been described under different names, we obtain Schroeter's estimate (in 1892) of 20,000 species. In illustration of the very different estimates that have been made, however, may be mentioned that of De Bary in 1872 of 150,000 species, and that of Cooke in 1895 of 40,000, and Massee in 1899 of over 50,000 species, the fact being that no sufficient data are as yet to hand for any accurate census. As regards their geographical distribution, Fungi, like flowering plants, have no doubt their centres of origin and of dispersal; but we must not forget that every exchange of wood, wheat, fruits, plants, animals, or other commodities involves transmission of Fungi from one country to another; while the migrations of birds and other animals, currents of air and water, and so forth, are particularly efficacious in transmitting these minute organisms. Against this, of course, it may be argued that parasitic forms can only go where their hosts grow, as is proved to be the case by records concerning the introduction of *Puccinia malvacearum*, *Peronospora viticola*, *Hemileia vastatrix*, &c. Some Fungi—*e.g.*, moulds and yeasts—appear to be distributed all over the earth. That the north temperate regions appear richest in Fungi may be due only to the fact that North America and Europe have been much more thoroughly investigated than other countries; it is certain that the tropics are the home of very numerous species. Again, the accuracy of the statement that the fleshy Agaricini, Polyporei, Pezizæ, &c., are relatively rarer in the tropics may depend on the fact that they are more difficult to collect and remit for identification than the abundantly recorded woody and coriaceous forms of these regions. When we remember that practically all Asia with the exception of parts of the Himalaya, Ceylon, and Java, the whole of Africa except the Cape and parts of Egypt and Algeria, and South America except a small stretch of the south-east coast, the Andes, and Brazil are practically unexplored as regards Fungi, that we know almost nothing of the Fungi of New Zealand, Canada, and the Pacific Islands, the West Indies, or even of those of Turkey, the greater part of Russia and Spain, and that new species are constantly being discovered in the United States, Australia, and Northern Europe—the best explored of all—it is clear that no very accurate census of Fungi can as yet be made, and no generalizations of value as to their geographical distribution are possible.

The existence of fossil Fungi is undoubted, though very few of the identifications can be relied on as regards species or genera. They extend back beyond the Carboniferous, where they occur as hyphæ, &c., preserved in the fossil woods, but the best specimens are probably those in amber and in siliceous petrifactions of more recent origin.

Organs.—Individual hyphæ or their branches often exhibit specializations of form. In many Basidiomycetes minute branches arise below the septa, their tips curve over the outside of the latter, and fuse with the cell above just beyond it, forming a *clamp-connexion*. Many parasitic hyphæ put out minute lateral branches, which pierce the cell-wall of the host and form a peg-like (*Trichosphæria*), sessile (*Cystopus*), or stalked (*Hemileia*), knot-like, or a more or less branched (*Peronospora*) or coiled (*Protomyces*) *haustorium*. In *Rhizopus* certain hyphæ creep horizontally on the surface of the substratum, and then anchor their tips to it by means of a tuft of short branches (*Appressorium*), the walls of which soften and gum themselves to it, then another branch shoots out from the tuft and repeats the process, like a strawberry runner. Appressoria are also formed by some parasitic Fungi, as a minute flattening of the tip of a very short branch (*Erysiphe*), or the swollen end of any hypha which comes in contact with the surface of the host (*Piptocephalis*, *Syncephalis*), haustoria piercing in each case the cell-wall below. In *Botrytis* the appressoria assume the form of dense tassels of short branches. In *Arthrobotrys* side-branches of the mycelium sling themselves around the host (*Tylenchus*) much as tendrils round a support.

Many Fungi (*Phallus*, *Agaricus*, *Fumago*, &c.) when strongly growing put out ribbon-like or cylindrical cords, or sheet-like mycelial plates of numerous parallel hyphæ, all growing together equally, and fusing by anastomoses, and in this way extend long distances in the soil, or over the surfaces of leaves, branches, &c. These mycelial strands may be white and tender, or the outer hyphæ may be hard and black, and very often the resemblance of the subterranean forms to a root is so marked that they are termed *Rhizomorphs*. The outermost hyphæ may even put forth thinner hyphæ, radiating into the soil like root-hairs, and the convergent tips may be closely appressed and so divided by septa as to resemble the root-apex of a higher plant (*Armillaria mellea*).

Sclerotia.—Fungi, like other plants, are often found to store up large quantities of reserve materials (oil, glycogen, carbohydrates, &c.) in special parts of their vegetative tissues, where they lie accumulated between a period of active assimilation and one of renewed activity, forming reserves to be consumed particularly during the formation of large fructifications. These reserve-stores may be packed away in single hyphæ or in swollen cells, but the hyphæ containing them are often gathered into thick cords or *mycelial strands* (*Phallus*, mushroom, &c.), or flattened and anastomosing ribbons and plates, often containing several kinds of hyphæ (*Merulius lacrymans*). In other cases the strands undergo differentiation into an outer layer with blackened, hardened cell-walls and a core of ordinary hyphæ, and are then termed *Rhizomorphs* (*Armillaria mellea*), capable not only of extending the fungus in the soil, like roots, but also of lying dormant, protected by the outer casing. Such aggregations of hyphæ frequently become knotted up into dense masses of interwoven and closely packed hyphæ, varying in size from that of a pin's head or a pea (*Peziza*, *Coprinus*) to that of a man's fist or head, and weighing 10 to 25 ℔ or more (*Polyporus Mylittæ*, *P. tumulosus*, *Lentinus Wœrmanni*, *P. Sapurema*, &c.). The interwoven hyphæ fuse and branch copiously, filling up all interstices. They also undergo cutting up by numerous septa into short cells, and these often divide again in all planes, so that a pseudoparenchyma results, the walls of which may be thickened and swollen internally, or hardened and black on the exterior. In many cases the swollen cell-walls serve as reserves, and sometimes the substance is so thickly deposited in strata as to obliterate the lumen, and the hyphæ become nodular (*Polyporus sacer*, *P. rhinoceros*, *Lentinus Wœrmanni*). The various Sclerotia, if kept moist, give rise to the fructifications of the Fungi concerned, much as a potato-tuber does to a potato-plant, and in the same way the reserve materials are consumed. They are principally Polyporei, Agaricini, Pezizæ; none are known among the Phycomycetes, Uredineæ, or Ustilagineæ. The functions of mycelial strands, Rhizomorphs, and Sclerotia are not only to collect and store materials, but also to extend the fungus, and in many cases similar strands act as organs of attack. The same functions of storage in advance of fructification are also exercised by the stromata so common in Ascomycetes.

Tissue Differentiations.—The simpler mycelia consist of hyphæ all alike and thin-walled, or merely differing in the diameter of the branches of various orders, or in their relations to the environment, some plunging into the substratum like roots, others remaining on its surface, and others (aërial hyphæ) rising into the air. Such hyphæ may be multicellular, or they may consist of simple tubes with numerous nuclei and no septa (*Phycomycetes*), and are then non-cellular. In the more complex tissue-bodies of higher Fungi, however, we find considerable differences in the various layers or strands of hyphæ.

An epidermis-like or cortical protective outer layer is very common, and is usually characterized by the close septation of the densely interwoven hyphæ and the thickening and dark colour of their outer walls (Sclerotia, *Xylaria*, &c.). Fibre-like hyphæ with the lumen almost obliterated by the thick walls occur in mycelial cords (*Merulius*). Latex-tubes abound in the tissues of *Lactarius*, *Stereum*, *Mycena*, *Fistulina*, filled with white or coloured milky fluids, and Istvanffi has shown that similar tubes with fluid or oily contents are widely spread in other Hymenomycetes. Sometimes fatty oil or watery sap is found in swollen hyphal ends, or such tubes contain coloured sap. *Cystidia* and *Paraphyses* may be also classed here. In *Merulius lacrymans* Hartig has observed thin-walled hyphæ with large lumina, the septa of which are perforated like those of sieve-tubes.

As regards its composition, the cell-wall of Fungi exhibits variations of the same kind as those met with in higher plants. While the fundamental constituent is a cellulose in many Mucorini and other Phycomycetes, in others bodies like pectose, callose, &c., commonly occur, and Wisselingh's researches show that chitin, a gluco-proteid common in animals, forms the main constituent in many cases, and is probably deposited directly as such, though, like the other substances, it may be mixed with cellulose. As in other cell-walls, so here the older membranes may be altered by deposits of various substances, such as resin, calcium oxalate, colouring matters; or more profoundly altered throughout, or in definite layers, by lignification, suberization (*Trametes*, *Dædalia*), or swelling to a gelatinous mucilage (*Tremella*, *Gymnosporangium*), while cutinization of the outer layers is common. One of the most striking alterations of cell-walls is that termed *carbonization*, in which the substance gradually turns black, hard, and brittle, as if charred—e.g., *Xylaria*, *Ustulina*, some sclerotia. At the other extreme the cell-walls of many Lichen-Fungi are soft and colourless, but turn blue in iodine, as does starch. The young cell-wall is always tenuous and flexible, and may remain so throughout, but in many cases thickenings and structural differentiations, as well as the changes referred to above, alter the primary wall considerably. Such thickening may be localized, and *pits* (e.g., *Uredospores*, septa of Basidiomycetes), *spirals*, *reticulations*, *rings*, &c. (capillitium fibres of *Podaxon, Calostoma, Battarrea*), occur as in the vessels of higher plants, while sculptured networks, pittings, and so forth are as common on fungus-spores as they are on pollen grains.

Cell-Contents.—The cells of Fungi, in addition to protoplasm, nuclei, and sap-vacuoles, like other vegetable cells, contain formed and amorphous bodies of various kinds. Among those directly visible to the microscope are oil drops, often coloured (*Uredineæ*) crystals of calcium oxalate (*Phallus, Russula*), proteid crystals (*Mucor, Pilobolus*, &c.), and resin (Polyporei). The oidia of Erysipheæ contain fibrosin bodies and the hyphæ of Saprolegnieæ cellulin bodies, but starch apparently never occurs. Invisible to the microscope, but rendered visible by reagents, are, glycogen (*Mucor*, Ascomycetes, yeast, &c.). In addition to these cell-contents we have good indirect evidence of the existence of large series of other bodies, such as proteids, carbohydrates, organic acids, alkaloids, enzymes, &c. These must not be confounded with the numerous substances obtained by chemical analysis of masses of the fungus, as there is often no proof of the manner of occurrence of such bodies, though we may conclude with a good show of probability that some of them also exist preformed in the living cell. Such are sugars (glucose, mannite, &c.), acids (acetic, citric, and a whole series of lichen-acids), aetherial oils and resinous bodies, often combined with the intense colours of Fungi and Lichens, and a number of powerful alkaloid poisons, such as Muscarin (*Amanita*), Ergotin (*Claviceps*), &c.

Among the enzymes already extracted from fungi are *invertases* (yeasts, moulds, &c.), which split cane-sugar, and other complex sugars with hydrolysis into simpler sugars such as dextrose and levulose; *diastases*, which convert starches into sugars (*Aspergillus*, &c.); *cytases*, which dissolve cellulose similarly (*Botrytis*, &c.); *peptases*, using the term as a general one for all enzymes which convert proteids into peptones and other bodies (*Penicillium*, &c.); *lipases*, which break up fatty oils (*Empusa, Phycomyces*, &c.); and *oxydases*, which bring about the oxidations and changes of colour observed in *Boletus*, &c. That such enzymes are formed in the protoplasm is evident from the behaviour of hyphæ, which have been observed to pierce cell-membranes, the chitinous coats of insects, artificial collodion films and layers of wax, &c. Whether the material which Buchner extracted from yeast-cells, finely ground and subjected to extremely high pressures, and which is capable of rapidly breaking down sugar to form carbon dioxide and alcohol, is, as he believes, a true enzyme, or merely finely divided protoplasmic remnants, is not yet clear; if it is an enzyme, its properties are remarkable. That a fungus can secrete more than one enzyme, according to the materials its hyphæ have to attack, has been shown by the extraction of diastase, inulase, trehalase, invertase, maltase, raffinase, malizitase, emulsin, trypsin, and lipase from *Aspergillus* by Bourquelot, and similar events occur in other Fungi. The same fact is indicated by the wide range of organic substances which can be utilized by *Penicillium* and other moulds, and by the behaviour of parasitic Fungi which destroy various cell-contents and tissues. Many of the coloured pigments of Fungi are fixed in the cell-walls or excreted to the outside (*Peziza æruginosa*). Matruchot has used them for staining the living protoplasm of other Fungi by growing the two together. Striking instances of coloured mycelia are afforded by *Corticium sanguineum*, blood red; *Elaphomyces Leveillei*, yellow-green; *Chlorosplenium æruginosum*, verdigris green; and the *Dematei*, brown or black.

Nuclei.—Although many Fungi have been regarded as devoid of nuclei, and all have not as yet been proved to contain them, the numerous investigations of recent years have revealed them in the cells of all forms thoroughly examined, and we are justified in concluding that the nucleus is as essential to the cell of a fungus as to that of other organisms. The hyphæ of many contain numerous, even hundreds of nuclei (Phycomycetes); those of others have several (*Aspergillus*) in each segment, or only two (*Exoascus*), or one (*Erysiphe*) in each cell. Even the isolated cells of the yeast plant have each one nucleus. As a rule the nuclei of the mycelium are very minute (1·5–2 μ in Phycomyces), but those of many asci and spores are large and easily rendered visible. As with other plants, so in Fungi the essential process of fertilization consists in the fusion of two nuclei, but owing to the absence of sexual organs from all but a very few Fungi, a peculiar interest attaches to certain nuclear fusions in the vegetative cells or in young spores of many forms, the significance of which is by no means clear. Thus in Ustilagineæ the Chlamydospores, in Uredineæ the Uredo-, Teleuto-, and Æcidiospores, each contain two nuclei when young which fuse as the spores mature. In many young asci a similar fusion of two or even four nuclei occurs, and also in basidia, in each case the nucleus of the Ascus or of the Basidium resulting from the fusion subsequently giving rise by division to the nuclei of the ascospores and basidiospores respectively. Since this fusion may occur in young asci which have arisen from a fertilized ascogonium (*Sphærotheca*) as well as in such as are not developed as the result of such a sexual process (*Exoascus*), it has been regarded as a secondary phenomenon, the true significance of which is still unexplained, and not as being itself the sexual act. Nuclear division may be accompanied by all the essential features of Karyokinesis (*Peziza Stevensoniana*), or may be direct (mushroom).

Spores.—No agreement has ever been arrived at regarding the consistent use of the term spore. This is apparently owing to the facts that too much has been attempted in the definition, and that differences arise according as we aim at a morphological or a physiological definition. Physiologically, any cell or group of cells separated off from a hypha or unicellular fungus, and capable of itself growing out—germinating—to reproduce the fungus, is a spore; but it is evident that so wide a definition does not exclude the ordinary vegetative cells of sprouting Fungi, such as yeasts, or small sclerotium like cell-aggregates of forms like *Coniothecium*. Morphologically considered, spores are marked by peculiarities of form, size, colour, place of origin, definiteness in number, mode of preparation, and so forth, such that they can be distinguished more or less sharply from the hyphæ which produce them. The only physiological peculiarity exhibited in common by all spores is that they germinate and initiate the production of a new fungus-plant. Whether a spore results from the sexual union of two similar gametes (*zygospore*) or from the fertilization of an egg-cell by the protoplasm of a male organ (*oospore*); or is developed asexually (*gonidium*) as a motile (*zoospore*) or a quiescent body cut off from a hypha (*conidium*) or developed along its course (*oidium* or *chlamydospore*), or in its protoplasm (*endospore*), are matters of importance which have their uses in the classification and terminology of spores, though in many respects they are largely of academic interest.

Klebs has recently attempted to divide spores into three categories as follows:—(1) *Kinospores*, arising by relatively simple cell-divisions and subserving rapid dissemination and propagation, *e.g.*, zoospores, conidia, endogonidia, stylospores, &c.; (2) *Paulospores*, due to simple rearrangement of cell contents, and subserving the persistence of the fungus through periods of exigency, *e.g.*, gemmæ, chlamydospores, resting-cells, cysts, &c.; (3) *Carpospores*, produced by a more or less complex formative process, often in special fructifications, and subserving either or both multiplication and persistence, *e.g.*, zygospores, oospores, Brand-spores, æcidiospores, ascospores, basidiospores, &c. Little or nothing is gained by these definitions, however, which are especially physiological. In practice these various kinds of spores of Fungi receive further special names in the separate groups, and names, moreover, which will appear, to those unacquainted with the history, to have been given without any consistency or regard to general principles; nevertheless, for ordinary purposes these names are far more useful in most cases, owing to their descriptive character, than the proposed new names which have been only partially accepted.

Sporophores.—In some of the simpler Fungi the spores are not borne on or in hyphæ which can be distinguished from the vegetative parts or mycelium, but in the vast majority of cases the sporogenous hyphæ either ascend free into the air or radiate into the surrounding water as distinct branches, or are grouped into special columns, cushions, layers, or complex masses obviously different in colour, consistency, shape, and other characters from the parts which gather up and assimilate the food-materials. The term "receptacle" sometimes applied to these spore-bearing hyphæ is better replaced by *Sporophore*. The sporophore is *obsolete* when the spore-bearing hyphæ are not sharply distinct from the mycelium, *simple* when the constituent hyphæ are isolated, and *compound* when the latter are conjoined. The chief distinctive characters of the sporogenous hyphæ are their orientation, usually vertical; their limited apical growth; their peculiar branching, form, colour, contents, consistency; and their spore-production. According to the characters of the last, we might theoretically divide them into *Conidiophores, Sporangiophores, Gametophores, Oïdiophores*, &c.; but since the two latter rarely occur, and more than one kind of spore or spore-case may occur on a sporophore, it is impossible to carry such a scheme fully into practice.

A simple sporophore may be merely a single short hypha, the end of which stops growing and becomes cut off as a conidium by the formation of a septum, which then splits and allows the conidium to fall. More generally the hypha below the septum grows forwards again, and repeats this process several times before the terminal conidium falls, and so a chain of conidia results, the oldest of which terminates the series (*Erysiphe*); when the primary branch has thus formed a *basipetal* series, branches may arise from below and again repeat this process, thus forming a tuft (*Penicillium*). Or the primary hypha may first swell at its apex, and put forth a series of short peg-like branches (*sterigmata*) from the increased surface thus provided, each of which develops a similar basipetal chain of conidia (*Aspergillus*), and various combinations of these processes result in the development of numerous varieties of exquisitely branched sporophores of this type (*Botrytis, Botryosporium, Verticillium*, &c.).

A second type is developed as follows:—The primary hypha forms a septum below its apex as before, and the terminal conidium, thus abstricted, puts out a branch at its apex, which starts as a mere point and rapidly swells to a second conidium; this repeats the process, and so on, so that we now have a chain of conidia developed in *acropetal* succession, the oldest being below, and, as in *Penicillium*, &c., branches put forth lower down may repeat the process (*Hormodendron*). In all these cases we may speak of simple *conidiophores*. The simple sporophore does not necessarily terminate in conidia, however. In *Mucor*, for example, the end of the primary hypha swells into a spheroidal head (*Sporangium*), the protoplasm of which undergoes segmentation into more or less numerous globular masses, each of which secretes an enveloping cell-wall and becomes a spore (*endospore*), and branched systems of sporangia may arise as before (*Thamnidium*). Such may be termed *Sporangiophores*. In *Sporodinia* the branches give rise also to short branches, which meet and fuse their contents to form *zygospores*. In *Peronospora*, *Saprolegnia*, &c., the ends of the branches swell up into sporangia, which develop zoospores in their interior (*zoosporangia*), or their contents become oospheres, which may be fertilized by the contents of other branches (*pollinodia*) and so form egg-cases (*oogonia*). Since in such cases the sporophore bears sexual cells, they are conveniently termed *gametophores*.

Compound sporophores arise when any of the branched or unbranched types of spore-bearing hyphæ described above ascend into the air in consort, and are more or less crowded into definite layers, cushions, columns, or other complex masses. The same laws apply to the individual hyphæ and their branches as to simple sporophores, and as long as the conidia, sporangia, gametes, &c., are borne on their external surfaces, it is quite consistent to speak of these as compound sporophores, &c., in the sense described, however complex they may become. Among the simplest cases are the sheet-like aggregates of sporogenous hyphæ in *Puccinia*, *Uromyces*, &c., or of basidia in *Exobasidium*, *Corticium*, &c., or of asci in *Exoascus*, *Ascocorticium*, &c. In the former, where the layer is small, it is often termed a *Sorus*, but where, as in the latter, the sporogenous layer is extensive, and spread out more or less sheet-like on the supporting tissues, it is more frequently termed a *Hymenium*. Another simple case is that of the columnar aggregates of sporogenous hyphæ in forms like *Stilbum*, *Coremium*, &c. These lead us to cases where the main mass of the sporophore forms a supporting tissue of closely crowded or interwoven hyphæ, the sporogenous terminal parts of the hyphæ being found at the periphery or apical regions only. Here we have the cushion-like type (*stroma*) of *Nectria* and many Pyrenomycetes, the clavate "receptacle" of *Clavaria*, &c., passing into the complex forms met with in *Sparassis*, *Xylaria*, *Polyporei*, and *Agaricini*, &c. In these cases the compound sporophore is often termed the *Hymenophore*, and its various parts demand special names (*Pileus*, *Stipes*, *Gills*, *Pores*, &c.) to denote peculiarities of distribution of the *Hymenium* over the surface.

Other series of modifications arise in which the tissues corresponding to the *stroma* invest the sporogenous hyphal ends, and thus enclose the spores, asci, basidia, &c., in a cavity. In the simplest case the *stroma*, after bearing its crop of conidia or oidia, develops ascogenous branches in the loosened meshes of its interior (e.g., *Onygena*). Another simple case is where the plane or slightly convex surface of the *stroma* rises at its margins and overgrows the sporogenous hyphal ends, so that the spores, asci, &c., come to lie in the depression of a cavity—e.g., *Solenia*, *Cyphella*—and even simpler cases are met with in *Mortierella*, where the zygospore is invested by the overgrowth of a dense mat of closely branching hyphæ, and in *Gymnoascus*, where a loose mat of similarly barren hyphæ covers in the tufts of asci as they develop.

In such examples as the above we may regard the hymenium (*Solenia*, *Cyphella*), zygospores, or asci as truly invested by later growth, but in the vast majority of cases the processes which result in the enclosure of the spores, asci, &c., in a "fructification" are much more involved, inasmuch as the latter is developed in the interior of hyphal tissues, which are by no means obviously homologous with a *stroma*. Thus in *Penicillium*, *Eurotium*, *Erysiphe*, &c., hyphal ends which are the initials of ascogenous branches, are invested by closely packed branches at an early stage of development, and the asci develop inside what has by that time become a complete investment. Whether a true sexual process precedes these processes or not does not affect the present question, the point being that the resulting spheroidal "fructification" (*Cleistocarp*, *Perithecium*) has a definite wall of its own not directly comparable with a stroma. In other cases (*Hypomyces*, *Nectria*) the perithecia arise on an already mature stroma, while yet more numerous examples can be given (*Poronia*, *Hypoxylon*, *Claviceps*, &c.) where the perithecia originate below the surface of a stroma formed long before. Similarly with the various types of conidial or oidial "fructifications," termed *Pycnidia*, *Spermogonia*, *Æcidia*, &c. In the simplest of these cases—e.g., *Fumago*—a single mycelial cell divides by septa in all three planes until a more or less solid clump results. Then a hollow appears in the centre owing to the more rapid extension of the outer parts, and into this hollow the cells lining it put forth short sporogenous branches, from the tips of which the spores (*Stylospores*, *Conidia*, *Spermatia*) are abstricted. In a similar way are developed the pycnidia of *Cicinnobolus*, *Pleospora*, *Cucurbitaria*, *Leptosphæria*, and others. In other cases (*Diplodia*, *Æcidium*, &c.) conidial or oidial "fructifications" arise by a number of hyphæ interweaving themselves into a knot, as if they were forming a *sclerotium*. The outer parts of the mass then differentiate as a wall or investment, and the interior becomes a hollow, into which hyphal ends grow and abstrict the spores. Much more complicated are the processes in a large series of "fructifications," where the mycelium first develops a densely-packed mass of hyphæ, all alike, in which labyrinths of cavities subsequently form by separation of hyphæ in the previously homogeneous mass, and the hymenium covers the walls of these cavities and passages as with a lining layer. Meanwhile differences in consistency appear in various strata, and a dense outer protective layer (*Peridium*), soft gelatinous layers, and so on are formed, the whole eventually attaining great complexity—*e.g.*, puff-balls, earth-stars, and various *Phalloideæ*.

Spore-distribution.—Ordinary conidia and similarly abstricted dry spores are so minute, light, and numerous that their dispersal is ensured by any current of air or water, and we also know that rats and other burrowing animals often carry them on their fur; similarly with birds, insects, slugs, worms, &c., on claws, feathers, proboscides, &c., or merely adherent to the slimy body. In addition to these accidental modes of dispersal, however, there is a series of interesting adaptations on the part of the fungus itself. Passing over the locomotor activity of zoospores (*Pythium*, *Peronospora*, *Saprolegnia*) we often find spores held under tension in sporangia (*Pilobolus*) or in asci (*Peziza*) until ripe, and then forcibly shot out by the sudden rupture of the sporangial wall under the pressure of liquid behind—mechanism comparable to that of a pop-gun, if we suppose air replaced by watery-sap. Even a single conidium, held tense to the last moment by the elastic cell-wall, may be thus shot forward by a spurt of liquid under pressure in the hypha abstricting it (e.g., *Empusa*), and similarly with basidiospores (*Coprinus*, *Agaricus*, &c.). A more complicated case is illustrated by *Sphærobolus*, where the entire mass of spores, enclosed in its own peridium, is suddenly shot up into the air like a bomb from a mortar by the elastic retroversion of a peculiar layer which, up to the last moment, surrounded the bomb, and then suddenly splits above, turns inside out, and drives the former as a projectile from a gun. Gelatinous or mucilaginous degenerations of cell-walls are frequently employed in the interests of spore dispersal. The mucilage surrounding endospores of *Mucor*, conidia of *Empusa*, &c., serve to gum the spore to animals. Such gums are formed abundantly in *pycnidia*, and, absorbing water, swell and carry out the spores in long *tendrils*, which emerge for days and dry as they reach the air, the glued spores gradually being set free by rain, wind, &c. In oidial chains (*Sclerotinia*) a minute double wedge of wall-substance arises in the middle lamella between each pair of contiguous oidia, and by its enlargement splits the separating lamella. These *disjunctors* serve as points of application for the elastic push of the swelling spore-ends, and as the connecting outer lamella of cell-wall suddenly gives way, the spores are jerked asunder. In many cases the slimy masses of spermatia (*Uredineæ*), conidia (*Claviceps*), basidiospores (*Phallus*, *Coprinus*), &c., emit more or less powerful odours, which attract flies or other insects, and it has been shown that bees carry the fragrant oidia of *Sclerotinia* to the stigma of *Vaccinium* and infect it, and that flies carry away the fœtid spores of *Phallus*, just as pollen is dispersed by such insects. Whether the strong odour of trimethylamine evolved by the spores of *Tilletia* attracts insects is not known.

Classification.—Modern workers are agreed that the vast majority of the Fungi proper fall principally into three great groups, the Phycomycetes, Ascomycetes, and Basidiomycetes, the differences of opinion between various authorities referring chiefly to the details of delimitation of subordinate groups within these, and the relations of these to one another. Even the extreme divergence between the views of De Bary and Brefeld permits this statement, since the principal differences between their schemes concern (1) the relations of origin of the Ascomycetes and Basidiomycetes to the Phycomycetes, (2) the position of the Ustilagineæ within the system, (3) the exact rank of the Uredineæ and their possible relations to Ascomycetes—their alliance with Basidiomycetes not being questioned, and (4) the delimitations of minor groups. Almost all authorities are agreed that Schizomycetes and Myxomycetes are independent groups not coming into the true Fungi at all, a view we adopt here.

When we come to examine the schemes of classification in detail, however, there are many points to be considered. Whether we take the system of Saccardo (1882–92), of

Brefeld and Von Tavel (1892), of Van Tieghem (1893), or of Schroeter (1892), the two former only of which have materially influenced modern mycology, the same truth comes out; each is a purely morphological scheme, and all agree in the main subdivisions, but differ in details as regards the delimitations of frontiers and the inter-relations of the subordinate groups. Saccardo's system is floristic, and designed apart from theory to facilitate the recognition of species, and the recording of synonyms. It has never been drawn up in tabular form, and admits numerous artificial devices to aid in the determination of imperfectly studied forms.

Brefeld's system, which has been more widely accepted than any other since De Bary, is based on (1) the denial of any trace of sexual organs in Ustilagineæ, Uredineæ, Ascomycetes and Basidiomycetes, or indeed in any fungi outside the group of Phycomycetes; (2) on the purely morphological interpretation of the homologies of spores, asci and sporangia, and basidia in the various groups; and (3) on theoretical conclusions from these interpretations as to the evolution of the higher groups from the lower. The following is a brief tabular survey of Brefeld's scheme, though in this form it does not clearly show the cross-connexions he assumes:—

A. **Phycomycetes.**—Alga-like Fungi, with unicellular thallus and sexual organs.

Class 1. OOMYCETES.—Sexual fructification in the form of Oospores; asexual in that of sporangia and conidia.

1. Antheridia and Oogonia as sporangia; asexual reproduction by means of sporangia:—*Monoblepharideæ.*
2. Antheridia reduced, Oogonia as sporangia; asexual reproduction by means of sporangia or conidia:—*Peronosporeæ, Ancylisteæ, Saprolegnieæ (? Chytridiaceæ).*
3. Antheridia and Oogonia reduced; asexual organs conidia:—*Entomophthoreæ.*

Class 2. ZYGOMYCETES.—Sexual fructification in the form of zygospores; asexual as sporangia and conidia.

(α) Exosporangial series:—

1. Sporangia only:—*Mucorinæ, Thamnideæ.*
2. Sporangia and conidia:—*Choanephoreæ.*
2. Conidia only:—*Chætocladieæ, Piptocephalideæ.*

(β) Carposporangial series:—*Rhizopeæ, Mortierelleæ.*

B. **Eumycetes.**—Higher Fungi, with segmented thallus and no sexual organs.

I. MESOMYCETES.—Intermediate forms between the Phycomycetes and Ascomycetes (Hemiasci) on the one hand, and between Phycomycetes and Basidiomycetes (Hemibasidii) on the other.

Class 3. HEMIASCI.—Fructification in the form of sporangia and conidia; sporangia ascus-like.

(α) Exohemiasci:—*Ascoideæ, Protomycetes.*

(β) Carpohemiasci:—*Theleboleæ.*

Class 4. HEMIBASIDII.—Fructification in the form of conidia, no sporangia; conidiophores basidium-like:—*Ustilageæ, Tilletiæ.*

II. MYCOMYCETES, including the vast majority of higher Fungi.

Class 5. ASCOMYCETES.—Fructification as sporangia and conidia; the sporangia definite, and termed Asci.

(α) *Exoasci.*—Asci free, *i.e.*, exoascous:—*Endomycetes, Taphrineæ, Saccharomycetes.*

(β) *Carpoasci.*—Asci enclosed in "fructifications," *i.e.*, carpoascous.

(1) Angiocarpous:—*Gymnoasceæ, Perisporiaceæ, Pyrenomycetes.*

(2) Hemiangiocarpous:—*Hysteriaceæ, Discomycetes, Helvellaceæ.*

Class 6. BASIDIOMYCETES.—Fructification as conidia, no sporangia; Conidiophores definite, and termed Basidia.

(α) *Protobasiomycetes.*—Basidia septate.

(i) Basidia tranversely septate.

(a) Gymnocarpic series:—*Uredineæ, Auricularieæ.*

(b) Angiocarpic series:—*Pilacreæ.*

(ii) Basidia vertically septate:—*Tremellineæ.*

(β) *Autobasidiomycetes.*—Basidia without septa.

(a) Gymnocarpic series:—*Dacryomycetes.*

(b) Angiocarpic:—*Gastromycetes, Phalloideæ.*

(c) Gymnocarpic and Hemiangiocarpic:—*Hymenomycetes.*

Put shortly, Brefeld regards it as proved that the sexual process, so well seen in many Phycomycetes (e.g., *Pythium*), and confirming their derivation from Algæ such as *Vaucheria*, gradually disappears within the limits of the group (e.g., *Peronospora, Phytophthora*), never to reappear in the Fungi. Contrary to the view of De Bary, who considered the Peronosporeæ as the starting-point for the great Ascomycetous series, and saw homologies between the sexual organs of the former and the organs initiating the inception of the cleistocarps of Erysipheæ, Brefeld regards the asci of the latter and of other Ascomycetes as simply sporangia which have become definite in shape, size, and the number of their spores, instead of being indefinite in these respects. In this view he is confirmed by his conviction that the sporangia of *Ascoidea* and *Protomyces* are on the way to become fixed and definite asci, and that the spore-producing cells of yeast have practically become such, while *Thelebolus* can be compared to a sporangium of *Mortierella* with the pedicel suppressed, and with an envelope of barren hyphæ comparable to the weft at the base of the latter. The obviously weak point in this argument is that no explanation is left for the difficult cases of Erysipheæ, *Dipodascus, Eremascus, Eurotium, Pyronema confluens, Collema,* and Laboulbeniaceæ, beyond mere denial that the structures observed are sexual organs, a denial which is seriously discounted by the observations of Harper on *Sphærotheca*, Bauer on *Collema*, and Thaxter on Laboulbeniaceæ, observations which in the opinion of many authorities establish beyond reasonable doubt that a sexual process does occur in these Fungi. It is even more difficult to reconcile this view with the facts of conjugation recently discovered in certain yeasts and described by Barker (*Proc. R.S.*, 1901). As regards Dangeard's views, see below. It is impossible in the space at command to do more than call attention to salient features in the principal groups.

A. PHYCOMYCETES.—Most of the recent work in this group concerns the studies in Cytology by Wager, Dangeard, &c., and the effect of external conditions on the formation of sporangia and zygotes by Klebs. Brefeld's speculations on the morphology have been referred to.

The *Oomycetes* are characterized by the general development of oospheres and pollinodia (antheridia), and in the typical cases by the fertilization of the former by motile antherozoids or nuclear contents discharged from the latter, the sexual organs being therefore dissimilar. Most of them are aquatic or parasitic, and interesting series of degenerations, loss of sexuality, motile and non-motile asexual spores occur. The group is of theoretical importance owing to their alga-like characters, and to the fact that De Bary regarded the oogonium with its oospheres and the pollinodium as the starting-point whence could be derived the sexual organs in certain Ascomycetes (*e.g.*, Erysipheæ), and thus of the whole Ascomycetous series of Fungi.

The *Saprolegnieæ* comprise about fifty to sixty species of chiefly aquatic Fungi. *Pythium* causes the "damping off" of seedlings, its hyphæ penetrating the cell-walls and rapidly destroying the watery tissues of the living plant, and also living on the dead remains. As the free ends emerge again into the air they swell up into spherical bodies, each of which may either fall off as a *conidium* and germinate by means of a germ tube, which again infects the host; or the germ-tube is put forth while the conidial swelling is still attached and itself swells up into a *zoosporangium*, the protoplasm in which develops swarm-spores. In the rotting tissues branches of the older mycelium similarly swell up at the ends (*oogonia*) and the contents become an *oosphere*, into which the protoplasmic contents of a short branch (*pollinodium* or "antheridial branch"), developed elsewhere on the hypha, are poured and fertilize it; the oosphere thus becomes an *oospore*. *Pythium* is of theoretical importance (1) as a fungus where true sexual reproduction is perfected, (2) as illustrating the dependence of zoospore-formation on the conditions and the indeterminate nature of *conidia*, and (3) as a case where the saprophytic and parasitic habits are alike practised. *Pythium* is also (4) the best type of the group, showing possible transition to the rest of the Saprolegnieæ, e.g., *Saprolegnia*, *Achlya*, &c., with cylindrical zoosporangia, and usually several oospores in the oogonia, and becoming parthenogenetic in extreme cases; the Peronosporineæ, distinguished chiefly by the more pronounced conidiophores and abstriction of conidia; and the Monoblepharideæ. Klebs has shown that the development of zoosporangia or of oogonia and pollinodia respectively in *Saprolegnia* is dependent on the external conditions; so long as a continued stream of suitable food-material is ensured the mycelium grows on without forming reproductive organs, but directly the supplies of nitrogenous and carbonaceous food fall below a certain degree of concentration sporangia are developed. Further reduction of the supplies of food effects the formation of oogonia. This explains the sequence of events in the case of a *Saprolegnia*-mycelium radiating from a dead fly in water. Those parts nearest the fly and best supplied develop barren hyphæ only; in a zone at the periphery, where the products of putrefaction dissolved in the water form a dilute but easily accessible supply, the zoosporangia are developed in abundance; oogonia, however, are only formed in the depths of this radiating mycelium, where the supplies of available food materials are least abundant. Saprolegnieæ do not form motile spermatozoids, statements alleging their existence not having been confirmed. Nevertheless, the nuclear masses passed over to the oospheres in those species in which fertilization is completed are doubtless homologous with spermatozoids. Each zoospore has one nucleus. The oogonia are multinucleate, reduction occurring before fertilization. The possible origin of this group from Siphoneæ—e.g., *Vaucheria*-like Algæ—has been suggested, and in connexion with the primitive forms—e.g., *Pythium*—there is much to be said in support of the supposition.

Peronosporeæ are a group of endophytic parasites—about 100 species—of great importance as comprising the agents of the vine mildew (*Plasmopara*), potato disease (*Phytophthora*), onion mildew (*Peronospora*), and several other epidemic diseases. The mycelium usually sends haustoria into the cells of the host, and puts out sharply marked conidiophores through the stomata, the branches of which abstrict numerous "conidia"; these either germinate directly, or their contents break up into zoospores, which escape and, after swarming for some time, germinate and infect the host-plant. This behaviour of the "conidia," sometimes as true conidial spores, sometimes as zoosporangia, may occur in one and the same species (*Cystopus candidus*, *Phytophthora infestans*), and reminds us of the similar phenomena in *Pythium*; in other cases the direct germination is characteristic for genera—e.g., *Bremia*, *Peronospora*—while others emit zoospores—e.g., *Plasmopara*, &c. In *Cystopus* the "conidia" are abstricted in basipetal chain-like series from the ends of hyphæ, which come to the surface in tufts and break through the epidermis as white pustule-like groups. Each conidium contains numerous nuclei, which do not fuse. The Peronosporineæ form oogonia, with one oosphere and pollinodia on the older mycelium, as in *Pythium*, and in some (*Phytophthora omnivora*) the fertilizing tube passes its protoplasm into the oosphere; in others no fertilization occurs (parthenogenesis), and in *Phytophthora infestans* the power of forming oogonia seems to have been lost altogether. Wager has shown that in *Cystopus* the pollinodium, which contains several nuclei, passes a nucleus into the oosphere, which unites with one of the hundred or more nuclei in the latter; the other nuclei pass to the periphery and take no part in the process. In the ripe oospore thirty-two nuclei are formed by repeated division. Magnus states that *Peronospora parasitica*, while unable to infect the older tissues of *Capsella*, is able to enter the hypertrophied cushions of these tissues infected by *Cystopus candidus*.

Monoblepharidineæ comprise three species resembling Saprolegnia, but the oogonium opens and exposes the one oosphere. The antheridial branch also opens and sets free a few amœboid spermatozoids, each with one flagellum. The spermatozoid creeps on the outside of the oogonium, enters the orifice, and fertilizes the oosphere. Resemblances between *Monoblepharis* and *Œdogonium* are interesting, as pointing to another possible origin of Fungi from Algæ.

Chytridineæ.—These parasitic and minute, chiefly aquatic, forms may be looked upon as degenerate Oomycetes, since a sexual process and feeble unicellular mycelium occur in some; or they may be regarded as series of primitive forms leading up to higher members. There is no means of deciding the question. Some authorities include them in Oomycetes, but on the whole their simple structure, minute size, usually uniciliate zoospores, and their negative characters justify their retention as a separate group. It contains less than 200 species, chiefly parasitic on or in Algæ and other water-plants or animals, of various kinds, or in other Fungi, seedlings, pollen, and higher plants. They are often devoid of hyphæ, or put forth fine protoplasmic filaments into the cells of their hosts. After absorbing the cell-contents of the latter, which it does in a few hours or days, the fungus puts out a sporangium, the contents of which break up into numerous minute swarm-spores, usually one-ciliate, rarely two-ciliate. Any one of these soon comes to rest on a host-cell, and either pierces it and empties its contents into its cavity, where the further development occurs (*Olpidium*), or merely sends in delicate protoplasmic filaments (*Rhizophydium*) or a short hyphal tube of, at most, two or three cells, which acts as a haustorium, the further development taking place outside the cell-wall of the host (*Chytridium*). In some cases resting spores are formed inside the host (*Chytridium*), and give rise to zoosporangia on germination. In a few species a sexual process is described, consisting in the conjugation of similar cells (*Zygochytrium*) or the union of two dissimilar ones (*Polyphagus*). In the development of distinct pollinodial and oogonial cells the allied Ancylistineæ show close alliances to *Pythium* and the Oomycetes. On the other hand, the uniciliate zoospores of *Polyphagus* have slightly amœboid movements, and in this and the pseudopodium-like nature of the protoplasmic processes, such forms suggest resemblances to the Myxomycetes. Opinions differ as to whether the Chytridineæ are degraded or primitive forms, and the group still needs critical revision. Many new forms will doubtless be discovered, as they are rarely collected on account of their minuteness. Some forms cause damping off of seedlings—e.g., *Olpidium Brassicæ*; others discoloured spots and even tumour-like swellings—e.g., *Synchytium Scabiosæ*, *S. Succisæ*, *Urophlyctis*, &c., on higher plants. Analogies have been pointed out between Chytridiaceæ and unicellular Algæ, such as Chlorosphæraceæ, Protococcaceæ, "Palmellaceæ," &c., some of which are parasitic, and suggestions may be entertained as to possible origin from such Algæ.

The *Zygomycetes* (*Mucorini*), of which nearly 150 species are described, have become especially important from a theoretical standpoint, since they furnish the series whence Brefeld derives the vast majority of the Fungi. They are characterized especially by the *zygospores*, but the asexual organs (*sporangia*) exhibit interesting series of changes, beginning with the typical sporangium of *Mucor* containing numerous endospores, passing to cases where, as in *Thamnidium*, these are accompanied with more numerous small sporangia (*sporangioles*) containing few spores, and thence to *Chætocladium* and *Piptocephalis*, where the sporangioles form but one spore and fall and germinate as a whole; that is to say, the monosporous sporangium has become a *conidium*, and Brefeld regards these and similar series of changes as explaining the relation of ascus to conidium in higher Fungi. According to his view, the ascus is in effect the *sporangium* with several spores, the conidium the *sporangiole* with but one spore, and that not loose but fused with the sporangiole wall. On this basis, with other interesting morphological comparisons, Brefeld erected his hypothesis that the Ascomycetes and Basidiomycetes diverge from the Zygomycetes, the former having particularly specialized the ascus (sporangial) mode of reproduction, the latter having specialized the conidial (indehiscent one-spored sporangiole) mode. In addition to sporangia and the conidial spores referred to, some Mucorini show a peculiar mode of vegetative reproduction by means of *Gemmæ* or *Chlamydospores*—*i.e.*, short segments of the hyphæ become stored with fatty reserves and act as spores. The gemmæ formed on submerged Mucors may bud like a yeast, and even bring about alcoholic fermentation in a saccharine solution.

The classification of the Mucorini depends on the prevalence and characters of the conidia, and of the sporangia and zygospores—*e.g.*, the presence or absence of a *columella* in the former, the formation of an investment round the latter. Most genera are saprophytes, but some—*Chætocladium*, *Piptocephalis*—are parasites on other Mucorini, and one or two are associated casually with the rotting of tomatoes and other fruits, bulbs, &c., the fleshy parts of which are rapidly destroyed if once the hyphæ gain entrance. Even more important is the question of mycosis in man and other animals, referred to species of *Mucor*, and recently investigated by Lucet and Costantin. Klebs's demonstration that transpiration is the important factor in determining the formation of sporangia, while zygote-development depends on totally different conditions, is valuable, as are also his other researches on *Sporodinia* and *Mucor*.

B. Eumycetes.—With the exception of Brefeld's re-grouping of the lower forms into Hemi-asci and Hemibasidii (Mesomycetes), it will be noticed that very little alteration has been brought about in the classification of the main groups.

I. Mesomycetes.

Hemi-asci.—This name was proposed by Brefeld to include a number of forms which in his opinion exhibit the transition from sporangium-bearing Phycomycetes to the true Ascomycetes. They are all small Fungi with a septate mycelium and no trace of sexual reproduction, the spores being developed in sporangia which resemble asci in most respects, but differ in being somewhat indefinite as regards the number of spores produced, and in form, size, and position. The group comprises a somewhat heterogeneous collection of types, and severe criticism may be passed on the retention of such genera as *Ascoidea*, *Protomyces*, *Thelebolus*, and (by some authors) *Saccharomyces*, &c., in one circle of alliance; the difficulties are evaded in part by Schroeter's device of separating *Saccharomycetes* and constituting a new group (Protoascineæ) of them and a few other forms. In *Ascoidea* and *Protomyces* the ascus-like sporangia are exposed (Exo-hemiasci), but in *Thelebolus* they are covered in by a web of hyphæ (Carpo-hemiasci).

Hemi-basidii, Ustilagineæ.—The Bunts and Smuts which damage our grain and fodder plants comprise about 400 species of internal parasites, found in all countries on herbaceous plants, and especially on Monocotyledons. They are remarkable for their dark spores developed in gall-like excrescences on the leaves, stems, &c., or in the fruits of the host. The discovery of the yeast-conidia of these Fungi, and their thorough investigation by Brefeld, have thrown new lights on the group, as also have the results elucidating the nature of the ordinary dark spores—Smuts, Bunt, &c.—which by their mode of origin and development are *Chlamydospores*. When the latter germinate a slender "promycelium" is put out; in *Ustilago* and its allies this is transversely septate, and bears lateral conidia (sporidia); in *Tilletia* and its allies non-septate, and bears a terminal tuft of conidia (sporidia). Brefeld regards the promycelium as a kind of *basidium*, bearing lateral or terminal conidia (comparable to *basidiospores*), but since the number of basidiospores is not fixed, and the basidium has not yet assumed very definite morphological characters, Brefeld terms the group *Hemi-basidii*, and regards them as a sort of half-way stage in the evolution of the true Basidiomycetes from Phycomycetes, the *Tilletia* type leading to the true basidium (Autobasidium), the *Ustilago* type to that of the Protobasidiomycetes, with lateral spores. The yeast-conidia, which bud off from the conidia or their resulting mycelium when sown in nutrient solutions, are developed in successive crops by budding exactly as in the yeast plant, but they cannot ferment sugar solutions. It is the rapid spread of these yeast-conidia in manure and soil waters which makes it so difficult to get rid of Smuts, &c., in the fields, and they, like the ordinary conidia, readily infect the seedling wheat, oats, barley, or other cereals. Infection in these cases can only occur in the seedling at the place where root and shoot meet, and the infecting hypha having entered the plant goes on living in it and growing up with it as if it had no parasitic action at all. When the flowers form, however, the mycelium sends hyphæ into the young ovaries and rapidly replaces the stores of sugar and starch, &c., which would have gone to make the grain, by the soot-like mass of spores so well known as *Smut*, &c. These spores adhere to the grain, and unless destroyed, by "steeping" or other treatment, are sown with it, and again produce sporidia and yeast-conidia which infect the seedlings. In other species the infection occurs elsewhere, the chief condition apparently being that the vulnerable tissue must be in the embryonic state.

II. Mycomycetes.

Ascomycetes.—Here the main groups are retained much as in older classifications, but an additional group, not regarded in Brefeld's scheme, the *Laboulbeniaceæ*, must be added owing to the importance they have attained in Thaxter's hands.

The *Exoasci* are usually regarded as comprising about 100 species of small Fungi, the mycelium of which is obsolete or septate and often breaks up into single cells, with a pronounced tendency to sprouting (yeast-forms). The asci are formed directly on the mycelium or by the direct conversion of the isolated cells, and are therefore fully exposed and devoid of any investment. They form the simplest of the Ascomycetes, the Endomycetes, comprising the true yeasts and their allies, being mostly ferment-Fungi with isolated four-spored asci, and the Taphrineæ, about fifty species of chiefly parasitic forms, having an endophytic mycelium, which develops eight-spored asci in layers breaking through the epidermis of the host-plant. Many of these Taphrineæ are important parasites—*e.g.*, Pocket plums and Witches' Brooms on Birches, &c., are due to their action. *Exoascus* and *Ascocorticium* present interesting parallels to *Exobasidium* and *Corticium* among the Basidiomycetes, the former having asci where the latter have basidia. Schroeter places the Endomycetes in a group by themselves (*Protoascineæ*) and the Taphrineæ in another, *Protodiscineæ*. Perhaps the term Proto-ascomycetes might be employed for both.

Saccharomyces, the genus into which the true yeasts which ferment various sugars and form endogenous spores are put, has attained an importance of late even beyond that to which it was brought by Pasteur's researches on alcoholic fermentation, chiefly owing to the exact results of the investigations of Hansen, who first applied the methods of pure cultures to the study of these organisms, and showed that many of the inconsistencies hitherto existing in the literature were due to the coexistence in the cultures of several species or races of yeasts morphologically almost indistinguishable, but physiologically very different. About fifty species of *Saccharomyces* are described more or less completely, but since many of these cannot be distinguished by the microscope, and some have been found to develop physiological races or varieties under special conditions of growth, the limits are still far too ill-defined for complete botanical treatment of the genus. A typical yeast is able to develop new cells by budding when submerged in a saccharine solution, and to ferment the sugar—*i.e.*, so to break up its molecules that, apart from small quantities used for its own substance, masses of it out of all proportion to the mass of yeast used become resolved into other bodies, such as carbon dioxide and alcohol, the process requiring little or no oxygen. Brefeld regards the budding process as the formation of *conidia*. Under other conditions, of which the temperature is an important one, the nucleus in the yeast-cell divides, and each daughter-nucleus again, and four *spores* are formed in the mother cell, a process obviously comparable to the typical development of ascospores in an ascus. Under yet other conditions the quiescent yeast-cells floating on the surface of the fermented liquor grow out into elongated sausage-shaped or cylindrical cells and branching cell-series, which mat together into mycelium-like *veils*. At the bottom of the fermented liquor the cells often obtain fatty contents and thick walls, and behave as resting cells (*chlamydospores*). The characters employed by experts for determining a species of yeast are the sum of its peculiarities as regards form and size; the shapes, colours, consistency, &c., of the colonies grown on certain definite media; the optimum temperature for spore-formation, and for the development of the *veils*, and the behaviour as regards the various sugars.

The following summary of some of the principal characteristics of half-a-dozen species will serve to show how such peculiarities can be utilized for systematic purposes:—

Species.	Optimum Temperature for		Characters of			Sugars Fermented and Products, &c.
	Spores.	Veils.	Fermentation.	Cells.	Spores.	
S. cerevisceæ I. . .	30°	20°–28°	High	Rounded	Globoid	Invert maltose and saccharose and form alcohol 4–6 vol. per cent.
S. Pastorianus I. .	27°–5°	26°–28°	Low	Rounded	Globoid	
S. ellipsoideus . .	25°	33°–34°	Low	Rounded	Globoid	
S. anomalus . .	28°–31°	?	High	Elliptical	Hat shaped	Ditto, and evolves fragrant ether.
S. Ludwigii . .	30°–31°	?	?	Elongated	Globoid	Will not invert maltose.
S. membranæfaciens	30°	?	High	Elongated	Globoid	Inverts neither maltose nor saccharose.

Two questions of great theoretical importance have been raised over and over again in connexion with yeasts, namely, (1) the morphological one as to whether yeasts are merely degraded forms of higher Fungi, as would seem implied by their tendency to form elongated, hypha-like cells in the veils, and their development of "ascospores" as well as by the wide occurrence of yeast-like "sprouting forms" in other Fungi (e.g., *Mucor*, Exoasci, Ustilagineæ, higher Ascomycetes and Basidiomycetes); and (2) the question as to the physiological nature and meaning of fermentation. With regard to the first question no satisfactory proof has as yet been given that Saccharomycetes are derivable by culture from any higher form, the recent statements to that effect not having been confirmed on re-examination by Klöcker and Schionning. At the same time there are strong grounds for insisting on the resemblances between *Endomyces*, a hyphal fungus bearing yeast-like asci, and such a form as *Saccharomyces anomalus*. Concerning the second question, the most recent investigations by E. Buchner show that by means of prolonged grinding, and the use of very high pressures, a something sufficiently soluble in, or miscible with, water to pass through fine filters can be obtained which causes sugar to break up into carbon dioxide and alcohol in the absence of living yeast-cells, and this has been confirmed by Green. The question whether this extracted body, which Buchner calls *Zymase*, is a true enzyme, or merely finely particulate protoplasm, has been much debated. The strongest arguments in favour of its enzyme nature are its extreme diffusibility or solubility in water, its passage through filters, and the statements that it can be dried and kept for short periods, and still retain its powers of exciting alcoholic fermentation on again distributing in water, and that it will act in presence of chloroform. In considering the bearing of these facts on the theory of fermentation proposed by Pasteur, and now so widely adopted, it must not be forgotten that although Buchner's discovery disposes of the view that alcoholic fermentation is a vital phenomenon inseparable from the presence of living yeast-cells, it does not preclude the reply that the alleged enzyme is a product of the living protoplasm, if not an integral part of it.

Whether *Schizo-saccharomyces*, a yeast which divides into two cells, which then fuse and produce spores, and *Zygo-saccharomyces*, a form in which the sporogenous cells conjugate before spore-formation, are true Saccharomycetes is still an open question. In any case, the behaviour of these genera reopens the question of the autonomy of the group.

Gymnoasceæ, which Fischer proposes to group with Aspergillaceæ, Onygenaceæ, and the truffle-like Elaphomycetes, &c., as a separate group, termed *Plectascineæ* in reference to the occurrence of the asci on irregular branches scattered throughout the interior of the very loose tissue, are kept as a separate group of about twenty species by Brefeld. They are remarkable for the loose investment of the ascigerous branches, and *Ctenomyces* for its habitat—old feathers.

The *Perisporiaceæ*, including the somewhat heterogeneous Erysipheæ, Perisporeæ, and Tuberaceæ, number probably about 1000 species. The interesting points regarding the sexuality of Erysipheæ are discussed elsewhere. Tuberaceæ comprises the underground truffles, some of which are symbiotic with the roots of trees, on which they form *Mycorhiza*. *Eurotium* (*Aspergillus*) has become still more classical since Klebs gave us a study of the conditions necessary for the development of its reproductive organs. *Onygena*, a remarkable horn-destroying fungus which long defied cultivation, has been shown by Marshall Ward to require the action of the digestive juices in an animal's stomach in order that the spores may germinate, and its life-history is now worked out. *Penicillium*, the common mould, which has played for the plant-physiologist the part that the frog does for the animal physiologist, has been shown to grow on the most unlikely poisonous substances —*e.g.*, solutions containing arsenic, copper, sulphuric acid, &c.— and has been found to form very different enzymes. It is an active agent in the destruction of wood, as shown by Marshall Ward. The significance of the "sexual organs" described by Brefeld and De Bary in this and in *Eurotium* still requires elucidation. *Aspergillus Oryzæ* plays an important part in saccharifying the starch of rice, maize, &c., by means of the abundant diastase it excretes, and, in symbiosis with a yeast which ferments the sugar thus formed, has long been used by the Japanese in the preparation of the alcoholic liquor, *saké*. The process has now been successfully introduced into European commerce. The Gymnoasceæ, Perisporiaceæ, and Pyrenomycetes are classed as Angiocarpous by Brefeld to emphasize the fact that their asci are developed in permanently closed fructifications (Cleistocarps), or in such as only open by an orifice above (Perithecia).

The *Discomycetes* in the wider sense, including the Hysteriaceæ, Phacidiaceæ, Helvellaceæ, &c., comprise not fewer than 4000, and probably nearer 5000 species, of which the well-known *Peziza*-form is the type, though extreme forms of Hysteriaceæ on the one hand and of Helvellaceæ on the other depart far from it in shape, &c.

Woronin's continued and beautiful work on *Sclerotinia* has led to much important information as to the parasitism of this group of Pezizæ. The conidia are fragrant, and carried by bees to the stigma of a bilberry; here they germinate with the pollen, and the hyphæ race the pollen-tubes down the style, and infest the ovules, where they develop sclerotia and mummify the fruits. From the sclerotium the Peziza-form develops. The conidia have remarkable disjunctors. One species is *heterœcious*, the only case known of heterœcism outside the Uredineæ. The Discomycetes and their immediate allies are termed Hemiangiocarpous, because however much their fructifications are closed at first, they ultimately open and expose the layers of asci (Apothecia).

Laboulbeniaceæ are a group of about 150 species of Fungi found on insects, especially beetles, and principally known in America from the researches of Thaxter. The plant is a small, dark brown, erect structure (receptacle) of a few cells, and 1–10 mm. high, attached to the insect by the lowermost end (foot), and easily mistaken for a hair or similar appendage of the insect. The receptacle ends above in *appendages*, each consisting of one or a few cells, some of which are the *male organs*, others the *female organs*, and others again may be barren *hairs*. The male organ (*antheridium*) consists of a few cells, the terminal one of which either abstricts from its end, or emits from its interior the non-motile *antherozoids*, reminding us of those of the Florideæ. The female organ is essentially a flask-shaped structure; the neck of the flask growing out as the *trichogyne*, and the belly composed of an axial *carpogenic cell* surrounded by investing cells, and with one cell (*trichophoric*) between it and the trichogyne. These three elements—trichogyne, trichophoric cell, and carpogenic cell—are regarded as the procarp. The antherozoids have been shown by Thaxter to fuse with the trichogyne, after which the axial cell below (*carpogenic cell*) undergoes divisions, and ultimately forms *asci* containing *ascospores*, while cells investing this form a *perithecium*, the whole structure reminding us essentially of the fructification of a Pyrenomycete. Many modifications in details occur, and the plants may be diœcious. No injury is done to the infested insects, and the importance of the type turns on the resemblances between the mode of fertilization referred to and that of the Red Seaweeds.

Basidiomycetes.—The principal advances in this group concern the discovery of accessory organs of reproduction—conidia and chlamydospores—and the important work on the Protobasidiomycetes, both initiated by Brefeld and his co-workers.

Uredineæ, of which nearly 2000 species are described, are intercellular parasites on higher plants, and so generally of some shade of orange-yellow or rusty-red, owing to oily cell-contents of such colours, that they are termed Rust Fungi, a designation the more apt since the myriads of spores dust off like iron-rust. Of the five different kinds of spores—Uredospores, Teleutospores, Sporidia, Æcidiospores, and Spermatia—the Teleutospore is the most constant, and the divisions into genera are based chiefly on its characters. It may consist of one, two, three, or more cells variously grouped, may germinate forthwith or only after a resting period, have specific markings on the walls, and so forth. The subdivisions of the larger genera depend on the coexistence of the Uredo- or Æcidium-form, or both, with the Teleutospores, and on their behaviour. The Teleutospores put forth on germination a promycelium, which is transversely septate and bears lateral conidia (sporidia), and so obviously resemble *Ustilago* in these respects that Brefeld names them accordingly—a chlamydospore putting forth a basidium which bears basidiospores. The close resemblances to the corresponding organs in Auriculariеæ have long been noticed, whence some authors regard Uredineæ as true protobasidiomycetes; their parasitism and other peculiarities of habit, and the frequent co-existence of other specialized chlamydospores (Uredo, Æcidium) and conidia (Spermatia) sufficiently distinguish them. The remarkable phenomenon of *Heterœcism*—*i.e.*, the development of one or more forms (Uredo- and Teleuto-spores) on one host, and others (Æcidium and Spermatia) on another host distantly related—is now known in about fifty species of several genera, of which the following are examples:—

Species.	Teleutspores on	Æcidium on
Coleosporium Senecionis	*Pinus*	*Senecio*
Melampsora Betulina	*Betula*	*Larix*
Calyptospora Gœppertiana	*Vaccinium*	*Abies*
Gymnosporium Sabinæ	*Juniperus*	*Pyrus*
Uromyces Pisi	*Pisum*, &c.	*Euphorbia*
Puccinia graminis	*Triticum*, &c.	*Berberis*
P. rubigo-vera	*Triticum*, &c.	*Anchusa*
P. coronata	*Avena*	*Rhamnus*
P. Phalaridis	*Digraphis*	*Arum*
P. Caricis	*Carex*	*Urtica*
Cronartium ribicolum	*Ribes*	*Pinus*
Chrysomyxa Rhododendri	*Rhododendron*	*Picea*

In some of these the Teleutospores are accompanied or preceded by Uredospores, in others not, and similarly the Æcidia may or may not have accompanying spermogonia. Further, some species may attack several or even many different genera and species of the same natural order—e.g., *Uromyces Pisi* on various Vicieæ, *Puccinia graminis* on several Gramineæ—while others seem rigidly confined to one host. But the most remarkable phenomenon is the specialized parasitism of particular races or varieties of some species of *Puccinia*, &c., a complex subject which may be illustrated as follows:—Under the designation Wheat Rust it was formerly assumed that one species of *Puccinia* (*P. graminis*) was indicated. We now know that two or three species, differing in the morphological characters and life-history, were comprised under that name, one only of which is the species *P. graminis*. The extensive researches of Eriksson have shown, however, that this species occurs on about a hundred different grasses, but, although no visible differences can be detected between these, if we try to infect oat or wheat with the spores from the fungus on barley the results are negative, though they succeed on rye; similarly the one on wheat will not infect oat, rye, or barley, and that on oat refuses to infect wheat, rye, or barley, and so on with others. Yet all these forms (races, varieties) are the same species, and their Teleutospores infect the barberry and produce on it the Æcidium-form. The explanation offered is that these are so many specialized or adapted races, so attuned to the particular conditions of life offered by the tissues of a given host-species, or group of such, that the spores evolved in this environment cannot adapt themselves to the conditions presented by another set of host species.

The *Protobasidiomycetes* comprise, in addition to the Uredineæ, about 150 species, of which *Tremella* and *Auricularia* are the principal types, and the union of the groups into one sub-class is based on the long recognized resemblances between the promycelium of Uredineæ and the protobasidium of Auricularieæ. The very remarkable genus *Pilacre* also comes here, and is regarded by Brefeld as the prototype of the angiocarpous Gastromycetes.

The *Autobasidiomycetes* comprise the Hymenomycetes and Gastromycetes of older systematists, and with approximately the same delimitations except that the smaller subdivisions of the Gastromycetes are more sharply marked and raised to higher positions by Fischer, the authority on this group.

In the *Hymenomycetes*, of which 10,000 to 11,000 species are known, several forms have now been cultivated from spore to spore in pure cultures, and no trace of sexual organs has been discovered; the cystidia have quite other functions, as Brefeld showed in *Coprinus*. In many genera the young mycelia form oidia, and in some (*Nyctalis, Fistulina, Polyporus*) well developed chlamydospores and conidia are found, and even conidiophores of special forms—e.g., *Botrytis*-like—occur. Sclerotia are also common, in some cases of large size, and the histological differentiation of tissues is often remarkable. Many Agarics and Polyporei are serious timber-destroying Fungi, even parasitic, or attacking the roots and stems of conifers, &c.—e.g., *Armillaria mellea, Polyporus annosus*, &c.—as Hartig first showed. *Merulius* is the fungus of the "dry-rot" proper, but several others attack and destroy standing and fallen timber, as well as works of construction. For the interesting and important modes of action of these wood-destroying Fungi, the reader must consult the special works.

Physiology.—The physiology of the Fungi comes under the head of that of plants generally, and the works of Pfeffer, Sachs, Vines, Darwin, and Klebs may be consulted for details. Space is here permitted only for general reference to certain phenomena peculiar to these plants, the life-actions of which are restricted and specialized by their peculiar dependence on organic supplies of carbon and nitrogen, so that most Fungi resemble the colourless cells of higher plants in their nutrition. Like these they require water, small but indispensable quantities of salts of potassium, magnesium, sulphur, and phosphorus, and supplies of carbonaceous and nitrogenous materials in different stages of complexity in the different cases. Like these, also, they respire oxygen, and are independent of light; and their various powers of growth, secretion, and general metabolism, irritability, and response to external factors show similar specific variations in both cases. It is quite a mistake to suppose that, apart from the chlorophyll function, the physiology of the fungus-cell is fundamentally different from that of ordinary plant-cells. Nevertheless, certain biological phenomena in Fungi are especially pronounced, and of these the following require particular notice.

Sexuality.—Until a short time ago all botanists were in agreement that while the Phycomycetes exhibited an undoubted sexual process—conjugation of similar organs resulting in the zygospore of Mucorini, &c., and the fertilization of the oosphere in its oogonium by the contents of a much smaller pollinodium in the Oosporeæ—the higher Fungi showed no traces of such except in the small group of Erysipheæ, where De Bary had shown the existence of an act of fertilization in *Sphærotheca* and its allies and in certain other Ascomycetes and Lichens: in these latter Stahl and others had described processes which were accepted with more or less reserve as sexual, but in which the organs concerned differed essentially from those in the Erysipheæ. In spite of numerous investigations, resulting in several suggestions not borne out by facts, no trace of sexual organs or of a sexual process could be discovered in the great group of the Basidiomycetes, nor in the Uredineæ, Ustilagineæ, and the vast mass of higher Ascomycetes, and since closer observation showed that even in the Oosporeæ, where both the morphological structures and physiological processes interpreted as sexual appear in their most convincing manner, a gradual reduction or abortion of the sexual process and organs can be traced, the conclusion was gained that as we ascend the scale of the Fungi the sexual process is gradually lost, and that these organisms have come to replace it by other physiological processes, possibly nutritive, and connected with the large accessions of energy obtained in their highly elaborated food-materials. This conclusion was carried to extremes by Brefeld and the morphological school of which he was the head; they denied the accuracy of the observations which ascribed sexual organs to the Ascomycetes, and pointed out that whereas De Bary had never been able to see a transmission of the contents of the so-called male organ of *Sphærotheca*, &c., to the contents of the so-called female organ, the structures interpreted as sexual were capable of another interpretation—viz., as being merely barren branches commencing to envelope the young ascogonium. Meanwhile, a criterion of the sexual process had been discovered, principally owing to Strasburger's work. It was found that the essential event is the fusion of two nuclei, and that however closely the fusion of two cells or two masses of protoplasm may simulate a sexual union, it is not such unless this essential event is consummated. As this was, of course, not shown to occur, the doubts gained ground as failure after failure to find sexuality was reported. With improvements in method, renewed attempts to penetrate the details led to the proof that the sexual process in the typical Oomycetes—*Peronospora, Cystopus*, &c.—is complete in cases where it was claimed to be so by De Bary and his school, as well as in some other members of the Phycomycetes and allies—*Polyphagus, Basidiobolus*—and Wager especially has convinced us that the conclusions drawn by De Bary from less complete data were essentially sound. In 1883 Eidam described a simple fusion of the ends of two hyphæ as resulting directly in the formation of the ascus in *Eremascus*, and in 1892 Lagerheim brought forward an equally simple case in *Dipodascus*; and, quite recently, Barker has shown that even so simple an Ascomycete as a yeast may conjugate previous to the development of spores. These examples lend support to the contention that a sexual process occurs in *Penicillium, Eurotium*, and *Erysipheæ*. In 1895 the accuracy of De Bary's work on *Sphærotheca* was confirmed by Harper's demonstration, that not only does the antheridium fuse with the oogonium, but that two nuclei are found in the latter after the union, and that these two nuclei conjugate to produce an oospore. At this stage Harper's work would appear to support De Bary's conclusions at every point, but he went farther, and showed that when the fertilized oospore of *Sphærotheca* develops it puts out an ascogonial filament, destined to form the ascus, and that here again two nuclei occur and conjugate in the cell which is to be the future ascus. From the product of their fusion, the nuclei of the ascopores then develop by repeated divisions.

Meanwhile Dangeard and his fellow-workers had brought forward a new and startling view of the sexuality of the higher Fungi. These observers practically confirmed the fusion of nuclei and the truly sexual nature of the process in Phycomycetes, though the different behaviour of the several, sometimes numerous, nuclei observed in the oosphere and antheridial tube, &c., of these multinucleate plants exhibit many peculiarities, for a description of which the literature, and especially Wager's works, must be consulted. In the Ascomycetes, however, Dangeard finds that each cell which is to become an ascus contains two nuclei, which fuse and then divide up to form the spores. This is affirmed for *Exoascus*, *Peziza*, *Aspergillus*, *Sphærotheca*, and other genera. Moreover, Dangeard and his followers find the same thing in Ustilagineæ; each young spore has two nuclei which fuse before it becomes a resting spore, whereas no such "sexual process" occurs in the yeast-conidia. In Uredineæ also each young Æcidiospore, Uredospore, and Teleutospore is initiated by the fusion of two nuclei. Similarly in the Basidiomycetes, each basidium at first contains two nuclei, and these fuse and their product gives rise by division to the nuclei passed into the basidiospores, and since this was found in many examples from Hymenomycetes and Protobasidiomycetes, Dangeard concludes it is universal in the group, and that the higher Fungi are not devoid of sexuality but that this process here consists in conjugation of nuclei in the initials of the principal sporogenous cells, asci and basidia respectively. Only by further research can the matter be cleared up. Meanwhile it stands somewhat as follows: In Phycomycetes there is an undoubted sexual process, where well developed sexual organs are recognizable and fusion of male and female nuclei occurs. The differences in detail concern the number and behaviour of the extra nuclei concerned, and the morphological differentiation of the sexual organs. In the group itself the process would seem to disappear, at any rate under certain conditions (*e.g.*, in Saprolegnieæ), in which, as Klebs has shown, both sexual and asexual reproduction are very sensitive to changes in the environment. In the Uredineæ, Ustilagineæ, Protobasidiomycetes, Basidiomycetes, and the vast majority of Ascomycetes, no organs capable of interpretation as morphologically differentiated sexual organs can be discovered, in spite of numerous and repeated attempts to find them; but within the initial cells which will become resting spores (Ustilagineæ), Æcidiospores, Uredospores, or Teleutospores (Uredineæ), Asci (Ascomycetes) or Basidia (Basidiomycetes), nuclear fusions occur of such a nature that they remind us forcibly of a sexual process. Within the group Ascomycetes at least three types of morphologically differentiated sexual organs and sexual processes have been described in addition to the foregoing, viz., direct conjugation of the tips of similar hyphal branches (*Eremascus*) leading to the direct formation of an ascus from the product of fusion; the fertilization of an oosphere in its oogonium by the contents of an antheridial branch (*Sphærotheca*) leading to the development of the product of fusion into an ascogonial apparatus, and the much more complex case of *Pyronema confluens*, which Harper has recently re-investigated, confirming De Bary's results and extending them in a most remarkable manner, and, finally, the case of *Collema*, and the *Laboulbeniaceæ*, where an ascogenous apparatus is initiated by the formation of a trichogyne borne on a group of cells below (the female sexual organ) and minute spermatia (male organs) abstricted or emitted by certain other branches, the sexual process being consummated by the fusion of the contents of the spermatium with the trichogyne and their transmission to the cells below. The details of this process have not been traced in the latter Fungi, but Bauer's work on the Collemaceæ and Oltmann's on the similar organs in Florideæ render it impossible to overlook the possibilities here involved. Whether Dangeard's contention that his nuclear fusions are the true sexual process in all cases, and that Harper, Stahl, Thaxter, and others have fallen into error in interpreting their observations, is to be accepted, or whether these nuclear fusions are only secondary phenomena, as has been contended by those who compare them to the fusion of nuclei in the embryo sac of the Phanerogams, cannot as yet be decided, and the whole problem, together with numerous subsidiary matters of homology consequent on its decision, remains for the present a burning question in Mycology. It is not improbable that these nuclear fusions in sporogenous cells merely indicate that nuclear masses are in all cases mutually attractive in a high degree during a certain, extremely sensitive, phase of their existence: if this is so, the phenomenon may be one of nutrition—or, even, parasitism—and our ideas as to the sexual significance of such fusions may have to be modified.

Parasitism.—Some Fungi, though able to live as saprophytes, occasionally enter the body of living plants, and are thus termed facultative parasites. The occasion may be a wound (*e.g.*, *Nectria*, *Dasyscypha*, &c.), or the enfeeblement of the tissues of the host, or invigoration of the Fungus, the mycelium of which then becomes strong enough to overcome the host's resistance (*Botrytis*). Many Fungi, however, cannot complete their life-history apart from the host-plant. Such *obligate* parasites may be *Epiphytic* (*Erysipheæ*), the mycelium remaining on the outside and at most merely sending *haustoria* into the epidermal cells, or *Endophytic* (*Uredineæ*, *Ustilagineæ*, &c.), when the mycelium is entirely inside the organs of the host. An epiphytic Fungus is not necessarily a parasite however, as many saprophytes (*Moulds*, &c.) germinate and develop a loose mycelium on living leaves, but only enter and destroy the tissues after the leaf has fallen; in some cases, however, these saprophytic epiphytes can do harm by intercepting light and air from the leaf (*Fumago*, &c.), and such cases make it difficult to draw the line between saprophytism and parasitism. Endophytic parasites may be *intracellular*, when the Fungus or its mycelium plunges into the cells and destroys their contents directly (*Olpidium*, *Lagenidium*, *Sclerotinia*, &c.), but they are far more frequently *intercellular*, at any rate while young, the mycelium growing in the lacunæ between the cells (*Peronospora*, *Uredineæ*) into which it may send short (*Cystopus*), or long and branched (*Peronospora Calotheca*) haustoria, or it extends in the middle lamella (*Ustilago*), or even in the solid substance of the cell-wall (*Botrytis*). No sharp lines can be drawn however, since many mycelia are intercellular at first and subsequently become intracellular (*Ustilagineæ*), and the various stages doubtless depend on the degrees of resistance which the host tissues are able to offer. Similar gradations are observed in the direct effect of the parasite on the host, which may be *local* (*Hemileia*) when the mycelium never extends far from the point of infection, or *general* (*Phytophthora*) when it runs throughout the plant. Destructive parasites rapidly ruin the whole plant-body (*Pythium*), whereas restrained parasites only tax the host slightly, and ill effects may not be visible for a long time, or only when the Fungus is epidemic (*Rhytisma*). A parasite may be restricted during a long incubation-period however, and rampant and destructive later (*Ustilago*). The latter fact, as well as the extraordinary fastidiousness, so to speak, of parasites in their choice of hosts or of organs for attack, point to reactions on the part of the host plant, as well as capacities on that of the parasite, which may be partly explained in the light of what we now know regarding enzymes and chemotropism. Some parasites attack many hosts and almost any tissue or organ (*Botrytis cinerea*), others are restricted to one family (*Cystopus candidus*) or genus (*Phytophthora infestans*) or even species (*Melampsora Padi*), and it is customary to speak of root-parasites, leaf-parasites, &c., in expression of the fact that a given parasite occurs only on such organs—e.g., *Dematophora necatrix* on roots, *Calyptospora Gœppertiana* on stems, *Ustilago Scabiosæ* in anthers, *Claviceps purpurea* in ovaries, &c. Associated with these relations are the specializations which parasites show in regard to the age of the host. Many parasites can enter a seedling, but are unable to attack the same host when older—e.g., *Pythium*, *Ustilago*, *Phytophthora omnivora*.

Chemotropism.—Taken in conjunction with Pfeffer's beautiful discovery that certain chemicals exert a distinct attractive influence on Fungus hyphæ (*chemotropism*), and the results of Miyoshi's experimental application of it, the phenomena of enzyme-secretion throw considerable light on the processes of infection and parasitism of Fungi. Pfeffer showed that certain substances in definite concentrations cause the tips of hyphæ to turn towards them; other substances, though not innutritious, repel them, as also do nutritious bodies if too highly concentrated. Marshall Ward showed that the hyphæ of *Botrytis* pierce the cell-walls of a lily by secreting a cytase and dissolving a hole through the membrane. Miyoshi then demonstrated that if *Botrytis* is sown in a lamella of gelatine, and this lamella is superposed on another similar one to which a chemotropic substance is added, the tips of the hyphæ at once turn from the former and enter the latter. If a thin cellulose membrane is interposed between the lamellæ, the hyphæ nevertheless turn chemotropically from the one lamella to the other and pierce the cellulose membrane in the process. The hyphæ will also dissolve their way through a lamella of collodion, paraffin, parchment paper, elder-pith, or even cork or the wing of a fly, to do which it must excrete very different enzymes. If the membrane is of some impermeable substance, like gold-leaf, the hyphæ cannot dissolve its way through, but the tip finds the most minute pore and traverses the barrier by means of it, as it does a stoma on a leaf. We may hence conclude that a parasitic hypha pierces some plants or their stomata and refuses to enter others, because in the former case there are chemotropically attractive substances present which are absent from the latter, or are there replaced by repellent substances.

Symbiosis.—The remarkable case of life in common first observed in Lichens, where a Fungus and an Alga unite to form a compound organism—the Lichen—totally different from either, has now been proved to be universal in these plants, and Lichens are in all cases merely Algæ enmeshed in the interwoven hyphæ of Fungi. Furthermore, the species of Algæ have been determined, and Lichens artificially synthesized by sowing the Alga and the Fungus together and watching the latter enslave the former. The Fungus concerned is usually an Ascomycete (Ascolichenes), but several Basidiolichenes are now known in which it is a Basidiomycete. This dualism, where the one constituent (Alga) furnishes carbohydrates, and the other (Fungus) ensures a supply of mineral matters, shade, and moisture, has been termed *Symbiosis*. Since then numerous other cases of Symbiosis have been demonstrated. Many trees are found to have their smaller roots invaded by Fungi and deformed by their action, but so far from these being injurious, experiments go to show that this Mycorhiza (fungus-root) is necessary for the well-being of the tree. This is also the case with numerous other plants of moors and woodlands—*e.g.*, Ericaceæ, Pyrolaceæ, Gentianaceæ, Orchidaceæ, Ferns, &c. Recent experiments have shown that the difficulties of getting Orchid seeds to germinate are due to the absence of the necessary Fungus, which must be in readiness to infect the young seedling immediately it emerges from the seed. The well-known failures with rhododendrons, heaths, &c., in ordinary garden soils are also explained by the need of the fungus-infected peat for their roots. The rôle of the Fungus appears to be to supply materials from the leaf-mould around, in forms which ordinary root-hairs are incapable of providing for the plant; in return the latter supports the Fungus at slight expense from its abundant stores of reserve materials. Numerous other cases of Symbiosis have been discovered among the Fungi of fermentation, of which those between *Aspergillus* and yeast in saké manufacture, and between yeasts and bacteria in kephir and in the ginger-beer plant are best worked out. For cases of Symbiosis see article BACTERIOLOGY.

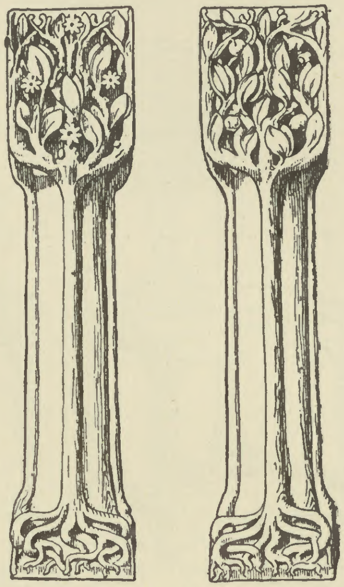
(H. M. W.)

Furnes, a town of Belgium, in the province of West Flanders, 27 miles south-west of Bruges, near the French frontier, the central point of a system of canals to Nieuport, Dunkirk, Bergues, and Ypres, with a station on the line from Dixmude to Dunkirk. It has tanyards and a factory for linen goods. Population (1897), 5636.

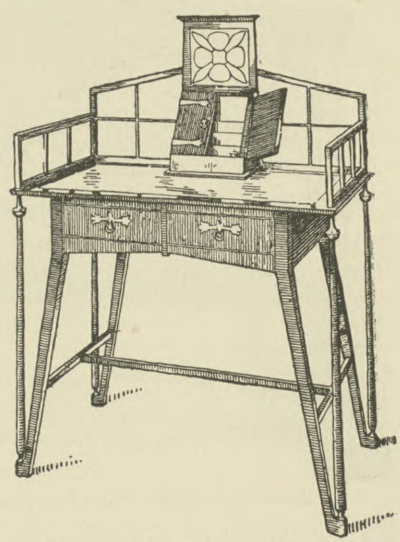
Furness, Horace Howard (1833——), American Shakespearean scholar, was born in Philadelphia, 2nd November 1833, being the son of William Henry Furness, minister of the First Unitarian Church in that city, a powerful preacher and writer. He graduated at Harvard in 1854, and was admitted to the bar in 1859, but soon devoted himself to the study of Shakespeare. He accumulated a collection of illustrative material of great richness and extent, and brought out in 1871 the first volume of a new Variorum edition, designed to represent and summarize the conclusions of the best authorities in all languages—textual, critical, and annotative. Twelve volumes had appeared by the year 1900, as follows: *Romeo and Juliet*, 1871; *Macbeth*, 1873; *Hamlet*, 2 vols., 1877; *King Lear*, 1880; *Othello*, 1886; *The Merchant of Venice*, 1888; *As You Like It*, 1890; *The Tempest*, 1892; *A Midsummer Night's Dream*, 1895; *The Winter's Tale*, 1898; *Much Ado about Nothing*, 1899. The edition has been generally accepted as a thorough and scholarly piece of work; its chief fault is that, beginning with *Othello* (1886), the editor used the First Folio text as his basis, while in others he makes the text of the Cambridge (Globe) editors his foundation.

Furniture.—A decided effort to inaugurate a recognized style in furniture has been made during the last few years, and with the advent of the Paris Exhibition of the year 1900 this effort was called the "New Style," a name first given in France, several years ago, to the work of a number of Paris furniture makers who migrated to Nancy, and who profess to be free from all old traditions, and only to seek inspiration from Nature. How far Nature is likely to inspire an art so essentially utilitarian as cabinet-making is not at once apparent. It is generally admitted that the pioneers of the new style of original thought, as devoted to useful art, were William Morris and his friends about 1860. (See Morris, William, and Arts and Crafts.) That some of the works of Morris and his school were too quaint to become types of the furniture of the future is true enough. But some of the pieces were admirable both for design and execution, and worthy to inspire, as they have inspired, subsequent designers in furniture both in England and on the Continent. The Arts and Crafts Society, founded in 1880 by Walter Crane and others, has carried on the work of producing and exhibiting all kinds of "Art allied to Industry," and has fostered originality of design in furniture, and exercised great influence on artists and artist workmen throughout Europe, where many similar associations have been founded. In the Arts and Crafts Exhibition of 1899 were some chairs designed by C. E. Voysey, which may be noted as having frames of thick square uprights, tapering at the back to high points. By the same artist was a wooden mantel-piece, also of heavy workmanship. The mantel-shelf, instead of the architectonic cornice with its various members, was of one piece, with slight carving on its ogee surface, upheld by two masses of wood bulging towards their bases. Again, two wooden column supports of a mantel-piece by W. Aumonier were of a novel style; the capitals were groups of leaves and tendrils forming squares, and undercut so that the shaft could be seen through the capital; a base was formed by carved roots round the bole. The Guild of Handicraft have also carried out some furniture designs of merit by C. R. Ashbee, notably some writing cabinets. The arrangement of them is that of the old-fashioned bureau, the workmanship is very good, and a pretty and useful feature consists in the place contrived in the upper part of the cabinet for an electric lamp.



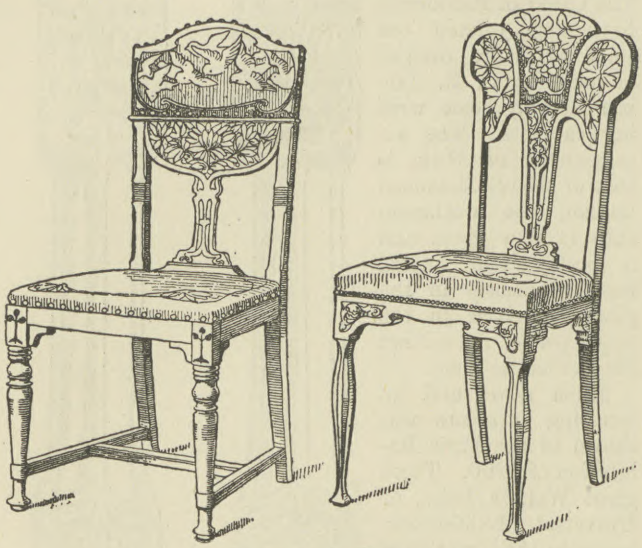
Carved Wood Columns, by W. Aumonier.

Much novel and interesting furniture was shown in the Paris Exhibition of 1900. These great World's Fairs, or Universal Exhibitions, began in 1851, and have borne good fruit, not only in encouraging competition to show the best work in all industries, but also in stimulating the establishment of state museums, where the best models of art designs, both ancient and modern, are permanently on view. The South Kensington Museum in London followed the Exhibition of 1851; the Austrian Museum for Art, &c., was founded after the Exhibition of 1863; and in other countries the same useful results followed. The Paris Exhibition was the most extensive of all, and the furniture there, both English and foreign, could be studied as the outcome of all that was newest in design, material, and execution in the world of art and industry. The display of English furniture in Paris was in itself sufficient to prove that the English cabinet-makers are most to be praised for what may be called the general excellence and suitability of their furniture. No doubt the remarkable exhibition of furniture of the Chippendale and Sheraton period at Bethnal Green in 1896 partly accounts for the continued influence of their patterns and traditions on English furniture.



Writing-Desk, by Henry, London.

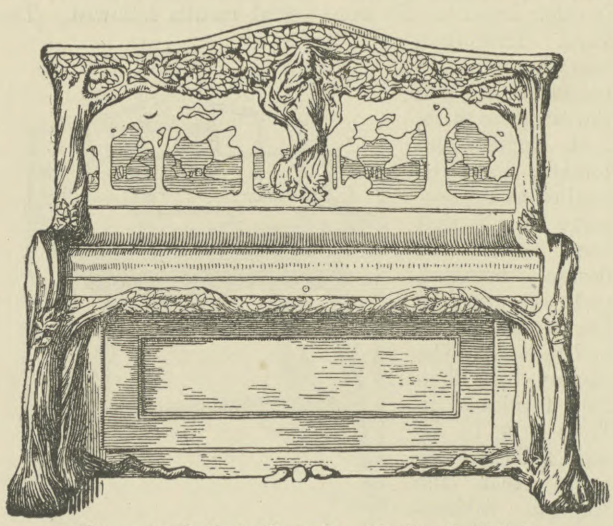
British manufacturers do not err by losing sight of constructive utility in order to experiment with fanciful decoration, and their work is, for the most part, solid and good. The four or five principal English firms who have shown examples of modern interiors have worthily carried out the traditions of former times: no attempt at mere quaintness spoils the furniture, and the novelties shown of material and workmanship do not detract from the feeling of repose and comfort, which must be considered an essential. The error most common in reproducing set



Chairs, by G. Hulbe.

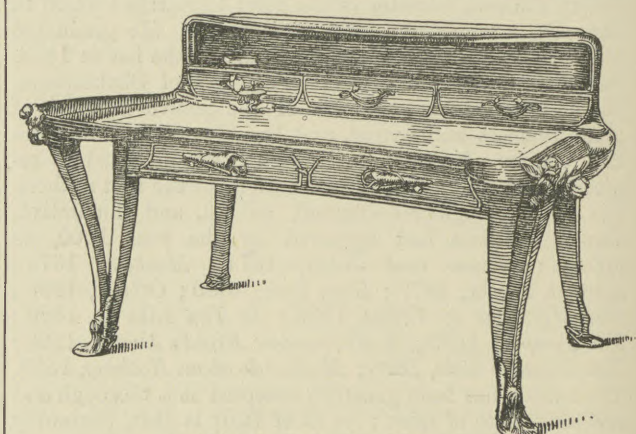
pieces, such as sideboards, cabinets, &c., from old types, is the disposition to "improve," *i.e.*, add to the carving or other decoration; as a rule, this has a questionable effect.

The French makers of the new style of furniture seem in some instances to have a positive distaste for straight lines. They delight in strange curves, usually sweeping curves with sudden twists. Wardrobes and china closets



Piano, by Baldwin Piano Co., Cincinnati, U.S.A.

are pyramidal, chairs and seats have raking legs, table-legs are fortified with bronze, &c. One cabinet is made to represent a leaf-clad arbour, with tree-trunks, branches, and boughs entwined to the life. A pianoforte in the American section of the Exhibition was no less extreme an instance of the new taste, a tree trunk being carved along the front of its bed. Such an instrument as a pianoforte is entirely artificial; the very wood of it is taken from the choicest part of the tree, dried and prepared with the utmost care. How is this symbolized by a stem to imitate nature, however well sculptured? It is obvious that an interior furnished in this manner must be lacking every desirable qualification for home life. A piece of furniture is not a painting; it has a use, and the use must be kept in sight throughout. The naturalism of the Nancy workers extends to the working of the metal; the ormoulu lines of flower and leaf-work are fastened along the edge of cabinets and wardrobes, and then carried up to the tops, where they bend over and form a sort of buttress to support a shelf. In chair frames the craftsmen bind all parts of the seat, as if a kind of strap were necessary round a decaying object. As lightness is a merit in chairs, brass bars and straps ought not to be necessary to their security. The marquetry work of this modern school is also purely realistic, and the attempt is made, notably by Gallé of Nancy, by various coloured woods to represent



Desk, by Majorelles, Nancy.

nature in colours, a questionable use of that form of decoration when applied to furniture intended for use. A typical work by Majorelles of Nancy, a desk, is much better; the lines give an impression of strength and solidity, and the metal work, handles, &c., although representing water-lilies and their leaves in successful imitation, are arranged with some reference to the uses of the object they decorate. A peculiarity of some of the tables of the New Style is the assumed insufficiency of four or any number short of eight legs. The top boards spread over at the corners, and wherever that occurs an extra leg, sometimes curved, springs from the foot of the corner leg and stretches over to support this extension.

In many of the pieces of furniture, in the Arts and Crafts and other Exhibitions in England and abroad, there has been an effort to make furniture of old types as unlike old furniture as possible, either by a simplicity, sometimes amounting to rudeness of construction, or by exaggeration of some feature of the design. (J. H. P.)

Furnivall, Frederick James (1825——), English philologist and editor, was born at Egham, 4th February 1825, being the son of a surgeon. He was called to the bar in 1849, but his attention was soon diverted to philological studies and social problems. He gave Frederick Denison Maurice valuable assistance in founding the Working Men's College, and for half a century indefatigably promoted the study of early English literature, partly by his own work as editor, and still more efficaciously by the agency of the numerous learned societies of which he was both founder and director, especially the Early English Text Society (1864), which has been of inestimable service in promoting the study of early English. He also established and conducted the Chaucer, Ballad, New Shakspere, and Wyclif Societies; and at a later period societies for the special study of Browning and Shelley. As an editor he published the *Percy Ballads* and many other ancient English books; but his most important labours have been devoted to Chaucer, whose study he has greatly assisted by his "Six-Text" edition of the *Canterbury Tales.* He laboured much for the Philological Society, and was one of the original promoters of its great English Dictionary. The completion of his half century of labour was acknowledged in 1900 by a handsome testimonial, including the preparation of a volume of philological essays by various writers specially dedicated to him. Dr Furnivall has views of his own on phonetic spelling, which have not obtained general acceptance.

Fürth, a town of Bavaria, Germany, district Middle Franconia, 5 miles by rail north-west of Nüremberg. It is the seat of several large industries, such as brewing, the production of chromo-lithographs and picture-books, the manufacture of mirror and mirror-frames, bronze and gold-leaf wares, pencils, toys, haberdashery, optical instruments, silver-work, turnery, chicory, machinery, fancy boxes and cases, &c., and an extensive trade is carried on in these goods, and in hops, metals, wool, groceries, coals, &c. Population (1885), 35,455; (1900), 53,874.

Fusilier.—A fusilier was a soldier armed with a fusil. In the early years of the 16th century there appeared a small-arm with a lock in which the spark to ignite the charge was obtained by the percussion of a flint and steel. A specimen exists as old as 1500–20. It was called a snaphance (Dutch, *snap-haan* = snap-cock), a term applied indifferently to the lock and the weapon. The snaphance must have been well known in England in 1594, for it is mentioned in Lilly's *Mother Bombie,* Act ii. scene 1. After a chequered existence of nearly a century and a half, an improved model of the snaphance (which would now be called "snaphance, Mark II.") was produced about 1670, and drove the old fire-lock and wheel-lock completely out of the field. This arm the French called *fusil,* and the English afterwards christened it Brown Bess. The French raised a regiment of fusiliers in 1671, and in 1685 England raised the (7th) Royal Fusiliers.

Fusion.—The term Fusion is generally applied to the melting of a solid substance, or the change of state of aggregation from the solid to the liquid. The term "liquefaction" is frequently employed in the same sense, but is often restricted to the condensation of a gas or vapour. The converse process of *Freezing* or *Solidification,* the change from the liquid to the solid state, is subject to the same laws, and must be considered together with fusion. The *Solution* of a solid in a foreign liquid, and the deposition of *Crystallization* of a solid from a solution, are so closely related to the fusion of a pure substance, that it will also be necessary to consider some of the analogies which they present.

1. *General Phenomena.*—There are two chief varieties of the process of fusion, namely, Crystalline and Amorphous, which are in many ways distinct, although it is possible to find intermediate cases which partake of the characteristics of both. The melting of ice may be taken as a typical case of crystalline fusion. The passage from rigid solid to mobile liquid occurs at a definite surface without any intermediate stage or plastic condition. The change takes place at a definite temperature, the *Fusing* or *Freezing Point* (abbreviated F.P.), and requires the addition of a definite quantity of heat to the solid, which is called the *Latent Heat of Fusion.* There is also in general an abrupt change of volume at the moment of fusion, which amounts in the case of ice to a contraction of 9 per cent. Typical cases of amorphous solidification are those of silica, glass, plastic sulphur, pitch, alcohol, and many organic liquids. In this type the liquid gradually becomes more and more viscous as the temperature falls, and ultimately attains the rigidity characteristic of a solid, without any definite freezing-point or latent heat. The condition of the substance remains uniform throughout, if its temperature is uniform; there is no separation into the two distinct phases of solid and liquid, and there is no sudden change of volume at any temperature.

In the case of crystalline fusion it is necessary to distinguish two cases, the Homogeneous and the Heterogeneous. In the first case, the composition of the solid and liquid phases are the same, and the temperature remains constant during the whole process of fusion. In the second case, the solid and liquid phases differ in composition; that of the liquid phase changes continuously, and the temperature does not remain constant during the fusion. The first case comprises the fusion of pure substances, and that of eutectics, or cryohydrates; the second is the general case of an alloy or a solution. These have been very fully studied and their phenomena greatly elucidated in recent years.

There is also a sub-variety of amorphous fusion, which may be styled *Colloid* or *Gelatinous,* and may be illustrated by the behaviour of solutions of water in gelatine. Many of these jellies melt at a fairly definite temperature on heating, and coagulate or set at a definite temperature on cooling. But in some cases the process is not reversible, and there is generally marked hysteresis, the temperature of setting and other phenomena depending on the rate of cooling. This case has not yet been fully worked out; but it appears probable that in many cases the jelly possesses a spongy framework of solid, holding liquid in its meshes or interstices. It might be regarded as a case of "heterogeneous" amorphous fusion, in which the liquid separates into two phases of different composition, one of which solidifies before the other. The two phases cannot, as a rule, be distinguished optically, but it is generally possible to squeeze out some of the liquid phase when the jelly has set, which proves that the substance is not really homogeneous. In very complicated mixtures, such as acid lavas or slags containing a large proportion of silica, amorphous and crystalline solidification may occur together. In this case the crystals separate first during the process of cooling, the mother liquor increases gradually in viscosity, and finally sets as an amorphous ground-mass or matrix, in which crystals of different kinds and sizes, formed at different stages of the cooling, remain embedded. The formation of crystals in an amorphous solid after it has set is also of frequent occurrence. It is termed *Devitrification,* but is a very slow process unless the solid is in a plastic state.

2. *Homogeneous Crystalline Fusion.*—The fusion of a solid of this type is characterized most clearly by the perfect constancy of temperature during the process. In fact, the law of constant temperature, which is generally stated as the first of the so-called "laws of fusion," does not strictly apply except to this case. The constancy of the F.P. of a pure substance is so characteristic that change of the F.P. is often one of the most convenient tests of the presence of foreign material. In the case of substances like ice, which melt at a low temperature and are easily obtained in large quantities in a state of purity, the point of fusion may be very accurately determined by observing the temperature of an intimate mixture of the solid and liquid while slowly melting as it absorbs heat from surrounding bodies. But in the majority of cases it is more convenient to observe the freezing-point as the liquid is cooled. By this method it is possible to ensure perfect uniformity of temperature throughout the mass by

stirring the liquid continuously during the process of freezing, whereas it is difficult to ensure uniformity of temperature in melting a solid however gradually the heat is supplied, unless the solid can be mixed with the liquid. It is also possible to observe the F.P. in other ways, as by noting the temperature at the moment of the breaking of a wire, of the stoppage of a stirrer, or of the maximum rate of change of volume, but these methods are generally less certain in their indications than the point of greatest constancy of temperature in the case of homogeneous crystalline solids.

3. *Superfusion, Supersaturation.* — It is generally possible to cool a liquid several degrees below its normal freezing-point without a separation of crystals, especially if it is protected from agitation, which would assist the molecules to rearrange themselves. A liquid in this state is said to be "undercooled" or "superfused." The phenomenon is even more familiar in the case of solutions (*e.g.*, sodium sulphate or acetate) which may remain in the "metastable" or "supersaturated" condition for an indefinite time if protected from dust, &c. The introduction into the liquid under these conditions of the smallest fragment of the crystal, with respect to which the solution is supersaturated, will produce immediate crystallization, which will continue until the temperature is raised to the saturation point by the liberation of the latent heat of fusion. The constancy of temperature at the normal freezing-point is due to the equilibrium of exchange existing between the liquid and solid. Unless both solid and liquid are present, there is no condition of equilibrium, and the temperature is indeterminate. The corresponding case of a superheated solid, existing in metastable equilibrium at a temperature above its normal fusing-point, might theoretically occur, but has not as yet been observed.

4. *Effect of Pressure on the F.P.*—The effect of pressure on the fusing-point depends on the change of volume during fusion. Substances which expand on *freezing*, like ice, have their freezing-points lowered by increase of pressure; substances which expand on *fusing*, like wax, have their melting-points raised by pressure. In each case the effect of pressure is to retard increase of volume. This effect was first predicted by James Thomson on the analogy of the effect of pressure on the boiling-point, and was numerically verified by Lord Kelvin in the case of ice, and later by Bunsen in the case of paraffin and spermaceti. The equation by which the change of the F.P. is calculated may be proved by a simple application of the Carnot cycle, exactly as in the case of vapour and liquid. (See THERMODYNAMICS, § 4.) If L be the latent heat of fusion in mechanical units, v' the volume of unit mass of the solid, and v'' that of the liquid, the work done in an elementary Carnot cycle of range $d\theta$ will be $dp(v''-v')$, if dp is the increase of pressure required to produce a change $d\theta$ in the F.P. Since the ratio of the work-difference or cycle-area to the heat-transferred L must be equal to $d\theta/\theta$, we have the relation

$$d\theta/dp=\theta(v''-v')/L \quad . \quad . \quad . \quad . \quad (1).$$

The sign of $d\theta$, the change of the F.P., is the same as that of the change of volume $(v''-v')$. Since the change of volume seldom exceeds 0·1 c.c. per gramme, the change of the F.P. per atmosphere is so small, that it is not as a rule necessary to take account of variations of atmospheric pressure in observing a freezing-point. A variation of 1 cm. in the height of the barometer would correspond to a change of ·0001° C. only in the F.P. of ice. This is far beyond the limits of accuracy of most observations. Although the effect of pressure is so small, it produces, as is well known, remarkable results in the motion of glaciers, the moulding and regelation of ice, and many other phenomena. It has also been employed to explain the apparent inversion of the order of crystallization in rocks like granite, in which the arrangement of the crystals indicates that the quartz matrix solidified subsequently to the crystals of felspar, mica, or hornblende embedded in it, although the quartz has a higher melting-point. It is contended that under enormous pressure the freezing-points of the more fusible constituents might be raised above that of the quartz, if the latter is less affected by pressure. Thus Bunsen found the F.P. of paraffin wax 1·4° C. below that of spermaceti at atmospheric pressure. At 100 atmospheres the two melted at the same temperature. At higher pressures the paraffin would solidify first. The effect of pressure on the silicates, however, is much smaller, and it is not so easy to explain a change of several hundred degrees in the F.P. It seems more likely in this particular case that the order of crystallization depends on the action of superheated water or steam at high temperatures and pressures, which is well known to exert a highly solvent and metamorphic action on silicates.

5. *Variation of Latent Heat.*—Person in 1847 endeavoured to show by the application of the first law of thermodynamics that the increase of the latent heat per degree should be equal to the difference $(s''-s')$ between the specific heats of the liquid and solid. If, for instance, water at 0° C. were first frozen and then cooled to $-t$° C., the heat abstracted per gramme would be $(L'+s't)$ calories. But if the water were first cooled to $-t$° C., and then frozen at $-t$° C., by abstracting heat L'', the heat abstracted would be $L''+s''t$. Assuming that the heat abstracted should be the same in the two cases, we evidently obtain $L'-L''=(s''-s')t$. This theory has been approximately verified by Petterson, by observing the freezing of a liquid cooled below its normal F.P. (*Jour. Chem. Soc.* 24, p. 151). But his method does not represent the true variation of the latent heat with temperature, since the freezing, in the case of a superfused liquid, really takes place at the normal freezing-point. A quantity of heat $s''t$ is abstracted in cooling to $-t$, $(L'-s''t)$ in raising to 0° and freezing at 0°, and $s't$ in cooling the ice to $-t$. The latent heat L'' at $-t$ does not really enter into the experiment. In order to make the liquid freeze at a different temperature, it is necessary to subject it to pressure, and the effect of the pressure on the latent heat cannot be neglected. The entropy of a liquid ϕ'' at its F.P. reckoned from any convenient zero ϕ_0 in the solid state may be represented by the expression

$$\phi''-\phi_0=\int s'd\theta/\theta+L/\theta \quad . \quad . \quad . \quad . \quad (2).$$

Since $\theta d\phi''/d\theta=s''$, we obtain by differentiation the relation

$$dL/d\theta=s''-s'+L/\theta \quad . \quad . \quad . \quad . \quad (3),$$

which is exactly similar to the equation for the specific heat of a vapour maintained in the saturated condition. If we suppose that the specific heats s' and s'' of the solid and liquid at equilibrium pressure are nearly the same as those ordinarily observed at constant pressure, the relation (3) differs from that of Person only by the addition of the term L/θ. Since s'' is greater than s' in all cases hitherto investigated, and L/θ is necessarily positive, it is clear that the latent heat of fusion must increase with rise of temperature, or diminish with fall of temperature. It is possible to imagine the F.P. so lowered by pressure (positive or negative) that the latent heat should vanish, in which case we should probably obtain a continuous passage from the liquid to the solid state similar to that which occurs in the case of amorphous substances. According to equation (3), the rate of change of the latent heat of water is approximately 0·80 calorie per degree at 0° C. (as compared with 0·50, Person), if we assume $s''=1$, and $s'=0·5$. Putting $(s''-s')=0·5$ in equation (2), we find $L=0$ at -160° C. approximately, but no stress can be laid on this estimate, as the variation of $(s''-s')$ is so uncertain.

6. *Freezing of Solutions and Alloys.*—The phenomena of freezing of heterogeneous crystalline mixtures may be illustrated by the case of aqueous solutions and of metallic solutions or alloys, which have been most widely studied. The usual effect of an impurity, such as salt or sugar in solution in water, is to lower the freezing-point, so that no crystallization occurs until the temperature has fallen below the normal F.P. of the pure solvent, the depression of F.P. being nearly proportional to the concentration of the solution. When freezing begins, the solvent generally separates out from the solution in the pure state. This separation of the solvent involves an increase in the strength of the remaining solution, so that the temperature does not remain constant during the freezing, but continues to fall as more of the solvent is separated. There is a perfectly definite relation between temperature and concentration at each stage of the process, which may be represented in the form of a curve as AC in Fig. 1, called the *Freezing-Point Curve.* The equilibrium temperature, at the surface of contact between the solid and liquid, depends only on the composition of the liquid phase and not at all on the quantity of solid present. The abscissa of the F.P. curve represents the composition of that portion of the original solution which remains liquid at any temperature. If instead of starting with a dilute solution we start with a "*saturated*" solution of the solid in the solvent at any point D on the diagram, the dissolved substance or "*solute*" generally separates out as the solution is cooled, and the concentration diminishes

with fall of temperature in a definite relation, as indicated by the curve CB, which is called the *Solubility Curve*. Though often called by different names, the two curves AC and CB are essentially of a similar nature. To take the case of an aqueous solution of salt as an example, along CB the solution is saturated with respect to salt, along AC the solution is saturated with respect to ice. When the point C is reached along either curve, the solution is saturated with respect to both salt and ice.

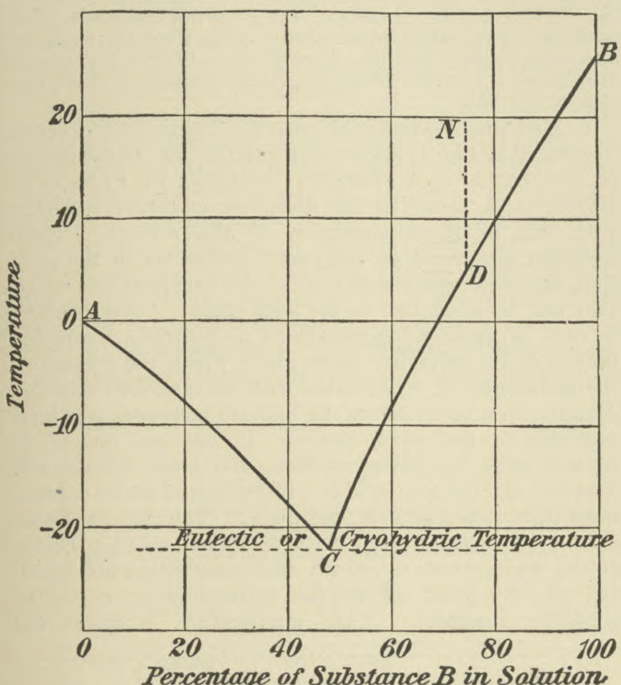


Fig. 1.—F.P. or Solubility Curve: simple case.

The concentration cannot vary further, and the temperature remains constant, while the salt and ice crystallize out together, maintaining the exact proportions in which they exist in the solution. The resulting solid was termed a *Cryohydrate* by Guthrie, but it is really an intimate mixture of two kinds of crystals, and not a chemical compound or hydrate containing the constituents in chemically equivalent proportions. The lowest temperature attainable by means of a *Freezing Mixture* is the temperature of the F.P. of the corresponding cryohydrate. In a mixture of salt and ice with the least trace of water a saturated brine is quickly formed, which dissolves the ice and falls rapidly in temperature, owing to the absorption of the latent heat of fusion. So long as both ice and salt are present, if the mixture is well stirred, the solution must necessarily become saturated with respect to both ice and salt, and this can only occur at the cryohydric temperature, at which the two curves of solubility intersect.

The curves in Fig. 1 also illustrate the simplest type of freezing-point curve in the case of alloys of two metals A and B which do not form mixed crystals or chemical compounds. The alloy corresponding to the cryohydrate, possessing the lowest melting-point, is called the *Eutectic Alloy*, as it is most easily cast and worked. It generally possesses a very fine-grained structure, but is not a chemical compound. (See Alloys.)

To obtain a complete F.P. curve even for a binary alloy is a laborious and complicated process, but the information contained in such a curve is often very valuable. It is necessary to operate with a number of different alloys of suitably chosen composition, and to observe the freezing-points of each separately. Each alloy should also be analysed after the process if there is any risk of its composition having been altered by oxidation or otherwise. The freezing-points are generally best determined by observing the gradual cooling of a considerable mass, which is well stirred so long as it remains liquid. The curve of cooling may most conveniently be recorded, either photographically, using a thermocouple and galvanometer, as in the method of Sir W. Roberts-Austen, or with pen and ink, if a platinum thermometer is available, according to the method put in practice by Heycock and Neville. A typical set of curves obtained in this manner are shown in Fig. 2. When the pure metal A in cooling reaches its F.P. the temperature suddenly becomes stationary, and remains accurately constant for a considerable period. Often it falls slightly below the F.P. owing to

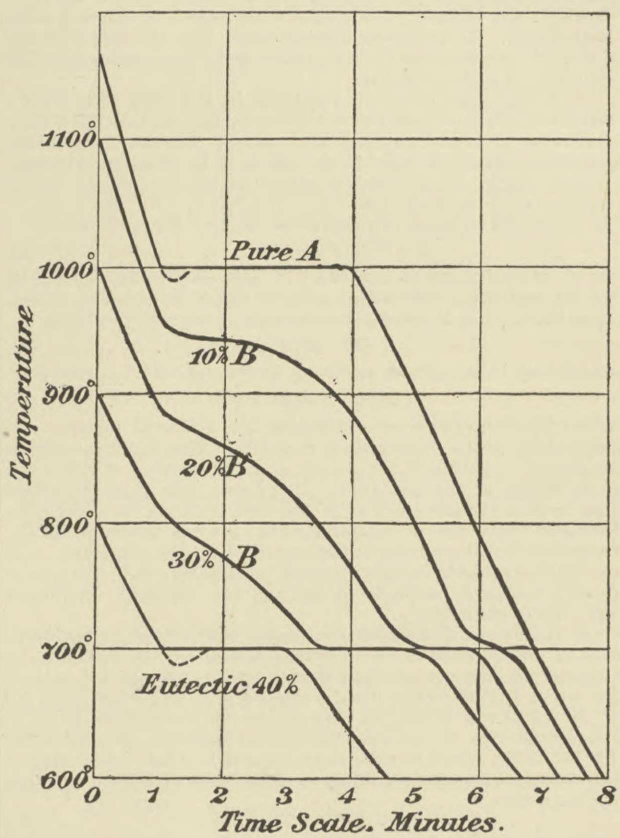

Fig. 2.—Cooling Curves of Alloys: typical case.

superfusion, but rises to the F.P. and remains constant as soon as freezing begins. The second curve shows the cooling of A with 10 per cent. of another metal B added. The freezing begins at a lower temperature with the separation of pure A. The temperature no longer remains constant during freezing, but falls more and more rapidly as the proportion of B in the liquid increases. When the eutectic temperature is reached there is a second F.P. or arrest at which the whole of the remaining liquid solidifies. With 20 per cent. of B the first F.P. is further lowered, and the temperature falls faster. The eutectic F.P. is of longer duration, but still at the same temperature. For an alloy of the composition of the eutectic itself there is no arrest until the eutectic temperature is reached, at which the whole solidifies without change of temperature. There is a great advantage in recording these curves automatically, as the primary arrest is often very slight, and difficult to observe in any other way.

7. *Change of Solubility with Temperature.*—The lowering of the F.P. of a solution with increase of concentration, as shown by the

F.P. or solubility curves, may be explained and calculated by equation (1) in terms of the "*osmotic pressure*" of the dissolved substance by analogy with the effect of mechanical pressure. It is possible in salt solutions to strain out the salt mechanically by a suitable filter or "semi-permeable membrane," which permits the water to pass, but retains the salt. To separate one gramme of salt requires the performance of work PV against the osmotic pressure P, where V is the corresponding diminution in the volume of the solution. In dilute solutions, to which alone the calculation can be satisfactorily applied, the volume V is the reciprocal of the concentration C of the solution in grammes per unit volume, and the osmotic pressure P is equal to that of an equal number of molecules of gas in the same space, and may be deduced from the usual equation of a gas,

$$P = R\theta/VM = R\theta C/M \quad . \quad . \quad . \quad . \quad (4),$$

where M is the molecular weight of the salt in solution, θ the absolute temperature, and R a constant which has the value 8·32 joules, or nearly 2 calories, per degree C. It is necessary to consider two cases, corresponding to the curves CB and AB in Fig. 1, in which the solution is saturated with respect to salt and water respectively. To facilitate description we take the case of a salt dissolved in water, but similar results apply to solutions in other liquids, and alloys of metals.

(*a*) If unit mass of salt is separated in the solid state from a saturated solution of salt (curve CB) by forcing out through a semi-permeable membrane against the osmotic pressure P the corresponding volume of water V in which it is dissolved, the heat evolved is the latent heat of saturated solution of the salt Q together with the work done PV. Writing $(Q+PV)$ for L, and V for $(v''-v')$ in equation (1), and substituting P for p, we obtain

$$Q + PV = V\theta dP/d\theta \quad . \quad . \quad . \quad . \quad (5),$$

which is equivalent to equation (1), and may be established by similar reasoning. Substituting for P and V in terms of C from equation (4), if Q is measured in calories, $R=2$, and we obtain

$$QC = 2\theta^2 dC/d\theta \quad . \quad . \quad . \quad . \quad (6),$$

which may be integrated, *assuming Q constant*, with the result

$$2 \log_e C''/C' = Q/\theta' - Q/\theta'' \quad . \quad . \quad . \quad (7),$$

where C', C'' are the concentrations of the saturated solution corresponding to the temperatures θ' and θ''. This equation may be employed to calculate the latent heat of solution Q from two observations of the solubility. It follows from these equations that Q is of the same sign as $dC/d\theta$, that is to say, the solubility increases with rise of temperature if heat is absorbed in the formation of the saturated solution, which is the usual case. If, on the other hand, heat is liberated on solution, as in the case of caustic potash or sulphate of calcium, the solubility diminishes with rise of temperature.

(*b*) In the case of a solution saturated with respect to ice (curve AB), if one gramme of water having a volume v is separated by freezing, we obtain a precisely similar equation to (5), but with L the latent heat of fusion of water instead of Q, and v instead of V. If the solution is dilute, we may neglect the external work Pv in comparison with L, and also the heat of dilution, and may write P/t for $dP/d\theta$, where t is the depression of the F.P. below that of the pure solvent. Substituting for P in terms of V from equation (4), we obtain

$$t = 2\theta^2 v/LVM = 2\theta^2 w/LWM \quad . \quad . \quad . \quad (8),$$

where W is the weight of water and w that of salt in a given volume of solution. If M grammes of salt are dissolved in 100 of water, $w=M$, and $W=100$. The depression of the F.P. in this case is called by van t' Hoff the "Molecular Depression of the F.P." and is given by the simple formula

$$t = {\cdot}02\theta^2/L \quad . \quad . \quad . \quad . \quad . \quad (9).$$

Equation (8) may be used to calculate L or M, if either is known, from observations of t, θ, and w/W. The results obtained are sufficiently approximate to be of use in many cases in spite of the rather liberal assumptions and approximations effected in the course of the reasoning. In any case the equations give a simple theoretical basis with which to compare experimental data in order to estimate the order of error involved in the assumptions. We may thus estimate the variation of the osmotic pressure from the value given by the gaseous equation, as the concentration of the solution or the molecular dissociation changes. The most uncertain factor in the formula is the molecular weight M, since the molecule in solution may be quite different from that denoted by the chemical formula of the solid. In many cases the molecule of a metal in dilute solution in another metal is either monatomic, or forms a compound molecule with the solvent containing one atom of the dissolved metal, in which case the molecular depression is given by putting the atomic weight for M. In other cases, as Cu, Hg, Zn, in solution in cadmium, the depression of the F.P. per atom, according to Heycock and Neville, is only half as great, which would imply a diatomic molecule. Similarly As and Au in Cd appear to be triatomic, and Sn in Pb tetratomic. Intermediate cases may occur in which different molecules exist together in equilibrium in proportions which vary according to the temperature and concentration. The most familiar case is that of an electrolyte, in which the molecule of the dissolved substance is partly dissociated into ions. In such cases the degree of dissociation may be estimated by observing the depression of the F.P., but the results obtained cannot always be reconciled with those deduced by other methods, such as measurement of electrical conductivity, and there are many difficulties which await satisfactory interpretation.

Exactly similar relations to (8) and (9) apply to changes of boiling-point or vapour pressure produced by substances in solution (see VAPORIZATION), the laws of which are very closely connected with the corresponding phenomena of fusion; but the consideration of the vapour phase may generally be omitted in dealing with the fusion of mixtures where the vapour pressure of either constituent is small.

8. *Hydrates.*—The simple case of a freezing-point curve, illustrated in Fig. 1, is generally modified by the occurrence of compounds of a character analogous to hydrates of soluble salts, in which the dissolved substance combines with one or more molecules of the solvent. These hydrates may exist as compound molecules in the solution, but their composition cannot be demonstrated unless they can be separated in the solid state. Corresponding to each crystalline hydrate there is generally a separate branch of the solubility curve along which the crystals of the hydrate are in equilibrium with the saturated solution. At any given temperature the hydrate possessing the least solubility is the most stable. If two are present in contact with the same solution, the more soluble will dissolve, and the less soluble will be formed at its expense until the conversion is complete. The two hydrates cannot be in equilibrium with the same solution except at the temperature at which their solubilities are equal, *i.e.*, at the point where the corresponding curves of solubility intersect. This temperature is called the

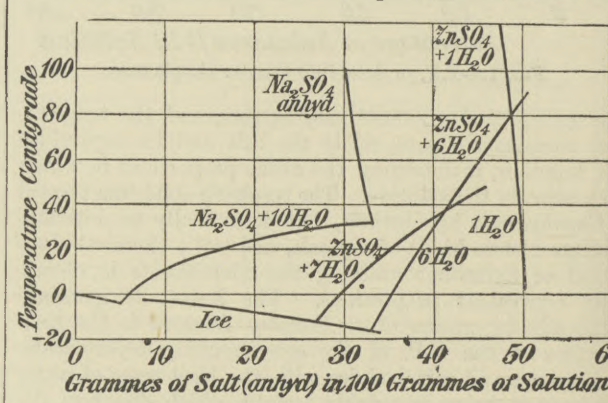

FIG. 3.—Solubility Curves of Hydrates.

"*Transition Point.*" In the case of $ZnSO_4$, as shown in Fig. 3, the heptahydrate, with seven molecules of water, is the least soluble hydrate at ordinary temperatures, and is generally deposited from saturated solutions. Above 39° C., however, the hexahydrate, with six molecules, is less soluble, and a rapid conversion of the hepta- into the hexahydrate occurs if the former is heated above the transition point. The solubility of the hexahydrate is greater than that of the heptahydrate below 39°, but increases more slowly with rise of temperature. At about 80° C. the hexahydrate gives place to the monohydrate, which dissolves in water with evolution of heat, and diminishes in solubility with rise of temperature. If intermediate hydrates exist, as is possible, they are more soluble, and cannot be isolated. Both the mono- and hexahydrates are capable of existing in supersaturated equilibrium at ordinary temperatures far below their transition points, provided that the less soluble hydrate is not present in the crystalline form. The solubility curves can therefore be traced, as in Fig. 3, over an extended range of temperature. The equilibrium of each hydrate with the solvent, considered separately, would present a diagram of two branches similar to Fig. 1, but as a rule only a small portion of each curve can be realized, and the complete solubility curve, as experimentally determined, is composed of a number of separate pieces corresponding to the ranges of minimum solubility of different hydrates. Failure to recognize this, coupled with the fact that in strong and viscous solutions the state of equilibrium is but slowly attained, is the probable explanation of the remarkable discrepancies existing in many recorded data of solubility.

9. *Metallic Compounds.*—The F.P. curves of metallic solutions or alloys, which are often very complicated, are most easily understood by the analogy which the crystalline compounds formed in the process of solidification bear to the familiar aqueous hydrates. For instance, the F.P. curve of solutions of sodium in mercury (Fig. 4) presents seven or more branches, each of which probably corresponds to the separation of a compound of the nature of a hydrate, except the terminal branches AB, HHg, which correspond to the separation of pure Na and pure Hg respectively. The summit F corresponds to the

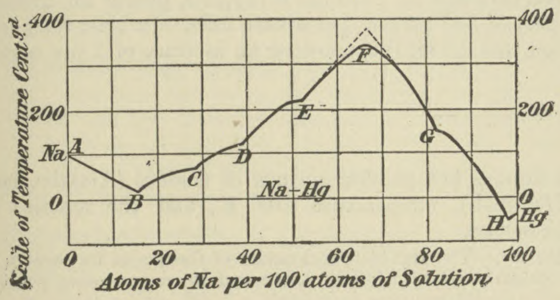

Fig. 4.—Freezing-point Curve of Alloys of Na and Hg.

compound $NaHg_2$, the F.P. of which, at 350° C., is much higher than that of either constituent.

In cases like this, where a well-marked compound is formed, the portion of the curve between the summit corresponding to the compound and the melting-point of the pure metal, as between the points F and Hg in the F.P. curve of NaHg, often bears a close resemblance to the simple case represented in Fig. 1. But there is a characteristic difference to be noted. On the analogy of the ideal case we should expect to find the two branches on either side of a summit like F meeting at a well-defined angle, as indicated by the dotted lines, and not showing continuous curvature. The slope of the curve on one side of the summit should be that corresponding to the depression of the F.P. of the compound F by Na in dilute solution, as calculated by formula (8), the slope on the other side that corresponding to dilute solutions of Hg in F. The experimental evidence goes, however, to show that in most cases these summits are rounded, and not sharp. This would indicate, according to Neville and Le Chatelier, that the compound is partly dissociated at its melting-point. The observed point of fusion corresponding to the summit of the curve is depressed below the ideal point of fusion by the presence of dissociated atoms of the components. It is highly probable that in many cases these loose chemical compounds, like some aqueous hydrates, are partly dissociated before the true point of fusion is reached.

10. *Formation of Mixed Crystals.*—An important exception to the general type already described, in which the addition of a dissolved substance *lowers* the F.P. of the solvent, is presented by the formation of mixed crystals, or "solid solutions," in which the solvent and solute occur mixed in varying proportions. This isomorphous replacement of one substance by another, in the same crystal with little or no change of form, has long been known and studied in the case of minerals and salts, but the relations between composition and melting-point have seldom been investigated, and much still remains obscure. In this case the process of freezing does not necessitate the performance of work of separation of the constituents of the solution, the F.P. is not necessarily depressed, and the effect cannot be calculated by the usual formula for dilute solutions. One of the simplest types of F.P. curve which may result from the occurrence of mixed crystals, is illustrated by the case of alloys of gold and silver, or gold and platinum, in which the F.P. curve is nearly a straight line joining the freezing-points of the constituents. The equilibrium between the solid and liquid, in both of which the two metals are capable of mixing in all proportions, bears in this case an obvious and close analogy to the equilibrium between a mixed liquid (*e.g.*, alcohol and water) and its vapour. In the latter case, as is well known, the vapour will contain a larger proportion of the more volatile constituent. Similarly in the case of the formation of mixed crystals, the liquid should contain a larger proportion of the more *fusible* constituent than the solid with which it is in equilibrium. The composition of the crystals which are being deposited at any moment will, therefore, necessarily change as solidification proceeds, following the change in the composition of the liquid, and the temperature will fall until the last portions of the liquid to solidify will consist chiefly of the more fusible constituent, at the F.P. of which the solidification will be complete. If, however, as seems to be frequently the case, the composition of the solid and liquid phases do not greatly differ from each other, the greater part of the solidification will occur within a comparatively small range of temperature, and the initial F.P. of the alloy will be well marked. It is possible in this case to draw a second curve representing the composition of the *solid* phase which is in equilibrium with the liquid at any temperature. This curve will not represent the average composition of the crystals, but that of the outer coating only which is in equilibrium with the liquid at the moment. Roozeboom (*Zeit. Phys. Chem.*, xxx. p. 385) has attempted to classify some of the possible cases which may occur in the formation of mixed crystals on the basis of Gibbs's thermodynamic potential, the general properties of which may be qualitatively deduced from a consideration of observed phenomena. But although this method may enable us to classify different types, and even to predict results in a qualitative manner, it does not admit of numerical calculation similar to equation (8), as the Gibbs's function itself is of a purely abstract nature, and its form is unknown. There is no doubt that the formation of mixed crystals may explain many apparent anomalies in the study of F.P. curves. The whole subject has been most fruitful of results in recent years, and appears full of promise for the future. For further details in this particular branch the reader may consult a report by Neville (*Brit. Assoc. Rep.*, 1900), which contains numerous references to original papers by Roberts-Austen, Le Chatelier, Roozeboom, and others.

(H. L. C.)

Fustel de Coulanges, Numa Denis (1830–1889), French historian, was born at Paris, 18th March 1830, being of Breton descent. After studying at the École Normale he was sent to the French school at Athens in 1853, and after his return filled various educational offices until, in 1860, he was appointed professor of history at the university of Strasburg. After the conquest of Strasburg by Germany he returned to Paris, and filled a professorship at the École Normale. In 1878 a professorship of mediæval history was created for him, which, except for a brief period during which he was director of the École Normale, he held until his death on 12th September 1889. His principal works are *La Cité Antique* (1862) and *Histoire des institutions politiques de l'ancienne France* (1875). In the former, which went through a great number of editions, he traces the influence of religion in moulding antique institutions, especially those of prehistoric times; in the latter, founded on a course of lectures originally delivered to the Empress Eugénie, he investigates the effect of the Roman and Frankish conquests upon Gaulish society, which he considers to have been less than usually supposed. The continuation of the work was interrupted by the author's death; but the various sections, which had been thoroughly revised by him, were republished as separate books. The eulogium of Fustel de Coulanges has been pronounced by MM. Albert Sorel, Paul Guiraud, and Jules Simon, whose oration has been reproduced in his *Notices et Portraits*. (R. G.)

Fyzabad, or FAIZABAD, a city, district, and division of British India, in Oudh. The city is on the left bank of the river Gogra, 78 miles by rail east of Lucknow. Population (1881), 71,405; (1891), 78,921; (1901), 74,076. The municipal income in 1897–98 was Rs. 72,678. The registered death-rate in 1897 was 57 per thousand. The cantonments accommodate a battery of artillery, and a European and a native infantry regiment. There is a Government college. The DISTRICT has an area of 1728 miles. Population (1881), 1,081,419; (1891), 1,216,959, giving an average density of 704 persons per square mile; (1901), 1,298,086, showing an increase of 7 per cent. The land revenue and rates were Rs. 13,16,315; the incidence of assessment being R. 1–1–1 per acre; the cultivated area in 1896–97 was 623,677 acres, of which 313,834 were irrigated from wells and tanks; the number of police was 3196; the number of vernacular schools in 1896–97 was 68, with 4003 pupils; the registered death-rate in 1897 was 31·67 per thousand. There are six printing-presses, two of which are owned by English firms; 77 indigo factories, employing 8781 persons, with an out-turn valued at Rs. 5,65,000. The district is traversed throughout its length by the line of the Oudh and Rohilkhand railway from Lucknow to Jaunpur, 66 miles in all, with eight stations. Tanda, with a population in 1891 of 19,724, is the largest producer of cotton goods in Oudh. The DIVISION OF FYZABAD has an area of 12,177 square miles, and had a population in 1881 of 6,062,140, and in 1891 of 6,794,272, giving an average density of 557 persons per square mile. In 1901 the population was 6,904,315, showing an increase of 2 per cent.

Gablonz (Bohemian or Czech, *Jablonec*), the chief town of a district in Bohemia, Austria. It possesses several new technical and special schools and a large hospital. It is the chief seat of the glass pearl and imitation jewellery manufacture, and has also an important textile industry, and produces large quantities of papier-mâché and other paper goods, hardware, &c. Gablonz has increased its population by 345 per cent. since 1857, a rate of progress only surpassed in Bohemia by Prague, Pilsen, and Aussig. Population (1890), 14,653; (1900), 21,086.

Gabrovo, a town in the department of Selvi, in the principality of Bulgaria. It is picturesquely situated at the foot of the Balkans near the famous Shipka pass, on the Jantra, an affluent of the Danube, 22 miles south-west of Trnovo. The Jantra in its course through the town breaks into several streams, and is crossed by six bridges. At one point a great rock divides it into two streams and forms a double cascade. Owing to its fine supply of water-power the town has become an important centre of the cloth industry. Cord spinning is also carried on, and there are several tanneries. The population is almost entirely Christian, and there is a large nunnery. The first modern school of Bulgaria, founded in the town in 1835, has become a higher-class school. Population about 8000.

Gadag, or GARAG, a town of British India, in the Dharwar district of Bombay, 43 miles east of Dharwar town. It is an important railway junction on the Southern Mahratta system, with a growing trade in raw cotton, and also in the weaving of cotton and silk. There are fourteen factories for ginning and pressing cotton. Population about 24,000.

Gadara, now Umm Keis, altitude 1194 feet, one of the cities of the Syrian Decapolis, a strong fortress, and the political centre of a small district, Gadaris, which possibly extended to the Sea of Galilee. The extensive ruins are now being rapidly destroyed by the natives. In the Yarmúk valley, about 2½ miles north of the town, are the famous hot sulphur springs of Gadara (Amatha, now el-Hammah), temperature 110° F., and the remains of bath-houses.

History.—The first historical notice of Gadara is its capture by Antiochus the Great; but its name and its commanding position in a fertile district seem to indicate a much earlier existence. It was given by Augustus (30 B.C.) to Herod the Great, at whose death it was re-annexed to Syria. In the Middle Ages it was called Kedar by the Crusaders, and Jadar by the Arabs, a name preserved in the modern Jedúr Umm Keis. Gadara was a Greek city; its coins bear Greek legends, and the inscriptions that have been found on its site are Greek. Its governing and wealthy classes were probably of Greek origin, whilst the people, urban and rural, were Hellenized and Judaized Aramaeans. The community was Hellenistically organized, with a democratic senate at its head, and, whilst dependent on Syria, and acknowledging the supremacy of Rome, it managed its own internal affairs. The city used the era of Pompey (64 B.C.). Gadara, though not mentioned in the Bible, is referred to in the expression "the country of the Gadarenes" (R.V., Matt. viii. 28); but the reading is uncertain, and the scene of the miracle was probably on the eastern shore of the lake.

W.)

Gade, Niels Wilhelm (1817–1890), Danish composer, was born at Copenhagen, 22nd February 1817, his father being a musical instrument maker. At first intended for his father's trade, his bent for a musician's career, made evident by the ease and skill with which he learnt to play upon a number of instruments, was not to be denied. Yet, though he became proficient on the violin under Wexschall, and in the elements of theory under Weyse and Berggreen, he was to a great extent self-taught. His opportunities of hearing and playing in the great masterpieces were many, since he was a member of the court band. In 1841 his opus 1—the still popular *Nachklänge aus Ossian* overture—gained the local musical society's prize, the judges being Spohr and Schneider; and it also attracted the notice of the king to Gade, who received a stipend which enabled him to go to Leipzig and Italy.

In 1844 he conducted the Gewandhaus concerts in Leipzig during Mendelssohn's absence, and at the latter's death Gade became chief conductor. In 1848, on the outbreak of the Holstein war, Gade returned to Copenhagen, where he was appointed organist and conductor of the Musik-Verein, a society which prospered exceedingly under him. He succeeded Gläser as court conductor in 1861, and was pensioned by the Government in 1876—the year in which he visited Birmingham to conduct his *Crusaders*. This work, and the *Frühlingsfantasie*, the *Erlkönigs Tochter*, *Frühlingsbotschaft*, and *Psyche* (written for Birmingham in 1882), have enjoyed a wide popularity. Indeed, they represent the strength and the weakness of Gade's musical ability quite as well as any of his eight symphonies (the best of which are the first and fourth, while the fifth has an obbligato pianoforte part). Gade was distinctly a romanticist, but his music rarely glows with the warmth one finds in Grieg or Sinding, or even J. P. E. Hartmann, Gade's father-in-law. It is highly polished and beautifully finished, lyrical rather than dramatic and effective. But it rarely stirs one's deeper self. Much of the pianoforte music, the "Aquarellen," the "Spring Flowers," for instance, enjoyed a considerable vogue, as did the "Novelletten" trio; but Gade's only opera, *Mariotta*, never passed beyond the confines of the Copenhagen Opera House. Gade died at his birthplace, 21st December 1890. (R. H. L.)

Gainesville, capital of Cooke county, Texas, U.S.A., near the Red river, on the Gulf, Colorado, and Sante Fé, and the Missouri, Kansas, and Texas railways, at an altitude of 730 feet. Population (1880), 2667; (1890), 6594; (1900), 7874, of whom 269 were foreign-born and 1201 negroes.

Gainsborough, a market-town in the Gainsborough parliamentary division of Lincolnshire, England, on the Trent, 145 miles north of London. There are three parish churches, a Roman Catholic church, and various Nonconformist chapels. Recent erections include an Albert Hall, new town hall, and a Church of England Institute. There are agricultural implement and engineering works. Area of urban district, 2118 acres; population (1881), 10,873; (1901), 17,660. Area of civil parish, 3446 acres.

Gaisford, Thomas (1779–1855), English classical scholar, was born at Iford, Wiltshire, on the 22nd of December 1779. Proceeding to Oxford in 1797, he became successively student and tutor of Christ Church, and was in 1811 appointed regius professor of Greek at the University. Taking orders, he held (1815–47) the college living of Westwell, in Oxfordshire, and other ecclesiastical preferments simultaneously with his professorship. In 1831 he was appointed Dean of Christ Church, and presided over the destinies of his college until his death on the 2nd of June 1855. As curator of the Bodleian and principal delegate of the University Press he was instrumental in securing the co-operation of distinguished European scholars as collators, notably Bekker and Dindorf. Gaisford was a recondite and critical Greek scholar, of European reputation. Among his numerous contributions to Greek literature may be mentioned, Hephæstion's *Encheiridion* (Oxford, 1810); *Poetæ Græci Minores* (*ibid.*, 1814–20), *Herodotus, cum notis variorum* (*ibid.*, 1824), *Suidas* (*ibid.*, 1834), *Etymologicum Magnum* (*ibid.*, 1848). In 1856 the Gaisford prize, for Greek composition, was founded at Oxford to perpetuate his memory.

Galapagos Islands, an archipelago of five larger and ten smaller islands, situated in the Pacific Ocean, exactly under the equator, from 500 to 600 miles west of Ecuador, to which country they belong. The name is derived from *galapago*, a tortoise, on account of the giant species, the characteristic feature of its fauna.

The origin, distribution, and development of the biological conditions of islands so distinctly oceanic as the Galapagos have given its chief importance to this volcanic archipelago since it was visited in the *Beagle* by Darwin. Of the seven species of these giant reptiles known to science (although at the discovery of the islands there were probably fifteen) all are indigenous, and each is confined to its own islet. There also occurs a peculiar genus of lizards with two species, the one marine, the other terrestrial. The majority of the birds are of endemic species peculiar to different islets—and their number is greater than was believed—while more than half belong to peculiar genera. More than half of the flora is unknown elsewhere. A convict settlement still exists on Chatham, but no longer on Charles Island; there are nearly 300 inhabitants, living in low thatched or iron roofed huts, under the supervision of a police commissioner and other officials. A Spaniard, with large estates on which sugar was grown and refined for the Guayaquil market, was in 1901 the sole employer of labour on the island. Charles Island, the most valuable of the group, is being cultivated by a small colony under an American. On many of the islets numerous tropical fruits are to be found growing wild, but they are no doubt escapes from cultivation, just as the large herds of wild cattle, horses, donkeys, pigs, goats, and dogs—the last large and fierce—which occur so abundantly on most of the islands have escaped from domestication. The shores of the larger islands are fringed with a dense barrier of mangroves, backed by an often impenetrable thicket of tropical undergrowth, which, as the ridges are ascended, give place to taller trees and deep green bushes which are covered with orchids and trailing moss (*orchilla*), and from which creepers hang down interlacing the vegetation.

Since 1860 several visits have been paid to the group by scientific investigators—by Dr Habel in 1868; Messrs Baur and Adams, and the naturalists of the *Albatross*, between 1888 and 1891; and in 1897–98 by Mr Charles Harris, whose journey was specially undertaken at the instance of the Hon. Walter Rothschild of Tring. Very complete collections have therefore, as a result of these expeditions, been brought together; but their examination does not materially change the facts upon which the conclusions arrived at by Darwin—from the evidence of the birds and plants—were based; but he "no doubt would have paid more attention to [the evidence afforded by Land-tortoises], if he had been in possession of facts with which we are acquainted now" (*Günther*). These were that the group "has never been nearer the mainland [of America] than it is now, nor have its members been at any time closer together"; and that the character of the flora and fauna is the result of species straggling over from the mainland, at long intervals of time, to the different islets, where in their isolation they have gradually varied in different degrees and ways from their ancestors. Equally indecisive is the further exploration as to evidence for the opinion held by other naturalists that the endemic species of the different islands have resulted from subsidences, through volcanic action, which have reduced one large island mass into a number of islets, wherein the separated species became differentiated during their isolation. The presence of these giant reptiles on the group, each species on its own islet, is still the chief fact on which a former land connexion with the continent of America may be sustained. "Nearly all authorities agree that it is not probable that they have crossed the wide sea between the Galapagos Islands and the American continent, although, while they are helpless and quite unable to swim, they can float on the water. If their ancestors had been carried out to sea once or twice by a flood and safely drifted as far as the Galapagos Islands" (*Wallace*), "they must have been numerous on the continent" (*Rothschild and Hartert*). No remains, and of course no living species, of these tortoises are known to exist or have existed on the mainland. Rothschild and Hartert seem to think that "it is more natural to assume the disappearance of a great stock of animals, the remains of which have survived, . . . than to assume the disappearance in comparatively recent times (*i.e.*, in the Eocene period or later) of enormous land masses." Past elevations of land (and doubtless equally great subsidences) have, we know, taken place in South America since the Eocene, and on a somewhat similar distribution of giant tortoises in the Mascarene region has long been based the conclusion that extensive areas of land have subsided in the Indian Ocean. "But so much we may claim at present, that Dr Baur's theory of the origin of the Galapagos fauna, when applied to the problem offered by the tortoises in the Indian Ocean, is actually . . . supported by geological and biological facts" (*Günther*). The Galapagos Islands continue to be of some commercial importance to the Government of Ecuador, on account of the guano and the orchilla moss found on them and exported to Europe. Except on Charles Island, where settlement existed longest, little or no influence of the presence of man is evident in the group; still, the running wild of dogs, cats, and especially goats as regards the vegetation, must in the course of a comparatively short period greatly modify the biological condition of the islets.

Galashiels, a parliamentary burgh and manufacturing town, situated since 1891 wholly in Selkirkshire, Scotland, on the river Gala, 40 miles south-south-west of Edinburgh by rail. There are now 16 woollen mills and 2 hosiery factories, 2 iron foundries, 2 engineering works, 3 dye-works, and a boot factory. Recent erections include 2 United Free churches, St Paul's parish church, a cottage hospital, and Gala public school. There is a free library, and waterworks have been completed. Population (1881), 15,330; (1901), 13,598.

Galatia.—I. *Galatia Proper*, a large inland district of Asia Minor, which was occupied by Gauls in the 3rd century B.C. Their position was that of a military aristocracy dwelling amongst an inferior race. Some of them settled down in the towns, but for the most part they lived in fortified villages and led a pastoral life. As the military powers of the Gauls declined, they began to mix with the Phrygian natives and adopt their religion; but they long retained much of the Gallic character, and their language was still in use in the 4th century of our era. In the 1st century, when St Paul made his missionary journeys, though the townsmen spoke Greek, the rural population was little affected by Greek civilization. But after the foundation of Constantinople the Hellenization of the country was more rapid. Galatia included a great portion of the viláyet of Angora. (See ANGORA.) It is a pastoral, agricultural country, and consists of a series of larger or smaller plains lying between bare desolate hills. Its scenery is monotonous; it is almost devoid of trees, except on its northern frontier; its cities are far apart, and its climate—a long severe winter and short hot summer—is trying.

II. The *Roman Province* was constituted 25 B.C. It consisted of parts of Lycaonia, Phrygia, with Iconium, Derbe, Lystra, Isaura, and Western Pisidia, to the borders of Pamphylia. The province was enlarged by the addition of the Paphlagonian territories of Deiotarus (who had been called king of Galatia by the Romans, and who died in 40 B.C.), 5 B.C.; Sebastopolis, 2 B.C.; Comana, A.D. 35; Pontus, A.D. 63; and Cappadocia and Armenia Minor, A.D. 72. About 106 Trajan reduced the province by taking away Armenia Minor, Cappadocia, and Pontus, and in 137 the southern and central parts of Lycaonia were attached to Cilicia. Under Diocletian's reorganization, about 297, Galatia became a province of the Diocesis Pontica, and in 413 this was divided into Galatia Prima and Galatia Salutaris. The question whether the "churches of Galatia," to which St Paul addressed his Epistle, were situated in South Galatia or in North Galatia, has been discussed by Professor W. M. Ramsay, who rightly maintains that they were the churches planted in Derbe, Lystra, Iconium, and Antioch. (See GALATIANS.)

Galatians.—It can no longer be said that "Galatia is never used in the New Testament, except in its older colloquial sense as equivalent to 'Gallogræcia,' or 'Eastern Gaul.'" It is now generally recognized that in 1 Peter i. Galatia is used for the whole Roman province of that name, which in the apostolic age included far more than Gallogræcia. But we are here concerned to consider where "the churches of Galatia" were to which St Paul's Epistle, generally known as the Epistle to the Galatians, was addressed. The contents of the Epistle make it clear that "the churches of Galatia" were of St Paul's own founding. We naturally turn then to the Acts of the Apostles, to inquire whether there is any mention of these churches there. We do not find the word Γαλατία anywhere in the Acts, but twice the adjective Γαλατικός is used (xvi. 6, xviii. 23). It has been generally thought until recent years that the first of these two passages gives the occasion of the founding of the churches of Galatia, a revisit to which is spoken of in the other passage. A careful examination of the passage xvi. 6 ff. has convinced the writer of this article that this view is no longer tenable. His reasons are given at length in the Norrisian Essay for 1898 (*Destination and Date of the Epistle to the Galatians*).

It is the habit of the author of the Acts of the Apostles, when he is telling of St Paul's missionary work in cities before unvisited by him, to give details of the effect of his preaching and of the events of his stay in those cities. Now we observe that in Acts xvi. 6 there is no detailed account of the Apostle's missionary work, so that, if it be the case that we have here the occasion of the planting of "the churches of Galatia," the general rule observed by the author of the Acts here finds its exception. We read: "But they went through [διῆλθον] the Phrygo-Galatian region [τὴν Φρυγίαν καὶ Γαλατικὴν χώραν], forbidden [*or* being forbidden] by the Holy Ghost to preach the word in Asia." If by "the Phrygo-Galatian region" is intended missionary ground new to the Apostle, we have a very brief record of the founding of churches. There is an entire absence of detail. After the Apostle had revisited the churches founded by him on his first missionary journey, the churches of Derbe, Lystra, Iconium, and Antioch (all of which were in the *Roman province* of Galatia), he would naturally pass on to Asia. But Asia was forbidden him as ground for missionary work. We might then understand Acts xvi. 6 to mean that the travellers went through the Phrygo-Galatian region *because* they were forbidden by the Holy Ghost to preach the word in Asia. "The Phrygo-Galatian region" would then be new ground, and might include Galatia proper or Gallogræcia. This is the interpretation of the participial clause given by supporters of the North-Galatian theory, as distinguished from the advocates of the South-Galatian theory, who hold that "the churches of Galatia" addressed by St Paul in his Epistle were the churches of Derbe, Lystra, Iconium, and Antioch, these being, as has been already said, in the province of Galatia. A serious objection to the North-Galatian interpretation of Acts xvi. 6, is that the preaching to those to whom the Epistle was written becomes due to a prohibition imposed by the Holy Ghost against speaking the word in Asia, whereas in the Epistle St Paul writes as if his first preaching had been due to some sickness or bodily infirmity (Gal. iv. 13). It is recognized by those who hold the North-Galatian theory that the route into Galatia was a very unlikely one for St Paul to take, and that his course can only be interpreted as due to some special guidance, such guidance being intended by the words of Acts xvi. 6, κωλυθέντες ὑπὸ τοῦ ἁγίου πνεύματος λαλῆσαι τὸν λόγον ἐν τῇ 'Ασίᾳ. But this cannot be reconciled satisfactorily with Gal. iv. 13. The present writer is of opinion that the proper way to interpret this κωλυθέντες participial clause is not retrospectively as giving the reason why the travellers went through the Phrygo-Galatian region, but as part of the predicate. They went through the Phrygo-Galatian region forbidden by the Holy Ghost to preach the word in Asia. The Phrygo-Galatian region is then not new ground at all, but that part of the province of Galatia which was Phrygian, where St Paul had already preached on his first missionary journey. This interpretation of the phrase "the Phrygo-Galatian region" is due to Professor W. M. Ramsay, who has steadily advocated the South-Galatian theory. In spite of opposition, the theory has been gaining adherents in Great Britain, though the opposition to it in Germany can claim some names of repute.

It has been urged as a serious objection to the South-Galatian theory that St Paul in the Epistle addresses his readers as "Galatians" (Gal. iii. 1). This appellation, it has been said, would be extremely inappropriate unless those addressed were nationally Galatians, and not only belonging to the province of Galatia. This objection has been met by Ramsay in *Studia Biblica*, vol. iv. (*The "Galatia" of St Paul and the "Galatic territory" of Acts*), and in his *Historical Commentary on the Galatians* (notes on iii. 1). And we may remark here that this argument might be turned against supporters of the North-Galatian theory, for it is not likely that a large percentage of inhabitants even of Gallogræcia were Gauls. There would be a mixture of Gaul, Phrygian, and Greek; thus Γαλαταὶ might be just as inappropriate as an appellation of the converts in Gallogræcia.

It has been well argued by Professor Ramsay that "the development and importance of the territory on the northern side of the plateau—*i.e.*, Northern Galatia and Northern Phrygia—belong to the period following after A.D. 292, and result from a transference of the centre of government, first to Nicomedia and afterwards to Constantinople. Under the earlier Roman Empire the southern side of the plateau was far more important than the northern side." This argument is worked out at length in Ramsay's *Historical Geography of Asia Minor*.

The reader who wishes to explore the subject thoroughly should study Ramsay's *The Church in the Roman Empire before A.D. 170*, and his *St Paul the Traveller and Roman Citizen*, with the other works mentioned in this article, also the articles on Galatia, &c., in Hastings's *Dictionary of the Bible*. (E. H. A.)

Galatz, a town and port of Rumania, on the left bank of the Danube, about 90 miles from Sulina on the Black Sea, and 130 miles north-east of Bucharest by rail. Its situation on the Danube between the rivers Sereth and Pruth makes it a position of mercantile importance. Great improvements have been carried out; all the main thoroughfares are paved, and the streets lighted with gas, the fine quays being lighted by electricity. Galatz ceased to be a free port in 1876. Large docks under government control have been constructed, covering an area of 88,000 square metres at low water. The depth is 5 metres at low water. The dock buildings consist of a grain warehouse with 338 silos constructed of iron and cement, having a total accommodation for about 25,000 tons of grain; a depôt for goods, several sheds for goods in transit, an engine room, and administrative offices with a room for samples. Extensive private grain storehouses are also in proximity to the docks and quays. Much of the grain trade has been absorbed by Braila, but the wood export industry has been much developed, and with the opening of the Galatz–Bêrlad railway, which brings much of the rich agricultural country of the north-west of Moldavia into direct touch with the former, Galatz will probably regain much of her ascendency. The navigation of the Sulina branch of the Danube has been greatly improved, vessels of 2500 tons being able to ascend to Galatz. There are large steam saw mills, flour mills, a brewery, soap and candle factories, oil works; a fine prison has been built, as well as extensive barracks, and military and civil hospitals. Electric tramways were started in 1900. The total imports amounted in 1898 to £2,363,595, and the total exports to £1,013,563. The average annual amount of shipping of all nations clearing from Sulina is 1500 vessels of 1,499,887 tons. Population 62,678, of whom 14,000 are Jews.

Galena, capital of Jo Daviess county, Illinois, U.S.A., on the Galena river, near the Mississippi. Three railways, the Chicago, Burlington, and Quincy, the Chicago and North-Western, and the Illinois Central, intersect here. The lead and zinc mines, to which Galena owes its existence and former prosperity, now produce but little, and the business of the city has decreased. Population (1880), 6451; (1890), 5635; (1900), 5005, of whom 918 were foreign-born.

Galena, a city of Cherokee county, Kansas, U.S.A., at the intersection of two railways, in the midst of the lead and zinc region. The development of these mines has given the city a rapid growth. Population (1890), 2496; (1900), 10,155, of whom 251 were foreign-born and 580 negroes.

Galesburg, capital of Knox county, Illinois, U.S.A., in a rich agricultural region, on a level site, at an altitude of 756 feet. It has excellent railway connexions by means of the Atchison, Topeka, and Santa Fé, the Chicago, Burlington, and Quincy, and the Fulton County Narrow Gauge railways. There are extensive manufactures of agricultural implements, carriages, waggons, &c., and the Chicago, Burlington, and Quincy Railway has yards and works here. Knox College and Lombard University, both co-educational institutions, are situated here. The former had, in 1899, 39 instructors and 413 students; the latter, 15 instructors and 116 students. Population (1880), 11,437; (1890), 15,264; (1900), 18,607, of whom 3602 were foreign-born and 738 negroes.

Galicia (German, *Galizien*; Polish, *Halicz*), a Crown land of the Cisleithan part of the Austro-Hungarian monarchy. Its population in 1880 was 5,958,907, and in 1890 was 6,607,816, equivalent to 218 inhabitants per square mile; in 1900 it was 7,295,538. The population grows solely by natural increase, there being practically no immigration, while there was a loss of 67,400 by emigration in the decade 1880–90. In 1890 the proportion of females to males was 1027 to 1000. Racially, 53·34 per cent. were Poles, 43·1 Ruthenians, the remainder being made up of Germans (3·46 per cent.) and about 500 Slovenes and Rumanians. Considered by religions, 45·38 per cent. were Roman Catholic, 42·22 per cent. Greek Catholic (mostly Ruthenians), 11·66 per cent. Jews, the remainder consisting of Protestants and Armenian Catholics. Provisional returns for 1898 gave a marriage-rate of 7·8, a birth-rate of 37·08, and a death-rate of 24·8. Of the births in 1897, 14·4 per cent. were illegitimate. The marriage, birth, and death rates are diminishing. Galicia sends 78 members to the Reichsrath, of whom 15 are returned by the new universal suffrage curia. The Diet is composed of 1 German, 133 Polish, and 17 Ruthenian members. Apart from the Polish Academy of Science, educational requirements are provided for by the Universities of Lemberg and Cracow

(2852 students), a Polytechnic (376 students), an Academy of Art, 3 theological seminaries, 30 gymnasia and *real* gymnasia, 12 academies of music, 337 commercial, agricultural, mining, and other technical and continuation schools, together with 11 intermediate and 3863 elementary schools. Only 65 per cent. of the children attend school. In 1880 the proportion of illiterates was 77·1, in 1890, 68·2 per cent.—a degree of illiteracy only exceeded in Austria by Bukovina and Dalmatia. Of the 203 periodicals and newspapers published in 1898, there were 153 in the Polish language, 25 in Ruthenian, 16 in Hebrew, 4 in German, 1 in Russian, and 4 were polyglot. More than three-fourths of the population are engaged in agriculture and forestry, and about 12 per cent. in mining, industry, and trade. Although there has been an increase in the proportion of arable land, Galicia is backward in agriculture, as in most other branches of production. It has the largest area under potatoes and legumes of any Austrian Crown land. The various classes of live stock show a moderate increase, with the exception of sheep, mules, and asses, which have greatly diminished. Its wealth of valuable timber is one of its chief resources. The principal mining products in 1897 were —coal (8 million metric centners), lignite (607,000 m.c.), petroleum (2,752,000 m.c.), and ozocerite (68,815 m.c.), in addition to smaller quantities of iron, lead, and zinc ore. The total production of salt in 1897 (34·75 per cent. of the total Austrian production) was 1,438,951 metric centners, value £739,970. Manufactures are still comparatively unimportant, with the exception of spirits, of which Galicia has 36·75 per cent. of the entire Austrian production. In 1897 there were 3082 kilometres of railway, 17·70 per cent. of the total length in Austria, 13,759 kms. of roads, and 2102 kms. of waterway, of which 1287 were only available for floating timber. There were 817 post and 351 telegraph offices, with 6168 kms. of line and 15,901 of wire.

This province enjoys a larger degree of autonomy than any other part of the empire. Indeed, owing to the absence of central control, due to the official employment of the Polish language, it may be said to be practically self-governed. Except from the standpoint of international policy—the Poles of Galicia are loyal, politically accommodating, and devoted to the dynasty—this experiment is not regarded as particularly successful. Nearly every department of the administration leaves much to be desired; the material and moral condition of the populace is unsatisfactory, and even that of the large landed proprietors, who have monopolized political power and influence, is less favourable than might fairly be expected, considering the advantages they have secured from the central Parliament. The treatment of the Ruthenians, who form nearly half the population, has excited animosity between the two races, and is considered certain to lead to difficulties if an opportunity offers; while the old feud between the peasant and the noble is as bitter as ever, and has latterly manifested itself in a dangerous form of agrarian socialism.

See SZUJSKI, *Die Polen und Ruthenen in Galizien*, Vienna, 1882; JANDAUREK, *Das Königreich Galizien*, Vienna, 1884; and histories by HOPPE, Vienna, 1793, and ENGEL, 1793. (Æ. O'N.)

Galilee. See PALESTINE.

Galilee, Sea of, the name most frequently used in the New Testament for the lake called in the O.T. the Sea of Chinnereth or Chinneroth, and, once in the N.T., the "lake of Gennesareth," a corruption of the old name, which is commonly used by Josephus and in the Targums. By St John the lake is called the "Sea of Tiberias," and this name survives in the modern Bahr Tabaríeh. In the Gospels its shores are closely connected with the Galilean ministry of Christ and the homes of most of the Apostles. The Sea of Galilee is, like the Dead Sea, a "rift" lake situated in the Jordan-ʿAraba depression. (See DEAD SEA.) It has an area of 64 square miles. The maximum depth is 145 to 150 feet. The present level is 682·5 feet below that of the sea, but deposits show that originally the lake formed part of the inland sea which filled the Jordan valley in Pleistocene times. During the rainy season the surface level rises from 2 to 4 feet. The shores are for the most part formed of fine gravel (limestone, basalt, and flint), mixed with fragments of shells. Some yards from the shore the bed of the lake is uniformly covered with a fine greyish mud. Oleanders fringe the lake, and the large papyrus grows at ʿAin et-Tin, and near the mouth of the Jordan. The heat in summer is tropical, but is relieved after noon by a strong northwest breeze, which causes a fall of 10° to 11° F. The slopes of the surrounding limestone hills, overlain here and there by basalts, which have a bare steppe-like appearance for half the year, are clothed with green in spring. The lake was once surrounded by towns with a large population, but Tiberias and Mejdel (Magdala) alone are now inhabited. The lake, in which Molyneux first took soundings in 1847, was examined in 1890 by M. Barrois. The most interesting features are—the great range of the diurnal variations of temperature at the surface, the relatively small depth of the zone (hardly 49 feet) influenced by these variations, the uniform temperature (59° F.) of the deeper zones between 65 feet and 131 feet, and the existence of at least one sub-aqueous hot spring. The water is generally used for drinking, but it is flat, slightly brackish, and not very clear. The surface is usually placid, but it is liable to be disturbed by short, sudden storms. The lake swarms with fish, which are caught with nets by a guild of fishermen, whose boats are the only representatives of the many ships and boats which plied on the lake as late as the 10th century. Fishing was a lucrative industry at an early date, and the Jews ascribed the laws regulating it to Joshua. The fish, which were classed as clean and unclean, the good and bad of the parable (Matt. xiii. 47, 48), belong to the genera *Chromis*, *Barbus*, *Capoeta*, *Discognathus*, *Nemachilus*, *Blennius*, and *Clarias*; and there is a great affinity between them and the fish of the East African lakes and streams. There are eight species of Chromis, most of which hatch their eggs and raise their young in the buccal cavities of the males. The *Chromis simonis* is popularly supposed to be the fish from which Peter took the piece of money (Matt. xvii. 27). The most remarkable fish is the *Clarias macracanthus* (Arab, *Burbur*), called coracinus by Josephus, who says that it lived in the Nile and in the spring of Capharnaum. It was found by Lortet in the springs of ʿAin Mudáwara, ʿAin et-Tin, and ʿAin Tabghah, on the lake shore where muddy, and in Lake Huleh. It is a scaleless, snake-like fish, often nearly 5 feet long, which resembles the *C. anguillaris* of Egypt. From the absence of scales it was held by the Jews to be unclean, and some commentators suppose it to be the serpent of Matt. vii. 10 and Luke xi. 11. Large numbers of grebes —great crested, eared, and little—gulls, and pelicans frequent the lake. On its shores are terrapins, crabs, and innumerable sandhoppers; and at varying depths in the lake several species of *Melania*, *Melanopsis*, *Neritina*, *Corbicula*, and *Unio* have been found.

(C. W. W.)

Galion, a city of Crawford county, Ohio, U.S.A., on the Erie and the Cleveland, Cincinnati, Chicago, and St Louis railways, at an altitude of 1167 feet. It has

"A Bohemian Woman and her Children." By L. Gallait.

railway and iron works. Population (1880), 5635; (1890), 6326; (1900), 7282—703 foreign-born.

Gallait, Louis (1810–1887), Belgian painter, was born at Tournay, in Hainaut, Belgium, 9th May 1810. He first studied in his native town under Hennequin. In 1832 his first picture, "Tribute to Cæsar," won a prize at the exhibition at Ghent. He then went to Antwerp to prosecute his studies under Mathieu Ignace Van Brée, and in the following year exhibited at the Brussels Salon "Christ Healing the Blind." This picture was purchased by subscription and placed in the cathedral at Tournay. Gallait next went to Paris, whence he sent to the Belgian Salons "Job on the Dunghill," "Montaigne Visiting Tasso in Prison"; and, in 1841, "The Abdication of Charles V.," in the Brussels Gallery. This was hailed as a triumph, and gained for the painter a European reputation. Official invitations then caused him to settle at Brussels, where he died on the 20th of November 1887. Among his greater works may be named: "The Last Honours paid to Counts Egmont and Horn by the Corporations of the Town of Brussels," now at Tournay; "The Death of Egmont," in the Berlin Gallery; the "Coronation of Baudouin, Emperor of Constantinople," painted for Versailles; "The Temptation of St Anthony," in the Palace at Brussels; "The Siege of Antioch," "Art and Liberty," a "Portrait of M. B. Dumortier," and "The Plague at Tournay," all in the Brussels Gallery. "A Gipsy Woman and Her Children" (see Plate) was painted in 1852. "M. Gallait has all the gifts that may be acquired by work, taste, judgment, and determination," wrote Théophile Gautier; his art is that of a man of tact, a skilled painter, happy in his dramatic treatment, but superficial. No doubt, this Walloon artist, following the example of the Flemings of the Renaissance and the treatment of Belgian classical painters and the French Romantic School, sincerely aimed at truth; unfortunately, misled by contemporary taste, he could not conceive of it excepting as dressed in sentimentality. As an artist employed by the State he exercised considerable influence, and for a long period he was the leader of public taste in Brussels.

Galle, or Point de Galle, town and port of Ceylon, on the south-west coast. The opening of the Suez Canal in 1869, and the construction of a breakwater at Colombo, leading to the transfer of the mail and most of the commercial steamers to the capital port of the island, made a great difference to Galle. Although a few steamers still call to coal and take in some cargo, yet the loss of the Peninsular and Oriental and other steamer agencies reduced it to a very subordinate position; nor has the extension of the railway, 70½ miles from Colombo, and beyond Galle 26½ miles to Matara, very much improved matters. The houses occupied by Europeans in or near the town are now very few. The tea-planting industry has, however, spread to the neighbourhood, and a great deal is done in digging plumbago and in growing grass for the distillation of citronella oil. The export trade for 1899 was chiefly represented by cocoanut oil, 47,731 cwt.; plumbago, 57,549 cwt.; coir yarn, fibre, and rope, 68,930 cwt.; while of tea 348,067 ℔ were shipped. In import trade there was a declared value of about 50,000 rupees (£3400) of cotton goods in the same year. Both the export and import trade for the district, however, chiefly passes through Colombo. Population (1891), 33,853; (1901), 37,248.

Gallenga, Antonio Carlo Napoleone (1810–1895), Italian author and patriot, born at Parma on 4th November 1810, was the eldest son of a Piedmontese of good family, who served for ten years in the French army under Massena and Napoleon. He had finished his education at the University of Parma, when the French Revolution of 1830 caused a ferment in Italy. He sympathized with the movement, and within a few months was successively a conspirator, a State prisoner, a combatant, and a fugitive. For the next five years he lived a wandering life in France, Spain, and Africa. In August 1836 he embarked for New York, and three years later he proceeded to England, where he supported himself as a translator and teacher of languages. His first book, *Italy; General Views of its History and Literature*, which appeared in 1841, was well received, but was not successful financially. On the outbreak of the Italian Revolution in 1848 he at once put himself in communication with the insurgents. He filled the post of Chargé d'Affaires for Piedmont at Frankfort in 1848–49, and for the next few years he travelled incessantly between Italy and England, working for the liberation of his country. In 1854, through Cavour's influence, he was elected a deputy to the Italian Parliament. He retained his seat until 1864, passing the summer in England and fulfilling his parliamentary duties at Turin in the winter. On the outbreak of the Austro-French war of 1859 he proceeded to Lombardy as war correspondent of *The Times*. The campaign was so brief that the fighting was over before he arrived, but his connexion with *The Times* endured for twenty years. He was a forcible and picturesque writer, with a command of English remarkable for an Italian. He materially helped to establish that friendly feeling towards Italy which became traditional in England. In 1859 Gallenga purchased the Falls, at Llandogo on the Wye, as a residence, and thither he retired in 1885. He died at this house on 17th December 1895. He was twice married. Among his chief works are a *Historical Memoir of Frà Dolcino and his Times*, 1853; a *History of Piedmont*, 3 vols., 1855, Italian translation 1856; *Country Life in Piedmont*, 1858; *The Invasion of Denmark*, 2 vols., 1864; *The Pearl of the Antilles* [travels in Cuba], 1873; *Italy Revisited*, 2 vols., 1875; *Two Years of the Eastern Question*, 2 vols., 1877; *The Pope* [Pius IX.] *and the King* [Victor Emmanuel], 2 vols., 1879; *South America*, 1880; *A Summer Tour in Russia*, 1882; *Iberian Reminiscences*, 2 vols., 1883; *Episodes of my Second Life*, 1884; *Italy, Present and Future*, 2 vols., 1887. Gallenga's earlier publications appeared under the pseudonym of Luigi Mariotti. (E. I. C.)

Gallieni, Joseph Simon (1849–——), French soldier and administrator, was born at Saint-Béat, in the department of Haute-Garonne, on 24th April 1849. He left the military academy of Saint-Cyr in July 1870 as a second lieutenant in the Marines, becoming lieutenant in 1873 and captain in 1878. He saw service in the Franco-German war, and between 1877 and 1881 took an important part in the explorations and military expeditions by which the French dominion was extended in the basin of the Upper Niger. He rendered a particularly valuable service by obtaining, in March 1881, a treaty from Ahmadu, chief of Segu, giving the French exclusive rights of commerce on the Upper Niger. For this he received the gold medal of the Société de Géographie. From 1883 to 1886 Gallieni was stationed in Martinique. On 24th June 1886 he attained the rank of lieutenant-colonel, and on 20th December was nominated governor of Haute-Fleuve (Senegal). He obtained several successes against

Ahmadu in 1887, and compelled Samory to agree to a treaty by which he abandoned the left bank of the Niger. In connexion with his service in West Africa Gallieni published two works — *Voyage au Sudan Français, 1879–1881* (Paris, 1885), and *Deux Campagnes au Sudan Français* (Paris, 1891), which, besides possessing great narrative interest, give information of considerable value in regard to the resources and topography of the country. In 1888 Gallieni was made an officer of the Legion of Honour. In 1891 he attained the rank of colonel, and from 1893 to 1895 he served in Tongking, commanding the second military division of the territory. In 1899 he published his experiences in *Trois Colonnes au Tonkin.* In September 1896 Madagascar was made a French colony, and after the unsuccessful administration of Laroche, Gallieni was appointed resident-general and commander-in-chief. By a vigorous military system he succeeded in clearing of brigands the great routes to the capital, and eventually in completing the subjugation of the island. He then turned his attention to the destruction of the political supremacy of the Hovas and the restoration of the autonomy of the other tribes. The execution of the queen's uncle, Ratsimamanga, and of Rainandrianampandry, the minister of the interior, in October 1896, and the exile of Queen Ranavalona herself in 1897, on the charge of fomenting rebellion, broke up the Hova hegemony; but the application of the tariff of French customs and other like measures were disastrous to British and American trade, and struck a serious blow at the commercial prosperity of the island.

Galliffet, Gaston Alexandre Auguste de, Marquis, Prince de Martignes (1830– ——), French general, was born in Paris on 23rd January 1830. He entered the army in 1848, was commissioned as sub-lieutenant in 1853, and served with distinction at the siege of Sebastopol in 1855 (Legion of Honour), in the Italian campaign of 1859 under General Douay, and in Algeria in 1860. He displayed great gallantry as a captain at the siege and storm of Puebla, in Mexico, in 1863, when he was severely wounded (majority and officer, Legion of Honour). He went again to Algeria in 1864, took part in expeditions against the Arabs, and became colonel in 1867, with the command of the 3rd Regiment of Chasseurs d'Afrique. In the Franco-German war of 1870–71 he commanded this regiment in the Army of the Rhine, was promoted to be general of brigade on 30th August, and commanded the three regiments of Chasseurs d'Afrique at the battle of Sedan, leading them in person in a splendid charge on the heights of Floing, and winning the admiration of his enemies. Made prisoner of war at the capitulation of Sedan, he returned to France during the siege of Paris by the French Army of Versailles, and commanded a brigade against the Communists. The severity of his methods against the Communists came to be permanently associated with his name. In 1872 he took command of the Batna subdivision of Algeria, and commanded an expedition against El Golea, surmounting great difficulties in a rapid march across the desert, and inflicting severe chastisement on the revolted tribes (commander, Legion of Honour). On the general reorganization of the army he commanded the 31st infantry brigade of the 8th Army Corps, and the department Cher. Promoted general of division in 1875, he successively commanded the 15th infantry division at Dijon, the 9th Army Corps at Tours, and in 1882 the 12th Army Corps at Limoges. In 1885 he became a member of the Supreme Council of War. He conducted the cavalry manœuvres in successive years, and attained a European reputation on all cavalry questions. Decorated with the Grand Cross of the Legion of Honour in 1887, he received a military medal for his able conduct of the autumn manœuvres in 1891, and after again commanding at the manœuvres of 1894 he retired from the active list. Afterwards he took an important part in French politics, as War Minister (22nd June 1899 to 29th May 1900) in M. Waldeck-Rousseau's Cabinet, and distinguished himself by the firmness with which he dealt with certain cases of unrest in the army.

Gallipoli, a fortified seaport town and episcopal see of the province of Lecce, Apulia, Italy, on the east side of the Gulf of Taranto, and 59 miles by rail south from Brindisi. It exports olive oil (£113,000 to £236,000 annually), wine (£185,500 in 1899), dried figs (£12,000 average), &c., to the average value of £300,000 annually (£454,500 in 1899); and imports cereals, flour, timber, and other commodities (£11,000 in 1888, £153,200 in 1899). The port was cleared by 407 vessels of 188,180 tons in 1888, and by 913 vessels of 338,670 tons in 1899. The harbour was dredged to a depth of 16¼ feet in 1884, and further improved at a later date. Population, 11,000.

Gallipoli, a seaport of Turkey, on the Thracian Chersonesus, chief town of the sanjak of the same name. Its chief industries consist of two steam flour mills, and a sardine factory which exports 15,000 to 16,000 cases (100 boxes to a case) annually. The sanjak, of which the population is 95,500, comprises four *kazas* (cantons), namely (1) Maitos, noted for its excellent cotton; (2) Keshan, lying inland north of Gallipoli, noted for its cattle-market, the district producing also grain, linseed, and canary seed; (3) Myriofyto; and (4) Sharkeui, on the coast of the Sea of Marmora, which once produced wine that was highly esteemed and was largely exported to France for blending. Heavy taxation, however, amounting to 55 per cent. of the value of the wine, broke the spirit of the viticulturists, most of whom uprooted their vines and replanted their lands with mulberry trees, making sericulture their occupation, an industry which is year by year assuming larger proportions. All this region has been depressed by a succession of bad crops, and the people oppressed by excessive taxation rigidly exacted. The country folk have been reduced to indigence, their lands, their cattle, and in many cases their household goods, having been sold by the authorities to cover arrears of taxes. (E. W*.)

Galston, a police burgh and manufacturing town of Ayrshire, Scotland, on the river Irvine, 5 miles east by south of Kilmarnock by rail. There is a blanket factory, 2 lace and muslin and 3 hosiery factories, and a paper millboard factory. There are coal mines in the vicinity. The institute contains a library and recreation rooms. A Roman Catholic church was erected in 1886 by the marquis of Bute. Galston figures frequently in Burns's poems. Population (1881), 4085; (1901), 4876.

Galt, a town in Waterloo county, Ontario, Canada, 23 miles N.N.W. of Hamilton, on the Grand river and on the Grand Trunk and Canadian Pacific railways. It has excellent water privileges, which furnish power for flour mills, and axe, machinery, paper, and other manufactories. Exports in 1899–1900 were valued at $165,913, imports at $729,931. Population (1881), 5187; (1900), 7746.

Galton, Francis (1822– ——), English anthropologist, son of S. T. Galton, of Duddeston, Warwickshire, His grandfather was the poet-naturalist Erasmus Darwin, and his cousin was the famous propounder of the doctrine of evolution. Francis Galton was born in 1822, and educated at King Edward VI.'s Grammar School, Birmingham. Electing to study medicine, he attended classes at Birmingham Hospital, and afterwards "walked" King's College, London. Graduating at Trinity College, Cambridge, in 1844, he next travelled for two years and ascended the White Nile, thus being a pioneer of the modern explorers of that part of the Dark Continent. In 1850 he made an exploration, with Dr John Anderson, of Damaraland and the Ovampo country in South-West Africa, starting from Walfisch Bay. These tracts had practically never been traversed before, and on the appearance of the published account of his journey and experiences under the title of *Narrative of an Explorer in Tropical South Africa* (1853) Galton was awarded the gold medal of the Royal Geographical Society. His *Art of Travel; or, Shifts and Contrivances in Wild Countries*, was first published in 1855. In 1861 he visited the north of Spain, and published the fruits of his observations of the country and the people in the first of a series of volumes which he edited, entitled *Vacation Tourists.* He then turned to meteorology, the result of his investigations appearing in *Meteorographica*, published in 1863. This was the first serious attempt to chart the weather on an extensive scale, and in this work also the author first established the existence and theory of anti-cyclones. Galton succeeded Admiral Fitzroy as a member of the meteorological committee of the Board of Trade, and was appointed one of the committee entrusted with the parliamentary grant for the Meteorological Office. He next devoted himself to the study of heredity, and with his researches on this subject and his anthropological investigations his name will be most closely associated. In 1869 appeared his *Hereditary Genius, its Laws and Consequences*, a work which excited much interest in scientific and medical circles. This was followed by *English Men of Science, their Nature and Nurture*, published in 1874; and *Inquiries into Human Faculty and its Development*, issued in 1883. Then followed, in the order named, *Life-History Album*, 1884; *Record of Family Faculties*, 1884 (tabular forms and directions for entering data, with a preface); *Natural Inheritance*, 1889; *Decipherment of Blurred Finger-Prints*, 1893; and *Finger-Print Directories*, 1895. Galton is also the author of several memoirs on anthropometric subjects, and on new statistical processes applicable to anthropometry, including that of composite portraiture. His writings on heredity have been especially popular. He has had a long connexion with the leading scientific societies, and in 1886 he received the gold medal of the Royal Society.

Galveston, seaport and capital of Galveston county, Texas, U.S.A., on Galveston Island, Gulf of Mexico, at the entrance to Galveston Bay. It is the fourth city of the state in population, and first in commercial importance, and it is one of the important commercial centres of the South. Six railways meet in it, and its excellent harbour has had its entrance deepened by jetties, at the expense of the United States. Through these agencies Galveston has become one of the largest cotton shipping ports of the country, shipping 900,000 bales of cotton annually. Its exports increased from $15,700,000 in 1888 to $68,428,621 in 1898, placing it second only to New Orleans among the southern ports. Of these exports 70 per cent. consisted of raw cotton. It has regular steamship lines to the ports of the Gulf, Atlantic, West Indies, and Europe. In the autumn of 1900 it was nearly destroyed by a West Indian hurricane, but was rapidly rebuilt. Its manufactures are by no means comparable with its commerce. In 1890 the capital invested was $5,122,612, employing 1932 hands and producing $5,724,545 of products. These were of great variety. The assessed valuation of real and personal property, on a basis of about two-thirds of the full value, was in 1899 $26,777,338, the net debt of the city $2,839,146, and the rate of taxation $26·30 per $1000. Population (1880), 22,248; (1890), 29,084; (1900), 37,789, of whom 6339 were foreign-born and 8291 negroes.

Galway, a maritime county of Ireland, province of Connaught, bounded on the N. by Mayo and Roscommon; on the E. by Roscommon, King's County, and Tipperary; on the W. by the Atlantic Ocean; and on the S. by Clare and Galway Bay. The area of the administrative county in 1900 was 1,463,430 acres, of which 196,365 were tillage, 755,888 were pasture, 851 fallow, 25,166 plantation, 141,925 turf bog, 54,876 marsh, 221,259 barren mountain, and 67,100 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, includes the parliamentary borough of Galway, and the portion of Ballinasloe formerly situated in Roscommon, but is diminished to the extent of six electoral divisions added to other counties. The population in 1881 was 242,005, and in 1891 214,712, of whom 108,283 were males and 106,429 females, divided as follows among the different religions: Roman Catholics, 208,364; Protestant Episcopalians, 5340; Presbyterians, 628; Methodists, 324; and other denominations, 56. The average number of persons to an acre in the whole county was ·14. Of the total population, 191,673 persons inhabited the rural districts, being an average of 134 persons to each square mile under crops and pasture. The population in 1901 was 192,146 (Roman Catholics, 186,870; Protestant Episcopalians, 4435; Presbyterians, 589; Methodists, 181; others, 71), being a decrease of 10·5 per cent., as compared with a decrease of 11·3 per cent. from 1881 to 1891. The following table gives the number of births, deaths, and marriages in various years:—

Year.	Births.	Deaths.	Marriages.
1881	5638	3323	708
1891	4707	3370	651
1899	4373	2755	650

The birth-rate per 1000 in 1899 was 20·7, and the death-rate 13·0; the rate of illegitimacy was ·9 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1899 was 196,794, of whom 94,295 were males and 102,499 females. The chief towns in the county are Galway, Ballinasloe, and Tuam.

Education.—The following table gives the degree of education in 1891 (excluding the town of Galway):—

	Males.	Females.	Total.	Percentage.		
				R. C.	Pr. Ep.	Presb.
Read and write	51,837	47,694	99,531	55·3	91·0	94·4
Read only	8,358	8,792	17,150	9·8	4·0	2·8
Illiterate	29,065	31,364	60,429	34·9	5·0	2·8

In 1881 the percentage of illiterates among Roman Catholics was 47·5. In 1891 (including the town of Galway) the number of superior schools was 11, with 489 pupils (Roman Catholics 325, and Protestants 164), and the number of primary schools was 445, with 30,743 pupils (Roman Catholics 29,720, and Protestants 1023). The number of pupils on the rolls of the national schools on 30th September 1899 was 39,485, of whom 38,850 were Roman Catholics and 635 Protestants.

Administration.—The county is divided into four parliamentary divisions, north, south, east, and Connemara, the number of registered electors in 1900 being respectively 10,475, 8148, 8936, and 8423. The rateable value in 1900 was £472,941. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises two urban and ten rural sanitary districts. By the same Act the county of the town of Galway was abolished.

Agriculture.—The following tables give the acreage under crops, including meadow and clover, and the amount of live stoek in 1881, 1891, 1895, and 1900. The figures for 1900 are for the new administrative county.

Year.	Wheat.	Oats.	Barley, Rye, Beans, &c.	Potatoes.	Turnips.	Other Green Crops.	Meadow and Clover.	Total.
1881	3544	54,352	6923	50,533	12,307	7066	85,345	220,070
1891	5258	42,962	4542	41,621	12,594	9313	91,220	207,510
1895	2766	42,220	4440	38,900	11,789	8135	95,186	203,436
1900	4054	36,710	3615	36,768	11,077	8986	95,155	196,365

In 1899 the total value of the cereal and other crops was estimated by the Registrar-General at £1,366,245. The number of acres under pasture in 1881 was 741,803 ; in 1891, 717,775 ; and in 1900, 755,888.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	29,070	14,763	173,445	530,912	53,768	10,549	757,922
1891	32,828	18,373	200,188	683,560	63,125	14,623	858,609
1895	33,566	17,967	190,552	602,944	63,500	13,207	877,143
1900	28,986	18,207	198,385	653,456	69,874	13,668	924,903

The number of milch cows in 1891 was 44,852 and in 1900 45,170. It is estimated that the total value of cattle, sheep, and pigs in 1899 was £3,975,514, the third largest amount in the Irish counties. In 1900 the number of holdings not exceeding 1 aere was 1980 ; between 1 and 5, 4553 ; between 5 and 15, 11,951 ; between 15 and 30, 8762 ; between 30 and 50, 3498 ; between 50 and 100, 2410 ; between 100 and 200, 1340 ; between 200 and 500, 765 ; and above 500, 222—total, 35,481. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1900, was 1529, amounting to £416,170. The number of loans for agricultural improvements sanctioned under section 31 of the Land Act, 1881, between 1882 and 1900, was 653, and the amount issued was £46,323. The total amount issued on loan for all classes of works under the Land Improvement Aets from the commencement of operations in 1847 to 31st March 1900 was £392,919.

Fisheries.—In 1899 1414 vessels, employing 4877 hands, were registered in the deep-sea and coast fishery districts of Galway and Clifden. In the same year 344 persons were employed in the salmon fishery districts of Galway and Connemara.

(W. H. Po.)

Galway, a maritime town and parliamentary borough (returning one member), capital of the above county, on the north side of Galway Bay, and on the Midland Great Western Railway. The town commissioners were abolished in 1898, and an urban district council substituted. There is an extensive line of quays, and a canal runs from the harbour to Lough Corrib and Lough Mask. In all, 193 vessels of 37,376 tons entered in 1899, and 80 of 16,798 tons cleared. The number of vessels registered in 1899 in the fishery district was 793, and the number of men and boys employed 2503. A light railway now runs from Galway to Clifden. Population (1881), 15,417 ; (1901), 13,414.

Gambetta, Léon (1838–1882), French statesman, was born at Cahors on the 3rd of April 1838. His father, a Genoese, who had established himself as a grocer and had married a Frenchwoman, is said to have been his son's prototype in vigour and fluency of speech. In his sixteenth year young Gambetta lost by an accident the sight of his left eye, which eventually had to be removed. Notwithstanding this privation, he highly distinguished himself at the public school of Cahors, and in 1857 proceeded to Paris to study law. His southern vehemence gave him great influence among the students of the Quartier Latin, and he was soon known as an inveterate enemy of the Imperial Government. He was called to the bar in 1859, but, although contributing to a Liberal review, edited by M. Challemel Lacour, did not make much way until, on the 17th of November 1868, he was selected to defend a journalist prosecuted for having promoted the erection of a monument to the representative Baudin, killed in resisting the *coup d'état* of 1851. Gambetta seized his opportunity, and assailed both the *coup d'état* and the Government with an eloquence of invective which made him immediately famous. In May 1869 he was returned to the Assembly, both by the first circumscription of Paris and by Marseilles, defeating Hippolyte Carnot for the former constituency and Thiers and Lesseps for the latter. He elected to sit for Marseilles, and lost no opportunity of attacking the Empire in the Assembly. He opposed the war with Germany, but did not refuse to vote supplies when it was determined upon. When the news of the disaster at Sedan reached Paris, Gambetta led the agitation which substituted the Republic for the

Léon Gambetta.
(From a photograph by Carjat et Cie., Paris.)

Empire, and was one of the members of the new Government of National Defence. He advised his colleagues to leave Paris and conduct the Government from some provincial city. This advice was rejected from dread of another revolution in Paris, and a delegation to organize resistance in the provinces was despatched to Tours, but when this was seen to be inefficient Gambetta himself (7th October) quitted Paris in a balloon, and upon arriving at Tours took the supreme direction of affairs as Minister of the Interior and of War. Aided by M. de Freycinet, a young officer of engineers, as his assistant secretary of war, he displayed prodigies of energy and intelligence. He speedily organized an army, which might possibly have effected the relief of Paris if Metz had held out, but the treacherous surrender of Bazaine brought the army of the Crown Prince into the field, and success was impossible. After the defeats of the French near Orleans early in December the seat of government had to be transferred to Bordeaux, and when Paris surrendered at the end of January, Gambetta, though resisting and protesting, was compelled to submit to the capitulation concluded with Prince Bismarck. He immediately resigned his office. Elected by nine departments to the National Assembly meeting at Bordeaux, he chose to sit for Strasburg, which by the terms of the treaty about to be submitted to the Assembly for ratification was to be ceded to Prussia, and when the treaty was adopted he resigned in protest and retired to Spain. It is difficult to determine whether patriotism or political calculation had more influence on his conduct. He returned to France in June, was elected by three departments in July, and commenced an agitation for the definitive establishment of the Republic. In 1871 he established a journal, *La République Française*, which soon became the most influential in France. His orations at public meetings were more effective than those delivered in the Assembly, especially that made at Bordeaux on his return, and that at Grenoble on 26th November 1872, in which he spoke of political power having passed to *les nouvelles couches sociales*. When Thiers fell from power in May 1873, and a Royalist was placed at the head of the Government in the person of Marshal MacMahon, Gambetta gave proof that the demagogue had ripened into the statesman. He unceasingly urged his friends to a moderate course, and by his tact and parliamentary dexterity, no less than by his eloquence, was mainly instrumental in the voting of the Constitution in February 1875. This policy he continued during the early days of the now consolidated Republic, and gave it the appropriate name of "Opportunism." It was not until 4th May 1877, when the peril from reactionary intrigues was notorious, and the clerical party had begun a campaign for the restoration of the temporal power of the Pope, that he delivered his famous speech denouncing "Clericalism" as "the enemy." On 16th May Marshal MacMahon, in order to support the clerical reactionaries, perpetrated his parliamentary *coup d'état*, and on 15th August Gambetta, in a speech at Lille, gave him the alternative *se soumettre ou se démettre*. This was during the great electoral contest, the result of which left MacMahon, equally unwilling to resign or to provoke civil war, no choice but to dismiss his advisers and form a moderate Republican ministry under the premiership of M. Dufaure. When the resignation of the Dufaure Cabinet brought about the abdication of Marshal MacMahon, Gambetta did not become a candidate for the Presidency, but allowed this to devolve upon M. Grévy; nor did he attempt to form a ministry, but accepted the office of President of the Chamber of Deputies (January 1879). This position, which he filled with much ability, did not prevent his occasionally descending from the presidential chair to make speeches, one of which, advocating an amnesty to the Communards, was especially memorable. He evidently thought that the time was not ripe for asserting his own claims to direct the policy of the Republic, and seemed inclined to observe a neutral attitude as far as possible; but events hurried him on, and early in 1881 he placed himself at the head of a movement for restoring *scrutin de liste*, or the system by which deputies are returned by the entire department which they represent, so that each elector votes for several representatives at once, in place of *scrutin d'arrondissement*, the system of small constituencies, giving one member to each district and one vote to each elector. A bill to re-establish *scrutin de liste* was passed by the Assembly on 19th May 1881, but rejected by the Senate on 19th June. The Ferry Cabinet then in office was unable to retain its ground, and Gambetta was unwillingly entrusted by M. Grévy with the formation of a ministry in November 1881 — known as *Le Grand Ministère*. He now experienced the Nemesis of his over-cautious system of abstinence from office for fear of compromising his popularity. Every one suspected him of aiming at a dictatorship; attacks, not the less formidable for their injustice, were directed against him from all sides, and his Cabinet fell ingloriously in February 1882, after an existence of only sixty-six days. Had he remained in office the face of the world might now have been different, for his declarations leave no doubt that he would have cultivated the British alliance and co-operated with Great Britain in Egypt. It is only surprising that, feeling as he did, he should not have protested against the desertion of Great Britain by the Freycinet administration. His fortunes were presenting a most interesting problem when, on 31st December 1882, at his house in Ville d'Avray, near Sèvres, he came to a violent end, by a shot from a pistol, in circumstances which have never been fully explained. France awoke to a sense of her obligation to him, and his public funeral on the 6th of January 1883 evoked one of the most overwhelming displays of national sentiment ever witnessed on a similar occasion.

Gambetta is the only politician produced by France between 1870 and 1900 who merits the reputation of greatness. He rendered France three inestimable services: by preserving her self-respect through the gallantry of the resistance he organized during the German war, by his tact in persuading extreme partisans to accept a Moderate Republic, and by his energy in overcoming the usurpation attempted by the advisers of Marshal MacMahon. Had he remained in power he might have rendered yet another by giving a sound direction to her foreign policy. His fall, which could have been but temporary, was not so much owing to popular ingratitude as to a serious fault of his own, his want of loyalty to his colleagues, whom he systematically used for his own purposes, until at length he found himself distrusted and isolated. His death, however, at the early age of forty-four, cut short a career which had given promise of greater things than have been accomplished by any of those who tried to maintain his traditions. In many respects he strikingly resembles Danton, but he was too humane and good-natured to have participated in a Reign of Terror. (R. G.)

Gambia, the most northerly of the British West African dependencies. The total area of the colony and Protectorate is 3550 square miles, but before the delimitation of the frontier in 1891, in accordance with the Anglo-French agreement of 1889, the outside districts which now form the Protectorate constituted a wholly undefined sphere of influence, and the settlements (including St Mary's Island, British Combo, the Ceded Mile, McCarthy's Island, and other islets) had an area of about 69 square miles. The general effect of the delimitation was to recognize as British a narrow strip of land extending for about 6 miles on each side of the river to a distance of about 250 miles from the sea. The land outside these limits and beyond the Barraconda rapid is recognized as French. The breadth of the colony near the coast is somewhat greater. Gambia, as its name implies, derives its character and value from the river, which is navigable throughout the colony, while large ocean-going ships can always cross the bar at its mouth and enter the port of Bathurst (population about 6000). Steamers already run to McCarthy's Island, and the line will be continued to Yarbutenda (243 miles from Bathurst). The banks of the river, for about 100 miles from its mouth, are fringed with mangrove swamps, behind which are plains densely covered with grass and interspersed with clumps of timber. Beyond this point the banks become steep and thickly wooded, the valley of the river from McCarthy's Island to Barraconda being enclosed by low rocky hills of volcanic character, surrounded by park-like scenery. Since 1888 the Gambia has been a separate Crown colony, with a governor, still termed administrator, and an executive and legislative council. The executive council includes one nominated member, and the legislative two unofficial members. The Protectorate is divided into seventeen districts, each placed under a head chief, supervised by travelling commissioners. The population of the settlements was returned in 1898 as 14,300, having remained nearly stationary since 1881. The population of the Protectorate has been estimated at about 200,000. The native tribes are almost exclusively negro: Mandingoes, Jolofs, Jolas, &c. The Europeans in the settlements number about sixty. Education is in a very backward

SKETCH MAP OF GAMBIA.

condition, in spite of mission schools supported by Government. Mahommedanism is reported to be increasing, "and with it temperance and decency." The climate of Bathurst is fairly healthy during the dry season. The temperature is subject to great variations, the thermometer sometimes varying from 68° to 98° on the same day. It is always warmer by 20° or more up the river than near the sea coast. The mean temperature at Bathurst at noon in the shade is from 72° to 82°. The average rainfall is about 50 inches, but, with the exception of a few showers in May and June, there is no rain excepting between July and October. The dry east wind, known as the "harmattan," blows from December to March. The agricultural resources of the colony remain undeveloped. Land can be hired for 2d. an acre per annum for twenty-one years, and there is stated to be an opening for capital in the cultivation of sisal hemp, &c. A botanical station was opened in 1894, but as yet has led to little results. Ground nuts (*Arachis hypogœa*) are the staple product, and account for more than four-fifths of the total exports. They go mainly to Marseilles, where the oil derived from them is sold as olive. In 1899 the exports amounted to 34,353 tons of the value of £210,005, as against about 20,000 tons of the value of about £127,000 in 1897. Next to ground nuts, but at a long interval, the most important product is india-rubber. Beeswax, palm kernels, and hides are also exported in small quantities. The principal imports are cotton goods, kola nuts (from Sierra Leone), tobacco, and spirits. The revenue for 1899 amounted to nearly £47,000. Over £36,000 was derived from custom duties, of which over £11,000 was from ground nuts. There is no public debt, and there was in 1899 an available surplus of more than £43,000. The cost of the Protectorate is covered by direct taxation. A hut tax has encountered no opposition from the natives.

Game Laws.—There have not been any changes since 1879 in the laws affecting winged game, except the alteration of the close season for partridges in Ireland, which is now from 1st February to 31st August, and the passing of a temporary Act, still annually continued, for the protection of that occasional summer visitor, the sand-grouse. The Wild Birds' Protection Acts have not in any district been used to alter the close time for game birds. A measure of protection against the inconsiderate preservation of game has been given by a decision of the High Court, that persons who overstock with game lands over which they have sporting rights are liable for damage thereby caused to the crops of the occupiers.

In 1880 the Ground Game Act was passed, at the instance of Sir William Harcourt, "in the interests of good husbandry, and for the better security of capital and labour invested by occupiers of land in the cultivation of the soil." With these objects the Act gives to the occupier of the land (whether he be also owner or not, and whether his occupation be under lease or only under an agreement for a lease), as incident to and inseparable from his occupation, the right to kill and take hares and rabbits on the land. The right of the occupier is indefeasible, and he cannot divest himself of it by contract with his landlord, or even by letting his sporting rights over the land; but, where the terms of occupation do not otherwise provide, the landlord, as the lessee of the sporting rights, or persons having right of chase or free warren, may take ground game *concurrently* with the occupier. The mode of exercise of the right is subject to certain limitations. Traps must not be set except in rabbit burrows, nor may poison be used. Firearms may not be used at night as defined in the Night Poaching Act, nor may they be used at any time except (1) by the occupier himself, and (2) with his authority by some *one* other person. But the occupier may authorize the taking or capture of hares and rabbits by other means by members of his own household resident on the land, persons in his ordinary service on the land, and persons *bonâ fide* employed for reward in taking and destroying ground game. The authority must be in writing, and must be produced on demand to persons who have a concurrent right to take the game, or an authorized agent. No game licence is necessary, and the occupier may sell the hares and rabbits taken.

There is no close time for hares or rabbits in England or Scotland, except Sundays and Christmas Day. In Ireland there is a close time from 20th April to 12th August. But hares and leverets killed in the United Kingdom may not be sold in March, April, May, June, or July; and occupiers of moorland and unenclosed land which is not arable (except detached portions not exceeding 25 acres) may exercise their right to take ground game only from 11th December to 31st March. The terms for which licences to kill game are issued were altered in 1883, and they are now of four kinds:—

Those taken out after 31st July:—			
To expire on the next 31st July . . .	£3	0	0
To expire on the next 31st October . .	2	0	0
Those taken out after 1st November:—			
To expire on the next 31st July . . .	2	0	0
Those taken out for any continuous period of fourteen days specified in the licence . .	1	0	0

The necessity of licences to deal in game was in 1893 extended to game killed abroad, but the penalties for selling in close time do not extend to such game. Since

1894 the authority of justices of the peace to grant game-dealers' licences has been transferred to borough or district councils in places outside London. The terms on which they may be granted have not been changed, but have been construed so as to preclude their grant to large stores in London which have also a licence for the sale of beer.

See OKE's *Game Laws*, 4th ed., by Willis Bund, 1897.—WARRY. *The Game Laws of England*, 1897.—MARCHANT and WATKINS. *The Wild Birds' Protection Acts*, 1897. (W. F. C.)

Gaming.—There was no new legislation between 1879 and 1902 for the punishment of gaming except the Betting and Loans (Infants) Act, 1892, passed at the instance of Lord Herschell, which makes persons guilty of misdemeanour who, with a view to profit, send to any one whom they know to be an infant a document inviting him to enter into a betting or wagering transaction. The Act was intended to protect lads at school and college from temptation by bookmakers. The powers of making bye-laws for the peace, order, and good government of their districts, possessed by municipal boroughs—and since 1888 by County Councils—and extended in 1899 to the new London boroughs, have in certain cases been exercised by making bye-laws forbidding any person to "frequent or use any street or other public place, on behalf either of himself or any other person, for the purpose of book-making, or betting, or wagering, or agreeing to bet or wager with any person, or paying, or receiving, or settling bets." This and similar bye-laws have been held valid. The police and the Anti-Gambling League have during the last few years shown great activity in the enforcement of the Acts against betting and gaming. Some results of this activity have been to add baccarat banque and *chemin de fer* to the list of unlawful games, and to establish that a man cannot be convicted of keeping a common gaming-house because on a single occasion he invites friends in to play an unlawful game; and also to apply to persons found in gaming-houses the provisions of the old Act of Hen. VIII. by binding them over not to frequent such places. A further result has been to produce a large crop of decisions on the Betting Act of 1853, showing a considerable divergence of judicial opinion. The House of Lords has held that the Tattersall's enclosure or betting ring on a race-course is not a "place" within the statute; and members of a *bonâ fide* club who bet with each other in the club are not subject to the penalties of the Act. But the word "place" has been held to include a public-house bar, an archway, a small plot of waste ground, and a book-maker's stand, and even a book-maker's big umbrella, and it is difficult to extract from the judges any clear indication of the nature of the "places" to which the Act applies. The Act is construed as applying only to ready-money betting when the stake is deposited with the book-maker, and only to places used for betting with persons physically resorting thereto; so that bets by letter, telegram, or telephone do not fall within its penalties. The arm of the law has been found long enough to punish as thieves "welshers," who receive and make off with deposits or bets which they never mean to pay if they lose.

The construction put by the judges on § 18 of the Gaming Act, 1845, which avoids contracts made by way of gaming and wagering, enabled turf commission agents to recover from their principals bets made and paid for them. But the Gaming Act, 1892, rendered null and void any promise, express or implied, to pay any person any sum of money paid by him under, or in respect of, any contract or agreement rendered null and void by the Gaming Act, 1845, or to pay any sum of money by way of commission, fee, reward, or otherwise in respect of any such contract or agreement, or of any services in relation thereto or in connexion therewith. By the combined effect of these two enactments, the recovery by the winner of bets or of stakes on games is absolutely barred; but persons who have deposited money to abide the event of a wager are not debarred from crying off and recovering their stake before the event is decided, or even after the decision of the event and before the stake is paid over to the winner;[1] and a man who pays a bet for a friend or customer has now no legal means of recovering the money, unless indeed some actual deceit was used to induce him to pay in ignorance that it was a bet. But a person who has received a bet on account of another can still, it would seem, be compelled to pay it over, and the business of a betting man is treated as so far lawful that income-tax is charged on its profits, and actions between parties in such a business for the taking of partnership accounts have been seriously entertained by Chancery judges.

The effect of these enactments on speculative dealings in shares or other commodities calls for special consideration. It seems to be correct to define a wagering contract as one in which two persons, having opposite opinions touching the issue of an event (past or future), of which they are uncertain, mutually agree that on the determination of the event one shall win, and the other shall pay over a sum of money, or other stake, neither party having any other interest in the event than the sum or stake to be won or lost. This definition does not strike at contracts in "futures," under which the contractors are bound to give or take delivery at a date fixed of commodities not in existence at a date of the contract. Nor are such contracts rendered void because they are entered into for purposes of speculation; in fact, their legality is expressly recognized by the Sale of Goods Act of 1893. And contracts to buy or sell stocks and shares are not void because entered into by way of speculation and not for purposes of investment. But a transaction in any commodity, though in form commercial, falls within the Gaming Acts if in substance the transaction is a mere wager on the price of the commodity at a date fixed by the contract. It does not matter whether the dealing is in stocks or in cotton, nor whether it is entered into on the Stock Exchange, or on any produce exchange, or elsewhere; nor is it conclusive in favour of the validity of the bargain that it purports to bind the parties to take or deliver the article dealt in. The courts are entitled to examine into the true nature of the transaction; and where the substantial intention of the parties is merely to gamble in differences, the fact that it is carried out by a series of contracts, regular and valid in form, will not be sufficient to exclude the application of the Gaming Acts.

In very many cases transactions with "outside stock-brokers" or "bucket shops" have been held to be mere wagers, although the contracts purported to give options to demand delivery or acceptance of the stocks dealt with; and the cover deposited by the "client" has been treated as a mere security for performance of the bargain, and recoverable if sued for in time, *i.e.*, before it is used for the purpose for which it is deposited. There was not up to 1902 any authoritative decision as to the application of the Gaming Act 1892 to transactions on the London Stock Exchange through a stockbroker who is a member of "the House"; but the same principle appears to be applicable where the facts of the particular deal clearly indicate that the intention was to make a mere time bargain, or to pay or receive differences only. In the event of the bankruptcy of a person involved in speculations, the bankruptcy officials exclude from proof against the estate all claims founded on any dealing in the nature of a wager; and on the same principle the bankrupt's trustee cannot recover sums won by the bankrupt by gaming transactions.

In the *United States*, many of the states make gaming

[1] So held, *Burge* v. *Ashley*, 1900; 1 Q.B. 744, May 1900.

a penal offence when the bet is upon an election, or a horse-race, or a game of hazard. Betting contracts and securities given upon a bet are often made void, and this may destroy a gaming note in the hands of an innocent purchaser for value. The subject lies outside of the province of the Federal Government.

Gandia, a Mediterranean port of Spain, in the province of Valencia. It is a station on the Madrid-Alicante railway. There are some modern public buildings — schools, a theatre, and several parish churches—besides the palace of the dukes of Osuna and a Jesuit convent. The principal local industries are manufactures of leather, silks, velvet, and ribbons. In 1898, 348 vessels of 142,175 tons entered. The value of the imports, chiefly coal, guano, timber, and flour, was £147,464; of the exports, mainly oranges, tomatoes, wine, raisins, onions, and cloth, £346,471. The greater part of the exports, except cloth and tomatoes, went to England. Population about 10,000.

Gando. See NIGERIA.

Ganjam, a district of British India, in the extreme north-east of the Madras Presidency. It has an area of 6037 square miles. The population in 1891 was 1,896,803, being 226 persons per square mile. In the hill tracts alone the density is only 88 per square mile; for the rest of the district it rises to 325. In 1901 the population was 2,011,488, showing an increase of 6 per cent. The total amount of land revenue and rates is returned as Rs. 18,45,758, the incidence of assessment per acre being Rs. 2–2–2 in *ryotwari* and R. 0–3–8 in *zamindari* lands; the number of police is 1134. In 1897–98, out of a total cultivated area of 479,108 acres 239,443 were irrigated (115,757 from government canals). There are two large systems of government irrigation in the district: (1) the Rushikulya project, upon which Rs. 46,44,423 has been spent, and which showed a deficit in 1897–98 of Rs. 1,42,119; and (2) the Ganjam minor rivers system, on which Rs. 44,846 has been spent, and which shows a profit of Rs. 6,513, or 15 per cent. The principal crops are rice, other food grains, pulse, oil seeds, and a little sugar-cane and cotton. Salt is evaporated, as a government monopoly, along the coast. Sugar is refined, according to German methods, at Aska, where rum also is produced. A considerable trade is conducted at the ports of Gopalpur and Calingapatam, which are only open roadsteads. In 1897–98 the total sea-borne trade was valued at Rs. 30,55,430, of which more than half was coasting trade. The district is traversed throughout by the East Coast railway, which was opened from Madras to Calcutta in 1900. There are colleges at Berhampur and Parlakimedi. In 1896–97 the number of schools was 1763, attended by 39,389 pupils. There are eight printing-presses and several libraries, reading-rooms, and literary institutes. The registered death-rate in 1897 was 50·1 per thousand.

Gap, Canal of, or CANAL DU DRAC, a very important French irrigation channel derived from the Drac in the upper Champsaur Valley, at an altitude of 3838 feet. It is thence carried partly by aqueducts to the Puy de Manse, through which a tunnel 3916 yards in length leads it from the basin of the Isère to that of the Durance, its course of 10 miles involving the construction of ninety-eight artificial works. Here, at the water-tower, in the valley of the Luye, at a point only about 96 feet lower than its origin, it divides into two branches, the Charance and the Rochette. The former, taking nearly four-fifths of the total volume of water, or 685 gallons per second, goes west, south-west, and south for a length of 16 miles, and the latter, taking little more than one-fifth of the total, or 195 gallons per second, goes east, south-west, south, and west for about 17 miles. Both branches then give origin to secondary canals, and these again to smaller ones, making a total length of about 445 miles. The area affected by this system of canals is 18,600 acres, of which 16,500 acres are capable of irrigation, but of this only about one-fourth is actually irrigated. Full utilization of the work has been hindered by want of capital and labour; nevertheless, the extent to which it has been developed has resulted in great improvements in the district, and extension of the cultivable area. The work was commenced in 1864; in 1880 irrigation began to be applied, and in 1888 the work was completed.

Gapan, a town in the southern part of the province of Nueva Ecija, Luzon, Philippine Islands. It lies at the centre of a rich tobacco-producing region, and the forests in its vicinity contain the finest of hardwoods. Its climate is comparatively cool and healthful. The principal languages spoken are Tagalog and Ilocano. Population, 20,000.

Gard, a department in the south of France, bordering on the Mediterranean, and watered by the Rhône, the Gard, and the Hérault.

Area, 2270 square miles. From 417,099 in 1886 the population increased to 418,470 in 1901. Births in 1899, 8813, of which 268 illegitimate; deaths, 9315; marriages, 3164. There were in 1896 1020 schools, with 55,000 pupils. Three per cent. of the population is illiterate. Out of 1,037,879 acres composing the area of the department under cultivation in 1896, 494,229 acres were plough-land and 130,970 acres in vineyards. The cereals yielded in 1899 a value of less than £500,000. The production of the vines, on the other hand, exceeded the value of £2,532,000. Gard takes the first rank among the departments of France for the production of the mulberry, which in 1899 yielded a value of £132,000, a figure, however, slightly exceeded by the produce of Ardèche in that year, and of silk-worm cocoons, which amounted in 1898 to 35,826 cwts., a figure slightly in excess of the production of Ardèche. The live stock in 1899 numbered 20,670 horses, 14,480 asses, 8290 cattle, 404,500 sheep, 43,970 pigs, and 27,850 goats. The mining industry produced in 1898 1,974,000 metric tons of coal and lignite, of the value of £1,036,000, and 113,000 tons of iron, lead, and manganese, valued at £192,000. The salt-pans yielded in 1898 81,000 metric tons of salt, of the value of £56,000. Metallurgy is in a very advanced state in the arrondissement of Alais, its total production in 1898 amounting to 58,000 metric tons of cast-iron, 5000 tons of iron, and 40,000 tons of steel. The other industries, textile and paper manufactures, are less developed. Nîmes, the capital, has a population of 80,355 (1901).

Garda, a lake of North Italy, partly in Lombardy, partly in Venetia, partly in Tirol. According to Martinelli, the lake has an area of 143 square miles, a depth of 1135 feet, and it lies at an altitude of 213 feet above sea-level. The mean surface temperature is 66° Fahr. Between 60 and 100 feet in depth the temperature decreases rapidly from 64° to 55°, and from the latter level down to the bottom decreases gradually to 45·9°. There are meteorological observatories at Riva, Salò, and Desenzano. The west shore from Gargnano to Salò is known as the Riviera Benacense, and is reputed to be the warmest district of North Italy.

Gardiner, a city of Kennebec county, Maine, U.S.A., on the western bank of the Kennebec river, 6 miles below Augusta, on the Maine Central Railroad. The city rises somewhat steeply from the river, is laid out with much regularity, with the business streets paved. It has excellent water power in the Cobosseecontee river, which flows through it to the Kennebec, and this has given rise to large and varied manufactures, including several lumber mills. Gardiner has also a brisk business in ice, which is cut mainly from the Kennebec, and shipped to Boston, New York, and southern cities. Population

(1880), 4439; (1890), 5491; (1900), 5501, of whom 537 were foreign-born.

Gardiner, Samuel Rawson (1829–1902), English historian, son of Rawson Boddam Gardiner, was born near Alresford, Hants, 4th March 1829. He was educated at Winchester and Christ Church, Oxford, where he obtained a first class in *literæ humaniores*. He was subsequently elected to fellowships at All Souls (1884) and Merton (1892). For some years he was professor of modern history at King's College, London, and devoted his life to historical work. He is the historian of the Puritan revolution, and has written its history in a series of volumes, originally published under different titles, beginning with the accession of James I.; the seventeenth, the third volume of the *History of the Commonwealth and Protectorate*, appeared in 1901, and two more were meant to complete the whole work, ending with the Restoration. The series is *History of England from the Accession of James I. to the Outbreak of the Civil War, 1603–1642*, 10 vols.; *History of the Great Civil War, 1642–1649*, 4 vols.; and *History of the Commonwealth and Protectorate, 1649–1660*. His treatment is exhaustive and philosophical, taking in, along with political and constitutional history, the changes in religion, thought, and sentiment during his period, their causes and their tendencies. Of the original authorities on which his work is founded many of great value exist only in manuscript, and his researches in public and private collections of manuscripts at home, and in the archives of Simancas, Venice, Rome, Brussels, and Paris, were indefatigable and fruitful. His accuracy is universally acknowledged. He was perhaps drawn to the Puritan period by the fact of his descent from Cromwell and Ireton, but he has certainly written of it with no other purpose than to set forth the truth. In his judgments of men and their actions he is unbiassed, and his appreciations of character exhibit a remarkable fineness of perception and a broad sympathy. Among many proofs of these qualities it will be enough to refer to what he says of the characters of James I., Bacon, Laud, Strafford, and Cromwell. On constitutional matters he writes with an insight to be attained only by the study of political philosophy, discussing in a masterly fashion the dreams of idealists and the schemes of government proposed by statesmen. Throughout his work he gives a prominent place to everything which illustrates human progress in moral and religious as well as political conceptions, and specially to the rise and development of the idea of religious toleration, finding his authorities not only in the words and actions of men of mark, but in the writings of more or less obscure pamphleteers, whose essays indicate currents in the tide of public opinion. His record of the relations between England and other States proves his thorough knowledge of contemporary European history, and is rendered specially valuable by his researches among manuscript sources which have enabled him to expound for the first time some intricate pieces of diplomacy.

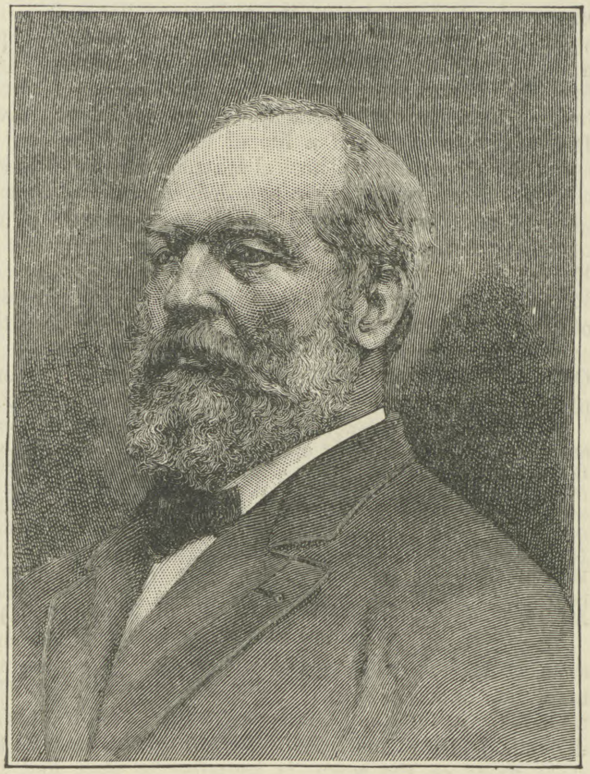
Gardiner's work is long and minute; the fifty-seven years which it covers are a period of exceptional importance in many directions, and the actions and characters of the principal persons in it demand careful analysis. He is perhaps apt to attach an exaggerated importance to some of the authorities which he was the first to bring to light, to see a general tendency in what may only be the expression of an individual eccentricity, to rely too much on ambassadors' reports which may have been written for some special end, to enter too fully into the details of diplomatic correspondence. In any case the length of his work is not the result of verbiage or repetitions. His style is clear, absolutely unadorned, and somewhat lacking in force; he appeals constantly to the intellect rather than to the emotions, and is seldom picturesque, though in describing a few famous scenes, such as the execution of Charles I., he writes with pathos and dignity. The minuteness of his narrative detracts from its interest; though his arrangement is generally good, here and there the reader finds the thread of a subject broken by the intrusion of incidents not immediately connected with it, and does not pick it up again without an effort. And Gardiner has the defects of his supreme qualities, of his fairness and critical ability as a judge of character; his work lacks enthusiasm, and leaves the reader cold and unmoved. Yet, apart from its sterling excellence, it is not without beauties, for it is marked by loftiness of thought, a love of purity and truth, and refinement in taste and feeling. He wrote other books, mostly on the same period, but his great history is that by which his name will live. It is a worthy result of a life of unremitting labour, a splendid monument of historical scholarship. His position as a historian was formally acknowledged: in 1862 he was given a civil list pension of £150 per annum, "in recognition of his valuable contributions to the history of England"; he was honorary D.C.L. of Oxford, LL.D. of Edinburgh, and Ph.D. of Göttingen, and honorary student of Christ Church, Oxford; and in 1894 he declined the appointment of regius professor of modern history at Oxford, lest its duties should interfere with the accomplishment of his history. He died 24th February 1902.

Among the more noteworthy of Mr Gardiner's separate works are: *Prince Charles and the Spanish Marriage*, 2 vols., London, 1869; *Constitutional Documents of the Puritan Revolution, 1625–1660*, 1st ed., Oxford, 1889, 2nd ed., Oxford, 1899; *Oliver Cromwell*, London, 1901; *What Gunpowder Plot Was*, London, 1897; *Outline of English History*, 1st ed., London, 1887, 2nd ed., London, 1896; and *Student's History of England*, 2 vols., 1st ed., London, 1890–91, 2nd ed., London, 1891–92. He edited collections of papers for the Camden Society, and also the *English Historical Review*. (W. Hu.)

Gardner, a town of Worcester county, Massachusetts, U.S.A., at an altitude of 1034 feet. It is on the main line and a branch of the Fitchburg Railroad. The town has an area of 23 square miles of hill country, diversified with ponds. The principal village, bearing the same name as the town, is irregular in plan, and has extensive manufactures, largely of chairs, for which it is widely known. Population of the town (1880), 4988; (1890), 8424; (1900), 10,813, of whom 3449 were foreign-born and 53 coloured.

Garfield, James Abram (1831–1881), twentieth President of the United States, was born 19th November 1831, in a log cabin in the little frontier town of Orange, Cuyahoga county, in Ohio. His early years were spent in the performance of such labour as fell to the lot of every farmer's son in the new states, and in the acquisition of such education as could be had in the district schools held for a few weeks each winter. But life on a farm was not to his liking, and at sixteen he left home and set off to make a living in some other way. A book of stories of adventure on the sea, which he read over and over again when a boy, had filled him with a longing for a seafaring life. He decided, therefore, to become a sailor, and tramping across the country to Cleveland, he sought employment from the captain of a lake schooner. But the captain drove him from the deck, and, wandering on in search of work, he fell in with a canal boatman who engaged him. During some months young Garfield served as bowsman, deck-hand, and driver of a canal boat. An attack of the ague sent him home, and on recovery, having resolved to attend a high school and fit himself to become a teacher, he passed the next four years in a hard struggle with poverty and in an earnest effort to secure an education. He worked as a teacher, a carpenter, and a farmer; studied Greek and Latin, and finally entered Williams College. On graduation, in 1856, Garfield became professor of ancient languages and literature in Hiram College, Ohio, and had risen to the presidency of the institution when the Civil War opened and he joined the army.

Meanwhile his entrance into political life had been made. In the early days of the Republican party, when the shameful scenes of the Kansas struggle were exciting the whole country, and during the campaigns of 1857 and 1858, he became known as an effective speaker and ardent



James Abram Garfield.

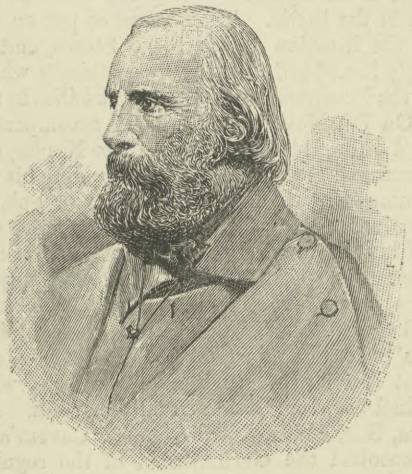
anti-slavery man. His reward for these services was election to the Ohio Senate as the member from Portage and Summit counties. When the cotton states seceded, Garfield appeared as a warm supporter of vigorous measures. He was one of the six Ohio senators who voted against the proposed amendment to the Federal Constitution forbidding Congress ever again to legislate on the subject of slavery in the States; he upheld the right of the Government to coerce seceded states; defended the "Million War Bill"; and when the call came for 75,000 troops he moved that Ohio furnish 20,000 soldiers and three million of dollars as her share. He at once offered his services to the governor, and became lieutenant-colonel and then colonel of the 42nd Ohio Volunteers. He served in Kentucky; was with Grant at Pittsburg Landing; was under Rosecrans in the Army of the Cumberland, and was his chief of staff; fought at Chickamauga, and was made a major-general of volunteers for gallantry in that great fight. In 1862 he was elected a member of Congress from the Ashtabula district of Ohio, and took his seat in the House of Representatives in December 1863. In Congress he joined the Radical wing of the Republican party, advocated the confiscation of rebel property, approved and defended the Wade-Davis manifesto denouncing the tameness of Lincoln, and was soon recognized as a hard worker and ready speaker. Capacity for work brought him places on important committees, and his ability as a speaker enabled him to achieve distinction on the floor of the House and to rise to leadership. Between 1863 and 1873 Garfield delivered speeches of importance on "The Constitutional Amendment to Abolish Slavery," "The Freedman's Bureau," "The Reconstruction of Rebel States," "The Public Debt and Specie Payment," "Reconstruction," "The Currency," "Taxation of United States Bonds," "Enforcing the 14th Amendment," "National Aid to Education," and "The Right to Originate Revenue Bills." The year 1874 was one of disaster to the Republican party. The greenback issue, the troubles growing out of reconstruction in the South, the Credit Mobilier and the "Salary Grab," disgusted thousands of independent voters and sent a wave of Democracy over the country. A Republican Convention in his district demanded his resignation and denounced his support of the hated measures, and re-election seemed impossible. But he defended himself in two pamphlets, "Increase of Salaries" and "Review of the Transactions of the Credit Mobilier Company," made a village-to-village canvass, and was victorious. In 1876 Garfield for the eighth time was again chosen to represent his district; and when, in 1877, James G. Blaine was made a senator from Maine, the leadership of the House of Representatives passed to Garfield, and he became the Republican candidate for Speaker. But the Democrats had a majority in the House, and he was defeated. Mr Hayes, the new President, having chosen John Sherman to be his Secretary of the Treasury, an effort was now made to send Garfield to the United States Senate in Sherman's place. But the President needed his services in the House, and he was not elected to the Senate until 1880.

The time had now come (1880) when the Republican party must nominate a candidate for the Presidency. General Grant had served two terms (1869–77), and by the unwritten law of custom ought not to be given another. But the "bosses" of the Republican party in three great states—New York, Pennsylvania, and Illinois—were determined that Grant should be renominated. These men and their followers were known as the "Stalwarts." Opposed to them were two other factions, one supporting Mr James G. Blaine of Maine, and the other Mr John Sherman of Ohio. When the convention met and the balloting began, the contest along these factional lines started in serious earnest. For eight-and-twenty ballots no change of any consequence was noticeable. Though votes were often cast for ten names, there were but two real candidates before the convention, General Grant and Mr Blaine. That the partisans of neither would yield was certain. That the choice therefore rested with the supporters of the minor candidates was manifest, and with the cry, "Anything to beat Grant!" an effort was made to find some man on whom the opposition could unite. Such a man was Garfield. His long term of service in the House, his leadership of his party on its floor, his candidacy for the Speakership, and his recent election to the United States Senate, marked him out as the available man. Between the casting of the first and the thirty-third ballot Garfield had sometimes been given two and at others no votes. On the thirty-fourth he received seventeen, on the next fifty, and on the next almost the entire vote hitherto cast for Blaine and Sherman, and was declared nominated. In November Garfield was duly elected, and he was inaugurated 4th March 1881; but on 2nd July, while on his way to attend the commencement exercises at Williams College, the new President was shot by a crazy office-seeker named Guiteau, and, after a lingering sickness, died from the effects of his wound on 19th September 1881. (J. B. McM.)

Garhwal, (1) a district of British India, in the Kumaon division of the North-West Provinces, and (2) an adjoining native state. Both lie among the Himalayas, containing the headwaters of the Ganges. The district of Garhwal is exceedingly mountainous. At least two peaks rise above 25,000 feet. Its area is 5629 square miles. In 1881 it had a population of 345,629, and in 1891 of 407,818, giving an average density of 72 persons per square mile. In 1901 the population was 429,892, showing an increase of 5 per cent. The land revenue and rates were ₨.1,77,723, the incidence of assessment being just over 8 annas per acre; the cultivated area in 1896–97 was 262,484 acres, of which 355 were under tea; the number of police was 130; the number of vernacular schools in 1896–97 was 93, with 3937 pupils; the registered death-rate in 1897 was 23·67 per thousand. It includes Deoprayag, one of the holiest places of Hindu pilgrimage. The administrative headquarters are at Pauri, but Srinagar is the largest place; neither of these is a municipality. The STATE OF GARHWAL is also known as Tehri, after its capital. Its area is 4164 square miles. In 1891 it had a population of 241,242, being 58 persons per square mile. In 1901 the population was 267,608, showing an increase of 11 per cent. The revenue in 1897–98 amounted to ₨.3,21,287, and the expenditure to ₨.2,87,328. There is a reserve of more than ₨.8,00,000, No tribute is payable.

Garibaldi, Giuseppe (1807–1882), Italian patriot, was born at Nice on 4th July 1807. As a youth he fled from home to escape a clerical education, but afterwards joined his father in the coasting trade. After joining the *Giovine Italia* he entered the Sardinian navy, and, with a number of companions on board the frigate *Euridice*, plotted to seize the vessel and occupy the arsenal of Genoa at the moment when Mazzini's Savoy expedition should enter Piedmont. The plot being discovered, Garibaldi fled, but was condemned to death by default on 3rd June 1834. Escaping to South America in 1836, he was given letters of marque by the Republic of Rio Grande do Sul, which had revolted against Brazil. After a series of victorious engagements he was taken prisoner and subjected to severe torture, which dislocated his limbs. Regaining liberty, he renewed the war against Brazil, and took Porto Allegro. During the campaign he met his wife, Anita, who became his inseparable companion and mother of three children, Anita, Ricciotti, and Menotti. Passing into the service of Montevideo, he was sent to Corrientes with a small flotilla to support the insurrection, but was overtaken by Admiral Brown, against whose fleet he fought for three days. When his ammunition was exhausted he burned his ships and escaped. Returning to Montevideo, he formed the Italian Legion, with which he won the battles of Cerro and Sant' Antonio in the spring of 1846, and assured the freedom of Montevideo. Refusing all honours and recompense, he prepared to return to Italy upon receiving news of the incipient revolutionary movement. In October 1847 he wrote to Pius IX. offering his services to the Church, whose cause he for a moment believed to be that of national liberty.

Landing at Nice on 24th June 1848, he placed his sword at the disposal of Charles Albert, and, after various difficulties with the Piedmontese War Office, formed a volunteer army 3000 strong, but shortly after taking the field was obliged, by the defeat of Custozza, to flee to Switzerland. Proceeding thence to Rome, he was entrusted by the Roman Republic with the defence of San Pancrazio against the French, where he gained the victory of 30th April 1849, remaining all day in the saddle, although wounded in the side at the beginning of the fight. From 3rd May until 30th May he was continuously engaged against the Bourbon troops at Palestrina, Velletri, and elsewhere, dispersing an army of 20,000 men with 3000 volunteers. After the fall of Rome he started for Venice across the swamps of the Romagna, hotly pursued by the Austrians. Near Ravenna he lost his wife, Anita, who died of fever. Venice having fallen, Garibaldi went to Genoa, where he was arrested and expelled. Emigrating to New York, he, in order to earn a living, became first a chandler, and afterwards a trading skipper, returning to Italy in 1854 with a small fortune, with which he purchased the island of Caprera. On the outbreak of war in 1859 he was placed



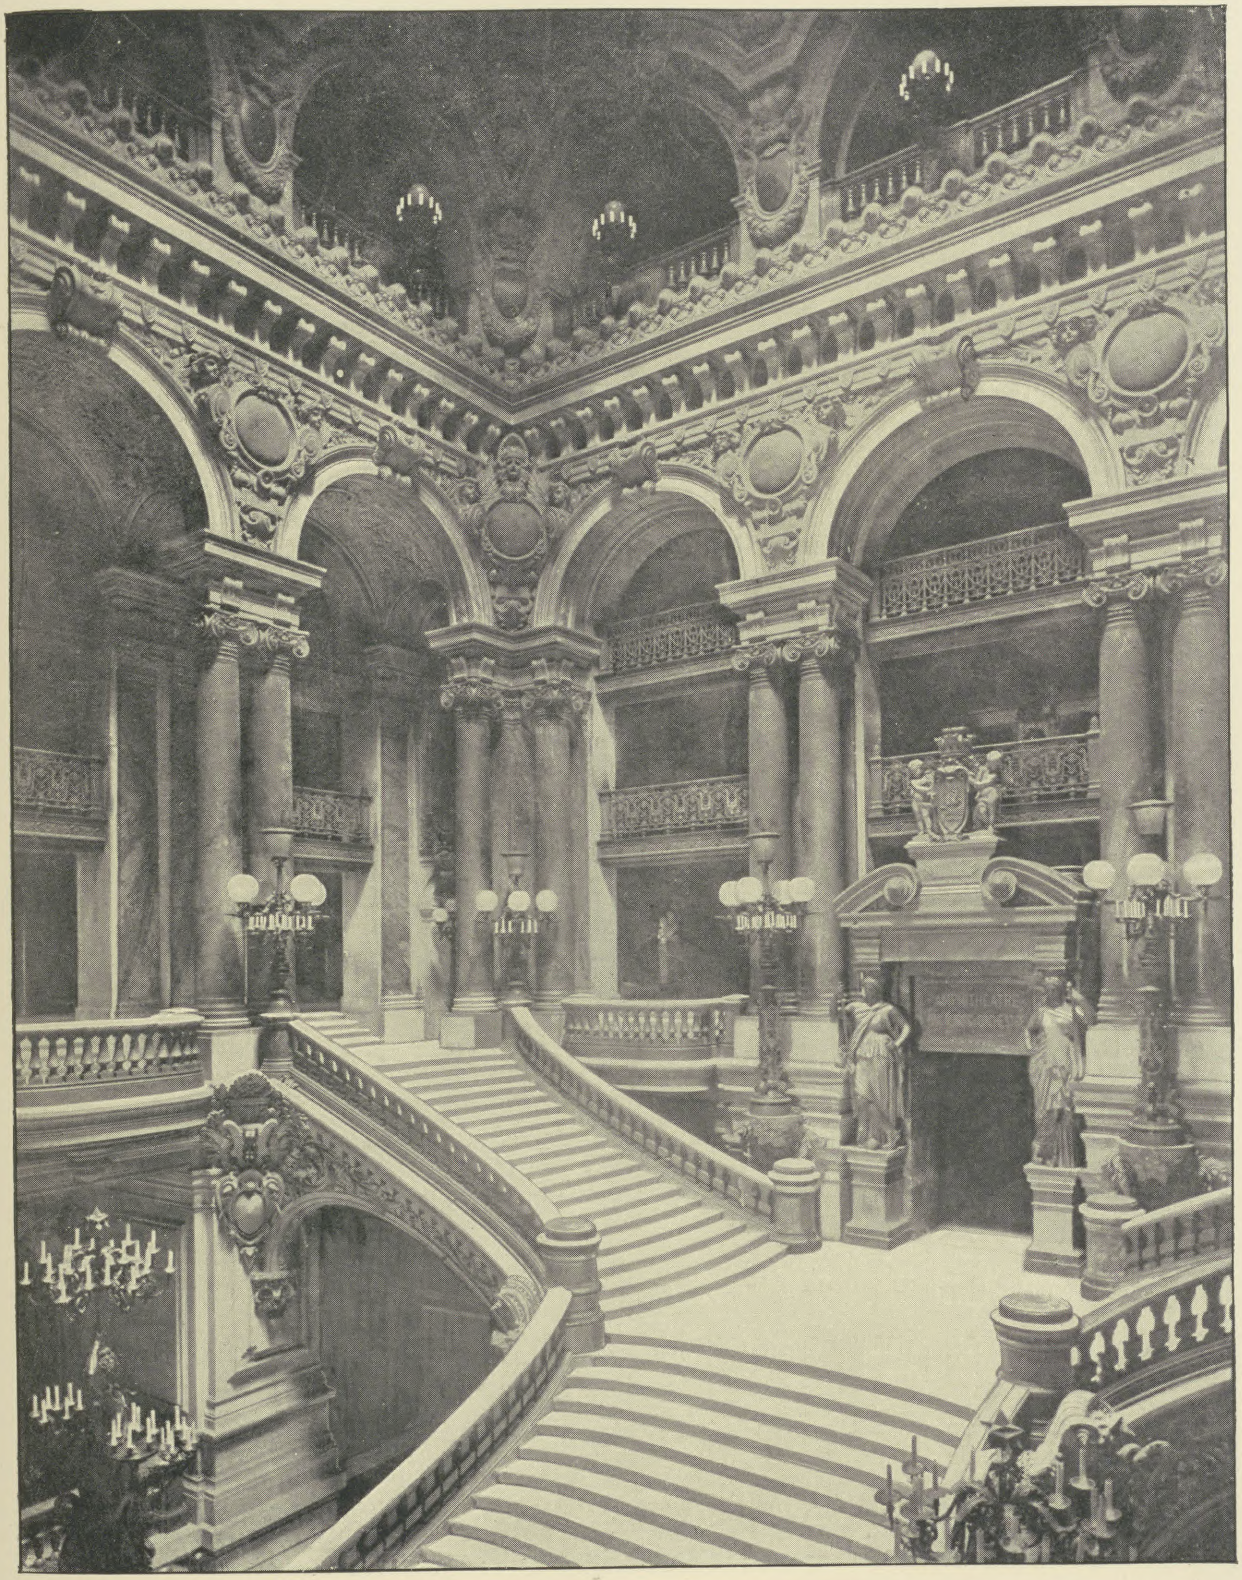
GIUSEPPE GARIBALDI.
(From a photograph by Elliott and Fry, London.)

in command of the Alpine infantry, defeating the Austrians at Casale on 8th May, crossing the Ticino on 23rd May, and, after a series of victorious fights, liberating Alpine territory up to Tirol. When about to cross the Austrian frontier he was stopped by the armistice of Villafranca. Returning then to Como to wed the Countess Raimondi, by whom he had been aided during the campaign, he was apprised, immediately after the wedding, of certain circumstances which caused him at once to abandon that lady and to start for Central Italy. Forbidden to invade the Romagna, he returned indignantly to Caprera, where with Crispi and Bertani he planned the invasion of Sicily. Assured by Sir James Hudson of the sympathy of England, he began active preparations for the expedition to Marsala. At the last moment he hesitated, but Crispi succeeded in persuading him to sail from Genoa on 5th May 1860 with two vessels carrying a volunteer corps of 1070 strong. Calling at Talamone to embark arms and money, he reached Marsala on 11th May, and landed under the protection of the British vessels *Intrepid* and *Argus*. On 12th May the dictatorship of Garibaldi was proclaimed at Salemi, on 15th May the Neapolitan troops were routed at Calatafimi, on 25th May Palermo was taken, and on the 6th of June 20,000 Neapolitan regulars, supported by nine frigates and protected by two forts, were compelled to capitulate. Once established at Palermo, Garibaldi organized an army to liberate Naples and march upon Rome, a plan opposed by the emissaries of Cavour, who desired the immediate annexation of Sicily to the Italian kingdom. Expelling Lafarina and driving out Depretis, who represented Cavour, Garibaldi routed the Neapolitans at Milazzo on 20th July. Messina fell on 20th July, but Garibaldi, instead of crossing to Calabria, secretly departed for Aranci Bay in Sardinia, where Bertani was fitting out an expedition against the Papal States. Cavour, however, obliged the expedition to sail for Palermo. Returning to Messina, Garibaldi found a letter from Victor Emmanuel II. dissuading him from invading the kingdom of Naples. Garibaldi replied asking "permission to disobey." Next day he crossed the Strait, won the battle of Reggio on 21st August, accepted the capitulation of 9000 Neapolitan troops at San Giovanni and of 11,000 more at Soveria. The march upon Naples became a triumphal progress, which the wiles of Francesco II. were powerless to arrest. On 7th September Garibaldi entered Naples, while Francesco fled to Gaeta. On 1st October he routed the remnant of the Bourbon army 40,000 strong on the Volturno. Meanwhile the Italian troops had occupied the Marches, Umbria, and the Abruzzi, a battalion of Bersaglieri reaching the Volturno in time to take part in the battle. Their presence put an end to the plan for the invasion of the Papal States, and Garibaldi unwillingly issued a decree for the *plébiscite* which was to sanction the incorporation of the Two Sicilies in the Italian realm. On 7th November Garibaldi accompanied Victor Emmanuel during his solemn entry into Naples, and on the morrow returned to Caprera, after disbanding his volunteers and recommending their enrolment in the regular army.

Indignation at the cession of Nice to France and at the neglect of his followers by the Italian Government induced him to return to political life. Elected deputy in 1861, his anger against Cavour found violent expression. Bixio attempted to reconcile them, but the publication by Cialdini of a letter against Garibaldi provoked a hostility which, but for the intervention of the king, would have led to a duel between Cialdini and Garibaldi. Returning to Caprera, Garibaldi awaited events. Cavour's successor, Ricasoli, enrolled the Garibaldians in the regular army; Rattazzi, who succeeded Ricasoli, urged Garibaldi to undertake an expedition in aid of the Hungarians, but Garibaldi, finding his followers ill-disposed towards the idea, decided to turn his arms against Rome. On 29th June 1862 he landed at Palermo and gathered an army under the banner "*Roma o morte.*" Rattazzi, frightened at the prospect of an attack upon Rome, proclaimed a state of siege in Sicily, sent the fleet to Messina, and instructed Cialdini to oppose Garibaldi. Circumventing the Italian troops, Garibaldi entered Catania, crossed to Melito with 3000 men on 25th August, but was taken prisoner and wounded by Cialdini's forces at Aspromonte on 27th August. Liberated by an amnesty, Garibaldi returned once more to Caprera amidst general sympathy.

In the spring of 1864 he went to London, where he was accorded an enthusiastic reception and given the freedom of the City. From England he returned again to Caprera. On the outbreak of war in 1866 he assumed command of a volunteer army and, after the defeat of the Italian troops at Custozza, took the offensive in order to cover Brescia. On 3rd July he defeated the Austrians at Monte Saello, on the 7th at Lodrone, on the 10th at Darso, on the 16th at Condino, on the 19th at Ampola, on the 21st at Bezzena, but, when on the point of invading Trent, he was ordered by Victor Emmanuel to retire. Replying simply, "I obey," he returned to Caprera to mature his designs against Rome, which had been evacuated by the French in pursuance of the Franco-Italian Convention of 15th September 1864. Gathering volunteers in the autumn of 1867, he prepared to enter Papal territory, but was arrested at Sinalunga by the Italian Government and conducted to Caprera. Eluding the surveillance of the Italian cruisers, he returned to Florence, and, with the complicity of the second Rattazzi cabinet, entered Roman territory at Passo Corese on 23rd October. Two days later he took Monterotondo, but on 2nd November his forces were dispersed at Mentana by French and Papal troops. Recrossing the Italian frontier, he was arrested at Figline and taken back to Caprera, where he eked out his slender resources by writing several romances. In 1870 he formed a fresh volunteer corps and went to the aid of France, defeating the German troops at Chatillon, Autun, and Dijon. Elected a member of the Versailles Assembly, he resigned his mandate in anger at French insults, and withdrew to Caprera until, in 1874, he was elected deputy for Rome. Popular enthusiasm induced the Minghetti cabinet to propose that a sum of £40,000 with an annual pension of £2000 be conferred upon him as a recompense for his services, but the proposal, though adopted by Parliament (27th May 1875), was indignantly refused by Garibaldi. Upon the advent of the Left to power, however, he accepted both gift and pension, and worked energetically upon the scheme for the Tiber embankment to prevent the flooding of Rome. At the same time he succeeded in obtaining the annulment of his marriage with the Countess Raimondi (with whom he had never lived) and contracted another marriage with the mother of his children, Clelia and Manlio. In 1880 he went to Milan for the inauguration of the Mentana monument, and in 1882 visited Naples and Palermo, but was prevented by illness from being present at the 600th anniversary of the Sicilian Vespers. A few months later, on 2nd June 1882, his death at Caprera plunged the whole of Italy into mourning. (H. W. S.)

Garnier, Jean Louis Charles (1825–1898), French architect, designer of the new Opera House in Paris, was born in that city on the 6th of November 1825. He was educated in a primary school, and it was intended that he should pursue his father's craft, that of a wheelwright. His mother, however, having heard that with a little previous study he might enter an architect's office and eventually become a *vérificateur* (measuring surveyor), and earn as much as six francs a day, and foreseeing that in consequence of his delicate health he would be unfit to work at the forge, sent him to the Petite École de Dessin, in the Rue de Médecine, the cradle of so many of the great artists of France, to learn drawing and mathematics. His progress was such as to justify his being sent first into an architect's office and then to the well-known atelier of Lebas, where he began his studies in preparation for the examination of the École des Beaux Arts, which he passed in 1842, at the age of seventeen. Shortly after his admission it became necessary that he should support himself, and accordingly he worked during the day in various architects' offices, among them in that of M. Viollet-le-Duc, and confined his studies for the École to the evening. In 1848 he carried off, at the early age of twenty-three, the Grand Prix de Rome, and, with his comrades in sculpture, engraving, and music, set off for the Villa de Medicis. His principal works were the measured drawings of the Forum of Trajan and the temple of Vesta in Rome, and the temple of Serapis at Pozzuoli. In the fifth year of his travelling studentship he went to Athens and measured the temple at Aegina, subsequently working out a complete restoration of it, with its polychromatic decoration, which was published as a monograph in 1877. The elaborate set of drawings which he was commissioned by the duc de Luynes to make of the tombs of the house of Anjou were not published, owing to the death of his patron; and since Garnier's death they have been given to the library of the École des Beaux Arts, along with other drawings he made in Italy. On his return to Paris in 1853 he was appointed surveyor to one or two Government buildings, with a very moderate salary, so that the commission given him by M. Baltard to make two water-colour drawings of the Hôtel de Ville, to be placed in the album presented to Queen Victoria in 1855, on the occasion of her visit to Paris, proved very acceptable. These two drawings are now in the library at Windsor. In 1860 came, at last,



Staircase in the Grand Opera House, Paris. Designed by J. L. C. Garnier.

Garnier's chance: a competition was announced for a design for a new Imperial Academy of Music, and out of 163 competitors Garnier was one of five selected for a second competition, in which, by unanimous vote, he carried off the first prize, and the execution of the design was placed in his hands. Begun in 1861, but delayed in its completion by the Franco-German war, it was not till 1875 that the structure was finished, at a cost of about 35,000,000 francs (£1,420,000). The history of the building is partly that of Paris, for during the war it was utilized as the municipal storehouse of provisions. The building externally is too well known to need any description; of the interior, the staircase and the magnificent hall are the finest portion, and alike in conception and realization have never been approached. Of Garnier's other works, the most remarkable are the Casino at Monte Carlo, the Bischoffsheim villa at Bordighera, the Hôtel du Cercle de la Librairie in Paris; and, among tombs, those of the musicians Bizet, Offenbach, Massé, and Duprato. In 1874 he was elected a member of the Institute of France, and after passing through the grades of chevalier, officer, and commander of the Legion of Honour, received in 1895 the rank of grand officer, a high distinction that had never before been granted to an architect. Charles Garnier's reputation was not confined to France; it was recognized by all the countries of Europe, and in England he received, in 1886, the royal gold medal of the Royal Institute of Architects, given by Queen Victoria. Besides his monograph on the temple of Aegina, he wrote several works, of which *Le Nouvel Opéra de Paris* is the most valuable. For the International Exhibition of 1889 he designed the buildings illustrating the "History of the House" in all periods, and a work on this subject was afterwards published by him in conjunction with M. Ammann. Not the least of his claims to the gratitude of his country were the services which he rendered on the various art juries appointed by the State, the Institute of France, and the École des Beaux Arts, services which in France are rendered in an honorary capacity. Garnier died on the 3rd of August 1898. (R. P. S.)

Garo Hills, The, a district of British India, in the Hills division of Assam. It takes its name from the Garos, a tribe of doubtful ethnical affinities and peculiar customs, by whom it is almost entirely inhabited. It consists of the last spurs of the Assam hills, which here run down almost to the bank of the Brahmaputra, where that river debouches upon the plain of Bengal and takes its great sweep to the south. The district was first constituted in 1866, and some trouble was experienced in enforcing authority over certain of the villages. The administrative headquarters are at Tura, of which the population in 1891 was 1045. The area of the district is 3270 square miles. In 1881 it had a population of 109,548, and in 1891 of 121,570, giving an average density of 37 persons per square mile, the highest in the hills of the province. There were 1184 Christians, of whom 21 were Europeans or Americans. In 1901 the population was 138,289, showing an increase of 14 per cent. The land revenue was Rs.63,214, the incidence of assessment being R.0–14–4 per acre; the number of police was 262; the number of boys at school in 1896–97 was 773, being 8·41 per cent. of the male population of school-going age; the number of girls at school was 178, or 1·96 per cent. The American missionaries maintain a small training school for teachers. The public buildings at Tura were entirely destroyed by the earthquake of 12th June 1897, and the roads in the district were greatly damaged by subsidence and fissures.

Garonne, a river of France, rising in the Maladetta group of the Pyrenees. The total course of the river in the valley of Aran, in Spanish territory, is about 30 miles, and the area drained 135,900 acres. It enters France at an altitude of 1800 feet, supplies motive power to several mills in the vicinity of Fos, and flows through the gorge of St Béat. The Neste, which joins it at the hill of Montrejeau, brings nearly as much water as the main stream. Between this point and Port Ste Marée the river describes a great curve of about 30 miles around the plateau of Lannemezan. At St Martory it gives off the irrigation canal of that name to water the plains of Toulouse, and at Portet, 5 miles above Toulouse, it is joined on the right bank, at an altitude of 430 feet, by the Ariège. Below Toulouse the Garonne flows through wide plains, accompanied by a lateral canal at a distance varying from half a mile to 3 miles. At Agen the lateral canal passes by a magnificent bridge aqueduct from the right to the left bank.

This canal extends from Toulouse to Castets, a length of 120 miles, or, including branches, of 132 miles. The mean depth in the level stretches is about 7 feet, and boats drawing 6 feet can navigate it except between Beaurégard and Laboulbène, where the depth is only $4\frac{3}{4}$ feet. At Toulouse, where the canal leaves the Garonne, it connects with the Canal du Midi. The Tarn and the Avance are each crossed by a bridge aqueduct, and the Bassanne by a siphon aqueduct. Below Castets a dyke, 6 miles long, protects it from river inundations. The canal was begun in 1838 and finished in 1856, at a cost of £2,500,000. It is crossed by 139 bridges. The number of boats plying on the canal in 1900 was 6184, mean tonnage 51, total tonnage 317,615, conveying chiefly agricultural produce and provisions, building materials, wood, and industrial products.

The Garonne has a breadth of 130 yards at Toulouse, 160 at Agen, 160 to about 200 to Podensac, where the river begins to widen out; and at Bordeaux, 15 miles from the head of the estuary, it is from 540 to 650 yards wide. The breadth continues to increase, and at its confluence with the Dordogne it has a width of nearly 2200 yards, interrupted, however, by the Isle of Cazeau. It is officially divided into six sections. The figures for traffic here given are those for 1900:—

1. Pont-du-Roi to Toulouse, 48 miles; mean depth, $2\frac{1}{2}$ feet; crossed by 5 bridges. Navigable only between Roquefort and Toulouse. Number of boats, 1117; total tonnage, 11,737.
2. Toulouse to mouth of Tarn, 50 miles; mean depth, $1\frac{1}{2}$ feet; crossed by 8 bridges. Number of boats, 27; total tonnage, 114.
3. Mouth of Tarn to Agen, 28 miles; mean depth, $1\frac{1}{2}$ feet; crossed by 11 bridges. Number of boats, 139; total tonnage, 12,238.
4. Agen to Castets, 66 miles; mean depth, $3\frac{1}{4}$ feet; crossed by 10 bridges. Number of boats, 2435; total tonnage, 71,367.
5. Castets to Bec d'Ambès, 48 miles; mean depth, 9·8 feet; crossed by 3 bridges. Number of boats, 30,841; total tonnage, 1,268,489.
6. Bec d'Ambès to ocean, 47 miles; mean depth, 21 feet. Number of boats, 16,159; total tonnage, 345,726. (E. J. H*.)

Garonne-Haute, a department in the south of France, watered by the Garonne, and separated from Spain by the Pyrenees.

Area, 2458 square miles. The population diminished from 481,169 in 1886 to 439,769 in 1901. Births in 1899, 7489, of which 675 were illegitimate; deaths, 10,023; marriages, 2977. There were in 1896 1122 primary schools, with 55,000 pupils, and 3 per cent. of the population was illiterate. Out of 1,423,378 acres under cultivation in 1896, 924,207 acres were plough-land and 118,614 acres vineyards. The wheat crop of 1899 yielded a value of £1,530,000; oats, £380,000; rye, £20,000; barley, £46,000; vines, £550,000; the natural pastures and grass lands, £1,032,000. The live stock in 1899 included 30,780 horses, 167,080 cattle, 234,710 sheep, and 100,260 pigs. There are marble quarries, and rock-salt was obtained in 1898 to the extent of 8000 metric tons. The industry in metals produced in 1898 only 2475 tons of iron. In 1901 Toulouse, the capital, had 147,696 inhabitants.

Garrucha, a Mediterranean seaport of Spain, in the province of Almeria. An old castle is now used as a carabineer barrack. The bay affords shelter even for large vessels, and is every year more frequented by foreign vessels, chiefly British, French, and Dutch, and by coasting vessels, many of which come in ballast and clear with valuable cargoes. In the neighbourhood the rearing of live stock is a thriving industry, and the inhabitants of rural districts around send large quantities of wheat, fruit, and vegetables to the port. In 1898 the value of the imports was £170,170; of the exports, £460,570. The imports were chiefly coal and coke from England, lead ore, bar iron, machinery, timber and deals, petroleum, rice, barley, and soap. The exports were iron ore (£95,056), silver, lead, copper mat, esparto, oranges and lemons, dried figs, marble, and lead ore. Almost all the lead and copper mat went to England, and also the esparto. In the coasting trade in 1898, 311 vessels entered and 309 cleared. In the foreign trade, 116 vessels of 125,079 tons entered, and 115 of 147,843 tons cleared. Population over 5000.

Garrús, a small province of Persia, situated between Khamseh and Azerbaïján in the north and Kurdistan and Hamadan in the south. Its population is estimated at 80,000, and its capital, Bíjár, has a population of 3000. The province is fief of the chief of the Garrús Kurds, and pays a yearly revenue of about £3000 and supplies a battalion of infantry (the 34th) to the army.

Garston, a seaport, railway station, and urban district in the Widnes division of Lancashire, England, 6 miles south of Liverpool, on the Mersey. The docks, belonging to the London and North-Western Railway Company, employ most of the working population. Population (1891), 13,444; (1901), 17,288.

GAS AND GAS LIGHTING.

THE last twenty-five years of the 19th century will always be looked back to as the most important epoch in the history of the great gas industry, this period having been marked not only by many improvements in the manufacture of illuminating gas, but by a complete revolution in the methods of enriching it and utilizing it for the production of light. In 1875 the London Argand, giving a duty of 3·2 candles illuminating power per cubic foot of ordinary 16-candle gas, was looked upon as the most perfect burner of the day, and little hope was entertained that any burner capable of universal adoption would surpass it in its power of developing light from the combustion of coal gas; but the beginning of the new century found the incandescent mantle and Bunsen burner yielding six times the light that was then produced by the consumption of an equal volume of gas. In this article the chief changes which have taken place in the manufacture of gas, its purification and enrichment, since the issue of the ninth edition of this work, will be dealt with, and then the even more important alterations in the methods used for its consumption will be fully discussed.

Gas Manufacture.

No very radical alterations have taken place in the methods employed in the destructive distillation by which the volatile constituents of the coal are driven off by heat as crude gas and tar vapour, while the residue remains behind as coke. The retorts are made of fireclay, and in all but small country works the old single-ended retort, which was about 9 feet in length, has given way to a more economical construction, known as doubles, double-ended, or through retorts, in which a retort 18 to 20 feet long is fitted with a mouthpiece and ascension pipe at each end. The number of "through" retorts in the retort bench varies from three to twelve, the common practice being to place two at the bottom, three in the middle tier, and two above, these being known as bottoms, middles, and tops. Considerable economy has been introduced in the heating of the retorts by the adoption of regenerative furnaces, the use of which on the Continent is universal, and is now fairly general in Great Britain. In this system of firing a mixture of carbon monoxide and nitrogen is produced by passing air through incandescent gas coke in a generator placed below the bench of retorts, and the heating value of the gases so produced is increased in most cases by the admixture of a small proportion of steam with the primary air supply, the steam being decomposed by contact with the red-hot coke in the generator into water gas, a mixture of carbon monoxide and hydrogen. (See Gaseous Fuel.) The gases so formed vary in proportion with the temperature of the generator and the amount of steam, but generally contain 32 to 38 per cent. of combustible gas, the remainder being the residual nitrogen of the air and carbon dioxide. These gases enter the combustion chamber around the retorts at a high temperature, and are there supplied with sufficient air to complete their combustion, this secondary air supply being heated by the hot products of combustion on their way to the exit flue. This method of firing results in a saving of about one-third the weight of coke used in the old form of furnace per ton of coal carbonized, and also enables higher temperatures to be obtained.

Retorts.

The importance of labour-saving appliances in gas works has been fully realized in recent years, and in the retort-house mechanical charging and drawing machines are now largely used, while by the use of sloping instead of horizontal retorts gravitation is employed to facilitate the same operations. In both arrangements the coal as it is taken from the stores is broken to the size of nuts in a crusher, and elevated to convenient hoppers above the benches. With the horizontal retorts a mechanical charging machine, worked by compressed air, delivers the coal into the retorts, and with the assistance of a drawing machine, using similar motive power, the work of feeding the retorts with raw material and withdrawing the residual coke is performed expeditiously, with considerable economy and less discomfort than was formerly the case. West's compressed-air drawing and charging machines are an example of this system; they are designed for working retorts in every tier, being provided with mechanism for elevating the charging and drawing frames to the various levels. For further economy retort benches of four and five tiers are sometimes constructed, and the general practice is to draw and charge all the retorts on one level at the same time, working from end to end of the retort house. In the gravitation method the retorts are inclined to the horizon at an angle to suit the slip of the class of coal used. This angle is between 28° and 34°. The coal, previously elevated to the hoppers, is dropped into feeding chambers so arranged that they can travel from end to end of the retort house and deposit the coal into the retorts. When the retort is to be charged an iron stop or barrier is placed in the lower mouthpiece and the door closed. The shoot is placed in the upper mouthpiece, and the stop or door which retains the coal in the chamber is released; the coal is then discharged into the retort, and, running down the incline, is arrested by the barrier, and banks up, forming a continuous backing to the coal following. By experience with the class of coal used, and the adjustment of the stops in the shoot, the charge can be run into the retort to form an even layer of any desired depth. For the withdrawal of the residual coke at the end of carbonization the lower mouthpiece door is opened, the barrier removed, the coke in the lower part of the retort is "tickled" or gently stirred with an iron rod to overcome a slight adhesion to the retort, and the entire mass readily discharges itself. Guides are placed in front of the retort to direct its course to coke hoppers or conveyers below, and to prevent scattering of the hot material. This system shows the greater economy in the cost of carbonizing the coal, but the large outlay and considerable wear and tear of the mechanical appliances involved have so far prevented a very general adoption of the process.

The increase in the temperature of distillation to which the coal is subjected increases considerably the volume of gas produced per ton of coal carbonized, and at the same time gives a decrease in the candle-power; but as the latter is not as great in proportion as the gain in volume, it is generally found that the candle-feet per ton of coal $\left(\frac{\text{vol. per ton} \times \text{illuminating value}}{5}\right)$ is higher than when lower temperatures were used, while the tar is also altered in character, becoming more viscid and rather less in volume as the temperature of distillation increases. In most works the yield of gas per ton of ordinary gas coal carbonized is from 10,000 to 11,000 cubic feet.

Little or no change has taken place in the treatment of the crude gas as it flows from the retort up the ascension pipe and through the dip pipe and hydraulic main to the condensers, exhauster scrubbers, and purifiers; but a clearer conception is being gained as to the actions taking place in the latter, and they are now generally so handled as to secure increased purity in the gas. In general practice slaked lime is employed for the removal of carbon dioxide and the greater quantity of sulphur compounds, while a catch-box or purifier of oxide of iron serves to remove the last traces of sulphuretted hydrogen. Not fewer than four lime purifiers are employed, and as the one which is first in the series becomes exhausted, *i.e.*, begins to show signs of allowing carbon dioxide to pass through it unabsorbed, it is filled with fresh slaked lime, and is made the last of the series, the one which was second becoming first; and this procedure goes on continuously. This operation is necessitated by the fact that carbon dioxide has the power of breaking up the sulphur compounds formed by the lime, so that until all carbon dioxide is absorbed with formation of calcium carbonate, the withdrawal of sulphuretted hydrogen cannot proceed, while since it is calcium sulphide formed by the absorption of sulphuretted hydrogen by the slaked lime that absorbs the vapour of carbon bisulphide, purification from the latter can only be accomplished after the necessary calcium sulphide has been formed. The foul gas leaving the scrubbers contains, as a general average, 30 grains of sulphuretted hydrogen, 40 grains of carbon bisulphide, and 200 grains of carbon dioxide per 100 cubic feet. On entering the first purifier, which contains calcium sulphocarbonate and other combinations of calcium and sulphur in smaller quantity, the sulphuretted hydrogen and bisulphide vapour have practically no action upon the material, but the carbon dioxide immediately attacks the calcium sulphocarbonate, forming calcium carbonate with the production of carbon bisulphide vapour, which is carried over with the gas into the second box. In the connexion between the first and second box the gas is found to contain 500 grains of sulphuretted hydrogen and 80 grains of carbon bisulphide per 100 cubic feet, but no trace of carbon dioxide. In the second box the formation of calcium sulphocarbonate takes place by the action of carbon bisulphide upon the calcium sulphide with the liberation of sulphuretted hydrogen, which is carried over to the third purifier. The gas in the connecting pipe between the second and third box will be found to contain 400 grains of sulphuretted hydrogen and 20 grains of carbon bisulphide. The contents of the third box, being mostly composed of slaked lime, by the action of sulphuretted hydrogen upon which calcium sulphide is very rapidly formed, will practically remove the remaining impurities, and the outlet gas will show 20 grains of sulphuretted hydrogen and 8 grains of carbon bisulphide per 100 cubic feet. The catch-box of oxide of iron will then remove all traces of sulphuretted hydrogen. It will be noticed that in the earlier stages the quantity of the sulphur impurities is actually increased between the purifiers; in fact, the greater amount of sulphiding procures the ready removal of the carbon bisulphide, but it is the carbon dioxide in the gas that is the disturbing element, inasmuch as it decomposes the combinations of sulphur and calcium. Consequently it is a paramount object in this system to prevent this latter impurity finding its way through the first box of the series. The finding of any traces of carbon dioxide in the gas between the first two boxes is generally the signal for a new clean purifier being put into action, and the first one shut off, emptied, and recharged with fresh lime. The impregnated material is sometimes sold for dressing certain soils. The action of oxide of iron in the catch-box depends on its power of combining with sulphuretted hydrogen to form sulphide of iron. Such is the affinity of the oxide for this impurity that it may contain 50 to 60 per cent. by weight of free sulphur after revivification, and still remain active. Upon removing the material from the vessel and exposing it to the atmosphere the oxide undergoes a revivifying process, the oxygen of the air displacing the sulphur from the sulphide as free sulphur, and converting the iron into hydrated oxide of iron. This revivification can be carried on a number of times till the material when dry contains about 50 per cent. free sulphur, and even occasionally 60 per cent. and over; it is sold to manufacturers of sulphuric acid, to be used in the sulphur kilns of their plant.

Purification.

The fact that coal gas of an illuminating power of from 14 to 16 candles can be made in ordinary circumstances at a fairly low rate, while every candle-power added to the gas increases the cost in an enormous and rapidly growing ratio, has, from the earliest days of the gas industry, caused the attention of inventors to be turned to the enrichment of coal gas. This up to 1890 had been almost universally carried out in practice by an admixture of rich cannel coal with the ordinary gas coal in the retorts, with a consequent heavy increase in the cost of the gas. But in that year cannel coal, which had been gradually growing dearer and dearer, reached a prohibitive price, with the result that other methods of enrichment were gradually adopted; and although cannel has fallen in price, it will never again be used on a large scale for the enrichment of coal gas, as not only are other methods cheaper and more convenient, but the available supplies of cannel are limited, and any large readoption of its use would soon result in increase in price. The methods which have from time to time been advocated to replace the use of cannel in the enrichment of illuminating gas may be classified as follows:—

Enrichment.

1. Enriching the gas by vapours and permanent gases obtained by decomposing the tar formed at the same time as the gas.

2. Mixing with the coal gas oil gas, obtained by decomposing crude oils by heat.

3. The carburetting of low-power gas by impregnating it with the vapours of volatile hydrocarbons.

4. Mixing with coal gas water gas which has been highly carburetted by passing it with the vapours of various hydrocarbons through superheaters in order to give permanency to the hydrocarbon gases. These methods may now be considered in detail.

1. *Enrichment by Tar.*—From the earliest days of the gas industry attempts have been made to utilize tar for the production and enrichment of gas. The patent literature of the 19th century contains many hundreds of such schemes, most of which were still-born; a few spent a short and sickly existence, but none achieved success. The reason is not difficult to understand. In order to make gas from tar two methods may be adopted—(*a*) Condensing the tar in the ordinary way, and afterwards using the whole or portions of it for cracking into a permanent gas; (*b*) cracking the tar vapours before condensation by passing the gas and vapours through superheaters. If the first method be adopted, the trouble which presents itself, and in a few hours brings the apparatus to grief, is that the tar contains 60 per cent. of pitch, which rapidly chokes and clogs up all the pipes. If an attempt be made to use a temperature at which the pitch is decomposed, it is found that a non- or very poorly luminous gas is the result, while a heavy deposit of carbon remains in the superheater or retort; and even at a high temperature easily condensable vapours escape, which afterwards create trouble in the pipes. In order to get over the difficulties arising from the choking by the pitch, attempts have been made to distil the tar at a low temperature and utilize the 40 to 50 per cent. of oil so obtained for gasifying, but here the small yield of oil and the expense of handling and distilling have prevented tar from competing with other processes of enrichment. A more economical way was to distil the tar so as to leave the pitch behind, and then, instead of condensing the vapours to oil, to pass them through a heated chamber, and thus raise their temperature above the critical point. But as soon as this was tried it was found that the lighter vapours, which distilled off first, only required a temperature to crack them which was totally inadequate to render the heavier vapours coming off later in the distillation uncondensable; while if the heat was so arranged as to crack the heavy vapours, it broke up the lighter ones into gases of very poor illuminating power. These troubles of course arise from the same cause as in the earlier experiments on carburetting gas, by passing over or through volatile naphthas—viz., that the tar, like the naphthas, is a mixture of many compounds varying in composition and properties. In order (as far as possible) to surmount this trouble, Mr George Davis proposed to distil the tar so as to remove pitch, and then to get rid of the naphthalene and anthracene, using the remainder, four-fifths of which can be gasified, for enriching the gas. He calculated that coal yields 0·7 per cent. of its weight of tar, 0·4 of which is got rid of as pitch, and the remaining 0·28 per cent. can be converted into gas, a gallon of the oil yielding 80 cubic feet of 50-candle gas. He inferred that from a ton of ordinary coal, by utilizing the tar in this way, 10,465 cubic feet of 18·4-candle gas could be obtained, instead of 10,000 of 17-candle gas.

The most apparently successful attempt to utilize certain portions of the liquid products of distillation of coal was the Dinsmore process, in which the coal gas and the vapours which, if allowed to cool, would form tar were made to pass through a heated chamber, and a certain proportion of otherwise condensable hydrocarbons were thus rendered incondensable. Even with a poor class of coal it was claimed that 9800 cubic feet of 20 to 21 candle gas could be made by this process, whereas by the ordinary process 9000 cubic feet of 15-candle gas would have been produced. This process, although strongly advocated by the gas engineer who experimented with it, could not have been commercially very successful, as nothing has been heard of it for some years. The eventual solution of the question of enrichment of gas by hydrocarbons derived from tar may be arrived at by a process which prevents the formation of part of the tar during the carbonization of the coal, but all experience points to the impossibility of again decomposing tar in such a way as to be economically successful for enrichment when once it has been formed.

2. *Enrichment by Oil Gas.*—The second method by which a coal gas of poor quality may be enriched up to any desired standard is by mixing with it "oil gas," obtained by decomposing crude oil by heat. The earliest attempts in this direction were to spray oil upon the red-hot mass in the retort during carbonization; but experience soon showed that this was not an economical method of working, and that it was far better to decompose the liquid hydrocarbon in the presence of the diluents which are to mingle with it and act as its carrier, since if this were done a higher temperature could be employed, and more of the heavier portions of the oil converted into gas, without at the same time breaking down the gaseous hydrocarbons too much. For instance, if a petroleum oil is decomposed by itself, the resulting gas would consist largely of hydrogen and methane, and the heavy hydrocarbons would probably vary from 16 to 26 per cent., a considerable quantity of carbon separating; but if it were decomposed in the presence of a stream of diluting gas, a far larger percentage of illuminants of the higher marsh gas series (ethane, &c.) would be produced, and a comparatively small quantity of hydrogen and methane. This is due to the fact that when the hydrocarbons are undiluted they can easily be broken down by heat to hydrogen and carbon; whereas when they are diluted, a far higher temperature is necessary to effect this action, and so the degradation of the hydrocarbons is stopped at an earlier stage.

In carburetting a poor coal gas with paraffin it must be borne in mind that, as the coal is undergoing distillation, in the earlier stages a rich gas is given off, but towards the end of the operation the gas is very poor in illuminants and rich in hydrogen, the methane disappearing with the other hydrocarbons, and the increase in hydrogen being very marked. Mr Lewis T. Wright employed a coal requiring six hours for its distillation, and took samples of the gas at different periods of the time. On analysis these yielded the following results :—

	Time after beginning Distillation.			
	10 Minutes.	1 Hour 30 Minutes.	3 Hours 25 Minutes.	5 Hours 35 Minutes
Sulphuretted hydrogen	1·30	1·42	0·49	0·11
Carbon dioxide .	2·21	2·09	1·49	1·50
Hydrogen . .	20·10	38·33	52·68	67·12
Carbon monoxide	6·19	5·68	6·21	6·12
Marsh gas . .	57·38	44·03	33·54	22·58
Illuminants .	10·62	5·98	3·04	1·79
Nitrogen . .	2·20	2·47	2·55	0·78

This may be regarded as a fair example of the changes which take place in the quality of the gas during the distillation of the coal. In carburetting such a gas by injecting paraffin into the retort, many of the products of the decomposition of the oil being vapours, it would be wasteful to do so for the first two hours, as a rich gas is being given off which has not the power of carrying in suspension a much larger quantity of hydrocarbons without being saturated with them. Consequently, to make it bear along with it any further quantity, in a condition not easily deposited, the paraffin would have to be broken down to a great extent, and the temperature necessary to do this would seriously affect the quality of the gas given off by the coal. When, however, the distillation had gone on for three hours the rich portions of the coal gas would all have distilled off, and the temperature of the retort would have reached its highest point; this would be the best time to feed in the oil.

Undoubtedly the best process which has been proposed for the production of oil gas to be used in the enrichment of coal gas is the "Young" or "Peebles" process, which depends on the principle of washing the oil gas retorted at a moderate temperature by means of the oil which is afterwards to undergo decomposition, whereby it is freed from all condensable vapours, and only permanent gases are allowed to escape to the purifiers. In doing this very considerable quantities of the olefines and other fixed gases are also absorbed, but no loss takes place, as these are again driven out by the heat in the subsequent retorting. Two cast-iron retorts about 10 feet in length, set so as to incline downwards to the far end, are used at Peebles's. They are fitted with the usual doors and ascension pipes, but in each door there is a small pet-cock, by opening which the colour of the gas can be seen. This should be of the palest lemon, as it is found that if any darker colour or an approach to brown is produced, decomposition of tar (besides other troubles) will begin. The oil is admitted through small cocks about 2 feet up the ascension pipe, and falls down through the ascending gas on to steel plates, which extend 3 feet into the retort, so as to prevent as far as possible the direct impact of the oil upon the bottom of the iron retort. The temperature of the retorts is from 800° to 900° C. The gas on leaving the retorts passes up the ascension pipes to the hydraulic main and through a coil of horizontal condensing pipes to the scrubber, which is of the "Young" pattern, and made in four compartments. The oil cistern is placed on top of the scrubber, and the supply pipe from it is so arranged that the oil can be made to flow into any or all of the sections. After passing through the scrubber the oil flows back along the bottom of the horizontal condensers in an opposite direction to that in which the gas is passing, and thence into the hydraulic main. From the main it passes through a seal into a small cistern containing a float connected with an indicator close to the oil feed taps in front of the working bench, so that the supply of oil can be regulated in accordance with the rate of decomposition. The oil used is what is technically known as "blue" oil, and has an average specific gravity of about ·850. Each retort will make 500 cubic feet of gas per hour, and 5½ cwt. of a very dense graphitic coke are obtained for each ton of oil decomposed. This coke collects almost entirely at the back of the retorts, and being non-adherent, is readily removed. The surface of the coke is practically horizontal, which suggests that either it has flowed to the back of the retort as pitch and has been there carbonized, or that carbon deposited in the ascension pipes and front of the retort has been washed there by the oil.

The gas obtained by the Young process, when tested by itself in the burners most suited for its combustion, gives on the photometer an illuminating value averaging from 50 to 60 candle-power, but it is claimed that the enriching power of the gas is considerably greater. The reason is, that the duty obtained from any burner is entirely dependent, firstly, on the regulation of the size of the flame, so that the gases as they burn shall get the correct proportion of oxygen within a given distance from the tip of the burner; and, secondly, upon the temperature of the flame itself. Hence every variety of gas will give different illuminating values according to the burner used, the burner adapted for a poor or medium gas being utterly unfitted for rich gas, a point which is too often overlooked in testing the illuminating power of gases as well as in their practical consumption. A 16-candle coal gas requires a very large burner to develop its maximum illuminating power as a flat flame, but as the richness of the gas in heavy hydrocarbons increases, the size of the burner has also to be rapidly decreased, in order to allow sufficient air to get to the flame; and the smaller the flame, the greater will be the cooling influence of the burner and of the nitrogen of the air upon it, with the result that a burner has to be selected for each quality of gas of such size that it will just not smoke. For instance: with an oil gas capable of emitting a light equal to 50 candles per 5 cubic feet, it would be found that the No. 2 Bray burner would give a heavy smoky flame, which will become still more smoky with increase in the size of the burner; but if a No. 0 Bray were employed, a smokeless flame would be obtained which would give an illuminating power equal to slightly under 50 candles per 5 cubic feet of gas consumed; and as the size of the burner is reduced the illuminating power recorded would also decrease, until, with a No. 000, it would only record 35 candles per 5 cubic feet, the falling off being due to the cooling of the flame. With such a gas, therefore, the No. 0 burner would give the highest results; and when experimenting with gases of over 60 candle-power it is impossible to get a burner which will develop the maximum value, as the burner has to be so small, in order to prevent smoking, that cooling destroys a large percentage of the illuminating value. Hence it is frequently found that the enrichment value of a rich oil gas is higher than would be expected from its photometric value.

The fundamental objections to oil gas for the enrichment of coal gas are, firstly, that its manufacture is a slow process, requiring as much plant and space for retorting as coal gas; and, secondly, that although on a small scale it can be made to mix perfectly with coal gas and water gas, great difficulties are found in doing this on the large scale, because in spite of the fact that, theoretically, gases of such widely different specific gravities ought to form a perfect mixture by diffusion, it is found that layering of the gases is very apt to take place in the holder, and thus there is an increased liability to wide variations in the illuminating value of the gas sent out.

3. *Enrichment by Volatile Hydrocarbons.*—The carburetting of poor coal gas by passing it over or through highly volatile hydrocarbons, such as the lighter naphthas and benzene, has always been a favourite notion, but the great trouble which in the past has presented itself in the various carburetting systems is, that all the commercial samples of naphtha are mixtures of various hydrocarbons, having each their own boiling-point; therefore, when used in any of the old forms of carburetter they gave up their more volatile constituents very freely at the beginning of the experiment, while the amount rapidly diminished as the boiling-point of the residue became higher. Hence, when 2113 cubic feet of poor coal gas were passed through a naphtha having a specific gravity of ·869 and a boiling-point of 103° C., the temperature during the experiment being 22° C. (72° F.), the first 80 cubic feet of the gas took up 23·2 grains of the naphtha, whilst the last 450

cubic feet took up only 7·3 grains. The increase of evaporation with increase of temperature presented itself as another difficulty, for, with an ordinary form of carburetter exposed to changes of the atmosphere, the enrichment of the gas, which reached 44·4 per cent. in the summer, the average temperature being 72° F. (22° C.), fell in winter to only 22 per cent., with an average temperature of 37° F. (3° C.). Much, however, depends on the form of the carburetter. In one experiment, when gas was passed through a box containing a layer of naphtha, it took up only about 3·2 grains, but when the naphtha was sucked up by cotton fibres the gas took up as much as 22 to 23 grains in the same time owing to the large surface exposed, the same naphtha being used in both cases. A most important point is that only a poor gas can be enriched in this manner, a rich gas losing some of its illuminating power. The best method of carburetting poor coal gas at the burner is that known as the albo-carbon process, in which solid naphthalene is vaporized in a chamber by means of a strip of metal kept hot by the flame, the vapour mixing with the gas passing through the chamber.

Of recent years the idea of carburetting coal gas in bulk has been revived by the construction of an ingenious apparatus, devised by Messrs Maxim and Clarke, which to a great extent overcomes the difficulties of the old forms of carburetter. This process not only does away with the trouble that the more volatile portion of the naphtha or gasoline used enriches the gas to an undue extent at the beginning of the process, but it also carburets the gas used in large works and establishments, so that each portion obtains its proper share of hydrocarbon. For small installations the apparatus consists of a circular copper retort, which is kept automatically filled to a fixed level with gasoline from a reservoir outside the building. The retort is jacketed, and steam or hot water is passed round it to volatilize the gasoline, which passes over baffle plates in the top of the retort and then through an automatic regulator into a small holder sealed with mercury. The gas to be carburetted has to pass through this holder, and as it does so the gasoline vapour is supplied to it in the following way:—The holder works on a vertical spindle which passes down the tube into the gasoline retort, and is so arranged that when no gas is passing through the opening is closed and no gasoline can enter the holder. As gas is admitted the holder rises and lifts the spindle with it, allowing the gasoline vapour to rush up through grooves cut in the bottom of it; the higher the spindle is drawn the larger the openings become, and so the supply of gasoline increases *pari passu* with the amount of gas entering the holder.

Since about 1885 the price of benzol has been rapidly falling, owing to the large quantities produced in the coke ovens, which in the old days used to be burnt to waste, but are now recovered in the processes of coking which are becoming more and more widely adopted. The quantity of benzol produced in 1901 in Germany amounted to about 5,000,000 gallons per annum, and this quantity will be increased more than fourfold as the various coke works which do not at present recover the by-products are forced by competition to erect recovery plant. The wonderful carburetting power of benzol is well known, a very large proportion of the total illuminating power of coal gas being due to the presence of a minute trace of its vapour carried in suspension; with 90 per cent. benzol at a low price it is by far the cheapest enriching material that can be obtained, and at many gas works it is used in various forms of carburetter for enriching poor coal gas up to the requisite illuminating power.

4. *Enrichment by Carburetted Water Gas.*—In the last decade of the 19th century the most successful and most generally adopted method of enrichment was by means of carburetted water gas mixed with poor coal gas. When steam acts upon carbon at a high temperature, the resulting action may be looked upon as giving a mixture of equal volumes of hydrogen and carbon monoxide, both of which are inflammable but non-luminous gases. This water gas is then carburetted, *i.e.*, rendered luminous by passing it through chambers in which oils are decomposed by heat, and the mixture of oil gas diluted with water gas is made of such richness as to give an illuminating value of 24 or 25 candles. This mixed with the poor coal gas brings up its illuminating value to the required limit. Coke or anthracite is heated to incandescence by an air blast in a generator lined with firebrick, and the heated products of combustion as they leave the generator and enter the superheaters are supplied with more air, which causes the combustion of the carbon monoxide present in the producer gas and heats up the firebrick baffles with which the superheater is filled. When the necessary temperature of the fuel and superheater has been reached, the air blasts are cut off and steam is blown through the generator, forming water gas, which meets the enriching oil at the top of the first superheater, called the carburetter, and carries the vapours with it through the main superheaters, where the fixing of the hydrocarbons takes place. The chief advantage of this apparatus is that a low temperature can be used for fixing owing to the enormous surface for superheating, and thus to a great extent the deposition of carbon is avoided. This form of apparatus has been very generally adopted in Great Britain as well as in America, and practically all carburetted water gas plants are founded upon the same set of actions. Important factors in the use of carburetted water gas for enrichment are that it can be made with enormous rapidity and with a minimum of labour; and not only is the requisite increase in illuminating power secured, but the volume of enriched gas is increased by the bulk of carburetted water gas added, which in usual English practice amounts to from 25 to 50 per cent. The public at first strongly opposed its introduction, on the grounds of the poisonous properties of the carbon monoxide, which is present in it to the extent of about 28 to 30 per cent. Still, when this comes to be diluted with 60 to 75 per cent. of ordinary coal gas, containing as a rule only 4 to 6 per cent. of carbon monoxide, the percentage of poisonous monoxide in the mixture falls to below 16 per cent., which experience has shown to be a fairly safe limit.

The price of oil suitable for carburetting has during the past few years nearly doubled, and this fact has caused the gas industry to consider other methods by which the volume of the gas obtainable from coal can be increased by admixture with "blue" or non-luminous water gas. In Germany, at several important gas-works, non-luminous water gas is passed into the foul main of the gas plant in the desired proportion, and the mixture of water gas and coal gas is then carburetted to the required extent by benzol vapour, a process which at the present price of oil and benzol is distinctly more economical than the use of carburetted water gas. Extensive experiments are also being made on the Continent and in England upon passing water gas in the desired proportion through the crown of the retort in which the distillation of the coal is proceeding so as to prevent overheating of the gas and vapours by too long contact with the crown and sides of the retorts, the water gas so used also holding in suspension some of the more volatile hydrocarbons that would otherwise condense in the tar. In 1896 Mr Carl

Dellwik introduced a modification in the process of making water gas which entirely altered the whole aspect of the industry. In all the attempts to make water gas up to that date the incandescence of the fuel had been obtained by "blowing" so deep a bed of fuel that carbon monoxide and the residual nitrogen of the air formed the chief products, this mixture being known as "producer" gas. In the Dellwik process, however, the main point is the adjustment of the air supply to the fuel in the generator in such a way that carbon dioxide is formed instead of carbon monoxide. Under these conditions the producer gas ceases to exist as a by-product, and the gases of the blow consist merely of the incombustible products of complete combustion, carbon dioxide and nitrogen, the result being that more than three times the heat is developed for the combustion of the same amount of fuel, and double the quantity of water gas can be made per pound of fuel, than was before possible. The runs or times of steaming can also be continued for longer periods. The possibility of making 70,000 cubic feet of water gas per ton of coke used in the Dellwik generator, as against 34,000 cubic feet per ton made by previous processes, reduces the price of water gas to about 3d. per 1000, so that the economic value of using it in admixture with coal gas and then enriching the mixture by any cheap carburetting process is manifest. During the past few years it has become more and more evident that the universal adoption of the incandescent mantle for lighting purposes makes the illuminating value of the gas a secondary consideration, and the whole tendency of the future will be the production of low candle-power gas at a cheap rate for fuel purposes and incandescent lighting.

Gas Lighting.

Industrial history shows the great utility of brisk competition, and in no case is this more marked than in the utilization of gas for the emission of light. From 1820, when Neilson of Glasgow first discovered the principle of the union jet burner, and gave the world an easy and at the same time fairly effective method of consuming the then newly invented illuminant, until quite recent times, coal gas had been consumed by the methods which had sufficed for illumination in the early days; and in all probability the methods of consumption would have continued to be of the same inefficient character down to the present time had it not been for the appearance of the electric light as a competitor in the latter part of the 'seventies, and the dread which suddenly arose in the minds of those interested in gas manufacture as to the effect of this brilliant rival on their commercial status. It is true that the germs of important methods of consuming gas had already been sown, but the time had not been ripe for their development, and it was only the absolute necessity of combating the inroads of electricity that caused the adoption of new and improved methods for developing the light latent in coal gas.

Regenerative burners.

In the early 'fifties Sir Edward Frankland had already pointed out that the heating of the air supply to a flame marvellously increased the light which that flame emitted. He devised a burner which consisted of an ordinary Argand, having in addition to the usual chimney a second external one which extended some distance below the first, and was closed at the bottom by a glass plate fitted air-tight to the pillar carrying the burner, so that the air needed to support the combustion of the gas had to pass down the annular space between the two chimneys, and in its passage became highly heated, partly by contact with the hot inner glass and partly by radiation. He claimed that the use of this burner gave an increase of 67 per cent. in the light over that obtained by the combustion of the same volume of gas in an ordinary Argand. In 1854 the Rev. W. R. Bowditch brought out a burner identical in nearly every respect with the above, and as this was brought prominently forward, it attracted considerable attention, with the result that the inception of the regenerative burner has been generally ascribed to Bowditch, whereas this honour was undoubtedly due to Frankland. This burner has been revived from time to time since its first invention, but has always failed, owing to the inner chimney not being able to withstand the intense heat to which it was subjected; it is of interest as being the first inception of the idea of the modern regenerative burner. In 1879 Friedrich Siemens, of Dresden, brought out his big burner, which, although one of the most effective, was also one of the most unsightly from its big overhead feed pipe. It was really first made for heating purposes, but the light it gave was so far ahead of any effect which had been obtained up to that time, that, with certain modifications, it was adopted for lighting purposes. In 1881 Mr Thwaite published in the *English Mechanic* a description of an overhead recuperative burner under the name of the Hygienic lamp; and from that time up to the present regenerative burners—good, bad, and indifferent—have increased and multiplied with great rapidity, the chief differences between them being in their names and slight details of design.

The fact that the luminosity of a coal gas flame depends upon the number of carbon particles liberated within it, and the temperature to which these carbon particles can be heated, at once points to the fact that the methods by which the light developed from a flame of coal gas can be augmented are the increase in the number of the carbon particles by increasing the material which will deposit them, and raising the temperature to which the carbon particles already present have been heated. The first process is carried out by enrichment, the second is best obtained by regeneration, the action of which is limited by the power possessed by the material of which burners are composed to withstand the superheating. Although with a perfectly-made recuperative burner it might be possible for a short time to get as high a duty as 16 candles per cubic foot from ordinary coal gas, such a burner constructed of the ordinary materials would only last a few hours, so that for practical use and a reasonable life for the burner 10 candles per cubic foot was about the highest commercial duty that could be reckoned on. This limitation naturally caused inventors to search for methods by which the emission of light could be obtained from coal gas other than by the incandescence of the carbon particles contained within the flame itself, and the fact that a coal gas flame consumed in an atmospheric burner under conditions necessary to develop from it its maximum heating power could be utilized to raise particles having a higher emissivity for light than carbon to incandescence, led to the gradual evolution of incandescent gas-lighting, which undoubtedly marks another of the most important eras in the history of gas as an illuminant.

Incandescent mantles.

Existing systems of lighting by means of incandescent mantles are the result of many years of experimental toil and disappointment, and from the day when Talbot in 1835 first noticed that blotting-paper soaked in a solution of calcium chloride and burnt in the flame of a spirit lamp leaves a white network of ashes, which heated in the feeblest flame emits a brilliant light, down to the latest developments of the Welsbach mantle, there have been many thousands of experimental failures and still-born attempts which have neither seen nor created light. That all solids can be made to emit light when heated to a certain temperature has of course always been known. The fact that at any given temperature some substances would emit more light than others gave rise to the Drummond light, in which a block of lime raised to the highest temperature possible by the intensity of the oxy-hydrogen or oxy-coal gas blast emitted a light which until the advent of the electric arc remained unrivalled. The amount of material which has in this case to be raised to incandescence rendered this very high temperature necessary, and it was gradually recognized that if instead of a block of lime a basket-work of thin filaments made of lime and magnesia could be employed better results would follow, since instead of the costly oxy-hydrogen or oxy-coal gas flame an ordinary gas and air blowpipe working at a slight pressure could be used. This was practically adopted in the Clamond mantle, which was probably the first oxide mantle which had any extended commercial existence. The same principle was utilized in the Fahnejelm comb, which was heated to incandescence by water gas. The Clamond mantle, as shown at the Crystal Palace Exhibition of 1882–83, consisted of a conical basket composed of threads of calcined magnesia. A mixture of the hydrate and acetate of magnesium, converted into a paste or cream by means of water, was moulded to the required shape, and then ignited; the heat decomposed the acetate, which in its partial fusing during decomposition formed a luting material which glued the particles of magnesium oxide produced into a solid mass, while the hydrate gave off water and became oxide. The basket was supported with its apex downwards in a little platinum wire cage, and a mixture of coal gas and air was driven into it from an inverted burner above it. Long, however, before this oxide mantle made its appearance Lewis had introduced a mantle made of fine platinum wire, which, when raised to incandescence by a blast of air and coal gas, gave for a certain period what was then considered a very high duty for gas consumed, but the rapid falling off of its power of emitting light proved a fatal obstacle to its commercial success. This deterioration was partly due to the surface of the platinum becoming corroded by the formation of traces of carbide of platinum from the action of the hydrocarbon in the flame, and partly to the deposition on its surface of traces of foreign metals due to the breaking up of the carbonoxyl compounds, of which the gas contained minute quantities. It was this latter trouble that at a more recent date militated against what at first appeared a very promising attempt to utilize thin platinum-iridium wire for the manufacture of an unbreakable incandescent mantle. The year 1886 marks the first appearance of the Welsbach system of incandescent mantles, which after many years of struggle and effort at length attained a well-earned success. Dr Auer von Welsbach, whose researches on the rare metals and their compounds had already gained him a great reputation, conceived the idea of making a mantle of refractory oxides by the methods which had been previously shadowed by Talbot and others. His process consisted in soaking an open fabric of cotton in a solution of the nitrates of the metals of which he required the oxides, drying it, and burning off the organic matter, the nitrates at the same time becoming converted into their respective oxides, which retained the shape of the original fabric. Various modifications have been introduced in the manufacture of the fabric and in the composition of the dipping material, until at the present time the incandescent mantle is far and away superior in light-emissivity to any other method for producing light from coal gas.

In the system of lighting by means of incandescent mantles the most important feature is the burner, which must give a non-luminous flame, else deposition of carbon will soon ruin the mantle as regards its light-giving powers. A non-luminous flame can be obtained either by burning a mixture of air and gas, mixed before combustion, or by burning the coal gas in so thin a sheet of flame that the air can permeate it with sufficient freedom to render it non-luminous. The former method is now employed in nearly all systems of incandescent lighting, but the latter is used in Paris in one form of the De Mare system, in which a fringe of light-giving oxides is heated by a small flat flame burner burning with a non-luminous flame. The extended use of incandescent mantles has produced many improvements in the atmospheric burners employed in connexion with them, and has led to a study of the factors necessary to obtain the best results. One of the most promising directions in which this has taken place has been the gradual realization of the fact that in order to secure the highest results the mixture of air and gas must not only be in such proportions as to ensure perfect combustion, but that the mixture itself must be so perfect that each molecule of combustible matter shall find itself side by side with the oxygen necessary for its combustion at the burner tip, as it is manifest that the intensity of the flame is greatly increased by the proper regulation of this factor. The chemical actions taking place in a Bunsen burner can be divided into two distinct parts: the first occur on the surface of the inner visible cone of the flame, where the hydrogen and hydrocarbons of the gas enter into partial combination with the oxygen of the air which has been previously mixed with the gas, forming a mixture of carbon dioxide and monoxide with some water vapour; and the second takes place in the outer flame, which is produced by the combustion of the hydrogen and carbon monoxide escaping from the inner zone, the products of the completed combustion being carbon dioxide and water vapour. The appearance of the Bunsen flame varies with the amount of air which is drawn in with the gas. Under normal conditions the zones of the flame have a violet-blue colour, and as more air is admitted the flame grows fiercer and the inner zone acquires a green tint. A still further addition of air causes the mixture to become so highly explosive that it flashes back into the tube of the burner. In the Bandsept and Kern burners the mixture of air and gas can be so regulated that not only is the green cone in the interior of the flame formed, but owing to the explosive point of the mixture being reached it is drawn down on to the surface of the gauze "atomizers" or mixers, through which it cannot pass, so that the flame consists of practically only the outer cone of the ordinary Bunsen, by which method a more even equality in temperature can be obtained than with the ordinary flame.

Atmospheric burners for mantles.

The most successful form of mantle is made by taking a cylinder of cotton net about 8 inches long, one end of which is sewn together with an asbestos thread, a loop of the same material or of thin platinum wire being fixed across the constricted portion to provide a support by which the mantle may be held by the carrying rod, which is either external to the mantle or (as is most often the case) fixed centrally in the burner head. After being sewn, the cotton net is soaked in a solution of the nitrates of the requisite metals until the microscopic fibres of the cotton are entirely filled with liquid. A longer soaking is not advantageous, as the acid nature of the liquid employed tends to weaken the fabric and render it more delicate to handle. The cotton is then wrung out to free it from the excess of liquid attached to the exterior of the threads, and is stretched over a conical mould and dried. It is

Mantle manufacture.

then ready for "burning off," a process in which the organic matter is removed and the nitrates are converted into oxides. The flame of an atmospheric burner is first applied to the constricted portion at the top of the mantle, whereupon the cotton gradually burns downwards, the shape of the mantle to a great extent depending on the regularity with which the combustion takes place. A certain amount of carbon is left behind after the flame has died out, and this is burnt off by the judicious application of a flame from an atmospheric blast burner to the interior. The action which takes place during the burning off is as follows:—The cellulose tubes of the fibre are filled with the crystallized nitrates of the metals used, and as the cellulose burns the nitrates decompose, giving up oxygen and forming fusible nitrites, which in their semi-liquid condition are rendered coherent by the rapid shrinkage which takes place. As the action continues the nitrites become oxides, losing their fusibility, so that by the time the organic matter has disappeared a coherent thread of oxide is left in place of the nitrate-laden thread of cotton. The great drawback in the early days of incandescent lighting was that the mantles had to be sent out unburnt and the consumer had to burn them off when required, as no process was known by which the burnt mantle could be rendered sufficiently strong to bear carriage. As the success of the mantle depends upon its fitting the flame, and as the burning off requires considerable skill, this was a great difficulty. Moreover, the acid nature of the nitrates present in the fibres rapidly rotted them, unless they had been subjected to the action of ammonia gas, which neutralized any excess of acid; but it was found that treatment with ammonia rendered the mantles after burning off even more fragile than before, as the fusible nitrates were converted into hydrates, which could not be pressed together into a coherent mass during the burning off. It was discovered, however, that the burnt-off mantle could be temporarily strengthened by being dipped in collodion, a solution of soluble gun-cotton in ether and alcohol together with a little castor oil or similar material to prevent excessive shrinkage during drying: when the mantle was removed from the solution a thin film of solid collodion was left on it, and this burned away on the application of a light when required, no bad after-effects being left.

The oxides first used in England for Welsbach mantles consisted of mixtures of zirconia, lanthania, and yttria, or zirconia and lanthania, but these gave a very fragile mantle, and only yielded 4 to 7 candles per cubic foot of gas consumed. In 1886 the second Welsbach patent was taken out, which covered the use of thoria, either alone or mixed with zirconia, magnesia, yttria, erbia, neodidymia, lanthania, alumina, &c. The idea which was held at that time was that a pure thoria mantle had a very high power of light emission, but in point of fact really pure thoria emits practically no light at all, although later experience showed that it possessed important properties for mantle-making, its refractory nature giving the mantle a stability unattainable by any other known body. The thoria mantles made under this patent gave a duty of 6 candles per cubic foot of gas consumed, but when made with pure thoria they give a duty of less than 1 candle per cubic foot of gas, and the other mixtures specified in the patent give results which hardly come within the range of practical utility. About 1891, mantles on the Continent began to show a marked improvement, and in 1891–92 it was reported that Welsbach had produced new mantles yielding as much as 16 and 17 candles per cubic foot of gas consumed, and the same improvement was manifested in the English mantles. The cause was shown in the following year, 1893, in a patent taken out by Mr Moeller, in which protection was sought for a combination of thoria with very small traces—not exceeding 1 or 2 per cent.—of the oxides of certain other rare metals, such as uranium, cerium, terbium, neodidymium, samarium, prazeodymium, yttrium, and lanthanum. The present mantles nearly all consist of 99 per cent. thoria with 1 per cent. cerium, this latter oxide having qualities far in advance of any of the others mentioned.

It will be seen from the above description that the mantles of to-day are the outcome of three stages—(1) The method of making the mantle, and the use of the oxides of the rare earths; (2) using thoria instead of zirconia as the basis of the mantle; and (3) the effect of traces of other oxides on the light-emissivity of the thoria. In the days prior to Welsbach's discovery the rare earths had been studied by but few, although several famous chemists, foremost among them Bunsen, had devoted special attention to them, and no method was known by which they could be obtained in a state of absolute purity. The price of the raw materials being excessive, their purification was not pushed to the extreme limits, and consequently the candle-power of the earlier mantles was more often influenced by the impurities present in the materials used than by the actual composition of the mantle. Many experiments have been made in order to determine the effect of the percentage of ceria when added to thoria on the light-emissivity of the mantle, and the results obtained show that, starting with a pure thoria mantle giving practically no light, the candle-power rapidly increases as traces of ceria are added to it, until the maximum is reached, when increase in the amount of ceria decreases the light emitted, the colour of the light also acquiring a yellowish tint, which gradually deepens to a reddish character with excess of ceria. These results show such a narrow limit for the production of the highest light-emissivity, that a very careful proportioning of the liquid for soaking the mantle is necessary. The effect of varying proportions of ceria upon the life of the mantle shows that with a Welsbach mantle made in the ordinary manner by soaking the fabric in the nitrates solution, the higher the initial illuminating value the greater is the falling off in light over a given space of time. It is generally found that the light from a Welsbach mantle increases for a certain period and then steadily falls, the initial increase being probably due to the mantle shaping itself to the flame, while the subsequent diminution in power is chiefly due to dust particles containing silica, which are drawn in over the surface of the mantle by the chimney draught and, fusing on the outside of the fine filaments, form silicates which have a much lower power of light-emissivity than the original oxides.

Effect of Ceria.

Many theories have been advanced to explain the marvellous power possessed by the minute trace of ceria in exciting the light-giving power of the mantle. The explanation put forward by Dr Drossbach, that the ceria has some occult power of converting the heat rays into light, is now regarded as untenable. Drs Killing and Moschelles are of opinion that the ceria (CeO_2), at a high temperature under the influence of the hydrogen and carbon monoxide, becomes reduced to cerous oxide (Ce_2O_3) with liberation of oxygen, which, combining on the surface of the ceria with the combustible gases of the flame, induces a far higher temperature in the ceria than exists in the thoria, the cerous oxide then undergoing oxidation to the higher compound by the action of the excess of air present. This theory, however, would imply that the more ceria were present the greater would be the light-emitting power of the mantle; but this is not so, as any increase over 1 per cent. tends to reduce the light-giving power. In the explanation of Dr Bunte, which is the one most generally accepted, the action is ascribed to a catalysis of the same nature as causes a piece of platinum foil after cleaning to become red-hot when a mixture of coal gas and air is allowed to impinge upon it, the action being due to the power which the platinum possesses of condensing within its pores both coal gas and air, and rendering them so chemically active that they unite upon the surface of the metal and emit sufficient heat to raise it to a bright red. Dr Bunte found that at 1200° F. (649° C.) a mixture of hydrogen and oxygen, in the proportion of two to one, when passed through a heated porcelain tube, combined to form water, and that the presence of thoria in the tube had no influence upon the temperature at which the combination took place. When he passed the same mixture through a tube containing ceria, the action commenced at 600° F. (315·5° C.), and his inference was that this catalytic action, by localizing a high temperature in the small particles of ceria spread over the surface of the inert thoria, is the cause of the high light-emissivity. Proof of Drossbach's theory ought easily to have been obtained by observing the way in which the rare oxides and mixtures behave when out of contact with air, but Dr Bunte found on experiment that there was very little difference in the noticeable light radiation from bodies of such widely different light-emissivity as carbon, magnesia, thoria, or the mixtures used in the Welsbach mantle. In order to prove this fact he used a thick-walled tube of retort carbon, the thickness of the walls of the centre portion of which for a length of 4 inches was reduced to 0·059 inch. When a strong current of electricity was passed through the thin-walled portion it was raised to a white heat, about 3630° F. (1999° C.), the tube being protected from burning away at this point by a coating of magnesia covered by an outer wrapper of asbestos paper. In the interior of the tube small square prisms of magnesia were placed, coated with the substance under examination, and each prism compared side by side in the hottest portion of the tube, a small sight-hole being left at the end of the carbon tube for observation purposes. By using double prisms, one coated with the substance to be tested and the other with a standard material of known composition, it was found that there was practically no difference in the various materials. This was also confirmed by some experiments made by Mr Campbell Swinton, in which various mantle materials were enclosed in a vacuum tube and submitted to cathode rays: he found that although the mixture of 99 per cent. thoria and 1 per cent. cerium in a vacuum heated up to incandescence more rapidly than pure thoria alone and cooled down afterwards more rapidly, its incandescence was only very slightly greater than that of the thoria alone. Many other facts can be adduced to support the theory that the light is due to the particles of ceria being heated to a higher temperature than that of the flame. The luminosity of an ordinary flame has been shown to be due to the splitting up of the molecule of acetylene with the liberation of endothermic heat, by which the carbon particles are heated to a temperature far above that which exists in the flame. So in the same way the heat of the flame which heats the whole mantle *plus* the locally intensified points of excessively high temperature, due to the catalytic action of the ceria upon the oxygen, carbon monoxide, and hydrogen, probably accounts for the intense light-emissivity of the mantle. Additional confirmation of the fact is gained from the circumstance that similar results, though not so marked, are obtained by the use of other materials known to have catalytic powers. The quantity of ceria may seem so small that it does not appear possible for it to play any important part in the light-giving power of the mantle. Dr Bunte, however, points out that in an ordinary gas flame the luminosity is due to liberated carbon particles heated to an intense degree; the carbon is chiefly obtained from the decomposition of unsaturated hydrocarbons, which only form about 5 per cent. of the volume of the gas. Supposing all the carbon of the unsaturated hydrocarbons to be liberated, it may be calculated that about 54 milligrams of carbon are separated from a litre of coal gas, or 23·6 grains from 1 cubic foot. Thus 4 per cent. of ethylene and 1 per cent. of benzene give per litre of gas 60 cc. of carbon vapour from the benzene and 40 cc. from the ethylene, in all 100 cc., equal to about 54 milligrams of carbon. The volume of the luminous portion of a flame consuming 5·297 cubic feet per hour, with an illuminating power of 17·5 candles, is about 2 cc. at 32° F. (0° C.). It therefore contains $2 \times 54 \div 1000$ mg. or 0·1 mg. (0·0015 grain) of incandescent carbon, and this small quantity is sufficient to yield a light of 17·5 candles. In a Welsbach mantle the amount of ceria is about 4 mg., 0·06 grain, or forty times the quantity of incandescent carbon in an ordinary flame, and this will explain why the Welsbach mantle gives a light of 80 candles when the Argand burner affords only 16 candles.

Improvements in mantles.

Of late years improved methods have arisen in the manufacture of some mantles, the principle of the Clamond mantle being revived. As already mentioned, these Clamond baskets were made by weaving together threads made from a paste of magnesia and magnesium acetate, which after baking could be rendered incandescent by means of an ordinary burner. On 4th November 1890 an improvement on this method was patented by Lungren. It was found that in the weaving the threads at the points of intersection did not weld properly, as the first threads laid on the mould dried before the cross threads were put on, so that on pressing them together the dry threads cut through the softer ones and did not unite with them, with the result that it was difficult to get a coherent mantle. Lungren, however, mixed the earths into a paste with a combustible elastic material, formed the thread, and then wove the mantle from it, the binding material being afterwards burnt out. Suitable materials are said to be glue mixed with glycerine, indiarubber dissolved in naphtha, &c. At the present time collodion is being largely used as a vehicle for holding the incandescent oxides. Among numerous other applications it has been employed for the manufacture of artificial silk, and large factories have been erected in Europe for this purpose. The usual method is to convert wood pulp into collodion by nitration. This collodion is then dissolved in as little alcohol and ether as possible, and the solution is squeezed under great pressure through capillary glass tubes, the bore of which is less than one-hundredth of a millimetre. The filament dries a few inches from the orifice of the tube, and ten or twelve of them are twisted together and wound on to a bobbin. The twisted thread is then denitrated by dipping the skeins into a solution of ammonium sulphide, by which they are converted into ordinary cellulose and lose their excessive inflammability. After washing and drying the skeins are ready for weaving into fabric. This artificial silk was utilized by De Mare in 1894 for making mantles by adding to the collodion the necessary salts, and in the next year Knofler and then Plaissetty patented the manufacture of mantles by a similar process to De Mare's, the difference between them being that Knofler used ammonium sulphide for denitrating purposes, while Plaissetty employed calcium sulphide, the objection to which is the trace of lime left in the material. Another process is the Lehner, in which the high pressures employed for the formation of the filament in the early processes are done away with, the solution used being of a more liquid character and the thread hardened by passing through certain organic solutions. This form of silk has been found well adapted for the manufacture of mantles, and the finished mantles are far superior to the older makes.

Mantles made in the above way are evidently developments of the Clamond class, as the filaments are made by squeezing the material through small holes to form rods or threads, leaving a thread of even density when the collodion is burnt off. In the Auer mantle, however, the filaments on burning off each leave a minute rod of oxides having a dense central portion surrounded by a more or less spongy coating, formed by the salts on the exterior of the filament, which are kept in a porous condition by the escape through them of the gases given off during the burning of the organic matter. In the Welsbach mantle this filamentary matter is twisted in the thread into what, after burning off, becomes practically a fluted column of oxides, but in the Clamond mantle each separate filament stands out by itself, so that the complete thread is really a bundle of filaments, the number of which varies according to the make of the mantle. The Lehner mantle, for instance, contains more filaments than the Knofler or Plaissetty. This difference in structure between the two classes has a very important effect on the life and strength of the mantle. The decrease in light due to the formation of silicates from dust on the surface of the mantle is considerably less in the case of the Clamond type than with the ordinary Welsbach mantle; the Welsbach mantle after 500 to 600 hours' burning becomes but a mere shadow of its former self, and yields only about a third of the original light, whereas mantles such as the Knofler and Lehner keep up their light-emitting power to a much greater extent, more especially in the case of the latter.

In Germany nearly 90 per cent. of the gas lighting is done by the aid of the incandescent mantle, but in England it has only reached to about 30 per cent. of the whole. It is, however, rapidly spreading, and, with improvements in the strength and lasting power of the mantle, and a cheapening in price, must soon pass into general use. Moreover, in spite of the cost of breakages and renewals, the fact that the use of the mantle increases sevenfold the light obtainable from a cubic foot of gas, as compared with what was possible with the flat flame or Argand, renders gas lighting the cheapest method of obtaining artificial light. (V. B. L.)

Gas Engines. See ENGINES.

Gaseous Fuel.—Natural gas (see *Ency. Brit.*, 9th ed. vol. ix. p. 809, and vol. xxiii. p. 813) has become of practical importance only in some states of the United States, especially in Pennsylvania, where it still plays a very great part for both household and industrial purposes, hundreds of gas wells having been bored and long pipe lines having been constructed. The gas, which contains from 68 to 94 per cent. of methane, with a little hydrogen, ethylene, &c., is evidently an accumulation of many ages, and is gradually approaching exhaustion, the maximum yield having been reached in 1890. The gas used in 1899 was valued at $11\frac{1}{2}$ million dollars.

Of much more importance, and that in a constantly increasing proportion, is artificial gas of all kinds. It is necessary to distinguish between the gaseous fuel obtained as a by-product of certain technical operations and that prepared on purpose. In the former case the combustible gases have been and are still frequently wasted, but their utilization is becoming more and more extended. This is true especially of the gases from blast-furnaces and from coke-ovens. Of the gaseous fuel prepared on purpose there are two different classes. The first comprises combustible gases generated by the destructive distillation of coal, lignite, bituminous schist, cheap oils, and substances of analogous character. By far the most important case of this kind is the manufacture of coal gas, which is primarily made for the purpose of illumination, but which serves also as a fuel for domestic use, for laboratories, and to some extent even for industrial purposes. In all cases belonging to this class only a comparatively small proportion of the heat-value of the coal is obtained in the shape of gaseous fuel, by far the greater portion remaining behind in the shape of coke. Where the latter is the principal object of the operation, as in the manufacture of coke for metallurgical purposes, the gases necessarily evolved are still wasted in the great majority of cases, although their fuel value is almost equal to that of ordinary illuminating gas.

An entirely different class of gaseous fuels comprises those produced by the incomplete combustion of the total carbon contained in the raw material, where the result is a mixture of gases which, being capable of combining with more oxygen, can be burnt and employed for heating purposes. Apart from some descriptions of waste gases belonging to this class (of which the most notable are those from blast-furnaces), we must distinguish two ways of producing such gaseous fuels entirely different in principle, though sometimes combined in one operation. The incomplete combustion of carbon may be brought about by means of atmospheric oxygen, by means of water, or by a simultaneous combination of these two actions. In the first case the chemical reaction is

$$C + O = CO \quad . \quad . \quad . \quad (a);$$

the nitrogen accompanying the oxygen in the atmospheric air necessarily remains mixed with carbon monoxide, and the resulting gases, which always contain some carbon dioxide, some products of the destructive distillation of the coal, &c., are known as *producer gas* or *Siemens gas*. In the second case the chemical reaction is mainly

$$C + H_2O = CO + H_2 \quad . \quad . \quad (b);$$

that is to say, the carbon is converted into monoxide and the hydrogen is set free. As both of these substances can combine with oxygen, and as there is no atmospheric nitrogen to deal with, the resulting gas (*water gas*) is, apart from a few impurities, entirely combustible. Another kind of water gas is formed by the reaction

$$C + 2H_2O = CO_2 + 2H_2 \quad . \quad . \quad (c),$$

but this reaction, which converts all the carbon into the incombustible form of CO_2, is considered as an unwelcome, although never entirely avoidable, concomitant of (*b*).

The reaction by which water gas is produced being endothermic (as we shall see), this gas cannot be obtained except by introducing the balance of energy in another manner. This might be done by heating the apparatus from without, but as this method would be uneconomical, the process is carried out by alternating the endothermic production of water gas with the exothermic combustion of carbon by atmospheric air. Pure water gas is not, therefore, made by a continuous process, but alternates with the production of other gases, combustible or not. But instead of constantly interrupting the process in this way, a continuous operation may be secured by simultaneously carrying on both the reactions (*a*) and (*b*) in such proportions that the heat generated by (*a*) at least equals the heat absorbed by (*b*). For this purpose the apparatus is fed at the same time with atmospheric air and with a certain quantity of steam, preferably in a superheated state. Gaseous mixtures of this kind have been made, more or less intentionally, for a long time past. One of the best known of them, intended less for the purpose of serving as ordinary fuel than for that of driving machinery, is the Dowson gas.

An advantage common to all kinds of gaseous fuel, which indeed forms the principal reason why it is intentionally produced from solid fuel, in spite of inevitable losses in the course of the operation, is the following. The combustion of solid fuel (coal, &c.) cannot be carried on with the theoretically necessary quantity of atmospheric air, but requires a considerable excess of the latter, at least 50 per cent., sometimes 100 per cent. and more. This is best seen from the analyses of smoke gases. If all the oxygen of the air were converted into CO_2 and H_2O, the amount of CO_2 in the smoke gases should be in the case of pure carbon nearly 21 volumes per cent., as carbon dioxide occupies the same volume as oxygen; while ordinary coal, where the hydrogen takes up a certain quantity of oxygen as well, should show about 18·5 per cent. CO_2. But the best smoke gases of steam boilers show only 12 or 13 per cent., much more frequently only 10 per cent. CO_2, and gases from reverberatory furnaces often show less than 5 per cent. This means that the volume of the smoke gases escaping into the air is from $1\frac{1}{2}$ to 2 times (in the case of high-temperature operations often 4 times) greater than the theoretical minimum; and as these gases always carry off a considerable quantity of heat, the loss of heat is all the greater the less complete is the utilization of the oxygen and the higher the temperature of the operation. This explains why, in the case of the best-constructed steam-boiler fires provided with heat economizers, where the smoke gases are deprived of most of their heat, the proportion of the heat value of the fuel actually utilized may rise to 70 or even 75 per cent., while in some metallurgical operations, in glass-making and similar cases, it may be below 5 per cent.

One way of overcoming this difficulty to a certain extent is to reduce the solid fuel to a very fine powder, which can be intimately mixed with the air so that the consumption of the latter is only very slightly in excess of the theoretical quantity; but this process, which has been only recently introduced on a somewhat extended scale, involves much additional expense and trouble, and cannot as yet be considered a real success. Generally, too, it is far less easily applied than gaseous fuel. The latter can be readily and intimately mixed with the exact quantity of air that is required and distributed in any suitable way, and much of the waste heat can be utilized for a preliminary heating of the air and the gas to be burned by means of "recuperators."

We shall now describe the principal classes of gaseous fuel.

A. *Ordinary Coal Gas.*—Although this gas is primarily manufactured for illuminating purposes, it is now extensively used for cooking, frequently also for heating domestic rooms, baths, &c., and to some extent also for industrial operations on a small scale, where cleanliness and exact regulation of the work are of particular importance. In chemical laboratories it is preferred to every other kind of fuel wherever it is available. The manufacture of coal gas having been described elsewhere in this work (see GAS AND GAS-LIGHTING), we need here only point out that it is obtained by heating bituminous coal in fireclay retorts and purifying the products of this destructive distillation by cooling, washing, and other operations. The residual gas, the ordinary composition of which is given in the table below, amounts to about 10,000 cubic feet for a ton of coal, and represents about 21 per cent. of its original heating value, 56·5 per cent. being left in the coke, 5·5 per cent. in the tar, and 17 per cent. being lost. As we must deduct from the coke that quantity which is required for the heating of the retorts, and which, even when employing good gas producers, amounts to 12 per cent. of the weight of the coal, or 10 per cent. of its heat value, the total loss of heat rises to 27 per cent. Taking, further, into account the cost of labour, the wear and tear, and the capital interest on the plant, coal gas must always be an expensive fuel in comparison with coal itself, and cannot be thought of as a general substitute for the latter. But in many cases the greater expense of the coal gas is more than compensated by its easy distribution, the facility and cleanliness of its application, the general freedom from the mechanical loss, unavoidable in the case of coal fires, the prevention of black smoke, and so forth. The following table shows the average composition of coal gas by volume and weight, together with the heat developed by its single constituents, the latter being expressed in kilogram calories per cubic metre (0·252 kilogram calories = 1 British heat unit; 1 cubic metre = 35·3 cubic feet; therefore 0·1123 calories per cubic metre = 1 British heat unit per cubic foot).

Constituents.	Volume per cent.	Weight per cent.	Heat-value per Cubic Metre Calories.	Heat-value per Quantity contained in 1 Cub. Met.	Heat-value per cent. of Total.
Hydrogen, H_2	47	7·4	2,582	1213	22·8
Methane, CH_4	34	42·8	8,524	2898	54·5
Carbon monoxide, CO	9	19·9	3,043	273	5·1
Benzene vapour, C_6H_6	1·2	7·4	33,815	405	7·7
Ethylene, C_2H_4	3·8	8·4	13,960	530	9·9
Carbon dioxide, CO_2	2·5	8·6			
Nitrogen, N_2	2·5	5·5			
Total	100·0	100·0	...	5319	100·0

One cubic metre of such gas weighs 568 grams. "*Rich gas*," viz., such made by the destructive distillation of certain bituminous schists, of oil, &c., contains much more of the heavy hydrocarbons, and its heat-value is therefore much higher than the above. The carburetted water gas, very generally made in America, and sometimes employed in England for mixing with coal gas, is of varying composition; its heat-value is generally rather less than that of coal gas (see below).

B. *Coke-oven Gas.*—In the United Kingdom the great bulk of metallurgical coke is still made by the old "beehive" ovens, in which all the volatile products of the destructive distillation of coal are completely wasted. Only about 5 per cent. of British coke is made in ovens fitted with apparatus for the recovery of the by-products; in Germany these are employed for nearly half of the coke made, and they are also coming into extensive use in America. The gas drawn away from these ovens, and remaining after the condensation of the tar and ammonia, is everywhere applied to the heating of the coke-ovens themselves, thus effecting a considerable increase in the yield of coke. But in all the better systems there is a considerable surplus of gas applicable to extraneous purposes. Its composition resembles that of ordinary coal gas, but as it contains less heavy hydrocarbons (especially when intentionally deprived of its benzene vapour), its heat-value is much less. Still, being a waste product and costing practically nothing, it is worthy of much more attention than it has hitherto received, especially in Great Britain.

C. *Producer Gas, Siemens Gas* (see *Ency. Brit.*, 9th ed., xxii. 182).—As we have seen above, this gas is made by the incomplete combustion of fuel. The materials generally employed for its production are anthracite, coke, or other fuels which are not liable to cake during the operation, and thus stop the draught or otherwise disturb the proccss, but by special measures also bituminous coal, lignite, peat, and other fuel may be utilized for gas producers. The fuel is arranged in a deep layer, generally from four feet up to ten feet, and the air is introduced from below, either by natural draught or by means of a blast, and either by a grate or only by a slit in the wall of the "gas producer." Even if the primary action taking place at the entrance of the air consisted in the complete combustion of the carbon to dioxide, CO_2, the latter, in rising through the high column of incandescent fuel, must be reduced to monoxide: $CO_2 + C = 2CO$. But as the temperature in the producer rises pretty high, and as in ordinary circumstances the action of oxygen on carbon above 1000° C. consists almost entirely in the direct formation of CO, we may regard this compound as primarily formed. It is true that ordinary producer gas always contains more or less CO_2, but this is evidently formed higher up by air entering through leakages in the apparatus. If we ignore the hydrogen contained in the fuel, the theoretical composition of producer gas would be 33·3 per cent. CO and 66·7 per cent. N, both by volume and weight. Its weight per cubic metre is 1·251 grams, and its heat-value 1013 calories per cubic metre, or less than one-fifth of the heat-value of coal gas. Practically, however, producer gas contains a small percentage of gases, increasing its heat-value, like hydrogen, methane, &c., but on the other hand it is never free from carbon dioxide to the extent of from 2 to 8 per cent. Its heat-value may therefore range between 800 and 1100 calories per cubic metre. Even when taking as the basis of our calculation a theoretical gas of 33·3 per cent. CO, we find that there is a great loss of heat-value in the manufacture of this gas. Thermo-chemistry teaches us that the reaction $C + O$ develops 29·5 per cent. of the heat produced by the complete oxidation of C to CO_2, thus leaving only 70·5 per cent. for the stage $CO + O = CO_2$. If, therefore, the gas given off in the producer is allowed to cool down to ordinary temperature, nearly 30 per cent. of the heat-value of the coal is lost by radiation. If, however, the gas producer is built in close proximity to the place where the combustion takes place, so that the gas does not lose very much of its heat, the loss is correspondingly less. Even then there is no reason why this mode of burning the fuel, *i.e.*, first with "primary air" in the producer ($C + O = CO$), then with "secondary air" in the furnace ($CO + O = CO_2$), should be preferred to the direct complete burning of the fuel on a grate, unless the above-mentioned advantage is secured, viz., reduction of the smoke gases to a minimum by confining the supply of air as nearly as possible to that required for the formation of CO_2, which is only possible by producing an intimate mixture of the producer gas with the secondary air. The advantage in question is not very great where the heat of the smoke gases can be very fully utilized, *e.g.*, in well-constructed steam boilers, salt-pans, and the like, and as a matter of fact gas producers have not found much use in such cases. But a very great advantage is attained in high-temperature operations, where the smoke gases escape very hot, and where it is on that account all-important to confine their quantity to a minimum.

It is precisely in these cases that another requirement frequently comes in, viz., the production at a given point of a higher temperature than is easily attained by ordinary fires. Gas-firing lends itself very well to this end, as it is easily combined with a preliminary heating up of the air, and even of the gas itself, by means of "recuperators." The original and best-known form of these, due to Siemens Brothers, consists of two brick chambers filled with loosely-stacked fire-bricks in such manner that any gases passed through the chambers must seek their way through the interstices left between the bricks, by which means a thorough interchange of temperature takes place. The smoke gases, instead of escaping directly into the atmosphere, are made to pass through one of these chambers, giving up part of their heat to the brickwork. After a certain time the draught is changed by means of valves, the smoke gases are passed through another chamber, and the cold air intended to feed the combustion is made to pass through the first chamber, where it takes up heat from the white-hot bricks, and is thus heated up to a bright red heat until the chamber is cooled down too far, when the draughts are again reversed. Sometimes the producer gas itself is heated up in this manner (especially when it has been cooled down by travelling a long distance); in that case four recuperator chambers must be provided instead of two. Another class of recuperators is not founded on the alternating system, but acts continuously; the smoke gases travel always in the same direction in flues contiguous to other flues or pipes in which the air flows in the opposite direction, an interchange of heat taking place through the walls of the flues or pipes. Here the surface of contact must be made very large if a good effect is to be produced. In both cases not merely is a saving effected of all the calories which are abstracted by the cold air from the recuperator, but as less fuel has to be burned to get a given effect, the quantity of smoke gas is reduced and thus a second advantage is secured.

Gas-firing in the manner just described can be brought about by very simple means, viz., by lowering the fire-grate of an ordinary fire-place to at least 4 ft. below the fire-bridge, and by introducing the air partly below the grate and partly behind the fire-place, at or near the point where the greatest heat is required. Usually, however, more elaborate apparatus is employed. Very many "gas producers" or "generators" have been constructed, commencing with Faber du Faur in Wasseralfingen (Würtemberg) in 1836, and Bischof of Mägdesprung in the Harz in 1839. But the greatest impetus to this mode of firing was given by Siemens Brothers, commencing in 1856, not only by the construction of their gas producers and heat recuperators, but also by the publicity they gave to the advantages of the system. They were followed by many other inventors, and gas-firing has now become universal in some of the most important industries, and nearly so in others. The present extension of steel-making and other branches of metallurgy is intimately connected with this system, as is the modern method of glass-making, of heating coal gas retorts, and so forth.

The composition of producer gas differs considerably, principally according to the material from which it is made. Analyses of ordinary producer gas (not such as falls under the heading of "semi-water gas," comp. sub F.) by volume show 22 to 33 per cent. CO, 1 to 7 per cent. CO_2, 0·5 to 2 per cent. H_2, 0·5 to 3 per cent. hydrocarbons, and 64 to 68 per cent. N_2.

D. *Blast-Furnace Gases.*—The gases issuing from the mouths of blast-furnaces in composition closely resemble those which are generated in gas producers, but they contain less CO and more CO_2. They represent an enormous aggregate heat-value, for it may be taken that the volume of gas given off per ton of iron made is about 4500 cubic metres (158,000 cubic ft.), and that each cubic metre is capable of yielding from 800 to 1000 calories. Although some of this heat has been utilized for a long time past (first by Faber du Faur in 1837), and since 1865 or 1870 all blast-furnaces have been provided with gas-collecting apparatus, the gas is mostly only applied to the heating of the blast, to the roasting of ore, and to the raising of steam for the blowing-engine, &c., a large proportion still being allowed to go to waste. Quite recently attempts have been made to utilize this gas in gas engines for the direct production of motive power, which, after providing for all the wants of the blast-furnace itself, is stated to leave an excess of 10 h.p. per ton of pig-iron made in twenty-four hours.

E. *Water Gas.*—The reaction of steam on highly heated carbonaceous matter was first observed by Fontana in 1780. This was four years before Cavendish isolated hydrogen from water, and thirteen years before Murdoch made illuminating gas by the distillation of coal, so that it was no wonder that Fontana's laboratory work was soon forgotten. Nor had the use of carburetted water gas, as introduced by Donovan in 1830 for illuminating purposes, more than a very short life. More important is the fact that during nine years the illumination of the town of Narbonne was carried on by incandescent platinum wire, heated by water gas, where also internally heated generators were for the first time regularly employed. The Narbonne process was abandoned in 1865, and for some time no real progress was made in this field in Europe. In America, however, Lowe, Strong, Tessié du Motay, and others, took up the matter, the first permanent success being obtained in 1873 by the introduction of Lowe's system at Phœnixville. In the United States the abundance of anthracite, as well as of petroleum naphtha, adapted for carburetting the gas, secures a great commercial advantage to this kind of illuminant over coal gas, so that now three-fourths of all American gas-works employ carburetted water gas. In Europe the progress of this industry was naturally much less rapid, but here also since 1882, when the apparatus of Lowe and Dwight was introduced in the town of Essen, great improvements have been worked out, principally by E. Blass, and by these improvements water gas obtained a firm footing also for certain heating purposes. The American process for making carburetted water gas, as an auxiliary to ordinary coal gas, was first introduced by the London Gas-Light and Coke Company on a large scale in 1890.

Water gas in its original state is called "blue gas," because it burns with a blue, non-luminous flame, which produces a very high temperature. According to the equation $C + H_2O = CO + H_2$, this gas consists theoretically of equal volumes of carbon monoxide and hydrogen. We shall presently see why it is impossible to avoid the presence of a little carbon dioxide and other gases, but we shall for the moment treat of water gas as if it were composed according to the above equation. The reaction $C + H_2O = CO + H_2$ is endothermic, that is, its thermal value is negative. One gram-molecule of carbon produces 97 great calories (1 great calorie or kilogram-calorie = 1000 gram-calories) when burning to CO_2, and this is of course the maximum effect obtainable from this source. If the same gram-molecule of carbon is used for making water gas, that is, $CO + H_2$, the heat produced by the combustion of the product is $68{\cdot}4 + 57{\cdot}6 = 126$ great calories, an apparent surplus of 29 calories, which cannot be got out of nothing. This is made evident by another consideration. In the above reaction C is not burned to CO_2, but to CO, a reaction which produces 28·6 calories per gram-molecule. But as the oxygen is furnished from water, which must first be decomposed by the expenditure of energy, we must introduce this amount = 68·5 calories in the case of liquid water, or 57·6 calories in the case of steam, as a negative quantity, and the difference, viz. $+28{\cdot}6 - 57{\cdot}6 = 29$ great calories, represents the amount of heat to be expended from another source in order to bring about the reaction of one gram-molecule of carbon on one gram-molecule of H_2O in the shape of steam. This explains why steam directed upon incandescent coal will produce water gas only for a very short time: even a large mass of coal will quickly be cooled down so much that at first a gas of different composition is formed and soon the process will cease altogether. We can avoid this by carrying it on in a retort heated from without by an ordinary coal fire, and all the early water gas apparatus were constructed in this way; but such a method is very uneconomical, and was long ago replaced by a process first patented by J. and T. N. Kirkham in 1854, and very much improved by successive inventors. This process consists in conducting the operation in an upright brick shaft, charged with anthracite, coke, or other suitable fuel. This shaft resembles an ordinary gas producer, but it differs in being worked, not in a continuous manner, which, as shown above, would be impossible, but by alternately blowing air and steam through the coal for periods of a few minutes each. During the first phase, when carbon is burned by atmospheric oxygen, and thereby heat is produced, this heat, or rather that part of it which is not carried away by radiation and by the products of combustion on leaving the apparatus, is employed in raising the temperature of the remaining mass of fuel, and is thus available for the second phase, in which the reaction (*b*) $C + H_2O = CO + H_2$ goes on with the abstraction of a corresponding amount of heat from the incandescent fuel, so that the latter rapidly cools down, and the process must be reversed by blowing in air, and so forth. The formation of exactly equal volumes of carbon monoxide and hydrogen goes on only at temperatures over 1200° C., that is, for a very few minutes. Even at 1100° C. a little CO_2 can be proved to exist in the gas, and at 900° its proportion becomes too high to allow the process to go on. About 650° C. the CO has fallen to a minimum, and the reaction is now essentially (*c*) $C + 2H_2O = CO_2 + 2H_2$; soon after the temperature of the mass will have fallen to such a low point that the steam passes through it without any perceptible action. The gas produced by reaction (*c*) contains only two-thirds of combustible matter, and is on that account less valuable than proper water gas formed by reaction (*b*); moreover, it requires the generation of twice the amount of steam, and its presence is all the less desirable since it must soon lead to a total cessation of the process. In ordinary circumstances it is evident that the more steam is blown in during a unit of time, the sooner reaction (*c*) will set in; on the other hand, the more heat has been accumulated in the producer the longer can the blowing-in of steam be continued.

The process of making water gas consequently comprises two alternating operations, viz., first, "blowing-up" by means of a current of air, by which the heat of the mass of fuel is raised to about 1200° C.; and, secondly, "steaming," by injecting a current of (preferably superheated) steam until the temperature of the fuel had fallen to about 900° C., and too much carbon dioxide appears in the product. During the steaming the gas is carried off by a special conduit into a scrubber, where the dust mechanically carried away in the current is washed out, and the gas is at the same time cooled down nearly to the ordinary temperature. It is generally stored in a gas-holder, from which it is conducted away as required. It is never quite free from nitrogen, as the producer at the beginning of steaming contains much of this gas, together with CO or CO_2. The proportion of hydrogen may exceed 50 per cent., in consequence of reaction (*c*) setting in at the close of the steaming. Ordinary "blue" water gas, if, as usual, made from coke or anthracite, contains 48–52 per cent. H_2, 40–41 per cent. CO, 1–5 per cent. CO_2, 4–5 per cent. N_2, and traces of hydrocarbons, especially methane. If made from bituminous coal it contains more of the latter. If "carburetted" (a process which increases its volume 50 per cent. and more) by the vapours from superheated petroleum naphtha, the proportion of CO ranges about 25 per cent., with about as much methane, and from 10 to 15 per cent. of "illuminants" (heavy hydrocarbons). The latter, of course, greatly enhance the fuel-value of the gas. Pure water gas would possess the following fuel-value per cubic metre:—

$$\begin{array}{ll} 0{\cdot}5 \text{ cub. met. } H_2 = 1291 & \text{calories} \\ 0{\cdot}5 \quad ,, \quad ,, \quad CO = 1522 & ,, \\ \hline \qquad\qquad\quad 2813 & ,, \end{array}$$

Ordinary "blue" water gas has a fuel-value of at least 2500 calories. Carburetted water gas, which varies very much in its percentage of hydrocarbons, sometimes reaches nearly the heat-value of coal gas, but such gas is only in exceptional cases used for heating purposes.

We must now turn to the "blowing-up" stage of the process. Until recently it was assumed that during this stage the combustion of carbon cannot be carried on beyond the formation of carbon monoxide, for as the gas producer must necessarily contain a deep layer of fuel (generally about 6 to 10 feet), any CO_2 formed at first would be reduced to CO; and it was further assumed that hardly any CO_2 would be formed from the outset, as the temperature of the apparatus is too high for this reaction to take place. But as the combustion of C to CO produces only 29·5 per cent. of the heat produced when C is burned into CO, the quantity of fuel consumed for "blowing-up" is very large, and in fact considerably exceeds that consumed in "steaming." There is, of course, a further loss by radiation and minor sources, and the result is that 1 kilogram of carbon yields only about 1·2 cub. met. of water gas. Each period of blowing-up generally occupies from 8 to 12 minutes, that of steaming only 4 or 5 minutes. This low yield of water gas until quite recently appeared to be unavoidable, and the only question seemed to be whether and to what extent the gas formed during blowing-up, which is in fact identical with ordinary producer gas (Siemens gas), could be utilized. In America, where the water gas is mostly employed for illuminating purposes, at least part of the blowing-up gas is utilized for heating the apparatus in which the naphtha is volatilized and the vapours are "fixed" by superheating. This process, however, never utilizes anything like the whole of the blowing-up gas, nor can this be effected by raising and superheating the steam necessary for the second operation; indeed, the employment of this gas for raising steam is not very easy, owing to the irregularities of and constant interruptions in the supply. In some systems the gas made during the blowing-up stage is passed through chambers, loosely filled with bricks, like Siemens recuperators, where it is burned by "secondary" air: the heat thus imparted to the brickwork is utilized by passing through the recuperator, and thus superheating the steam required for the next steaming operation. In many cases, principally where no carburetting is practised, the blowing-up gas is simply burned at the mouth of the producer, and is thus altogether lost; and in no case can it be utilized without great waste. This state of matters was entirely changed by the invention of Dellwik, improved by Fleischer, who found that the view that it is unavoidable to burn the carbon to monoxide during the blowing-up holds good only for the pressure of blast formerly applied. This did not much exceed that which is required for overcoming the frictional resistance within the producer. If, however, the pressure is considerably increased, and the height of the column of fuel reduced, both of these conditions being strictly regulated in accordance with the result desired, it is easy to attain a combustion of the carbon to dioxide, with only traces of monoxide, in spite of the high temperature. Evidently the excess of oxygen coming into contact with each particle of carbon in a given unit of time produces other conditions of chemical equilibrium than those existing at lower pressures. At any rate, experience has shown that by this process, in which the full heat-value of carbon is utilized during the blowing-up stage, the time of heating-up can be reduced from 10 to 1½ or 2 minutes, and the steaming can be prolonged from 4 or 5 to 8 or 10 minutes, with the result that twice the quantity of water gas formerly obtained, viz. 2·5 cub. met., is made from 1 kilogram of carbon.

The application of water gas as a fuel mainly depends upon the high temperatures which it is possible to attain by its aid, and these are principally due to the circumstance that it forms a much smaller flame than coal gas, not to speak of Siemens gas, which contains at most 33 per cent. of combustible matter against 90 per cent. or more in water gas. The latter circumstance also allows the gas to be conducted and distributed in pipes of moderate dimensions. Its application, apart from its use as an illuminant (with which we are not concerned here), was formerly retarded by its high cost in comparison with Siemens gas and other sources of heat, but as this state of affairs has been changed by the invention of the Dellwik-Fleischer process, its use is rapidly extending, especially for metallurgical purposes.

F. *Mixed Gas* (*Semi-Water Gas*).—This class is sometimes called Dowson gas, irrespective of its method of production, although it was made and extensively used a long time before Mr Dowson constructed his apparatus for generating such a gas principally for driving gas engines. By a combination of the processes for generating Siemens gas and water gas, it is produced by injecting into a gas producer at the same time a certain quantity of air and a corresponding quantity of steam, the latter never exceeding the amount which can be decomposed by the heat-absorbing reaction, $C + H_2O = CO + H_2$, at the expense of the heat generated by the action of the air in the reaction $C + O = CO$. Such gas used to be frequently obtained in an accidental way by introducing liquid water or steam into an ordinary gas producer for the purpose of facilitating its working by avoiding an excessive temperature, such as might cause the rapid destruction of the brickwork and the fusion of the ashes of the fuel into troublesome cakes. It was soon found that by proceeding in this way a certain advantage could be gained in regard to the consumption of fuel, as the heat abstracted by the steam from the brickwork and the fuel itself was usefully employed for decomposing water, its energy thus reappearing in the shape of a combustible gas. It is hardly necessary to mention explicitly that the total heat obtained by any such process from a given quantity of carbon (or hydrogen) can in no case exceed that which is generated by direct combustion; some inventors, however, whether inadvertently or intentionally, have actually represented this to be possible, in manifest violation of the law of the conservation of energy.

Some of the best-known apparatus belonging to this class are the Munich or Schilling-Bunte generator, the Wilson producer, and the Loomis producer. The Dowson producer has been already mentioned. The gas they yield differs very much in composition, but is always much richer in hydrogen (of which it contains sometimes as much as 20 per cent.) and poorer in carbon monoxide (sometimes down to 20 per cent.) than Siemens gas; generally it contains more of CO_2 than the latter. The proportion of nitrogen is always less, about 50 per cent. It is therefore a more concentrated fuel than Siemens gas, and better adapted to the driving of gas engines. It costs hardly more to make than ordinary Siemens gas, except where the steam is generated and superheated in special apparatus, as is done in the Dowson producer, which, on the other hand, yields a correspondingly better gas. As is natural, its properties are some way between those of Siemens gas and of water gas; but they approach more nearly the former, both as to cost and as to fuel-value, and also as to the temperatures reached in combustion. This is easily understood if we consider that gas of just the same description can be obtained by mixing one volume of real water gas with the four volumes of Siemens gas made during the blowing-up stage—an operation which is certainly too expensive for practical use.

A modification of this gas is the *Mond gas*, which is made, according to Mond's patent, by means of such an excess of steam that most of the nitrogen of the coke is converted into ammonia (Grouven's reaction). Of course much of this steam passes on undecomposed, and the quantity of the gas is greatly increased by the reaction $C + 2H_2O = CO_2 + 2H_2$; hence the fuel-value of this gas is less than that of gas made in other ways. Against this loss must be set the gain of ammonia which is recovered by means of an arrangement of coolers and scrubbers, and, except at very low prices of ammonia, the profit thus made is probably more than sufficient to cover the extra cost. But as the process requires very large and expensive plant, and its profits would vanish in the case of the value of ammonia becoming much lower (a result which would very probably follow if it were somewhat generally introduced), it is no matter of surprise that it has hitherto found only a very limited application.

G. *Air Gas.*—By forcing air over or through volatile inflammable liquids a gaseous mixture can be obtained which burns with a bright flame and which can be used for illumination. Its employment for heating purposes is quite exceptional, *e.g.*, in chemical laboratories, and we abstain, therefore, from describing any of the numerous appliances, some of them bearing very fanciful names, which have been devised for its manufacture. (G. L.)

Gas Plants for Power Purposes.—The term *Producer Gas*, *Generator Gas*, or *Poor Gas* (*gaz pauvre*), as the French prefer to call it, is applied to non-luminous heating gas made by passing air, or air and steam together, through incandescent carbonaceous fuel. As is well known, the ordinary town gas used for lighting purposes (see p. 590 *ante*, and 9th edition, vol. x. p. 87) is produced by the destructive distillation of bituminous coal in retorts highly heated by external fires. The apparatus in which producer gas is made has no external fire, and the small amount of distillation which occurs is of secondary importance. The producer usually consists of a vertical cylindrical or rectangular iron casing, lined with fire-bricks; on the top there is a feeding hopper and valve, and near the bottom is a grate or hearth on which a fire is built up. In some producers air is drawn into the producer by suction, in some it is forced in by a blower, and in others a jet of steam is used to inject the air. In the latter case the air is mixed with steam when it enters the fire. (See GASEOUS FUEL.)

When air alone is used, the oxygen combines with the carbon of the fuel, and either or both of the following reactions occur, according to the temperature and other conditions in the producer. At first carbon dioxide (CO_2) may be formed, and in that case the greater part of this is afterwards reduced to the monoxide (CO), as it ascends the column of heated fuel. The well-known reactions which occur are thus expressed: $C + O_2 = CO_2$, and $CO_2 + C = 2CO$. If the temperature developed is about 1000° C. or higher, carbon monoxide is probably formed without the intermediate formation of carbon dioxide, but in practice there is always more or less of the dioxide mixed with the monoxide. When bituminous coal is used in the producer some of the hydrocarbons are oxidized, others are decomposed and converted into olefiant gas (C_2H_4) and marsh gas (CH_4), while others leave the producer in the form of condensable vapours which mix with the currents of hot gas. When steam is mixed with the air it is decomposed on coming in contact with the heated fuel, and the resultant gases are hydrogen, carbon monoxide, and carbon dioxide. The reactions are $H_2O + C = H_2 + CO$ and $2H_2O + C = 2H_2 + CO_2$.

The earlier examples of gas-producers were used for furnace work; and, owing to Sir William Siemens's skilful application of producer gas to the regenerative furnaces which he devised (see GASEOUS FUEL and *Ency. Brit.*, 9th ed., vol. xxii. p. 37), his system and various modifications of it are much used in all manufacturing countries for metallurgical and other work. Fig. 1 represents an

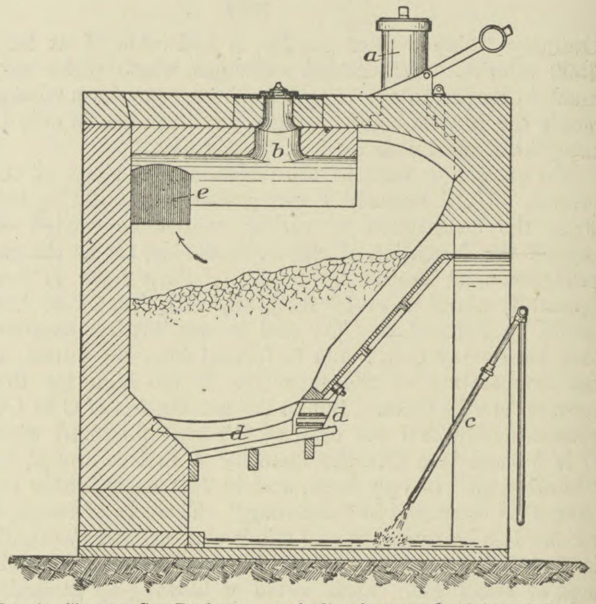


FIG. 1.—Siemens Gas Producer. *a*, feeding hopper; *b*, stoking holes; *c*, water supply (in some producers steam is introduced instead of water); *d*, *d*, horizontal and inclined fire-bars; *e*, gas outlet.

ordinary type of Siemens producer. In producers used for furnace work the hot crude gas is taken directly from the producer to the furnace, and the gas is usually made with bituminous or semi-bituminous coal; the tarry vapours distilled off in the producer mix with the gas and enrich it, and all are burnt in the furnace.

The chemical composition of ordinary producer gas, as used in furnaces, depends somewhat on the nature of the coal used, but it usually contains about 24 to 27 per cent. of carbon monoxide, and only 5 to 10 per cent. of hydrogen. It is not suitable for driving gas engines, as it is too weak and does not ignite promptly enough in the cylinder. For engine work the gas should contain not less than 15 per cent. of hydrogen, and its calorific power should not be less than 1200 calories per cubic metre, or 140 British thermal units per cubic foot, at 0° C. and 760 mm.; moreover, it must not carry tar or other impurities, and it must be cool and fairly constant in quality and pressure. It was therefore necessary not only to improve the quality of the gas, but to devise complete apparatus for cooling and cleaning it, and for fulfilling the other conditions required. The first to do this was J. E. Dowson. The Dowson plant was tried for the first time with a small Otto engine in 1879 by Messrs Crossley of Manchester, and in 1881 the same engine and gas plant were tested by Mr D. K. Clark, on behalf of the committee of the Smoke Abatement Exhibition, South Kensington, who awarded the inventor a special prize given by Sir William Siemens. As a measure of what this has led to, it may be mentioned that up to the end of 1899 gas engines developing an aggregate of about 60,000 h.p. were working with gas made in the Dowson plant. From time to time various other gas plants for engine work have been introduced, and broadly they may be divided into three types, as follows:—

A. Producer with jet of superheated steam forcing in air, *e.g.*, the *Dowson* plant.

B. Producer without steam-jet, and with blower to force in air, *e.g.*, the *Lencauchez* and the *Mond* plants.

C. Producer without steam-jet and without blower, the air being drawn into the producer by a suction-pump attached to the gas engine, *e.g.*, the *Bénier* plant.

The first type, A, is represented in Fig. 2.

The boiler is provided with superheating tubes, and a jet of dry steam is used for the double purpose of supplying the steam to be decomposed, and of carrying an induced current of air into the gas generator to maintain combustion of the fuel and develop the high temperature required for the necessary chemical reactions to take place. In practice about 90 per cent. of the steam produced in the boiler is decomposed in the gas generator, the remainder being lost; and it may here be noted that the percentage of hydrogen in the gas is not an exact measure of the quantity of steam decomposed, as some of the hydrogen is derived from the coal in the generator. In practical work, when anthracite is used in the generator, about ⅘ lb of steam is decomposed for each pound of anthracite consumed, and this can be done without having more than about 5 per cent. of carbon dioxide in the resultant gas. The following table gives the results of tests made by different authorities with the Dowson gas plant, when working with anthracite in the generator:—

Table showing Results of Tests with Dowson Gas Plant.

No. of Trial.	Date of Trial.	Locality.	B.H.P. of Plant.	Volume of Gas produced, at 0° C. and 760 mm. per kilo. of Anthracite consumed in Generator + Coke consumed in Boiler. * By calorimetric bombs.

From this summary it will be seen that the average calorific power of the gas tested is 1432 calories per cubic metre, or 161 B.T.U. per cubic foot, at 0° C. and 760 mm.; while the average heat-efficiency of the plant is 78·9 per cent., one plant giving as much as 81·1 and another 82·3 per cent. If an efficiency of 80 per cent. is assumed, the loss of heat may be accounted for approximately as follows:—

Loss in steam boiler	7 per cent.
Steam not decomposed in generator .	1 ,, ,,
Unburnt anthracite lost in ashes . .	2 ,, ,,
Sensible heat of gas lost in cooling and scrubbing and in radiation from the generator	10 ,, ,,
	20 per cent.

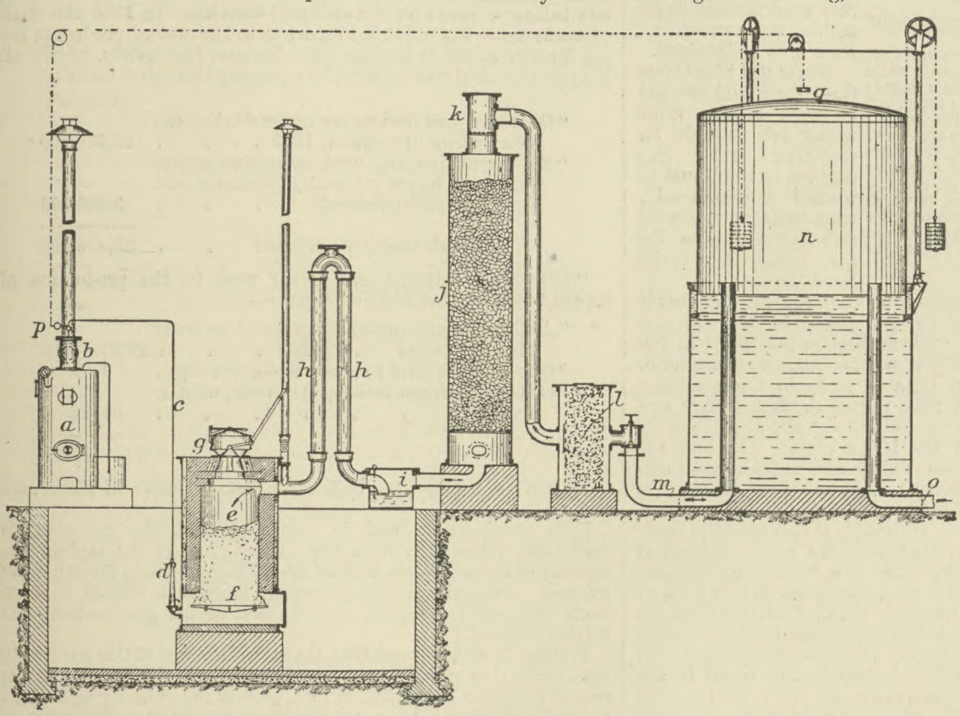

FIG. 2.—Dowson Gas Plant. *a*, boiler; *b*, steam superheater; *c*, steam pipe; *d*, air injector; *e*, gas generator; *f*, fire-bars; *g*, feeding hopper; *h*, *h*, cooling pipes; *i*, hydraulic box with water seal; *j*, coke scrubber; *k*, washer; *l*, sawdust scrubber; *m*, inlet of gasholder; *n*, gasholder; *o*, outlet of gasholder; *p*, valve with weighted lever to regulate admission of steam to gas generator; *q*, weight to actuate lever *p* by rise or fall of gasholder.

In the Lencauchez plant, which is an example of the second type, B, there is no boiler, the gas being made by forcing air from a blower into the gas generator, and there saturating it with moisture before it enters the fire. When good gas has been made and the engine is running, the blower is driven by the engine, but when the latter is not working it is driven by hand power. Some of these plants are working in France, and though a few have been tested for the fuel consumption per h.p., none appear to have been tested thoroughly as to their heat-efficiency, &c. Professor Witz of Lille refers to this plant in his *Moteurs à Gaz*, but seems doubtful about the heat value of the gas. Dr Ludwig Mond's plant (see also GASEOUS FUEL) was devised primarily for the recovery of ammonium sulphate, and the gas produced was of secondary importance. At first all the gas was used for heating furnaces, but afterwards trials with a gas engine showed that it was suitable for such work, and several engines are now working with it at the chemical works of Messrs Brunner, Mond, and Company. To be profitable, a recovery plant of this kind must be worked on a large scale, night and day; in the existing plant each producer makes gas enough for about 2000 h.p. an hour, and the bulk of the gas is still used for furnace work. The plant is worked with bituminous coal, the tar being removed by an elaborate system of washing and scrubbing. The calorific power of the gas, calculated from its published analysis, is 1385 calories per cubic metre, or 155·6 B.T.U. per cubic foot, at 0° C. and 760 mm. The percentage of hydrogen (24·8) is high, but against this the carbon monoxide is only 13·2, while the carbon dioxide is as high as 12·9. It has been proposed to work a plant of this type without the recovery of ammonium sulphate, and if this were done the working would be nearly on the same lines as those of the Lencauchez plant.

In the third type of plant, C, *e.g.*, Bénier's (Fig. 3), there is no steam boiler or air-blower, the air being drawn into the producer by a suction-pump attached to the engine. The quantity of air drawn in varies with the load on the engine; and, as it is governed by the engine itself, the storage of gas in a holder is dispensed with altogether. The whole plant consists merely of a producer, a washer, and a scrubber. Water is vaporized in the fire-grate, which is of special construction, and the water vapour mixes with the air before the latter enters the fuel column. The idea is ingenious, but the results obtained have not been encouraging. Professor Witz of Lille tested it carefully with an engine of about 15 b.h.p. The first trial was with English anthracite of good quality, and the calorific power of the gas was only 1149 calories per cubic metre, or 129 B.T.U. per cubic foot, at 0° C. and 760 mm. The engine developed 27·6 i.h.p., but only 14·59 b.h.p.; while the consumption of anthracite was 714 grams, or 1·57 ℔ per b.h.p. per hour. A second trial was made with ordinary gas coke in the generator, and the calorific power of the gas was then as low as 1035 calories per cubic metre, or 116 B.T.U. per cubic foot, at 0° C. and 760 mm. The engine developed 14·7 b.h.p., and the consumption of coke was 752 grams, or 1·66 ℔ per b.h.p. per hour. These results were with a full load on the engine, and it is probable that the gas would have been still weaker if the load had been much reduced, as the temperature of the fuel most favourable for making the gas would not have been maintained.

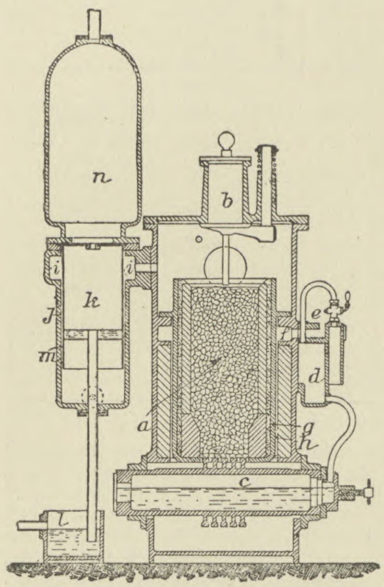

FIG. 3.—Bénier Gas Plant. *a*, gas generator; *b*, feeding hopper; *c*, revolving grate with water inside; *d*, chamber to receive steam from *c*; *e*, air inlet; *f*, mixing chamber for steam and air at atmospheric pressure; *g*, inner casing of generator; *h*, annular space for steam and air to pass from *f* to bottom of fire, the steam and air being heated on the way; *i*, *i*, annular space for hot gas from generator; *j*, cylinder with water inside; *k*, inner tube, of which lower end is dipped in water, with overflow leading to tank *l*; *m*, annular space for gas to pass from *i* to interior of *k*; *n*, chamber for gas.

Water gas plants (see GASEOUS FUEL) are not included among those which are suitable for working with gas engines, as they must be worked intermittently, with frequent reversals, and the quality of the gas necessarily varies considerably.

Fuel.

Owing to the difficulty of removing tar from generator gas made with bituminous coal, most of the gas plants in use with gas engines are worked with anthracite (*Ency. Brit.*, 9th ed., ii. 106). Formerly it was necessary to use nuts or cobbles, but with a suitable grate in the generator the size known as peas (which have passed through $\frac{3}{4}$ inch and over $\frac{3}{8}$ or $\frac{3}{16}$ inch openings in the screens at the pit) is extensively employed, being cheaper than the larger sizes. The best anthracite is found in the Swansea Valley and neighbouring districts; and, owing to the development of the gas-power industry, a new trade has sprung up for suitable anthracite, and a considerable quantity is exported. Some anthracite is also found in Scotland, but, with the exception of that from the neighbourhood of Coltness, it is not good; even the latter is a little more troublesome to work with than the Welsh for gas engines, as it is more or less mixed with bituminous compounds. On the Continent anthracite is found in Belgium, at Kohlscheid near Aachen (Aix-la-Chapelle) in Germany, and in Russia and Spain; a *charbon maigre* (lean coal) which is anthracitic, but of inferior quality, is also found in the department of the Nord and elsewhere in France. There are immense beds of excellent anthracite in Pennsylvania; there is some in Japan, and it is reported that there are large fields of it undeveloped in China. Ordinary gas coke can also be used for generator gas instead of anthracite, provided it is of good quality, clean, and in small pieces; and there are some installations of gas power (*e.g.*, at the Elswick Works of Messrs Armstrong, Whitworth, and Company) where no other fuel has been adopted, and where the results have been satisfactory. Coke that yields an excessive amount of clinker, as well as much tar and sulphur, should be avoided. With bituminous coal the difficulties are increased when the plant is worked on a comparatively small scale, *e.g.*, 200 b.h.p.; but promising trials with bituminous coal have recently been made in a modified plant of the type A, and it is expected that plants of moderate size will soon be working with tar-yielding coal. Dr Mond's large plant is the only one which is worked regularly with bituminous coal and yields a gas suitable for gas engines.

Reference to the table will show that in type A the production of gas at 0° C. and 760 mm. is about 5 cubic metres per kilogram, or 80 cubic feet per ℔, of anthracite consumed in the gas generator. When this gas is used for driving an engine the total fuel consumption (including anthracite in the generator and coal or coke in the little boiler which supplies it with steam) is about 1 ℔ (454 grams) per b.h.p. per hour. The consumption of water varies with the size and type of plant used. For type A it is as under, and in order that a comparison may be made with the water required for a steam boiler of the same h.p., the figures for the latter are added on the basis of 20 ℔ of water per b.h.p.

	Pounds of Water per Hour.	
	Gas Plant.	Steam Boiler.
100 brake h.p. . .	300	2000
200 ,, ,, . .	400	4000
300 ,, ,, . .	500	6000

With ordinary care the cost of repairs is moderate. For type A the following averages (based on several years' experience) may be taken as approximately correct, exclusive of painting:—

For 100 brake h.p.	plant	about	£4	per	annum.
,, 200	,,	,,	,,	6	,,	,,
,, 300	,,	,,	,,	8	,,	,,
,, 400	,,	,,	,,	12	,,	,,
,, 500	,,	,,	,,	14	,,	,,

Cost of gas.

The cost of the gas depends somewhat on the price of fuel and wages, and on the scale of production. In a plant of moderate size of type A working with anthracite peas costing 16s. per ton, the gas usually costs from 2d. to 3d. per 1000 cubic feet filled into the gasholder, including fuel, wages, and repairs. Gas of this kind made with anthracite nuts has been used regularly for several years at the Gloucester County Asylum for driving engines, as well as for all the cooking and baking of bread for the staff and inmates. In 1895 the clerk of works made the following report as to the cost of producing the gas for a year, and it is given here because, fortunately, nearly all the gas produced was measured by passing through a meter:—

	Cubic feet.
"Quantity produced as per meter during the year ending 31st March 1895 . . .	22,211,700
"Estimated quantity used by engine pumping three hours a day at 3000 cubic feet per hour (not registered) . . .	3,285,000
"Total quantity produced . .	25,496,700

"Details of material and labour used in the production of 25,496,700 cubic feet of Dowson gas:—

	£	s.	d.
"Anthracite coal [nuts], 124 tons 19 cwts. at 21s. 2d. per ton	£132	4	10
"One year's repairs to plant at 6d. per day .	9	2	6
"Gasman's wages, making gas only, at 21s. a week	54	12	0
	£195	19	4

"Thus costing $1\frac{7}{8}$d. per 1000 cubic feet, exclusive of slack used for steam boiler."

[The small boiler used in connexion with the gas plant is fired with ashes, &c., from the various fires in the asylum; no account of these is kept, as they are treated as waste for any other purpose. Recently the gas generators have been altered so as to work with anthracite peas, and the cost of the gas has been still further reduced.]

It must be remembered that the calorific power of this gas is only one-fourth that of ordinary town gas; the cost of the generator gas should therefore be multiplied by 4, so that the quantity equivalent to 1000 cubic feet of town gas usually costs from 8 to 12 pence.

The loss of fuel in a gas generator when standing with a fire in it is much smaller than in a steam boiler of the same h.p. A series of tests extending over several days, made at Messrs Crossley's works with a 250-h.p. generator, showed an average loss of only $5\frac{1}{2}$ pounds per standing hour. In smaller plants it is even less.

Heat-efficiency.

The heat-efficiency of the gas plant is a measure of the heat lost in the transformation of the solid fuel into gas suitable for working an engine. To determine this efficiency, account should be taken of all the fuel consumed in connexion with the apparatus used for making the gas, and a balance-sheet should be prepared showing what percentage of the heat energy contained in all the fuel consumed is available in the gas finally passed into the holder. This basis of comparison should be adopted for all types of gas plants, since no other can be correct. If the steam decomposed in the gas generator is produced in an independent boiler, as in type A, the fuel consumption in the latter should be included; or if air is forced into the generator by engine power, as in type B, the expenditure of heat-energy which this involves should be included. The heat-value of the fuel, as well as that of the gas, should be determined, also the volume of gas produced per unit of fuel consumed. For practical purposes it is more simple to determine the heat-value of the gas by a calorimeter (Dowson's or Junker's), or by a calorimetric bomb (Mahler's), than by analysing the gas.

The calorific powers given in Table A and elsewhere are based on the following heat values:—

Hydrogen . . .	3,070	calories per cubic metre.
Marsh gas, CH_4 . .	9,550	,, ,,
Olefiant gas, C_2H_4 .	14,970	,, ,,
Carbon monoxide, CO .	3,070	,, ,,

The calorific power of the fuel, where it was not tested by calorimeter, has been calculated from the formula

$$80{\cdot}8\ C + 345\left(H - \frac{O}{8}\right) + 25\ S,$$

where C, H, O, and S represent the percentages of carbon, hydrogen, oxygen, and sulphur in the fuel. One cubic metre of CO, CO_2, or CH_4 contains 537·6 grams of carbon, and one cubic metre of C_2H_4 contains 1075·2 grams of carbon. All the calculations as to calorific power are also based on the standard temperature and pressure of 0° C and 760 mm., and all the steam derived from the combustion of the fuel or gas is treated as condensed. Some experimenters do not treat the steam as though it were condensed, and deduct its latent heat from the heat-value of the gas. It should, however, be remembered that in considering the production of gas in a gas plant, and in stating a balance-sheet of the heat units, we should on the one side give all those in the solid fuel consumed, and on the other side the total heat units the gas derived from it is capable of yielding when burnt to the best advantage. When the hydrogen in the gas is burnt steam is produced, and the latent heat of this steam is available for heating purposes; the latent heat of the steam should therefore be included in the heat units derivable from combustion of the gas. It happens that in the gas engine of to-day the exhaust products leave at a high temperature, so that the steam formed on combustion of the hydrogen in the cylinder is not condensed; if there were complete expansion the steam would be condensed. The present loss of the latent heat of the steam is due entirely to the engine, and should not be debited to the process of making the gas.

Theoretically, one volume of generator gas requires little more than one volume of air for its combustion, whereas ordinary town gas requires from 5 to 6 volumes of air to one of gas. For this reason it is possible to get into an engine cylinder of given capacity four times more of generator gas than town gas, with the proportion of air required. In practice the same cylinders are used for both kinds of gas; but the maximum h.p. obtainable with generator gas is usually from 10 to 12 per cent. less than with town gas. In engines of the Otto type a space is provided in the cylinder in which the charge of gas and air is compressed, and as this remains full of spent products of combustion after the exhaust is closed, it follows that these products mix with and dilute the next ingoing charge of gas. This is disadvantageous for generator gas, as it is already weakened by the presence of about 50 per cent. of nitrogen and carbon dioxide; and in the early engines, where a compression of only 35 lb per square inch was in vogue, it was difficult to ensure prompt and regular ignition of the charge. When the slide-valve was superseded, it became possible to raise the compression before ignition without trouble from excessive friction, and this is now usual. Fig. 4 represents an indicator diagram taken on a Crossley engine working with Dowson gas, and in this

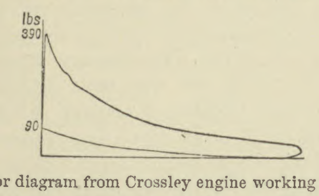

FIG. 4.—Indicator diagram from Crossley engine working with Dowson gas.

Pressures { Compression before ignition 90 lb per sq. inch.
Maximum after explosion . 390 ,, ,,
Mean ,, ,, . 94·6 ,, ,, }

the compression is 90 lb, while the mean pressure is as high as 94·6 lb per square inch. When running at 170 revolutions per minute the engine developed a maximum of 44·1 i.h.p. and 38·6 b.h.p.; at a speed of 220 revolutions per minute it gave a maximum of 57·3 i.h.p. and 48·8 b.h.p. With the earlier low compression the molecules of oxygen, surrounded more or less by inert gas, were too far apart from those of the hydrogen and carbon monoxide, and the high compression now used has remedied this defect to a great extent. A still further improvement is the removal or *scavenging* of all products of combustion from the compression space in the cylinder. Apart from ensuring a more prompt and more regular ignition of the charge, scavenging reduces the risk of the explosive mixture being fired prematurely. With non-scavenging engines of large size there is often a good deal of trouble owing to the liability of the new charge to be fired by some of the hot residual products in the cylinder. By scavenging, these hot products are displaced by air, which also helps to cool the cylinder and piston. Another consideration is that if, from any cause, the explosive charge in a non-scavenging engine is not fired, there is a much stronger charge to fire after the next intake of gas, because some of the products of combustion from the last charge fired are displaced by new gas and air. After a misfire in a non-scavenging engine of large size the explosive force is excessive, and has to be provided for by specially strengthening the engine. With a scavenging engine this trouble is avoided.

A steam engine is associated with a boiler, which should be able at all times to yield the maximum quantity of steam required; and in the same way the gas plant should be able to supply the maximum quantity of gas required by the engine or engines associated with it. If the gas generator or generators have ample producing power, there is no need to store much gas in a holder; the gas should be made as quickly as it can be consumed, just as a steam boiler makes steam as quickly as it is wanted. A gas plant need not occupy more ground space than is required for a horizontal boiler of about the same horse-power, and no chimney-stalk is needed. To avoid an over-production of gas when the load on the engine falls off, the rate at which the gas is made should be governed automatically to suit a varying rate of consumption. In the Dowson plant this is done by using the rise and fall of the gasholder to regulate the quantity of steam and air sent into the generator (Fig. 2); the maximum production of the latter can be reduced easily by 30 or 40 per cent., and in some sizes by 50 per cent., without appreciably affecting the quality of the gas. Two or more gas generators can work together as easily as a bench of retorts in a lighting gas plant. Generator gas does not condense or deteriorate by cooling or storage, or by travelling through long pipes; on the contrary, for the good working of an engine it is desirable that the charge of gas admitted to the cylinder should be cool, so that a given volume may yield as much energy as possible. Generator gas is made rapidly, and in a plant of moderate size it usually leaves the generator at a temperature of about 900° F. (500° C.). Special attention should therefore be given to the cooling of the gas, so that when it leaves the gasholder its temperature should not be higher than that of the surrounding air; it should also be well washed and scrubbed. The gas plant, as a whole, should be compact and easy to work, and its first cost should not be excessive. As a final note, it is interesting to observe that a modern Dowson gas plant is now working regularly at the historical works of Boulton and Watt, at Soho, Birmingham, and that the holder used for this gas is one which was erected there by William Murdoch, the pioneer of gas lighting (see *Ency. Brit.*, 9th ed., vol. x. p. 88).

Gastein, a valley in the Austrian duchy of Salzburg, celebrated for its mineral springs. The visitors number about 8000 annually, of whom three-fourths stay at Wildbad (population, 558). There is now a Protestant church belonging to the German Emperor. The mountain torrent, the Ache, supplies motive-power for the electric lighting of the district, which has made considerable progress in the matter of accommodation for its increasing stream of visitors, including a sheltered glass gallery, or kurhaus, for rainy weather. It was at Gastein (August–September 1879) that Prince Bismarck negotiated the Austro-German Treaty with Count Julius Andrassy. In 1890 the population of the entire valley was 4372, and in 1900, 4436.

Gateshead, a municipal, parliamentary, and county borough of Durham, England. It has greatly extended, but although one of the largest towns in the county, neither its streets nor its public buildings, except perhaps its ecclesiastical buildings, make any claim to architectural beauty. The area of the borough is 3300 acres; population (1881), 65,845; (1891), 85,692; (1901), 109,887. Between 1881 and 1899 the rateable value increased from £220,000 to £359,562. The birth and death rates, 36·2 and 20·4 per 1000 respectively, show no great change over a series of years. The number of voters for the borough member of Parliament is (1900) 17,065. For municipal purposes the town is divided into ten wards, each of which returns three members to the Town Council. The town possesses a children's hospital, a very efficient school of art, and public library, and a workhouse, built at a cost of £40,000, providing accommodation for 1000 inmates. The School Board has seventeen schools under its control. Technical education is provided in the Higher Grade School (1891). A large day school for girls has also been established. Steam trams run through the main streets, and the Corporation have built suitable swimming-baths and wash-houses. More than two thousand hands are employed in the North-Eastern locomotive depôt. Large gas works of the Newcastle and Gateshead Gas Company are also situated in the borough.

Gauhati, a town of British India, in the Kamrup district of Assam, on the left bank of the Brahmaputra, with a population in 1881 of 11,695, and in 1891 of 8283. The municipal income in 1897–98 was Rs.46,800. It is still the headquarters of the district, though no longer a military cantonment, and is the river terminus of a section of the Assam–Bengal railway. There are a government high school, with 195 pupils in 1896–97, a law class, a training school for masters, and four printing-presses. Gauhati suffered very severely from the earthquake of 12th June 1897.

Gaya, a city and district of British India, in the Patna division of Bengal. The city is situated 85 miles south of Patna by rail. Population (1881), 76,415; (1891), 80,383; (1901), 71,186. During the Mutiny the large store of treasure here was conveyed safely to Calcutta by Mr Money. The city contains a government high school, with 351 pupils in 1896–97, a hospital, with a Lady Elgin branch for women, and five printing-presses. The district of Gaya comprises an area of 4712 square miles. It had a population in 1881 of 2,124,682, and in 1891 of 2,138,331, giving an average density of 454 persons per square mile. Classified according to religion, Hindus numbered 1,911,254; Mahommedans, 226,705; Christians, 174, of whom 74 were Europeans; "others," 198. In 1901 the population was 2,064,077, showing a decrease of 3 per cent. The land revenue and rates were Rs.17,73,901; the number of police was 767; the number of boys at school in 1896–97 was 29,015, being 18·5 per cent. of the male population of school-going age; the registered death-rate in 1897 was 37·07 per thousand. Opium is largely cultivated, indigo hardly at all. There are forty-one lac factories, employing 1200 persons, with an annual out-turn valued at Rs.31,45,000. The district is traversed in the south by the Grand Trunk Road, and three branches of the East Indian Railway now run to Gaya city. In 1901 it suffered severely from the plague.

Gayangos y Arce, Pascual de (1809–1897), Spanish scholar and Orientalist, was born at Seville, 21st June 1809. At the age of thirteen he was sent for education to France, where he passed several years, and studied Arabic under Silvestre de Sacy. After a visit to England, where he married, he obtained a post in the Spanish Treasury, and was afterwards translator to the Foreign Office. In 1836 he returned to England, became well known in English society, wrote extensively in English periodicals, and translated Almakkari's *History of the Mahommedan Dynasties in Spain* for the Royal Asiatic Society. In England he also made the acquaintance of the American historian of Spanish literature, Ticknor, to whom he was very serviceable. In 1843 he returned to Spain as professor of Arabic at the university of Madrid, which post he held until 1881, when he was made director of public instruction. This office he resigned upon being elected senator for the district of Huelva. His latter years were almost equally divided between Spain and England, where he made a catalogue of the Spanish manuscripts in the British Museum: he had previously continued the work commenced by Mr Bergenroth in cataloguing the manuscripts relating to England in the archives of Simancas. His best known original work is his dissertation on Spanish romances of chivalry in Aribau's *Biblioteca de Autores Españoles*. He died in London on 4th October 1897.

Gaza, now Ghuzzeh, the most southerly of the five allied Philistine cities, situated, near the sea, at the point where the old trade routes from Egypt and Petra to Syria met. It was always a strong border fortress and a place of commercial importance. The earliest notice of it is in the Tell el-Amarna tablets, in a letter from the local governor, who then held it for Egypt. The history of Gaza is that of its many sieges from the time of Alexander to that of Richard Cœur de Lion. Under the Romans it prospered, but under the Moslems it gradually declined, and before the 14th century it had lost all its importance. Christianity made way slowly, and paganism was dominant until 400, when the temples and statues of Dagon (Marnas) were destroyed by imperial edict. The prosperity of Ghuzzeh has partially revived through the growing trade in barley, of which the average annual export to Great Britain for 1897–99 was over 30,000 tons. The population numbers 25,000, including 1000 Christians. The dress of the people is Egyptian rather than Syrian. The Church Missionary Society maintains a mission, with schools for both sexes, and a hospital.

Geelong, a seaport town, in the county of Grant, Victoria, Australia, on the western arm (Corio Bay) of Port Phillip Bay, 45 miles south-west of Melbourne, with which it is connected by rail. Corio Bay is entered by two channels across the bar, one of which—the New Channel—has a depth of 23½ feet. The harbour has four jetties, affording extensive quayage, and vessels drawing 17 to 19 feet can lie alongside at low water. The first woollen mill in the state was established here, and the cloths, tweeds, and woollen fabries of the town are noted throughout Australia. Extensive vineyards were destroyed under the Phylloxera Aet, but replanting has commenced throughout the district. There are three parks and a botanie garden. There are extensive tanneries and rope works, and at Fyansford, 3 miles distant, is a large paper mill. Five reservoirs for water supply have a capacity of over 500 million gallons. Population of the town of Geelong (1881), 9721; (1901), 12,399; of the borough of Geelong West (1881), 4845; (1901), 5860.

Geestemünde, a seaport town of Prussia, province of Hanover, on the right bank of the Weser, immediately south of Bremerhaven. It is a centre of the German North Sea fishing and the seat of a superior school of navigation. Since 1888 upwards of £800,000 has been spent upon harbour works and improvements. In 1899 the port was entered by 2416 vessels of 347,469 tons. Population (1885), 14,200; (1900), 20,113.

Gefle, a seaport town of Sweden, on a bay of the east coast, 112 miles by rail north-north-west from Stockholm. It is the ehief port of the productive eounty of Dalecarlia (Kopparberg), with its iron and copper mines and big forests, and the third eommereial port of the kingdom. The exports, which totalled £804,000 in 1885 and £1,705,400 in 1900, consist almost entirely of timber (£508,700 in 1887; £1,048,300 in 1900), iron and steel (£222,600 in 1888; £381,850 in 1900), and wood-pulp (£50,000 in 1892; £268,450 in 1900). The imports increased from £366,600 in 1885 to £678,400 in 1900. In 1900 the port was eleared by 918 vessels of 505,000 tons, of which 83 of 77,605 tons were British. The harbour, which has two entrances of about 20 feet depth, is usually elosed for four or five months in the winter. In 1897 the town authorities voted £60,000 for deepening and improving it. Large vessels usually load in the roads at Gråberg, 6 miles distant. In 1898 Gefle possessed a mercantile fleet of 40 to 50 vessels of some 22,000 tons. It is also a place of some industrial activity. At Skutskär (population 2000 in 1897), a new place at the mouth of the river, are a wood-pulp mill and one of the largest sawmills in Sweden. Population (1880), 18,758; (1890), 23,484; (1900), 29,522.

Gegenbaur, Carl (1826- ——), German anatomist, was born on the 21st August 1826 at Würzburg, at the university of which he was student (1845) and afterwards *docent*. In 1852–53 he studied the marine fauna on the Sieilian eoast. In 1855 he was appointed to a medical chair at Jena, where after 1865 his fellow-worker, Ernst Haeckel, was professor of zoology; and in 1858 Gegenbaur became ordinary professor of anatomy. In 1873 he was appointed to Heidelberg, where he became professor of anatomy and director of the Anatomical Institute. In 1875 he became editor of the *Morphologisches Jahrbuch*, but the work by which perhaps he is best known is his *Grundriss der vergleichenden Anatomie* (1874, 2nd edition 1878). This was translated into English by W. F. Jeffery Bell (*Elements of Comparative Anatomy*, 1878), with additions by Professor E. Ray Lankester. While reeognizing the importance of eomparative embryology in the study of descent, Gegenbaur lays stress on the higher value of comparative anatomy as the basis of the study of homologies, *i.e.*, of the relations between corresponding parts in different animals, as, for example, the arm of man, the foreleg of the horse, and the wing of a fowl. A distinetive piece of work was effected by him in 1871 in supplementing the evidenee adduced by Huxley in refutation of the theory of the origin of the skull from expanded vertebræ, whieh, formulated independently by Goethe and Oken, had been championed by Owen. Huxley demonstrated that the skull is built up of eartilaginous pieees; Gegenbaur showed that "in the lowest (gristly) fishes, where hints of the original vertebræ might be most expected, the skull is an unsegmented gristly brain-box, and that in higher forms the vertebral nature of the skull cannot be maintained, since many of the bones, notably those along the top of the skull, arise in the skin." Other publieations by Gegenbaur include a *Text-Book of Human Anatomy* (1883), the *Epiglottis* (1892), and *Comparative Anatomy of the Vertebrates in Relation to the Invertebrates* (vol. i., 1898).

Geibel, Emanuel (1815–1884), German poet, was born at Lübeck, 17th Oetober 1815, and was the son of a pastor in the eity. He was originally intended for his father's profession, but, determining to devote himself to philology and literature, accepted in 1838 a tutorship at Athens, where he remained until 1840. In the same year he brought out, in conjunction with his friend Ernst Curtius, a volume of translations from the Greek. His first poems, the *Zeitstimmen*, appeared in 1841; a tragedy, *King Roderick*, followed in 1849. In the same year he received a pension from the King of Prussia, which he retained until his invitation to Munich by the King of Bavaria in 1851 as honorary professor at the university. In the interim he had produced *König Sigurds Brautfahrt*, an epic, and *Juniuslieder*, lyrics in a more spirited and manlier style than his early poems. A volume published at Munich in 1857, and principally consisting of poems on elassical subjects, denoted a further considerable advance in objectivity, and the series was worthily elosed by the *Herbstlieder*, published in 1877. He had quitted Munich in 1869 and returned to Lübeck, where he died on the 6th of April 1884. His works further include two tragedies, *Brunhild*, 1858, and *Sophonisbe*, 1869, and translations of French and Italian popular poetry. Beginning with writing, as hostile eritics affirmed, "for boarding-school misses," Geibel gradually acquired vigour of thought and style, and, after Rückert and Platen, is perhaps the best representative of the modern German school of the poetry of literary culture. (R. G.)

Geikie, Sir Archibald (1835- ——), Scottish geologist, was born at Edinburgh on 28th December 1835. He was educated at the High School and University of Edinburgh, and in 1855 was appointed an assistant on the Geological Survey. Wielding the pen with no less facility than the hammer, he inaugurated his long list of works with *The Story of a Boulder; or, Gleanings from the Note-Book of a Geologist* (1858). His ability at once attracted the notice of his chief, Sir Roderick Murchison, with whom he formed a lifelong friendship, and whose biographer he subsequently became. The geological map of Scotland published in 1862 was their joint work. In 1865 appeared Geikie's *Scenery of Scotland* (3rd edition 1901), which was, he claimed, "the first attempt to elueidate in some detail the history of the topography of a country." At this time the Edinburgh school of geologists—prominent among them Sir Andrew Ramsay, with his *Physical Geology and Geography of Great Britain*—were maintaining the supreme importance of denudation in the eonfiguration of land-surfaces, and particularly the erosion of valleys by the action of running water. This view, now universally accepted, met with opposition from the old-fashioned school, who held that the main features of the earth's surface were determined by eataclysms of Nature. Geikie's book was an able contribution, based on extensive personal knowledge of the districts described, to the doctrines of the Edinburgh school, of which he himself soon began to rank as one of the leaders. Two years later, when a separate branch of the Geological Survey was established for Scotland, he was appointed director. On the foundation of the Murchison Professorship of Geology and Mineralogy at the University of Edinburgh in 1871, he became the first occupant of the chair. These two appointments he continued to hold till 1881, when he succeeded Sir Andrew Ramsay in the joint offices of Director-General of the Geological Survey of the United Kingdom and Director of the Museum of Practical Geology, London, from which he retired in February 1901. A feature of his tenure of the latter post was the impetus given to microscopic petrography, a branch of geology to which he had devoted special study, by a splendid collection of sections of British rocks. His official work on the Geological Survey culminated in his admirable *Geological Map of England and Wales, with descriptive notes* (1897). His intimate acquaintance with the geology of Scotland brought him face to face with, and helped him to solve, some of the most difficult problems of stratigraphy. Here he was greatly aided by his extensive travels, not only throughout Europe, but in Western America. In that world, new from the standpoint of geology no less than of civilization, the forces of Nature have acted both on a greater scale and with less complication. While the cañons of Colorado confirmed his long-standing views on erosion, the eruptive region of Oregon supplied him with valuable data for that study of volcanic phenomena which has been the chief work of his later years. His researches, first given to the world in his presidential addresses to the Geological Society in 1891 and 1892, were embodied in his great work on *The Ancient Volcanoes of Great Britain* (1897), which sums up the present state of our knowledge on the whole question of volcanic disturbances. He lays down the two important generalizations, that in the same area the sequence of volcanic matter erupted is constant, and that the composition and structure of lavas of all ages remain the same. Other results of his travels are collected in his *Geological Sketches at Home and Abroad* (1882). His experience as a field geologist resulted in an admirable text-book, *Outlines of Field Geology* (5th edition 1900). After editing and practically re-writing Jukes's *Student's Manual of Geology* in 1872, he published a *Text-Book* and a *Class-Book* of geology, which have taken rank as standard works of their kind. His writings are marked in a high degree by charm of style and power of vivid description. His literary ability has given him peculiar qualifications as a writer of scientific biography, and his *Memoir* of his old chief Sir Andrew Crombie Ramsay (1895) is a model of what such a work should be. His *Founders of Geology* consists of the inaugural course of Williams Lectures at the Johns Hopkins University, Baltimore, delivered in 1897. In 1898 he delivered the Romanes Lectures, and his address was published under the title of *Types of Scenery and their Influence on Literature*. The study of geography owes its improved position in Great Britain largely to his efforts. Among his works on this subject is *The Teaching of Geography* (1887). He was foreign secretary of the Royal Society from 1890 to 1894, president of the Geological Society in 1891 and 1892, and president of the British Association 1892. He received the honour of knighthood in 1891.

Geikie, James (1839– ——), younger brother of Sir Archibald, and like him a distinguished geologist, was born at Edinburgh on 23rd August 1839. He entered the Geological Survey in 1861, and in 1882 succeeded his brother as Murchison Professor of Geology and Mineralogy at the University of Edinburgh. He has taken as his special subject of investigation the origin of surface-features, and in particular the part played in their formation by glacial action. His views are embodied in his chief work, *The Great Ice Age and its Relation to the Antiquity of Man* (1874; 3rd edition 1894). He is the leader of the school that upholds the all-important action of land-ice, as against those geologists who assign chief importance to the work of pack-ice and icebergs. Continuing this line of investigation in his *Prehistoric Europe* (1881), he maintained the hypothesis of five inter-Glacial periods in Great Britain, and argued that the Palæolithic deposits of the Pleistocene period were not post- but inter- or pre-Glacial. His *Fragments of Earth Lore: Sketches and Addresses, Geological and Geographical* (1893), and *Earth Sculpture* (1898) are mainly concerned with the same subject. Like Forbes, Ramsay, and Tyndall, he has familiarized himself with the Alps, the classic ground for the investigation of the action of land-ice. His *Outlines of Geology* (1886), a standard text-book of its subject, reached its third edition in 1896. In 1887 he broke fresh ground with a volume of *Songs and Lyrics by H. Heine and other German poets, done into English verse.* His interest in geography is shown in the fact that since 1888 he has been editor of the *Scottish Geographical Magazine.*

Geislingen, a town of Würtemberg, Germany, 38 miles by rail east-south-east of Stuttgart. It has shops for the carving and turning of bone, ivory, wood, and horn, besides iron-works, machinery factories, glass-works, brewing, bleaching, &c. The Church of St Mary's contains wood-carving by Jörg Syrlin the Younger (1512). Here are ruins of the castle of Helfenstein (1552), a monument of the Emperor William I., and a drawing and modelling school. Population (1900), 7050.

Gellivare, or GELLIVARA, a mining town of Sweden, county Finmarken, 127 miles by rail north by west from Luleå, at the head of the Gulf of Bothnia. It owes its importance to the iron mines in the mountain 4½ miles to the north, situated in 67° 11′ N. lat. and rising to 2024 feet above sea-level (830 feet above Gellivare town). During the dark winter months work proceeds by the aid of the electric light. Some 3000 to 4000 men are employed at the mines. The output has increased at an enormously rapid rate—namely, from 85 tons in 1885 to 178,000 tons in 1892 and to over 1,000,000 tons in 1900. In 1864 the mines were acquired by an English company, but abandoned in 1867. In 1884 another English company took them up and completed a provisional railway from Luleå to Gellivare, besides executing a considerable portion of the preliminary works for the continuation of the line on the Norwegian side from Ofoten Fjord upwards. But this company, after extracting some 150,000 tons of ore in 1888–89, became bankrupt in the latter year. Two years later the mines passed into the hands of a Swedish company, and the railway was acquired by the Swedish Government (see LULEÅ). Population of parish (1900), 11,745.

Gelnhausen, a town of the province of Hesse-Nassau, Prussia, 27 miles by rail east-north-east of Frankfort-on-Main, on the Kinzig. On an island in the river are the ivy-covered ruins of the imperial palace which Frederick (Barbarossa) I. built before 1170, and which was destroyed by the Swedes during the Thirty Years' War. It has an interesting parish church, with three towers, built in the 13th century, and restored in 1876–79; also several other ancient buildings, such as the town-hall, the Princes' Court (now administrative offices), the Witches' Tower, &c. Indiarubber and cigars are manufactured, and wine is made. Gelnhausen became an imperial town in 1169, and in 1186 was the scene of a great Diet of the empire. In 1634 and 1635 it suffered severely from the Swedes. In 1803 the town became the property of Hesse-Cassel, and in 1866 was assigned to Prussia. Population (1900), 4591.

Gelsenkirchen, a town of Prussia, province of Westphalia, 19 miles by rail west of Dortmund. It has coal mines, iron furnaces, steel and boiler works, and soap factories. Population (1885), 20,289; (1900), 36,937.

Gems, Artificial.—The term "Artificial Gems" does not mean *imitations* of real gems, but the actual formation by artificial means of the real precious stone, so that the product is identical, chemically, physically, and optically, with the one found in nature. For instance, in chemical composition the lustrous diamond is nothing but crystallized carbon. Could we take black amorphous carbon in the form of charcoal or lamp-black and dissolve it in a liquid, and by the slow evaporation of that liquid allow the dissolved carbon to separate out, it would probably crystallize in the transparent form of diamond. This would be a true synthesis of diamond, and the product would be just as much entitled to the name as the choicest products of Kimberley or Golconda. But this is a very different thing from the imitation diamond so common in shop windows. Here the chemist has only succeeded in making a paste or glass having limpidity and a somewhat high refractivity, but wanting the hardness and "fire" of the real stone.

The Diamond.—Within the last few years chemists have actually succeeded in making the real diamond by artificial means, and although the largest yet made is not more than one-fiftieth of an inch across, the process itself and the train of reasoning leading up to such an achievement are sufficiently interesting to warrant a somewhat full description. Attempts to make diamonds artificially have been numerous, but, with the sole exception of those of Moissan, all have resulted in failure. The nearest approach to success was attained by Hannay in 1880 and Marsden in 1881; but their results have not been verified by others who have tried to repeat them, and the probability is that what was then thought to be diamond was in reality carborundum or carbide of silicon.

Attempts have been made by two methods to make carbon crystallize in the transparent form. One is to crystallize it slowly from a solution in which it has been dissolved. The difficulty is to find a solvent. Many organic and some inorganic bodies hold carbon so loosely combined that it can be separated out under the influence of chemical action, heat, or electricity, but invariably the carbon assumes the black amorphous form. The other method is to try to fuse the carbon by fierce heat, when from analogy it is argued that on cooling it will solidify to a clear limpid crystal. The progress of science in other directions has now made it pretty certain that the true mode of making diamond artificially is by a combination of these two methods. Until recently it was assumed that carbon was non-volatile at any attainable temperature, but it is now known that at a temperature of about 3600° C. it does volatilize, passing without liquefying directly from the solid to the gaseous state. Very few bodies act in this manner, the great majority when heated at atmospheric pressure to a sufficient temperature passing through the intermediate condition of liquidity. Some few, however, which when heated at atmospheric pressure do not liquefy, when heated at higher pressures in closed vessels obey the common rule, and first become liquid and then volatilize. Professor Dewar found the critical pressure of carbon to be about fifteen tons on the square inch; that is to say, if heated to its critical temperature (3600° C.), and at the same time subjected to a pressure of 15 tons to the square inch, it will assume the liquid form. Enormous as such pressures and temperatures may appear to be, they have been exceeded in some of Sir Andrew Noble's and Sir F. Abel's researches; in their investigations on the gases from gunpowder and cordite fired in closed steel chambers, these chemists obtained pressures as great as ninety-five tons to the square inch, and temperatures as high as 4000° C. Here then, if the observations are correct, we have sufficient temperature and enough pressure to liquefy carbon; and, were there only sufficient time for these to act on the carbon, there is little doubt that the artificial formation of diamonds would soon pass from the microscopic stage to a scale more likely to satisfy the requirements of science, if not those of personal adornment.

It has long been known that the metal iron in a molten state dissolves carbon and deposits it on cooling as black opaque graphite. Moissan has carried out a laborious and systematic series of experiments on the solubility of carbon in iron and other metals, and has come to the conclusion that whereas at ordinary pressures the carbon separates from the solidifying iron in the form of graphite, if the pressure be greatly increased the carbon on separation will form liquid drops, which on solidifying will assume the crystalline shape and become true diamond. Many other metals dissolve carbon, but molten iron has been found to be the best solvent. The quantity entering into solution increases with the temperature of the metal. But temperature alone is not enough; pressure must be superadded. Here Moissan ingeniously makes use of a property which molten iron possesses in common with some few other liquids — water, for instance — of increasing in volume in the act of passing from the liquid to the solid state. Pure iron is mixed with carbon obtained from the calcination of sugar, and the whole is rapidly heated in a carbon crucible in an electric furnace, using a current of 700 amperes and 40 volts. The iron melts like wax and saturates itself with carbon. After a few minutes' heating to a temperature above 4000° C.—a temperature at which the lime furnace begins to melt and the iron volatilizes in clouds — the dazzling, fiery crucible is lifted out and plunged beneath the surface of cold water, where it is held till it sinks below a red heat. The sudden cooling solidifies the outer skin of molten metal and holds the inner liquid mass in an iron grip. The expansion of the inner liquid on solidifying produces enormous pressure, and under this stress the dissolved carbon separates out in a hard, transparent, dense form—in fact, as diamond. The succeeding operations are long and tedious. The metallic ingot is attacked with hot aqua regia till no iron is left undissolved. The bulky residue consists chiefly of graphite, together with translucent flakes of chestnut-coloured carbon, hard black opaque carbon of a density of from 3·0 to 3·5, black diamonds—carbonado, in fact—and a small quantity of transparent colourless diamonds showing crystalline structure. Besides these there may be corundum and carbide of silicon, arising from impurities in the materials employed. Heating with strong sulphuric acid, with hydrofluoric acid, with nitric acid and potassium chlorate, and fusing with potassium fluoride—operations repeated over and over again—at last eliminate the graphite and impurities and leave the true diamond untouched. The precious residue on microscopic examination shows many pieces of black diamond, and other colourless transparent pieces, some amorphous, others crystalline. Although many fragments of crystals are seen, the writer has scarcely ever met with a complete crystal. All appear broken up, as if, on being liberated from the intense pressure under which they were formed, they burst asunder. Direct evidence of this phenomenon has been seen. A very fine piece of diamond, prepared in the way just described and carefully mounted on a microscopic slide, exploded during the night and covered the slide with fragments. This bursting paroxysm is not unknown at the Kimberley mines.

The artificial diamonds, so far, have not been larger than microscopic specimens, and none has measured more than about half a millimetre across. That, however, is quite enough to show the correctness of the train of reasoning leading up to the achievement, and there is no reason to doubt that, working on a larger scale, larger diamonds will result. Diamonds so made burn in the air when heated to a high temperature, with formation of carbonic acid; and in lustre, crystalline form, optical properties, density and hardness, they are identical with the natural stone.

It having been shown that diamond is formed by the separation of carbon from molten iron under pressure, it became of interest to see if in some large metallurgical operations similar conditions might not prevail. A special form of steel is made at some large establishments by cooling the molten metal under intense hydraulic pressure. In some samples of the steel so made Professor Rosel, of the university of Bern, has found microscopic diamonds. The higher the temperature at which the steel has been melted the more diamonds it contains, and it has even been suggested that the hardness of steel in some measure may be due to the carbon distributed throughout its mass being in this adamantine form. The largest artificial diamond yet formed was found in a block of steel and slag from a furnace in Luxembourg; it is clear and crystalline, and measures about one-fiftieth of an inch across.

A striking confirmation of the theory that natural diamonds have been produced from their solution in masses of molten iron, the metal from which has gradually oxidized and been washed away under cycles of atmospheric influences, is afforded by the occurrence of diamonds in a meteorite. On a broad open plain in Arizona, over an area of about 5 miles in diameter, lie scattered thousands of masses of metallic iron, the fragments varying in weight from half a ton to a fraction of an ounce. There is little doubt that these fragments formed part of a meteoric shower, although no record exists as to when the fall took place. Near the centre, where most of the fragments have been found, is a crater with raised edges, three-quarters of a mile in diameter and 600 feet deep, bearing just the appearance which would be produced had a mighty mass of iron—a falling star—struck the ground, scattered it in all directions, and buried itself deeply under the surface, fragments eroded from the surface forming the pieces now met with. Altogether ten tons of this iron have been collected, and specimens of the Cañon Diablo meteorite are in most collectors' cabinets. Dr Foote, a mineralogist, when cutting a section of this meteorite, found the tools injured by something vastly harder than metallic iron, and an emery wheel used for grinding it was ruined. He attacked the specimen chemically, and soon afterwards announced to the scientific world that the Cañon Diablo meteorite contained diamonds, both black and transparent. This startling discovery was subsequently verified by Professors Friedel and Moissan, and also by the writer.

The Ruby.—It is evident that of the other precious stones only the most prized are worth producing artificially. Apart from their inferior hardness and colour, the demand for what are known as "semi-precious stones" would not pay for the necessarily great expenses of the factory. Moreover, were it to be known that they were being produced artificially, the demand—never very great—would almost cease. The only other gems, therefore, which need be mentioned in connexion with their artificial formation are those of the corundum or sapphire class, which include all the most highly prized gems, rivalling, and sometimes exceeding, the diamond in value. Here a remarkable and little-known fact deserves notice. Excepting the diamond and sapphire, each of the precious stones—the emerald, the topaz, and amethyst—possesses a more noble, a harder, and more highly-prized counterpart of itself, alike in colour, but superior in brilliancy and hardness; still more strange, the precious stone to which its special name is usually attached is the variety the least prized. The ruby itself might almost be included in the same category. The true ruby consists of the earth alumina, in a clear, crystalline form, having a minute quantity of the element chromium as the colouring matter. It is often called the "Oriental Ruby," or red sapphire, and when of a paler colour, the "Pink Sapphire." But the ruby as met with in jewellers' shops of inferior standing is usually no true ruby, but a "spinel ruby" or "balas ruby," sometimes very beautiful in colour, but softer than the Oriental ruby, and different in chemical composition, consisting essentially of alumina and magnesia and a little silica, with the colouring matter chromium. The colourless basis of the true Oriental precious stones being taken as crystallized alumina or white sapphire, when the colouring matter is red the stone is called ruby, when blue sapphire, when green Oriental emerald, when orange-yellow Oriental topaz, and when violet Oriental amethyst. Clear, colourless crystals are known as white sapphire, and are very valuable. It is evident, therefore, that whosoever succeeds in making artificially clear crystals of white sapphire has the power, by introducing appropriate colouring matter, to make the Oriental ruby, sapphire, emerald, topaz, and amethyst. All of these stones, even when of small size, are costly and readily saleable, while when they are of fine quality and large size they are highly prized, a ruby of fine colour, and free from flaws, a few carats in weight, being of more value than a diamond of the same weight.

This being the case, it is not surprising that repeated attempts have been made to effect the crystallization of alumina. This is not a matter of difficulty, but unfortunately the crystals generally form thin plates, of good colour, but too thin to be useful as gems. In 1837 Gaudin made true rubies, of microscopic size, by fusing alum in a carbon crucible at a very high temperature, and adding a little chromium as colouring matter. In 1847 Ebelmen produced the white sapphire and rose-coloured spinel by fusing the constituents at a high temperature in boracic acid. Shortly afterwards he produced the ruby by employing borax as the solvent. The boracic acid was found to be too volatile to allow the alumina to crystallize, but the use of borax made the necessary difference. But it was not till about the year 1877 that MM. Frémy and Feil first published a method whereby it was possible to produce a crystallized alumina from which small stones could be cut. They first formed lead aluminate by the fusion together of lead oxide and alumina. This was kept in a state of fusion in a fireclay crucible (in the composition of which silica enters largely). Under the influence of the high temperature the silica of the crucible gradually decomposes the lead aluminate, forming lead silicate, which remains in the liquid state, and alumina, which crystallizes as white sapphire. By the admixture of 2 or 3 per cent. of a chromium compound with the original materials the resulting white sapphire became ruby. More recently MM. Frémy and Verneuil obtained artificial rubies by reacting at a red heat with barium fluoride on amorphous alumina containing a small quantity of chromium. The rubies obtained in this manner are thus described by MM. Frémy and Verneuil: "Their crystalline form is regular; their lustre is adamantine; they present the beautiful colour of the ruby; they are perfectly transparent, have the hardness of the ruby, and easily scratch topaz. They resemble the natural ruby in becoming dark when heated, resuming their rose-colour on cooling." Des Cloizeau says of them that "under the microscope some of the crystals show bubbles. In converging polarized light the coloured rings and the negative black cross are of a remarkable regularity."

Other experimentalists have attacked the problem in other directions. Besides those already mentioned, Elsner, De Senarmont, Deville, and Caron and Debray have succeeded with more or less success in producing rubies. The general plan adopted has been to form a mixture of salts fusible at a red heat, forming a liquid in which alumina will dissolve. Alumina is now added till the fused mass will take up no more, and the crucible is left in the furnace for a long time, sometimes extending over weeks. The solvent slowly volatilizes, and the alumina is deposited in crystals, coloured by whatever colouring oxide has been added.

Mention has been made above of a stone frequently substituted for the true ruby, called the "spinel" or "balas" ruby. The spinel and ruby occur together in nature, stones from Burma being as often spinel as true Oriental ruby. In the artificial production of the ruby it sometimes happens that spinel crystallizes out when true Oriental ruby is expected. The fusion bath is so arranged that only red-coloured alumina shall crystallize out, but it is difficult to have all the materials of such purity as to ensure the complete absence of silica and magnesia. In this case, when these impurities have accumulated to a certain point they unite with the alumina, and spinel then separates, as it crystallizes more easily than ruby. When all the magnesia and silica have been eliminated in this way the bath resumes its deposition of crystalline ruby. A few years ago rubies of fine colour and of considerable size were shown in London, made on the Continent by a secret process. The writer has seen several cut stones so made weighing over a carat each, the uncut crystals measuring half an inch along a crystal edge, and weighing over 70 grains, and a clear plate of ruby cut from a single crystal weighing over ten grains. Ruby has lately been made by Sir W. Roberts-Austen as a by-product in the production of metallic chromium. Oxide of chromium and aluminium powder are intimately mixed together in a refractory crucible, and the mixture is ignited at the upper part. The aluminium and chromium oxide react with evolution of so much heat that the reduced chromium is melted. Such is the intensity of the reaction that the resulting alumina is also completely fused, floating as a liquid on the molten chromium. Sometimes the alumina takes up the right amount of chromium to enable it to assume the ruby colour. On cooling the melted alumina crystallizes in large flakes, which on examination by transmitted light are seen to be true ruby. The development of the red colour is said by Greville-Williams only to take place at a white heat. It is not due to the presence of chromic acid, but to a reaction between alumina and chromic oxide, which requires an elevated temperature.

The Sapphire.—Daubrée has shown that when a full quantity of chromium is added to the bath from which white sapphire crystallizes the colour is that of ruby, but when much less chromium is added the colour is blue, forming the true Oriental sapphire. The real colouring matter of the Oriental sapphire is not definitely known, some chemists considering it to be chromium, and others cobalt. Artificial sapphires have been made of a fair size and perfectly transparent by the addition of cobalt to the igneous bath of alumina, but the writer does not consider them equal in colour to true Oriental sapphire.

The Oriental Emerald.—The stone known as emerald consists chemically of silica, alumina, and glucina. Like the ruby, it owes its colour to chromium, but in a different state of oxidation. As already mentioned, there is another stone which consists of crystallized alumina coloured with chromium, but holding the chromium in a different state of oxidation. This is called the Oriental emerald, and, owing to its beauty of colour, its hardness, and rarity, it is more highly prized than the emerald itself, and commands higher prices. The Oriental emerald has been produced artificially in the same way as the ruby, by adding a larger amount of chromium to the alumina bath and regulating the temperature.

The Oriental Amethyst.—The amethyst is rock crystal (quartz) of a bluish-violet colour. It is one of the least valuable of the precious stones. The sapphire, however, is found occasionally of a beautiful violet colour; it is then called the Oriental amethyst, and, on account of its beauty and rarity, is of great value. It is evident that if to the igneous bath of alumina some colouring matter, such as manganese, is added capable of communicating a violet colour to the crystals of alumina, the Oriental amethyst will be the result. Oriental amethyst has been so formed artificially, but the stone being known only as a curiosity to mineralogists and experts in precious stones, and the public not being able to discriminate between the violet sapphire and amethystine quartz, there is no demand for the artificial stone.

The Oriental Topaz.—The topaz is what is called a semi-precious stone. It occurs of many colours, from clear white to pink, orange, yellow, and pale green. The usual colour is from straw-yellow to sherry colour. The exact composition of the colouring matter is not known; it is not entirely of mineral origin, as it changes colour and sometimes fades altogether on exposure to light. Chemically the topaz consists of alumina, silica, and fluorine. It is not so hard as the sapphire. There is also a yellow variety of quartz, which is sometimes called "false topaz." The Oriental topaz, on the other hand, is a precious stone of great value. It consists of clear crystalline sapphire coloured with a small quantity of ferric oxide. It has been produced artificially by adding iron instead of chromium to the matrix from which the white sapphire crystallizes.

The Zircon.—The zircon, jargoon, or hyacinth is a very beautiful stone, varying in colour, like the topaz, from red and yellow to green and blue. It is sometimes met with colourless, and such are its refractive powers and brilliancy that it has been mistaken for diamond. It is a compound of silica and zirconia. H. Sainte-Claire Deville formed the zircon artificially by passing silicium fluoride at a red heat over the earth zirconia in a porcelain tube. Octahedral crystals of zircon are then produced, which have the same crystalline form, appearance, and optical qualities as the natural zircon. (W. C.)

General Average. See AVERAGE, GENERAL.

Geneva, a canton and city of Switzerland. It was the last to be admitted into the Confederation (in 1815), and so ranks last. In point of population the city now ranks as the third in Switzerland, being surpassed by both Zürich and Basel. The canton has an area of 107 square miles (88·8 square miles being "productive," 11·1 square miles of this being covered by forests and 7·4 square miles by vineyards). The population of the canton in 1900 was 131,714, divided linguistically thus: French-speaking, 110,058; German-speaking, 13,766; Italian-speaking, 7300. The population of the city was in 1888 stated at 71,807, and in 1900 it was (with Carouge and other suburbs) 104,044. The canton is divided into three administrative districts, one taking in the town itself, and the two others the regions on the left and right banks of the Rhone respectively. The cantonal constitution of 1847 is still in force, but has been modified in various particulars. Both the legislature (in the proportion of one member per 1000 inhabitants, or a fraction over 500) and the executive (of seven members) are elected by a direct popular vote, while in each case since 1892 the principles of proportional representation have the force of law. Three thousand five hundred citizens have the right of requiring a "facultative referendum" as to any legislative projects, while 2500 citizens have the "right of initiative" as to the revision of the cantonal constitution, or as to any legislative projects. At the end of 1897 the Genevese people refused to adopt the principle of the separation of Church and State, but in some cases the alienated country churches have been restored to the Romanists, the Old Catholics being there in such small numbers that they could not themselves use these edifices. In the town the monument of the duke of Brunswick now forms a conspicuous feature, while the restored 15th-century "chapel of the Maccabees," attached to the cathedral, is very interesting to antiquaries. In 1890 the "Musée Ariana," a magnificent collection of art treasures, was bequeathed to the town by its owner, M. Revilliod, and is now open to the public. The restoration of the cathedral has also proceeded apace. The university of Geneva (founded as an "académie" by Calvin, and raised in 1873 to the rank of a university) was attended in the winter of 1898–99 by 250 matriculated students, and in that of 1899–1900 by 773 (besides 280 hearers). In 1900 the State revenue of the canton was 9,100,432 francs, and the State expenditure 8,764,802 francs, but the budget for 1901 reckons a deficit of 463,000 francs. In 1897 the public debt of the canton was 30,945,400 francs.

Geneva, Lake of, the largest lake of which any portion belongs to Switzerland. According to Professor Forel, its area is 582·36 square kilometres, or 225 square miles, but the Swiss Government estimate of 1898 makes it slightly less, 577·84 square kilometres, or 223 square miles. The latest estimate allots 123½ square miles of the lake to Vaud, 11½ square miles to Geneva, 4¾ square miles to the Valais, and 83¼ square miles to France. The Petit Lac occupies 30½ square miles of M. Forel's area. The length of the entire lake, from Geneva to Chillon, is 39½ miles, but along its axis 45 miles. The maximum depth is 309·7 metres, or 1015½ feet, but the mean depth is only 152·7 metres, or 500 feet. Its greatest width (between Morges and Amphion) is 8½ miles (13·8 kilometres), but the normal width is 5 miles, or 8·1 kilometres. Its height above the sea-level is estimated at 371·9 metres (1200 feet) by Forel, and at 375 metres (1230¼ feet) by the Swiss Government officials in 1898. Professor F. A. Forel (of Morges) has made a most complete and detailed study of the lake from every point of view. The results of his prolonged investigations were given to the world in his monumental work, entitled *Le Léman.* Professor Forel mentions (vol. i. pp. 17 *et seqq.*) a curious fact which deserves to be noticed here. Near the Jardin Anglais in Geneva, on the left bank of the Rhone, there are several erratic blocks in the lake, of which one is called the Pierre du Niton (from a popular tradition that it was once an altar of Neptune). Now this rock was taken many years ago as the base of the Government survey, known later as the Dufour Map. Its height was then determined at 376·64 metres (1236 feet), or later at 376·84 metres. But Professor Forel found that its true height above the sea was only 373·5 metres (1225¼ feet), so that all the heights on the two great Swiss maps are thus nearly 3 metres (nearly 10 feet) too large. (W. A. B. C.)

Geneva, a village of Ontario county, New York, U.S.A., in 42° 52′ N. and 76° 59′ W., at the foot of Seneca Lake, on the Lehigh Valley and the New York Central and Hudson River railways, at an altitude of 453 feet. The manufactures consist mainly of iron and steel goods. The village is widely known for the nurseries in the surrounding country, the products of which are distributed to all parts of the United States. Hobart College, situated here, is a Protestant Episcopal institution, founded in 1822. In 1899 it had 15 instructors and was attended by 92 students. Population (1880), 5878; (1890), 7557; (1900), 10,433, of whom 1916 were foreign-born and 193 negroes.

Genoa, chief port and commercial city of Italy, seat of a university and of an archbishopric, near the middle of the Gulf of Genoa, 119 miles north-west of Leghorn by rail, in 44° 24′ 16″ N. lat., 8° 54′ 15″ E. long. After the inclusion of Sampierdarena and the suburban communes in the city (1872–73) the population numbered 160,000, and was at later periods (1881), 179,515; (1890), 206,033; (1901), 234,809, including 11,469 floating population. The duke of Galliera's gift of £800,000 to the city in 1875 permitted the enlargement of the harbour, which was begun in 1877 by a Venetian company. The works included the Molo Lucedio, which more than doubled the length of the mole that starts from the lighthouse; the Nuove Calate, and the quays of Paleocazia, Sapri, Caracciolo, Biagio Assereto, Cristoforo Colombo, Andrea Doria, Federico Guglielmo (for passenger steamers), Adolfo Parodi, Morosini, and Guglielmo Embriaco. All these quays were equipped with the most modern sheds and appliances. Towards the west, outside the harbour, near the Calata delle Grazie, was built the Molo Giano, to which docking basins and repairing yards were afterwards added. Simultaneously Via Carlo Alberto, skirting the harbour, was enlarged; the porticos with the marble terrace, near Piazza Caricamento, were demolished; and under the terrace in Via Milano (formerly Via alla Lanterna) were placed the Magazzini Generali. The opening of the Gothard tunnel (1882), which extended the commercial range of the port through Switzerland to Mannheim, necessitated yet further enlargement of the harbour. In 1897 a convention to this end was agreed to between the municipality and the Italian Government. These new works included the enlargement of the existing railway station at Piazza Principe, and the creation of another; the cutting of railway tunnels and the widening of the wharf at the Federico Guglielmo bridge. Meanwhile an English company—the Customs and Bonded Warehouses Company—has constructed two huge groups of parallel buildings, several storeys high, on the Molo Vecchio, as a warehouse and bonded stores. The neighbouring Mandraccio, formerly a stagnant pool, has been filled up so as to gain further warehouse room. The total traffic of the port in 1899 was 3,966,493 tons, of which 215,814 tons were exported; 370,697 were goods in transit; duty was paid on 3,006,092 tons, while 373,890 tons were placed in bond. The port was visited by 12,970 vessels, representing an aggregate tonnage of 9,049,877 tons. The commerce is constantly increasing, and has now attained a greater volume than that of any Mediterranean port except Marseilles.

The only new line of local railway is that known as the Succursale dei Giovi, built to relieve the pressure of traffic which the opening of the Gothard tunnel placed upon the old Giovi line. The new line from Genoa to Ronco Scrivia is 23 miles long. It contains a tunnel quite as difficult as that of the Giovi at Busalla, and cost more than £3,000,000. At present surveys are being made for a new line to Piacenza. The first horse tramway was opened in 1878 by a French company, between the Piazza Annunziata and Sampierdarena. A tunnel was bored through the San Benigno Hill for the passage of the line. Subsequently the horse tramway system was extended to Pontedecimo and along the shore to Pegli and Voltri. The same company has also installed an omnibus service within the city. In 1893 the first electric tramway was opened between Piazza Corvetto and Piazza Manin. A German company has since extended the electric tramway service from the central Piazzi dei Ferrari to Staglieno and Nervi. Other lines run from Piazza Raibetta along Via San Lorenzo, Via Carignano, Via Circonvallazione a Mare and a Monte to the Righi, which is reached by an electric funicular railway. Towards the west, lines run from Piazza Caricamento to Pontedecimo and Pegli. A non-electric funicular railway belonging to a Genoese company has been built between the central Piazza Portello and the elevated Corso Magenta. A cog-wheel funicular runs from the hill of San Rocco to the summit of Granarolo, whence a magnificent view is to be obtained. An important electric line was in 1901 in course of construction to Laguardia, a famous sanctuary upon a high hill to the west of the city.

Much has been done by the municipality to improve the streets. In Via Roma, which, with the Galleria Mazzini, was planned in 1871 and completed in 1876, a part of the Palazzo Spinola, which formerly obstructed traffic, has been cut away. Piazza Corvetto has been laid out between the two sides of the Acquasola Promenade. Via Circonvallazione a Monte has been completed and extended. In 1890 Corso Firenze was begun, and a carriage road built to the Height of Oregona. Behind Via Milano, Via Venezia has been laid out and is now being connected with the magnificent Circonvallazione a Monte. In 1891 Via a Mare, which ran from Piazza Caricamento to the Molo Giano, was extended and enlarged as far as the Bisagno Esplanade, and named Corso Aurelio Saffi. In the Carignano district the grandiose Galliera Hospital has been built, and Via Corsica laid out as far as the Rotonda, the favourite rendezvous of the Genoese. Corso Mentana, Corso Alessandro Volta, and Corso Silvio Pellico were added. Between the monumental bridge, which connects the two divisions of Via Venti Settembre and Via Corsica, a wide thoroughfare named Corso Andrea Podestà has been laid out.

The organization of the Italo-American Exhibition in 1892 (fourth centenary of the discovery of America by Columbus) necessitated several important works, namely, the opening of a new thoroughfare between Porta d'Arco and Porta Pila, the demolition of the Fronti Bassi, separating the city from the Bisagno quarter, the embankment of the river Bisagno, the reconstruction of the Pila Bridge, and the lowering of Via Minerva, the name of which was changed to Corso Buenos Ayres. New streets have been constructed in the same quarter, namely, Corso Galliera, Via Torino, Via della Libertà, Via Casa Regis, Via Barabino, Via Volturno, and Via Ferruccio. New streets have also been laid out in the San Fruttuoso and Cavaletto quarters. The road from Piazza Manin to Staglieno has been completed, the colonnades in Via Carlo Alberto and Piazza Caricamento have been restored, Piazza Principe has been reorganized, and the cemetery of Staglieno embellished with a semicircular colonnade. A large new prison has been built by the Government, and a new public market erected in Via Venti Settembre. Several public monuments have been restored, namely, Porta Soprana, Palazzo San Giorgio, the cathedral of San Lorenzo (of which the three naves have been restored in Gothic style), the ancient church of San Donato, and the temple of the Immacolata. A munificent bequest of the duchess of Galliera provided means for the reorganization of the museum in Palazzo Bianco (in Via Garibaldi), which, with the Palazzo Rosso, containing the celebrated picture gallery, has become municipal property. New monuments have been erected to Mazzini, Garibaldi, Nino Bixio, Victor Emmanuel II., Raffaele Rubatino (founder of the Navigazione Generale), the duke of Galliera (by Monteverde), and to the duchess of Galliera (also by Monteverde). Many new school buildings have been erected since 1875, and those previously existing much enlarged. There are twenty-five boys' schools, with a total of 9120 scholars and 287 teachers; twenty-four girls' schools, with 8042 scholars and 241 teachers. In addition there are three technical evening and Sunday schools, with 750 pupils, who are instructed in Italian literature, French, English, algebra, geometry, chemistry, and physics; a boys' school of arts and crafts, founded in 1892; and two superior female schools, one named after Queen Margherita and the other after the duchess of Galliera, with more than 400 pupils. The sums voted by the municipality for education have increased from £33,000 in 1877 to £76,000 in 1899. Further sums are provided by the provincial council. One of the most important educational institutes is the superior school of practical commerce, founded by private initiative. It has 100 students, who take a three years' course. A new lyceum has been founded by the municipality. The previously existing nautical school is in a flourishing condition. Since 1880 the university has been promoted from secondary to primary status, and now includes the faculties of jurisprudence, medicine, mathematical and natural sciences, and philosophy and letters. The students in 1900 numbered 1400.

The development of industry has kept pace with that of the harbour. The Ansaldo shipbuilding yards now construct armoured cruisers both for the Italian navy and for foreign governments. The Odero yards, for the construction of merchant and passenger steamers, have been similarly extended. The two docking basins near the Calata delle Grazie are respectively 540 feet and 670 feet long. A number of foundries and metallurgical works supply material for repairs and shipbuilding. The sugar-refining industry has been introduced by two important companies, and most of the capital employed in sugar-refining in other parts of Italy has been subscribed at Genoa, where the administrative offices of the principal companies and individual refiners are situated. The old industries of maccaroni and cognate products maintain their superiority. Tanneries and cotton spinning and weaving mills have considerably extended throughout the province. Cement works have acquired an extension previously unknown, more than thirty firms being now engaged in that branch of industry.

New charitable institutions have arisen. In 1876 the Galliera Asylum for the poor was founded with a capital of nearly £80,000. In 1877 the duchess of Galliera gave £400,000 for the creation of three hospitals, one known as Sant' Andrea Apostolo (300 beds), in Carignano, for invalids born in Liguria; a second, for invalid children, at San Bartolomeo degli Armeni; and a third, for convalescent patients, at Cornigliano. These three hospitals now possess an endowment of more than £1,000,000. In 1881 the Tollot Infant Asylum was founded with a legacy of £60,000 bequeathed by Giuseppina Tollot. It has accommodation for 300 children. Other infant asylums provide for an aggregate of nearly 1000 children. The Pammatone Hospital, founded in 1429 by Bartolomeo Bosco, now contains 857 beds. It possesses an endowment of £530,000. The municipality pays it an annual subsidy of £7500 as contribution to the expense of nursing indigent patients. The Hospital for Incurables has 650 beds, and receives from the Pammatone Hospital children whose cases are not chronic. The Lunatic Asylum in Via Brera, with a capacity for 600 inmates, has now a capital of £210,000. A branch asylum has been built near the sea at the expense of the provincial authorities. The Pauper Asylum and Workhouse, situated above Murassi, deals with the fluctuating mendicant population. It receives an annual subsidy of £320 from the municipality. The Foundling Hospital, dating from the 15th century, has been detached from the Pammatone. It costs £8000 a year, of which the provincial authorities provide £7000. A Sailors' Orphan Asylum, a Public Dormitory, a Hospital for Cripples, a Patronato Scholastico, for supplying indigent children with food, have also been founded. A munificent priest, Francesco Montebruno, has established an Artigianelli Institute with a capital of £40,000, for training foundling children in arts and crafts. Its inmates at present number 150 boys and 80 girls. Altogether, Genoa has 180 bequests and legacies for charitable purposes.

The municipal budget for 1900 showed a revenue of £708,760 and an expenditure of £746,760. Taxes and *octroi* yield about £500,000 a year. The chief item of expenditure is represented by interest on the municipal debt (£124,600). The present indebtedness is £2,280,000, more than £800,000 of new debt having been incurred since 1890. (H. W. S.)

GEOGRAPHY.

GEOGRAPHY may be defined as the exact and organized knowledge of the distribution of phenomena on the surface of the Earth. The fundamental basis of geography is the vertical relief of the Earth's crust, which controls all mobile distributions. The grander features of the relief of the lithosphere or stony crust of the Earth control the distribution of the hydrosphere or collected waters which gather into the hollows, filling them up to a height corresponding to the volume, and thus producing the important practical division of the surface into land and water. The distribution of the mass of the atmosphere over the surface of the Earth is also controlled by the relief of the crust, its greater or lesser density at the surface corresponding to the lesser or greater elevation of the surface. The distribution of solar energy is entirely altered from the mathematical simplicity of the zones, which would characterize a uniform globe, by the dissimilar action of land and water with regard to radiant heat, and the influence of crust-forms on the direction of the resulting circulation. The influence of physical environment becomes clearer and stronger when the distribution of plant and animal life is considered, and if it is less distinct in the case of man, the reason is found in the modifications of environment consciously produced by human effort. Geography is a synthetic science, dependent for the data with which it deals on the results of specialized sciences such as astronomy, geology, oceanography, meteorology, biology, and anthropology, as well as topographical description (which has too long been supposed to be the whole of geography). The physical and natural sciences are concerned in geography only so far as they deal with the forms of the Earth's surface, or as regards the distribution of phenomena. The distinctive task of geography as a science is to investigate the control exercised by the crust-forms directly and indirectly upon the various mobile distributions. This gives to it unity and definiteness, and renders superfluous the attempts that have been made from time to time to define the limits which divide geography from geology on the one hand and from history on the other. It is essential to classify the subject-matter of geography in such a manner as to give prominence not only to facts, but to their mutual relations and their natural and inevitable order.

Definition and scope.

The fundamental conception of geography is form, including the figure of the Earth and the varieties of crustal relief. Hence mathematical geography, including cartography as a practical application, comes first. It merges into physical geography, which takes account of the forms of the lithosphere (geomorphology), and also of the distribution of the hydrosphere and the rearrangements resulting from the workings of solar energy throughout the hydrosphere and atmosphere (oceanography and climatology). Next follows the distribution of plants and animals (biogeography), and finally the distribution of mankind and the various artificial boundaries and redistributions (anthropogeography). The applications of anthropogeography to human uses give rise to political and commercial geography, in the elucidation of which all the earlier departments or stages have to be considered, together with historical and other purely human conditions. The evolutionary idea has revolutionized and unified geography as it did biology, breaking down the old hard-and-fast partitions between the various departments, and displacing the discovery and exploration of new lands as the central motive by the study of the nature and influence of actual terrestrial environments.

History of Geographical Theory.

The earliest conceptions of the Earth, like those held by the primitive peoples of the present day, are difficult to discover and almost impossible fully to grasp. Generalizations, as far as they were made from known facts, were usually expressed in symbolic language, and for our present purpose it is not profitable to speculate on the underlying truths which may sometimes be suspected in the old mythological cosmogonies.

The first definite geographical theories to affect the Western world were those evolved, or at least first expressed, by the Greeks.[1] The earliest theoretical problem of geography was the form of the Earth. The natural supposition that the Earth is a flat disc, circular or elliptical in outline, had in the time of Homer acquired a special definiteness by the introduction of the idea of the ocean river bounding the whole, an application of imperfectly understood observations. Thales of Miletus is claimed as the first exponent of the idea of a spherical Earth; but although this does not appear to be warranted, his disciple Anaximander (*c.* 580 B.C.) put forward the theory that the Earth had the figure of a solid body hanging freely in the centre of the hollow sphere of the starry heavens. The Pythagorean school of philosophers adopted the theory of a spherical Earth, but from metaphysical rather than scientific reasons; their convincing argument was that a sphere being the most perfect solid figure, was the only one worthy to circumscribe the dwelling-place of man. The division of the sphere into parallel zones and some of the consequences of this generalization seem to have presented themselves to Parmenides (*c.* 450 B.C.); but these ideas did not influence the Ionian school of philosophers, who in their treatment of geography preferred to deal with facts demonstrable by travel rather than with speculations. Thus Hecatæus, claimed by Tozer[2] as the father of geography on account of his *Periodos*, or general treatise on the Earth, did not advance beyond the primitive conception of a circular disc. He systematized the form of the land within the ring of ocean —the *oekumene*, or habitable world—by recognizing two continents: Europe to the north, and Asia to the south of the midland sea. Herodotus, equally oblivious of the sphere, criticized and ridiculed the circular outline of the *oekumene*, which he knew to be longer from east to west than it was broad from north to south. He also pointed out reasons for accepting a division of the land into three continents — Europe, Asia, and Africa. Beyond the limits of his personal travels Herodotus applied the characteristically Greek theory of symmetry to complete, in the unknown, outlines of lands and rivers analogous to those which had been explored. Symmetry was in fact the first geographical theory, and the effect of Herodotus's hypothesis that the Nile must flow from west to east before turning north in order to balance the Danube running from west

The idea of symmetry.

[1] A concise sketch of the whole history of geographical method or theory as distinguished from the history of geographical discovery is only to be found in the introduction to H. Wagner's *Lehrbuch der Geographie* (vol. i., Leipzig, 1900), which is in every way the most complete treatise on the principles of geography.

[2] *History of Ancient Geography*, Cambridge, 1897, p. 70.

to east before turning south lingered in the maps of Africa down to the time of Mungo Park.[1]

To Aristotle (384–322 B.C.) must be given the distinction of founding scientific geography. He demonstrated the sphericity of the Earth by three arguments, two of which could be tested by observation. These were—(1) that the Earth must be spherical, because of the tendency of matter to fall together towards a common centre; (2) that only a sphere could always throw a circular shadow on the moon during an eclipse; and (3) that the shifting of the horizon and the appearance of new constellations, or the disappearance of familiar stars, as one travelled from north to south, could only be explained on the hypothesis that the Earth was a sphere. Aristotle, too, gave greater definiteness to the idea of zones conceived by Parmenides, who had pictured a torrid zone uninhabited by reason of heat, two frigid zones uninhabited by reason of cold, and two intermediate temperate zones fit for human occupation. Aristotle defined the temperate zone as extending from the tropic to the arctic circle, but there is some uncertainty as to the precise meaning he gave to the term "arctic circle." Soon after his time, however, this conception was clearly established, and with so large a generalization the mental horizon was widened to conceive of a geography which was a science. Aristotle had himself shown that in the southern temperate zone winds similar to those of the northern temperate zone should blow, but from the opposite direction.

Aristotle and the sphere.

While the theory of the sphere was being elaborated the efforts of practical geographers were steadily directed towards ascertaining the outline and configuration of the *oekumene*, or habitable earth, the only portion of the terrestrial surface known to the ancients and to the mediæval peoples, and still retaining a shadow of its old monopoly of geographical attention in its modern name of the "Old World." The fitting of the *oekumene* to the sphere was the second theoretical problem. The circular outline had given way in geographical opinion to the elliptical with the long axis lying east and west, and Aristotle was inclined to view it as a very long and relatively narrow band almost encircling the globe in the temperate zone. His argument as to the narrowness of the sea between west Africa and east Asia, from the occurrence of elephants at both extremities, is difficult to understand, although it shows that he looked on the distribution of animals as a problem of geography.

Fitting the oekumene to the sphere.

Pythagoras had speculated as to the existence of antipodes, but it was not until the first approximately accurate measurements of the globe and estimates of the length and breadth of the *oekumene* were made by Eratosthenes (*c.* 250 B.C.) that the fact that, as then known, it occupied less than a quarter of the surface of the sphere was clearly recognized. It was natural, if not very logical, that the ocean river should be extended from a narrow stream to a world-embracing sea, and here again Greek theory, or rather fancy, gave its modern name to the greatest feature of the globe. The old instinctive idea of symmetry must often have suggested other *oekumene* balancing the known world in the other quarters of the globe. The Stoic philosophers, especially Crates of Mallos, arguing from the love of nature for life, placed an *oekumene* in each quarter of the sphere, the three unknown world-islands being those of the Antöken, Periöken, and Antipodes. This was a theory not only attractive to the philosophical mind, but eminently adapted to promote exploration. It had its opponents, however, for Herodotus showed that sea-basins existed cut off from the ocean, and it is still a matter of controversy how far the pre-Ptolemaic geographers believed in a water-connexion between the Atlantic and Indian oceans. It is quite clear that Pomponius Mela (*c.* A.D. 40), following Strabo, held that the southern temperate zone contained a habitable land, which he designated by the name *Antichthones.*

Problem of antipodes.

Aristotle left no work on geography, so that it is impossible to know what facts he would associate with the science of the Earth's surface. The word geography did not appear before Aristotle, the first use of it being in the *Peri Kosmon*, which is one of the writings doubtfully ascribed to him, and Berger considers that the expression was introduced by Eratosthenes.[2] Aristotle was certainly conversant with many facts, such as the formation of deltas, coast-erosion, and to a certain extent the dependence of plants and animals on their physical surroundings. He formed a comprehensive theory of the variations of climate with latitude and season, and was convinced of the necessity of a circulation of water between the sea and rivers, though, like Plato, he held that this took place by water rising from the sea through crevices in the rocks, losing its dissolved salts in the process. He speculated on the differences in the character of races of mankind living in different climates, and correlated the political forms of communities with their situation on a seashore, or in the neighbourhood of natural strongholds.

Aristotle's geographical views.

Claudius Ptolemæus (*c.* A.D. 150) concentrated in his writings the final outcome of all Greek geographical learning, and passed it across the gulf of the Middle Ages by the hands of the Arabs, to form the starting-point of the science in modern times. His geography was based more immediately on the work of his predecessor, Marinus of Tyre, and on that of Hipparchus, the follower and critic of Eratosthenes. It was the ambition of Ptolemy to describe and represent accurately the surface of the *oekumene*, for which purpose he took immense trouble to collect all existing determinations of the latitude of places, all estimates of longitude, and to make every possible rectification in the estimates of distances by land or sea. His work was mainly cartographical in its aim, and theory was as far as possible excluded. The symmetrically placed hypothetical islands in the great continuous ocean disappeared, and the *oekumene* acquired a new form by the representation of the Indian Ocean as a larger Mediterranean completely cut off by land from the Atlantic. The *terra incognita* uniting Africa and farther Asia was an unfortunate hypothesis which helped to retard exploration. Ptolemy used the word *geography* to signify the description of the whole *oekumene* on mathematical principles, while *chorography* signified the fuller description of a particular region, and *topography* the very detailed description of a smaller locality. He introduced the simile that geography represented an artist's sketch of a whole portrait, while chorography corresponded to the careful and detailed drawing of an eye or an ear.[3]

Ptolemy.

The Middle Ages saw geographical knowledge die out in Christendom, although it retained, through Arabic translations of Ptolemy, a certain vitality in Islam. The verbal interpretation of Scripture led Lactantius (*c.* A.D. 320) and other ecclesiastics to denounce the spherical theory of the Earth as heretical. The wretched subterfuge of Cosmas (*c.* A.D. 550) to explain the phenomena of the apparent

Geography in the Middle Ages.

movements of the sun by means of an earth modelled on the plan of the Jewish Tabernacle, gave place ultimately to the wheel-maps—the T in an O—which reverted to the primitive ignorance of the times of Homer and Hecatæus.[1]

The journey of Marco Polo, the increasing trade to the East, and the voyages of the Arabs in the Indian Ocean prepared the way for the re-acceptance of Ptolemy's ideas when his works became known through the Moors in Spain, and when the sealed books of the Greek original were translated into Latin by Angelus in 1410.

Revival of geography.

The old arguments of Aristotle and the old measurements of Ptolemy were used by Toscanelli and Columbus in urging a westward voyage to India; and mainly on this account did the crossing of the Atlantic rank higher in the history of scientific geography than the laborious feeling out of the coast-line of Africa. But not until the voyage of Magellan shook the scales from the eyes of Europe did modern geography begin to advance. Discovery had outrun theory; the rush of new facts made Ptolemy practically obsolete in a generation, after having been the fount and origin of all geography for a millennium.

Apianus.

The earliest evidence of the reincarnation of theoretical geography is to be found in the text-books by Peter Apian and Sebastian Munster. Apian in his *Cosmographicus Liber*, published in 1524, and subsequently edited and added to by Gemma Frisius under the title of *Cosmographia*, based the whole science on mathematics and measurement. He followed Ptolemy closely, enlarging on his distinction between geography and chorography, and expressing the artistic analogy in a rough diagram. This slender distinction was made much of by most subsequent writers until Nathanael Carpenter in 1625 pointed out that the difference between geography and chorography was simply one of degree, not of kind.

Munster.

Sebastian Munster, on the other hand, in his *Cosmographia Universalis* of 1544, paid no regard to the mathematical basis of geography, but, following the model of Strabo, described the world according to its different political divisions, and entered with great zest into the question of the productions of countries and into the manners and costumes of the various peoples. Thus early commenced the separation between what were long called mathematical and political geography, the one subject appealing mainly to mathematicians, the other to historians.

Throughout the 16th and 17th centuries the rapidly accumulating store of facts as to the extent, outline, and mountain and river systems of the lands of the Earth were put in order by the generation of cartographers of which Mercator was the chief; but the writings of Apian and Munster held the field for a hundred years without a serious rival, unless the many annotated editions of Ptolemy might be so considered. Meanwhile the new facts were the subject of original study by philosophers and by practical men without reference to classical traditions. Bacon argued keenly on geographical matters and was a lover of maps, in which he observed and reasoned upon such resemblances as that between the outlines of South America and Africa.

Cluverius.

Philip Cluver's *Introductio in Geographiam universam tam veteram quam novam* was published in 1624. Geography he defined as "the description of the whole Earth, so far as it is known to us." It is distinguished from cosmography by dealing with the Earth alone, not with the universe, and from chorography and topography by dealing with the whole Earth, not with a country or a place. The first book, of fourteen short chapters, is concerned with the general properties of the globe; the remaining six books treat in considerable detail of the countries of Europe and of the other continents. Each country is described with particular regard to its people as well as to its surface, and the prominence given to the human element is of special interest.

Carpenter.

A little-known book which appears to have escaped the attention of most writers on the history of modern geography was published at Oxford in 1625 by Nathanael Carpenter, fellow of Exeter College, with the title *Geographie delineated forth in Two Bookes, containing the Sphericall and Topicall parts thereof.* It is discursive in its style and verbose; but, considering the period at which it appeared, it is remarkable for the strong common sense displayed by the author, his comparative freedom from prejudice, and his firm application of the methods of scientific reasoning to the interpretation of phenomena. Basing his work on the principles of Ptolemy, he brings together illustrations from the most recent travellers, and does not hesitate to take as illustrative examples the familiar city of Oxford and his native county of Devon. He divides geography into *The Spherical Part*, or that for the study of which mathematics alone is required, and *The Topical Part*, or the description of the physical relations of parts of the Earth's surface, preferring this division to that favoured by the ancient geographers—into general and special. It is distinguished from other English geographical books of the period by confining attention to the principles of geography, and not describing the countries of the world.

Varenius.

A much more important work in the history of geographical method is the *Geographia Generalis* of Bernhard Varenius, a German medical doctor of Leyden, who died at the age of twenty-eight in 1650, the year of the publication of his book. It was so highly esteemed that an annotated edition was published in Cambridge in 1672 by Sir Isaac Newton, with the addition of the plates which had been planned by Varenius, but not produced by the original publishers.

"The reason why this great man took so much care in correcting and publishing our author was, because he thought him necessary to be read by his audience, the young gentlemen of Cambridge, while he was delivering lectures on the same subject from the Lucasian Chair."[2]

The treatise of Varenius is a model of logical arrangement and terse expression; it is a work of science and of genius; one of the few of that age which can still be studied with profit. The English translation renders the definition thus: "Geography is that part of *mixed mathematics* which explains the state of the Earth and of its parts, depending on quantity, viz., its figure, place, magnitude, and motion, with the celestial appearances, &c. By some it is taken in too limited a sense, for a bare description of the several countries; and by others too extensively, who along with such a description would have their political constitution."

Varenius was reluctant to include the human side of geography in his system, and only allowed it as a concession to custom, and in order to attract readers by imparting interest to the sterner details of the science. His division of geography was into two parts—(i.) General or universal, dealing with the Earth in general, and explaining its properties without regard to particular countries; and (ii.) Special or particular, dealing with each country in turn from the chorographical or topographical point of view. General geography was divided into—(1) the *Absolute* part, dealing with the form, dimensions, posi-

[1] The period of the early Middle Ages is dealt with in Beazley's *Dawn of Modern Geography*, London, 1897.

[2] From translator's preface to the English version by Mr Dugdale (1733), entitled *A Complete System of General Geography*, revised by Dr Peter Shaw, London, 1756.

tion, and substance of the Earth, the distribution of land and water, mountains, woods, and deserts, hydrography (including all the waters of the Earth), and the atmosphere; (2) the *Relative* part, including the celestial properties, *i.e.*, latitude, climate zones, longitude, &c.; and (3) the *Comparative* part, which "considers the particulars arising from comparing one part with another"; but under this head the questions discussed were longitude, the situation and distances of places, and navigation. Varenius does not treat of special geography, but gives a scheme for it under three heads—(1) *Terrestrial*, including position, outline, boundaries, mountains, mines, woods and deserts, waters, fertility and fruits, and living creatures; (2) *Celestial*, including appearance of the heavens and the climate; (3) *Human*, but this was added out of deference to popular usage.

This system of geography founded a new epoch, and the book—translated into English, Dutch, and French—was the unchallenged standard for more than a century. The framework was capable of accommodating itself to new facts, and was indeed far in advance of the knowledge of the period. The method included a recognition of the causes and effects of phenomena as well as the mere fact of their occurrence, and for the first time the importance of the vertical relief of the land was fairly recognized.

The physical side of geography continued to be elaborated after Varenius's methods, while the historical side was developed separately. Both branches, although enriched by new facts, remained stationary so far as method is concerned until nearly the end of the 18th century. The compilation of "geography books" by uninstructed writers led to the pernicious habit, which is not yet wholly overcome, of reducing the general or "physical" part to a few pages of concentrated information, and expanding the particular or "political" part by including unrevised travellers' stories and uncritical descriptions of the various countries of the world. Such books were in fact not geography, but merely compressed travel.

Bergmann.

The next marked advance in the theory of geography may be taken as the nearly simultaneous studies of the physical Earth carried out by the Swedish chemist, Torbern Bergmann, acting under the impulse of Linnæus, and by the German philosopher, Immanuel Kant. Bergmann's *Physical Description of the Earth* was published in Swedish in 1766, and translated into English in 1772 and into German in 1774. It is a plain, straightforward description of the globe, and of the various phenomena of the surface, dealing only with definitely ascertained facts in the natural order of their relationships, but avoiding any systematic classification or even definitions of terms.

Kant.

The problems of geography had been lightened by the destructive criticism of the French cartographer D'Anville (who had purged the map of the world of the last remnants of traditional fact unverified by modern observations) and rendered richer by the dawn of the new era of scientific travel, when Kant brought his logical powers to bear upon them. Kant's lectures on physical geography were delivered in the University of Königsberg from 1765 onwards.[1] Geography appealed to him as a valuable educational discipline, the joint foundation with anthropology of that "knowledge of the world" which was the result of reason and experience. In this connexion he divided the communication of experience from one person to another into two categories — the narrative or historical and the descriptive or geographical; both history and geography being viewed as descriptions, the former a description in order of time, the latter a description in order of space.

Physical geography he viewed as a summary of nature, the basis not only of history but also of "all the other possible geographies," of which he enumerates five, viz., (1) *Mathematical geography*, which deals with the form, size, and movements of the Earth and its place in the solar system; (2) *Moral geography*, or an account of the different customs and characters of mankind according to the region they inhabit; (3) *Political geography*, the divisions according to their organized governments; (4) *Mercantile geography*, dealing with the trade in the surplus products of countries; (5) *Theological geography*, or the distribution of religions. Here there is a clear and formal statement of the interaction and causal relation of all the phenomena of distribution on the Earth's surface, including the influence of physical geography upon the various activities of mankind from the lowest to the highest. Notwithstanding the form of this classification, Kant himself treats mathematical geography as preliminary to, and therefore not dependent on, physical geography. Physical geography itself is divided into two parts: a general, which has to do with the Earth and all that belongs to it—water, air, and land; and a particular, which deals with special products of the Earth—mankind, animals, plants, and minerals. Particular importance is given to the vertical relief of the land, on which the various branches of human geography are shown to depend.

Humboldt.

Alexander von Humboldt was the first modern geographer to become a great traveller, and thus to acquire an extensive stock of first-hand information on which an improved system of geography might be founded. The impulse given to the study of natural history by the example of Linnæus; the results brought back by Sir Joseph Banks, Dr Solander, and the two Forsters, who accompanied Cook in his voyages of discovery; the studies of De Saussure in the Alps, and the lists of desiderata in physical geography drawn up by that investigator, combined to prepare the way for Humboldt. The theory of geography was advanced by Humboldt mainly by his insistence on the great principle of the unity of nature. He brought all the "observable things," which the eager collectors of the previous century had been heaping together regardless of order or system, into relation with the vertical relief and the horizontal forms of the Earth's surface. Thus he demonstrated that the forms of the land exercise a directive and determining influence on climate, plant life, animal life, and on man himself. This was no new idea; it had been familiar for centuries in a less definite form, deduced from *à priori* considerations, and so far as regards the influence of surrounding circumstances upon man, Kant had already given it full expression. Humboldt's concrete illustrations and the remarkable power of his personality enabled him to enforce these principles in a way that produced an immediate and lasting effect. The treatises on physical geography by Mrs Mary Somerville and Sir John Herschel (the latter written for the eighth edition of the *Encyclopædia Britannica*) showed the effect produced by the stimulus of Humboldt's work in Great Britain.

Ritter.

Humboldt's contemporary, Carl Ritter, extended and disseminated the same views, and in his interpretation of "Comparative Geography" he laid stress on the importance of forming conclusions, not from the study of one region by itself, but from the comparison of the phenomena of many places. Impressed by the influence of terrestrial relief and climate on human movements, Ritter was led deeper and deeper into the study of history and archæology. His monumental "Vergleichende

[1] Printed in *Schriften zur Physischen Geographie*, vol. vi. of Schubert's edition of the collected works of Kant, Leipzig, 1839. First published with notes by Rink in 1802.

Geographie," which was to have made the whole world its theme, died out in a wilderness of detail in twenty-one volumes before it had covered more of the Earth's surface than Asia and a portion of Africa. Some of his followers showed a tendency to look on geography rather as an auxiliary to history than as a study of intrinsic worth.

Geography as a natural science.

During the rapid development of physical geography many branches of the study of nature, which had been included in the cosmography of the early writers, the physiography of Linnæus and even the *Erdkunde* of Ritter, had been so much advanced by the labours of specialists that their connexion was apt to be forgotten. Thus geology, meteorology, oceanography, and anthropology developed into distinct sciences. The absurd attempt was, and sometimes is still, made by geographers to include all natural science in geography; but it is more common for specialists in the various detailed sciences to think, and sometimes to assert, that the ground of physical geography is now fully occupied by these sciences. Political geography has been too often looked on from both sides as a mere summary of guide-book knowledge, useful in the schoolroom, a poor relation of physical geography that it was rarely necessary to recognize.

The science of geography, passed on from antiquity by Ptolemy, re-established by Varenius and Newton, and systematized by Kant, included within itself definite aspects of all those terrestrial phenomena which are now treated exhaustively under the heads of geology, meteorology, oceanography, and anthropology; and the inclusion of the requisite portions of the perfected results of these sciences in geography is simply the gathering in of fruit matured from the seed scattered by geography itself.

The study of geography was advanced by improvements in cartography (see MAPS), not only in the methods of survey and projection, but in the representation of the third dimension by means of contour lines introduced by Buache in 1737, and the more remarkable because less obvious invention of isotherms and isobars introduced by Humboldt in 1817.

The teleological argument in geography.

The "argument from design" had been a favourite form of reasoning amongst Christian theologians, and, as worked out by Paley in his *Natural Theology*, it served the useful purpose of emphasizing the fitness which exists between all the inhabitants of the Earth and their physical environment. It was held that the Earth had been created so as to fit the wants of man in every particular. This argument was tacitly accepted or explicitly avowed by almost every writer on the theory of geography, and Carl Ritter distinctly recognized and adopted it as the unifying principle of his system. As a student of nature, however, he did not fail to see, and as professor of geography he always taught, that man was in very large measure conditioned by his physical environment. The apparent opposition of the observed fact to the assigned theory he overcame by looking upon the forms of the land and the arrangement of land and sea as instruments of Divine Providence for guiding the destiny as well as for supplying the requirements of man. This was the central theme of Ritter's philosophy; his religion and his geography were one, and the consequent fervour with which he pursued his mission goes far to account for the immense influence he acquired in Germany.

The theory of evolution in geography.

The evolutionary theory, more than hinted at in Kant's "Physical Geography," has, since the writings of Charles Darwin, become the unifying principle in geography. The conception of the development of the plan of the Earth from the first cooling of the surface of the planet throughout the long geological periods, the guiding power of environment on the circulation of water and of air, on the distribution of plants and animals, and finally on the movements of man, give to geography a philosophical dignity and a scientific completeness which it never previously possessed. The influence of environment on the organism may not be quite so potent as it was once believed to be, in the writings of Buckle for instance,[1] and certainly man, the ultimate term in the series, reacts upon and greatly modifies his environment; yet the fact that environment does influence all distributions is established beyond the possibility of doubt. In this way also the position of geography, at the point where physical science meets and mingles with mental science, is explained and justified. The change which took place during the 19th century in the substance and style of geography may be best seen by comparing the eight volumes of Malte-Brun's *Géographie Universelle* (Paris, 1812–29) with the twenty-one volumes of Reclus's *Géographie Universelle* (Paris, 1876–95).

In estimating the influence of recent writers on geography it is usual to assign to Peschel the credit of having corrected the preponderance which Ritter gave to the historical element, and restoring physical geography to its old pre-eminence.[2] As a matter of fact, each of the leading exponents of theoretical geography at the present time—such as Richthofen, Wagner, Ratzel, Davis, Penck, De Lapparent, and Reclus—has his individual point of view, one devoting more attention to the results of geological processes, another to anthropological conditions, and the rest viewing the subject in various blendings of the extreme lights.

The two conceptions which may now be said to animate the theory of geography are the genetic, which depends upon processes of origin, and the morphological, which depends on facts of form and distribution.

THE PRINCIPLES OF GEOGRAPHY.

As regards the scope of geography, the order of the various departments and their inter-relation, there is little difference of opinion, and the principles of geography[3] are now generally accepted by modern geographers. The order in which the various subjects are treated in the following sketch is the natural succession from fundamental to dependent facts, which corresponds also to the evolution of the diversities of the Earth's crust and of its inhabitants.

Mathematical geography.

The fundamental geographical conceptions are mathematical, the relations of space and form. The figure and dimensions of the Earth are the first of these. They are ascertained by a combination of actual measurement of the highest precision on the surface and angular observations of the positions of the heavenly bodies. The science of geodesy is part of mathematical geography, of which the arts of surveying and cartography are applications. The motions of the Earth as a planet must be taken into account, as they render possible the determination of position and direction by observations of the heavenly bodies. The diurnal rotation of the Earth furnishes two fixed points or poles, the axis joining which is fixed or nearly so in its direction in space. The rotation of the Earth thus fixes the directions of north and south and defines those of east and west. The angle which the Earth's axis makes with the plane in which the planet revolves round the sun determines the varying seasonal distribution of solar radiation over the surface and the mathematical zones of climate. Another important consequence of rotation is the deviation produced in moving bodies relatively to the surface. In the form known as Ferrell's Law this runs: "If a body moves in any direction on the Earth's surface, there is a deflecting force which arises from the Earth's rotation which tends to deflect it to the right in the northern hemisphere but to the left in the southern hemisphere." The deviation is of importance in the movement of air, of ocean currents, and to some degree of rivers.[4]

Physical geography.

In popular usage the words "physical geography" have come to mean geography viewed from a particular standpoint rather than any special department of the subject. The popular meaning is better conveyed by the word physiography, a term which appears to have been introduced by Linnæus, and was re-invented as a substitute for the cosmography of the Middle Ages by Professor Huxley. Although the term has since been limited by some writers to one particular part of the subject, it seems best to maintain the original and literal meaning. In the stricter sense, physical geography is that part of geography which involves the processes of contemporary change in the crust and the circulation of the fluid envelopes. It thus draws upon physics for the explanation of the phenomena with the space-relations of which it is specially concerned. Physical geography naturally falls into three divisions, dealing respectively with the surface of the lithosphere—geomorphology; the hydrosphere—oceanography; and the atmosphere—climatology. All these rest upon the facts of mathematical geography, and the three are so closely inter-related that they cannot be rigidly separated in any discussion. Oceanography and climatology are treated in some detail in special articles, the latter forming an essential part of meteorology.

Geomorphology.

Geomorphology is the part of geography which deals with terrestrial relief, including the submarine as well as the subaërial portions of the crust. The history of the origin of the various forms belongs to geology, and can be completely studied only by geological methods. But the relief of the crust is not a finished piece of sculpture; the forms are for the most part transitional, owing their characteristic outlines to the process by which they are produced; therefore the

[1] *History of Civilization*, vol. i., 1857.

[2] See H. J. Mackinder in *British Association Report* (Ipswich), 1895, p. 738, for a summary of German opinion, which has been expressed by many writers in a somewhat voluminous literature.

[3] This phrase is old, appearing in one of the earliest English works on geography, William Cuningham's *Cosmographical Glasse conteinyng the pleasant Principles of Cosmographie, Geographie, Hydrographie, or Navigation*, London, 1559.

[4] See also S. Günther, *Handbuch der Mathematischen Geographie*, Stuttgart, 1890.

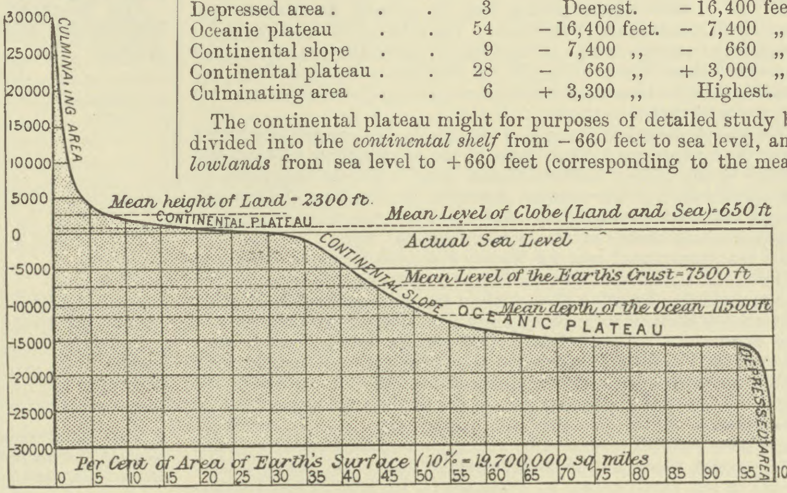
geographer must, for strictly geographical purposes, take some account of the processes which are now in action modifying the forms of the crust. Opinion differs greatly as to the extent to which the geographer's work should overlap that of the geologist.

The primary distinction of the forms of the crust is that between elevations and depressions. Granting that the geoid or mean surface of the ocean is a uniform spheroid, the distribution of land and water approximately indicates a division of the surface of the globe into two areas, one of elevation and one of depression. The increasing number of measurements of the height of land in all continents and islands, and the very detailed levellings in those countries which have been thoroughly surveyed, enable the average elevation of the land above sea level to be fairly estimated, although many vast gaps in accurate knowledge remain, and the estimate is not an exact one. The only part of the sea-bed the configuration of which is at all well known is the zone bordering the coasts where the depth is less than about 100 fathoms or 200 metres, *i.e.*, those parts which sailors speak of as "in soundings." Actual or projected routes for telegraph cables across the deep sea have also been sounded with extreme accuracy in many cases; but beyond these lines of sounding the vast spaces of the ocean remain unplumbed save for the rare researches of scientific expeditions, such as those of the *Challenger*, the *Valdivia*, and the *Albatross*. Thus the best approximation to the average depth of the ocean is little more than an expert guess.

Crustal relief.

The chief element of uncertainty as to the largest features of the relief of the Earth's crust is due to the unexplored area in the Arctic region and the far vaster regions of the Antarctic, of which we know nothing. We know that the Earth's surface if unveiled of water would exhibit a great region of elevation arranged with a certain rough radiate symmetry round the north pole, and extending southwards in three unequal arms which taper to points in the south. A great depression surrounds the unknown south polar region in a continuous ring and extends northwards in three vast hollows lying between the arms of the elevated area. So far it is possible to speak with certainty, but it is permissible to take a few steps into the twilight of dawning knowledge and indicate the chief subdivisions which are likely to be established in the great crust-hollow and the great crust-heap. The boundary between these should obviously be the mean surface of the sphere.

Sir John Murray deduced the mean height of the land of the globe as about 2250 feet above sea level, and the mean depth of the oceans as 2080 fathoms or 12,480 feet below sea level.[1] Calculating the area of the land at 55,000,000 square miles (or 28·6 per cent. of the surface), and that of the oceans as 137,200,000 square miles (or 71·4 per cent. of the surface), he found that the volume of the land above sea level was 23,450,000 cubic miles, the volume of water below sea level 323,800,000, and the total volume of the water equal to about $\frac{1}{666}$th of the volume of the whole globe. From these data, as revised by A. Supan,[2] H. R. Mill calculated the position of mean sphere level at about 10,000 feet or 1700 fathoms below sea level. He showed that an imaginary spheroidal shell, concentric with the Earth and cutting the slope between the elevated and depressed areas at the contour-line of 1700 fathoms, would not only leave above it a volume of the crust equal to the volume of the hollow left below it, but would also divide the surface of the Earth so that the area of the elevated region was equal to that of the depressed region.[3]



Areas of the crust, according to Murray.

A similar observation was made almost simultaneously by Romieux,[4] who further speculated on the equilibrium between the weight of the elevated land mass and that of the total waters of the ocean, and deduced some extremely interesting relations between them. Murray, as the result of his study, divided the Earth's surface into three zones—the *continental area* containing all dry land, the *transitional area* including the submarine slopes down to 1000 fathoms, and the *abysmal area* consisting of the floor of the ocean beyond that depth; and Mill proposed to take the line of mean-sphere level, instead of the empirical depth of 1000 fathoms, as the boundary between the transitional and abysmal areas.

An elaborate criticism of all the existing data regarding the volume relations of the vertical relief of the globe was made in 1894 by Professor Hermann Wagner, whose recalculations of volumes and mean heights—the best results which have yet been obtained—led to the following conclusions.[5]

Areas of the crust, according to Wagner.

The area of the dry land was taken as 28·3 per cent. of the surface of the globe, and that of the oceans as 71·7 per cent. The mean height deduced for the land was 2300 feet above sea level, the mean depth of the sea 11,500 feet below, while the position of mean-sphere level comes out as 7500 feet (1250 fathoms) below sea level. From this it would appear that 43 per cent. of the Earth's surface was above, and 57 per cent. below, the mean level. It must be noted, however, that since 1895 the soundings of Nansen in the north polar area, of the *Valdivia* in the Southern Ocean, and of various surveying ships in the North and South Pacific, have proved that the mean depth of the ocean is very considerably greater than had been supposed, and mean-sphere level must therefore lie deeper than the calculations of 1895 show; possibly not far from the position deduced from the freer estimate of 1888. By the device of a hypsographic curve co-ordinating the vertical relief and the areas of the Earth's surface occupied by each zone of elevation, according to the system introduced by Supan,[6] Wagner showed his results graphically.

This curve with the values reduced from metres to feet is reproduced below.

Wagner subdivides the Earth's surface, according to elevation, into the following five regions:—

WAGNER'S DIVISIONS OF THE EARTH'S CRUST.

Name.	Per cent. of Surface.	From	To
Depressed area . . .	3	Deepest.	−16,400 feet.
Oceanie plateau . . .	54	−16,400 feet.	− 7,400 ,,
Continental slope . . .	9	− 7,400 ,,	− 660 ,,
Continental plateau . . .	28	− 660 ,,	+ 3,000 ,,
Culminating area . . .	6	+ 3,300 ,,	Highest.

The continental plateau might for purposes of detailed study be divided into the *continental shelf* from −660 feet to sea level, and *lowlands* from sea level to +660 feet (corresponding to the mean level of the whole globe).[7] *Uplands* reaching from 660 feet to 2300 (the approximate mean level of the land), and *highlands*, from 2300 upwards, might also be distinguished.

Arrangement of world-ridges and hollows.

A striking fact in the configuration of the crust is that each continent, or elevated mass of the crust, is diametrically opposite to an ocean basin or great depression; the only partial exception being in the case of southern South America, which is antipodal to eastern Asia. Professor Lapworth has generalized the grand features of crustal relief in a scheme of attractive simplicity. He sees throughout all the chaos of irregular crust-forms the recurrence of a certain harmony, a succession of folds or waves which build up all the minor features.[8] One great series of crust waves from east to west is crossed by a second great series of crust waves from north to south, giving rise by their interference to six great elevated masses (the continents), arranged in three groups, each consisting of a northern and a southern member separated by a

[6] *Petermanns Mitteilungen*, xxxv. (1889), p. 19.

[7] The areas of the continental shelf and lowlands are approximately equal, and it is an interesting circumstance that, taken as a whole, the actual coast-line comes just midway on the most nearly level belt of the Earth's surface, excepting the ocean floor. The detailed configuration of some portions of the continental slope has been made the subject of speculation by Hull in *Trans. Victoria Inst.*, London, xxxi. (1899), p. 269, and of discussion by Hudleston in *Geological Mag.* vi. (1899), pp. 97, 145.

[8] *British Association Report* (Edinburgh), 1892, p. 699.

minor depression. These elevated masses are divided from one another by similar great depressions.

Lapworth's fold-theory.

He says :—"The surface of each of our great continental masses of land resembles that of a long and broad arch-like form, of which we see the simplest type in the New World. The surface of the North American arch is sagged downwards in the middle into a central depression which lies between two long marginal plateaux, and these plateaux are finally crowned by the wrinkled crests which form its two modern mountain systems. The surface of each of our ocean floors exactly resembles that of a continent turned upside down. Taking the Atlantic as our simplest type, we may say that the surface of an ocean basin resembles that of a mighty trough or syncline, buckled up more or less centrally in a medial ridge, which is bounded by two long and deep marginal hollows, in the cores of which still deeper grooves sink to the profoundest depths. This complementary relationship descends even to the minor features of the two. Where the great continental sag sinks below the ocean level, we have our gulfs and our Mediterraneans, seen in our type continent, as the Mexican Gulf and Hudson Bay. Where the central oceanic buckle attains the water-line we have our oceanic islands, seen in our type ocean, as St Helena and the Azores. Although the apparent crust-waves are neither equal in size nor symmetrical in form, this complementary relationship between them is always discernible. The broad Pacific depression seems to answer to the broad elevation of the Old World—the narrow trough of the Atlantic to the narrow continent of America."

Suess's theory.

The most thorough discussion of the great features of terrestrial relief in the light of their origin is that by Professor Suess,[1] who points out that the plan of the Earth is the result of two movements of the crust—one, subsidence over wide areas, giving rise to oceanic depressions and leaving the continents protuberant ; the other, folding along comparatively narrow belts, giving rise to mountain ranges. This theory of crust blocks dropped by subsidence is opposed to Lapworth's theory of vast crust-folds, but geology is the science which has to decide between them.

Geomorphology is concerned, however, in the suggestions which have been made as to the cause of the distribution of heap and hollow in the larger features of the crust. Élie de Beaumont, in his speculations on the relation between the direction of mountain ranges and their geological age and character, was feeling towards a comprehensive theory of the forms of crustal relief ; but his ideas were too geometrical, and his theory that the Earth is a spheroid built up on a rhombic dodecahedron, the pentagonal faces of which determined the direction of mountain ranges, could not be proved.[2] The theory brought forward by Lowthian Green[3] that the form of the Earth is a spheroid based on a regular tetrahedron is more serviceable, because it accounts for three very interesting facts of the terrestrial plan—(1) the antipodal position of continents and ocean basins ; (2) the triangular outline of the continents ; and (3) the excess of sea in the southern hemisphere. Recent investigations have recalled attention to the work of Lowthian Green, but the question is still in the controversial stage.[4] The study of tidal strain in the Earth's crust by Professor G. H. Darwin has led that physicist to indicate the possibility of the triangular form and southerly direction of the continents being a result of the differential or tidal attraction of the sun and moon.[5]

In any case it is fully recognized that the plan of the Earth is so clear as to leave no doubt as to its being due to some general cause which should be capable of detection.

The continents.

If the level of the sea were to become coincident with the mean level of the lithosphere, there would result one tri-radiate land-mass of nearly uniform outline and one continuous sheet of water broken by few islands. The actual position of sea level lies so near the summit of the crust-heap that the varied relief of the upper portion leads to the formation of a complicated coast-line and a great number of detached portions of land. The hydrosphere is, in fact, continuous, and the land is all in insular masses : the largest is the Old World of Europe, Asia, and Africa ; the next in size, America ; the third, possibly, Antarctica ; the fourth, Australia ; the fifth, Greenland. After this there is a considerable gap before New Guinea, Borneo,

Madagascar, Sumatra, and the vast multitude of smaller islands descending in size by regular gradations to mere rocks. The contrast between island and mainland was natural enough in the days before the discovery of Australia, and the mainland of the Old World was traditionally divided into three continents. These "continents," "parts of the Earth," or "quarters of the globe," proved to be convenient divisions ; America was added as a fourth, and subsequently divided into two, while Australia on its discovery was classed sometimes as a new continent, sometimes merely as an island, sometimes compromisingly as an island-continent, according to individual opinion. The discovery of the insularity of Greenland might again give rise to the argument as to the distinction between island and continent. Although the name of continent was not applied to large portions of land for any physical reasons, it so happens that there is a certain physical similarity or homology between them which is not shared by the smaller islands or peninsulas.

Homology of continents.

The typical continental form is triangular as regards its sea level outline. The relief of the surface typically includes a central plain, sometimes dipping below sea level, bounded by lateral highlands or mountain ranges, loftier on one side than on the other, the higher enclosing a plateau shut in by mountains. South America and North America follow this type most closely ; Eurasia (the land mass of Europe and Asia) comes next, while Africa and Australia are farther removed from the type, and the structure of Antarctica and Greenland is unknown.

If the continuous, unbroken, horizontal extent of land in a continent is termed its *trunk*,[6] and the portions cut up by inlets or channels of the sea into islands and peninsulas the *limbs*, it is possible to compare the continents in an instructive manner.

The following table is from the statistics of Professor H. Wagner,[7] his metric measurements being transposed into British units :—

COMPARISON OF THE CONTINENTS.

	Area (total) mil. sq. m.	Mean height, feet.	Area trunk, mil. sq. m.	Area peninsulas, mil. sq. m.	Area islands, mil. sq. m.	Area limbs, mil. sq. m.	Area limbs, per cent.
Old World .	35·8	2360					
New World .	16·2	2230					
Eurasia . .	20·85	2620	15·42	4·09	1·34	5·43	26
Africa . .	11·46	2130	11·22	...	0·24	0·24	2·1
North America	9·26	2300	6·92	0·78	1·56	2·34	25
South America	6·84	1970	6·76	0·02	0·06	0·08	1·1
Australia .	3·43	1310	2·77	0·16	0·50	0·66	19
Asia . .	17·02	3120	12·93	3·05	1·04	4·09	24
Europe . .	3·83	980	2·49	1·04	0·30	1·34	35

Islands.

The usual classification of islands is into continental and oceanic. The former class includes all those which rise from the continental shelf, or show evidence in the character of their rocks of having at one time been continuous with a neighbouring continent. The latter rise abruptly from the oceanic abysses. Oceanic islands are divided according to their geological character into volcanic islands and those of organic origin, including coral islands. More elaborate subdivisions according to structure, origin, and position have been proposed.[8] In some cases a piece of land is only an island at high water, and by imperceptible gradation the form passes into a peninsula. The typical peninsula is connected with the mainland by a relatively narrow isthmus ; the name is, however, extended to any limb projecting from the trunk of the mainland, even when, as in the Indian peninsula, it is connected by its widest part.

Coasts.

Small peninsulas are known as promontories or headlands, and the extremity as a cape. The opposite form, an inlet of the sea, is known when wide as a gulf, bay, or bight, according to size and degree of inflexion, or as a fjord or ria when long and narrow. It is convenient to employ a specific name for a projection of a coast-line less pronounced than a peninsula, and for an inlet less pronounced than a bay or bight ; outcurve and incurve may serve the turn. The varieties of coast-lines were reduced to an exact classification by Richthofen, who grouped them according to the height and slope of the land into cliff-coasts (*Steilküsten*)—narrow beach coasts with cliffs, wide beach coasts with cliffs, and low coasts, subdividing each group according as the coast-line runs parallel to or crosses the line of strike of the mountains, or is not related to mountain structure.

[6] *Rumpf*, in German, the language in which this distinction was first made.

[7] *Lehrbuch der Geographie*, Hanover and Leipzig, 1900, Bd. i. S. 245, 249.

[8] See, for example, F. G. Hahn's *Insel-Studien*, Leipzig, 1883.

A further subdivision depends on the character of the inter-relation of land and sea along the shore producing such types as a fjord-coast, ria-coast, or lagoon-coast. This extremely elaborate subdivision may be reduced, as Wagner points out, to three types—the continental coast where the sea comes up to the solid rock-material of the land; the marine coast, which is formed entirely of soft material sorted out by the sea; and the composite coast, in which both forms are combined.

Coast-lines. On large-scale maps it is necessary to show two coast-lines, one for the highest, the other for the lowest tide; but in small-scale maps a single line is usually wider than is required to represent the whole breadth of the inter-tidal zone. The measurement of a coast-line is difficult, because the length will necessarily be greater when measured on a large-scale map where minute irregularities can be taken into account. It is usual to distinguish between the general coast-line measured from point to point of the headlands disregarding the smaller bays, and the detailed coast-line which takes account of every inflexion shown by the map employed, and follows up river entrances to the point where tidal action ceases. The ratio between these two coast-lines represents the "coastal development" of any region.

Submarine forms. While the forms of the sea-bed are not yet sufficiently well known to admit of exact classification, they are recognized to be as a rule distinct from the forms of the land, and the importance of using a distinctive terminology is felt. Efforts are being made to arrive at a definite international agreement on this subject.[1]

In our present state of knowledge it would probably be sufficient to use *depression* as the general term for any hollow of the sea-bed, and to distinguish a relatively narrow depression as a *furrow* if the slope of the sides be gentle, and as a *trough* if the slope of the sides be steep. A relatively wide depression might be called a *basin* when the slope is gentle, and a *caldron* when it is abrupt. The word *deep*, often used in the general sense of a deep depression, might be reserved to indicate the deepest portion of a basin or caldron. The nearly flat part of the sea-bed in a depression might be termed a *floor*, and the steeply-sloping side of a depression, or of an elevation, a *wall*. The general term *elevation* might be applied to any inequality rising above the general level of the ocean floor; if relatively narrow it might be termed a *rise*, and if relatively wide a *bank*. For any elevation coming to within five fathoms of the surface, so as to become a danger to navigation, the word *shoal* should be retained. It is convenient to recognize one other form, the *shelf*, a nearly horizontal bank attached to land or to a wall, and bordered on the deeper side by an abrupt descent.

Land forms. The forms of the dry land are of infinite variety, and have been studied in great detail.[2] From the descriptive or topographical point of view, geometrical form alone should be considered; but the origin and geological structure of land forms must in many cases be taken into account when dealing with the function they exercise in the control of mobile distributions. The geographers who have hitherto given most attention to the forms of the land have been trained as geologists, and consequently there is a general tendency to make origin or structure the basis of classification rather than form alone.

The six elementary land forms. The fundamental form-elements may be reduced to the six proposed by Professor Penck as the basis of his double system of classification by form and origin.[3] These may be looked upon as being all derived by various modifications or arrangements of the single form-unit, the *slope* or inclined plane surface. No one form occurs alone, but always grouped together with others in various ways to make up districts, regions, and lands of distinctive characters. They are:—

(1) The *plane* or gently inclined uniform surface.

(2) The *scarp* or steeply inclined slope; this is necessarily of small extent except in the direction of its length.

(3) The *valley*, composed of two lateral parallel slopes inclined towards a narrow strip of plain at a lower level which itself slopes downwards in the direction of its length. Many varieties of this fundamental form may be distinguished.

(4) The *mount*, composed of a surface falling away on every side from a particular place. This place may either be a point, as in a volcanic cone, or a line, as in a mountain range or ridge of hills.

(5) The *hollow* or form produced by a land surface sloping inwards from all sides to a particular lowest place, the converse of a mount.

(6) The *cavern* or space entirely surrounded by a land surface.

Geology and land forms. These forms never occur scattered haphazard over a region, but always in an orderly subordination depending on their mode of origin. The dominant forms result from crustal movements, the subsidiary from secondary reactions during the action of the primitive forms on mobile distributions. The geological structure and the mineral composition of the rocks are often the chief causes determining the character of the land forms of a region. Thus the whole of the scenery of a limestone country depends on the solubility and permeability of the rocks, leading to the typical Karst-formations of caverns, swallow-holes, and underground stream courses, with the contingent phenomena of dry valleys and natural bridges. A sandy beach or desert owes its character to the mobility of its constituent sand-grains, which are readily drifted and piled up in the form of dunes. A region where volcanic activity has led to the embedding of dykes or bosses of hard rock amongst softer strata produces a plain broken by abrupt and isolated eminences.[4]

Classification of mountains. It would be impracticable to go fully into the varieties of each specific form; but, partly as an example of modern geographical classification, partly because of the exceptional importance of mountains amongst the features of the land, one exception may be made. The classification of mountains into types has usually had regard rather to geological structure than to external form, so that some geologists would even apply the name of a mountain range to a region not distinguished by relief from the rest of the country if it bear geological evidence of having once been a true range. A mountain may be described (it cannot be defined) as an elevated region of irregular surface rising comparatively abruptly from lower ground. The actual elevation of a summit above sea level does not necessarily affect its mountainous character; a gentle eminence, for instance, rising a few hundred feet above a tableland, even if at an elevation of say 15,000 feet, could only be called a hill.[5] But it may be said that any abrupt slope of 2000 feet or more in vertical height may justly be called a mountain, while abrupt slopes of lesser height may be called hills. Existing classifications, however, do not take account of any difference in kind between mountain and hills, although it is common in the German language to speak of *Hügelland*, *Mittelgebirge*, and *Hochgebirge* with a definite significance.

The simple classification employed by Professor James Geikie[6] into mountains of accumulation, mountains of elevation, and mountains of circumdenudation, is not considered sufficiently thorough by German geographers, who, following Richthofen, generally adopt a classification dependent on six primary divisions, each of which is subdivided. The terms employed, especially for the subdivisions, cannot be easily translated into other languages, and the English equivalents in the following table are only put forward tentatively:—

RICHTHOFEN'S CLASSIFICATION OF MOUNTAINS.[7]

I. *Tektonische Gebirge*—Tectonic mountains.
 (*a*) *Bruchgebirge oder Schollengebirge*—Block mountains.
  1. *Einseitige Schollengebirge oder Schollenrandgebirge*—Scarp or tilted block mountains.
   (i.) *Tafelscholle*—Table blocks.
   (ii.) *Abrasionsscholle*—Abraded blocks.
   (iii.) *Transgressionsscholle*—Blocks of unconformable strata.
  2. *Flexurgebirge*—Flexure mountains.
  3. *Horstgebirge*—Symmetrical block mountains.
 (*b*) *Faltungsgebirge*—Fold mountains.
  1. *Homöomorphe Faltungsgebirge*—Homomorphic fold mountains.
  2. *Heteromorphe Faltungsgebirge*—Heteromorphic fold mountains.
II. *Rumpfgebirge oder Abrasionsgebirge*—Trunk or abraded mountains.

IV. *Aufschüttungsgebirge*—Mountains of accumulation.
V. *Flachböden*—Plateaux.
   (*a*) *Abrasionsplatten*—Abraded plateaux.
   (*b*) *Marines Flachland*—Plain of marine erosion.
   (*c*) *Schichtungstafelland*—Horizontally stratified tableland.
   (*d*) *Uebergusstafelland*—Lava plain.
   (*e*) *Stromflachland*—River plain.
   (*f*) *Flachböden der atmosphärischen Aufschüttung*—Plains of æolian formation.
VI. *Erosionsgebirge*—Mountains of erosion.

From the morphological point of view it is more important to distinguish the groups of mountain forms, such as the *mountain mass* or group of mountains radiating from a centre, with the valleys furrowing their flanks spreading towards every direction; the *mountain chain* or line of heights, forming a long narrow ridge or series of ridges separated by parallel valleys; the *dissected plateau* or highland, divided into mountains of circumdenudation by a system of deeply-cut valleys; and the *isolated peak*, usually a volcanic cone or a hard rock mass left projecting after the softer strata which embedded it have been worn away (Monadnock of Professor Davis).

Mountain forms.

The geographical distribution of mountains is intimately associated with the great structural lines of the continents of which they form the culminating region. Lofty lines of fold mountains form the "backbones" of North America in the Rocky Mountains and the west coast systems, of South America in the Cordillera of the Andes, of Europe in the Pyrenees, Alps, Carpathians, and Caucasus, and of Asia in the mountains of Asia Minor, converging on the Pamirs and diverging thence in the Himalaya and the vast mountain systems of Central and Eastern Asia. The remarkable line of volcanoes around the whole coast of the Pacific and along the margin of the Caribbean and Mediterranean Seas is one of the most conspicuous features of the globe.

Distribution of mountains.

If land forms may be compared to organs, the part they serve in the economy of the Earth may, without straining the term, be characterized as function. The first and simplest function of the land surface is that of guiding loose material to a lower level. The downward pull of gravity suffices to bring about the fall of such material, but the path it will follow and the distance it will travel before coming to rest depend upon the land form. The loose material may, and in an arid region does, consist only of portions of the higher parts of the surface detached by the expansion and contraction produced by heating and cooling due to radiation. Such broken material rolling down a uniform scarp would tend to reduce its steepness by the loss of material in the upper part and by the accumulation of a mound or scree against the lower part of the slope. But where the side is not a uniform scarp, but made up of a series of ridges and valleys, the tendency will be to distribute the detritus in an irregular manner, directing it away from one place and collecting it in great masses in another, so that in time the land form assumes a new appearance. Snow accumulating on the higher portions of the land, when compacted into ice and caused to flow downwards by gravity, gives rise, on account of its more coherent character, to continuous glaciers, which mould themselves to the slopes down which they are guided, different ice-streams converging to send forward a greater volume. Gradually coming to occupy definite beds, which are deepened and polished by the friction, they impress a characteristic appearance on the land, which guides them as they traverse it, and, although the ice melts at lower levels, vast quantities of clay and broken stones are brought down and deposited in terminal moraines where the glacier ends.

Functions of land forms.

Land waste.

Glaciers.

Rain is by far the most important of the inorganic mobile distributions upon which land forms exercise their function of guidance and control. The precipitation of rain from the aqueous vapour of the atmosphere is dictated by the form and altitude of the land surface and the direction of the prevailing winds, which itself is largely influenced by the land. It is on the windward faces of the highest ground that most rain falls, and all that does not evaporate or percolate into the ground is conducted back to the sea by a route which depends only on the form of the land. More mobile and more searching than ice or rock rubbish, the trickling drops are guided by the deepest lines of the hillside in their incipient flow, and as these lines converge, the stream, gaining strength, proceeds in its torrential course to carve its channel deeper and entrench itself in permanent occupation. Thus the stream-bed, from which at first the water might be blown away into a new channel by a gale of wind, ultimately grows to be the strongest line of the landscape. As the main valley deepens, the tributary stream-beds are deepened also, and gradually cut their way headwards, enlarging the area whence they draw their supplies. Thus new land forms are created—valleys of curious complexity, for example—by the "capture" and diversion of the water of one river by another, leading to a change of watershed.[1] The minor tributaries become more numerous and more constant, until the system of torrents has impressed its own individuality on the mountain side. As the river leaves the mountain, ever growing by the accession of tributaries, it ceases, save in flood time, to be a formidable instrument of destruction; the gentler slope of the land surface gives to it only power sufficient to transport small stones, gravel, sand, and ultimately mud. Its valley banks are cut back by the erosion of minor tributaries, or by rain-wash if the climate be moist, or left steep and sharp while the river deepens its bed if the climate be arid. The outline of the curve of a valley's sides ultimately depends on the angle of repose of the detritus which covers them, if there has been no subsequent change, such as the passage of a glacier along the valley, which tends to destroy the regularity of the cross-section. The slope of the river bed diminishes until the plain compels the river to move slowly, swinging in meanders proportioned to its size, and gradually, controlled by the flattening land, ceasing to transport material, but raising its banks and silting up its bed by the dropped sediment, until, split up and shoaled, its distributaries struggle across its delta to the sea. This is the typical river of which there are infinite varieties, yet every variety would, if time were given, and the land remained unchanged in level relatively to the sea, ultimately approach to the type. Movements of the land either of subsidence or elevation, changes in the land by the action of erosion in cutting back an escarpment or cutting through a col, changes in climate by affecting the rainfall and the volume of water, all tend to throw the river valley out of harmony with the actual condition of its stream. There is nothing more striking in geography than the perfection of the adjustment of a great river system to its valleys when the land has remained stable for a very lengthened period. Before full adjustment has been attained the river bed may be broken in places by waterfalls or interrupted by lakes; after adjustment the bed assumes a permanent outline, the slope diminishing more and more gradually, without a break in its symmetrical descent. Excellent examples of the indecisive drainage of a new land surface, on which the river system has not had time to impress itself, are to be seen in northern Canada and in Finland, where rivers are separated by scarcely perceptible divides, and the numerous lakes frequently belong to more than one river system.

Rain.

River systems.

Adjustment of rivers to land.

The action of rivers on the land is so important that it has been made the basis of a system of physical geography by Professor W. M. Davis, who classifies land surfaces in terms of the three factors—structure, process, and time.[2] Of these time, during which the process is acting on the structure, is the most important. A land may thus be characterized by its position in the "geographical cycle," or cycle of erosion, as young, mature, or old, the last term being reached when the base-level of erosion is attained, and the land, however varied its relief may have been in youth or maturity, is reduced to a nearly uniform surface or peneplain. By a re-elevation of a peneplain the rivers of an old land surface may be restored to youthful activity, and resume their shaping action, deepening the old valleys and initiating new ones, starting afresh the whole course of the geographical cycle. It is, however, not the action of the running water on the land, but the function exercised by the land on the running water, that is considered here to be the special province of geography. At every stage of the geographical cycle the land forms, as they exist at that stage, are concerned in guiding the condensation and flow of water in certain definite ways. Thus, for example, in a mountain range at right angles to a prevailing sea-wind, it is the land forms which determine that one side of the range shall be richly watered and deeply dissected by a complete system of valleys, while the other side is dry, indefinite in its valley systems, and sends none of its scanty drainage to the sea. The action of rain, ice, and rivers conspires with the movement of land waste to strip the layer of soil from steep slopes as rapidly as it forms, and to cause it to accumulate on the flat valley bottoms, in the graceful flattened cones of alluvial fans at the outlet of the gorges of tributaries, or in the smoothly-spread surface of alluvial plains.

The geographical cycle.

The whole question of the régime of rivers and lakes is sometimes treated under the name hydrography, a name used by some writers in the sense of marine surveying, and by others as synonymous with oceanography. For the study of rivers alone the name potamology[3] has been suggested by Penck, and the

subject being of much practical importance has received a good deal of attention.[1]

The study of lakes has also been specialized under the name of limnology.[2] The existence of lakes in hollows of the land depends upon the balance between precipitation and evaporation. A stream flowing into a hollow will tend to fill it up, and the water will begin to escape as soon as its level rises high enough to reach the lowest part of the rim. In the case of a large hollow in a very dry climate the rate of evaporation may be sufficient to prevent the water from ever rising to the lip, so that there is no outflow to the sea, and a basin of internal drainage is the result. This is the case, for instance, in the Caspian Sea, the Aral and Balkhash lakes, the Tarim basin, the Sahara, inner Australia, the great basin of the United States, and the Titicaca basin. These basins of internal drainage are calculated to amount to 22 per cent. of the land surface. The percentages of the land surface draining to the different oceans are approximately —Atlantic, 34·3 per cent.; Arctic Sea, 16·5 per cent.; Pacific, 14·4 per cent.; Indian Ocean, 12·8 per cent.[3]

Lakes and internal drainage.

The parts of a river system have not been so clearly defined as is desirable, hence the exaggerated importance popularly attached to "the source" of a river. A well-developed river system has in fact many equally important and widely-separated sources, the most distant from the mouth, the highest, or even that of largest initial volume not being necessarily of greater geographical interest than the rest. The whole of the land which directs drainage towards one river is known as its basin, catchment area, or drainage area—sometimes, by an incorrect expression, as its valley or even its watershed. The boundary line between one drainage area and others is rightly termed the watershed, but on account of the ambiguity which has been tolerated it is better to call it water-parting, or, as in America, divide. The only other important term which requires to be noted here is *thalweg*, a word introduced from the German into French and English, and meaning the deepest line along the valley, which is necessarily occupied by a stream unless the valley is dry.

Terminology of river systems.

The functions of land forms extend beyond the control of the circulation of the atmosphere, the hydrosphere, and the water which is continually being interchanged between them; they are exercised with increased effect in the higher departments of biogeography and anthropogeography.

The sum of the organic life on the globe is termed by some geographers the biosphere, and it has been estimated that the whole mass of living substance in existence at one time would cover the surface of the Earth to a depth of one-fifth of an inch.[4] The distribution of living organisms is a complex problem, a function of many factors, several of which are yet but little known. They include the biological nature of the organism and its physical environment, the latter involving conditions in which geographical elements, direct or indirect, preponderate. The direct geographical elements are the arrangement of land and sea, continents and islands standing in sharp contrast, and the vertical relief of the globe, which interposes barriers of a less absolute kind between portions of the same land area or oceanic depression. The indirect geographical elements, which, as a rule, act with and intensify the direct, are mainly climatic; the prevailing winds, rainfall, mean and extreme temperatures of every locality depending on the arrangement of land and sea and of land forms. Climate thus guided affects the weathering of rocks, and so determines the kind and arrangement of soil. Different species of organisms come to perfection in different climates; and it may be stated as a general rule that a species, whether of plant or animal, once established at one point, would spread over the whole zone of the climate congenial to it unless some barrier were interposed to its progress. In the case of land and fresh-water organisms the sea is the chief barrier; in the case of marine organisms, the land. Differences in land forms do not exert great influence on the distribution of living creatures directly, but indirectly such land forms as mountain ranges and internal drainage basins are very potent through their action on soil and climate. A snow-capped mountain ridge or an arid desert forms a barrier between different forms of life which is often more effective than an equal breadth of sea. In this way the surface of the land is divided into numerous natural regions, the flora and fauna of each of which include some distinctive species not shared by the others. The distribution of life is discussed in the various articles in this Encyclopædia dealing with biological, botanical, and zoological subjects.[5]

Biogeography.

The classification of the land surface into areas inhabited by distinctive groups of plants has been attempted by many phytogeographers, but without resulting in any scheme of general acceptance. The simplest classification is perhaps that of Drude according to climatic zones, subdivided according to continents. This takes account of—(1) the *Arctic-Alpine* zone, including all the vegetation of the region bordering on perpetual snow; (2) the *Boreal* zone, including the temperate lands of North America, Europe, and Asia, all of which are substantially alike in botanical character; (3) the *Tropical* zone, divided sharply into (*a*) the tropical zone of the New World, and (*b*) the tropical zone of the Old World, the forms of which differ in a significant degree; (4) the *Austral* zone, comprising all continental land south of the equator, and sharply divided into three regions the floras of which are strikingly distinct—(*a*) South American, (*b*) South African, and (*c*) Australian; (5) the *Oceanic*, comprising all oceanic islands, the flora of which consists exclusively of forms whose seeds could be drifted undestroyed by ocean currents or carried by birds. To these might be added the antarctic, which is still practically unknown. Many subdivisions and transitional zones have been suggested by different authors.

Floral zones.

From the point of view of the economy of the globe this classification by species is perhaps less important than that by mode of life and physiological character in accordance with environment. The following are the chief areas of vegetational activity usually recognized:—(1) The ice-deserts of the arctic and antarctic and the highest mountain regions, where there is no vegetation except the lowest forms, like that which causes "red snow." (2) The tundra or region of intensely cold winters, forbidding tree-growth, where mosses and lichens cover most of the ground when unfrozen, and shrubs occur of species which in other conditions are trees, here stunted to the height of a few inches. A similar zone surrounds the permanent snow on lofty mountains in all latitudes. The tundra passes by imperceptible gradations into the moor, bog, and heath of warmer climates. (3) The temperate forests of evergreen or deciduous trees, according to circumstances, which occupy those parts of both temperate zones where rainfall and sunlight are both abundant. (4) The grassy steppes or prairies where the rainfall is diminished and temperatures are extreme, and grass is the prevailing form of vegetation. These pass imperceptibly into—(5) the arid desert, where rainfall is at a minimum, and the only plants are those modified to subsist with the smallest supply of water. (6) The tropical forest, which represents the maximum of plant luxuriance, stimulated by the heaviest rainfall, greatest heat, and strongest light. These divisions merge one into the other, and admit of almost indefinite subdivision, while they are subject to great modifications by human interference in clearing and cultivating. Plants exhibit the controlling power of environment to a high degree, and thus vegetation is usually in close adjustment to the bolder geographical features of a region.

Vegetation areas.

The divisions of the Earth into faunal regions by Dr P. L. Sclater have been found to hold good for a large number of groups of animals as different in their mode of life as birds and mammals, and they may thus be accepted as based on nature. They are six in number:—(1) *Palæarctic*, including Europe, Asia north of the Himalaya, and Africa north of the Sahara; (2) *Ethiopian*, consisting of Africa south of the Atlas range, and Madagascar; (3) *Oriental*, including India, Indo-China, and the Malay Archipelago north of Wallace's line, which runs between Bali and Lombok; (4) *Australian*, including Australia, New Zealand, New Guinea, and Polynesia; (5) *Nearctic* or North America, north of Mexico; and (6) *Neotropical* or South America. Each of these divisions is the home of a special fauna, many species of which are confined to it alone; in the Australian region, indeed, practically the whole fauna is peculiar and distinctive, suggesting a prolonged period of complete biological isolation. In some cases, such as the Ethiopian and Neotropical and the Palæarctic and Nearctic regions, the faunas, although distinct, are related, several forms on opposite sides of the Atlantic being analogous, *e.g.*, the lion and puma, ostrich and rhea. Where two of the faunal realms meet there is usually, though not always, a mixing of faunas. These facts have led some naturalists to include the Palæarctic and Nearctic regions in one, termed *Holarctic*, and to suggest transitional regions, such as the *Sonoran*, between North and South America, and the *Mediterranean*, between Europe and Africa, or to create sub-regions, such as Madagascar and New Zealand. Oceanic islands

Faunal realms.

have, as a rule, distinctive faunas and floras which resemble, but are not identical with, those of other islands in similar positions.

Biological distribution as a means of geographical research. The study of the evolution of faunas and the comparison of the faunas of distant regions have furnished a trustworthy instrument of pre-historic geographical research, which enables earlier geographical relations of land and sea to be traced out, and the approximate period, or at least the chronological order of the larger changes, to be estimated. In this way, for example, it has been suggested that a land, "Lemuria," once connected Madagascar with the Malay Archipelago, and that a northern extension of the antarctic land once united the three southern continents.

The distribution of fossils frequently makes it possible to map out approximately the general features of land and sea in long-past geological periods, and so to enable the history of crustal relief to be traced.[1]

Reaction of organisms on environment. While the tendency is for the living forms to come into harmony with their environment and to approach the state of equilibrium by successive adjustments if the environment should happen to change, it is to be observed that the action of organisms themselves often tends to change their environment. Corals and other quick-growing calcareous marine organisms are the most powerful in this respect by creating new land in the ocean. Vegetation of all sorts acts in a similar way, either in forming soil and assisting in breaking up rocks, in filling up shallow lakes, and even, like the mangrove, in reclaiming wide stretches of land from the sea. Plant life, utilizing solar light to combine the inorganic elements of water, soil, and air into living substance, is the basis of all animal life. This is not by the supply of food alone, but also by the withdrawal of carbonic acid from the atmosphere, by which vegetation maintains the composition of the air in a state fit for the support of animal life. Man in the primitive stages of culture is scarcely to be distinguished from other animals as regards his subjection to environment, but in the higher grades of culture the conditions of control and reaction become much more complicated, and the department of anthropogeography is devoted to their consideration.

Anthropogeography. The first requisites of all human beings are food and protection, in their search for which men are brought into intimate relations with the forms and productions of the Earth's surface. The degree of dependence of any people upon environment varies inversely as the degree of culture or civilization, which for this purpose may perhaps be defined as the power of an individual to exercise control over the individual and over the environment for the benefit of the community. The development of culture is to a certain extent a question of race, and although forming one species, the varieties of man differ in almost imperceptible gradations with a complexity defying classification (see ANTHROPOLOGY). Professor Keane groups man round four leading types, which may be named the black, yellow, red, and white, or the Ethiopic, Mongolic, American, and Caucasic. Each may be subdivided, though not with great exactness, into smaller groups, either according to physical characteristics, of which the form of the head is most important, or according to language.

Types of man. The black type is found only in tropical or sub-tropical countries, and is usually in a primitive condition of culture, unless educated by contact with people of the white type. They follow the most primitive forms of religion (mainly fetishism), live on products of the woods or of the chase, with the minimum of work, and have only a loose political organization. The red type is peculiar to America, inhabiting every climate from polar to equatorial, and containing representatives of many stages of culture which had apparently developed without the aid or interference of people of any other race until the close of the 15th century. The yellow type is capable of a higher culture, cherishes higher religious beliefs, and inhabits as a rule the temperate zone, although extending to the tropics on one side and to the arctic regions on the other. The white type, originating in the north temperate zone, has spread over the whole world. They have attained the highest culture, profess the purest forms of monotheistic religion, and have brought all the people of the black type and most of those of the yellow under their domination.

The actual number of human inhabitants in the world has been calculated as follows :—

	By Continents.[2]
Asia .	875,000,000
Europe .	392,000,000
Africa .	170,000,000
America .	143,000,000
Australia and Polynesia .	7,000,000
Total .	1,587,000,000

	By Race.[3]
White (Caucasic)	770,000,000
Yellow (Mongolic)	540,000,000
Black (Ethiopic)	175,000,000
Red (American)	22,000,000
Total .	1,507,000,000

In round numbers the population of the world is about 1,600,000,000, and, according to an estimate by Ravenstein,[4] the maximum population which it will be possible for the Earth to maintain is 6000 millions, a number which, if the present average rate of increase continues, will be reached within 200 years.

While highly civilized communities are able to evade many of the restrictions of environment, to overcome barriers to intercommunication interposed by land or sea, to counteract the adverse influence of climate, and by the development of trade even to inhabit countries which cannot yield a food supply, the mass of mankind is still completely under the control of those conditions which in the past determined the distribution and the mode of life of the whole human race.

Influence of environment on man. In tropical forests primitive tribes depend on the collection of wild fruits, and in a minor degree on the chase of wild animals, for their food. Clothing is unnecessary ; hence there is little occasion for exercising the mental faculties beyond the sense of perception to avoid enemies, or the inventive arts beyond what is required for the simplest weapons and the most primitive fortifications. When the pursuit of game becomes the chief occupation of a people there is of necessity a higher development of courage, skill, powers of observation and invention ; and these qualities are still further enhanced in predatory tribes who take by force the food, clothing, and other property prepared or collected by a feebler people. The fruit-eating savage cannot stray beyond his woods, which bound his life as the water bounds that of a fish ; the hunter is free to live on the margin of forests or in open country, while the robber or warrior from some natural stronghold of the mountains sweeps over the adjacent plains and carries his raids into distant lands. Wide grassy steppes lead to the organization of the people as nomads whose wealth consists in flocks and herds, and their dwellings are tents. The nomad not only domesticates and turns to his own use the gentler and more powerful animals, such as sheep, cattle, horses, camels, but even turns some predatory creatures, like the dog, into a means of defending their natural prey. They hunt the beasts of prey destructive to their flocks, and form armed bands for protection against marauders or for purposes of aggression on weaker sedentary neighbours. On the fertile low grounds along the margins of rivers or in clearings of forests, agricultural communities naturally take their rise, dwelling in villages and cultivating the wild grains, which by careful nurture and selection have been turned into rich cereals. The agriculturalist as a rule is rooted to the soil. The land he tills he holds, and acquires a closer connexion with a particular patch of soil than either the hunter or the herdsman. In the temperate zone, where the seasons are sharply contrasted, but follow each other with regularity, foresight and self-denial were fostered, because if men did not exercise these qualities seed-time or harvest might pass into lost opportunities and the tribes would suffer. The more extreme climates of arid regions on the margins of the tropics, by the unpredictable succession of droughts and floods, confound the prevision of uninstructed people, and make prudence and industry qualities too uncertain in their results to be worth cultivating. Thus the civilization of agricultural peoples of the temperate zone grew rapidly, yet in each community a special type arose adapted to the soil, the crop, and the climate. On the sea-shore fishing naturally became a means of livelihood, and dwellers by the sea, in virtue of the dangers to which they are exposed from storm and unseaworthy craft, are stimulated to a higher degree of foresight, quicker observation, prompter decision, and more energetic action in emergencies than those who live inland. The building and handling of vessels also, and the utilization of such uncontrollable powers of nature as wind and tide, helped forward mechanical invention. To every type of coast there may be related a special type of occupation and even of character ; the deep and gloomy fjord, backed by almost impassable mountains, bred bold mariners whose only outlet for enterprise was seawards towards other lands—the *viks* created the vikings. On the gently sloping margin of the estuary of a great river a view of tranquil inland life was equally presented to the shore-dweller, and the ocean did not present the only prospect of a career. Finally the mountain valley, with its patches of cultivable soil on the alluvial fans of tributary torrents, its narrow pastures on the uplands only left clear of snow in summer, its intensified extremes of climate and its isolation, almost equal to that of an island, has in all countries produced a special type of brave and hardy people, whose utmost effort may bring them comfort, but not wealth, by honest toil, who know little of the outer world, and to whom the natural outlet for ambition is marauding on the fertile plains. The highlander and viking, products of the valleys raised high amid the mountains or half-drowned in the sea, are everywhere of kindred spirit.

It is in some such manner as these that the natural conditions of regions, which must be conformed to by prudence and utilized

[1] See particularly A. de Lapparent, *Traité de Géologie*, 4th ed. Paris, 1900.

[4] In *Proc. R. G. S.* xiii. (1891), p. 27.

by labour to yield shelter and food, have led to the growth of peoples differing in their ways of life, thought, and speech. The initial differences so produced are confirmed and perpetuated by the same barriers which divide the faunal or floral regions, the sea, mountains, deserts, and the like, and much of the course of past history and present politics becomes clear when the combined results of differing race and differing environment are taken into account.[1]

Density of population.

The specialization which accompanies the division of labour has important geographical consequences, for it necessitates communication between communities and the interchange of their products. Trade makes it possible to work mineral resources in localities where food can only be grown with great difficulty and expense, or which are even totally barren and waterless, entirely dependent on supplies from distant sources.

The population which can be permanently supported by a given area of land differs greatly according to the nature of the resources and the requirements of the people. Pastoral communities are always scattered very thinly over large areas; agricultural populations may be almost equally sparse where advanced methods of agriculture and labour-saving machinery are employed; but where a frugal people are situated on a fertile and inexhaustible soil, such as the deltas and river plains of Egypt, India, and China, an enormous population may be supported on a small area. In most cases, however, a very dense population can only be maintained in regions where mineral resources have fixed the site of great manufacturing industries. The maximum density of population which a given region can support is very difficult to determine; it depends partly on the race and standard of culture of the people, partly on the nature and origin of the resources on which they depend, partly on the artificial burdens imposed, and very largely on the climate. Density of population is measured by the average number of people residing on a unit of area; but in order to compare one part of the world with another the average should, strictly speaking, be taken for regions of equal size or of equal population; and the portions of the country which are permanently uninhabitable ought to be excluded from the calculation.[2] Considering the average density of population within the political limits of countries, the following list is of some value; the figures for a few smaller divisions of large countries are added (in brackets) for comparison:—

Average Population on 1 Square Mile.

(For 1890 or 1891.)

Country.	Density of population.	Country.	Density of population
(Saxony)	650[3]	Greece	95
Belgium	560[3]	European Turkey	90
Java	510[4]	Spain	90
(England)	500	European Russia	55[4]
(Bengal)	470[4]	Sweden	30
Holland	390	United States	30
United Kingdom	300	Mexico	15
Japan	285	Norway	15
Italy	280	Persia	12 (estimate)
China proper	270[4] (estimate)	New Zealand	7
German Empire	250	Brazil	4·5
Austria	210	Argentina	2·3
Indian Empire	185[4]	Eastern States of Australia	1·7
France	185	Dominion of Canada	1·4
Switzerland	185	Siberia	1
Denmark	140[4]	West Australia	0·17
Hungary	140[4]		
Portugal	135		
Ceylon	120[4]		

Migration.

The movement of people from one place to another without the immediate intention of returning is known as migration, and according to its origin it may be classed as centrifugal (directed *from* a particular area) and centripetal (directed *towards* a particular area). Centrifugal migration is usually a matter of compulsion; it may be necessitated by natural causes, such as a change of climate leading to the withering of pastures or destruction of agricultural land, to inundation, earthquake, pestilence, or to an excess of population over means of support; or to artificial causes, such as the wholesale deportation of a conquered people; or to political or religious persecution. In any case the people are driven out by some adverse change; and when the urgency is great they may require to drive out in turn weaker people who occupy a desirable territory, thus propagating the wave of migration, the direction of which is guided by the forms of the land into inevitable channels. Many of the great historic movements of peoples were doubtless due to the gradual change of geographical or climatic conditions; and the slow desiccation of Central Asia has been plausibly suggested as the real cause of the peopling of modern Europe and of the mediæval wars of the Old World, the theatres of which were critical points on the great natural lines of communication between east and west.

In the case of centripetal migrations people flock to some particular place where exceptionally favourable conditions have been found to exist. The rushes to goldfields and diamond-fields are typical instances; the growth of towns on coalfields and near other sources of power, and the rapid settlement of such rich agricultural districts as the wheat-lands of the American prairies, are other examples.

There is, however, a tendency for people to remain rooted to the land of their birth, when not compelled or induced by powerful external causes to seek a new home.

Political geography.

Thus arises the spirit of patriotism, a product of purely geographical conditions, thereby differing from the sentiment of loyalty, which is of racial origin. Where race and soil conspire to evoke both loyalty and patriotism in a people, the moral qualities of a great and permanent nation are secured. It is noticeable that the patriotic spirit is strongest in those places where people are brought most intimately into relation with the land; dwellers in the mountain or by the sea, and, above all, the people of rugged coasts and mountainous archipelagoes, have always been renowned for love of country, while the inhabitants of fertile plains and trading communities are frequently less strongly attached to their own land.

Amongst nomads the tribe is the unit of government, the political bond is personal, and there is no definite territorial association of the people, who may be loyal but cannot be patriotic. The idea of a country arises only when a nation, either homogeneous or composed of several races, establishes itself in a region the boundaries of which may be defined and defended against aggression from without. Political geography takes account of the partition of the Earth amongst organized communities, dealing with the relation of races to regions, and of nations to countries, and considering the conditions of territorial equilibrium and instability.

Boundaries.

The definition of boundaries and their delimitation is one of the most important parts of political geography. Natural boundaries are always the most definite and the strongest, lending themselves most readily to defence against aggression. The sea is the most effective of all, and an island state is recognized as the most stable. Next in importance comes a mountain range, but here there is often difficulty as to the definition of the actual crest-line, and mountain ranges being broad regions, it may happen that a small independent state, like Switzerland or Andorra, occupies the mountain valleys between two or more great countries. Rivers do not form effective international boundaries, although between dependent self-governing communities they are convenient lines of demarcation. A desert, or a belt of country left purposely without inhabitants, like the mark, marches, or debatable lands of the Middle Ages, was once a common means of separating nations which nourished hereditary grievances. The "buffer-state" of modern diplomacy is of the same ineffectual type. A less definite though very practical boundary is that formed by the meeting-line of two languages, or the districts inhabited by two races. The line of fortresses protecting Austria from Italy lies in some places well back from the political boundary, but just inside the linguistic frontier, so as to separate the German and Italian races occupying Austrian territory. Arbitrary lines, either traced from point to point and marked by posts on the ground, or defined as portions of meridians and parallels, are now the most common type of boundaries fixed by treaty. In Europe and Asia frontiers are usually strongly fortified and strictly watched in times of peace as well as during war. In South America strictly defined boundaries are still the exception, and the claims of neighbouring nations continually give rise to wars or arbitrations.[5]

Forms of government.

The modes of government amongst civilized peoples have little influence on political geography; some republics are as arbitrary and exacting in their frontier regulations as some absolute monarchies. It is, however, to be noticed that absolute monarchies are confined to the east of Europe and to Asia, Japan being the only constitutional monarchy east of the Carpathians. Limited monarchies are (with the exception of Japan) peculiar to Europe, and in these the degree of democratic control may be said to diminish as one passes eastwards from the United Kingdom. Republics, although represented

[3] Almost exclusively industrial.

[4] Almost exclusively agricultural.

[5] For the history of territorial changes in Europe, see Freeman, *Historical Geography of Europe*, 2 vols., London, 1881; and for the official definition of existing boundaries, see Hertslet, *The Map of Europe by Treaty*, 4 vols., London, 1875, 1891; *The Map of Africa by Treaty*, 3 vols., London, 1896.

in Europe, are the peculiar form of government of America, and are unknown in Asia.

The forms of government of colonies present a series of transitional types from the autocratic administration of a governor appointed by the home Government to complete democratic self-government. The latter occurs only in the temperate possessions of the British empire, in which there is no great preponderance of a coloured native population. New colonial forms have been developed during the partition of Africa amongst European Powers, the sphere of influence being especially worthy of notice. This is a vaguer form of control than a protectorate, and frequently amounts merely to an agreement amongst civilized Powers to respect the right of one of their number to exercise government within a certain area at any future time.

The central governments of all civilized countries concerned with external relations are closely similar in their modes of action, but the internal administration may be very varied. In this respect a country is either centralized, like the United Kingdom or France, or federated of distinct self-governing units like Germany (where the units include kingdoms, at least three minor types of monarchies, municipalities and a crown land under a nominated governor), or the United States, where the units are democratic republics. The ultimate cause of the predominant form of federal government may be the geographical diversity of the country, as in the cantons occupying the once isolated mountain valleys of Switzerland, the racial diversity of the people, as in Austria-Hungary, or merely political expediency, as in republics of the American type.

The minor subdivisions into provinces, counties, and parishes, or analogous areas, may also be related in many cases to natural features or racial differences perpetuated by historical causes. The territorial divisions and subdivisions often survive the conditions which led to their origin; hence the study of political geography is allied to history as closely as the study of physical geography is allied to geology, and for the same reason.

Towns.

The aggregation of population in towns was at one time mainly brought about by the necessity for defence, a fact indicated by the defensive sites of many old towns. In later times, towns have been more often founded in proximity to valuable mineral resources, and at critical points or nodes on lines of communication. These are places where the mode of travelling or of transport is changed, such as seaports, river ports, and railway termini, or natural resting-places, such as a ford, the foot of a steep ascent on a road, the entrance of a valley leading up from a plain into the mountains, or a crossing-place of roads or railways.[1] The existence of a good natural harbour is often sufficient to give origin to a town and to fix one end of a line of land communication.

Lines of communication.

In countries of uniform surface or faint relief, roads and railways may be constructed in any direction without regard to the configuration. In places where the low ground is marshy, roads and railways often follow the ridge-lines of hills, or, as in Finland, the old glacial eskers, which run parallel to the shore. Wherever the relief of the land is pronounced, roads and railways are obliged to occupy the lowest ground winding along the valleys of rivers and through passes in the mountains. In exceptional cases obstructions which it would be impossible or too costly to turn are overcome by a bridge or tunnel, the magnitude of such works increasing with the growth of engineering skill and financial enterprise. Similarly the obstructions offered to water communication by interruption through land or shallows are overcome by cutting canals or dredging out channels. The economy and success of most lines of communication depend on following as far as possible existing natural lines and utilizing existing natural sources of power.[2]

Commercial geography.

Commercial geography may be defined as the description of the Earth's surface with special reference to the discovery, production, transport, and exchange of commodities. The transport concerns land routes and sea routes, the latter being the more important. While steam has been said to make a ship independent of wind and tide, it is still true that a long voyage even by steam must be planned so as to encounter the least resistance possible from prevailing winds and permanent currents, and this involves the application of oceanographical and meteorological knowledge. The older navigation by utilizing the power of the wind demands a very intimate knowledge of these conditions, and it is probable that a revival of sailing ships may in the present century vastly increase the importance of the study of maritime meteorology.

The discovery and production of commodities require a knowledge of the distribution of geological formations for mineral products, of the natural distribution, life-conditions, and cultivation or breeding of plants and animals, and of the labour market. Attention must also be paid to the artificial restrictions of political geography, to the legislative restrictions bearing on labour and trade as imposed in different countries, and, above all, to the incessant fluctuations of the economic conditions of supply and demand and the combinations of capitalists or workers which affect the market.[3] The term "applied geography" has been employed to designate commercial geography, the fact being that every aspect of scientific geography may be applied to practical purposes, including the purposes of trade. But apart from the applied science, there is an aspect of pure geography which concerns the theory of the relation of economics to the surface of the Earth.

Conclusion.

It will be seen that as each successive aspect of geographical science is considered in its natural sequence the conditions become more numerous, complex, variable, and practically important. From the underlying abstract mathematical considerations all through the physical, biological, anthropological, political, and commercial development of the subject runs the determining control exercised by crust-forms acting directly or indirectly on mobile distributions; and this is the essential principle of geography.

Progress of Geographical Discovery.

Recent exploration.

The last quarter of the 19th century witnessed no abatement of the spirit of exploration, almost all the remoter parts of the less known continents having been sought out and investigated. The marked lead taken by British explorers in the first part of the century has not been maintained; for many travellers from Germany, France, the United States, Italy, Austria-Hungary, Russia, and the Scandinavian countries have shared in the triumphs of discovery. The character of the explorations also has largely altered; the work has become more scientific, the surveys more exact, and the collections more systematic. The action of the Royal Geographical Society in supplying practical instruction to intending travellers, in astronomy, surveying, and the various branches of science useful to collectors, has had much to do with bringing about this change. The great development of photography has also been a notable aid, by placing at the disposal of travellers a faithful and ready means of recording the features of a country and the types of inhabitants.

With the exception of the Arctic and the Antarctic regions, very few places now remain absolutely unknown, and these only on account of the severity of natural conditions or the fanaticism of native peoples. The explorer ambitious to fill up a blank space on the map has now to turn his attention to a few comparatively small districts in the sub-arctic lands of Asia and North America, lying remote from the rivers which form the natural lines of communication; or to the highest parts of the great mountain ranges of Asia, the central wilds of the vast tropical forests of the Amazon basin, some corners of the Congo basin, the interior of Borneo and New Guinea; or to the heart of the arid deserts of the tropical continents. Although the greater part of the world has been explored and mapped, the accuracy of the work varies greatly, and only a small fraction of the land-surface has been surveyed with high precision.[4] And after the topographical and hypsometrical surveys are completed, much work remains to be done before statistics are available to enable all the distributions with which geography is concerned to be mapped with approximate completeness.

Geographical societies and publications.

The progress of exploration has been aided by the remarkable development of geographical societies, especially in France and Germany, since the war of 1870. There were in 1896 no fewer than 107 of these societies in the world (83 of them in Europe), with a total membership exceeding 50,000 persons; and in connexion with them, or appearing separately, there were 153 journals or magazines devoted entirely to geographical subjects.[5] In Germany there are professorships of geography in practically all universities, but the higher study of the subject has not been adequately encouraged hitherto in other countries. The superior quality of the exploring work done by recent travellers trained in Germany cannot be denied, where scientific study in the field, as distinct from mere surveying or the collection of specimens, is taken into account.

Europe.—In Europe the only region where exploration in the ordinary sense of the term has been carried out is Iceland, which has been very carefully studied from every point of view by several travellers, pre-eminent amongst whom is Dr Thorvald Thoroddsen, a native of the island. In all countries the topographical surveys have been pushed forward and, in the United Kingdom, France, Germany, Switzerland, and Austria-Hungary, practically completed by the respective governments. Detailed surveys of the coast have been similarly completed by the hydrographic departments of the maritime states, while private effort has been directed towards the sounding of the smaller lakes, many of the larger ones having been surveyed by national or international organizations. In this respect, Forel in Switzerland, Delebecque and Belloc in France, Ule and Halbfass in Germany, Simony, Penck, and Richter in Austria, Marinelli in Italy, Anuchin in Russia, Mill in England, and Murray and Pullar in Scotland may be mentioned.

Iceland.

Topographical surveys.

Lake surveys.

Detailed exploration of the Alps, Pyrenees, Carpathians, and Norwegian mountains have been made by the members of numerous Alpine clubs (see MOUNTAINEERING); and E. A. Martel in France has initiated the special study of caverns, a fascinating branch of minor exploration, to which the name Speleology has been applied, and to which attention is now directed in all European countries.

Mountain exploration.

Speleology.

The regional description of countries has only been carried out with systematic thoroughness in Finland, where the Geographical Society of Helsingfors has produced a remarkable *Atlas de Finlande*, with a volume of explanatory text, in a French as well as a Swedish edition. In Germany, under the stimulus of the German Geographical Congress (*Deutsche Geographentag*), a series of valuable monographs on different parts of the empire has been produced under the title of *Forschungen zur Deutschen Landes- und Volkskunde*, commenced in 1885 under the editorship of Professor A. Kirchhoff. Similar memoirs abound in the geographical journals of France, Austria, Russia, and in the geological publications of the United States and Canada. A systematic geographical description of the British Isles, based on the one-inch Ordnance Survey map, and utilizing the official statistics of all distributions, was suggested by Dr H. R. Mill in 1896, and a specimen memoir published in 1900.[1] All these are efforts to bring together synthetically the masses of discrete information accumulated by costly public surveys, which at present convey no definite impression to the mind, because the facts of the mobile distributions with which many of them deal are treated without reference to the land-forms.

Regional descriptions.

Asia.—Although made as long ago as 1864, the journey of Prince Peter Kropotkin in the Trans-Baikal province of Siberia and northern Manchuria was not generally known in western Europe until recently. It supplied him with data which led to an entire change in the theory of the mountain system of Asia as a whole, and opened the way to a generation of profitable exploration. Next in importance come the journeys of Baron von Richthofen in China in the years 1868–72, in which the geological structure and the vast mineral wealth of that country were first clearly established. It was a purely scientific journey, and after thirty years led to an important political result, for it was on Richthofen's recommendation that the bay of Kiaochow was selected for the German *pied-à-terre* in China, and the province of Shantung as a German "sphere of influence."

Kropotkin.

Richthofen.

During the whole period under consideration Dr Gustav Radde of the Tiflis Museum has been carrying on a series of exploring journeys in the Caucasus, where also the Russian surveyors have been at work.

Caucasus and Trans-Caspian.

M. Lessar did valuable service on the Turkestan frontier, and General Annenkoff succeeded in bridging the Trans-Caspian deserts by the railway which was opened to Samarcand in 1888, and to Tashkent and Ardijan in 1899, thus furnishing ready access to the borders of Chinese Turkestan.

In 1876 M. Potanin settled the question of the eastern extension of the Altai, and more recently he and other Russian explorers made important researches on the mountain systems of northern China, the northern buttresses of the Tibet plateau, and the Pamirs. The name of Prjevalsky deserves special distinction in this respect. Commencing his serious explorations in 1871, he rediscovered in 1885 the remarkable lake, Lob-nor, in which the Tarim river terminates, and made numerous attempts to penetrate to Lhasa, both from the north and from the east, on one occasion getting to within 160 miles of the forbidden city before being turned back. He had set out on a fresh expedition in 1888 when he died near Issyk-kul. The expedition was carried on by Pyevtsoff, Roborovski, Kosloff, and Bogdanovich, who have since continued to do valuable work in exploring and surveying the borders of Tibet and Mongolia.

Russian explorers in Tibet.

Prjevalsky.

Obrucheff and other Russian explorers in ever-increasing numbers, in the south of the Russian possessions and in north-western China, have cleared up the orography of that region; and the surveys of the Russian railway engineers have carried the line of exact measurements across the whole breadth of Eurasia from sea to sea.

Russian explorers in Siberia.

The Kurile islands in the north-east of Asia have been carefully charted by Captain H. J. Snow, an old sealing skipper, whose knowledge of these little-frequented seas is unique.

Snow.

The problems of Tibet and Central Asia have held the first place in the exploration of Asia, and the former has acquired a romantic interest and a quite fanciful importance on account of the determination of the Tibetan authorities that no European shall be permitted to enter Lhasa. Tibetan exploration was for many years promoted by the Indian Government by the training of native surveyors, amongst whom the names of Nain Singh, Krishna or Kishin Singh (known during his service as A-K), Lama Ugyen Gyacho (known as U-G), and Sarat Chandra Das deserve special distinction. The conscientious surveys of these men in Tibet, in circumstances of the greatest difficulty, have made it possible to prepare fairly accurate general maps of Tibet, and the long stay in Lhasa of Kishin and Chandra Das has given much information as to that city as it was in 1878 and 1882. Exploration by Europeans in Tibet has not been encouraged by the Indian Government, although British officers are permitted to make journeys at their own risk. In this way Captain Bower crossed Tibet from west to east in 1891–92, starting from Leh, and Captain Wellby in 1896 crossed from the same starting-point, but kept farther north. Both made important route surveys through regions which had never previously been traversed by a European. Neither was allowed to enter Lhasa; nor was Mr Littledale more fortunate in 1895, when, after a fine journey across Tibet from the north, he came within 50 miles of the capital, but was obliged to turn westwards and leave the country.

Indian native surveyors in Tibet.

British explorers in Tibet.

M. Bonvalot and Prince Henry of Orleans crossed Tibet from the north by a different route in 1890, but turning eastwards, they terminated their journey (one of the longest land journeys ever made) in French Indo-China. M. Dutreuil de Rhins, after four years spent in the exploration of the northern barrier ranges of Tibet, made a march southwards towards Lhasa, but being turned eastwards, made his way to the neighbourhood of Sining, where he lost his life during an altercation with the Tibetans in 1894.

French explorers in Tibet.

The journeys of Mr W. W. Rockhill, of the American diplomatic service, who entered Tibet from China in 1889, although falling short of Lhasa, have added much to our knowledge of the Tibetan land and people.

Rockhill.

The difficult country of eastern Tibet and western China is still but imperfectly known, although many important expeditions have thinned the veil of darkness which covered it before 1875, when Mr Margary made his way across from China towards Bhamo, but was murdered by the Chinese close to the frontier of Burma. In 1877 Captain W. Gill ascended the Yangtse-kiang, and made his way safely across to the Irrawaddy, and during 1877–78 Mr Colborne Baber pursued extensive explorations throughout the provinces of Szechuen and Yunnan. A finely-equipped expedition under the Hungarian Count Béla Szechenyi investigated the whole west of China and east of Tibet from the upper Yangtse to Koko-nor in 1877–80, and, returning southwards, emerged in Burma with a magnificent collection of scientific specimens. In 1883 Mr A. R. Colquhoun crossed from Canton to Bhamo by a new route, and even as late as 1898 Captain Wingate made a similar journey, in which he crossed several considerable areas of Yunnan where no European had been before. Mrs Bishop's travels in the upper Yangtse district in 1896–97, and Dr Jack's in 1901, also touched new ground. In 1895 M. Bonin, working his way up from the French possessions, was able to rectify the maps of the upper course of the Yangtse; and numerous commercial and missionary journeys have recently contributed to our knowledge.

Exploration in western China.

The problem of the complicated river-system of Indo-China, north-eastern India, and Tibet has been nearly solved by the labours of the native Indian surveyors, the British civil and military officers in Assam and Burma, and by the journeys of several independent travellers. In Indo-China itself the most important recent work is the expedition of M. Pavie to the upper Mekong in 1886–89, when his large scientific staff gave an excellent account of the country.

Indo-China.

The great deserts of Mongolia and eastern Turkestan and the northern edge of the Tibetan plateau, including the mountain range of the Kuen Lun, have held the persistent attention of Russian government explorers, and occasionally attracted

[1] *Geographical Journal*, xv. (1900), 205, 353.

Exploration in inner Asia.

adventurous students and sportsmen of many nationalities. These have mapped the country in a preliminary way from the Pamirs to China, leaving, however, many important blanks between their respective routes. The splendid services of Prjevalsky, who travelled over most of inner Asia and first fixed the source of the Yellow river, have already been referred to. Mr A. D. Carey and Mr Dalgleish, after crossing western Tibet from India in 1885–87, carried their surveys down the Khoten river eastwards, and then south through Tsaidam, and west again to Urumtsi. Captain Frank Younghusband travelled from China to India through Mongolia, Eastern Turkestan, and across the Pamirs in 1886–87, a journey of exceptional interest. In 1896, and again in 1898–99, Captain Deasy conducted an expedition which did much for the exploration of the eastern Pamirs, the Yarkand region, and the regions of the south and south-east as far as the Kuen Lun mountains.

Turfan oasis.

In 1889–90, after an expedition in the Tian Shan, the brothers Grum-Grjmailo described the curious oasis of Turfan, in the very centre of Asia, to which a depth of 100 feet below sea-level was subsequently assigned by Pyevtsoff, and as a result of the long-continued meteorological observations, specially established at Lukchun, in the hollow, the depth has been proved to be 56 feet below sea-level. Drs Futterer and Holderer made an important geological journey across Asia, from the Pamirs to China, in 1898–99, following the northern edge of the Tarim basin, crossing the Gobi desert, and entering China from Koko-nor. The most interesting and most fruitful of recent journeys were undoubtedly those of Dr Sven Hedin, who from 1894 to 1897 was engaged exploring, mapping, collecting natural history specimens, and studying ethnography in the Pamirs, on Mustagh-ata, which he ascended to nearly 20,000 feet, in the Takla-makan desert, which he was the first to cross, and where he discovered ancient ruins of the highest interest, at Lob-nor, and on the northern edge of Tibet, where he traversed an absolutely unknown region south of the Tian Shan. He again (1899–1902) engaged in explorations in the same region.

Sven Hedin.

All recent travellers in Eastern Turkestan have found no small help and encouragement in Kashgar from the British agent, Mr George Macartney, and the Russian consul-general, Petrovsky, who, by their influence and local knowledge, more than once turned an expedition which threatened to be a failure into a success.

The Pamirs.

The Pamirs have been carefully studied by the joint British and Russian Boundary Commissions, by which, from 1872 to 1895, surveys were made by special expeditions, and the actual boundary demarcated on the ground by stone pillars. The region no longer exercises the mysterious fascination which attracted the explorers of the 'seventies and 'eighties. Amongst those the names of Ujfalvy, Bonvalot, and Capus (1877), and Severtsoff (1878), may be specially mentioned; reference must also be made to the later exploring journeys of Mr Littledale, Lord Curzon to the source of the Oxus, Dr Sven Hedin, and the Danish Lieutenant Olufsen.

Kafiristan.

Space fails for a record of the adventurous journeys of British and Russian officers through Afghan territory, but the exploration of the mysterious valleys of Kafiristan by Sir George Robertson in 1890–91 must be mentioned. That region was so rigorously guarded by its pagan mountaineers, who had held out successfully for four hundred years against Mahommedan invasion, that it was believed by Sir Henry Yule to be the last part of the world which should remain unknown. Sir Martin Conway in 1892, and Mr Douglas Freshfield in 1899, broke new ground in the exploration of portions of the higher Himalaya not previously reached.

Himalaya.

Persia.

Persia has been explored in several directions by British officers, with native surveyors supplied by the Government of India. The work of Colonel Sawyer in the Bakhtiari country in 1890, and of Major Sykes in Eastern Persia, may be particularly mentioned; and many others have done good work, which has been ably supplemented by General Houtum Schindler at Tehran and by Russian officers in the north.

Malay Archipelago.

The unknown area in the centre of Borneo has been reduced by expeditions equipped by the Dutch Government, by the British North Borneo Company, and by the Government of Sarawak, in whose service Dr C. Hose has done admirable work in the Baram district. Valuable surveys have been completed in Java by the Dutch Government. A considerable area of unknown country remains in Sumatra, in spite of recent expeditions.

Arabia.

Arabia has been scarcely touched since the travels of Mr Doughty in the north in 1876–77. The journeys of the French Orientalist M. Huber in the north, and those of Dr E. Glaser, Dr L. Hirsch, and Mr and Mrs Theodore Bent in the Hadramut in the south, are the most important in recent years.

Palestine.

The labours of the Palestine Exploration Fund have resulted in the detailed survey of the whole of Palestine on the scale of one inch to a mile by the British Ordnance Survey.

Africa.—The last quarter of the 19th century has filled the map of Africa with authentic topographic details, and left few blanks of any size, while surveys of high accuracy have been commenced at several points. Practically the whole continent has been parcelled out since 1884 amongst the European Powers as colonies, protectorates, or spheres of influence, within each of which the dominant Power treats exploration as a duty. As the work of exploration and survey has become closer and more detailed, journeys of startling novelty have become less frequent, and the most solid of the recent accessions to knowledge have resulted from the labours of a succession of hard-working colonial officials toiling individually in obscurity.

Congo basin.

The great journey of Sir H. M. Stanley along the Congo from Lake Tanganyika to the sea in 1875–76 initiated a new era in African exploration. The number of travellers soon became so great that the once marvellous feat of crossing the continent from sea to sea has been performed by more than twenty expeditions, some of which have scarcely added to the knowledge possessed before they set out. The branches of the Congo were gradually explored by scientific investigators, missionaries, and the officers of the Congo Free State, which was founded under the sovereignty of the king of the Belgians in 1879. The relation of the Congo basin to the neighbouring river systems was brought out by the journeys of many travellers. Chief among these were the Portuguese Serpa Pinto, who crossed Africa from St Paul de Loando to the east coast in 1877–79; Capello and Ivens, who a few years later (1884–86) traced out a great part of the Congo-Zambezi watershed; the English missionary Grenfell, who discovered the Ubangi in 1884–85; the German Major von Wissmann, who explored the Kasai river and made his way across Africa more than once (1881–82); the Russian Junker, who, in the course of a long sojourn (1879–87) in the Sudan, thoroughly explored the Bahr-el-Ghazal province and the basin of the Welle, a river the relation of which to the Congo drainage was long a subject of controversy—settled finally by Van Gèle in 1887. Stanley's Emin Pasha Relief Expedition of 1889 also helped to fill up the map of the northern slopes of the Congo basin by the exploration of the Aruwimi. In 1893–94 Count Götzen, in the course of a journey across Central Africa, defined the eastern edge of part of the Congo basin, and discovered Lake Kivu in the great rift between Lakes Tanganyika and Albert Edward. The journeys of MM. de Brazza, Crampel, Maistre, Fourneau, and many other officials of French Congo have determined the relations between the Congo, Lake Chad, and the Niger drainage areas. The only portion of the Congo basin which still affords scope for pioneer exploration is in the south-west, where the upper streams descending from the watershed with the Zambezi have not been fully mapped. Some light has been thrown on the south-eastern part of the basin by the Katanga expeditions of Captains Bia, Delcommune, and Stairs, and by the missionaries Arnot and Coillard; while in the source-region of the Congo about Lakes Mweru and Bangweolo those of Lieutenant V. Giraud in 1883–84 and of Mr Poulett Weatherley in 1899 have been important. The whole watershed of the Congo-Zambezi was traced in 1899–1900 by Major Gibbons, who had previously explored the upper Zambezi, and Captain Lemaire, who had ascended one of the upper tributaries of the Kasai.

East Africa.

In East Africa the period of surveys following on exploration has been fairly inaugurated, and the Uganda railway line united Victoria Nyanza and the coast in 1902, not only facilitating access to the interior, but supplying an invaluable base for surveys to the north and south of the route. In 1879–80 Mr Joseph Thomson crossed East Africa to Lakes Tanganyika and Nyasa, and in 1883 he made a daring journey across the country of the dangerous Masai tribe to Victoria Nyanza, rediscovering Mount Kenya, and getting the first information as to the great Rift Valley containing Lake Naivasha, perhaps the most remarkable feature in the geography of Africa.

The Somali peninsula and its hinterland towards Abyssinia and Uganda was the last part of East Africa to yield up its secrets. It was penetrated from the south by Count Teleki and Lieutenant von Höhnel in 1887–88, when Lakes Rudolf and Stefanie were discovered, and from the north in 1885 by the brothers James, who reached the river Webi, and by Dr Donaldson Smith, who passed right through to Uganda in 1894. Italian explorers, amongst whom Bottego (who traced the Omo to Lake Rudolf in 1897) may be specially mentioned, did much valuable exploring work in this region, and the final problems of its hydrography have been practically solved by the journeys of Mr H. S. H. Cavendish in 1898, Captain Wellby, Messrs Grogan and Sharp, and Dr Donaldson Smith in 1899. Mr Grogan's expedition was the first to traverse the whole length of Africa from Cape Town to the Mediterranean by land.

East African mountains.

The lofty mountains of East Africa have naturally attracted a good deal of attention. Kilimanjaro, which is included in German East Africa, was ascended to above the snow-line by Sir H. H. Johnston in 1884, and since 1887 it has been repeatedly climbed and the summit attained by Professor Hans Meyer, who has made it the subject of a valuable monograph. Kenya, lying farther north, on the equator, in the British sphere, has also been successfully ascended. Count Teleki was the first to get above the forest zone; Dr J. W. Gregory, in 1894, made a more complete study, and passed the snow-line; while Mr H. J. Mackinder, in 1899, reached the summit. The snowy peaks of Ruwenzori, discovered by Sir H. M. Stanley in 1889, have not yet been scaled, although the explorations of this mountain group by Mr Scott Elliot in 1894, by Mr J. E. S. Moore in 1900, and especially by Sir H. H. Johnston, who ascended to 14,800 feet in 1900, have added much to our knowledge. The region of the great central lakes, Tanganyika and Nyasa, has been thoroughly explored; the latter, from the time of Dr Stewart's journey in 1877, has been studied by the missionaries of Nyasaland and the Government of British Central Africa. The survey of Tanganyika by Mr E. C. Hore in 1878–80 has been completed and extended by subsequent work, the position of the lake in longitude having been rectified by Mr Fergusson on Mr Moore's expedition.

The French, whose sphere of influence in Africa is larger than that of any other Power, have justified their claim to extensive territory by their diligence in exploration. While the Austrian traveller Oscar Lenz was successful in crossing the Sahara from Marocco to Timbuktu in 1880, the French Commandant Monteil made the more difficult journey from the Niger to Tripoli in 1894, and in 1899 M. Fourcau, after twelve years' experience of exploration in the Sahara, succeeded in crossing the desert from Algeria to Lake Chad, after great danger from the Tuareg tribes, who had massacred Colonel Flatters at the oasis of Aïr in 1880. The western portion of the Sudan, especially the district between the great bend of the Niger and the Gulf of Guinea, has been thoroughly explored by Captain Binger and other French officials. The lower course of the Niger and its neighbouring lands in the British sphere of influence have also been fully explored by officials of the Royal Niger Company, and later by those of British Nigeria.

French explorers in West Africa.

The most extensive journey ever made by any French traveller in Africa was that of Commandant Marchand in 1898 from French Congo through the Central Sudan and the Bahr-el-Ghazal province to the upper Nile, and thence through Abyssinian territory to the French Red Sea colony of Jibuti.

In South Africa the most important work has been the extension northwards of accurate triangulations by the Cape Government, and the opening up of the plateau region between the Limpopo and the Zambezi by the British South Africa Company, a work in which the explorations carried on for many years by Mr F. C. Selous were of the greatest value.

South Africa.

Australia.—During the last quarter of the 19th century exploration on a large scale in Australia was only possible in the two western states, but surveying has been proceeding steadily in the three eastern states. The chief difficulty explorers have had to contend with has been the extremely arid and capricious climate of the interior, and in a less degree the fierceness of some of the native tribes. The introduction of camels, however, has facilitated desert expeditions.

On the establishment of the overland telegraph from the south to the north coast in 1872, Mr Ernest Giles made an unsuccessful attempt to penetrate to the west coast from near Charlotte Waters telegraph station; and in the following year, starting farther south, he got half-way to the west coast. He repeated the attempt in 1875, and then succeeded in passing from the head of St Vincent Gulf to Perth. In 1876 he returned by a still more remarkable journey north of the tropic, again crossing the whole breadth of West Australia. West Australia had been crossed twice before this, once in 1873 by Colonel Warburton travelling with camels from Alice Springs on the telegraph line to Oakover river on the west coast, and again in 1874 by Sir John Forrest with horses only, from the Murchison river to near Peake station on the telegraph line. Between 1885 and 1887 Mr D. Lindsay explored the interior of South Australia, crossing the continent twice, from south to north and from north to south. Again in 1891–92, as leader of the exploring expedition fitted out by Sir Thomas Elder, he carried out additional work in the interior. Mr E. Favenc in 1888, and Mr Tietkins in 1889, made important journeys in the interior of West Australia. In 1896–97 Mr David Carnegie, starting from Coolgardie, traversed the deserts northwards to Hall's Creek in the north, and returned by a different route, accomplishing important surveys of a very desolate country. The development of the gold-fields of West Australia has led to innumerable journeys of great difficulty, comparatively few of which have been described. The scientific exploring expedition fitted out by Mr W. A. Horn in 1894 included in its staff several biological and geological professors of Australian universities, and by its thorough exploration of a considerable area about the MacDonnell Ranges, almost in the centre of the Australian continent, added much to the accurate knowledge of the desert region.

In New Guinea the most valuable explorations have probably been those made by Sir William Macgregor, when governor of British New Guinea, who, in addition to the survey of parts of the coast, made several expeditions into the interior, in the course of one of which, in 1889, he ascended and named Mount Victoria, the highest summit of the Owen Stanley range. Important journeys have also been made by Messrs Macfarlane, Chalmers, and other missionaries. Dr Otto Finsch made a journey both in British and German New Guinea in 1884–85, for the purpose of scientific exploration, and in the German colony the officials have made several difficult journeys of exploration, the chief being perhaps that by Tappenbeck and Lauterbach on the Ramu or Ottillien river. Few parts of the world outside the polar circles, however, remain so little known as the interior of New Guinea.

British New Guinea.

German New Guinea.

North America.—All the great features of this continent were known before 1875, and the explorations since that time have been mainly carried out by the Geological and Land Survey Departments of Canada and the United States. The construction of the Canadian Pacific Railway, which was opened from sea to sea in 1886, rendered necessary a careful study of the difficult country between the Rocky Mountains and the Pacific in the search for a practicable route. The geological surveyors of Canada have been unceasingly at work in the detailed mapping of the settled districts, and they have also made many exploring journeys of great magnitude. Thus, the late Dr G. M. Dawson explored the upper course of the Yukon in 1887, ten years before the gold discoveries at Klondike attracted the attention of the world to that difficultly accessible region. Mr MacConnel of the Geological Survey and Mr W. Ogilvie of the Dominion Land Survey extended the work of exploration and survey during the height of the gold fever. Dr R. Bell and the brothers Tyrrell mapped the shores of Hudson Bay and the desolate stretches of the barren grounds between that sea and the Mackenzie river, and Mr A. P. Low made important journeys in the interior of the great peninsula of Labrador.

Exploration by Canadian geological surveyors.

Conjointly with delegates from the United States, the Dominion land surveyors have mapped the disputed boundary belt between Alaska and British Columbia. The long-doubtful height of Mount St. Elias has been definitely fixed, and the mountain itself was climbed by the duke of the Abruzzi in 1897. The still higher summit of Mount Logan has been trigonometrically measured as 19,500 feet. Many expeditions in Alaska have been sent out by the United States Government, and the geography of the interior of the peninsula has been fairly well sketched in as regards its main features.

Alaska boundary surveys.

The Coast and Geodetic Survey, the United States Geological Survey, and the surveys of many of the individual states, have made great progress in mapping the country. The names of Professor Mendenhall of the Coast and Geodetic Survey, and of Mr Clarence King, Major J. W. Powell, and Mr I. C. Russell of the Geological Survey, may be specially associated with recent progress.

Exploration by United States surveyors.

The peninsula of Lower California was explored between 1885 and 1894 under the auspices of the Californian Academy of San Francisco, and American travellers, including Drs Lenk and Felix and Professor A. Heilprin, helped forward the exploration of the less known parts of Mexico. In the south of that country, and in northern Guatemala, scientific and archæological studies were carried out by Messrs Salvin, Godman, and Maudslay, whose results are being published in the magnificent volumes entitled *Biologia Centrali-Americana.*

Mexico.

Central and South America.—South America has always been a continent of uncertain boundaries, and many recent exploring journeys promoted by the governments of South American republics have been carried out with the direct purpose of defining or demarcating frontiers.

In Central America minute surveys were made for the Panama Canal and also for the projected Nicaragua Canal. The independent researches made since 1888 by Dr Carl Sapper of the Guatemala Geological Survey cleared up the complex and ill-understood orography of Central America, and definitely proved that neither the Rocky Mountains nor any other North American range is continuous with the Andes. Dr Pittier of Costa Rica extended these researches to the borders of South America.

Central America.

In the West Indies the researches of North American geologists, especially Professor J. W. Spencer and Dr R. T. Hill, enabled the true relation of the island chain to the two continents to be determined.

West Indies.

On the mainland the Sierra Nevada de Santa Marta and the Goajir peninsula were explored for the first time by Mr F. A.

A. Simons in 1878–80, and again by Professor W. Sievers in 1886, this geologist having already studied and elucidated the orography of the Venezuelan Coast Range in 1884–85.

Venezuela.

In the uplands of Guiana Mr Everard F. im Thurn succeeded in reaching the previously inaccessible summit of Roraima in 1884, and the long-continued journeys of M. Coudreau and M. Créveau in French Guiana and the adjacent parts of Brazil have fully delineated the territory which was long contested by the two countries.

Guiana.

The great river Amazon and its branches flow through the least-known part of South America, and although many expeditions have been engaged in tracing the rich ramifications of the river system, the wild woodlands between the converging streams are still in large part untrodden by any white man. The earlier work of exploration in the western republics by Drs Reiss and Stübel was continued by the latter in the Amazon basin in 1876–77. In 1881 M. Charles Wiener explored the upper tributaries with the view of finding the best routes across the Andes to navigable waters. Dr A. Hettner between 1882 and 1890 carried on extensive travels in the Andean and Amazonian region of Peru, Bolivia, and Brazil. The problem of the boundary between the Amazonian provinces of Peru and Bolivia has given prominence to the Inambari question, to the solution of which the Bolivian geographers Pando and Ballivian have devoted many journeys on the Madre de Dios and Inambari rivers. Amongst the explorers of South America Colonel G. E. Church takes a high place, his travels in connexion with railway surveys touching almost every country in the continent. M. Coudreau travelled and mapped new routes in the Rio Negro basin in 1884–85, and the Xingu region was entered by him from the north in 1897, when he was the first to explore the district between the Tocantins and Xingu; he died on a journey in the Trombetas basin in 1899.

Amazon basin.

The trackless province of Matto Grosso was explored from the south through the tributaries of the Xingu river by Dr Karl von den Steinen in 1884–88, then by Dr Ehrenreich, and in continuation of the same series of researches by Dr Herrmann Meyer in 1896 and again in 1899. The result has been not only of geographical importance, but has brought in a harvest of new knowledge in all departments of science, especially in ethnography.

The Andes have always invited exploration, but until the assistance of professional Alpine guides was called in the highest peaks proved effective obstacles to the mountaineer. In 1880 Mr Edward Whymper climbed Chimborazo and other great peaks in Ecuador; in 1897 two members of Mr E. A. Fitzgerald's expedition reached the summit of Aconcagua, the highest point on the American continents, and in 1898 Sir Martin Conway climbed the highest of the Bolivian Andes, Illimani and Illampu (Sorata). The main geographical interest presented by the Andes in recent years is the definition of the word *Cordillera* as applied to them. By the terms of the treaty of 1881 the boundary between Chile and the Argentine Republic is defined as "the line of the highest crests of the Cordillera of the Andes which divide the waters." But since the watershed does not coincide with the highest line of the Andes in Patagonia, it has been necessary to make careful surveys of the almost unknown country in the disputed zone. On the Argentine side the work of Dr Francisco Moreno from 1875 onwards has been of the highest importance, including the discovery of several of the great lakes of the Patagonian lake-district; and on the Chilean side the explorations of Professor A. Bertrand, Dr H. Steffen, and Dr Paul Krüger have greatly elucidated the difficult orography of the forest-clad and rain-drenched western slopes of the Patagonian Andes. The mapping of the disputed area was undertaken in 1902 by a British commission under Sir Thomas Holdich.

Andes.

Patagonia.

The coasts of southern Chile and Magellan Strait have been surveyed in parts by the Chilean navy, and various short journeys have been made in Tierra del Fuego by travellers of all nationalities, amongst whom may be mentioned the French circumpolar observers in 1882, Dr Otto Nordenskjöld in 1895–96, and the scientific staff of the *Belgica* in 1897–98.

Tierra del Fuego.

Arctic Regions.—The last great polar expedition on the old lines was that under Sir George Nares in the *Alert* and *Discovery* in 1875–76, on which Lieutenant (afterwards Admiral) A. H. Markham reached the farthest north in 83° 20′. Since then small parties, whose leader had generally a special plan of his own to carry out, have been the rule. The voyage of the *Vega*, under Baron A. E. Nordenskiöld, along the north coast of Asia, which was arrested in 1878 not far from Bering Strait, was successfully completed in 1879; the North-East Passage was made for the first time, and Europe and Asia were circumnavigated. Since this achievement scarcely a year has elapsed in which several trading steamers did not make the voyage through the Kara Sea to the mouths of the Ob and Yenisei.

Nares.

Nordenskiöld in the "Vega."

In 1879 the *New York Herald* sent out an expedition under Captain W. G. de Long on the *Jeannette* (the *Pandora* of Sir Allen Young's voyage), which entered Bering Sea and tried to reach a high latitude. She was, however, caught in the ice-pack, and after drifting helplessly west and north for 21 months, she was crushed and sunk in 77° 15′ N. Her company escaped with difficulty to the New Siberian Islands, and thence to the coast of Siberia, where most of them perished. Some objects from the *Jeannette* were picked up on an ice-floe off Julianehaab in Western Greenland three years later, a circumstance which led to some controversy and to a great generalization.

The "Jeannette."

In 1879 Lieutenant Schwatka, of the United States army, made a remarkable sledge journey from the shore of Hudson Bay to King William Land, and returned in 1880 with a collection of relics of Franklin's expedition recovered from the Eskimo.

Schwatka's search.

Professor A. G. Nathorst and Baron de Geer commenced in 1882 a series of studies of Spitsbergen and other Arctic islands, which is still being continued by Swedish observers. Sir Martin Conway and Mr Garwood crossed Spitsbergen for the first time in 1897, and Professor Nathorst circumnavigated that island group and settled its true extent in 1898.

Spitsbergen.

Mr B. Leigh Smith, after several voyages to the far north in his Arctic yacht *Eira*, had the misfortune in 1881 to lose his vessel, which was nipped in the ice off Cape Flora, Franz Josef Land. His ship's company passed the winter in a hastily-constructed hut without casualty, and returned in the following year by boat to Novaya Zemlya, as remarkable and successful a journey as any in Arctic annals. Franz Josef Land was made the base of the Jackson-Harmsworth Polar Expedition in 1894–97, and although no high latitude was attained, fresh light was thrown on the geography of the Archipelago and valuable scientific observations were secured. Mr Jackson having indicated the impracticability of advancing north by land, the duke of the Abruzzi, on board the *Stella Polare*, started in 1899 to endeavour to push his way northwards from Franz Josef Land by sea. The ship was stopped in 82°, and Captain Cagni with two other Italians pushed northwards over the ice with dog-sledges, reaching 86° 33′ in 65° E. on 23rd April 1900, the farthest north point yet attained. It was proved that Petermann Land is non-existent. Mr E. B. Baldwin set out in 1901 with a lavishly-equipped American expedition to follow the same route northward.

Franz Josef Land. Leigh Smith.

Jackson.

Duke of the Abruzzi.

The year 1882 saw the most strenuous international efforts to obtain trustworthy data as to the meteorology and magnetic conditions of the North Polar area. On the initiative of Payer, and by the direct action of the German Government, twelve stations round the North Pole in high latitudes were occupied from July 1882 to August 1883 by British, United States, German, Russian, Austro-Hungarian, Swedish, Norwegian, Danish, and Finnish observers. Of these the most remarkable was the American station under Lieutenant (afterwards General) Greely in Grinnell Land, from which Lieutenant Lockwood succeeded in reaching a point in 83° 24′ N., about four miles beyond Admiral Markham's farthest.

International circumpolar stations.

Greely.

Dr A. Bunge and Baron Toll visited and explored the New Siberian Islands in 1886, and in 1900–02 Baron Toll again undertook a journey thither in the hope of passing beyond them and reaching Sannikoff Land, and also of repeating the North-East Passage.

Toll.

Baron Nordenskiöld in 1883 made a determined effort to penetrate the interior of Greenland from the west coast, but the two Lapps whom he sent on in advance on ski had to turn at 120 miles from the sea. In 1888 Dr Fridtjof Nansen was landed on the east coast of Greenland with the object of crossing the Inland Ice, he having conceived the idea of making a retreat unnecessary by keeping the one chance of safety in front. He successfully crossed the ice with a small party, the distance by his route being 260 miles.

Greenland.

Nansen.

The next journey of this explorer was the most remarkable polar voyage yet achieved. Dr Nansen again resolved to make a journey on which there should be no question of any line of retreat. From the drift of the *Jeannette* relics, and much other evidence which he had carefully collected and weighed, he was led to believe that a current flowed from the neighbourhood of the New Siberian Islands nearly over the Pole towards Greenland, and that a strongly-built ship frozen in at the proper place would be carried into a high latitude by the drifting ice. In June 1893 he set out, allowed his vessel, the *Fram*, to be frozen in the pack off the New Siberian Islands, and every point of his forecast as to the drift of the ship was literally verified. With one companion he left the ship in 84° N. and travelled on snow-shoes to 86° 14′, nearly 3° beyond any previous explorer. They returned on foot to Franz Josef Land, wintered in a hut, met Mr Jackson in the spring of 1896, and arrived in Europe simultaneously with the *Fram*, a coincidence probably without parallel.

The drift of the "Fram."

In northern Greenland Mr Peary set himself in 1891 to a task which he has pursued steadily for ten years in spite of almost overwhelming difficulties. In 1892 he sledged across the northern ice-cap from Inglefield Gulf to Independence Bay on the east coast, a distance of 600 miles, and back again; but though he repeated this achievement on subsequent occasions, he could not advance upon it. In 1898, and again in 1900, accompanied by some Eskimo, he endeavoured to reach the Pole by travelling over the ice and living in ice-huts, but he was forced to return to his base both times. He was still confident that the plan was practicable, and prepared to start again, resolved not to leave the work until it was accomplished. Captain Sverdrup, Nansen's captain in the *Fram*, took out that vessel in 1898 up Smith Sound, in the hope of being able to explore by sea to the north of Greenland, a voyage very frequently attempted before, and always in vain. No news of Sverdrup was received in 1900 or 1901.

Peary.

Sverdrup.

Dr Erich von Drygalski studied the glaciers of Umanak fjord in western Greenland in 1891 and 1892–93, and the Danish authorities have for many years sent vessels to explore and map portions of the still unknown East Greenland coast, Lieutenants Ryder and Amdrup having particularly distinguished themselves in this work.

Drygalski.

From the northern point of Spitsbergen the Swedish engineer Andrée with two companions started in a balloon of novel design on 11th July 1897, with the hope of being drifted by the wind over the Pole. Messages dated two days later were recovered, and several buoys were found which had been carried in the balloon, but nothing further has been heard of the explorers, whose fate does not admit of doubt.

Andrée.

In 1899 the Russian Admiral Makaroff took the great ice-breaking steamer *Yermak* on a trial trip to the Arctic Sea north of Spitsbergen, and the results confirmed his belief that a vessel of this kind can force a way through any floe-ice known to exist, although subsequent experiments have produced little result.

Exploration by ice-breaker.

Antarctic Regions.—The greatest unknown area of the Earth lies in the Antarctic regions, access to which is both difficult and dangerous. After the voyage of Sir James Ross, thirty years elapsed before a further step was taken. Then in 1873–74 the German Captain Dallman visited the neighbourhood of Grahamland. In 1874 H.M.S. *Challenger* was the first steam vessel to cross the Antarctic circle, which she did south of Kerguelen Island, but, not being protected against ice, she could not enter the pack. In the southern summer of 1892–93 several Scottish and Norwegian whalers visited the seas about Grahamland and, though they did but little exploration, brought back some definite additions to knowledge. In 1895 the Norwegian whaler *Antarctic* was the first steamer to push through the Antarctic pack, and Captain Kristensen with Mr Borchgrevink, who had shipped as a sailor, were the first men to land on the supposed Antarctic continent, which they did at Cape Adare. In 1897 a Belgian expedition under Captain de Gerlache, with a cosmopolitan scientific staff, sailed in the *Belgica*, and early in 1898 were caught in the ice-pack west of Grahamland, remaining fast, drifting in the ice for rather more than a year. The members of this expedition were the first to winter within the Antarctic circle, although the farthest point of the drift was only 71° 36′ S.

"Challenger."

Whalers.

"Belgica."

In 1898 Mr C. E. Borchgrevink was sent out by Sir George Newnes as commander of an expedition in the *Southern Cross*, and succeeded in landing early in 1899 with a competent scientific staff at Cape Adare, where they spent a whole year. On the return of the ship to Cape Adare in 1900 Mr Borchgrevink proceeded south to the ice-barrier, saw Mount Erebus, and was able to land on the ice in long. 165° W. and march a few miles inland to 78° 50′ S., a little beyond Ross's farthest point.

Borchgrevink.

A British expedition under Commander R. F. Scott, R.N., sailed in the *Discovery* in 1901, leaving New Zealand in December for Victoria Land. A German expedition under Professor E. von Drygalski in the *Gauss* made its departure southward simultaneously from Kerguelen, and a Swedish expedition under Dr Otto Nordenskjöld in the *Antarctic* left Buenos Aires for Weddell Sea. In 1902 Mr W. S. Bruce sails in command of a Scottish expedition to Weddell Sea; and the *Morning* takes out a relief party for the *Discovery*.

New expeditions.

The Oceans.—The exploration of the oceans has gone on without intermission since the great circumnavigation of H.M.S. *Challenger* in 1872–76, and the simultaneous voyage of the German man-of-war *Gazelle*. Much valuable information has been obtained in the cable-laying expeditions of telegraph ships, much also from the work of government surveying vessels, especially those of the British Navy, one of which, H.M.S. *Penguin*, obtained in 1896 the remarkable sounding of 5155 fathoms in the South Pacific to the east of the Kermadec Islands, a depth only exceeded by 5269 fathoms found by the U.S. telegraph ship *Nero* to the east of Guam in 1900. The Norwegian Government sent out an expedition to the North Atlantic on the *Voringen* in 1876–78, and the Russian frigate *Vityaz*, in her circumnavigation of the world in 1886–89, carried on much oceanographical work under Admiral Makaroff in the North Pacific.

The prince of Monaco, at first in his sailing yacht *Hirondelle*, and later in the fine steam yacht *Princesse Alice*, specially built for oceanographical work, has investigated the currents of the North Atlantic and the physical and biological conditions of several parts of that ocean. The Austrian ship *Pola*, under the direction of the Vienna Academy of Sciences, explored the Eastern Mediterranean, the Black Sea, and the Red Sea from 1890 to 1896.

The cruise of the German merchant steamer *Valdivia* in 1898–99, under the scientific direction of Professor Chun, was of more than ordinary importance, and although without the discipline of naval service, and under the sole charge of a scientific man, the expedition led to results greater than had ever before been obtained in so short a time and at such small expense. The voyage was merely a circumnavigation of Africa, but with wide loops, one of which led to the rediscovery of the long-lost Bouvet Island; another greatly extended our knowledge of the depths of the Southern Ocean towards the Antarctic Circle, and the third enabled a line of soundings to be run across a part of the Indian Ocean hitherto blank on the charts. The Pacific Ocean was the field of Professor A. Agassiz's researches in the United States Fish Commission steamer *Albatross* in 1899–1900, and the Dutch Government vessel *Siboga* was engaged at the same time in the little-known seas of the Malay Archipelago. (H. R. M.)

GEOLOGY.

During the years which have elapsed since the publication of the article on geology in the ninth edition of this Encyclopædia, the science has continued to make advances in every department of its domain, but its principles and broad conclusions remain with but little change. That article, therefore, still gives a fairly accurate and complete presentation of its subject. Innumerable fresh illustrations might now be inserted of the principles of the science, vast numbers of new facts might be cited which have come to light in the interval, many departments of the subject might be greatly expanded in the light of recent research. But in this supplementary article it will be sufficient to call attention only to the more important changes of view and additions to our knowledge of the larger questions with which geology deals.

1. Cosmical Aspects of Geology.

The astronomical relations of the Earth and their bearings on geological speculation have been much discussed in recent years. Of these questions, more particular reference may here be made to two—Croll's doctrines as to the origin of climates in the past, and the controversy as to the age of the Earth. The ingenious views propounded by James Croll (1821–90) regarding the influence of astronomical causes in determining variations of terrestrial climate were fully stated in the ninth edition article. His teaching was widely accepted by geologists, inasmuch as it seemed to offer a solution of one of the most difficult problems of geology, and to provide a possible basis for computing the absolute value of geological time. More recently his views were adopted with certain modifications, and enforced by Sir Robert Ball with his accustomed vigour.[1]

Origin of climates.

[1] Croll's original papers will be found chiefly in the *Philosophical Magazine* between the years 1864 and 1874. They were collected and incorporated with modifications in his volume *Climate and Time in their Geological Relations*, London, 1875. His views were also elaborated by him in his subsequently published *Discussions on Climate and Cosmology*, Edinburgh, 1885. Sir Robert Ball's work, *The Cause of an Ice-Age*, was published in London, 1891.

During his lifetime Croll's doctrine, though it commended itself to geologists, did not make way among physicists and astronomers. In particular, it was criticized by Professor Simon Newcomb, and defended by its author.[1] More recently it has been critically examined by Mr E. P. Culverwell, who regards it as "a vague speculation, clothed indeed with a delusive semblance of severe numerical accuracy, but having no foundation in physical fact, and built up of parts which do not dovetail one into the other."[2] This writer affirms that Croll's fundamental assumption that the midsummer and midwinter temperatures are directly proportional to the sun's heat at those seasons is not borne out by an appeal to observation. At Yakutsk, for example, which may be taken as an extreme case of range of temperature, if the excess of its midwinter temperature above that of space were due entirely to the midwinter sun-heat, then the midsummer temperature, also arising solely from direct sun heat, should be 5800° Fahr. above that of space, or if the midsummer excess were due only to the midsummer sun-heat, then the midwinter temperature ought to be – 228° Fahr. Mr Culverwell has calculated what parallels of latitude now receive the same amount of winter sun-heat as the parallels of 40°, 50°, 60°, 70°, 80°, and 90° received during a time of high eccentricity when winter occurred in aphelion. He finds that the daily average sun-heat received during the winter of high eccentricity by the parallel of 40° is now received by that of 42·2°, and that the parallel of 54° at the present time receives the same amount as that of 50° did then. He concludes that the lowering of the midwinter temperature from lat. 50° N. to 70° N., due to diminished winter sun-heat in the epoch of great eccentricity, cannot have been as much as from 3° to 5° Fahr. Such a small decrease could not have been sufficient to produce a glacial period within these latitudes. But it is not certain that the midwinter temperature did really fall during the epoch of maximum eccentricity. This temperature, in the case of the British Isles, depends not on direct sun-heat so much as on the heat transported by the Gulf stream. But during the time of high eccentricity the summer temperature of the regions whence the Gulf stream derives its warmth was far greater than it is now, so that it is conceivable that, instead of being colder in winter, the British climate may actually have been milder than it is now. The failure of the astronomical theory to afford a solution of the problem of the Ice Age leaves geologists once more face to face with one of the most perplexing questions with which they have to deal. At present no satisfactory explanation of it has been offered.

Age of the Earth.

Though the question of the *Age of the Earth* has continued to engage the attention of physicists, geologists, and palæontologists since 1880, no general agreement has been reached in regard to it. On the physical side the same three arguments are still adduced which were stated in the ninth edition article (p. 227), viz., the secular cooling of the Earth, the retardation of our planet's rotation by tidal friction, and the age of the sun's heat. But whereas Lord Kelvin (then Sir William Thomson) was formerly disposed to allow a period of 100 millions of years for the evolution of geological history, he has since maintained that the time "was more than 20 and less than 40 millions of years, and probably much nearer 20 than 40."[3] On the other hand, several physicists and mathematicians of eminence have expressed themselves less confidently on the validity of these arguments and conclusions, and with more appreciation of the importance of the views brought forward on the side of geology and palæontology. In an address from the chair of the Mathematical Section of the British Association in 1886, Professor George Darwin reviewed the controversy, and pronounced the following deliberate judgment in regard to it: "In considering these three arguments I have adduced some reasons against the validity of the first [tidal friction], and have endeavoured to show that there are elements of uncertainty surrounding the second [secular cooling of the Earth]; nevertheless, they undoubtedly constitute a contribution of the first importance to physical geology. Whilst, then, we may protest against the precision with which Professor Tait seeks to deduce results from them, we are fully justified in following Sir William Thomson, who says that 'the existing state of things on the Earth, life on the Earth—all geological history showing continuity of life—must be limited within some such period of past time as 100 million years.'"[4] Lord Kelvin has never dealt with the geological and palæontological objections against the limitation of geological time to a few millions of years. But Professor Darwin, in the address just cited, uttered the memorable warning: "At present our knowledge of a definite limit to geological time has so little precision that we should do wrong summarily to reject theories which appear to demand longer periods of time than those which now appear allowable" (*ibid.* p. 518).

In an address to the Mathematical Section of the American Association for the Advancement of Science in 1889, the vice-president of the Section, Mr R. S. Woodward, thus expressed himself with regard to the physical arguments brought forward by Lord Kelvin and Professor Tait in limitation of geological time. "Having been at some pains to look into this matter, I feel bound to state that, although the hypothesis appears to be the best which can be formulated at present, the odds are against its correctness. Its weak links are the unverified assumptions of an initial uniform temperature and a constant diffusivity. Very likely these are approximations, but of what order we cannot decide. Furthermore, if we accept the hypothesis, the odds appear to be against the present attainment of trustworthy numerical results, since the data for calculation, obtained mostly from observations on continental areas, are far too meagre to give satisfactory average values for the entire mass of the Earth."[5]

Still more emphatic is the protest made from the physical side by Professor John Perry. He has attacked each of the three lines of argument of Lord Kelvin, and has impugned the validity of the conclusions drawn from them. The argument from tidal retardation he dismisses as fallacious, following in this contention the previous criticism of the Rev. Maxwell Close and Professor George Darwin. In dealing with the argument based on the secular cooling of the Earth, he holds it to be perfectly allowable to assume a much higher conductivity for the interior of the globe, and that such a reasonable assumption would enable us greatly to increase our estimate of the Earth's antiquity. As for the third argument, from the age of the sun's heat, he points out that the sun may have been repeatedly fed by a supply of meteorites from outside, while the Earth may have been protected from radiation, and been able to retain much of its heat by being enveloped in a dense atmosphere. Remarking that "almost anything is possible as to the present internal state of the Earth," he concludes thus: "To sum up, we can find no published record of any lower maximum age of life on the Earth, as calculated by physicists, than 400 millions of years. From the three physical arguments Lord Kelvin's higher limits are 1000, 400 and 500 million years. I have shown that we have

[1] See *Phil. Mag.* for the years 1876, 1883, and 1884.

[5] *Smithsonian Report for 1890*, p. 194.

reasons for believing that the age, from all these, may be very considerably under-estimated. It is to be observed that if we exclude everything but the arguments from mere physics, the *probable* age of life on the Earth is much less than any of the above estimates; but if the palæontologists have good reasons for demanding much greater times, I see nothing from the physicist's point of view which denies them four times the greatest of these estimates."[1]

The arguments from the geological side against the physical contention that would limit the age of our globe to some 10 or 20 millions of years have been repeatedly stated.[2] They are based on the observed rates of geological and biological changes at the present time upon land and sea, and on the nature, physical history, and organic contents of the stratified crust of the Earth. Unfortunately, actual numerical data are not obtainable in many departments of geological activity, and even where they can be procured they have not yet been based on a sufficiently wide collection of accurate and co-ordinated observations. But in some branches of dynamical geology materials exist for at least a preliminary computation of the rate of change. This is more especially the case in respect of the wide domain of denudation. The observational records of the action of the sea, of springs, rivers, and glaciers are becoming gradually fuller and more trustworthy. A method of making use of these records for estimating the rate of denudation of the land was referred to in the ninth edition article (p. 278). Taking the Mississippi as a general type of river-action, it was shown that the amount of material conveyed by this stream into the sea in one year was equivalent to the lowering of the general surface of the drainage-basin of the river by $\frac{1}{6000}$ of a foot. This would amount to one foot in 6000 years, and 1000 feet in 6 million years. So that at the present rate of waste in the Mississippi basin a whole continent might be worn away in a few millions of years.

It is evident that as deposition and denudation are simultaneous processes, the ascertainment of the rate at which solid material is removed from the surface of the land supplies some necessary information for estimating the rate at which new sedimentary formations are being accumulated on the floor of the sea, and for a computation of the length of time that would be required at the present rate of change for the deposition of all the stratified rocks that enter into the composition of the crust of our globe. If the thickness of these rocks be assumed to be 100,000 feet, and if we could suppose them to have been laid down over as wide an area as that of the drainage basins from the waste of which they were derived, then at the present rate of denudation their accumulation would require some 600 millions of years. But, as Dr A. R. Wallace has justly pointed out, the tract of sea-floor over which the material derived from the waste of the terrestrial surface is laid down is at present much less than that from which this material is worn away. We have no means, however, of determining what may have been the ratio between the two areas in past time. Certainly ancient marine sedimentary rocks cover at the present day a much more extensive area than that in which they are now being elaborated. If we take the ratio postulated by Dr Wallace—1 to 19—the 100,000 feet of sedimentary strata would require 31 millions of years for their accumulation. It is quite possible, however, that this ratio may be much too high. There are reasons for believing that the proportion of coast-line to land area has been diminishing during geological time; in other words, that in early times the land was more insular, and is now more continental. So that the 31 millions of years may be much less than the period that would be required, even on the supposition of continuous uninterrupted denudation and sedimentation, during the whole of the time represented by the stratified formations.

But no one who has made himself familiar with the actual composition of these formations and the detailed structure of the terrestrial crust can fail to recognize how vague, imperfect, and misleading are the data on which such computations are founded. It requires no prolonged acquaintance with the Earth's crust to impress upon the mind that one all-important element is omitted, and indeed can hardly be allowed for from want of sufficiently precise data, but the neglect of which must needs seriously impair the value of all numerical calculations made without it. The assumption that the stratified formations can be treated as if they consisted of a continuous unbroken sequence of sediments, indicating a vast and uninterrupted process of waste and deposition, is one that is belied on every hand by the actual structure of these formations. It can only give us a minimum of the time required; for, instead of an unbroken series, the sedimentary formations are full of "unconformabilities"—gaps in the sequence of the chronological records—as if whole chapters and groups of chapters had been torn out of a historical work. It can often be shown that these breaks of continuity must have been of vast duration, and actually exceeded in chronological importance thick groups of strata lying below and above them. Moreover, even among the uninterrupted strata, where no such unconformabilities exist, but where the sediments follow each other in apparently uninterrupted sequence, and might be thought to have been deposited continuously at the same general rate, and without the intervention of any pause, it can be demonstrated that sometimes an inch or two of sediment must, on certain horizons, represent the deposit of an enormously longer period than a hundred or a thousand times the same amount of sediment on other horizons. A prolonged study of these questions leads to the profound conviction that in many parts of the geological record the time represented by sedimentary deposits must be vastly less than the time which is not so represented.

It has often been objected that the present rate of geological change ought not to be taken as a measure of the rate in past time, because the total sum of terrestrial energy has been steadily diminishing, and geological processes must consequently have been more vigorous in former ages than they are now. Geologists do not pretend to assert that there has been no variation or diminution in the activities of the various processes which they have to study. What they do insist on is that the present rate of change is the only one which we can watch and measure, and which will thus supply a statistical basis for any computations on the subject. But it has been dogmatically asserted that because terrestrial energy has been diminishing, therefore all kinds of geological work must have been more vigorously and more rapidly carried on in former times than now; that there were far more abundant and more stupendous volcanoes, more frequent and more destructive earthquakes, more gigantic upheavals and subsidences, more powerful oceanic waves and tides, more violent atmospheric disturbances with heavier rainfall, and more active denudation.

It is easy to make these assertions, and they look plausible; but, after all, they rest on nothing stronger than assumption. They can be tested by an appeal to the crust of the Earth, in which the geological history of our

[1] *Nature*, vol. li. p. 585 (18th April 1895).

[2] They are briefly given in the original article (pp. 226, 227). See, however, the presidential address to the British Association at the Edinburgh Meeting in 1892, pp. 15–21, and the President's Address to Section C of the Association at the Dover Meeting of 1899.

planet has been so fully recorded. Had such portentous manifestations of geological activity ever been the normal condition of things since the beginning of that history, there ought to be a record of them in the rocks. But no evidence for them has been found there, though it has been diligently sought for in all quarters of the globe. We may confidently assert that while geological changes may quite possibly have taken place on a gigantic scale in the earliest ages of the Earth's existence, of which no geological record remains, there is no proof that they have ever done so since the time when the very oldest of the stratified formations were deposited. There is no need to maintain that they have always been conducted precisely on the same scale as now, or to deny that they may have gradually become less vigorous as the general sum of terrestrial energy has diminished. But we may unhesitatingly affirm that no actual evidence of any such progressive diminution of activity has been adduced from the geological record in the crust of the Earth: that, on the contrary, no appearances have been detected there which necessarily demand the assumption of those more powerful operations which physicists have postulated, or which are not satisfactorily explicable by reference to the existing scale of nature's processes.

That this conclusion is warranted even with regard to the innate energy of the globe itself will be seen if we institute a comparison between the more ancient and the more recent manifestations of that energy. Take, for example, the proofs of gigantic plication, fracture, and displacement within the terrestrial crust. These, as they have affected the most ancient rocks of Europe, have been worked out in great detail in the north-west of Scotland. But they are not essentially different from or on a greater scale than those which have affected the Alps, and have involved strata of so recent a date as the older Tertiary formations. On the contrary, it may be doubted whether any denuded core of an ancient mountain-chain reveals traces of such stupendous disturbances of the crust as those which have given rise to the younger mountain-chains of the globe. It may, indeed, quite well have been the rule that instead of diminishing in intensity of effect, the consequences of terrestrial contraction have increased in magnitude, the augmenting thickness of the crust offering greater resistance to the stresses, and giving rise to vaster plications, faults, thrust-planes, and metamorphism, as this growing resistance had to be overcome.

The assertion that volcanic action must have been more violent and more persistent in ancient times than it is now has assuredly no geological evidence in its support. It is quite true that there are vastly more remains of former volcanoes scattered over the surface of the globe than there are active craters now, and that traces of copious eruptions of volcanic material can be followed back into some of the oldest parts of the geological record. But we have no proof that ever at any one time in geological history there have been more or larger or more vigorous volcanoes than those of recent periods. It may be said that the absence of such proof ought not to invalidate the assertion until a far wider area of the Earth's surface has been geologically studied. But most assuredly, as far as geological investigation has yet gone, there is an overwhelming body of evidence to show that from the earliest epochs in geological history, as registered in the stratified rocks, volcanic action has manifested itself very much as it does now, but on a less rather than on a greater scale. Nowhere can this subject be more exhaustively studied than in the British Isles, where a remarkably complete series of volcanic eruptions has been chronicled ranging from the earliest Palæozoic down to older Tertiary time. The result of a prolonged study of British volcanic geology (of which a summary will be given in pages 641–646) has demonstrated that, even to minute points of detail, there has been a singular uniformity in the phenomena from beginning to end. The oldest lavas and ashes differ in no essential respect from the youngest. Nor have they been erupted more copiously or more frequently. Many successive volcanic periods have followed each other after prolonged intervals of repose, each displaying the same general sequence of phenomena and similar evidence of gradual diminution and extinction. The youngest, instead of being the feeblest, were the most extensive outbursts in the whole of the prolonged series (see p. 638).

If now we turn for evidence of the alleged greater activity of all the epigene or superficial forces, and especially for proofs of more rapid denudation and deposition on the Earth's surface, we search for it in vain among the stratified formations of the terrestrial crust. Had the oldest of these rocks been accumulated in a time of great atmospheric perturbation, of torrential rains, colossal tides, and violent storms, we might surely expect to find among the sediments some proof of such disturbed meteorological and geographical conditions. We should look, on the one hand, for tumultuous accumulations of coarse unworn detritus, rapidly swept by rains, floods, and waves from land to sea, and on the other hand, for an absence of any evidence of the tranquil and continuous deposit of such fine laminated silt as could only settle in quiet water. But an appeal to the geological record is made in vain for any such proofs. The oldest sediments, like the youngest, reveal the operation only of such agents and such rates of activity as are still to be witnessed in the accumulation of the same kind of deposits. If, for instance, we search the most ancient thick sedimentary formation in Britain—the Torridon Sandstone of north-west Scotland, which is older than the oldest fossiliferous deposits—we meet with nothing which might not be found in any Palæozoic, Mesozoic, or Cainozoic group of similar sediments. We see an accumulation, at least 8000 or 10,000 feet thick, of sand, gravel, and mud, such as may be gathering now on the floor of any large mountain-girdled lake. The conglomerates of this ancient series are not pell-mell heaps of angular detritus, violently swept away from the land and huddled promiscuously on the sea-floor. They are built up of pebbles that have been worn smooth, rounded and polished by prolonged attrition in running water, and they follow each other on successive platforms with intervening layers of finer sediment. The sandstones are composed of well-waterworn sand, some of which has been laid down so tranquilly that its component grains have been separated out in layers according to their specific gravity, in such manner that they now present dark layers in which particles of magnetic iron, zircon, and other heavy minerals have been sifted out together, just as iron-sand may be seen gathered into thin sheets on sandy beaches at the present day. Again, the same series of primeval sediments includes intercalations of fine silt, which has been deposited as regularly and intermittently there as it has been among the most recent formations. These bands of shale have been diligently searched for fossils, as yet without success; but they may eventually disclose organic remains older than any hitherto found in Europe.

We now come to the consideration of the Palæontological evidence as to the value of geological time. Here the conclusions derived from a study of the structure of the sedimentary formations are vastly strengthened and extended. In the first place, the organization of the most ancient plants and animals furnishes no indication that they had to contend with any greater violence of storm, flood, wave, or ocean-current than is familiar to their modern descendants. The oldest trees, shrubs, ferns, and club-mosses display no special structures that suggest a difference in the general conditions of their environment. The most ancient crinoids, sponges, crustaceans, arachnids, and molluscs were as delicately constructed as those of to-day, and their remains are often found in such perfect preservation as to show that neither during their lifetime nor after their death were they subject to any greater violence of the elements than their living representatives now experience. Of much more cogency, however, is the evidence supplied by the grand upward succession of organic forms, from the most ancient stratified rocks up to the present day. No biologist now doubts for a moment that this marvellous succession is the result of a gradual process of evolution from lower to higher types of organization. There may be differences of opinion as to the causes which have governed this process and the order of the steps through which it has advanced, but no one who is conversant with the facts will now venture to deny that it has taken place, and that, on any possible explanation of its progress, it must have demanded an enormous lapse of time. In the Cambrian or oldest fossiliferous formations there is already a large and varied fauna, in which the leading groups of invertebrate life are represented. On no tenable hypothesis can these be regarded as the first organisms that came into being on our planet. They must have had a long ancestry, and as Darwin first maintained, the time required for their evolution may have been "as long as, or probably far longer than, the whole interval from the Silurian [Cambrian] age to the present day." The records of these earliest eras of organic development have unfortunately not survived the geological revolutions of the past; at least, they have not yet been recovered. But it cannot be doubted that they once existed and registered their testimony to the prodigious lapse of time prior to the deposition of the most ancient fossiliferous formations which have escaped destruction.

The impressive character of the evidence furnished by the sequence of organic forms throughout the great series of fossiliferous strata can hardly be fully realized without a detailed and careful study of the subject. Professor Poulton, in an address to the Zoological Section of the British Association at the Liverpool Meeting in 1896, showed how overwhelming are the demands which this evidence makes for long periods of time, and how impossible it is of comprehension unless these demands be conceded. The history of life upon the Earth, though it will probably always be surrounded with great and even insuperable difficulties, becomes broadly comprehensible in its general progress when sufficient time is granted for the evolution which it records; but it remains unintelligible on any other conditions.

Taken then as a whole, the body of evidence, geological and palæontological, in favour of the high antiquity of our globe is so great, so manifold, and based on such an ever-increasing breadth of observation and reflexion, that it may be confidently appealed to in answer to the physical arguments which would seek to limit that antiquity to ten or twenty millions of years. In the present state of science it is out of our power to state positively what must be the lowest limit of the age of the Earth. But we cannot assume it to be much less, and it may possibly have been much more, than the 100 millions of years which Lord Kelvin was at one time willing to concede.[1]

2. Geognosy.

In this department of geological inquiry petrographical research has been greatly pursued and extended. The methods of determining the microscopic structure of rocks have been considerably improved. Fresh light has been thrown on the composition, structure, and probable history of many rocks. A considerable number of new varieties of rocks has been added to the already sufficiently numerous list. Various schemes of classification have been proposed, but petrographers are still far from any general agreement as to a scheme that shall be at once natural and convenient. This subject has engaged the attention of the International Geological Congress, of which a special committee has been formed for the purpose of considering the question of petrographical nomenclature and classification.

The voluminous recent literature of this branch of geology will be found partly in the form of papers in the scientific serials and in the proceedings of scientific societies, and partly as independent general treatises or text-books. Of the latter the most important are:—F. Zirkel, *Lehrbuch der Petrographie*, 3 vols., 2nd edit., Leipzig, 1893–94: this is the most comprehensive treatise on rocks; H. Rosenbusch, *Mikroskopische Physiographie der Mineralien und Gesteine*, 3rd edit., Stuttgart, 1892–96: translated by Iddings, London, 1888; H. Rosenbusch, *Elemente der Gesteinslehre*, Stuttgart, 1898; A. Harker, *Petrology for Students*, 2nd edit., Cambridge, 1897.

3. Dynamical Geology.

The hypogene action whereby changes are effected within the crust of the earth manifests itself in volcanoes, earthquakes, secular movements of upheaval and depression, and in alterations of the texture, structure, and composition of rocks. In each of these sections of inquiry progress has been made in the accumulation of fresh facts, if not in the elaboration of a satisfactory hypothesis to account for them. To a few of the more important additions to our knowledge in some of these departments reference will here be made.

Volcanoes.—A large amount of observation has been devoted to the phenomena of volcanoes. The daily operations of such constantly active vents as Etna, Stromboli, Vesuvius, and Hawaii have been watched and recorded.[2]

Several important volcanic eruptions in various parts of the world have been investigated by competent observers, notably the stupendous catastrophe of Krakatoa in 1883 and that of Bandai-san, Japan, in 1888. The circumstances accompanying volcanic explosions have been more fully studied. Attention has been given to the

[1] The subject of the age of the Earth has also been discussed by Professor Joly and Professor Sollas. The former geologist, approaching the question from a novel point of view, has estimated the total quantity of sodium in the water of the ocean and the quantity of that element received annually by the ocean from the denudation of the land. Dividing the one sum by the other, he arrives at the result that the probable age of the Earth is between 90 and 100 millions of years (*Trans. Roy. Dublin Soc.*, ser. ii. vol. vii., 1899, p. 23; *Geol. Mag.*, 1900, p. 220). Professor Sollas believes that this limit exceeds what is required for the evolution of geological history, that the lower limit assigned by Lord Kelvin falls short of what the facts demand, and that geological time will probably be found to have been comprised within some indeterminate period between these limits. (Address to Section C, *Brit. Assoc. Report*, 1900.)

[2] For recent accounts of Vesuvius see:—H. J. Johnstone-Lavis, *Spettatore del Vesuvio*, Naples, 1887; *Nature*, vols. xxvi., xliv. pp. 160, 320, 352, lii. p. 342; G. Mercalli, *Vulcani e Fenomeni Vulcanici in Italia*, Milan, 1883; R. V. Manteucci, *Rend. R. Accad. Napoli*, 1897, 1898, 1899; *Boll. Soc. Geol. Ital.* vol. xvi. (1898); *Boll. Soc. Sismolog. Ital.* v. (1899–1900); *Rend. Accad. Lincei. Roma*, viii. (1899). On Etna:—S. von Waltershausen, *Der Etna*, Leipzig, 1880; Mercalli in the work just cited and notices of recent eruptions in *Nature*, vols. xix. xx. xxi. xxii. xxv. xxvii. xlvi. xlvii. and lv. On Stromboli:—Mercalli, *Vulcani, &c.*, p. 135; *Atti. Soc. Ital. Sci. Nat.*, vols. xxii. xxiv. xxvii. xxix. xxxi.; and notes in *Nature*, xliv. (1891), p. 280, xlvii. pp. 89, 453. On Hawaii:—J. D. Dana, *Characteristics of Volcanoes*, p. 125, London, 1890; and *Amer. Journ. Sci.* vols. xxxiii.–xxxvii. (1887–89); C. E. Dutton, *Amer. Journ. Sci.* vol. xxv. (1883), p. 219; *Ann. Rep. U.S. Geol. Survey* (1882–83); also notices in *Nature*, vols. xlvii. (1893), p. 499; l. (1894), pp. 91, 483; liii. (1896) p. 490.

phase of fissure eruptions, especially as manifested in recent times in Iceland and in more remote ages in Britain, India, and the western portions of the United States. A large body of evidence has been gathered bearing on the history of vulcanism in the geological past, and many features of the inner mechanism of volcanic vents, as well as of the phenomenon of the subterranean intrusions of igneous material, have been ascertained with a clearness which no modern volcano could supply.

Volcanic Explosions.—Of recent volcanic eruptions by far the most stupendous was the outburst of Krakatoa in Sunda Strait. It has thrown fresh light on the nature and the occurrence of the explosions which form so characteristic a feature in the régime of volcanoes. These phenomena have from the earliest times powerfully impressed the human imagination. In a few hours or days a great mountain is eviscerated with the most violent commotion, vast clouds of dust are projected high into the air and cover the noonday sky with the darkness of night, while terror, wounds, and death befall vast numbers of the population around. Such catastrophes have taken place at wide intervals since prehistoric times. It was by one of them that the crater of the islands which now form the Santorin group in the Grecian Archipelago was blown out after a human colony had settled around its flanks. Another, likewise older than the times of history, produced the vast chasm of the Val del Bove on the east side of Etna. The first of which any account has been handed down was that which destroyed the southern half of Monte Somma and buried the towns on the shores of the Bay of Naples in A.D. 79. Since that time other examples of the phenomenon in different degrees of intensity have been experienced in various parts of the world. But probably none of them has equalled in violence the great explosion of Krakatoa. Fortunately the events that preceded, accompanied, and followed that catastrophe were witnessed by many observers whose testimony has been collected and collated, so that the nature and sequence of these events have been recorded with a fulness previously unknown.

Eruption of Krakatoa.

At some early period a large volcano rose in the centre of the tract where now runs the Sunda Strait between Sumatra and Java. Long before any European had entered these waters a gigantic explosion took place by which the mountain was so completely blown away that only the outer portions of its base were left as a broken ring of islands. Subsequent eruptions gradually built up a new series of small cones within the great crater ring. Of these the most important rose to a height of 2623 feet above the sea and formed the peak of the volcanic island of Krakatoa. But compared with the great neighbouring volcanoes of Java and Sumatra, the islets of the Sunda Strait were comparatively unknown and neglected. Though densely wooded, Krakatoa was uninhabited, and no satisfactory map or chart of it had been made. In the year 1680 it appears to have suffered from a volcanic eruption, when great earthquakes took place and large quantities of pumice were ejected. But the effects of this disturbance had been so concealed by the subsequent spread of tropical vegetation that the very occurrence of the eruption has sometimes been called in question. At last, about the year 1877, earthquakes began to be of frequent occurrence in the Sunda Strait and continued for the next few years, as an indication that the volcanic energy which had been dormant for at least 200 years was once more waking into life. In 1883 the manifestations of subterranean commotion began to be more decided, for in the month of May of that year Krakatoa broke out in eruption. For some time the efforts of the volcano appear to have consisted mainly in the discharge of pumice and dust, with the usual accompaniment of detonations, tremors, and earthquakes. And so far the type of activity resembled that which had characterized the volcano ever since the time of the great explosion. But at last, on 26th August, a succession of paroxysmal explosions began which lasted till the morning of the 28th, but of which the four most violent took place on the morning of the 27th. The whole of the northern and lower portion of the island of Krakatoa, lying within the original crater ring of prehistoric times, was blown away; the northern part of the cone of Rakata almost entirely disappeared, leaving a vertical cliff which laid bare the inner structure of that volcano. Instead of the volcanic island which had previously existed, and rose from 300 to 1400 feet above the sea, there was now left a submarine cavity the bottom of which is here and there more than 1000 feet below the sea-level. This prodigious evisceration was the result of successive violent explosions of the superheated vapour and gas absorbed in the molten magma within the crust of the earth. The vigour and repetition of these explosions, it has been suggested, may have been caused by sudden inrushes of the water of the ocean as the throat of the volcano was cleared and the crater-ring was lowered and ruptured. The access of large bodies of cold water to the top of the column of molten lava would probably give rise at once to some minor explosions and then to a chilling of the surface of the lava and a consequent temporary diminution or even cessation of the volcanic eructations. But until the pent-up water-vapour in the lava below had found relief it would only gather strength until it was able with explosive energy to burst through the chilled crust and overlying water, and to hurl a vast mass of cooled lava, pumice, and dust into the air.

The amount of material discharged during the two days of paroxysmal energy was enormous, though there are no satisfactory data for even approximately estimating it. A large cavity was formed where the island had previously stood, and the sea-bottom around this crater was covered with a wide and thick sheet of fragmentary materials. Some of the surrounding islands received such a thick accumulation of ejected stones and dust as to bury their forests and greatly to increase the area of the land. So much was the sea filled up that a number of new islands rose above its level. But a vast body of the fine dust was carried far and wide by aërial currents, while the floating pumice was transported for many hundreds of miles on the surface of the ocean. At Batavia, 100 miles from the centre of eruption, the sky was darkened by the quantity of ashes borne across it, and lamps had to be used in the houses at mid-day. The darkness even reached as far as Bandong, a distance of nearly 150 miles. It was computed that the column of stones, dust, and ashes projected from the volcano shot up into the air for a height of seventeen miles or more. The finer particles coming into the higher layers of the atmosphere were diffused over a large part of the surface of the earth, and showed their presence by the brilliant sunset glows to which they gave rise. It was computed that within the tropics they were at first borne along by air-currents at the rate of about seventy-three miles an hour from east to west until within a period of six weeks they were diffused over nearly the whole space between the latitudes 30° N. and 45° S. Eventually they spread northwards and southwards and were carried over North and South America, Europe, Asia, South Africa, and Australasia. In the Old World they spread from the north of Scandinavia to the Cape of Good Hope.

Another remarkable feature of this stupendous volcanic event was the world-wide disturbance of the atmosphere. The culminating paroxysm of Krakatoa on the morning of

27th August gave rise to an atmospheric wave or oscillation, which, travelling outwards from the volcano as a centre, became a great circle at 180° from its point of origin, whence it continued travelling onwards and contracting till it reached a node at the antipodes to Krakatoa. It was then reflected or reproduced, travelling backwards again to the volcano, whence it once more returned in its original direction. "In this manner its repetition was observed not fewer than seven times at many of the stations, four passages having been those of the wave travelling from Krakatoa, and three those of the wave travelling from its antipodes, subsequently to which its traces were lost" (Sir R. Strachey).

The actual sounds of the volcanic explosions were heard over a vast area of the earth's surface, especially towards the west. Thus they were noticed at Rodriguez, nearly 3000 English miles away, at Bangkok in Siam (1413 miles), in the Philippine Islands (about 1450 miles), in Ceylon (2058 miles), and in West and South Australia (from 1300 to 2250 miles). On no other occasion have sound-waves ever been perceived at anything like the extreme distances to which the detonations of Krakatoa reached.

Not less manifest and far more serious were the effects of the successive explosions of the volcano upon the waters of the ocean. A succession of waves were generated which appear to have been of two kinds, long waves with periods of more than an hour, and shorter but higher waves, with irregular and much briefer intervals. The greatest disturbance, probably resulting from a combination of both kinds of waves, reached a height of about 50 feet. The destruction caused by the rush of such a body of sea-water along the coasts and low islands was enormous. All vessels lying in harbour or near the shore were stranded, the towns, villages, and settlements close to the sea were either at once, or by successive inundations, entirely destroyed, and more than 36,000 human beings perished. The sea-waves travelled to vast distances from the centre of propagation. The long wave reached Cape Horn (7818 geographical miles) and possibly the English Channel (11,040 miles). The shorter waves reached Ceylon and perhaps Mauritius (2900 miles).[1]

Eruption of Bandai-san.

The eruption of Bandai-san in the north of Japan in the year 1888 was likewise witnessed and chronicled by intelligent observers, whose evidence brings before us some additional particulars regarding the phenomena attendant on volcanic explosions. The ground rocks of the region are various granites, gneisses, and crystalline schists through which in Tertiary time a series of volcanic eruptions took place. The volcanic energy is said to have gradually declined down to the present day. A line of volcanic mountains runs in a general north and south direction along the axis of the island. Most of them are now extinct. But a few have remained in the solfataric stage; that is, they have from time to time given vent to explosions of vapour with more or less violence, but without the discharge of true ashes or lava. During a long period of comparative quiescence the cones have been deeply trenched by denudation and thickly clothed with forest. Hot springs still rise at many points, but except to a geological eye there is little in the general aspect of the country to suggest that its contours have resulted from former volcanic activity, or that they may be again modified by the same cause. Tradition tells that the volcanic mountain of Bandai-san had its summit burst open by an eruption, which, sending forth fire and smoke, split it into several peaks. The event was accompanied by a memorable catastrophe to the inhabitants, whereby fifty villages were buried under the waters which gathered in the hollow now occupied by Lake Inawishiro. But for ten centuries the volcano appears to have remained on the whole in a dormant condition. At last, on the morning of 15th July 1888, rumbling noises like distant thunder began to be heard by the inhabitants, until a tolerably severe earthquake took place that lasted more than twenty seconds and affected an area with a radius of about thirty miles. A quarter of an hour later, after further violent shaking of the ground, and while the commotion was still going on, a great explosion took place on the old volcanic cone of Bandai-san (6036 feet) followed by fifteen or twenty more during nearly two hours. Each of these paroxysms was accompanied by deafening detonations, while steam and dust were shot up into the air to a height of more than 4000 feet. By the last discharge the material is said to have been projected almost horizontally towards the valley on the north. The fine dust and vapour rapidly ascended into the higher regions of the atmosphere, where at a height of some 18,000 feet the material spread out into the usual pine-tree shape, and was gradually carried by the wind in a south-easterly direction, spreading out on its way, and passing out to sea. The area of land over which this fine dust fell was 790 square miles. How far it was carried across the Pacific was not ascertained. So thick was the canopy of dust that immediately around the mountain the day became black as night; and the vapour condensed into a warm rain which fell with the hot ashes. While the darkness still lasted the whole summit and side of the mountain gave way, and an immense avalanche of earth and rock rushed down the slopes, burying the Nagase with its villages and people, and devastating an area of 27 square miles. In all seven villages and 461 inhabitants were destroyed.

According to the observations of the Japanese geologists who at once proceeded to the spot to make a detailed investigation of the circumstances of the eruption, the fine dust that accompanied the successive explosions of steam was not pumice such as results from the sudden expansion of the superheated vapour absorbed in a molten magma, but fine powder of pre-existing andesitic rocks, which had been more or less decomposed by fumarole action. These observers believed that the dust resulted from the explosive force of the steam acting upon the older solidified lavas, and from the mechanical trituration of the stones against each other in their ascent and descent in the air. Some of it, mingling with the steam, fell as a hot mud that clung to the leaves and branches of the trees. It was estimated that no less an amount than 1587 millions of cubic yards of the mountain had been blown away and reduced to fragments and dust. The uppermost 540 feet of Bandai-san disappeared, and instead of the forest-covered slope on one side of the mountain there was left a vast horseshoe-shaped chasm, at the back of which the inside of the old crater was laid bare in a great cliff 1658 feet high, wherein were revealed the successive sheets of lava and fragmentary materials whereof the cone had been built up. The loosened and dislocated side of the mountain is described as having been launched downwards as a huge landslip that rushed into the plain below with a velocity of about 48 miles an hour. Most of the material that so travelled is spoken of as having been comparatively dry, though no doubt mingled with the hot rain from the condensed steam, and sweeping up the waters of streams and lakes so as to become in some places a pasty mud. The torrent of debris swelled up into great waves 130 to 200 feet high in front of obstructions, and was strewn with enormous blocks of stone; even at a considerable distance from the crater such blocks measured 15 or 30 feet on the side.

[1] "The Eruption of Krakatoa and subsequent Phenomena." *Report of the Krakatoa Committee of the Royal Society*, London, 1888.

Its surface rose into conical mounds or hills formed of blocks of stone, the cause of which has not been very satisfactorily explained.

Among the most marked circumstances of the explosions were the prodigious blasts of wind by which they were accompanied. The sudden radial expansion of the liberated volumes of steam at quick intervals produced violent disturbances of the air. It was estimated from the effects produced that the velocity with which these tornadoes were propagated outwards from the crater could not have been less than 90 miles an hour. The forests that lay in the pathway of the wind were utterly destroyed, only a few stems being left standing, each as bare as a telegraph pole. The trees fell with their heads pointing away from the crater, showing that the blasts radiated in straight lines. Places in the lee of protecting eminences escaped with little damage.

Another feature of the eruption which has given rise to some discussion was the production of numerous conical basin-like holes varying up to 10 feet in diameter and to more than 3 feet in depth. They were found in thousands around the crater, as well as on slopes a mile or more away from it. Three explanations have been proposed for these singular depressions: (1) they may have been caused by the collapse of the walls of underground springs, whereby the water was forcibly ejected to the surface; or (2) by the uprooting and removal of trees, whereby cavities were left in the ground; or (3) by the projection of stones from the crater and their fall through the loose soil and ashes that covered the surface. It is possible that examples of all of these modes of origin may have occurred. Holes left by the uprooting of trees were undoubtedly noticed. But according to the careful observations of the Japanese investigators, the vast majority of the holes arose from the third cause. Some of the cavities were dug open and the stones that formed them were found lying at the bottom, sometimes with crushed and bruised but still fresh green leaves lying below them, which they had carried with them in their descent from the surface. On rocky places which the stones could not penetrate, they were found in fragments scattered all about. This Japanese example is interesting as a well-attested illustration of the nature and effects of a true volcanic explosion from a long-dormant or seemingly extinct crater. It shows the enormous disruptive force of imprisoned steam even when no lava or true ashes are discharged. Like Vesuvius, Monte Somma, and other vents, it indicates how volcanic energy, which may have been quiescent since beyond the times even of tradition, may suddenly awake with destructive violence, and then relapse into its previous condition of apparent extinction.[1]

Fissure-eruptions.—With regard to fissure-eruptions, so much has been learnt since 1880 that this phase of volcanic action is now recognized as one which, in modern as well as ancient times, has given rise to the most voluminous outpourings of molten material from the earth's interior. It is from Iceland that the most detailed information has been obtained regarding recent eruptions of this kind. Mr Thoroddsen, a geologist resident on the island, has explored and mapped its geology and, in anticipation of an ample detailed work on which he is now engaged, has published a number of interesting and important contributions to our knowledge of the subject. He protests against the common misconception that volcanoes of the type of Etna and Vesuvius may be assumed to represent the general character of modern volcanic action. On the contrary, in Iceland, where the most copious lava-floods of historic times have been discharged, the regular Vesuvian cone, built of successive sheets of lava and ashes, is comparatively infrequent and unimportant among the manifestations of subterranean energy. It appears that the Icelandic eruptions are essentially due to the opening of fissures in the ground and to the outflow of lava from these over the surrounding country. Mr Thoroddsen has traced two systems of such fissures, of which one, developed in the south of the island, trends from south-west to north-east, while the other, in the northern districts, runs from south to north. The famous volcano, Hekla, is situated on a fissure belonging to the first system. Though built up of lavas and tuffs, it does not form a cone, but an oblong ridge, which has been split by a fissure along its length and bears a row of craters along the rent. The production of these dislocations has been observed in connexion with recent volcanic disturbances. Thus in 1875 a violent eruption took place at Askja, where two lines of fissure crossed each other, while many large rents were opened at the surface, some of which could be followed in a north and south direction for nearly 50 miles. Intense volcanic activity was displayed along some of these fissures. But in other cases no discharge of either lava or ashes has taken place. When lava is emitted it may flow out from the whole length of a fissure across a plain, without the production of any cones or craters, the molten material welling forth tranquilly either towards one or both sides. An example of this nature has been observed at the great Eldgjá fissure, which runs for more than 18 English miles with a depth of from 420 to 650 feet. From three points on this chasm lava spread out quietly, so as to cover an area of 270 English square miles, but without forming any craters or cones of scoriæ or ashes, except towards the southern narrowed end, where a row of low slag-cones made its appearance. More usually, however, the line of the fissure is marked by ramparts of slags and lava-blocks heaped up on each side, or by a row of cones immediately over the dislocation. The great Laki fissure of 1783, so well described and mapped by Dr A. Helland, is marked by hundreds of little cones running along the chasm for about 20 miles. From each of these craters two or more streams of lava issued, now to the one side, now to the other, which, uniting and surrounding the cones, formed vast fields of naked and rugged stone. The western stream reached a distance of more than 40 miles, but a lava of prehistoric time from one of the fissures of the Odádahraun flowed for upwards of 60 miles. The lava desert of this locality is formed of lava that has been discharged from about 20 vents, mostly on parallel fissures, and covers an area computed to be about 1700 English square miles. Mr Thoroddsen has estimated that the mass of lava there displayed, if poured out over Denmark, would have covered that country to a depth of 16 feet.

In connexion with the modern volcanic phenomena of Iceland, reference may be made here to a feature which is well illustrated among them—the production of what have been called explosion craters, that is, cavities opened in the ground by volcanic explosions, but with little or no surrounding cone of ejected materials. An interesting example of one of these cavities was produced by a violent explosion at Askja on 29th March 1875. Though it measures no more than 280 feet in diameter, so energetic was the explosion which blew it open that the pumiceous stones ejected at the time fell over an area of 468 English square miles, and the finer dust which was propelled into higher layers of the atmosphere was borne by north-westerly air-currents as far as Norway and Sweden. Nine years after the eruption Mr Thoroddsen,

[1] S. Sekiya and Y. Kikuchi, "The Eruption of Bandai-san," *Journ. College of Science, Imperial University of Japan*, vol. iii. part ii., Tôkyô, Japan (1889).

on visiting the place, found the bottom of the crater covered with bluish-green boiling mud.

These recent fissure-eruptions of Iceland serve to explain the history of some prehistoric and still more ancient areas of volcanic action, wherein extensive sheets of lava have been poured out with no relation to any great central cone from which they could have issued. Such are the vast lava-fields of Western America. In Idaho, Utah, Nevada, southwards into Arizona and New Mexico, northwards into Montana and westwards into Oregon, lavas have been piled up into wide plateaux, stretching out as deserts of black verdureless stone. In some cases the molten material has accumulated sheet above sheet to a depth of many hundred feet. Through this thick mass of material rivers have cut their way, forming gorges 700 feet deep or more, along the walls of which the successive beds of lava may be followed for miles. From these comparatively fresh outpourings of lava, trenched by winding ravines, it is no great step to the much older development of the same features displayed by the basalt-plateaux of Antrim and the Inner Hebrides, which date from older Tertiary time. There the phenomena of fissure-eruption are revealed in innumerable ranges of picturesque sea-cliff, and denudation has advanced so far as to lay bare much of the inner arrangement of such plateaux, which can never be studied among modern and still undenuded lava-fields. Still more ancient is the Cretaceous volcanic plateau of the Ghauts in the Bombay Presidency, where the same general phenomena are visible—innumerable dykes representing former fissures, widespread sheets of basalt, and an absence of any central cone from which the eruptions might be supposed to have emanated.

Distribution of Volcanic Action in Time.—In no branch of geological inquiry has more progress been made in recent years than in the collection and investigation of proofs that volcanoes were formerly rife in many parts of the Earth where they have long been extinct, and that their relics can be traced back through successive ages of the geological record to the time of the oldest formations of the Earth's crust. Materials have thus been accumulating for a history of volcanic action during the past, and though these materials have not yet been gathered from a wide enough area to allow, perhaps, satisfactory generalization for the planet as a whole, they are sufficiently ample for a few regions to indicate some of the main conclusions which fuller evidence will probably confirm and extend.

By far the most complete chronicle anywhere as yet obtained of the volcanic manifestations during the geological past is that presented in the British Isles.[1] Various fortunate circumstances have united to ensure this completeness. Few countries of the same size as Great Britain contain so ample and varied a representation of the series of systems and formations from which geological history is compiled. This record has been sedulously explored by innumerable observers since the first rise of geology; hence there is hardly any region of which the detailed geological structure and history have been so well ascertained. Each formation has been so fully studied that the various episodes of past time can be accurately assigned to their relative position in the chronological series. Then the peculiar position of Great Britain, along the outer or critical border-line of a continent, while placing it advantageously for witnessing and chronicling the successive revolutions of former ages—upheaval, depression, denudation, and deposition—has in a special measure been favourable for volcanic evolution. It is a familiar fact that at the present day volcanoes tend to group themselves near the sea, either on the edge of a continent, or in lines and groups of oceanic islands. Doubtless the same distribution has also held good in the past. Certainly nowhere can so ample and continuous a series of volcanic chronicles be found as in the British Isles, extending from a time earlier than that of the oldest fossiliferous rocks down to so late a period as the older Tertiary formations. This wonderfully full record includes illustrations of all the great types of volcanic activity that have been observed among modern volcanoes. On the one hand we have evidence of colossal eruptions, whereby hundreds of square miles of territory were buried under several thousand feet of lava; and on the other, of isolated vents with an energy so feeble as to be capable of nothing more than the explosion of the steam that produced them. In some parts of the country relics remain of the Vesuvian type of volcanoes, in others the volcanic materials have been supplied from fissures as in Iceland, while in not a few places the vents have the character of the *puys* of Central France and the Eifel. The lavas and tuffs of the older volcanic periods have been preserved by being submerged and buried under sedimentary accumulations. And they have subsequently been once more exposed to the day, in consequence of those geological revolutions of uplift and denudation whereby so large a part of the terrestrial crust has been made accessible to observation.

Geological history of volcanic action in the British Isles.

The oldest rocks of the British Isles are probably those comprised under the general name of Archæan or Lewisian gneiss, which form the chain of the Outer Hebrides and occupy many detached areas in the west of the counties of Sutherland and Ross. They include masses which recall the deep-seated bosses of eruptive material connected with volcanic discharges. But so extensive has been the denudation which they have undergone, even long anterior to Cambrian time, that if they were ever associated with any superficial manifestations of volcanic action, all trace of these has long since disappeared. Yet in the overlying Torridonian sandstones, which are certainly pre-Cambrian, fragments of lava-like rocks occur, suggestive of superficial eruptions before these sandstones were laid down. Another group of pre-Cambrian rocks rises along the borders of Wales and Shropshire into a chain of heights of which the Wrekin and Caer Caradoc are the most prominent. These rocks include acid tuffs and lavas which point to true volcanic action, and mark the earliest known eruptions in the long volcanic history of England and Wales. Perhaps to the same primeval period should be referred certain relics of volcanic discharges found in the Malvern Hills, and still more remarkably in Charnwood Forest. One characteristic feature of all these rocks is the prominence of the breccias and tuffs. It would seem that the pre-Cambrian volcanoes of England and Wales were specially remarkable for the vigour and continuance of their explosions and discharges of fragmentary material, rather than for the amount or variety of the lavas that flowed from them.

The most ancient series of fossiliferous rocks, to which the name of Cambrian is assigned, contains the records that form the first of the long succession of chapters of fairly continuous geological history. In Great Britain they are chiefly developed in Wales and the border English counties; they occupy a narrow belt 100 miles long in the north-west of Scotland, and certain groups of rock in the south-east of Ireland have been classed with them, though destitute of any of the characteristic Cambrian fossils. The Scottish and Irish developments of these primeval strata have not disclosed any trace of contemporaneous

[1] This subject will be found fully discussed in the author's *Ancient Volcanoes of Britain*, 2 vols., London, 1897.

volcanic action. But both in South and North Wales a remarkably full chronicle has been preserved of a long series of volcanic eruptions. Around St Davids in Pembrokeshire a mass of volcanic material, at least 1800 feet thick, forms the lowest visible portion of the Cambrian system. It consists chiefly of tuffs which represent successive showers of volcanic ashes thrown from submarine vents over the floor of the sea in which the earliest fossiliferous sediments were deposited. These tuffs present most of the characteristic features of Palæozoic volcanoes. They include both acid and basic varieties, which are represented in such a way as to show that both siliceous and basic lavas existed in the vents and were successively blown out in dust and lapilli. The volcanic series also includes some sheets of basic lava which in turn display some of the familiar features of later Palæozoic eruptions. Their slaggy bottoms, cellular structure, and identity of character with many of the lapilli in the tuffs in which they are intercalated, show them to be true lavas which flowed over the sheets of still unconsolidated ashes lying on the sea-bottom. Various intrusive bosses, sills, and dykes traverse the volcanic series of St Davids. Though some of the tuffs pass into coarse agglomerates, no remnant of a true volcanic neck or orifice has yet been noticed in the district. In North Wales relics of at least two distinct Cambrian volcanic centres have been detected. One of these lies in the picturesque district around the lower end of the lake of Llanberis and stretches thence towards Bangor; the other extends along the ground to the west of the great range of Cader Idris. We there meet with evidence of abundant volcanic explosions, marked by intercalated tuffs, and including occasional sheets of acid and basic lavas, and we learn that these records of subterranean energy ascend up to the very top of the Cambrian system and beyond it into the overlying Silurian formations. Though less voluminous in their discharges than the Silurian eruptions, those of Cambrian time were perhaps more long-continued over the region of Wales. In the Malvern Hills and in the neighbourhood of Nuneaton traces of other Cambrian volcanic centres have been found.

Unfortunately the Cambrian rocks have been so widely and deeply overspread by later formations that they only appear here and there at the surface where they have been ridged up by subterranean movements and laid bare by prolonged denudation. The next overlying system, known as Silurian, is exposed over a far wider area, and as it also has preserved a long series of volcanic records, we obtain from it a clearer view of the development and characteristics of the older Palæozoic volcanoes. Of the two sections into which it is divided the Lower is pre-eminently replete with volcanic intercalations which are widely distributed over the area of the British Isles on certain definite stratigraphical platforms. The eruptions appear to have come from many separate vents often placed far apart over the sea-floor. Some of these vents, more particularly in North Wales, were already in activity during the Cambrian period. But in Silurian time a much more vigorous display of volcanic energy took place. Each of the three great divisions of the Lower Silurian period was marked by outbursts of lava and ashes. In each volcanic district during the long intervals of quiescence that separated the several periods of subterranean activity, the ordinary sedimentation of the time went on undisturbed, and enclosed and preserved the remains of the organisms that lived on the sea-bottoms. The stupendous piles of material erupted in those ages now form some of the most picturesque mountainous regions in the country. In North Wales they constitute in whole or in great part Snowdon, Moel Siabod, Moel Wyn, the Arans, and Arenig Fawr, and they are prolonged southwards in Cader Idris. Again they form the material out of which the hills and valleys of part of the Lake District have been carved. Even where they rise into no conspicuous eminences they may be detected in so many places all over the southern uplands of Scotland as to show that they underlie the Silurian formations of that region as a great volcanic floor which, though for the most part concealed, has been brought up to the surface again and again on the crests of anticlinal folds. They reappear in the south-east and south of Ireland, and though it is now ascertained that much of the material which in that region has been considered to be tuff proves to be crushed igneous rocks simulating a pyroclastic structure, and that much of the "felstone" mapped as intercalated lava really occurs as intrusive sills, evidence enough remains that active vents rose over the sea-floor during older Palæozoic time in that part of Ireland. Far to the west, in the same long section of geological history, a group of submarine volcanoes rose in what is now the hilly district between Lough Mask and Killary Harbour.

But while it is clear that volcanic action was widespread over the area of the British Isles in the older half of the Silurian period, there is no less certainty that the volcanic centres often stood far apart from each other, were quite independent in their activity, and were not all, even in a geological sense, contemporaneous. The three great subdivisions of the Lower Silurian rocks—Arenig, Llandeilo, and Bala—which must represent a vast succession of ages, have each their volcanic chronicles. We thus learn that the eruptive energy shifted from one part of the region to another; that there were long intervals of quiescence in each district, and that before the close of the period in which the Lower Silurian rocks were deposited the whole series of volcanic foci had become extinct. The volcanoes that were active during the oldest or Arenig eruptions have left their memorials in the ranges of Cader Idris, Aran Mowddwy, Arenig, and Moel Wyn. These thick ranges of rock comprise trachytic or andesitic lavas and tuffs, together with sills of dolerite, felsite, and microgranite. It has been noticed that the upper parts of the series are more acid in composition than the lower—a chemical and petrographical sequence that reappears again and again all through the geological record in Great Britain. The site of another Arenig volcano is indicated by the andesitic tuffs and lavas that rise to the surface in Shropshire between Church Stoke and Pontesbury. To the same geological period we must assign the oldest visible parts of the volcanic platform which has been above alluded to as underlying the Silurian formations of the south of Scotland. This platform appears to extend over an area of nearly 2000 square miles. Whether the volcanic sheet is continuous underneath over this wide tract or is separated into distinct districts marking local centres of eruption will probably never be ascertained. It is interesting to note that while in Scotland the volcanic activity of Arenig times was prolonged in successive eruptions through the Llandeilo and Bala periods, the great volcano of Merionethshire became entirely extinct, and a long interval elapsed in that region when, so far as we know, volcanic action continued quiescent. The Llandeilo rocks of Wales contain no remains of any great volcano, but they are not entirely destitute of contemporaneous volcanic records, for numerous small isolated patches of lava and tuff can be traced at wide intervals down the east side of the principality and across to the coast of Pembrokeshire. Of these the most important is that of Builth; others make their appearance near St Lawrence, around Fishguard and on Abereiddy Bay. But no trace of Llandeilo eruptions has been detected among the volcanic records of North Wales.

The long interval of rest that elapsed after the eruptions of Arenig, the Arans, and Cader Idris, during which Llandeilo volcanoes were active in the southern half of the principality, while no volcanic activity showed itself in the northern half, was at last brought to a close in the north by a renewed and vigorous outburst over the site of Carnarvonshire during the Bala period. To this revival of subterranean energy we owe the mass of Snowdon and the picturesque mountain-groups around it. For a distance of at least 30 miles from south to north the lavas and ashes of this centre of eruption may be traced. Yet there can be no doubt that only a portion of these is now exposed at the surface, and that much of their original mass has been removed by denudation or lies concealed beneath the younger rocks that now form the surface. The mass of ejected material is probably not less than from 6000 to 8000 feet thick; in Snowdon alone the higher part of it amounts to 3100 feet. The lavas and tuffs are thickest around the probable centres of discharge, and are intercalated among the ordinary sediment of the Silurian sea-bottom, in such a manner as to demonstrate that they were erupted during the time when the Bala group of rocks was deposited in the form of sand, mud, and calcareous silt. The lavas are chiefly varieties of felsite or rhyolite, with some andesites towards the top. The tuffs largely developed on Snowdon are sometimes fine-grained well-stratified rocks, more or less mingled with ordinary sediment. They contain the fossils of the Bala group, and indeed occasionally become calcareous and pass into the Bala limestone, which is so marked a palæontological horizon in the Lower Silurian series of North Wales. In other cases the fragmentary materials consist of very coarse agglomerates, including large blocks of felsite and andesite. Some of the vents from which these various lavas, tuffs, and agglomerates were erupted are probably represented by a series of bosses which rise at intervals from Penmaenmawr into the peninsula of Lleyn —a distance of about 50 miles. The latest manifestation of volcanic energy in the district appears to have been the intrusion of a large number of basic sills both into the sedimentary strata and into the overlying volcanic pile. In a geological sense contemporaneously with the eruptions of Carnarvonshire, one or more vents were active farther to the east, on the site of the present Berwyn Hills; others made their appearance where Anglesey now stands. The Lake District, during the same period of geological history, became a centre of remarkable volcanic energy. Over an area of not less than 550 square miles the lavas and tuffs can still be traced there, and they probably extended originally far beyond their present visible limits. They were piled over each other to a depth of perhaps as much as 8000 or 9000 feet, and remain as the chronicle of the most prolonged and most continuous display of volcanic energy among the Palæozoic rocks of Great Britain. The earliest eruptions began in the Arenig period, and they followed each other so uninterruptedly that no marked interval of quiescence separated any of them, at least such as would be indicated by a thick group of intercalated sediments. By one discharge after another, lavas and ashes were heaped upon the sea-bottom until the close of the Bala period.

In southern Scotland and in south-eastern Ireland active vents were scattered over the sea-floor and continued their eruptions until towards the close of the same period of geological history. But after that time a complete quiescence ensued, and continued for a long interval. It is a remarkable fact that over England, Wales, southern Scotland, and south-eastern Ireland, where volcanic action had been so vigorous and prolonged during the Lower Silurian period, no trace has been found of any eruption during Upper Silurian time, except certain igneous rocks at Tortworth in Gloucestershire which may now be regarded as dating from that later epoch. Another centre of volcanic eruption contemporaneous with the deposition of the Upper Silurian formations lies on the coast of the Dingle promontory in the extreme west of Ireland, where nodular felsites, tuffs, and volcanic breccias are intercalated among highly fossiliferous strata of Wenlock and Ludlow age.

The next great cycle of geological time—that of the Devonian and Old Red Sandstone rocks—was marked by a renewal of volcanic energy, more especially over the site of Scotland. The Silurian sea had there given place to land, that enclosed a number of large lakes or inland seas, and it was in these basins that the volcanoes particularly displayed their activity. The largest sheet of water, to which the name of Lake Caledonia has for the sake of distinction been given, seems to have stretched across the midland valley of Scotland between the highlands and the southern uplands, and to have extended at least as far as Lough Erne in the north of Ireland. In this long and wide trough two lines of volcanoes lay towards the northern margin, where the Ochil and Sidlaw Hills now rise. These vents poured out sheets of andesitic and felsitic lavas which, together with abundant showers of ashes and stones, accumulated upon and among the red sandstones and coarse conglomerates that formed the ordinary sediments of the lake. The thickness of volcanic material thus discharged amounts in the Ochil chain to more than 6500 feet, but as the bottom of the whole pile is concealed, the total depth may far exceed that amount. The direction of this line of vents coincided with the trend of the long axis of the lake, that is, from north-east to south-west. In the same general direction, at a distance of perhaps 20 miles to the south, another volcanic bank ran from the neighbourhood of Edinburgh south-westwards through the group of the Pentland and Biggar Hills, by the head of Nithsdale, into the south of Ayrshire. These two chains of eruptive vents are probably prolonged far to the south-west. Traces of the northern series may be observed in the Isle of Arran and at the south end of Kintyre. Beyond the limits of Scotland some of the breccias are well developed on the Irish coast at the Red Bay, Antrim, while still farther to the south-west, between Dungannon and Omagh, numerous sheets of andesitic lava are interstratified among the red sandstones. Nor were the volcanic eruptions confined to this largest of the Lower Old Red Sandstone basins. They occurred on a considerable scale in the tract of Lorne, in the west of Argyllshire. Small scattered vents were opened on the south side of the Moray Firth, in the Orkney Isles, and still more conspicuously among the Shetlands. Possibly while some of these northern volcanoes were active, another group made its appearance in the south of Devonshire, where its lavas and tuffs can be traced in a tolerably continuous belt from Torbay into Cornwall. Long before the time of the Upper Old Red Sandstone vigorous volcanic activity had ceased over Great Britain. There appears to have been another long interval of quiescence during the deposition of the uppermost subdivision of the Old Red Sandstone, only broken, so far as we know, by the appearance of a group of small volcanic cones not far to the south of Limerick, and of another in the island of Hoy among the Orkneys.

The Carboniferous period witnessed another revival of volcanic energy and a considerable modification of the forms in which this energy manifested itself. The volcanoes now belonged to two distinct types, that of *plateaux* and that of *puys*. In the former the lavas and tuffs were discharged over wide areas, generally from small vents or fissures, and were gradually built up into masses several hundred feet thick. This type was the older of the two. It made its appearance at, or perhaps even before, the close of the Upper Old Red Sandstone period; but ceased before the Carboniferous Limestone began to be laid down. The second type showed itself in the appearance of small vents from which sometimes only ashes, and, even in the most vigorous examples, comparatively limited streams of lava were emitted. The pipes or funnels of these volcanoes are now marked by plugs of tuff or basalt, and are generally the most conspicuous and sometimes the only visible record of the volcanic action that produced them. Both volcanic types are developed almost entirely in the south of Scotland. The plateaux extend from Stirling, through the Campsie, Dumbartonshire, and Renfrewshire hills, to the heart of Ayrshire and the borders of Lanarkshire. They form the Garleton hills in Haddingtonshire, and they stretch in an interrupted band from the Merse of Berwickshire across the hilly country of the Slitrig and Liddesdale to the southern coast of Kirkcudbrightshire and into the English border. The *puys* are the more usual and more widespread type of Carboniferous volcanoes. Their chief development is to be found in the Lothians and Fife, where they are so abundant, well-preserved, and clearly exposed that this district may be regarded as classic ground for their study. The *puy* type is seen among the toadstones of Derbyshire and far to the south in the few scattered vents of West Somerset. It is also exemplified in Ireland by the neck of Croghan Hill, King's County, and by the remarkably interesting volcanic district of Limerick. Carboniferous eruptions began earliest and lasted longest in Scotland. They were feebler than those of the Old Red Sandstone, as these in turn were less voluminous and widespread than those of older Palæozoic time. They displayed as large a range of petrographical composition among their materials as those of previous ages, for they included such highly basic rocks as picrite, together with basalts and dolerites, andesites, trachytes, and phonolites, and even more acid rocks containing free quartz. They became extinct in England and Ireland long before the end of the deposition of the Carboniferous Limestone; in Scotland they likewise ceased generally within the same period, but in Ayrshire they prolonged a diminished activity until the Coal Measures began to accumulate.

The continued enfeeblement of volcanic energy over the area of the British Isles is strikingly displayed by the next group of small scattered vents and occasional sheets of lavas and tuffs, which are probably referable to the Permian period. These remains are almost wholly confined to the south of Scotland. In Ayrshire, where they are best developed, a number of "necks" of tuff and agglomerate rise through the Coal Measures. From these, and no doubt other buried vents a thin series of basic lavas and tuffs has been ejected, which overlies the Coal Measures and passes under a group of massive brick-red sandstones which are believed to represent the Permian sandstones of the north of England. Again in Nithsdale small patches of similar volcanic rocks are found intercalated in the prolongation of the same red sandstones. But for the most part, only the necks of the little volcanoes have been preserved, all trace of any material which may have been thrown out from them having been removed by denudation. In the east of Fife, within an area of about 70 square miles, upwards of eighty distinct vents have been counted. In a space of only about one square mile, near St Andrews, some two dozen separate "necks" have been detected, each marking the site of a volcanic orifice. It cannot be affirmed with certainty that all these vents belong to the Permian period, but some of them which pierce the very uppermost subdivision of the Coal Measures must be later than that group of strata, and may thus be considered as not older than Permian time. If some of the series be so late, there seems a probability that others, perhaps the whole, having the same general characters and mode of occurrence in the district, may be of similar age. The only other volcanic series that may be referable to the same part of the geological record lies in Devonshire near Exeter and Crediton. Lavas of basic and intermediate character are there intercalated among the presumably Permian red sandstones and breccias.

In our review of the volcanic history of Great Britain we have now arrived at one of its most important stages. The decay of energy traceable among the later Palæozoic periods becomes strikingly manifest in the scattered little vents of southern Scotland and Devonshire just referred to, which were, so far as yet known, the last Palæozoic manifestations of the underground fires. Throughout the whole of the Mesozoic rocks not a single trace of any contemporaneous eruption has been met with. And yet these rocks are admirably exposed over hundreds of square miles of inland country and for many miles of coast-sections. Had they contained any record of volcanic eruptions we may conclude that it would ere now have been detected. But this remarkable quiescence of Mesozoic time was not confined to Great Britain; we find that throughout the continent of Europe, with some trifling exceptions, there is a similar absence of any relic of contemporaneous volcanic disturbance. The gradual enfeeblement of energy in the Palæozoic periods was followed by a vast interval, in the voluminous sedimentary records of which no trace of volcanic action has for the most part been found.

After this momentous pause, the pent-up internal energy once more broke out with renewed vigour and on a scale not inferior to any of its earlier displays. Over the north of England, the southern half and west coast of Scotland, and the north of Ireland—a total area of more than 40,000 square miles, and therefore larger than either Ireland or Scotland—the solid crust of the earth was rent by thousands of fissures, having a general parallelism of direction from south-east to north-west. Up these innumerable dislocations molten rock rose from below, and solidified there in a great system of dykes, for which the British Isles have long been celebrated. So far as the geological record enables us to pronounce an opinion, nothing of the kind on so colossal a scale had taken place in any period in the history of the country since the wonderful dyke-intrusions in the Lewisian gneiss. From the independence of geological structure which the dykes maintain, they are evidently of comparatively late date. They cross indifferently all the various formations up to the Chalk and the volcanic plateaux which, on the strength of imbedded vegetable remains, have been pronounced to be older Tertiary, that is, about the age of the London Clay and other associated deposits in the south of England. When we consider the wide area over which these dykes extend, and reflect that they indicate a connexion with one or more subterranean reservoirs of molten materials which at some unknown, but probably not very great, depth beneath the surface extended over a tract of the terrestrial crust about 40,000 square miles in extent, we may surmise that this upwelling lava would hardly everywhere stop short of the surface, but would not improbably break forth here and there, so as to give rise to the ordinary phenomena of volcanic eruptions. In actual fact we see that such outbreaks have taken place on a vast scale in the north of Antrim and along the west coast of Scotland. If any superficial discharges occurred in the south of Scotland or the north of England, all trace of them has been removed by denudation. Late though the eruptions were in geological history, the time which separates them from the present day is so vast as to have allowed a stupendous waste of the surface, so that only a series of fragments of this youngest chapter of the volcanic chronicle has come down to us.

The great basalt plateaux of Antrim, Mull, Morven, and Skye consist of successive sheets of basaltic lava with occasional layers of tuff and seams of sediment containing remains of an older Tertiary terrestrial flora. These volcanic piles must originally have attained a great thickness. Their surface has been enormously wasted and lowered, yet even now they are more than 3000 feet thick in Mull. They must have been poured forth like the lava-floods of Iceland and the Snake river, stretching out as a level plain of black basalt and scoriæ over areas of many hundred square miles. Vast numbers of sills were injected among the strata beneath the volcanic pile, and likewise between the successive sheets of the pile itself. Huge sills or bosses of gabbro that disrupted the level lavas of the plateaux are now visible in the picturesque mountain-groups of the Cuillin hills, the Isle of Rum, Ben Buy in Mull, and the promontory of Ardnamurchan. Subsequently still more extensive intrusions of granitoid material broke into the basalt and into the gabbro, further disturbing the regularity of the plateaux. And lastly renewed dislocation of the crust and fissuring of all the Tertiary volcanic series led to the uprise of a new series of basaltic dykes. These latest manifestations of subterranean energy formed the concluding phase of the Tertiary eruptions, and they close the long record of the volcanic history of Britain. Since their time denudation has been unceasingly at work; the Tertiary plateaux, with their various invasions of eruptive material, have been dissected in countless valleys and ravines and on long ranges of sea-cliffs, and their structure has thus been revealed with a fulness of detail such as none of the earlier records presents for the consideration of the geologist. It may be remarked, in passing, that the lessons in the history of denudation derivable from the study of these Tertiary volcanic rocks are not less interesting nor less important than those which relate to vulcanism. Thus, there can be no doubt that the present topography of Scotland has been mainly carved out by subaërial action since the Tertiary eruptions. It can be demonstrated, for example, that wide and deep glens, such as that in which Loch Lomond lies, and long and deep sea-lochs and straits like the fjords of Skye and the Sound of Mull, have all been gradually excavated since that time.

Conclusions as to the history of vulcanism.

From the study of so remarkably varied and complete a chronicle as is found in Great Britain some conclusions of interest may be drawn regarding the history of vulcanism during the geological past. It is evident from the distribution of the British volcanic rocks that they have been erupted along the continental border, mostly over the sea-bottom and in a general north and south direction. One of the most impressive features of these rocks is their reappearance on different platforms during successive geological periods, and the persistence of volcanic energy which they thus prove to have been maintained in the British area during so vast a section of geological time. An attentive consideration of the distribution of these rocks furnishes ample proof that, in a number of instances, the same district became, at widely-separated intervals, the theatre of eruptions, while other tracts remained entirely and persistently free from any such manifestations of subterranean activity. The plateau-eruptions were connected with abundant fissures, represented now by multitudes of dykes. On the other hand, the ordinary volcanic vents, from the earliest times to the latest, do not furnish any evidence of having had their sites determined by important lines of fault or other dominant geological structure. But they do show a frequent preference for lines of hollow rather than hills and ridges. They made their appearance in areas that were subsiding, and the majority of them were submarine. Alike in the nature and composition of the erupted materials, and in the form in which the volcanic activity showed itself, the volcanoes of the geological past have their counterparts in those of recent time. There has been, indeed, a singularly persistent uniformity in the main characters of vulcanism throughout geological history. The Vesuvian and Icelandic types of volcano can be recognized even among those of the Palæozoic ages.

Another important fact in the history of vulcanism is clearly deducible from the geological records of Britain. There has been no gradual and progressive diminution in the intensity of the volcanic forces during past time, such as some physicists have asserted to have occurred as a necessary consequence of the slow cooling of the planet and its resultant loss of energy. If we take a broad view of the volcanic chronicle of Palæozoic time, we find evidence of many successive periods of eruptive activity, differing from one another in vigour and duration, and each showing a time of maximum energy, followed by a time of diminution, and then by a time of absolute quiescence. It is true that the later eruptions of the Palæozoic ages showed a marked diminution in number and area, as well as in the variety and amount of the igneous material ejected. It is likewise true that this obvious dying out of the subterranean forces was followed by the long and profound calm of Mesozoic time. Nevertheless it is no less certain that when these forces reawakened in the older Tertiary ages, they showed themselves on at least as vast a scale as ever, ranged over a wider region, and poured out more voluminous floods of lava.

Denudation has so extensively laid open the igneous rocks of former ages that innumerable points in the detailed structure of volcanic vents, fissures, and plateaux can be studied to which no access is possible in modern volcanoes. The whole history of a volcano or volcanic epoch, from its beginning to its end, is disclosed. We see that many vents were opened by gaseous explosions, without the aid of any concomitant or pre-existing fissure. We can trace the actual walls of a vent, and mark how the materials have been piled up within them. We can follow the effects of the volcanic heat upon the surrounding rocks, and of the uprise of heated vapours through the materials that choked up the orifice. And we discover how important a part in the subterranean operations of volcanoes is taken by the intrusion of sheets of molten material among the surrounding rocks.

One of the most interesting results of a study of the volcanic rocks of Great Britain is the proof thereby obtained of the gradual change in the condition of the molten magma during the course of a continuous volcanic episode. The evidence shows that the reservoirs which supplied the lavas usually began with the emission of material basic or intermediate in composition, which became finally more acid, and even gave forth such rocks as granite and felsite. Moreover, this sequence from basic to acid was repeated in successive geological periods sometimes even in the same region. It thus appears that the magma beneath a volcanic centre, after it has become acid, and after the volcanic activity has ceased, eventually, during the prolonged interval of quiescence, acquires once more a basic character, and goes through a similar gradual change of composition in the next volcanic cycle.

While the British records of ancient volcanic activity are more complete, and have been more fully explored than those of other countries, the progress of investigation has brought to light many new facts of interest and importance in regard to ancient eruptions in regions which have long been unvisited by any such outbreaks. Thus in the north-west of France a remarkable succession of four principal periods of eruption has been discovered by Prof. Barrois, who records the existence there of volcanoes in Cambrian and Lower Silurian time, of others in the ages of the Middle and Upper Silurian rocks, of a third series in the Upper Devonian, and of a fourth in the Carboniferous period. The Harz supplies volcanic rocks of Silurian, Devonian, Carboniferous, and Permian age. The volcanoes of this last-named period broke out also in Thuringia and Bohemia, and even as far as the shores of the Mediterranean to the west of Cannes. In Tirol active vents existed in Triassic time. The period of volcanic calm which is so marked in the geological record of the British Isles during Mesozoic times appears to have extended over the site of continental Europe, though some rocks in Portugal may possibly mark Cretaceous eruptions, while others in the Crimea have been cited as of Jurassic age. But it was in Tertiary time that volcanic energy recovered its ancient vigour over all the European area. The British examples already referred to were accompanied and followed by copious eruptions. During a long succession of geological periods on the Continent, in central France, Rhineland, Saxony, Bohemia, Hungary, Würtemberg, Italy, and other parts of Europe, innumerable vents were active from an early part of Tertiary time, and some may not have become extinct until shortly before the dawn of history.

Earthquakes (see also separate article).—Much information has been gathered in recent years regarding the movements of the earth's crust. Those of the sudden and paroxysmal kind embraced under the general term earthquakes have been studied by means of self-recording instruments in countries which, like Japan, are specially subject to them; while in other regions, where no such instruments are established, the phenomena have been subjected to a more exhaustive examination than was formerly attempted. We now know that what we call the "solid earth" is liable to continual vibrations and tremors which, though for the most part inappreciable by the ordinary senses, can be detected by delicate instruments, and are sufficiently pronounced to have frustrated observations to determine the lunar disturbance of gravity. Slight movements of this nature arise from changes of atmospheric pressure and temperature, and from movements in the soil caused by heavy rain and by frost. There are likewise slow and periodic changes of level within small limits. Some of these depend on daily, others on seasonal, conditions, such as temperature, moisture, and evaporation. It thus appears that the surface of the land is in a perpetual state of strain from the influence of forces acting from without.

Though it cannot yet be said that the origin of earthquakes is quite understood, some appreciable advance has been made towards the comprehension of this geological problem. There can be no doubt that any movement upon or within the earth, sufficiently violent to give a stroke or blow, and thereby generate an elastic wave or series of waves, will produce an earthquake. A sudden rock-fall or landslip from the side of a mountain, if of sufficient magnitude, may give rise to a widespread concussion of the ground. But the phenomena of true earthquakes arise from changes within the earth. In volcanic districts these precede or accompany the violent explosions by which steam, gases, ashes, and lava are projected from the earth's interior into the atmosphere. In non-volcanic regions they may arise from the sudden collapse of underground cavities, such, for instance, as has been caused by the solvent action of percolating water. But in none of these instances do earthquakes reach their greatest intensity and widest range of disturbance. It has now been established that earthquakes are most frequent and most violent in regions where there are no active volcanoes. Hence it is reasonably inferred that, although volcanic explosions undoubtedly give rise to severe concussion of the ground, this effect is comparatively local, while the more potent earthquakes extend over vast areas of the globe. It has further been noted that earthquakes are specially prevalent in mountain regions, also in tracts that lie along one or more lines of fault, or on the critical line between the continental plateaux and the ocean basins. In all these tracts the crust of the earth is probably in a state of strain and of unstable equilibrium. It has there been bent by tangential pressure and rupture, and has consequently become weakened and ready to give way again under an accumulation of the same cause. For years or centuries no change may take place along one of these lines of weakness, but eventually the strain becomes irresistible, and the crust gives way in a sudden snap. In the case of the more powerful earthquakes, the bending and fracturing, instead of being confined to a mere point, like the focus of a volcano, may stretch for many leagues along the axis of a mountain chain, or along the submarine front of a continent. And thus the cause of the concussion of the ground may be propagated through the crust for hundreds of miles beyond the centre at which the beginning of the snap took place.

The phenomena of earthquakes are discussed in the article on this subject. We are concerned only with their immediate geological relations. Though the progress of observation has not materially increased our information regarding the nature of the geological changes brought about by earthquakes, many new and striking illustrations of these changes have been noted. Of the numerous additional examples which have been chronicled of the effects produced upon the soil and general surface of a country, some of the most remarkable have been observed in Japan. Reference may be specially made to the severe earthquake which convulsed that country on 28th October 1891. By that visitation in 30 seconds 10,000 people were killed and twice that number were wounded; 128,750 houses were levelled with the ground, besides numerous temples, factories, and other buildings; railway bridges and viaducts were twisted and ruined, and hundreds of square miles of central Japan were laid waste. Green forest-covered mountains were denuded of their trees and turned into ridges of naked stone. Everywhere landslips were produced, and the valleys were blocked up with the rubbish, so that lakes were formed by the interrupted drainage. But, besides these superficial and more or less transient effects, others were noted of a more deep-seated and more lasting kind. The surface of the ground underwent a horizontal compression, whereby valleys and river-beds had their sides brought nearer to each other, so that in the reconstruction of the ruined bridges the engineers had to allow for a diminution of from 1 to 3 per cent. in the length required. A rupture of the ground could be traced for 60 miles, showing in many places as a long low cliff. On one side of this dislocation the ground had sunk some 20 feet, and other evidence was obtained of an alteration of the relative levels of the country. These remarkable results confirm observations made in other earthquake countries. They show the paramount influence of the rupturing of the terrestrial crust, and they serve to indicate that though no stupendous geological change may be made, even by the most violent earthquake, the repeated recurrence of such events may eventually entirely change the surface of a country.

Further light on the geological results of earthquakes has been obtained from a study of the effects of the great catastrophe which on 12th June 1897 devastated about 150,000 square miles in Assam and the adjacent parts of India, and of which the shock was felt over about 1,750,000 square miles of the earth's surface. A voluminous report on this event, prepared by Mr R. D. Oldham for the Geological Survey of India, has more especially added to our knowledge of the fissures in the ground which have so frequently been observed in great terrestrial disturbances. From the detailed narrative in this report, it appears that two distinct types of fissures could be recognized, one of a superficial, the other of a deep-seated origin. The ruptures of the first class probably start at the surface of the ground and descend to variable but, no doubt, shallow depths. They are probably produced by the wave-motion which is propagated outwards from the centre of shock, and are more especially developed in the alluvial plains, where their direction is often determined by that of a river-course, line of embankment, or roadway. The fissures of the second type arise from displacements within the terrestrial crust. They much less frequently appear at the surface, where they not merely affect the alluvial deposits, but even split through hills of crystalline rock, and where they are accompanied by evidence of great violence of shock. They are regarded by Mr. Oldham not as a result of the wave-motion, but as themselves a cause of that motion and as surface manifestations of the deeper-seated fracture of the crust to which the origination of the earthquake wave is to be ascribed. The tract of country within which this type of fissure was displayed extended in an east and west direction through the hills and plains of Assam for a maximum distance of perhaps 200 miles, with a maximum breadth of 50 miles. Along this belt, at a depth of not improbably less than five miles below the surface, a sudden rupture or overthrust of the terrestrial crust is believed to have taken place, accompanied by secondary thrust-planes and faults, some of which actually extended up to the surface of the ground.

Apart from great destruction of life and property, extensive prostration of forests, and other relatively evanescent though lamentable effects, this Indian earthquake of 1897 left many more lasting traces of its passage. The surface of the alluvial plains was thrown into undulations, and after the catastrophe did not return to its previous condition. Some portions remained permanently depressed, and now became receptacles for the interrupted drainage, which thus gathered in pools and lakes over the sunk land. Moreover, there was a horizontal displacement or torsion amounting sometimes to as much as 10 or 15 feet. River banks were pushed nearer to each other, and the beds of the narrowed streams were ridged up until sometimes they were on a level with the banks on either side. Vast numbers of landslips took place along the sides of the hills and river-courses, whereby the drainage was seriously affected. One of the most interesting observations contained in Mr Oldham's report has reference to the production of lakes along a river valley. One of the great lines of fault was traced for some 12 miles along the course of the Chedrang river. In some places its throw or vertical displacement amounted to as much as 35 feet, but elsewhere it diminished and disappeared. There was thus a differential movement whereby some portions of the river-bed were pushed up into the air, while other tracts of the valley were depressed below the level of the stream. The line of fault, which has an upthrow to the east, repeatedly crosses the river, which is consequently ponded back in a pool when the elevated side faces up stream, and tumbles over a waterfall when that side looks down stream. Wherever the line of fault could be traced in solid rock it was found to be a vertical fissure. A chain of pools and lakes has been formed along the valley. One of these sheets of water is fully half a mile long, between 300 and 400 yards broad, and 18 feet deep. Another of still larger dimensions occurs farther down the stream. Where the fault leaves the hills and runs out into the plain, much more extensive alterations of the drainage have taken place, wide tracts of ground have been submerged, and the sites of fields and villages are now covered by lakes 12 feet or more in depth. Similar effects have been produced over wide tracts of alluvial country which have not been directly affected by the deep-seated fractures, but have been thrown into undulations and traversed by superficial fissures. Some of the lakes formed by the depression of the ground are upwards of 20 feet in depth.

Secular Upheaval and Depression.—It is now recognized that the surface of the sea preserves no uniformity in its distance from the centre of the earth, but is liable to wide divergences therefrom. The term "sea-level" is thus apt to be somewhat misleading. The surface of the ocean in the equatorial regions must be more than thirteen miles farther from the centre than it is at the poles, so that any diminution in the rate of rotation would cause the ocean to sink at the equator and rise at the poles. The preponderance of water in the southern hemisphere appears to be due to an excess of heavy materials in the lithosphere under the Pacific Ocean, so that if any transference of such materials to the northern hemisphere were conceivably possible it would shift the level of the ocean. But these causes of difference in the distance of the surface of the sea from the earth's centre may be regarded as permanent. There are others, however, of a less fixed kind which affect sea-level, and any modification of which may at any time give rise to changes in that level. The attraction of large masses of high land raises the surface of the neighbouring ocean. Thus the influence of the chain of the Himalaya causes that surface to be 300 feet farther from the planet's centre at the mouth of the Indus than it is 1200 miles away in Ceylon. Hence any movement of the crust whereby the bed of the sea is raised into land, and especially into lofty land, will draw the ocean water towards the elevated region. The accumulation of masses of snow and ice, thousands of feet thick, at the pole will attract the oceanic water and lower the sea-level in other parts of the globe. The mere removal of so much snow and ice from the general body of water on the earth's surface must tend to lower the sea-level, so that fluctuations in the bulk of the polar ice-cap will be accompanied by corresponding variations in the general surface of the ocean. Any cause which may give rise to an excessive heaping up of ice at one pole, while the opposite pole is relieved of the ice-cap, will tend to shift the centre of gravity of the planet and to raise the level of the ocean where the frozen material accumulates. Again, in inland seas considerable variations of the water may arise from meteorological conditions, especially from excessive rain or drought, as has been registered in the Baltic and Gulf of Bothnia.

That some of these causes of alteration in the relative levels of sea and land are not without influence at present, and have come into play in the past history of the earth, may be freely conceded. We may grant that in various ways the sea may rise and fall even to the extent of hundreds of feet without any change in the position of the surface of the lithosphere. Obviously, it may often be hardly possible to distinguish the effects of such transferences of the oceanic water from those that have been produced by movements of the lithosphere itself. No fact is more abundantly demonstrable in geology than that the sea-floor has again and again been ridged up, convoluted, fractured, and elevated not only into land, but into chains of lofty mountains. But besides the more violent disturbances directly connected with mountain-making, others of a gentler kind appear to take place, not perhaps in any essential point differing from these, save in intensity and duration. These slower and more tranquil alterations of the relative levels of sea and land are sometimes in an upward, sometimes in a downward, direction. They must be caused either by a rise or fall of the sea-level or by an upheaval or depression of the surface of the lithosphere. The opinion of geologists is divided as to which of these two causes should be invoked. During most of the 19th century the general belief was that on the whole it is the land rather than the sea that rises and falls. In recent years, however, this view has been combated by Prof. Suess of Vienna, who holds that the limits of the dry land depend upon certain large indeterminate oscillations of the statical figure of the oceanic envelope; that not only are "raised beaches" to be thus explained, but that there are absolutely no vertical movements of the crust save such as may form part of the plication arising from secular contraction, and that the doctrine of secular fluctuations in the level of the continents is merely a remnant of the old Elevation-crater theory, destined to speedy extinction.[1]

Of the fact that within recent times large tracts of land have emerged from the sea, while other tracts have been submerged, there cannot be any question. If these changes arise solely from some alteration of the figure of the ocean, they can hardly be of merely local occurrence, nor can we suppose that they vary in amount within short distances, or change from an upward to a downward direction. Where any such local peculiarities make themselves manifest we are constrained to regard them as arising from unequal movements of the land and not from an advance or retreat of the sea.

One of the classic regions for the study of this question is the Scandinavian peninsula, together with the basin of the Baltic and the coast-line of Finland. The earlier observations were hardly precise enough and continued over a sufficiently long time to warrant perhaps the definite conclusions drawn from them. But since 1875 the investigation has been pursued with great care, and the result has been to afford good ground for the conclusion that, after every allowance has been made for seasonal variations of the sea-level in the Baltic and Gulf of Bothnia, there is trustworthy evidence of a gradual elevation of the Scandinavian peninsula. The axis of movement appears to coincide broadly with that of the peninsula, and to increase towards the interior of the land. In some places, both on the Kattegat and on the shores of the Gulf of Bothnia, the rate of rise is estimated at 25 centimetres or nearly 10 inches in a century; but at Quarken, where the gulf narrows, the rise on the west side has been computed at 1 metre or 3 feet 3 inches during the last hundred years. On the coast of Finland the upward movement gradually diminishes and disappears in the Baltic provinces, and at St Petersburg no change of level has been detected.[2]

Important observations have in recent years been made in the region of the Great Lakes of North America, which indicate that a slow elevation of the land is in progress towards the north-east, so that the water of the lakes is being driven towards the south-west. In the latter direction the shores are undergoing submergence, while towards the opposite quarter they are gaining ground. The rate of movement is estimated to be four-tenths of a foot in a hundred miles during a century.[3]

Much interesting information on this subject has recently been gathered in Japan, where volcanoes, earthquakes, and slower movements of the ground are developed on so striking a scale. Though volcanic action is abundant and vigorous in that country, observation shows that the most powerful earthquakes are not connected with volcanic eruptions. They originate partly in tracts of old crystalline rocks, but mainly under the sea beyond the eastern coast-line of the islands. We have seen that they sometimes give rise to important changes of level in the land. But besides such sudden alterations others have been watched which, while they are in progress, are in themselves inappreciable, and can only be detected after the lapse of more or less time. They are partly of an elevatory and partly of a subsiding nature. In order to obtain more ample and more definite information in regard to these changes, Prof. D. Kikuchi, of the Imperial University of Japan, in the year 1891 issued a circular to officials at the principal towns and villages round the coast, requesting them to furnish any evidence they could collect of advance or retreat of the sea.[4] Out of several thousand replies received, very few intimated that there had been no change. During fifty years, and even in some places within ten years, harbours had become shallow at rates varying from 1 foot in three to 1 foot in ten years. Some of this change must no doubt be attributed to the abundant deposit of sediment brought down by rivers from the land. But no amount of silting up will explain the concomitant uprise of cliffs carrying with them their faces pierced by boring shells, their seaworn caves, and the sea-beaches deposited at their feet. Prof. Milne, who has personally examined the evidence, concludes that some portions of the east coast of Japan are, at the lowest estimate, emerging from the sea at the rate of about an inch per annum. Elsewhere the change has been of an opposite kind. Grass and rice fields have disappeared, and have been replaced by beaches of sand or shingle; rocks have sunk, the height of the tide has increased and the depth of the sea has augmented at rates varying from 1 foot in sixteen years to 1 foot in five years; buildings and roads are now threatened, and the sea advances so rapidly that the inhabitants contemplate removing inland. Maps constructed a century ago show that the sites of former dwelling-places are now beneath the sea. Some of these changes may be accounted for by ordinary marine erosion without any change of level either in the sea or on the land. But their general concurrence, taken together with the submarine prolongation of land-valleys, seems to show that certain portions of the Japanese coast are actually undergoing submergence.

It is impossible to suppose that within the compass of a limited district the level of the sea can be at the same time both falling and rising. Any simultaneous change of sea-level within such a district must be nearly uniform and in the same direction. The actual observed divergences in direction and in rate of change are only explicable on the supposition that it is the land which is undergoing distortion, whereby some portions of it are pushed upwards, while others subside. Thus the evidence of recent changes of level in Japan confirms the general belief which has been recently impugned.

A study of the raised beaches of Great Britain affords further support to the view that it is the land rather than the sea that has shifted its level. These evidences of old sea-margins are traceable along the south coast of England at various levels. But it is in Scotland that the former "strand-lines" are most abundantly and most clearly developed. These lines sometimes consist of terraces of deposit, like the sand, gravel, and silt of the present shores, and are then properly described as "beaches." But in other places they are platforms of erosion, which have been cut along the edge of the land when the sea-margin stood at higher levels than it does now. They appear on both sides of the island, but are more especially marked on the west side from the Firth of Clyde to the coast of Ross-shire, and on the east side in the estuaries of the Forth and Tay and along the shores of the group of northern firths between Inverness and Helmsdale. Where most fully developed, as near Tain, they are at least five in number, and follow each other in successive platforms at heights of about 15, 25, 50, 75, and 100 feet. It is much to be desired that a careful topographical survey with accurate levellings were made of these terraces on both sides of the country, with the view of determining their variations in level. So far as present information goes, they do not preserve strict uniformity, and their local

differences appear to be too great for any variation of sea-level, and to require irregularities in the uprise of the land. One of the most remarkable peculiarities in their distribution is the fact that, although so well developed, up almost to the extreme north of the mainland of Scotland, they cease beyond that point. On the Orkney and Shetland Islands they have not been detected, although numerous sheltered inlets would have preserved them there had they ever been formed. The "submerged forests" of western Europe, quoted to prove sinking of land, have probably been mostly caused by mere local slipping of peat attacked and overspread by the sea.

Evidence of coral reefs.

One of the proofs formerly relied on in favour of widespread sinking of the lithosphere was the structure and distribution of coral islands. Darwin's striking hypothesis to account for these oceanic points of land captivated the imagination, while at the same time his explanation of the successive stages by which fringing reefs became barrier reefs, and barrier reefs became atolls, appeared so clear and convincing that the conclusion he drew was not only universally accepted, but was regarded as one of the most signal achievements in science ever accomplished by any geographical expedition. It was received as an established truth in geology that the rings of coral, so widely distributed over the Pacific and Indian Oceans, proved a vast subsidence of the floor of these sea-basins and the gradual submergence of wide tracts of land which once rose on their site. But the progress of investigation has shown that though Darwin's explanation may still hold good in some cases, it cannot be regarded as of universal application, and that more especially it can no longer be held to prove that widespread subsidence which was claimed for it. As far back as the year 1868 C. Semper met with some reefs among the Pelew Islands which he could not explain by Darwin's hypothesis of general subsidence, for only 60 miles away from them he found upraised coral reefs and an island entirely without reefs. He therefore concluded that these atolls had grown up upon an area of sea-floor that was rising rather than sinking.[1] A few years later J. J. Rein brought forward the coral reefs of Bermuda as examples that could be explained by the accumulation of calcareous organisms upon the bottom, without necessarily requiring subsidence.[2] Subsequently the subject was more fully investigated by Mr (afterwards Sir John) Murray, one of the naturalists attached to the *Challenger* expedition. From all that he had seen of coral reefs he was led to infer that they may arise without any assistance from a sinking of the sea-bottom. It appeared to him that they might grow outwards from the land upon the top of a steep slope of their own debris, broken off by the waves. He thought that this growth might continue seawards until the steep face of calcareous material had advanced into deep water, and thus that while the whole of it might be supposed to be actually coral that had grown upwards from the bottom, only the uppermost 20 fathoms or thereabouts might be coral rock still *in situ*, all below that upper layer being calcareous debris on which the living corals had built. He pointed out the obvious connexion between the distribution of coral reefs and that of volcanoes in the Pacific basin, and showed that the atolls appeared always to have been planted on the tops of submerged volcanic peaks. To the obvious objection that it was difficult to conceive the possibility of so vast a number of volcanic cones coming just up to the level at which coral-building polyps could begin their operations he replied that those which lay too deep might be brought up to the proper level by the gradual deposit of the remains of the organisms that abound in these waters, while those which rose too high might be cut down by the waves to the depth at which the reef-builders could commence.[3] These views have been further developed by Professor Alexander Agassiz, who has applied them in elucidation of the history of the Florida reefs and those of the West Indian Islands, Hawaii, Fiji, and Australia.[4] He has brought forward abundant evidence, additional to that originally furnished by Semper, that fringing reefs, barrier reefs, and atolls co-exist in the same region, and that no general subsidence can possibly explain their association. He has shown that the whole group of the Fiji Islands has been upraised to a height of more than 1000 feet, and he claims that the east coast of Australia, so famous for its great barrier reef, has risen as much as 2500 feet. Dr Guppy has supplied important evidence from the Solomon Islands, where he has found that fringing reefs, barrier reefs, and atolls have been formed in a region that is undergoing upheaval, and that the elevation has amounted to 900 feet or more.

With the view of obtaining accurate information as to the thickness of a living coral reef and the nature of its foundations, a committee of the Royal Society was appointed in 1896 to investigate the structure of the atoll of Funafuti, one of the group of the Ellice Islands. Professor Sollas, on whose initiative the research was started, was appointed to take charge of it, and he spent some time on the island. Though he made many interesting observations and brought away much valuable material to be worked out in regard to the composition and history of coral reefs, the boring came to a stop before any decisive results had been obtained. Subsequently the investigation was resumed by Professor Edgeworth David, of Sydney, New South Wales, under the auspices of the same committee. The boring was begun again, and continued to a depth of more than 1000 feet without meeting with any other than calcareous and dolomitic material. For a discussion of the results see under ANTHOZOA; but sufficient evidence has now been accumulated to show that coral atolls do not necessarily prove subsidence, and that they can no longer be brought forward as in themselves a demonstration of widespread submergence over the basins of the oceans.

4. Structural Geology.

In this division of the science, treating of the arrangement of the rocks in the crust of the earth, the chief progress made has been in the department that deals with the curvatures and dislocations which rocks have undergone since their formation. Though such changes of position may almost everywhere be detected, it is in mountain chains that they are most impressively developed and can be most profitably studied. Accordingly the Alps have long been classic ground for the investigation of these problems of geology. Even to the uninstructed traveller the proofs of gigantic movements are so manifest that he cannot miss them. No one, for instance, can sail up the Lake of the Four Cantons without marvelling at the way in which sheets of solid gray limestone, hundreds of feet in thickness, have been tossed and folded, as if they had been mere piles of carpet, showing their crumpled layers from the level of the water up to the crests of the mountains on either side. But when the geologist begins to explore this corrugated structure, he finds it infinitely more complicated than could ever have been anticipated. The oldest rocks have been placed above the youngest, and now cap the summits, while the later formations have been often plunged deep under the valleys. Fortunately the order of succession of the different members of the Alpine stratigraphical series can be satisfactorily deter-

mined, from experience in other lands which have escaped such intense disturbance. Partly by the evidence of fossils, and partly by that of lithological characters, the actual position of the several rocks and groups of rock can be fixed with considerable accuracy. It was indeed only after this knowledge had been laboriously acquired that geologists began to realize how vastly more complex the structure of the Alps is than could otherwise have been suspected.

At the beginning of the 19th century Leopold von Buch and Conrad Escher von der Linth attempted to grapple with the difficulties of Alpine structure. After them Bernhard Studer, Arnold Escher von der Linth, Murchison, and Sedgwick attacked the same problems and threw much light upon them. Studer's life-long devotion to Swiss geology did much to advance our knowledge of mountain-architecture. Arnold Escher carried on with brilliance and success the labours bequeathed to him by his father, and he imbued with his own enthusiasm his pupils Heim, Baltzer, and Mösch. These younger enthusiasts have thrown themselves with ardour into the study of the questions left to them by their predecessors. Heim has especially gained distinction by his minute and laborious investigations of the Glärnisch, Tödi, Windgällen, and other mountain groups, by his unrivalled drawings of the complicated intricacies of structure in these groups, and by the ample discussion of that structure in his beautifully illustrated volumes published in 1878, *Mechanismus der Gebirgsbildung*. This was by far the most important treatise that had yet appeared on the subject, and marks a great advance in the treatment of the problems of mountain-building. Fastening on the evidence of intense plication, Heim followed it up not only into the architecture of great mountain-masses, but downwards step by step in unbroken sequence, till he traced it into such minute details as can be appreciated in hand-specimens. He brought forward abundant proofs that the rocks of the Alps had undergone enormous pressure, in virtue of which they had been folded, compressed, and crushed, and had been reduced to a kind of plastic condition. He believed that the Mesozoic strata of the Alps had been thrown over in folds extending with gentle inclinations for many miles across the mountains, the so-called "double fold" of the Glarner Alps being the most conspicuous example. But he found no prominent place in his sections for dislocations, as important parts of the structure of the ground. It was not difficult to admit that in the deeper portions of the disturbed area of the terrestrial crust, under the vast pressure there existing, movements of the rocks might conceivably take place without faults, by an internal disruption or plasticity. But in the higher parts, where the pressure was greatly diminished, it might be expected that displacement by faulting of some kind would come into play.

That within some indeterminate limits the causes invoked by Heim were adequate to produce the effects ascribed by him to them, could not be doubted. But it was difficult to follow him when he applied his explanation to account for the disappearance of thick formations by mere plasticity. Thus, in the mountain-group culminating in the Hausstock, between the valley of the Linth and that of the Vorder Rhein, the Jurassic formations are represented by him as thrown into the immense "double fold" just alluded to, the two loops of which are supposed nearly to meet somewhere above the crest of the Hausstock. In the upper limb of the western fold these formations are some hundreds of feet in thickness, as shown on the eastern slopes of the Glärnisch. But only a short way below, on the side of the Linth, they are reduced to a few inches. It was not easy to see on what evidence such vast overfolding had been postulated, nor how, within a few hundred yards, a group of massive limestones could be rolled out to nearly the vanishing-point. Thus, while fully admitting the lasting value of Professor Heim's contribution to the unravelling of the architectural details of the mountains, geologists who had specially studied the subject could not but hesitate to accept all his deductions, and felt that there might still be some important feature in the structure that had been missed.

In particular the absence of dislocations in Professor Heim's sections of a region so prodigiously disturbed could not but attract attention. He was well aware that powerful lines of dislocation had been described by different geologists as existing in the Alps. Studer, for instance, had long before pointed out that along the line of the Lake of Thun there must be a dislocation across the strike, with a horizontal displacement of nearly two miles. Suess had remarked a series of north and south horizontal dislocations in the Alps, by which the eastern side was sometimes driven towards the north. Schafhäutl had noticed similar structures among the Bavarian Alps. But though Heim treated skilfully some of the relations between folding and faulting, showing in particular how the rupture of a closely pressed fold might give rise to a reversed fault, it was chiefly on the minute scale that he dealt with these phenomena, as they are developed in the "ausweichungs-clivage" of schistose rocks. Of greater ruptures in the Alpine region he remarks: "I may observe in passing that in contrast with the plications, large overthrust faults are not to be assumed without good reason to exist here and there in the Alps. What we directly see in the Alps are numberless plications which pass into cracks and faults, but true faults affecting the structure of a great mountain chain are but seldom to be seen; they appear to occur with extreme rarity in the Alps." [1]

The true reading of the complex structure of the Alps, however, seemed to require that dislocation as well as plication should be recognized as having contributed to the present arrangement of the rocks. The extreme plasticity required by Heim appeared to be hardly possible among hard sedimentary strata, lying under no greater pressure than that of the comparatively small depth of younger strata that covered them. It was conceivable that deep down beneath the Alps, where solid rocks had undergone enormous stresses under a great overlying thickness of the terrestrial crust, they would be crushed, and their component particles might be made to move over each other, possibly with an infinity of minute ruptures, but without any great dislocation. Yet in this mountain chain, where Tertiary strata had been involved in the plication, it could not be supposed that these strata could ever have been buried under more than, at the most, a few hundred or even thousand feet of younger sediments. It was therefore to be expected that at least the uppermost formations, while being driven together, would be not only plicated but disrupted, and that some portions of them would be found to have been pushed horizontally over other portions.

It had, however, become a settled belief among geologists that in the northern Alps dislocations were either entirely non-existent, or at least possessed no tectonic importance. They were ignored on the published geological maps of that region; and in Heim's beautifully artistic sections and drawings, while full justice is done to the wonderful plications of the region he discusses, faults are conspicuously absent. The first definite and systematic step in the inquiry how far dislocation as well as folding entered into the structure of the Swiss Alps was taken by

[1] *Mechanismus*, Band ii. p. 14.

Dr A. Rothpletz, who, after studying the structure of the Oberland and other parts of Switzerland, announced in 1881 to the Helvetian Society of Natural Science that he had been led to conclude that faults take a much more important place in the geological structure of that region than had up till then been supposed. He instanced three large dislocations which he said he had himself traced in the Oberland, and which, with many others observed by him elsewhere, had convinced him that the striking proofs of great plication had misled observers into the belief that dislocations were either entirely absent in the northern Alps, or at least were of no consequence in the general structure.[1] With great energy and perseverance he devoted himself to the further prosecution of an inquiry into the existence and effects of faults in mountain-structure, and traversed a large part of Switzerland in the research. Among the districts specially examined by him was that between the Reuss and Rhine, including the tract where the "double-fold" of the Glarner Alps was stated to occur. In the year 1883 he communicated to the German Geological Society a remarkable paper on the framework of the Swiss mountains lying on each side of the Rhine.[2] He therein proposed a totally different view of the structure which the "double-fold" was proposed to explain. He believed that this fold had no existence, but that the rocks had been brought into their positions by a gigantic horizontal displacement that had pushed up the older masses over the newer. He traced what he regarded as three main lines of these dislocations or overthrust faults, and indicated their trend upon a map. One of them was represented by him as running from the middle of the Lake of Lucerne by the head of the Lake of Zürich across to the Rhine above the Lake of Constance, and thence far to the east by Bolgenach. A second he traced from the head of the Lake of Lucerne, in a great curve through the mountains by the Glärnisch to Glarus, and thence in a very sinuous line across the Sernf valley and the Foo Pass to Sargans and beyond. A third was shown to follow the line of the Rhine valley as far down as Chur. He further pointed out that these gently inclined displacements were cut through and shifted by transverse faults, as in the valleys of the Reuss, Linth, and Rhine. As a first broad sketch of an altogether new version of mountain-structure, this paper marks a turning-point in the history of this branch of geology. It covered so much ground that it could hardly be free from imperfections which more detailed observation would correct, but it laid a foundation on which later students could satisfactorily advance.

Dr Rothpletz in successive publications has brought forward much additional detail in support of his views.[3] The writer of this article, who has had the great advantage of being conducted by the Bavarian geologist over some of his evidence in the Linththal, and of carefully examining the sections on which he relies, has no hesitation in declaring his belief that the horizontal displacements asserted to be there by Dr Rothpletz undoubtedly exist, and produce the effects claimed for them. One of the most notable localities in this district is that at the foot of the Sernf Thal, where the so-called Lochseite limestone occurs. According to the theory of the "double-fold," this limestone represents there the whole Jurassic formation of the region, squeezed out to a thickness of at most two or three feet. It lies between the Verrucano above and the Flysch below. But in reality it is not here at least a true limestone, but a band of crushed material permeated by calcite derived from the Flysch. This crushed calcareous band has resulted from a horizontal or gently inclined dislocation, the plane of which can actually be seen passing through the band. The older reddish brecciated conglomerate (Verrucano) which here lies uppermost has been thrust forward over the disturbed Eocene strata, and has had its component materials drawn out and its pebbles rearranged parallel with the plane of movement below.[4]

While Dr Rothpletz was pursuing his researches in Switzerland, another series of investigations was in progress in the north-west of Scotland, which eventually shed more fresh light on the problems of mountain-making. Working independently of each other, Professor Lapworth and the officers of the Geological Survey discovered that the geological structure of that region was much more complicated than had been supposed, and that it included a series of dislocations of so novel a kind that, although conspicuously visible when once recognized, their existence had never been even suspected by the geologists who first examined the ground. This complex structure was worked out in great detail by the officers of the Geological Survey between the years 1883 and 1888. They found that the rocks of that region had been ruptured by dislocations which had thrust them horizontally for great distances. The very lowest and oldest rocks had been torn up from below and launched forward in a westerly direction, sometimes for a distance of ten miles. Above one of these planes of movement the rocks were found to have been sometimes pushed over each other by small reversed faults, as cards may be slid one upon another. These minor dislocations were then seen to give way to another more nearly horizontal plane of intenser movement, whereby another slice of older rock was thrust forward. In this way a succession of thick slices of the more ancient formations may be observed to lie on clean-cut surfaces of much younger rocks. Such flat, gently inclined, or undulating surfaces of displacement have been termed by the Survey officers "thrust-planes." They exactly resemble the "Haupt-Längsverwerfungsspalten" which Dr Rothpletz has traced through the Swiss Alps. The rupturing has not taken place as a consequence of excessive plication. The rocks appear to have been dislocated as the immediate effect of intense tangential pressure, probably at no very great depth beneath the surface. But curvature has undoubtedly taken place in them during the displacement, particularly in front of a mass of piled-up strata which was being driven forward on a thrust-plane, and the front of which is apt to be dragged in under the advancing pile. Everywhere, however, the dominant feature is rupture, traceable from the largest dislocations in the thrust-planes down to the minute puckering and cleavage seen in "ausweichungsclivage" and to the crushing of the materials of the rocks and the production of "mylonite." Gradations can thus be traced through successive reversed faults, so small as to be visible in hand-specimens or only with a lens, up to those which extend from top to bottom of

[4] The existence of a thrust-plane at this locality is now admitted by Professor Heim, though he adheres to his view of the "double-fold." Compare his sections in the *Mechanismus*, Plate vii. section xiii. and Plate xvi. Fig. 7, with Plate vii. Figs. 2 and 3, in the *Livret Guide* of the International Geological Congress, 1894, and p. 104 of the text of that book; also *Beiträge zur Geol. Karte Schweiz*, 25th Lieferung (1891), p. 204. A special literature has grown up in reference to this so-called "Lochseiten Kalk." For the two opposite views regarding its stratigraphical relations, see Heim, *Mechanismus*, i. pp. 138–223, where the band is boldly affirmed to have been formed by the rolling out especially of the Jurassic limestone between the Verrucano and Flysch; and Rothpletz, *Zeitsch. Deutsch. Geol. Gesell.* xxxv. p. 165; *Ein Geologischer Querschnitt*, p. 243; *Das geotektonische Problem*, &c., Plate vii. Fig. 16.

a cliff and onwards to the maximum thrusts which can be followed for scores of miles across mountain and glen.

Each thrust-plane has a sole or floor over which the rock above has been driven. Under favourable conditions this sole is sharply defined from the immediately overlying material, which often displays evidence of intense crushing even though now in a hard compact condition. Its substance has been ground into powder, and has been made to move along the sole, so that in some cases it has acquired a "flow-structure" and might at first be taken for a felsite or rhyolite. Where a conglomerate has been the material driven over the thrust-plane, its pebbles may be observed to have been drawn out in the line of movement. Pegmatite-veins have been broken up and crushed into fine felspathic dust, so that every step may be traced from the obvious vein into a streaky felsite-like substance.

The major dislocations are usually inclined at a gentle angle in an easterly direction. Hence they behave like nearly horizontal strata, and can be traced winding up the sides of valleys for miles. Not only so, but they have been trenched by denudation in such a way that outliers of them have been left on the tops of hills, affording the singular appearance of a capping of the oldest rock of the district resting apparently quite regularly and conformably upon the newest. The thrust-planes can be followed along the strike for great distances. The most important of these extends for more than 100 miles from the north coast of Sutherland to Sleat in Skye. They have been shifted by ordinary transverse faults belonging to a much later period of movement.[1]

Similar structures have subsequently been found to play an important part in the geological structure of Scandinavia. Törnebohm, Holmquist, and other geologists have traced lines of thrust whereby, as in Scotland, enormous slices of the older rocks have been pushed horizontally over the top of much younger formations. As the most recent example which has been described, reference may be made here to the country lying to the south-east of the mountain Sulitelma on the confines of Sweden and Norway, where Mr P. T. Holmquist has mapped an important thrust-plane over an area of nearly 40 Swedish miles.[2] It is so gently inclined that its outcrop winds up the valleys, and portions of the thrust rocks have been left by denudation as outliers. The effect of the dislocation is to place a series of mica-schists and granulitic quartzites (so-called "Algonkian") above some of the oldest Cambrian strata which lie immediately on the Archæan gneiss and granite. Thus the same structure which deceived geologists in Scotland is repeated in Arctic Sweden, but the key to it has now been found, and though at first sight it might seem that the Scandinavian *Hyolithus* series passes upwards into mica-schists and quartzites, the horizontal thrust-plane has been recognized that accounts for the superposition of the older upon the younger rock. There can be little doubt that the same structure pervades a large part of the Scandinavian peninsula. As in Scotland, it chiefly affects there the older formations of the Earth's crust. But in the Alps it has been powerfully developed among the older Tertiary strata. It thus appears to have played an important part in the structure of mountains, and in the general movements of the Earth's crust from early geological time onwards. Nor is it confined to the more prominent elevations of the Earth's surface. In the south of England, for example, it may be seen in a feeble development in the Chalk of the coast between Weymouth and Studland Bay. There is reason, indeed, to believe that ruptures of the nature of overthrusts have been much more extensively developed throughout the terrestrial crust than has hitherto been supposed.

Various experiments have been made to reproduce artificially and on a small scale the structures displayed in the crust of the Earth. Curvature of strata was studied in this way by Hall, the founder of experimental geology, in the early years of the 19th century.[3] Since his day A. Favre,[4] Daubree,[5] F. Schardt,[6] and others have varied the methods of investigation, and have imitated with more or less success the phenomena exhibited among the rocks. Since the existence and nature of thrust-planes were realized, experimental research in this subject has been resumed by Mr H. M. Cadell[7] in Scotland and Mr Bailey Willis in Washington.[8] Mr Cadell, realizing that the structures which had been worked out by his Survey colleagues and himself in the north-west Highlands of Scotland pointed to the rupture of solid rocks under great stresses, and probably at no great depth beneath the surface, imitated them by placing in a box alternate thin layers of plaster-of-Paris between thicker layers of damp sand or loam. No weight was placed above the layers. The plaster, absorbing moisture from the materials above and below, set into hard brittle laminæ. Pressure was then applied to one end of the box, and a series of experiments was carried on with the view of observing the mechanical effects of the pushing of strata over an immovable surface, and of ascertaining the probable origin of thrust-planes. Some of his more interesting results may be here summarized. Horizontal pressure applied at one side is not propagated far forward into a mass of strata which have no great overlying cover of rock. The compressed mass, in such conditions, tends to find relief along a series of small gently-inclined thrust-planes which dip towards the side from which pressure is exerted. After a certain amount of heaping-up along a series of such minor thrust-planes which thus grow steeper, the heaped mass tends to rise and ride forward bodily along the sole of one or more major thrust-planes. Experiment showed that thrust-planes and reversed faults do not necessarily arise from the rupture of overfolds, but often spring up immediately from the application of horizontal pressure. What takes the form of a thrust-plane below may pass into an anticline above, and may never reach the surface, while a major thrust-plane above may and probably always does originate in a fold below. A thrust-plane may branch into smaller thrust-planes, or may pass into an overfold along the strike. The front portion of a mass of rock that is pushed forward along a thrust-plane tends to bow forward and roll under the back part. The peculiar arrangement in mountains known as fan-structure may be produced by the continued compression of a simple anticline, and thrust-planes strongly tend to arise at the sides of the fan. The compression that produces the fan imparts a schistose structure to its core.

5 and 6. Palæontological and Stratigraphical Geology.

It is in this department of the science that the largest amount of new material has been collected since 1875. In every one of the various systems of sedimentary forma-

tions into which the accessible part of the Earth's crust has been divided vast additions have been made to our knowledge of their fossil contents, geographical distribution, tectonic arrangement, and geological history. But while this mass of infinite detail has been accumulated, the broad outlines traced in the article on Geology in the ninth edition of this work remain, on the whole, not seriously affected. Two sections, however, of this department of the science have more especially advanced. One of these deals with the nature, arrangement, and probable history of the oldest known portions of the terrestrial crust; the other discusses the principles and methods according to which the investigation of the fossiliferous formations should be conducted.

Pre-Cambrian Geological History.—No part of the geological record has in recent years been more diligently studied than those earlier chapters which deal with the ages that preceded the deposition of the earliest fossiliferous formations. More especially has this research been prosecuted in Great Britain and in North America. Though many known problems in the subject remain unsolved, and doubtless many new problems will arise as the investigation is pursued, we are now in possession of a large body of information regarding the primeval parts of geological history, and can carry our eyes backwards into earlier stages of the Earth's progress than were formerly realized.

So far as research has yet gone all over the world, the distinctly fossiliferous formations terminate downwards in the Cambrian system. At the base of that system, strata specially characterized by the presence of the genus of trilobites known as *Olenellus* are taken as the starting-point of the Palæozoic series. But the variety of the fauna found in these and the overlying strata may be regarded as demonstrative proof that this fauna does not represent the first beginning of life on the globe. Some biologists, indeed, following Darwin, maintain that the time required for the evolution of *Olenellus* and its contemporaries may have been as long at least as all the ages that have passed since these organisms lived and died. But of earlier types of life than these only scanty traces have yet been found. By degrees, however, groups of sedimentary rocks are coming to be recognized in many different parts of the world below the *Olenellus* zone, which are not unlikely eventually to yield up some more definite relics of primeval life. In Europe the most complete and most unmistakable series of pre-Cambrian formations is developed in the north-west of Scotland and in Scandinavia. In North America pre-Cambrian rocks have been largely studied in recent years, and are now known to have a wide extent, vast thickness, and great variety. It will suffice to give here some account of the Scottish and the American groups.

In the west of the counties of Sutherland and Ross certain thick dolomites and limestones containing Upper Cambrian and possibly Lower Silurian fossils pass downwards into dolomitic shales and sandstones, with bands of rusty dolomite. These shales, besides being crowded with worm-castings, contain *Olenellus*, and thus mark the generally accepted base of the Cambrian system. They lie conformably, however, upon, and are closely linked with, white and pink quartzites, from 400 to 600 feet thick, which in some of their bands are crowded with worm-burrows and casts. This arenaceous series, terminating downwards in a conglomeratic base and lying unconformably on the rocks below, must clearly be regarded as part of the Cambrian system, though it lies below the lowest horizon in which *Olenellus* has yet been detected. Doubtless the quartz-sand, which is now represented by quartzite, did not afford a suitable habitat for trilobite life. If a band of shale or dolomite were met with in the quartzite, it might be expected to yield specimens of the distinctive crustacean.

Below the bottom of the quartzites of the north-west of Scotland lies a series of far more ancient rocks. They are separated from the Cambrian series by an important unconformability which must represent a vast interval of time. They thus constitute a true pre-Cambrian series, and bring before us the very beginnings of geological history in the west of Europe. They include two distinct assemblages of rock. Of these the lower and older consists of gneiss and other crystalline masses, while the upper and younger is composed of a thick mass of red sandstones, shales, and conglomerates. Between these two formations there is again a violent unconformability which must mark the passing of an enormous interval of time. The older rocks had already acquired their present crystalline structures and arrangement before the younger sediments were derived from their waste and were laid down upon them. Thus while the deposition of these sediments is shown to belong to a period vastly more remote than the Cambrian, the formation of the underlying crystalline rocks is pushed back into an inconceivably more distant past. Two widely separated periods of pre-Cambrian time can consequently be recognized in the north-west of Scotland. The oldest of these is known as Lewisian, the second as Torridonian.

Lewisian.—The rocks which contain the records of this earliest stage in the geological evolution of western Europe are well developed in the island of Lewis; hence the name that has been locally applied to them. What are no doubt the same formations cover wide areas in Scandinavia, where they are known as *urberget*, or primeval rocks. Similar masses reappear in various parts of Europe, repeating the same lithological types, though it cannot always be safely affirmed that they are the true stratigraphical equivalents of the crystalline rocks of the north-west. Again, in Canada and the United States vast tracts of country are occupied by rocks having the same general characters. As a comprehensive designation to embrace all these most ancient rocks the term Archæan is commonly used. But we have at present no means of deciding how far the rocks so designated in one country really belong to the same interval of geological time as those so designated elsewhere. It has been discovered, indeed, that what had been called Archæan formations in some countries are really of Palæozoic age. Hence there is a certain convenience in the use meanwhile of local names for the types of rock met with in widely separated regions. Such names remain appropriate and useful, even if we have to shift their stratigraphical position backwards or forwards.

The Lewisian rocks of north-west Scotland comprise a series of crystalline gneisses, the great majority of which are undoubtedly of igneous origin, but in one or two districts include what are probably highly metamorphosed sediments. Here and there among the crystalline gneisses there occur tracts which have more or less completely escaped deformation and wherein the materials are seen to consist of such perfectly recognizable rocks as in younger portions of the terrestrial crust are admitted to be deep-seated intrusions of igneous material. These comparatively uncrushed rocks are often highly basic, for they include gabbros, peridotites, picrites, pyroxene-granulites, and diorites. They occur as lenticular zones or belts, running for several hundred yards more or less parallel with the foliation of the gneiss, into which they graduate, and also as irregular patches about a quarter of a square mile in area. They are intersected by veins of gray pegmatite consisting mainly of quartz and felspar. These tracts may represent the original condition of the gneisses of the surrounding region. Judging from analogy, we may suppose them to be remnants of eruptive masses which were injected into the primeval crust of the earth and solidified there at some depth below the surface. They have in many respects their counterparts among the deeper-seated intrusions that have invaded the various stratified formations up even to those of Tertiary age. They obviously consist of at least two groups of intrusive material—an older and more abundant series of basic masses which seem to have risen in extensive bosses, and a later set of acid injections. Whether any of these eruptive materials were connected with superficial discharges remains unknown. They are not essentially different from the masses that are found about the roots of ancient volcanoes. But no trace of any lavas or tuffs in association with them has yet been discovered. For a long time nothing had been detected to show the nature of that part of the terrestrial crust into which these primeval injections had made their way. Obviously they were not themselves masses that had congealed above ground, so that all speculations about their representing a former terrestrial surface were wholly inadmissible. Eventually, however, the officers of the Geological Survey found a group of rocks which may be a portion of the overlying crust in and beneath which the eruptive masses consolidated. These rocks, seen at Loch Maree, Loch Carron, and Glenelg, comprise mica-schists, graphitic schists, and limestones, probably the remnants of a series of sedimentary formations, and if so, perhaps the oldest yet met with in Europe. The relations of the gneisses and other crystalline rocks to this presumably sedimentary series are somewhat obscure. We may believe, however, that the eruptive masses have been injected into the schists and limestones, and have been the cause of the development of new minerals in the calcareous bands, and of other changes suggestive of contact-metamorphism.

At some time subsequent to the intrusion of the acid pegmatite veins, the rocks were subjected to powerful tangential pressures, whereby they were crushed and sheared so as to acquire a foliated structure. The basic masses became rudely foliated gneisses, in which plagioclase felspar, augite, diallage, hornblende, quartz, and magnetite are the predominant minerals, while the acid pegmatites became gray acid gneisses composed mainly of opalescent quartz and felspar. The dip of the foliation-planes of these rocks is usually at gentle angles. The gradation of the non-foliated igneous rocks into the coarse gneisses can often be traced, and it can be seen that in some cases the foliation passes across the junction lines between the two varieties of original rock. How far there may have been bands of segregation in the eruptive bosses, like those, for instance, in the Tertiary gabbros of Skye, has not at present been determined. But it is quite possible that some at least of the bands of different mineral constitution, such as those of hornblende or pyroxene and felspar, may belong to the original igneous magma, and not to the time of the foliation. This much may at least be confidently affirmed—what has been called "the fundamental complex" of the Lewisian rocks has been formed out of eruptive basic materials and the pegmatites introduced into them prior to the first foliation.

But the igneous history does not end here. After the movements that converted so much of the eruptive masses into coarse gneisses, and possibly after an enormous interval of unrecorded time, another series of igneous injections took place. A remarkable succession of dykes, of different petrographical characters, invaded the older masses. The most striking of these are the dykes of dolerite and basalt which follow each other in great numbers, having a general north-westerly trend, and running for long distances, sometimes for ten or twelve miles, from the coast-line inland, until they pass under the Torridonian sandstones. These intrusions present many of the familiar features of the dykes of much later periods. They obviously rose in fissures that had been opened in rocks already cold, for they present the characteristic close-grained or "chilled" margins. After their uprise, a second group of dykes was injected along fissures which ran in a nearly east and west direction. The material of these intrusions consists of peridotites and palæo-picrites, and as they cut the dolerites they are obviously of later date. What length of interval separated these successive up-wellings of molten material in the terrestrial crust must be matter merely for speculation. Some considerable lapse of time may possibly have followed the appearance of the ultra-basic dykes before a third and decidedly acid group was erupted. Numerous instances have now, however, been observed of a close connexion between granite cores and highly basic peripheral parts of large intrusive bosses. The magma from which such bosses were fed included both acid and basic parts, rising together, but the latter tending to gather towards the outside, while the more voluminous acid body occupied the centre. There may therefore have been a closer genetic relation than might at first be supposed between the palæo-picrites and peridotites of the second series of dykes and the granites and pegmatites of the third series. This third system of dykes has a general trend towards west-north-west. Its members attain far larger proportions than their predecessors in the other two series, for they sometimes come together so as to form bands more than 500 yards wide. An interesting parallel presents itself between these various igneous protrusions and those of later geological ages, especially the Tertiary volcanic series of the Inner Hebrides and Antrim. In both cases there are large protrusions of basic material. In the younger example, among the Inner Hebrides, this material has been arranged in bands of different composition according to the original disposition of a heterogeneous magma; in the older a somewhat similar structure may be partly attributable to the same cause, though subsequent foliation has in some measure obscured its history. The system of basic and acid dykes ranging towards west and north-west is strikingly alike in the operations of two geological periods so infinitely remote from each other. Again, the order of appearance of the igneous materials has followed the same sequence in each case; the basic intrusions came first, and the acid last.

After these various groups of eruptive rock had been successively injected, the crust of the earth in the north-west of Scotland, under another series of powerful stresses, was ruptured by thrust-planes and also by more vertical lines of crushing or shearing. Of these dislocations, the officers of the Geological Survey have distinguished three series; one which runs more or less nearly parallel with the basalt and dolerite dykes, one trending nearly east and west, and one which stretches north-east and south-west, or north and south. The first two series are much the most important, and have effected some remarkable transformations both on the dykes and on the gneiss. Where the north-western lines of movement are more or less parallel with the trend of the basic dykes, the dolerites are changed into diorites, without the development of foliation, but where one of these lines runs along the margin of a dyke, or where several of them traverse it along its length, the basic rock passes into true hornblende-schist. Lenticles or eyes of uncrushed diorite may be traced, round which the more crushed parts have moved and have assumed the schistose condition. The more basic materials (peridotites, &c.) in the same circumstances have been crushed into soft talcose schists, while the granite of the dykes has been converted into granitoid gneiss. The vertical east and west lines of movement have had the effect of wrenching the rocks out of their normal course, sometimes for nearly a mile. Dykes fifty or sixty yards broad are crushed and drawn out in these lines, till they are reduced to a width of no more than four feet, while sometimes they are still further attenuated into detached lenticles enclosed in crushed and reconstructed gneiss. Not less decided have been the effects of these lines of movement upon the gneiss. As this rock approaches one of them, its usually gentle inclination becomes steep and the foliation planes are thrown into sharp folds. The folia are drawn out, and sometimes their component minerals are rearranged parallel to those in the hornblende-schist of the adjacent dykes, so that a secondary foliation has been superinduced. There has likewise been a mineralogical reconstitution of the materials of the gneiss; the original blue opalescent quartz has been drawn out and in large part changed into the ordinary clear vitreous variety, black mica has been formed out of the hornblende, and white mica out of the felspar, while the hornblende has in part been re-crystallized in needles of actinolite, and new or secondary felspar has been plentifully developed. Lastly, the gneiss has been ruptured by crush-lines and shear-planes, some of which have given rise in one place to coarse breccia, in another to thin schistose bands.

The newer foliation superinduced by these later movements has affected considerable areas of the gneiss. It sometimes entirely obliterates the earlier structure of the rock, but where not so well developed it may be seen crossing the bands of that structure, so that the gneiss then presents the curious result of a double foliation. The gentle arches and troughs of the first foliation, striking north-east and south-west, have been replaced by sharp folds which, according to the trend of the later movements, vary from west to north-west. In this way the original massive or igneous structure has been so profoundly modified, and over such extensive tracts, that it has survived only here and there in comparatively limited parts of the region. All the geological changes now described—the initial uprise of the first basic bosses, the long sequence of igneous invasions, and the successive movements of the crust that produced the first and subsequent foliation—took place long before the Torridonian rocks began to be formed. It is obvious that not only the intrusion of the igneous masses, but their subsequent conversion into gneisses and schists, could not have been effected save under the pressure of a considerable depth of overlying rock. We have no means of telling what was the nature or the thickness of that superjacent cover. It had been completely removed by denudation before the earliest of the surviving Torridonian sediments began to be laid down. From the pebbles in these sediments we may form vague conjectures as to the character of the rocks that have disappeared, but there is no proof that these pebbles actually came from the rocks under which the Lewisian gneiss received its complex structure. They may belong to some much younger era. They include pieces of gneiss, jasper, chert, quartzite, quartz-schist, mica-schist, and felsite. The quartzites are altered gray, buff, red, or liver-coloured sandstones. The cherts are usually black or yellow, which resemble those met with among sedimentary deposits; they have been searched for *Radiolaria*, but hitherto without success. The felsites are dark purplish compact rocks with a spherulitic, micro-pegmatitic, micro-poikilitic, or micro-crystalline ground-mass, in which are scattered porphyritic crystals of felspar, often oligoclase. The spherulitic varieties show occasional traces of perlitic structure.[1]

Torridonian.—It is impossible to form any conjecture as to the chronological value of the interval between the close of the Lewisian and the opening of the Torridonian periods in the geological history of the north-west of Scotland. All we can say regarding it is that, even when compared with other geological intervals, it must have been of enormous duration. A great thickness of rock was removed by denudation, and the Lewisian gneiss was exposed to the air. Some fragments of the land-surface thus carved out have been preserved under the Torridonian sediments, and have a singular interest as relics of the earliest known land in Europe. They show the surface of that land to have been in some parts as uneven as that of the Highlands of the present day. There were mountains at least 3000 feet high, separated by wide valleys from other ridges. The ground was worn down into rounded crags and rocky domes on which the gneiss and its dykes stood up bare to the sun and wind. This ancient topography may be traced among the wild group of mountains between Loch Marce and Loch Broom. It appears behind the hill of Queenaig in Assynt, and it comes out impressively along the south side of Loch Torridon. That it has been preserved is due to the deep mass of sediment under which it sank and was buried. This sedimentary accumulation is known as Torridonian from its large development in the district around Loch Torridon, on the west coast of Ross-shire. It has been subdivided by the Geological Survey into the following groups of strata in descending order :—

4. Cailleach Head group (1000 to 1500 feet thick) of sandstones, flags, dark and black shales, and calcareous bands.
3. Aultbea group (2000 to 3000 feet) of chocolate-coloured and red sandstones and flags, and gray micaceous flags, with partings of gray, green, and dark shale.
2. Applecross group (4000 to 5000 feet) of coarse arkose, with pebbles of gneiss, quartzite, quartz-schist, felsite, jasper, &c.
1. Diabeg group (500 feet and upwards, much thicker in Skye). Hard red sandstones and grits, gray graywackes, red mudstones, dark gray and black shales, limestones and calcareous bands, with, at the base, green epidotic grits, and in some places a band of conglomerate resting on the gneiss.

Where most fully developed the series of sediments exceeds 10,000 feet in thickness. It forms some of the most conspicuous and most peculiarly shaped mountains in Sutherland and Ross-shire, rising into pyramids and cones, the sides of which have been scarped into precipices and scooped out into cauldron-shaped corries. The nearly level stratification gives a singularly architectural aspect to these huge masses of reddish-brown bare rock, and affords to the eye a ready means of appreciating how potently the forces of denudation have been concerned in developing the present scenery of the region. Several features of interest are presented by this thick mass of sedimentary deposits. The well-rounded pebbles, the regular layers of alternating detritus, the intercalation of coarse and fine materials, the lamination of the shales, the intercalation of calcareous bands and limestones, towards both the top and the bottom of the series, indicate conditions of sedimentation in no respect different from those of Palæozoic and later times. There are no traces of the violent action which, as some physicists have maintained, should have been characteristic of the earliest geological ages. On the contrary, not only do the layers of sediment succeed each other as they do in any series of similar materials in other and later portions of the geological record, but down even to minute details we see examples of the gentle sifting operations of tidal, fluviatile, or lacustrine waters. Thin dark laminæ may be noticed intercalated among the paler grits and sandstones, and these on examination prove to consist mainly of magnetic iron ore and other heavy minerals which, as above remarked, have been sorted out by the currents from the lighter quartzose or felspathic sand, precisely as

[1] *Annual Report of Geological Survey* for 1895, p. 21.

grains of similar ore are gathered together by the tides and strewn as a thin layer above the quartz-sand of the beaches of to-day.

No break or unconformability has been detected in any part of this thick mass of stratified deposits. But owing to the remarkably uneven surface of gneiss on which the sediments were laid down, they are continually overlapping each other, so that different members of the series come to lie directly on the older rock. They were probably accumulated in a lake or inland sea, the floor of which was gradually sinking. As the hills and valleys were successively submerged, they were buried under a pile of sediment. The actual shore-line during this time of subsidence can be followed up the side of a mountain, and the geologist may stand with one foot on the gneiss which formed the dry land and the other on the consolidated gravel which was accumulated by the water. Some of this material is excessively coarse, passing indeed into boulder-beds that remind one of the boulder-clay of the Ice Age, or the moraines of the present day. Indeed, some of the rounded contours of gneiss as they pass under the Torridon sandstone, taken together with these overlying masses of boulders, are suggestive of ice action, though it is difficult to suppose that in these remote ages terrestrial climates had become so far differentiated as to include frost, snow, and ice even down to the 57th parallel of north latitude. So regular is the sedimentation of the Torridonian rocks, and so precisely similar to that of Palæozoic formations, that there seems no reason why fossils should not be looked for and found in these ancient strata. The most likely parts of the series, particularly the shales and the calcareous bands, have been carefully searched by the Geological Survey, but hitherto with only scant success. Various markings have been found which are not impossibly those made by annelids. Certain curious spicular bodies, partly filled with calcite and partly existing as empty casts in the shale, have likewise been obtained, but though they bear some resemblance to magnified sponge spicules, it is by no means certain that they are of organic origin. Quite recently renewed search has been rewarded by the discovery of a number of flattened nodules of dark compact material in the shales, which prove to be phosphatic. It may be suspected that the phosphate of lime in these aggregations was probably derived from organisms. The shells of *Lingula* and the tests of trilobites and other organisms have supplied materials for phosphatic nodules and layers among the older Palæozoic rocks, and possibly some such organisms have been concerned in the formation of the nodules in the Torridonian shales. A thin slice of one of the nodules placed under a microscope reveals numbers of thread-like fibres, not improbably of vegetable origin, together with aggregates of what appear to be cells, as if some kind of plant had been macerated and broken up into shreds. But this subject is still under investigation, and more definite information may before long be obtained in regard to it.[1]

Pre-Cambrian Rocks of North America.—In Canada and the United States, from below the lowest Cambrian strata, a vast mass of rocks emerges presenting a close parallel to those of Scotland, but with an ampler development and over a far wider region. It consists of two contrasted groups, the Archæan below and the Proterozoic or Algonkian above. It is most copiously represented in the Lake Superior region, where some of its members were studied long ago by Logan, the pioneer in this branch of geology. The Archæan division of that region consists of massive and gneissoid granites, massive and foliated syenites, gabbros and peridotites, and finely laminated or banded gneiss and schists. None of these rocks have been proved to be of sedimentary origin. The great majority, and probably the whole, are igneous masses of deep-seated origin which have had a more or less distinctly foliated structure imparted to them by great mechanical movements within the crust of the earth. But there are proofs that they belong to different periods of intrusion. Thus the massive granites, which show little or no trace of orogenic movements, are of comparatively late date. In short, the geological history of the "basement complex" of Canada and the neighbouring United States appears to have been broadly similar to that of the Lewisian equivalent in Scotland. Between the Archæan gneiss and the base of the Cambrian system, however, a far more copious stratigraphical series exists in the Lake Superior region than in Scotland. No fewer than three distinct divisions have been determined, each of ample dimensions and great variety, and separated from one another by unconformabilities that probably mark protracted intervals of time. These strata form a vast succession of sedimentary deposits with igneous intercalations. They have been grouped together under the general name of Proterozoic or Algonkian. In ascending order they consist of (1) Lower Huronian, (2) Upper Huronian, (3) Keweenawan.

1. The Lower Huronian (Keewatin) series, about 5000 feet thick, varies considerably in general character as it passes from district to district. It everywhere rests with a strong unconformability upon the gneiss, which must have undergone great denudation before the lowest Huronian sediments began to be laid down upon it. These lowest sediments are conglomerates or quartzites covered by dolomites, sometimes 1000 feet thick. The dolomites pass under slates and quartzites among which an important group of acid and basic volcanic rocks is intercalated. The uppermost subdivision consists of iron ores (siderite, hæmatitic slates), cherts, and jaspers, and in the Lower Marquette district ranges from 1000 to 1500 feet in thickness. The iron-carbonates suggest an organic origin, and possibly the cherts and jaspers may have been aggregated by marine organisms, like the cherts of the Cambrian, Lower Silurian, and Carboniferous formations, and the flints of the Chalk. After the Lower Huronian rocks were accumulated, they suffered from earth-movements by which they were folded, and even, in many places, violently plicated. Raised above sea-level, they underwent prolonged exposure and denudation before the next member of the series was deposited. So vast was this interval that it appears to have sufficed for the local removal of the whole depth of the Lower Huronian rocks and the erosion of part of the platform of gneiss below.

2. The Upper Huronian series rests with complete unconformability on everything older than itself. Where typically developed, in the Penokee district, it consists of three subdivisions. At the base comes a quartz-slate group, about 500 feet thick, with a conglomerate at the bottom and a persistent band of quartzite at the top. The central formation, about 800 feet thick, consists of cherty iron-carbonate, ferruginous slates and cherts, and actinolitic and magnetitic slates. The upper subdivision is stated to attain the enormous thickness of 12,000 feet. It consists of sedimentary material, ranging from clay-slate through graywacke and graywacke-slate to mica-slate. Possibly part of the great apparent thickness of the Upper Huronian series in this district is due to the masses of diabase that have been injected into it. The deposition of this subdivision was followed by another period of disturbance, during which the rocks were tilted, plicated, and raised above the sea. So great were the effects of the movements

[1] See J. J. H. Teall in *Summary of Progress of the Geological Survey* for 1899.

that the rocks here and there acquired foliated structures, and were transformed into schists and gneisses. Prolonged and gigantic denudation followed the upheaval. In some places the whole of the vast thickness of the series was eroded down to the underlying rocks before the next series began to be deposited.

3. The Keweenawan series is in large measure of volcanic origin. It attains far vaster dimensions than either of the other divisions of the Algonkian rocks; indeed, it is stated to attain in some places the hardly credible thickness of 50,000 feet. As most of the series consists of igneous rock, it might have been accumulated in a comparatively short time. The local character of its extravasation seems to be indicated by the fact that it rapidly dies out in particular directions. It is divisible into three members—(*a*) a lower mass of gabbros; (*b*) a vast succession of great sheets of basic and acid lavas comparable to the extensive basalt-fields of the Far West. With these rocks are intercalated sandstones and conglomerates, chiefly derived from the waste of the lavas on which they lie; (*c*) a group of sandstones and conglomerates, mainly made up of the detritus of the igneous rocks below. Again, the accumulation of a division of the Algonkian rocks was followed by terrestrial disturbance, by the elevation of the Keweenawan lavas and sediments, and by extensive denudation. Another prolonged interval ensued, during which what may have been lofty mountains were worn down to mere stumps. It was after this interval that the Cambrian system of North America commenced to be formed.[1]

In other portions of North America various different types of pre-Cambrian rocks have been discovered, but they generally consist of a sedimentary series resting upon gneiss. In some places they have yielded a few fossils. Thus in south-eastern Nova Scotia, from a mass of slates, schists, and conglomerates, the obscure form called *Eophyton* has been obtained. In Newfoundland, below the *Olenellus* zone at the base of the Cambrian system, lies unconformably a series of quartzites, sandstones, conglomerates, and slates more than 11,000 feet thick, in which two fossils, *Aspidella terranovica* and *Arenicolites spiralis*, have been found. Far to the west, in the Grand Cañon of the Colorado, two great groups of sedimentary strata, having a united thickness of nearly 12,000 feet, are covered unconformably by Middle Cambrian rocks. They have yielded a larger fauna, including a minute discinoid or patellinoid shell, a small lingula-like shell, a fragment of what appears to be a trilobite, and a *Stromatopora*-like form, probably organic. It is much to be desired that some more fossiliferous bands may be discovered among pre-Cambrian rocks. The definite progress that has been made in the investigation of this subject during the last few years encourages the hope that further and greater success will before long reward persistent search.

Zonal Stratigraphy.—The most prominent feature in the general progress of combined stratigraphical and palæontological research during the last quarter of the 19th century has been the wide extension of the principle of palæontological zones in the subdivision of the geological formations, and in their correlation in different countries. This principle was only a further development of William Smith's famous idea, "Strata identified by Organized Fossils." Several years ago it was carried out in much detail by various palæontologists in reference to the Jurassic formations, notably by Quenstedt and Oppel in Germany and D'Orbigny in France. The publication of Oppel's classic work *Die Juraformation Englands, Frankreichs und des südwestlichen Deutschlands* (1856–58) marked an epoch in the development of stratigraphical geology. Combining what had been done by various observers with his own laborious researches in France, England, Würtemberg, and Bavaria, he drew up a classification of the Jurassic system, grouping its several formations into zones, each characterized by some distinctly predominant fossil after which it was named. Thus the Lower Lias was subdivided by him into zones which received the following names: (1) Planorbis-bed, zone of *Ammonites planorbis;* (2) Angulatus-bed, zone of *Amm. angulatus;* (3) Bucklandi-bed, zone of *Amm. Bucklandi;* (4) Tuberculatus-bed, zone of *Pentacrinus tuberculatus;* (5) Obtusus-bed, zone of *Amm. obtusus;* (6) Oxynotus-bed, zone of *Amm. oxynotus;* (7) Raricostatus-bed, zone of *Amm. raricostatus.* Oppel had spent several years among the Swabian Jurassic rocks during his student days at Tübingen and Stuttgart. He had passed seven months in France, partly among the collections in Paris, partly making himself familiar with the localities in the field. In the same way he had devoted four summer months to the classic grounds of the Lias and Oolites of England. He had thus convinced himself that, all over the western half of Europe, the several zones which he had distinguished held their place. His results were speedily confirmed and his classification was adopted by geologists and palæontologists both on the Continent and in England. The method followed by him was eventually applied with success to other portions of the Mesozoic formations. Notably was this the case with regard to the Cretaceous system, which in France, through the labours of D'Orbigny, Hébert, and others, was partitioned not only into more or less definitely marked formations, but also into zones characterized by one or more distinctive species of organism. Thus the whole of the Mesozoic division of the geological record has been subdivided into fossil zones from the Trias up to the top of the Chalk.

Within undefined and no doubt variable geographical limits, these zones have been found to be remarkably persistent. They follow each other in the same general order, but not always with equal definiteness. The type fossil sometimes appears on a higher or a lower platform than it does elsewhere. Only to a limited degree is there any coincidence between lithological variations in the strata and the sequence of the fossil zones. In the Jurassic formations, indeed, where frequent alternations of different sedimentary materials are to be met with, it is in some cases possible to trace a definite upward or downward limit for a zone by some abrupt change in the sedimentation, such as from limestone to shale. But such a precise demarcation is impossible where no distinct bands of different sediment are to be seen. The fossil zones can then only be vaguely determined by finding their characteristic fossils, and noting where these begin to appear in the strata and where they cease. It would seem, therefore, that the sequence of fossil-zones or life-horizons has not depended merely upon changes in the nature of the conditions under which the organisms lived. We should naturally expect that these changes must have had a marked influence; that, for instance, a difference should be perceptible between the character of the fossils in a limestone and that of those in a shale or a sandstone. The environment when a limestone was in course of deposition would generally be one of clear water favourable for a more vigorous and more varied fauna than one where a shale series was accumulating, for then the water must have been discoloured, and only such animals would continue living in it or on the bottom as could maintain themselves in the midst of mud. But no such lithological reason, betokening geographical changes that would affect living creatures, can be adduced as a universally applicable explanation of the occurrence and

[1] For a useful summary of the state of our knowledge regarding the pre-Cambrian rocks of North America, see a memoir by Mr Charles R. van Hise in the *16th Annual Report U.S. Geol. Survey*, Part I., 1896.

limitation of palæontological zones. One of these zones may be only a few inches or feet or yards in vertical extent, and no obvious cause can be seen why its specially characteristic fossils should not be found just as frequently in the similar strata above and below. There is often little or no evidence of any serious change in the conditions of sedimentation, still less of any widespread physical disturbance, such as the catastrophes by which the older geologists explained the extinction of successive types of life. It has been suggested that, where the life-zones are well defined, sedimentation has been extremely slow, and that though these zones follow each other with no break in the sedimentation, they were really separated by prolonged intervals of time during which organic evolution could come effectively into play. But it is difficult to see how, for example in the Lower Lias, there could have been a succession of prodigious intervals when practically no sediment was laid down, and yet that the strata should show no sign of contemporaneous disturbance, but succeed each other as if they had been accumulated by one continuous process of deposit. It must be admitted that the problem of life-zones in stratigraphical geology has not yet been solved.

The principle of zonal classification has been extended into the investigation of the Palæozoic formations, though on the whole it has been less fully applied there than among the Mesozoic systems. Possibly when it is extended in the same detailed and patient way to the older rocks, it may be found not less useful in their elucidation. The Carboniferous Limestone of Great Britain, for instance, would be an excellent field for the application of the method of zonal classification. It is a thick mass of calcareous material almost entirely composed of organisms. We know that certain species range throughout its whole extent from bottom to top, but we have still to learn whether it can be subdivided into platforms, each characterized by the presence of some distinctive forms of life that are absent or much less frequent on platforms above or below. The most successful use of this method among the Palæozoic rocks has been made by Professor Lapworth among the Silurian formations. He has found that the species of graptolite have each a comparatively narrow vertical range, and that they may consequently be used for stratigraphical purposes. Applying the method, in the first instance, to the highly plicated Silurian rocks of the south of Scotland, he found that by means of graptolites he was able to work out the structure of the ground. Each great group of strata was seen to possess its own graptolitic zones, and by their means could be identified not only in the original complex Scottish area, but in England and Wales and in Ireland. It was eventually ascertained that the succession of zones determined to exist in Great Britain could be recognized on the Continent, in North America, and even in Australia. The brachiopods and trilobites have likewise been made use of for zonal purposes among the oldest sedimentary formations. The most ancient of the Palæozoic systems has as its fitting base the *Olenellus* zone. It is doubtless in the further application of zonal stratigraphy that the next important advances will be made in the detailed investigation of fossiliferous formations, and of the history of organic life upon the Earth. (A. GE.)

Geometrical Continuity.—In a report of the Institute prefixed to Poncelet's *Traité des propriétés projectives des figures* (Paris, 1822), it is said that he employed "ce qu'il appelle le *principe de continuité*." The law or principle thus named by him had, he tells us, been tacitly assumed as axiomatic by "les plus savans géomètres." It had been enunciated under another name by Kepler in cap. iv. 4 of his *Ad Vitellionem Paralipomena quibus Astronomiæ Pars Optica traditur* (Francofurti, 1604). Of sections of the cone, he says, there are five species from the "recta linea" or line-pair to the circle. From the line-pair we pass through an infinity of hyperbolas to the parabola, and thence through an infinity of ellipses to the circle. Related to the sections are certain remarkable points which have no name. Kepler calls them foci. The circle has one focus at the centre, an ellipse or hyperbola two foci equidistant from the centre. The parabola has one focus within it, and another, the "cæcus focus," which may be imagined to be *at infinity* on the axis *within or without the curve.* The line from it to any point of the section is parallel to the axis. To carry out the analogy we must speak paradoxically, and say that the line-pair likewise has foci, which in this case coalesce as in the circle and fall upon the lines themselves; for our geometrical terms should be subject to analogy. Kepler dearly loves analogies, his most trusty teachers, and intimate with all the secrets of nature, "*omnium naturæ arcanorum conscios.*" And they are to be especially regarded in geometry as, by the use of "however absurd expressions," classing extreme limiting forms with an infinity of intermediate cases, and placing the whole essence of a thing clearly before the eyes.

Here, then, we find formulated by Kepler the doctrine of the concurrence of parallels at a single point at infinity and the principle of continuity (under the name analogy) in relation to the infinitely great. Such conceptions so strikingly propounded in a famous work could not escape the notice of contemporary mathematicians. Henry Briggs, in a letter to Kepler from Merton College, Oxford, dated "10 Cal. Martiis 1625," suggests improvements in the *Ad Vitellionem Paralipomena*, and gives the following construction:—Draw a line CBADC, and let an ellipse, a parabola, and a hyperbola have B and A for focus and vertex. Let CC be the other foci of the ellipse and the hyperbola. Make AD equal to AB, and with centres CC and radius in each case equal to CD describe circles. Then any point of the ellipse is equidistant from the focus B and one circle, and any point of the hyperbola from the focus B and the other circle. Any point P of the parabola, in which the second focus is missing or infinitely distant, is equidistant from the focus B and the line through D, which we call the directrix, this taking the place of either circle when its centre C is at infinity, and every line CP being then parallel to the axis. Thus Briggs, and we know not how many "savans géomètres" who have left no record, had already taken up the new doctrine in geometry in its author's lifetime. Six years after Kepler's death in 1630 Girard Desargues, "the Monge of his age," brought out the first of his remarkable works founded on the same principles, a short tract entitled *Méthode Universelle de mettre en perspective les objets donnés réellement ou en devis* (Paris, 1636). Kepler as a modern geometer is best known by his *New Stereometry of Wine Casks* (Lincii, 1615), in which he replaces the circuitous Archimedean method of exhaustion by a direct "royal road" of infinitesimals, treating a vanishing arc as a straight line and regarding a curve as made up of a succession of short chords. Some 2000 years previously one Antipho, probably the well-known opponent of Socrates, had regarded a circle in like manner as the limiting form of a many-sided inscribed rectilinear figure. Antipho's notion was rejected by the men of his day as unsound, and when reproduced by Kepler it was again stoutly opposed as incapable of any sort of geometrical demonstration—not altogether without reason, for it rested on an assumed law of continuity rather than on palpable proof.

To complete the theory of continuity, the one thing needful was the idea of imaginary points implied in the algebraical geometry of Descartes, in which equations between variables representing co-ordinates were found often to have imaginary roots. Newton, in his two sections on "Inventio Orbium" (*Principia*, i. 4, 5), shows in his brief way that he is familiar with the principles of modern geometry. In two propositions he uses an auxiliary line which is supposed to cut the conic in X and Y, but, as he remarks at the end of the second (prop. 24), it may not cut it at all. For the sake of brevity he passes on at once with the observation that the required constructions are evident from the case in which the line cuts the trajectory. In the scholium appended to prop. 27, after saying that an asymptote is a tangent at infinity, he gives an unexplained general construction for the axes of a conic, which seems to imply that it has asymptotes. In all such cases, having equations to his loci in the background, he may have thought of elements of the figure as passing into the imaginary state in such manner as not to vitiate conclusions arrived at on the hypothesis of their reality.

Boscovich (1711–87), a careful student of Newton's works, has a full and thorough discussion of geometrical continuity at the end of his *Sectionum Conicarum Elementa*, his first principle being that all varieties of a defined locus have the same properties, so that what is demonstrable of one should be demonstrable in like manner of all, although some artifice may be required to bring out the underlying analogy between them. The opposite extremities of an infinite straight line, he says, are to be regarded as joined, as if the line were a circle having its centre at the infinity on either side of it. This leads up to the idea of a *veluti plus quam infinita extensio*, a line-circle containing, as we say, the line infinity. Change from the real to the imaginary state is contingent upon the passage of some element of a figure through zero or infinity, and never takes place *per saltum*. Lines being some positive and some negative, there must be negative rectangles and negative squares, such as those of the exterior diameters of a hyperbola. Boscovich's first principle was that of Kepler, by whose *quantumvis absurdis locutionibus* the boldest applications of it are covered, as when we say with Poncelet that all concentric circles in a plane touch one another in two imaginary fixed points at infinity. In G. K. Ch. von Staudt's *Geometrie der Lage* and *Beiträge zur G. der L.* (Nürnberg, 1847, 1856–60) the geometry of position, including the extension of the field of pure geometry to the infinite and the imaginary, is presented as an independent science, "welche des Messens nicht bedarf." (See GEOMETRY, PROJECTIVE, *Ency. Brit.*, 9th ed., vol. x.)

Ocular illusions due to distance, such as Roger Bacon notices in the *Opus Majus* (i. 126, ii. 108, 497; Oxford, 1897), lead up to or illustrate the mathematical uses of the infinite and its reciprocal the infinitesimal. Specious objections can, of course, be made to the anomalies of the law of continuity, but they are inherent in the higher geometry, which has taught us so much of the "secrets of nature." Kepler's excursus on the "analogy" between the conic sections hereinbefore referred to is given at length in an article on "The Geometry of Kepler and Newton" in vol. xviii. of the *Transactions of the Cambridge Philosophical Society* (1900). It had been generally overlooked, until attention was called to it by the present writer in a note read in 1880 (*Proc. C. P. S.* iv. 14–17), and shortly afterwards in *The Ancient and Modern Geometry of Conics, with Historical Notes and Prolegomena* (Cambridge, 1881). (C. T*.)

Geometry, Line, is the name applied to those geometrical investigations in which the straight line replaces the point as element. Just as ordinary geometry deals primarily with points and systems of points, this theory deals in the first instance with straight lines and systems of straight lines. In two dimensions there is no necessity for a special line geometry, inasmuch as the straight line and the point are interchangeable by the principle of duality; but in three dimensions the straight line is its own reciprocal, and for the better discussion of systems of lines we require some new apparatus, *e.g.*, a system of co-ordinates applicable to straight lines rather than to points. The essential features of the subject are most easily elucidated by analytical methods: we shall therefore begin with the notion of line co-ordinates, and in order to emphasize the merits of the system of co-ordinates ultimately adopted, we first notice a system without these advantages, but often useful in special investigations.

In ordinary Cartesian co-ordinates the two equations of a straight line may be reduced to the form $y=rx+s$, $z=tx+u$, and r, s, t, u may be regarded as the four co-ordinates of the line. These co-ordinates lack symmetry: moreover, in changing from one base of reference to another the transformation is not linear, so that the degree of an equation is deprived of real significance. For purposes of the general theory we employ homogeneous co-ordinates; if $x_1y_1z_1w_1$ and $x_2y_2z_2w_2$ are two points on the line, it is easily verified that the six determinants of the array

$$\begin{vmatrix} x_1y_1z_1w_1 \\ x_2y_2z_2w_2 \end{vmatrix}$$

are in the same ratios for all point-pairs on the line, and further, that when the point co-ordinates undergo a linear transformation so also do these six determinants. We therefore adopt these six determinants for the co-ordinates of the line, and express them by the symbols $l, \lambda, m, \mu, n, \nu$ where $l=x_1w_2-x_2w_1, \lambda=y_1z_2-y_2z_1$, &c. There is the further advantage that if $a_1b_1c_1d_1$ and $a_2b_2c_2d_2$ be two planes through the line, the six determinants

$$\begin{vmatrix} a_1b_1c_1d_1 \\ a_2b_2c_2d_2 \end{vmatrix}$$

are in the same ratios as the foregoing, so that except as regards a factor of proportionality we have $\lambda=b_1c_2-b_2c_1$, $l=c_1d_2-c_2d_1$, &c. The identical relation $l\lambda+m\mu+n\nu=0$ reduces the number of independent constants in the six co-ordinates to four, for we are only concerned with their mutual ratios; and the quadratic character of this relation marks an essential difference between point geometry and line geometry. For elementary analytical investigations cf. Cayley, "The Six Co-ordinates of a Line," *Camb. Phil. Trans.*, 1868, or *Collected Papers*, vol. v.; for example, the condition of intersection of two lines is

$$l\lambda'+l'\lambda+m\mu'+m'\mu+n\nu'+n'\nu=0$$

where the accented letters refer to the second line.

Since a line depends on four constants, there are three distinct types of configurations arising in line geometry—those containing a triply-infinite, a doubly-infinite, and a singly-infinite number of lines; they are called Complexes, Congruences, and Ruled Surfaces or Skews respectively (see SURFACES, THEORY OF). A *Complex* is thus a system of lines satisfying one condition—that is, the co-ordinates are connected by a single relation; and the degree of the complex is the degree of this equation supposing it to be algebraic. The lines of a complex of the nth degree which pass through any point lie on a cone of the nth degree, and those which lie in any plane envelop a curve of the nth class: there are n lines of the complex in any plane pencil, and this statement combines the former two, for it shows that the cone is of the nth degree and the curve is of the nth class. To find the lines common to four complexes of degrees n_1, n_2, n_3, n_4, we have to solve five equations, viz., the four complex equations together with the quadratic equation connecting the line co-ordinates, therefore the number of common lines is $2n_1n_2n_3n_4$. As an example of complexes we have the lines meeting a twisted curve of the nth degree, which form a complex of the nth degree.

A *Congruence* is the set of lines satisfying two conditions: thus a finite number m of the lines pass through any point, and a finite number n lie in any plane; these numbers are called the degree and class respectively, and the congruence is symbolically written (m, n). The simplest example of a congruence is the system of lines constituted by all those that pass through m points and those that lie in n planes; through any other point there pass m of these lines, and in any other plane there lie n, therefore the congruence is of degree m and class n. It has been shown by Halphen that the number of lines common to two congruences is $mm' + nn'$, which may be verified by taking one of them to be of this simple type. The lines meeting two fixed lines form the general (1, 1) congruence; and the chords of a twisted cubic form the general type of a (1, 3) congruence; Halphen's result shows that two twisted cubics have in general ten common chords. As regards the analytical treatment, the difficulty is of the same nature as that arising in the theory of curves in space, for a congruence is not in general the complete intersection of two complexes.

A *Ruled Surface*, *Regulus*, or *Skew* is a configuration of lines which satisfy three conditions, and therefore depend on only one parameter. Such lines all lie on a surface, for we cannot draw one through an arbitrary point; only one line passes through a point of the surface; the simplest example, that of a quadric surface, is really two skews on the same surface. The degree of a ruled surface *quâ* line geometry is the number of its generating lines contained in a linear complex. Now the number which meets a given line is the degree of the surface *quâ* point geometry, and as the lines meeting a given line form a particular case of linear complex, it follows that the degree is the same from whichever point of view we regard it. The lines common to three complexes of degrees, $n_1n_2n_3$, form a ruled surface of degree $2n_1n_2n_3$; but not every ruled surface is the complete intersection of three complexes.

Linear complex.

In the case of a complex of the first degree (or linear complex) the lines through a fixed point lie in a plane called the polar plane or nul-plane of that point, and those lying in a fixed plane pass through a point called the nul-point or pole of the plane. If the nul-plane of A pass through B, then the nul-plane of B will pass through A; the nul-planes of all points on one line l_1 pass through another line l_2. The relation between l_1 and l_2 is reciprocal; any line of the complex that meets one will also meet the other, and every line meeting both belongs to the complex. They are called conjugate or polar lines with respect to the complex. On these principles can be founded a theory of reciprocation with respect to a linear complex. This may be aptly illustrated by an elegant example due to Voss. Since a twisted cubic can be made to satisfy twelve conditions, it might be supposed that a finite number could be drawn to touch four given lines, but this is not the case. For, suppose one such can be drawn, then its reciprocal with respect to any linear complex containing the four lines is a curve of the third class, *i.e.*, another twisted cubic, touching the same four lines, which are unaltered in the process of reciprocation; as there is an infinite number of complexes containing the four lines, there is an infinite number of cubics touching the four lines, and the problem is porismatic.

The following are some geometrical constructions relating to the unique linear complex that can be drawn to contain five arbitrary lines. To construct the nul-plane of any point O, we observe that the two lines which meet any four of the given five are conjugate lines of the complex, and the line drawn through O to meet them is therefore a ray of the complex; similarly, by choosing another four we can find another ray through O: these rays lie in the nul-plane, and there is clearly a result involved that the five lines so obtained all lie in one plane. A reciprocal construction will enable us to find the nul-point of any plane. Proceeding now to the metrical properties and the statical and dynamical applications, we remark that there is just one line such that the nul-plane of any point on it is perpendicular to it. This is called the central axis; if d be the shortest distance, θ the angle between it and a ray of the complex, then $d \tan \theta = p$, where p is a constant called the pitch or parameter. Any system of forces can be reduced to a force R along a certain line, and a couple G perpendicular to that line; the lines of nul-moment for the system form a linear complex of which the given line is the central axis and the quotient G/R is the pitch. Any motion of a rigid body can be reduced to a screw motion about a certain line, *i.e.*, to an angular velocity ω about that line combined with a linear velocity u along the line. The plane drawn through any point perpendicular to the direction of its motion is its nul-plane with respect to a linear complex having this line for central axis, and the quotient u/ω for pitch (cf. Sir R. S. Ball, *Theory of Screws*).

The following are some properties of a configuration of two linear complexes. The lines common to the two complexes also belong to an infinite number of linear complexes, of which two reduce to single straight lines. These two lines are conjugate lines with respect to each of the complexes, but they may coincide, and then some simple modifications are required. The locus of the central axis of this system of complexes is a surface of the third degree called the cylindroid, which plays a leading part in the theory of screws as developed synthetically by Ball. Since a linear complex has an invariant of the second degree in its co-efficients, it follows that two linear complexes have a lineo-linear invariant. This invariant is fundamental: if the complexes be both straight lines, its vanishing is the condition of their intersection as given above; if only one of them be a straight line, its vanishing is the condition that this line should belong to the other complex. When it vanishes for any two complexes they are said to be in *involution*; the nul-points P, Q of any plane then divide harmonically the points in which the plane meets the common conjugate lines, and each complex is its own reciprocal with respect to the other. As regards a configuration of these linear complexes, the common lines from one system of generators of a quadric, and the doubly infinite system of complexes containing the common lines, include an infinite number of straight lines which form the other system of generators of the same quadric.

General line co-ordinates.

If the equation of a linear complex is $Al + Bm + Cn + D\lambda + E\mu + F\nu = 0$, then for a line not belonging to the complex we may regard the expression on the left-hand side as a multiple of the moment of the line with respect to the complex, the word moment being used in the statical sense; and we infer that when the co-ordinates are replaced by linear functions of themselves the new co-ordinates are multiples of the moments of the line with respect to six fixed complexes. The essential features of this co-ordinate system are the same as those of the original one, viz., there are six co-ordinates connected by a quadratic equation, but this relation has in general a different form. By suitable choice of the six fundamental complexes, as they may be called, this connecting relation may be brought into other simple forms of which we mention two: (i.) When the six are mutually in involution it can be reduced to $x_1^2+x_2^2+x_3^2+x_4^2+x_5^2+x_6^2=0$; (ii.) When the first four are in involution and the other two are the lines common to the first four it is $x_1^2+x_2^2+x_3^2+x_4^2-2x_5x_6=0$. These generalized co-ordinates might be explained without reference to actual magnitude, just as homogeneous point co-ordinates can be; the essential remark is that the equation of any co-ordinate to zero represents a linear complex, a point of view which includes our original system, for the equation of a co-ordinate to zero represents all the lines meeting an edge of the fundamental tetrahedron.

The system of co-ordinates referred to six complexes mutually in involution was introduced by Klein, and in many cases is more useful than that derived directly from point co-ordinates; *e.g.*, in the discussion of quadratic complexes: by means of it Klein has developed an analogy between line geometry and the geometry of spheres as treated by Darboux and others. In fact, in that geometry a point is represented by *five* co-ordinates, connected by a relation of the same type as the one just mentioned when the five fundamental spheres are mutually at right angles and the equation of a sphere is of the first degree. Extending this to four dimensions of space, we obtain an exact analogue of line geometry, in which (i.) a point corresponds to a line; (ii.) a linear complex to a hypersphere; (iii.) two linear complexes in involution to two orthogonal hyperspheres; (iv.) a linear complex and two conjugate lines to a hypersphere and two inverse points. Many results may be obtained by this principle, and more still are suggested by trying to extend the properties of circles to spheres in three and four dimensions. Thus the elementary theorem, that, given four lines, the circles circumscribed to the four triangles formed by them are concurrent, may be extended to six hyperplanes in four dimensions; and then we can derive a result in line geometry by translating the inverse of this theorem. Again, just as there is an infinite number of spheres touching a surface at a given point, two of them having contact of a closer nature, so there is an infinite number of linear complexes touching a non-linear complex at a given line, and *three* of these have contact of a closer nature (cf. Klein, *Math. Ann.* v.).

Lie has pointed out a different analogy with sphere geometry. Suppose, in fact, that the equation of a sphere of radius r is

$$x^2+y^2+z^2+2ax+2by+2cz+d=0,$$

so that $r^2=a^2+b^2+c^2-d$; then introducing the quantity e to make this equation homogeneous, we may regard the sphere as given by the six co-ordinates a, b, c, d, e, r connected by the equation $a^2+b^2+c^2-r^2-de=0$, and it is easy to see that two spheres touch if the polar form $2aa_1+2bb_1+2cc_1-2rr_1-de_1-d_1e$ vanishes. Comparing this with the equation $x_1^2+x_2^2+x_3^2+x_4^2-2x_5x_6=0$ given above, it appears that this sphere geometry and line geometry are identical, for we may write $a=x_1$, $b=x_2$, $c=x_3$, $r=x_4\sqrt{-1}$, $d=x_5$, $e=\frac{1}{2}x_6$; but it is to be noticed that a sphere is really replaced by two lines whose co-ordinates only differ in the sign of x_4, so that they are polar lines with respect to the complex $x_4=0$. Two spheres which touch correspond to two lines which intersect, or more accurately to two pairs of lines (p, p') and (q, q'), of which the pairs (p, q) and (p', q') both intersect. By this means the problem of describing a sphere to touch four given spheres is reduced to that of drawing a pair of lines (t, t') (of which t intersects one line of the four pairs (pp'), (qq'), (rr'), (ss'), and t' intersects the remaining four). We may, however, ignore the accented letters in translating theorems, for a configuration of lines and its polar with respect to a linear complex have the same projective properties. In Lie's transformation a linear complex corresponds to the totality of spheres cutting a given sphere at a given angle. A most remarkable result is that lines of curvature in the sphere geometry become asymptotic lines in the line geometry.

Some of the principles of line geometry may be brought into clearer light by admitting the ideas of space of four and five dimensions. Thus, regarding the co-ordinates of a line as homogeneous co-ordinates in five dimensions, we may say that line geometry is equivalent to geometry on a quadric surface in five dimensions. A linear complex is represented by a hyperplane section; and if two such complexes are in involution, the corresponding hyperplanes are conjugate with respect to the fundamental quadric. By projecting this quadric stereographically into space of four dimensions we obtain Klein's analogy. In the same way geometry in a linear complex is equivalent to geometry on a quadric in four dimensions; when two lines intersect the representative points are on the same generator of this quadric. Stereographic projection, therefore, converts a curve in a linear complex, *i.e.*, one whose tangents all belong to the complex, into one whose tangents intersect a fixed conic: when this conic is the imaginary circle at infinity the curve is what Lie calls a minimal curve. Curves in a linear complex have been extensively studied. The osculating plane at any point of such a curve is the nul-plane of the point with respect to the complex, and points of superosculation always coincide in pairs at the points of contact of stationary tangents. A rational curve of degree n in a linear complex has $2n-6$ stationary tangents; but conversely, when this is the case, the curve may not belong to a linear complex. Examples are afforded by the twisted cubic and the twisted quartic with two stationary tangents.

Non-linear complexes.

In giving an account of non-linear complexes we restrict the discussion mainly to the quadratic variety; comparatively little is known of those of higher degrees, and the known theorems do not differ essentially from those referring to the quadratic complex. The lines through a given point that belong to a complex of the nth degree lie on a cone of the nth degree: if this cone has a double line the point is said to be a singular point. Similarly, a plane is said to be singular when the envelope of the lines in it has a double tangent. It is very remarkable that the same surface is the locus of the singular points and the envelope of the singular planes: this surface is called the singular surface, and both its degree and class are in general $2n(n-1)^2$, which is equal to four for the quadratic complex. Following Plücker, we give an account of the lines of a quadratic complex that meet a given line. The cones whose vertices are on the given line all pass through eight fixed points and envelop a surface of the fourth degree; the conics whose planes contain the given line all lie on a surface of the fourth class and touch eight fixed planes. It is easy to see by elementary geometry that these two surfaces are identical. Further, the given line contains four singular points A_1, A_2, A_3, A_4, and the planes into which their cones degenerate are the eight common tangent planes mentioned above; similarly, there are four singular planes, a_1, a_2, a_3, a_4, through the line, and the eight points into which their conics degenerate are the eight common points above. The locus of the pole of the line with respect to all the conics in planes through it is a straight line called the *polar line* of the given one; and through this line passes the polar plane of the given line with respect to each of the cones. The name polar is applied in the ordinary analytical sense; any line has an infinite number of polar complexes with respect to the given complex, for the equation of the latter can be written in an infinite number of ways; one of these polars is a straight line, and is the polar line already introduced. The surface on which lie all the conics through a line l is called the Plücker surface of that line: from the known properties of (2, 2) correspondences it can be shown that the Plücker surface of l cuts l_1 in a range of the same cross ratio as that of the range in which the Plücker surface of l_1 cuts l. Applying this to the case in which l_1 is the polar of l, we find that the cross ratios of (A_1, A_2, A_3, A_4) and (a_1, a_2, a_3, a_4) are equal. The identity of the locus of the A's with the envelope of the a's follows at once; moreover, a line meets the singular surface in four points having the same cross ratio as that of the four tangent planes drawn through the line to touch the surface. The Plücker surface has eight nodes, eight singular tangent planes, and a double line, which have further properties. The relation between a line and its polar line is not a reciprocal one with respect to the complex; but Stahl has pointed out that the relation *is* reciprocal as far as the singular surface is concerned.

The singular lines of a complex $F=0$ are the lines common to F and the complex

$$\frac{\delta F}{\delta l}\frac{\delta F}{\delta \lambda}+\frac{\delta F}{\delta m}\frac{\delta F}{\delta \mu}+\frac{\delta F}{\delta n}\frac{\delta F}{\delta \nu}=0.$$

Singular lines. As already mentioned, at each line l of a complex there is an infinite number of tangent linear complexes, and they all contain the lines adjacent to l. If now l be a singular line, these complexes all reduce to straight lines which form a plane pencil containing the line l. Suppose the vertex of the pencil is A and its plane a, then it follows that the cone of any point on l touches a along l, and the curve of any plane through l touches l at A. Hence l is a double line for the cone of A and for the curve of a, so that A is a singular point and a is a singular plane. Conversely, a double line of a cone or curve is a singular line, and a singular line clearly touches the curves of all planes through it in the same point. This is the usual definition. Further, of the singular lines through A two coincide in l, and of those in a two coincide in l; and it follows almost at once that the locus of the A's coincides with the envelope of the a's, and forms part of the focal surface of the congruence of singular lines (see "Congruences," *infra*). Hence when a line touches a complex it touches the singular surface, for it belongs to a plane pencil like (Aa), and thus in Klein's analogy the analogue of a focus of a hypersurface being a bitangent line of the complex is also a bitangent line of the singular surface. The theory of cosingular complexes is thus brought into line with that of confocal surfaces in four dimensions, and guided by these principles the existence of cosingular quadratic complexes can easily be established, the analysis required being almost the same as that invented for confocal cyclides by Darboux and others. Of cosingular complexes of higher degree nothing is known.

To facilitate the discussion of the general quadratic complex we introduce Klein's canonical form. We have, in fact, to deal with two quadratic equations in six variables; and by suitable linear transformations these can be reduced to the form

$$a_1x_1^2+a_2x_2^2+a_3x_3^2+a_4x_4^2+a_5x_5^2+a_6x_6^2=0$$
$$x_1^2+x_2^2+x_3^2+x_4^2+x_5^2+x_6^2=0$$

subject to certain exceptions, which will be mentioned later.

Taking the first equation to be that of the complex, we remark that both equations are unaltered by changing the sign of any co-ordinate; the geometrical meaning of this is, that the quadratic complex is its own reciprocal with respect to each of the six fundamental complexes, for changing the sign of a co-ordinate is equivalent to taking the polar of a line with respect to the corresponding fundamental complex. It is easy to establish the existence of six systems of bitangent linear complexes, for the complex $l_1x_1+l_2x_2+l_3x_3+l_4x_4+l_5x_5+l_6x_6=0$ is a bitangent when

$$l_1=0, \text{ and } \frac{l_2^2}{a_2-a_1}+\frac{l_3^2}{a_3-a_1}+\frac{l_4^2}{a_4-a_1}+\frac{l_5^2}{a_5-a_1}+\frac{l_6^2}{a_6-a_1}=0,$$

and its lines of contact are conjugate lines with respect to the first fundamental complex. We therefore infer the existence of six systems of bitangent lines of the complex, of which the first is given by

$$x_1=0, \frac{x_2^2}{a_2-a_1}+\frac{x_3^2}{a_3-a_1}+\frac{x_4^2}{a_4-a_1}+\frac{x_5^2}{a_5-a_1}+\frac{x_6^2}{a_6-a_1}=0.$$

Each of these lines is a bitangent of the singular surface, which is therefore completely determined as being the focal surface of the (2, 2) congruence above. It is thence easy to verify that the two complexes $\Sigma ax^2=0$ and $\Sigma bx^2=0$ are cosingular if $b_r=\frac{a_r\lambda+\mu}{a_r\nu+\rho}$.

The singular surface of the general quadratic complex is the famous quartic, with sixteen nodes and sixteen singular tangent planes, first discovered by Kümmer. We cannot give a full account of its properties here, but we deduce at once from the above that its bitangents break up into six (2, 2) congruences, and the six linear complexes containing these are mutually in involution. The nodes of the singular surface are points whose complex cones are coincident planes, and the complex conic in a singular tangent plane consists of two coincident points. This configuration of sixteen points and planes has many interesting properties; thus each plane contains six points which lie on a conic, while through each point there pass six planes which touch a quadric cone. In many respects the Kümmer quartic plays a part in three dimensions analogous to the general quartic curve in two; it further gives a natural representation of certain relations between hyperelliptic functions.

Classification of quadratic complexes. As might be expected from the magnitude of a form in six variables, the number of projectively distinct varieties of quadratic complexes is very great; and in fact Weiler, by whom the question was first systematically studied on lines indicated by Klein, enumerated no fewer than forty-nine different types. But the principle of the classification is so important, and withal so simple, that we give a brief sketch which indicates its essential features. We have practically to study the intersection of two quadrics F and F′ in six variables, and to classify the different cases arising we make use of the results of Weierstrass on the equivalence conditions of two pairs of quadratics. As far as at present required, they are as follows:—Suppose that the factorized form of the determinantal equation Disct $(F+\lambda F')=0$ is

$$(\lambda-a)^{s_1+s_2+s_3\ldots}(\lambda-\beta)^{t_1+t_2+t_3+\ldots}\ldots$$

where the root a occurs $s_1+s_2+s_3\ldots$ times in the determinant, $s_2+s_3\ldots$ times in every first minor, $s_3+\ldots$ times in every second minor, and so on; the meaning of each exponent is then perfectly definite. Every factor of the type $(\lambda-a)^s$ is called an *elementartheil* (elementary divisor) of the determinant, and the condition of equivalence of two pairs of quadratics is simply that their determinants have the same elementary divisors. We write the pair of forms symbolically thus $[(s_1s_2\ldots), (t_1t_2\ldots), \ldots]$, letters in the inner brackets referring to the same factor. Returning now to the two quadratics representing the complex, the sum of the exponents will be six, and two complexes are put in the same class if they have the same symbolical expression; *i.e.*, the actual values of the roots of the determinantal equation need not be the same for both, but their manner of occurrence, as far as here indicated, must be identical in the two. The enumeration of all possible cases is thus reduced to a simple question in combinatorial analysis, and the actual study of any particular case is much facilitated by a useful rule of Klein's for writing down in a simple form two quadratics belonging to a given class—one of which, of course, represents the equation connecting line co-ordinates, and the other the equation of the complex. The general complex is naturally [111111]; the complex of tangents to a quadric is [(111), (111)] and that of lines meeting a conic is [(222)]. Full information will be found in Weiler's memoir, *Math. Ann.* vol. vii.

The detailed study of each variety of complex opens up a vast subject; we only mention two special cases, the harmonic complex and the tetrahedral complex. The harmonic complex, first studied by Battaglini, is generated in an infinite number of ways by the lines cutting two quadrics harmonically. Taking the most general case, and referring the quadrics to their common self-conjugate tetrahedron, we can find its equation in a simple form, and verify that this complex really depends only on seventeen constants, so that it is not the most general quadratic complex. It belongs to the general type in so far as it is discussed above, but the roots of the determinant are in involution. The singular surface is the "tetrahedroid" discussed by Cayley. As a particular case, from a metrical point of view, we have Painvin's complex generated by the lines of intersection of perpendicular tangent planes of a quadric, the singular surface now being Fresnel's wave surface. The tetrahedral or Reye complex is the simplest and best known of proper quadratic complexes. It is generated by the lines which cut the faces of a tetrahedron in a constant cross ratio, and therefore by those subtending the same cross ratio at the four vertices. The singular surface is made up of the faces or the vertices of the fundamental tetrahedron, and each edge of this tetrahedron is a double line of the complex. The complex was first discussed by Reye as the assemblage of lines joining corresponding points in a homographic transformation of space, and this point of view leads to many important and elegant properties. A (metrically) particular case of great interest is the complex generated by the normals to a family of confocal quadrics, and for many investigations it is convenient to deal with this complex referred to the principal axes. For example, Lie has developed the theory of curves in a Reye complex (*i.e.*, curves whose tangents belong to the complex) as solutions of a differential equation of the form $(b-c)xdydz+(c-a)ydzdx+(a-b)zdxdy=0$, and we can simplify this equation by a logarithmic transformation. Many theorems connecting complexes with differential equations have been given by Lie and his school. A line complex, in fact, corresponds to a Mongian equation having ∞^3 line integrals.

Congruences. As the co-ordinates of a line belonging to a congruence are functions of two independent parameters, the theory of congruences is analogous to that of surfaces, and we may regard it as a fundamental inquiry to find the simplest form of surface into which a given congruence can be transformed. Most of those whose properties have been extensively discussed can be represented on a plane by a birational transformation. But in addition to the difficulties of the theory of algebraic surfaces, a subject still in its infancy, the theory of congruences has other difficulties in that a congruence is seldom completely represented, even by two equations. A fundamental theorem is that the lines of a congruence are in general bitangents of a surface; in fact, since the condition of intersection of two consecutive straight lines is $ld\lambda+dmd\mu+dnd\nu=0$, a line l of the congruence meets two adjacent lines, say l_1 and l_2. Suppose l, l_1 lie in the plane pencil (A_1a_1) and l, l_2 in the plane pencil (A_2a_2), then the locus of the A's is the same as the envelope of the a's, but a_2 is the tangent plane at A_1 and a_1 at A_2. This surface is called the focal surface of the congruence, and to it all the lines l are bitangent. The distinctive property of the points A is that two of the congruence lines through them coincide, and in like manner the planes a each contain two coincident lines. The focal surface consists of two sheets, but one or both may degenerate into curves; thus, for example, the normals to a surface are bitangents of the surface of centres, and in the case of Dupin's cyclide this surface degenerates into two conics.

In the discussion of congruences it soon becomes necessary to introduce another number r, called the rank, which expresses the number of plane pencils each of which contains an arbitrary line and two lines of the congruence. The order of the focal surface is $2m(n-1)-2r$, and its class is $m(m-1)-2r$. Our knowledge of congruences is almost exclusively confined to those in which either m or n does not exceed two. We give a brief account of those of the second order without singular lines, those of order unity not being especially interesting. A congruence generally has singular points through which an infinite number of lines pass; a singular point is said to be of order r when the lines through it lie on a cone of the rth degree. By means of formulæ connecting the number of singular points and their orders with the class m of quadratic congruence Kümmer proved that the class cannot exceed seven. The focal surface is of degree four and class $2m$; this kind of quartic surface has been extensively studied by Kümmer, Cayley, Rohn, and others. The varieties (2, 2), (2, 3), (2, 4), (2, 5) all belong to at least one Reye complex; and so also does the most important class of (2, 6) congruences which includes all the above as special cases. The congruence (2, 2) belongs to a linear complex and forty different Reye complexes; as above remarked, the singular surface is Kümmer's sixteen-nodal quartic, and the same surface is focal for six different congruences of this variety. The theory of (2, 2) congruences is completely analogous to that of the surfaces called cyclides in three dimensions. Further particulars regarding quadratic congruences will be found in Kümmer's memoir of 1866, and the second volume of Sturm's treatise. The properties of quadratic congruences having singular lines, *i.e.*, degenerate focal surfaces, are not so interesting as those of the above class; they have been discussed by Kümmer, Sturm, and others.

Ruled surfaces. Since a ruled surface contains only ∞^1 elements, this theory is practically the same as that of curves. We pass over the point and plane theory of such surfaces with the remark that the degree and class are obviously equal, and deal exclusively with line geometry. Premising that if a linear complex contains more than n generators of a ruled surface of the nth degree it contains all the generators, we remark that for $n=2$ there are three linearly independent complexes, containing all the generators, and this is a well-known property of quadric surfaces. In ruled cubics the generators all meet two lines which may or may not coincide; these two cases correspond to the two main classes of cubics discussed by Cayley and Cremona. As regards ruled quartics, the generators must lie in one and may lie in two linear complexes. The first class is equivalent to a quartic in four dimensions and is always rational, but the latter class has to be subdivided into the elliptic and the rational, just like twisted quartic curves. A quintic skew may not lie in a linear complex, and then it is unicursal, while of sextics we have two classes not in a linear complex, viz., the elliptic variety, having thirty-six places where a linear complex contains six consecutive generators, and the rational, having six such places.

The general theory of skews in two linear complexes is identical with that of curves on a quadric in three dimensions, and is known. But for skews lying in only one linear complex there are difficulties; the curve now lies in four dimensions, and we represent it in three by stereographic projection as a curve meeting a given plane in n points on a conic. To find the maximum deficiency for a given degree would probably be difficult, but as far as degree eight the space-curve theory of Halphen and Nöther can be translated into line geometry at once. When the skew does not lie in a linear complex at all the theory is more difficult still; and we conclude by remarking that the deficiency of a skew surface, *quâ* line geometry of course, is equal to that of its line of striction when we deal with Euclidean space.

The earliest works of a general nature are PLÜCKER, *Neue Geometrie des Raumes*, Leipzig, 1868; and KÜMMER, "Ueber die algebraischen Strahlensysteme," *Berlin Academy*, 1866. Systematic development on purely synthetic lines will be found in the three volumes of STURM, *Liniengeometrie*, Leipzig, 1892, 1893, 1896; vol. i. deals with the linear and Reye complexes, vols. ii. and iii. with quadratic congruences and complexes respectively. For a highly suggestive review by Gino Loria see *Bulletin des sciences mathématiques*, 1893, 1897. A shorter treatise, giving a very interesting account of Klein's co-ordinates, is the work of KOENIGS, *La géometrie reglée et ses applications*, Paris, 1898. Many references to memoirs on line geometry will be found in HAGEN, *Synopsis der höheren Mathematik*, ii., Berlin, 1894; LORIA, *Il passato ed il presente delle principali teorie geometriche*, Milan, 1897; a clear résumé of the principal results is contained in the very elegant volume of PASCAL, *Repertorio di mathematiche superiori*, ii., Milan, 1900. Another treatise dealing extensively with line geometry is LIE, *Geometrie der Berührungstransformationen*, Leipzig, 1896. Many memoirs on the subject have appeared in the *Mathematische Annalen*; a full list of these will be found in the index to the first fifty volumes, p. 115. Perhaps the two memoirs which have left most impress on the subsequent development of the subject are KLEIN, "Zur Theorie der Liniencomplexe des ersten und zweiten Grades," *Math. Ann.* ii.; and LIE, "Ueber Complexe, insbesondere Linien- und Kugelcomplexe," *Math. Ann.* v. (J. H. GR.)

Geometry, Non-Euclidean.—Non-Euclidean Geometry, in the narrower sense, may be defined as the study of the consequences which follow from denying one or more of the (explicit or tacit) assumptions upon which the Euclidean system is founded. In a broader sense, for which the name Pangeometry is more appropriate, the word is used to describe systems which merely dispense with one or more of Euclid's assumptions, without making any decision as to the truth or falsity of these assumptions. The motives and scope of non-Euclidean Geometry can hardly be grasped without some knowledge of its growth and development. The present article, therefore, will begin with a historical sketch; it will then attempt to dispel some common confusions as to the meaning or the assumptions of non-Euclidean systems; and finally, it will briefly indicate the bearing of these systems upon Epistemology and the philosophy of space.

Definition.

"In pulcherrimo Geometriæ corpore," wrote Sir Henry Savile, in 1621, "duo sunt nævi, duæ labes nec quod sciam plures, in quibus eluendis et emaculendis cum veterum tum recentiorum . . . vigilavit industria." These two blemishes are the theory of parallels and the theory of proportion. The "industry of the moderns," in both respects, has given rise to important branches of mathematics, while at the same time showing that Euclid is more free from blemish than had been previously credible. It was from endeavours to improve the theory of parallels that non-Euclidean Geometry arose; and though it has now acquired a far wider scope, its historical origin remains instructive and interesting. To Euclid's successors, the axiom, or more properly the postulate, of parallels had signally failed to appear self-evident, and had failed equally to appear indemonstrable. Without the use of the postulate its converse is proved in Euclid's 28th proposition, and it was hoped that by further efforts the postulate itself could be also proved. The first step consisted in the discovery of equivalent axioms. Clavius in 1574 deduced the axiom from the assumption that a line whose points are all equidistant from a straight line is itself straight. Wallis in 1663 showed that the postulate follows from the possibility of similar triangles on different scales. Saccheri (1733) showed that it is sufficient to have a single triangle, the sum of whose angles is two right angles. Other equivalent forms may be obtained, but none shows any essential superiority to Euclid's. Indeed plausibility, which is chiefly aimed at, becomes a positive demerit where it conceals a real assumption.

Theory of parallels before Gauss.

A new method, which, though it failed to lead to the desired goal, proved in the end immensely fruitful, was invented by Saccheri, in a work entitled *Euclides ab omni nævo vindicatus* (Milan, 1733). If the postulate of parallels is involved in Euclid's other assumptions, contradictions must emerge when it is denied while the others are maintained. This led Saccheri to attempt a *reductio ad absurdum*, in which he mistakenly believed himself to have succeeded. What is interesting, however, is not his fallacious conclusion, but the non-Euclidean results which he obtains in the process. Saccheri distinguishes three hypotheses (corresponding to what are now known as Euclidean or parabolic, elliptic, and hyperbolic Geometry), and proves that some one of the three must be universally true. His three hypotheses are thus obtained: equal perpendiculars AC, BD are drawn to a straight line AB, and CD are joined. It is shown that the angles ACD, BDC are equal. The first hypothesis is that these are both right angles; the second, that they are both obtuse; and the third, that they are both acute. Many of the results afterwards obtained by Lobatchewsky and Bolyai are here developed. Saccheri fails to be the founder of non-Euclidean Geometry only because he does not perceive the possible truth of his non-Euclidean hypotheses. Some advance is made by Lambert (the demonstrator of the irrationality of π) in his *Theorie der Parallellinien* (written 1766; posthumously published, 1786). Though he still believed in the necessary truth of Euclidean Geometry, he confessed that, in all his attempted proofs, something remained undemonstrated. He deals with the same three hypotheses as Saccheri, showing that the second holds on a sphere, while the third would hold on a sphere of purely imaginary radius. The second hypothesis he succeeds in condemning, since, like all who preceded Riemann, he is unable to conceive of the straight line as finite and closed. But the third hypothesis, which is the same as Lobatchewsky's, is not even professedly refuted.[1]

Non-Euclidean Geometry proper begins with Gauss. The advance which he made was rather philosophical than mathematical: it was he (probably) who first recognized that the postulate of parallels is possibly false, and should be empirically tested by measuring the angles of large triangles. The history of non-Euclidean Geometry has been aptly divided by Klein into three very distinct periods. The first—which contains only Gauss, Lobat-

Three periods of non-Euclidean Geometry.

[1] On the theory of parallels before Lobatchewsky, see Stäckel und Engel, *Theorie der Parallellinien von Euklid bis auf Gauss*, Leipzig, 1895. The foregoing remarks are based upon the materials collected in this work.

chewsky and Bolyai—is characterized by its synthetic method and by its close relation to Euclid. The attempt at indirect proof of the disputed postulate would seem to have been the source of these three men's discoveries; but when the postulate had been denied, they found that the results, so far from showing contradictions, were just as self-consistent as Euclid. They inferred that the postulate, if true at all, can only be proved by observations and measurements. Only one kind of non-Euclidean space is known to them, namely, that which is now called hyperbolic. The second period is analytical, and is characterized by a close relation to the theory of surfaces. It begins with Riemann's inaugural dissertation, which regards space as a particular case of a *manifold*. The conception of measure of curvature is extended from surfaces to spaces, and a new kind of space, finite but unbounded (corresponding to the second hypothesis of Saccheri and Lambert), is shown to be possible. As opposed to the second period, which is purely metrical, the third period is essentially projective in its method. It begins with Cayley, who showed that metrical properties are projective properties relative to a certain fundamental quadric, and that different geometries arise according as this quadric is real, imaginary, or degenerate. Klein, to whom the development of Cayley's work is due, showed further that there are two forms of Riemann's space, called by him the elliptic and the spherical. Finally, it has been shown by Lie, that if figures are to be freely movable throughout all space in ∞^6 ways, no other three-dimensional spaces than the above four are possible.

Gauss. Gauss published nothing on the theory of parallels, and it was not generally known until after his death that he had interested himself in that theory from a very early date. In 1799, he announces that Euclidean Geometry would follow from the assumption that a triangle can be drawn greater than any given triangle. Though unwilling to assume this, we find him in 1804 still hoping to prove the postulate of parallels. In 1830 he announces his conviction that Geometry is not an *à priori* science; in the following year he explains that non-Euclidean Geometry is free from contradictions, and that, in this system, the angles of a triangle diminish without limit when all the sides are increased. He also gives for the circumference of a circle of radius r the formula $\pi k(e^{r/k} - e^{-r/k})$, where k is a constant depending upon the nature of the space. In 1832, in reply to the receipt of Bolyai's *Appendix*, he gives an elegant proof that the amount by which the sum of the angles of a triangle falls short of two right angles is proportional to the area of the triangle. From these and a few other remarks it appears that Gauss possessed the foundations of hyperbolic Geometry, which he was probably the first to regard as perhaps true. It is not known with certainty whether he influenced Lobatchewsky and Bolyai, but the evidence we possess is against such a view.[1]

Lobatchewsky. The first to publish a non-Euclidean Geometry was a Russian, Lobatchewsky, Professor of Mathematics in the new university of Kazañ.[2] In the place of the disputed postulate he puts the following: "All straight lines which, in a plane, radiate from a given point, can, with respect to any other straight line in the same plane, be divided into two classes, the *intersecting* and the *non-intersecting*. The *boundary line* of the one and the other class is called *parallel to the given line*." It follows that there are two parallels to the given line through any point, each meeting the line at infinity, like a Euclidean parallel. (Hence a line has two distinct points at infinity, and not one only as in ordinary Geometry.) The two parallels to a line through a point make equal acute angles with the perpendicular to the line through the point. If p be the length of the perpendicular, either of these angles is denoted by $\Pi(p)$. The determination of $\Pi(p)$ is the chief problem; it appears finally that, with a suitable choice of the unit of length,

$$\tan \tfrac{1}{2}\,\Pi(p) = e^{-p}.$$

Before obtaining this result it is shown that spherical trigonometry is unchanged, and that the normals to a circle or a sphere still pass through its centre. When the radius of the circle or sphere becomes infinite all these normals become parallel, but the circle or sphere does not become a straight line or plane. It becomes what Lobatchewsky calls a limit-line or limit-surface. The geometry on such a surface is shown to be Euclidean, limit-lines replacing Euclidean straight lines. (It is, in fact, a surface of zero measure of curvature.) By the help of these propositions Lobatchewsky obtains the above value of $\Pi(p)$, and thence the solution of triangles. He points out that his formulæ result from those of spherical trigonometry by substituting ia, ib, ic, for the sides a, b, c.

Bolyai. John Bolyai, a Hungarian, obtained results closely corresponding to those of Lobatchewsky. These he published in an appendix to a work by his father, entitled *Appendix Scientiam spatii absolute veram exhibens: a veritate aut falsitate Axiomatis XI. Euclidei (à priori haud unquam decidenda) independentem: adjecta ad casum falsitatis, quadratura circuli geometrica.*[3] This work was published in 1831, but its conception dates from 1823. It reveals a profounder appreciation of the importance of the new ideas, but otherwise differs little from Lobatchewsky's. Both men point out that Euclidean Geometry is a limiting case of their own more general system, that the geometry of very small spaces is always approximately Euclidean, that no *à priori* grounds exist for a decision, and that observation can only give an approximate answer. Bolyai gives also, as his title indicates, a geometrical construction, in hyperbolic space, for the quadrature of the circle, and shows that the area of the greatest possible triangle, which has all its sides parallel and all its angles zero, is πi^2, where i is what we should now call the space-constant.

Riemann. The works of Lobatchewsky and Bolyai, though known and valued by Gauss, remained obscure and ineffective until, in 1866, they were translated into French by J. Hoüel. But at this time Riemann's dissertation, *Ueber die Hypothesen welche der Geometrie zu Grunde liegen*,[4] was already about to be published. In this work Riemann, without any knowledge of his predecessors in the same field, inaugurated a far more profound discussion, based on a far more general standpoint; and by its publication in 1867, the attention of mathematicians and philosophers was at last secured. (The dissertation dates from 1854, but owing to changes which Riemann wished to make in it, it remained unpublished until after his death.)

Riemann's work contains two fundamental conceptions,

that of a *manifold*, and that of the *measure of curvature* of a continuous manifold possessed of what he calls flatness in the smallest parts. By means of these conceptions space is made to appear at the end of a gradual series of more and more specialized conceptions.

Definition of a manifold.

Conceptions of magnitude, he explains, are only possible where we have a general conception capable of determination in various ways. The manifold consists of all these various determinations, each of which is an element of the manifold. The passage from one element to another may be discrete or continuous; the manifold is called discrete or continuous accordingly. Where it is discrete two portions of it can be compared, as to magnitude, by counting; where continuous, by measurement. But measurement demands superposition, and consequently some magnitude independent of its place in the manifold. In passing, in a continuous manifold, from one element to another in a determinate way, we pass through a series of intermediate terms, which form a one-dimensional manifold. If this whole manifold be similarly caused to pass over into another, each of its elements passes through a one-dimensional manifold, and thus on the whole a two-dimensional manifold is generated. In this way we can proceed to n dimensions. Conversely, a manifold of n dimensions can be analysed into one of one dimension and one of $(n-1)$ dimensions. By repetitions of this process the position of an element may be at last determined by n magnitudes. Riemann proceeds to specialize the manifold by considerations as to measurement.

Measure of curvature.

If measurement is to be possible, some magnitude, we saw, must be independent of position; let us consider manifolds in which lengths of lines are such magnitudes, so that every line is measurable by every other. The co-ordinates of a point being $x_1, x_2, \ldots\ldots x_n$, let us confine ourselves to lines along which the ratios $dx_1 : dx_2 : \ldots\ldots : dx_n$ alter continuously. Let us also assume that the element of length, ds, is unchanged (to the first order) when all its points undergo the same infinitesimal motion. Then if all the increments dx be altered in the same ratio, ds is also altered in this ratio. Hence ds is a homogeneous function of the first degree of the increments dx. Moreover, ds must be unchanged when all the dx change sign. The simplest possible case is, therefore, that in which ds is the square root of a quadratic function of the dx. This case includes space, and is alone considered in what follows. It is called the case of flatness in the smallest parts. Its further discussion depends upon the measure of curvature, the second of Riemann's fundamental conceptions. This conception, derived from the theory of surfaces, is applied as follows. Any one of the shortest lines which issue from a given point (say the origin), is completely determined by the initial ratios of the dx. Two such lines, defined by dx and δx say, determine a pencil, or one-dimensional series, of shortest lines, any one of which is defined by $\lambda dx + \mu \delta x$, where the parameter $\lambda : \mu$ may have any value. This pencil generates a two-dimensional series of points, which may be regarded as a surface, and for which we may apply Gauss's formula for the measure of curvature at any point. Thus at every point of our manifold there is a measure of curvature corresponding to every such pencil; but all these can be found when $n.\overline{n-1}/2$ of them are known. If figures are to be freely movable, it is necessary and sufficient that the measure of curvature should be the same for all points and all directions at each point. Where this is the case, if a be the measure of curvature, the linear element can be put into the form

$$ds = \sqrt{\Sigma dx^2} / (1 + \tfrac{a}{4}\Sigma x^2).$$

If a be positive, space is finite, though still unbounded, and every straight line is closed—a possibility first recognized by Riemann. It is pointed out that, since the possible values of a form a continuous series, observations cannot prove that our space is strictly Euclidean. It is also regarded as possible that, in the infinitesimal, the measure of curvature of our space should be variable.

Criticism of Riemann.

There is one point, at least, upon which this profound work seems open to criticism, namely, as regards the introduction of co-ordinates. If we are to be able, without a vicious circle, to presuppose co-ordinates in discussing distance, it is evident that our co-ordinates must not presuppose distance. It then remains a question how they are to be defined—a question satisfactorily answered (as we shall see) by the projective method, but unanswerable from Riemann's metrical standpoint. Moreover, if our co-ordinates are to represent any kind of spatial magnitudes, we must assume the possibility of equal quantities in different places, and hence, it will be found, we shall be compelled to regard the measure of curvature as constant. Let us examine the consequences of supposing it variable. In the first place, the method of superposition would have become impossible, so that measurements could no longer be effected. As regards areas and volumes this is obvious, since congruent areas or volumes could not, generally speaking, exist in two different assigned regions. As regards lengths, it seems equally true that superposition would be impossible. For straight lines corresponding to different values of the measure of curvature differ, as we shall see later, not only in quantity, but also in quality. Hence two such lines cannot be fitted together, and are, strictly, neither equal nor unequal. Hence it would be impossible, in general, to divide a given length into equal portions, or to compare it numerically with other lengths. Thus a metrical co-ordinate system would become impossible. Moreover, Geometry would become akin to Geography; it would not consist of general theorems, but of descriptions of various localities. The variation of the space-constant would be not quantitative merely, but qualitative, and quantities in different places would be of different kinds. Thus the constancy of the measure of curvature is a precondition of any metrical co-ordinate system, and cannot be held doubtful while such a system is retained.[1] Another respect in which Riemann's language, though not fallacious, has proved unfortunate, is the use of the word curvature. This has led philosophers, and even mathematicians (*e.g.*, Newcomb), to suppose non-Euclidean spaces curved, and therefore necessarily contained in Euclidean spaces of more dimensions. So far is this from being the case that there is perfect reciprocity. Parabolic spaces can be contained both in elliptic and in hyperbolic spaces of one more dimension.[2] It has, consequently, become customary to speak of the reciprocal of the square root of Riemann's measure of curvature as the *space-constant*, in order to avoid all appearance of implying a curvature of non-Euclidean spaces.

Helmholtz.

The publication of Riemann's dissertation was closely followed by two works of Helmholtz,[3] again undertaken in ignorance of the work of predecessors. In these a proof is attempted that ds must be a rational integral quadratic function of the increments of the co-ordinates. This proof has since been shown by Lie to stand in need of correction (*v. infra*). Helmholtz's remaining works on the subject[4] are of

almost exclusively philosophical interest. We shall return to them later.

Beltrami. The only other writer of importance in the second period is Beltrami, by whom Riemann's work was brought into connexion with that of Lobatchewsky and Bolyai. As he gave, by an elegant method, a convenient Euclidean interpretation of hyperbolic plane Geometry, his results will be stated at some length.[1] The *Saggio* shows that Lobatchewsky's plane Geometry holds on surfaces of constant negative curvature, straight lines being replaced by geodesics. Such surfaces are capable of a conformal representation on a plane, by which geodesics are represented by straight lines. Hence if we take, as co-ordinates on the surface, the Cartesian co-ordinates of corresponding points on the plane, the geodesics must have linear equations.

Hence it follows that

$$ds^2=\frac{R^2}{w^4}\{(a^2-v^2)du^2+2uvdudv+(a^2-u^2)dv^2\}$$

where $w^2=a^2-u^2-v^2$, and $-1/R^2$ is the measure of curvature of our surface. The angle between two geodesics u=const., v=const. is θ, where

$$\cos\theta=uv/\sqrt{(a^2-u^2)(a^2-v^2)},\ \sin\theta=aw/\sqrt{(a^2-u^2)(a^2-v^2)}.$$

Thus $u=0$ is orthogonal to all geodesics v=const., and *vice versâ.* In order that $\sin\theta$ may be real, w^2 must be positive; thus geodesics have no real intersection when the corresponding straight lines intersect outside the circle

$$u^2+v^2=a^2.$$

When they intersect on this circle, $\theta=0$. Thus Lobatchewsky's parallels are represented by straight lines intersecting on the circle. Again, transforming to polar co-ordinates $u=r\cos\mu$, $v=r\sin\mu$, and calling ρ the geodesic distance of u, v from the origin, we have, for a geodesic through the origin,

$$d\rho=Radr/(a^2-r^2),\ \rho=\frac{R}{2}\log\frac{a+r}{a-r},\ r=a\tanh\frac{\rho}{R}.$$

Thus points on the surface corresponding to points in the plane on the limiting circle $r=a$, are all at an infinite distance from the origin. Again, considering r constant, the arc of a geodesic circle subtending an angle μ at the origin is

$$\sigma=Rr\mu/\sqrt{a^2-r^2}=\mu R\sinh\frac{\rho}{R},$$

whence the circumference of a circle of radius ρ is $2\pi R\sinh\rho/R$. Again, if α be the angle between any two geodesics

$$V-v=m(U-u),\ V-v=n(U-u),$$

then $\tan\alpha=a(n-m)w/\{(1+mn)a^2-(v-mu)(v-nu)\}$.

Thus α is imaginary when u, v is outside the limiting circle, and is zero when, and only when, u, v is on the limiting circle. All these results agree with those of Lobatchewsky and Bolyai. The maximum triangle, whose angles are all zero, is represented in the auxiliary plane by a triangle inscribed in the limiting circle. The angle of parallelism is also easily obtained. The perpendicular to $v=0$ at a distance δ from the origin is $u=a\tanh\frac{\delta}{R}$, and the parallel to this through the origin is $u=v\sinh\frac{\delta}{R}$. Hence $\Pi(\delta)$, the angle which this parallel makes with $v=0$, is given by

$$\tan\Pi(\delta).\sinh\frac{\delta}{R}=1,\ \text{or}\ \tan\tfrac{1}{2}\Pi(\delta)=e^{-\delta/R}$$

which is Lobatchewsky's formula. We also obtain easily for the area of a triangle the formula $R^2(\pi-A-B-C)$.

Beltrami's treatment connects two curves which, in the earlier treatment, had no connexion. These are limit lines and curves of constant distance from a straight line. Both may be regarded as circles, the first having an infinite, the second an imaginary radius. The equation to a circle of radius ρ and centre u_0v_0 is

$$(a^2-uu_0-vv_0)^2=\cosh^2\frac{\rho}{R}w_0^2w^2=C^2w^2 \quad \text{(say).}$$

This equation remains real when ρ is a pure imaginary, and remains finite when $w_0=0$, provided ρ becomes infinite in such a way that $w_0\cosh\frac{\rho}{R}$ remains finite. In the latter case the equation represents a limit line. In the former case, by giving different values to C, we obtain concentric circles with the imaginary centre u_0v_0. One of these, obtained by putting $C=0$, is the straight line $a^2-uu_0-vv_0=0$. Hence the others are each throughout at a constant distance from this line. (It may be shown that all motions in a hyperbolic plane consist, in a general sense, of rotations; but three types must be distinguished according as the centre is real, imaginary, or at infinity. All points describe, accordingly, one of the three types of circles.)

The above Euclidean interpretation fails for three or more dimensions. In the *Teoria fondamentale*, accordingly, where n dimensions are considered, Beltrami treats hyperbolic space in a purely analytical spirit. The paper shows that Lobatchewsky's space of any number of dimensions has, in Riemann's sense, a constant negative measure of curvature. Beltrami starts with the formula (analogous to that of the *Saggio*)

$$ds^2=\frac{R^2}{x^2}(dx^2+dx_1^2+dx_2^2+\ldots+dx_n^2)$$

where $\qquad x^2+x_1^2+x_2^2+\ldots+x_n^2=a^2.$

He shows that geodesics are represented by linear equations between $x_1, x_2, \ldots, x_n$, and that the geodesic distance ρ between two points x and x' is given by

$$\cosh\frac{\rho}{R}=\frac{a^2-x_1x'_1-x_2x_2'-\ldots-x_nx'_n}{\{(a^2-x_1^2-x_2^2-\ldots-x_n^2)(a^2-x_1'^2-x_2'^2-\ldots-x_n'^2)\}^{1/2}}$$

(a formula practically identical with Cayley's, though obtained by a very different method). In order to show that the measure of curvature is constant, we make the substitutions

$$x_1=r\lambda_1,\ x_2=r\lambda_2\ldots x_n=r\lambda_n,\ \text{where}\ \Sigma\lambda^2=1.$$

Hence $\qquad ds^2=(Radr/\overline{a^2-r^2})^2+R^2r^2d\Lambda^2/(a^2-r^2).$

where $\qquad d\Lambda^2=\Sigma d\lambda^2.$

Also calling ρ the geodesic distance from the origin, we have

$$\cosh\frac{\rho}{R}=\frac{a}{\sqrt{a^2-r^2}},\ \sinh\frac{\rho}{R}=\frac{r}{\sqrt{a^2-r^2}}.$$

Hence $\qquad ds^2=d\rho^2+\left(R\sinh\frac{\rho}{R}\right)^2d\Lambda^2.$

Putting $\qquad z_1=\rho\lambda_1,\ z_2=\rho\lambda_2,\ \ldots z_n=\rho\lambda_n,$
we obtain

$$ds^2=\Sigma dz^2+\frac{1}{\rho^2}\left\{\left(\frac{R}{\rho}\sinh\frac{\rho}{R}\right)^2-1\right\}\Sigma(z_idz_k-z_kdz_i)^2.$$

Hence when ρ is small, we have approximately

$$ds^2=\Sigma dz^2+\frac{1}{3R^2}\Sigma(z_idz_k-z_kdz_i)^2 \quad . \quad . \quad (1).$$

Considering a surface element through the origin, we may choose our axes so that, for this element,

$$z_3=z_4=\ldots=z_n=0.$$

Thus $\qquad ds^2=dz_1^2+dz_2^2+\frac{1}{3R^2}(z_1dz_2-z_2dz_1)^2 \quad . \quad . \quad (2).$

Now the area of the triangle whose vertices are (0, 0), (z_1, z_2), (dz_1, dz_2) is $\frac{1}{2}(z_1, dz_2-z_2dz_1)$. Hence the quotient when the terms of the fourth order in (2) are divided by the square of this triangle is $4/3R^2$; hence, returning to general axes, the same is the quotient when the terms of the fourth order in (1) are divided by the square of the triangle whose vertices are $(0, 0, \ldots 0)$, $(z_1, z_2, z_3, \ldots z_n)$, $(dz_1, dz_2, dz_3\ldots dz_n)$. But $-\frac{3}{4}$ of this quotient is defined by Riemann as the measure of curvature.[2] Hence the measure of curvature is $-1/R^2$, *i.e.*, is constant and negative. The properties of parallels, triangles, &c., are as in the *Saggio*. It is also shown that the analogues of limit surfaces have zero curvature; and that spheres of radius ρ have constant positive curvature $1/R^2\sinh^2\frac{\rho}{R}$, so that spherical geometry may be regarded as contained in the pseudospherical (as Beltrami calls Lobatchewsky's system).

Transition to the Projective Method. The *Saggio*, as we saw, gives a Euclidean interpretation confined to two dimensions. But a consideration of the auxiliary plane suggests a different interpretation, which may be extended to any number of dimensions. If, instead of referring to the pseudosphere, we merely *define* distance and angle, in the Euclidean plane, as those functions of the

[1] His papers are "Saggio di Interpretazione della Geometria non-Euclidea," *Giornale di Matematiche*, vol. vi. 1868; "Teoria fondamentale degli spazii di curvatura costante," *Annali di Matematica*, vol. ii., 1868–69. Both were translated into French by J. Hoüel, *Annales Scientifiques de l'École Normale supérieure*, vol. vi., 1869.

[2] Beltrami shows also that this definition agrees with that of Gauss.

co-ordinates which gave us distance and angle on the pseudosphere, we find that the Geometry of our plane has become Lobatchewsky's. All the points of the limiting circle are now at infinity, and points beyond it are imaginary. If we give our circle an imaginary radius the Geometry on the plane becomes elliptic. Replacing the circle by a sphere, we obtain an analogous representation for three dimensions. Instead of a circle or sphere we may take any conic or quadric. With this definition, if the fundamental quadric be $\Sigma_{xx}=0$, and if $\Sigma_{xx'}$ be the polar form of Σ_{xx}, the distance ρ between x and x' is given by the projective formula

$$\cos\frac{\rho}{k}=\frac{\Sigma xx'}{\sqrt{\Sigma_{xx}\,.\,\Sigma_{x'x'}}}.$$

That this formula is projective is rendered evident by observing that $e^{-2i\rho/k}$ is the anharmonic ratio of the range consisting of the two points and the intersections of the line joining them with the fundamental quadric. With this we are brought to the third or projective period. The method of this period is due to Cayley; its application to previous non-Euclidean Geometry is due to Klein.

The projective method contains a generalization of discoveries already made by Laguerre in 1853 as regards Euclidean Geometry. Metrical properties, in Euclidean space, are projective properties relative, in two dimensions, to the circular points and the line at infinity considered as a degenerate conic, or, in three dimensions, to the circle and the plane at infinity considered as a degenerate quadric. Substituting a proper conic, or quadric, real or imaginary, we obtain the recognized non-Euclidean results. (In three dimensions some restriction as to the kind of quadric is necessary, if the measurement of angles is to be unchanged, and if a finite rotation is to cause a return to the initial position. Tangent lines from any point to the Absolute or fundamental quadric make an infinite angle with all other lines through the point; it is therefore necessary that they should be imaginary. Hence the absolute, when expressed as the sum or difference of squares, must have all its signs positive, or three positive and one negative. This excludes the hyperboloid of one sheet.)

The two kinds of elliptic space.

This method leads to a discrimination, first made by Klein,[1] of two varieties of Riemann's space; Klein calls these elliptic and spherical. They are also called the polar and antipodal forms of elliptic space. The latter names will here be used. The difference is strictly analogous to that between the diameters and the points of a sphere. In the polar form two straight lines in a plane always intersect in one and only one point; in the antipodal form they intersect always in two points, which are antipodes. Similarly two diameters always determine a plane, but two points on a sphere do not determine a great circle when they are antipodes, and two great circles always intersect in two points. Again, a plane does not form a boundary among lines through a point: we can pass from any one such line to any other without passing through the plane. But a great circle does divide the surface of a sphere. So, in the polar form, a complete straight line does not divide a plane, and a plane does not divide space, and does not, like a Euclidean plane, have two sides.[2] But, in the antipodal form, a plane is, in these respects, like a Euclidean plane. The polar form alone, among the various spaces, gives absolute duality between points and planes, or, in two dimensions, between points and lines. The reason of this is simple. The measurement of angles is always elliptic; among the lines or planes through a point, those that make an infinite angle with the rest are imaginary, and for real values angles are periodic. Thus it is only where the measurement of length is also elliptic that complete duality prevails.

Projective co-ordinates.

A question, similar to that which arises in connexion with Riemann, may be asked concerning the nature of the co-ordinates employed in the projective treatment of metrical properties. The co-ordinates of elementary Geometry are always metrically defined. But if metrical properties are to be defined in terms of our co-ordinates, these must be defined in a new way. Anharmonic ratio itself, as commonly defined, involves lengths, and therefore requires a new definition when lengths are to be defined by its means. Klein has shown[3] how to fulfil these requirements by an appeal to von Staudt's quadrilateral construction. This construction gives a purely projective definition of a harmonic range, and enables us, starting from three given points on a line, to obtain as many other points on the line as we please by successive repetitions of the construction. In this way an order is assigned among the points of a line (or the planes through a line). Our co-ordinates then express the position of our point (or plane) in the series so obtained, and are thus wholly free from metrical presuppositions. In like manner, by two sets of quadrilateral constructions, we can assign the co-ordinates of a point in a plane or a plane through a point; and by three sets we can assign the co-ordinates of any point or plane in space. Any point whose co-ordinates are given may thus be found, provided these co-ordinates are rational. If they are irrational, the point can of course be assigned as a limit.

Sophus Lie.

By means of the projective method and the theory of continuous groups, Sophus Lie[4] has been enabled to give a complete answer to the question which Helmholtz attempted to solve, namely: What axioms are involved in the possibility of rigid bodies with six degrees of freedom? Assuming that any two points have a distance, which is some function of their co-ordinates, the group of motions must be such as to leave this function invariant. Hence it can be proved that ds^2 must be an integral quadratic function of the co-ordinates, and that motions are collineations which transform a certain quadric (the Absolute) into itself. In non-Euclidean Geometry this condition is also sufficient; in Euclidean Geometry it is necessary further to exclude similarity-transformations.

The axioms from which Lie starts are the following: Let

$$x_1=f(xyza_1a_2\ldots)$$
$$y_1=\phi(xyza_1a_2\ldots)$$
$$z_1=\psi(xyza_1a_2\ldots)$$

be an infinite collection of *real* transformations of the space x, y, z, concerning which we make the following assumptions:—

A. The functions f, ϕ, ψ are to be *analytic* functions of the co-ordinates x, y, z, and the parameters a_1, a_2, a_3.

B. In regard to all transformations of the collection, any two points $x_1\,y_1\,z_1$, $x_2\,y_2\,z_2$ are to have an invariant

$$\Omega(x_1y_1z_1\ x_2y_2z_2).$$

C. There is to be free mobility in the sense of Riemann and Helmholtz; *i.e.* (1) the point xyz can be transformed into any other; (2) if a point $x_1y_1z_1$ is kept fixed, every other point $x_2y_2z_2$ (*of general position*) can take up ∞^2 positions, given by the equation

$$\Omega(x_1y_1z_1x'_2y'_2z'_2)=\Omega(x_1y_1z_1x_2y_2z_2)\,;$$

(3) if two points are fixed a third can take up ∞^1 positions,

[1] *Math. Annalen*, iv. vi. 1871–72.

[2] For an investigation of these and similar properties, see Whitehead, *Universal Algebra*, Cambridge, 1898, Bk. vi. chap. ii. The polar form was independently discovered by Newcomb in 1877.

[3] *Math. Annalen*, iv. vi. vii. xxxvii.; *Vorlesungen über nicht-Euklidische Geometrie*, Göttingen, 1893, vol. i. pp. 308 *ff.*

[4] "Ueber die Grundlagen der Geometrie," *Leipziger Berichte*, 1890.

determined by two such equations as the above; (4) if three (non-collinear) points are fixed every point is fixed.

From these assumptions it follows at once that the transformations considered form a six-membered group. By a completely exhaustive method it is shown that, if the assumptions are to hold *without exception* throughout a certain region, then the group considered can only be the group of Euclidean or non-Euclidean motions, and the invariant Ω is the Euclidean or non-Euclidean distance. Helmholtz, in investigating the same problem, required a fourth axiom, which he called *Monodromy;* this demands that the curves described in a rotation (*i.e.*, a motion which leaves two points fixed) should be closed. [See *Wiss. Abh.* vol. ii. p. 624.] This axiom Lie finds unnecessary if, in three dimensions, free mobility is to hold unreservedly throughout a certain region. But if we admit groups in which, when one point is fixed, a certain straight line also remains fixed, then Helmholtz's axiom becomes necessary, but not sufficient.[1] In two dimensions the axiom is necessary even if free mobility holds without exception throughout a certain region, but not if it holds throughout the whole two-dimensional space.

Spaces not allowing free mobility in Lie's sense.

Thus if free mobility, in the above sense, be taken to hold universally, the above three axioms suffice to characterize space as of one of four kinds—Euclidean, hyperbolic, and the two elliptic varieties. It has been pointed out by Klein, however, that there are other possible spaces, allowing free mobility in a wider sense, *i.e.*, permitting transformations which leave metrical properties unchanged, and transform a chosen point into any other chosen point, but not containing as many such transformations. Such spaces still have constant measure of curvature, and their infinitesimal geometry belongs to one of the usual types. Their differences from these types may be best illustrated by an example, which is important on its own account.

Clifford's surface of zero curvature and finite extent.

In elliptic space, the locus of points at a constant perpendicular distance from a given straight line is a ruled quadric, any two of whose generators of the same set have an infinite number of common perpendiculars, all of equal length, as have also any generator and the axis of the surface. This surface is of zero curvature, but of finite extent, and it is transformed into itself by only ∞^2 motions.[2] Its properties may be developed by elementary considerations, as follows. Let the Absolute be

$$x^2+y^2+z^2+w^2=0,$$

and let the axis of the surface be $z=0$, $w=0$. The plane through (x, y, z, w) perpendicular to the axis is $x'/x=y'/y$, which meets the axis in $(x, y, 0, 0)$. The distance of $(x, y, 0, 0)$ from (x, y, z, w) is ρ,

where
$$\cos^2\frac{\rho}{k}=(x^2+y^2)^2/(x^2+y^2)(x^2+y^2+z^2+w^2)$$
$$=(x^2+y^2)/(x^2+y^2+z^2+w^2).$$

The surface is defined by $\rho=$constant. Hence its equation is

$$x^2+y^2=\cot^2\frac{\rho}{k}\cdot(z^2+w^2).$$

Putting $\cot\frac{\rho}{k}=p$, the generators of this surface are

$$\left.\begin{array}{l}x-pz=\lambda(pw-y)\\ \lambda(x+pz)=pw+y\end{array}\right\}\text{ and }\left\{\begin{array}{l}x-pz=\mu(pw+y)\\ \mu(x+pz)=pw-y\end{array}\right.$$

It is easily shown that the perpendicular to $z=0$, $w=0$ from any point of a generator is also perpendicular to the generator. Again if we put

$$\lambda=\tan\theta,\ \mu=\tan\phi,$$

we find $x:y:z:w=p\cos(\theta-\phi):p\sin(\theta-\phi):\cos(\theta+\phi):\sin(\theta+\phi)$; whence, on the surface (for which p is constant),

$$\frac{ds^2}{k^2}=\frac{(x^2+y^2+z^2+w^2)(dx^2+dy^2+dz^2+dw^2)-(xdx+ydy+zdz+wdw)^2}{(x^2+y^2+z^2+w^2)^2}$$
$$=d\theta^2+d\phi^2-2\frac{p^2-1}{p^2+1}d\theta d\phi$$
$$=d\theta^2+d\phi^2-2\cos\frac{2\rho}{k}d\theta d\phi.$$

This formula shows that the surface has zero measure of curvature, that its geodesics are given by linear equations in θ and ϕ, and that any two generators $\theta=$constant, $\phi=$constant, make an angle $2\rho/k$ with each other. Hence the whole surface may be divided into similar parallelograms, and since the length of a generator is πk, the area of the surface is $\pi^2k^2\sin\frac{2\rho}{k}$. Again, motions are collineations which transform $x^2+y^2+z^2+w^2$ into itself. Those motions which transform the above surface into itself also leave $(x^2+y^2)/(z^2+w^2)$ unchanged. Hence they leave x^2+y^2 and z^2+w^2 each unchanged. Hence they are given by

$$\begin{array}{ll}qx'=\ \ x\cos\alpha+y\sin\alpha & qz'=\ \ z\cos\beta+w\sin\beta\\ qy'=-x\sin\alpha+y\cos\alpha & qw'=-z\sin\beta+w\cos\beta\end{array}$$

where q is an arbitrary factor. Hence

$$x':y':z':w'=p\cos(\theta-\phi-\alpha):p\sin(\theta-\phi-\alpha):\cos(\theta+\phi-\beta):\sin(\theta+\phi-\beta).$$

Thus generators are transformed into others of the same set; the transformation is given by

$$\theta'=\theta-\tfrac{1}{2}(\alpha+\beta),\ \phi'=\phi+\tfrac{1}{2}(\alpha-\beta).$$

If $\alpha\pm\beta=0$, one set of generators is unchanged, and every point of the surface moves along these generators. The same transformation gives the same result for surfaces corresponding to other values of p. Thus there are motions of elliptic space in which all points move along parallel lines; in this respect, also, Clifford's parallels resemble Euclid's. The combination of two such motions, one altering θ only, the other ϕ only, gives the general motion leaving $p=$const. unchanged; and thus only ∞^2 motions transform this surface into itself. Since, however, the surface is homogeneous, there is a possible two-dimensional space with the same properties. Thus within each type of space we have varieties, differing as regards connectivity and *analysis situs.* In the case of positive measure of curvature, there are only the two usual varieties; but in the negative case there is, as Klein has shown, an infinite number.

Three prevalent misconceptions.

The philosophical questions raised by non-Euclidean Geometry have been rendered unduly difficult by some very prevalent misconceptions. Three of these are especially important. The first concerns the phrase "measure of curvature," the second concerns the projective definition of distance and angle, and the third concerns the relation of the axiom of congruence to rigid bodies.

There are, as we have seen, two principal types of Euclidean analogues to non-Euclidean spaces. There is the type preferred by Beltrami, and, unfortunately, popularized by Helmholtz (*Mind*, O.S., vol. i.), which compares the non-Euclidean plane to a Euclidean surface of constant curvature. There is, secondly, the type introduced by Cayley and Klein, in which, within Euclidean space, we introduce a new definition of distance. Both are extremely useful as analogies, but both have a tendency to pass for something more.

Measure of curvature.

The confusion resulting from the first of these analogies has led to the view that the surface of a sphere actually *is* a plane in the antipodal form of elliptic space.[3] Similarly it has been supposed (*e.g.*, by Newcomb) that non-Euclidean spaces of three dimensions should be regarded as figures in a four-dimensional Euclidean space, being related to it as the sphere to ordinary space. This has made it appear to philosophers that they had to do only with an increase in the number of dimensions. The rest of the apparatus seemed a mere wilful change of nomenclature—a circle was to be called a straight line, a sphere was to be called a plane, and so on. The same error underlies all these views. The conception of a space is essentially the conception of a totality; a figure having points external to it must in no circumstances be regarded as itself a space.

---

[1] *i.e.*, in addition to Euclidean and non-Euclidean motions, there are other groups, of which some satisfy the axiom of Monodromy. See Lie, *Theorie der Transformationsgruppen*, Leipzig, 1893, vol. iii. p. 470.

[2] This surface was discovered by Clifford; its generators of one set are (in his sense) parallel to each other and to the axis. See Klein, "Zur nicht-Euklidischen Geometrie," *Math. Annalen*, vol. xxxvii.

[3] See, *e.g.*, Lechalas, "Identité des plans de Riemann et des sphères d'Euclide," *Annales de la société scientifique de Bruxelles*, t. xx. (1896).

Now the important and interesting fact (which Riemann pointed out) is that we can conceive a point-manifold in which the measure of curvature is not zero, and in which, nevertheless, there is no hint of a reference to elements not contained in this manifold. In the usual theory of Euclidean surfaces there is a perpetual reference to points not on those surfaces—we have normals, tangent planes, &c. But Riemann pointed out how, by Gauss's method, such external reference could be avoided, provided we were willing to regard as identical all surfaces having the same formula for ds^2. For, from this formula, the measure of curvature can be found, and thence the geodesic Geometry of our surface follows. (In the formula for ds^2, two co-ordinates should be chosen which have a geometrical meaning on the surface—*e.g.*, geodesic polars.) Nevertheless (though Riemann appears to have overlooked this), the self-dependence of our Euclidean surface is only real when it is possible to effect measurements without leaving the surface, and this requires that the measure of curvature should be constant. When this condition is fulfilled the Geometry of our surface involves no reference to external space. But our surface still has external space outside it, and is thus not a space. What we have shown is, therefore, that a manifold *might* exist having the same internal relations as our surface, but destitute of the external relations which our surface also possesses. Such a manifold would be a Euclidean or non-Euclidean space of two dimensions. Such a space is radically different from a plane in three-dimensional space. Thus, *e.g.*, a plane has two sides and has position, while a two-dimensional space has neither. Hence we have three things to distinguish: (1) a sphere or pseudosphere in Euclidean space, (2) an elliptic or hyperbolic space of two dimensions, (3) a plane in an elliptic or hyperbolic space of three or more dimensions. Similarity in symbolic treatment does not show identity in the subject-matter treated. But the fact that we *can*, in treating of surfaces of constant curvature, abstract from relations to external space, shows that there is a logical possibility of a space containing similar internal relations without any external spatial relations. And in like manner, the possibility follows of three-dimensional spaces whose planes formally resemble Euclidean surfaces of constant curvature. On this point clearness is very important; for otherwise there is a danger of losing the essential and interesting point in non-Euclidean Geometry. A mere increase in the number of dimensions affords nothing radically novel; what *is* novel, is the discovery that space of a given number of dimensions may be of various kinds. Indeed, it is the very absence of reference to a higher Euclidean space which is chiefly interesting about the non-Euclidean spaces. From this point of view a direct investigation, starting from axioms like those of Lobatchewsky, Bolyai, and Newcomb, is preferable to more powerful but more symbolic methods.

The same reckless reference to spaces of higher dimensions, in which a given space may be supposed to be contained, has concealed the logical absurdity of regarding the measure of curvature as possibly variable. A figure contained in a space may have variable measure of curvature, since spatial quantities may still be equal in different places. But where a *space* is supposed to have variable measure of curvature, no such possibility exists. For it follows, in this case, as we saw in connexion with Riemann, that equal quantities in different places are impossible. Lengths in general differ qualitatively, and are therefore not measurable in terms of each other. Consequently no two quantities in different places can have a numerical ratio, since ratio implies division into equal parts. Hence metrical Geometry would collapse, and instead of a variable measure of curvature, we should have *no* measure of curvature. The essential thing about lengths is, that they are divisible quantities of the same kind, and therefore any two are equal or unequal, and have a numerical ratio. But when there is not a constant measure of curvature this essential property is lost; we can no longer say, of two lengths, that they must be equal or unequal. Hence homogeneity, or constant measure of curvature, is essential to metrical Geometry.

Motion irrelevant to Geometry.

Again, it is important to notice that we cannot appeal to *motion* in anything concerning the foundations of metrical Geometry. Motion, as used in Geometry, is not the motion of a single point, but the motion of many points, or even of all points. Now, if we ask how a motion is distinguished from other transformations, the only reply is, that it leaves metrical properties unchanged (with the restriction, strictly speaking, that it can be generated by infinitesimal steps). Thus metrical properties are presupposed in the definition of motion, and must not be defined by its means. Thus when Riemann, for example, assumes that ds is unaltered by the same infinitesimal motion of all the points of the infinitesimal arc, his argument is circular; for the *same* infinitesimal motion of a number of points can only be defined in terms of ds. The existence of equal spatial quantities in different places is presupposed in the definition of motion, and motion is not presupposed in metrical Geometry.

Relation between different space-constants.

A somewhat perplexing question arises, in connexion with the necessary all-inclusiveness of a space, as regards different values of the space-constant. Are there different possible hyperbolic spaces or elliptic spaces, having different space-constants, or is there only one space of each kind? Considering two spaces each as a whole, there seems no possibility of quantitative comparison between them, and it seems absurd to speak of one as having a greater or smaller space-constant than the other. All lengths in either can only be estimated relatively to the space-constant, which itself, except in relation to those lengths, has no particular magnitude. Nevertheless, we speak of our actual space as approximately Euclidean, and in relation to empirically given lengths we may certainly speak of greater or smaller space-constants. The following account seems to satisfy both these apparently opposite requirements. The space-constant of a space is one among lengths in that space, and has magnitude accordingly. The question, What is the ratio of the space-constant to some given length? has therefore a definite answer. But lengths in different spaces (even where both spaces are elliptic or both hyperbolic) differ in quality—they differ in the same way as do two shades of red. As is the case with shades of red, the different possible qualities form a continuous series; and the space-constants, along with all other lengths in their respective spaces, share these qualities, and thus acquire a place in a continuous series. Although each space-constant is a magnitude, each differs in quality from every other space-constant. No length in one space is greater or smaller than a given length in another space, and this extends also to their space-constants.[1] But when we ask, in our actual space, what is the ratio of the space-constant to (say) the diameter of the earth's orbit, the different possible answers correspond to different qualities which all our actual lengths may have—all of them have the same quality, but since the possible qualities form a continuous series (like shades of

[1] It is this necessity for a qualitative difference between lengths corresponding to different space-constants which, as we saw, makes impossible the metrical treatment of spaces without a definite space-constant.

colour), we do not know exactly which of the possibilities is actual. Thus, though one space-constant is not greater or smaller than another, we may legitimately inquire what is the ratio of our actual space-constant to empirically given lengths.

The second confusion resulting from the undue use of Euclidean analogies has been suggested by the projective treatment. Since all non-Euclidean results can be obtained, in Euclidean space, by a new measure of distance and angle, it seems superfluous to invent new spaces for the interpretation of the results in question. Thus Cayley always maintained the exclusive validity of Euclidean *space*, holding that, in non-Euclidean *Geometry*, he had merely substituted new measures in the old space. Against this view much may be said in detail, but the most cogent argument may be briefly stated. If there are such quantities as distance and angle, their measure can only be arbitrary so far as concerns the choice of a unit, and any different measure must be simply false; while if there are no such quantities, then they can have no measure at all. Thus it is in no case open to us to choose arbitrarily, among several functions differing by more than a constant factor, which of them shall express distance or angle: either one such choice or none must be correct. Passing to the actual case, we find that, when our co-ordinates express anharmonic ratios obtained by Staudt's construction, the distance of two arbitrary points on a line is obtained by keeping two of the points required for anharmonic ratio fixed. Thus only two variable points remain, and the logarithm of the anharmonic ratio thus obtained has always, however our fixed points are chosen, a certain resemblance to distance, consisting chiefly in the fact that it is additive. It may then be doubtful what pair of points on our line are to be fixed, but only one such pair can actually give the distance, unless indeed there be no such thing as distance. This may be easily seen by considering that our two fixed points, in virtue of the formula, are at an infinite distance from all other points on the line. If there be such a thing as distance, it is therefore necessary that our fixed points should be at infinity in some not purely conventional sense. The different types of straight line are really, and not merely artificially, distinguished by the property of having their points at infinity real and distinct, imaginary, or coincident. It is true we may take the other alternative, and deny the existence of distance altogether: there is nothing in pure projective Geometry to imply its existence. But then we cannot know that *all* the points of our line form a series. Only those obtained by successive quadrilateral constructions will form a series, unless we introduce order by Pieri's method (*I principii della Geometria di Posizione*, Turin, 1898—a work which marks a great advance in logical purity). And thus our arbitrary definition does not necessarily give a distance to every pair of points. It should be observed that we cannot, without assuming the metrical order obtained from distance, legitimately ask whether the points obtained by repeated quadrilateral constructions are evenly distributed (*überall dicht*), or whether they leave gaps. For such a question implies that our points have an order independent of that obtained by the quadrilateral construction, and this in turn implies distance. We can only ask whether the points we obtain are *all* the points of the line, but to this question projective Geometry gives no answer. Metrical Geometry, however, gives a negative answer, for the points projectively obtained form a denumerable series, while *all* the points form, in Cantor's phrase, a series of the power of the continuum (see NUMBER). Thus only a vanishing proportion of the points of a line form, with three given points, a range having, in the pure projective sense, an anharmonic ratio. Finally, there is a last curious restriction to the projective method. The uniqueness of the quadrilateral construction cannot be *projectively* proved without three dimensions, and hence there is no pure projective Geometry of spaces having only one or two dimensions.

Projective theory of distance.

A third confusion remains as regards the relation of the axiom of congruence to rigid bodies. The axiom of congruence is the axiom in virtue of which superposition may be used (as in Euclid's fourth proposition) to prove the equality of two figures. But there is some difficulty in stating precisely the requisite axiom. Helmholtz maintained (*e.g.*, *Wiss. Abh.* Bd. ii. pp. 614, 616) that it asserts the actual existence of rigid bodies, and thence inferred that Geometry is dependent upon Mechanics. He supported his view by reference to the process of measurement, in which the measure must be, at least approximately, a rigid body. In so far as it is not rigid our results are inaccurate—unless, indeed, we know how to allow for its changes of shape, which would imply some still more rigid body by which our measure is itself measured. Thus, in so far as measurement is trustworthy, it implies the existence of bodies which, during the motion required for superposition, do not greatly change in shape. But this is not an analysis of what is *meant* by spatial equality, and is not relevant to Geometry. The definition of a rigid body, like the definition of. geometrical motion, presupposes what is really meant by the axiom of congruence. A rigid body is one which, at different times, occupies equal spaces. Thus equality of spaces is logically prior to rigidity of bodies. How we discover two actual spaces to be equal is no concern of the geometer; all that concerns him is the existence of equal spaces, the fact that two spatial quantities may be equal or unequal. And this is indeed the true meaning of the axiom. Given two points at a certain distance apart, and any third point, the axiom asserts that there are, on any straight line through the third point, two points whose distance from the third point is equal to the given distance; it makes also similar assertions as regards areas and volumes. This is all that metrical Geometry requires as regards an axiom of spatial equality. The apparent use of motion is deceptive; what, in Geometry, is called a motion, is merely the transference of our attention from one figure or set of elements to another. Actual superposition, which is nominally employed by Euclid, is not required; all that is required is the transference of attention from the original figure to a new one, defined by the position of some of its elements and by certain properties which it shares with the original figure. This may be enforced by two simple considerations: (1) What is purely spatial cannot move: a given point, line, or plane is what it is in virtue of its place, and can never change that place. It is only what *occupies* space, *i.e.*, matter, that can move. (2) If rigid bodies formed any part of the *meaning* of congruence, it would be self-contradictory to assert, as science does assert, that no body is perfectly rigid. For before we can discuss whether or not a body is rigid, we must be able to decide as to its dimensions at different times; and if this *means* a comparison with a standard body, then it is a logical impossibility that the standard body should itself be supposed changeable. The standard body would be itself the unit, and could no more suffer change than any other absolute unit. The whole confusion appears to be due to not distinguishing between the process of measurement, which is of purely practical interest, and the meaning of equality, which is essential to all metrical Geometry.

Rigid bodies unnecessary in Geometry.

Four stages in specifying a space.

We may now proceed to specify the various stages in the particularization of spaces, pointing out what axioms lead to given portions of Geometry. We may distinguish four stages, each with its appropriate axioms. In the first stage we assume only the purely projective properties; in the second, we further assume distance; in the third, we assume that, in a space of n dimensions, there are $\infty^{\frac{1}{2}n\cdot\overline{n+1}}$ motions (*i.e.*, transformations leaving all distances unchanged); in the fourth, finally, we distinguish between the four usual types of space, and become confined to one among them. Thus all the axioms of the first three stages are common to Euclidean, hyperbolic, and elliptic spaces.

Projective axioms.

I. The pure projective theory knows nothing of distance, nor, consequently, of any order among points, lines, or planes, except that introduced by the quadrilateral construction. By means of this construction it defines a harmonic range, pencil, or sheaf; by the series of quadrilateral constructions (where any such series exists) required to reach a given point from three original points in the same straight line, it defines the anharmonic ratio of a range (with similar definitions for a pencil or sheaf). We can show that, where four elements have an anharmonic ratio at all, this is unaltered by projection; and we can establish the usual propositions concerning homography. For that (unknown) proportion of elements projectively obtainable from the requisite number of original elements, we can, in short, in a space of three or more dimensions, establish all the usual propositions of projective Geometry. In three dimensions the axioms required for this most general Geometry will be found to be the following:—

(1) Any two points (planes) in general determine a straight line, and any three which are not collinear in general determine a plane (point). The same line is determined by an infinite number of other pairs of points (planes), and the same plane (point) by an infinite number of other triplets of points (planes). A plane or line is said to contain any point which is one of those determining it, and a point or line is said to lie on any plane which is among those determining it.

(2) When two planes (points) both contain (lie on) two points (planes), they contain (lie on) the line determined by the two points (planes).

(3) A plane may also be determined by a determining point and the line joining two others of its determining points; and conversely, a point is determined by a plane and a line.

In these axioms the dualistic assertions regarding planes and points are not alternatives, but are both necessary. The corresponding axioms for any number of dimensions are of the same form, and are necessary to any Geometry of that number of dimensions; but in the case of two dimensions, they are not, by themselves, sufficient to found a Geometry. In order to apply the axioms to hyperbolic space it is necessary to take account of ideal elements.[1]

Axioms of distance.

II. With the assumption of distance a new set of axioms is introduced, and metrical Geometry becomes possible. Projective Geometry assumes one relation, the straight line, between any pair of points; we now introduce another relation, namely distance, which, unlike the straight line, is a quantity. All distances are regarded as quantities of the same kind, and thus the metrical homogeneity of space is involved. We are restricted, therefore, to spaces having a space-constant. In all of these, the angle-sum of a triangle differs from two right angles by some constant multiple of the area of the triangle. When this multiple is zero, the geometry of figures not exceeding some finite size is always Euclidean. But the space is not yet wholly specified; it may differ as to connectivity, as to finitude or infinity, and as to the number of degrees of freedom in motions. The axioms by which the nature of distance is specified are the following:—

(1) Any two points have a quantitative relation called distance, which, if both points are real, only vanishes when they coincide. Any two distances are quantities of the same kind. (Thus, if both are real, either they are equal, or one is greater than the other.)

(2) If p, q, r be three points in one straight line, the sum of the distances pq, qr is equal to the distance pr (distances in different directions being defined to have different signs, so that $pq+qp=0$).

(3) If a, b, c be any three points, and the distances ab, bc are finite, then the distance ac is finite. If ab is finite, and bc infinite, or *vice versâ*, then ac is infinite. Also if ab, bc are real, then ac is real.[2]

Free mobility.

III. The next step is to introduce free mobility in the sense defined by Lie's axiom C (*v. supra*). Free mobility in the general sense was already introduced by homogeneity, that is, any figure could be freely moved in $\infty^{\frac{1}{2}n\cdot\overline{n+1}}$ ways (supposing our space to have n dimensions). But Klein has pointed out that it does not follow from this that a space as a whole can be transformed into itself in the same number of ways. The addition of this further axiom to those given above shows that our space is of one of the four usual types.[3] All the spaces excluded by this axiom differ from those that remain in some discontinuous respect—*i.e.*, as regards their connectivity and *analysis situs*. The four types which remain, on the other hand, contain Euclidean space as a limiting case between hyperbolic space and either form of elliptic space, and are thus in a different position from the excluded types.

Differences among the four principal spaces.

IV. It remains to specify the differences between the four remaining types. These differences are chiefly metrical, but each space may also be distinguished by projective properties, provided we exclude ideal elements. Thus (1) in the antipodal form of elliptic space two straight lines in a plane intersect always in two points; in the other spaces they intersect at most in one point. (2) In the polar form of elliptic space two straight lines in a plane always intersect; in Euclidean and hyperbolic space they may or may not intersect. (3) In hyperbolic space intersection and non-intersection are equally general cases; in Euclidean space non-intersection is a limiting case. But these projective distinctions are overcome by introducing ideal elements wherever required, and by identifying antipodal points in antipodal elliptic space, and by this means projective propositions become identical for all four spaces. The metrical differences are more serious. In the first place, all non-Euclidean spaces have an absolute unit of length, the space-constant, just as all spaces, including Euclid's, have an absolute unit of angle. Hence lengths, in non-Euclidean geometries as in spherical trigonometry, appear only in their ratios to an absolute unit. The geometrical meaning of the space-constant, in the two forms of elliptic space, is simple: the length of a complete straight line is, in the polar form, πk, in the antipodal form, $2\pi k$ (where k is the space-constant). (In hyperbolic space, where the straight line is infinite, the geometrical meaning is less simple.) All questions concerning

[1] For the way in which this is done, see Pasch, *Neuere Geometrie*, Leipzig, 1882, esp. §§ 6–9.

[2] See Whitehead, *Universal Algebra*, Bk. vi. chap. i.

[3] See Klein, *Math. Annalen*, vol. xxxvii. pp. 554–565.

parallelism are of course metrical, as is the question concerning the sum of the angles of a triangle. Thus, speaking broadly, projective theorems are the same in all the spaces, while metrical theorems are different. But the measurement of angles and the Geometry in a point (*i.e.*, of lines through a given point) are the same in all spaces, being in fact elliptic. This is due to the fact that angular measurement is determined by those properties of linear measurement which are the same in all spaces. The circle is always a closed curve, since all lines through its centre always meet it in two points. Hence the lines in a plane through a point form a closed series, and the measurement of angles is elliptic.[1]

Two general questions.

The various possibilities which we have reviewed raise two distinct questions. The first of these is philosophical: Have we, as Kant maintained, any *à priori* ground for excluding all or some of the non-Euclidean spaces? The second, which presupposes a decision that some, at least, of the non-Euclidean spaces are *à priori* possible, is scientific: What empirical means have we for deciding which of the possible spaces is actual? What are the best observations, or are there any observations, upon which we may base an opinion? These questions are radically distinct, and it is important to discuss them separately.

Supposed à priori grounds for Euclidean space.

Kant had contended that space, on grounds independent of Geometry, is an *à priori* form of intuition, and that Geometry, consequently, has apodeictic certainty; while conversely he inferred, from the then admitted apodeictic character of Geometry, that space must be an *à priori* form of intuition. These two lines of argument, which supported one another, were called respectively the metaphysical and the transcendental deductions of space (*Critique of Pure Reason*, 2nd ed.) Against this theory non-Euclidean Geometry has, from the first, been regarded as a very powerful argument, and its promoters—Gauss, Lobatchewsky, Bolyai, Riemann, Helmholtz—have all pointed out the supposed refutation of Kant. Riemann and Helmholtz, who deal explicitly with the philosophical question, consider all geometrical axioms to be empirical,[2] though Riemann, at least, appears to regard arithmetic and algebra as *à priori*. It would seem, however, that non-Euclidean Geometry, though it gives Kant's doctrine something of the air of a paradox, cannot, strictly speaking, be considered as logically affecting that doctrine. A purely philosophical theory, such as that of Kant, can only be met by purely philosophical arguments; mathematics, though capable of *suggesting* new views, can hardly be capable of *proving* them. If the reasons which Kant adduces, in the metaphysical deduction, for holding space to be an *à priori* form of intuition be found valid, they are alone sufficient to prove his conclusion, and these reasons are wholly unaffected by non-Euclidean Geometry. Even the transcendental deduction, though robbed of most of its plausibility, can hardly be disposed of by mathematics alone—for mathematics alone, however many new Geometries it may invent, can never prove that the truth of Euclid is uncertain. Indeed, Kant's doctrine, as compared with those of the earlier idealists, is peculiarly adapted to meet the opponents of Euclid—so much so, indeed, as to suggest a possible influence of Lambert (*v. supra*), with whom Kant carried on a correspondence. In Kant's first published work (ed. Hartenstein, 1867, vol. i. pp. 21 *ff.*), he maintained the possibility of space with more than three dimensions, this being the only departure from Euclid with which he was then acquainted.

[1] See an article by B. Russell in the *Revue de métaphysique et de morale*, November 1899.

[2] See also Erdmann, *Axiome der Geometrie*, Leipzig, 1877.

In the *Critique of Pure Reason*, on the contrary, it is precisely the axiom of three dimensions which he instances as an example of apodeictic geometrical propositions (*ib.* vol. iii. p. 61). It was not the logical possibility of other spaces than Euclid's which could shake his doctrine; indeed, this was expressly admitted by the theory that all geometrical propositions are synthetic, *i.e.*, can be denied without contradiction. The essence of his answer to scepticism lay in the contention that we may be certain *à priori* of some propositions whose contradictory is not logically absurd. Thus Kant must be met, not by a simple appeal to non-Euclidean Geometry, but by the establishment of some philosophical proposition, *e.g.*, by one of the following three: (1) We have an intuition of non-Euclidean spaces; (2) in the sense in which Kant uses the word, we have no intuition of Euclidean space; (3) our intuitions are irrelevant in a logical inquiry concerning space. No one of these three propositions follows from non-Euclidean Geometry alone. Helmholtz maintained the first, but seems to have misunderstood Kant's meaning.[3] Both the second and third seem to be capable of proof; but their discussion, which belongs properly to the criticism of Kant, would carry us too far from our subject to be attempted here.

It remains to inquire whether spaces not belonging to the four main types are logically possible, and if so, why they have received so little attention from mathematicians. The reply seems to be, as regards those which have no space-constant, that, though they are logically possible, they differ from Euclidean space so materially as to be destitute of the interest belonging to spaces more akin to that in which we live. The spaces which have a space-constant, but do not fulfil Lie's axiom of free mobility, appear, however, to deserve just as much consideration as the four usual types, and to have failed to receive it only because of their recent discovery.[4] These types allow, so far as figures not exceeding a certain size are concerned, the usual kind of mobility throughout a certain region, and this is all that experience can warrant us in demanding. But spaces (if so they can be called) which have no space-constant, though possible logically, would be incapable, as we have seen, of metrical treatment. Although pure projective Geometry would still be possible, we have seen how narrow are the limits of this science. Thus the axioms of distance, as well as the projective axioms, are necessary to any Geometry at all closely resembling the Geometry of our actual space.

Scientific evidence as to the nature of actual space.

The scientific question, as to the best available evidence concerning the nature of actual space, is one beset with difficulties of a peculiar kind. Admitting non-Euclidean spaces to be possible, we must also admit, since Euclidean space is merely a limiting case to which other spaces may indefinitely approximate, that the space we live in, though approximately Euclidean, may be found, on closer examination, to be of one or other of the non-Euclidean types. But in making this closer examination, we are obstructed by the fact that all existing physical science assumes the Euclidean hypothesis. This hypothesis has been involved in all actual measurements of large distances, and in all the laws of astronomy and physics. The principle of simplicity would therefore lead us, in general, where an observation conflicted with one or more of those laws, to ascribe this anomaly, not to the falsity of Euclidean Geometry, but

[3] *Mind*, O.S., vols. i. iii.; see also Land's reply, *ib.* vol. ii.

[4] One of them, the surface of zero curvature in elliptic space, was discovered by Clifford, and expounded in a paper at the British Association in 1873, but the first publication on the subject was Klein's in 1890 (*Math. Annalen*, vol. xxxvii.)

to the falsity of the laws in question. This applies especially to astronomy. On the earth our means of measurement are many and direct, and so long as no great accuracy is sought they involve few scientific laws. Thus we acquire, from such direct measurements, a very high degree of probability that the space-constant, if not infinite, is yet large as compared with terrestrial distances. But astronomical distances and triangles can only be measured by means of the received laws of astronomy and optics, all of which have been established by assuming the truth of the Euclidean hypothesis. It therefore remains possible (until a detailed proof of the contrary is forthcoming) that a large but finite space-constant, with different laws of astronomy and optics, would have equally explained the phenomena. We cannot, therefore, accept the measurements of stellar parallaxes, &c., as conclusive evidence that the space-constant is large as compared with stellar distances. For the present, on grounds of simplicity, we may rightly adopt this view; but it must remain possible that, in view of some hitherto undiscovered discrepancy, a slight correction of the sort suggested might prove the simplest alternative. But conversely, a finite parallax for very distant stars, or a negative parallax for any star, could not be accepted as conclusive evidence that our space is non-Euclidean, unless it were shown—and this seems scarcely possible—that no modification of astronomy or optics could account for the phenomenon. Thus although we may admit a probability that the space-constant is large in comparison with stellar distances, a conclusive proof or disproof seems scarcely possible.

Finally, it is of interest to note that, though it is theoretically possible to prove, by scientific methods, that our space is non-Euclidean, it is wholly impossible to prove by such methods that it is accurately Euclidean. For the unavoidable errors of observation must always leave a slight margin in our measurements. A triangle might be found whose angles were certainly greater, or certainly less, than two right angles; but to prove them *exactly* equal to two right angles must always be beyond our powers. If, therefore, any man cherishes a hope of proving the exact truth of Euclid, such a hope must be based, not upon scientific, but upon philosophical considerations.

If we ask what is, for philosophy, the main value of non-Euclidean Geometry, two points may be mentioned.

Philosophical value of non-Euclidean Geometry.

The first lies in the clear separation of different sets of axioms, and the resulting logical analysis of geometrical results. We have seen how to separate clearly the portions of Geometry involving any assumption from those which are independent of it, and how to construct a hierarchy of more and more specialized systems, beginning with projective Geometry and ending finally with Euclid. By this means we discover more clearly than was formerly possible whether any two propositions in Geometry are logically connected, or are independent of one another. The attempts which, down to Legendre, occupied a long series of great mathematicians, to deduce the postulate of parallels from the rest of Euclid's assumptions, are now known to be vain; and the same impossibility has gradually appeared in regard to the passage from any one of the four stages enumerated above to a later stage. A restraining influence is thus exercised upon the wholesale deductions of philosophers, and an example is afforded of the synthetic nature of mathematical propositions. The second point which non-Euclidean Geometry elucidates is of more strictly philosophical interest. We have seen that there are a number of possible Geometries, each of which may be developed deductively with no appeal to actual facts. But no one of them, *per se*, throws any light on the nature of our space. Thus geometrical reasoning is assimilated to the reasoning of pure mathematics, while the investigation of actual space, on the contrary, is found to resemble all other empirical investigations as to what exists. There is thus a complete divorce between Geometry and the study of actual space. Geometry does not give us certain knowledge as to what exists. That peculiar position which Geometry formerly appeared to occupy, as an *à priori* science giving knowledge of something actual, now appears to have been erroneous. It points out a whole series of possibilities, each of which contains a whole system of connected propositions; but it throws no more light upon the nature of our space than arithmetic throws upon the population of Great Britain. Thus the plan of attack suggested by non-Euclidean Geometry enables us to capture the last stronghold of those who attempt, from logical or *à priori* considerations, to deduce the nature of what exists. The conclusion *suggested* is, that no existential proposition can be deduced from one which is not existential. But to *prove* such a conclusion would demand a treatise upon all branches of philosophy.

In addition to the works already referred to, the following are among the most important for a study of the subject:—FLYE, STE. MARIE. *Études analytiques sur la théorie des parallèles.* Paris, 1871.—FRISCHAUF. *Absolute Geometrie nach Johann Bolyai.* Leipzig, 1872; *Elemente der absoluten Geometrie*, Leipzig, 1876.—CLIFFORD. "Preliminary Sketch of Biquaternions," *Proc. Lond. Math. Soc.*, 1873; and *Collected Mathematical Papers.*—KILLING. *Die nicht-Euklidischen Raumformen in analytischer Behandlung.* Leipzig, 1885.—CLEBSCH-LINDEMANN. *Vorträge über Geometrie*, vol. ii., Leipzig, 1891.—KLEIN. *Vorlesungen über höhere Geometrie.* Göttingen, 1893.—VERONESE. *Grundzüge der Geometrie*, Leipzig, 1894 (translation from the Italian).—LIE. *Theorie der Transformationsgruppen*, Leipzig, 1893 (third section).—A bibliography of non-Euclidean literature down to the year 1878 was given by Halsted, *American Journal of Mathematics*, vols. i. ii. (B. A. W. R.)

George, Friedrich August, KING OF SAXONY (1832-——, the youngest son of King John of Saxony (died 1873) and the Queen Amelia, was born at Dresden on 8th August 1832. From an early age he received a careful scientific and military training, and in 1846 entered the active army as a lieutenant of artillery. In 1849–50 he was a student at the University of Bonn, but soon returned to military life, for which he had a predilection. In the Austro-Prussian war of 1866 he commanded the first Saxon cavalry brigade, and in the early part of the war of 1870–71 the first division of the Saxons, but later succeeded to the supreme command of the 12th (Saxon) Army Corps in the room of his brother, Albert (afterwards king) of Saxony. His name is inseparably associated with this campaign, during which he showed undoubted military ability and an intrepidity which communicated itself to all ranks under his command, notably at the battles of St Privat and Beaumont, in which he greatly distinguished himself. On his brother succeeding to the throne he became commander-in-chief of the Saxon army, and was in 1888 made a field-marshal by the Emperor William I. He married in 1859 the Infanta Maria, sister of King Louis of Portugal, and King Albert's marriage being childless, succeeded on his death in 1902 to the throne of Saxony.

George I., KING OF THE HELLENES (1845-——), second son of King Christian IX. of Denmark, was born at Copenhagen, 24th December 1845. After the expulsion of King Otho in 1862, the Greek nation, by a plebiscite elected the British prince, Alfred, duke of Edinburgh (subsequently duke of Coburg), to the vacant throne, and on his refusal the national assembly requested Great Britain to nominate a candidate. The choice of the British Government fell on Prince Christian William

Ferdinand Adolphus George of Schleswig-Holstein-Sonderburg-Glücksburg, whose election as King of the Hellenes, with the title George I., was recognized by the Powers 6th June 1863. The sister of the new sovereign, Princess Alexandra, had a few months before (10th March) married the Prince of Wales, afterwards King Edward VII., and his father succeeded to the Crown of Denmark in the following November. Another sister, the Princess Dagmar, subsequently married the Grand Duke Alexander Alexandrovitch, afterwards Emperor Alexander III. of Russia. On his accession, King George signed an act resigning his right of succession to the Danish throne in favour of his younger brother Prince Waldemar. He was received with much enthusiasm by the Greeks. Adopting the motto, "My strength is the love of my people," he has always ruled in strict accordance with constitutional principles, though not hesitating to make the fullest use of the royal prerogative when the intervention of the Crown seemed to be required by circumstances. His influence with foreign Courts and Governments has been largely instrumental in saving the country from the consequences of political aberrations, and proved invaluable after the misfortunes of 1897. King George married, 27th October 1867, the Grand Duchess Olga Constantinovna of Russia. His surviving children are Prince Constantine, Duke of Sparta, born 1868, married in 1889 to Princess Sophia of Prussia, daughter of the Emperor Frederick, and granddaughter of Queen Victoria; Prince George, born 1869, since November 1898 High Commissioner of the Powers in Crete; Prince Nicholas, born 1872; Prince Andrew, born 1882; Prince Christopher, born 1888; and a daughter, Princess Marie, born 1876, and married in 1900 to the Grand Duke George Michaïlovitch of Russia. Queen Olga, who is distinguished for her beneficence, has founded many charitable institutions in Greece. (See also GREECE: *History*.)

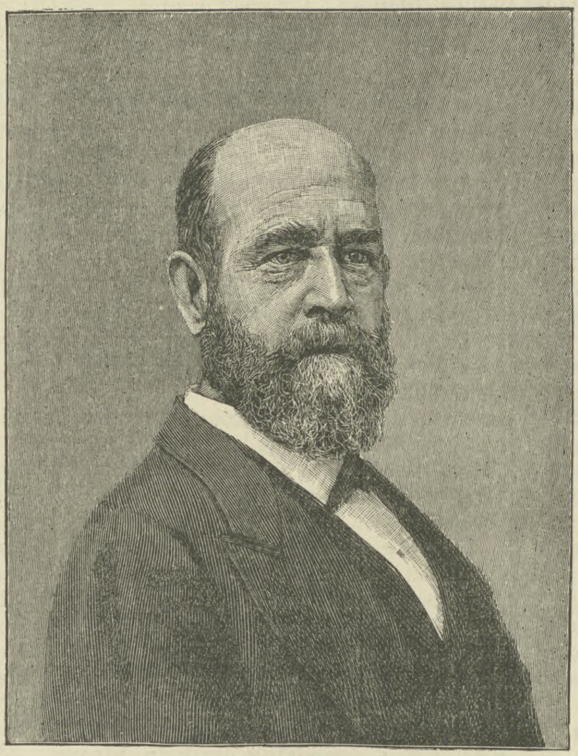
George V., KING OF HANOVER (1819–1878), only son of Ernest Augustus, duke of Cumberland, was born at Berlin on the 27th of May 1819. His mother was Princess Frederike of Mecklenburg, sister to Queen Louise of Prussia. He was educated partly in Berlin and partly in England. His father, the ablest of the sons of George III., on the death of William IV. became king of Hanover, which was henceforth separated from the British crown. George, while a child, lost the sight of one eye during an illness, and in 1833, while playing with Prince George of Cambridge (the duke of Cambridge) at Kew, struck his other eye with a purse which he was swinging; the injury, which was increased by an unsuccessful operation, resulted in total blindness. There were doubts whether he was qualified to succeed to the government, but his father decided that he should do so, as the law of the old empire only excluded princes who were born blind. The decision was a fatal one to the dynasty. Both from his father and still more from his uncle, Prince Charles of Mecklenburg, one of the most influential men at the Prussian Court, George had learnt to take a very high view of royal authority. His blindness prevented him from having that shrewdness and knowledge of the world which had been of such assistance to his father, and he easily fell into the hands of unwise, and perhaps disloyal and dishonest, advisers. A man of deep religious feeling, he formed a fantastic conception of the great place assigned to the house of Guelph in the Divine economy. It is therefore not surprising that from the time of his accession (1851) he was constantly involved in constitutional disputes with the Estates of his kingdom. When the crisis of 1866 came the Hanoverian Government had therefore a bad reputation in Germany as being opposed to the Liberal and National ideals of the time. George, wishing to adhere to the federal treaties, refused all offers both from Prussia and from Austria to enter into a special alliance, and especially declined to enter into any fresh union with Prussia in which he would be required to surrender any of his sovereign rights. The outbreak of war therefore found Hanover without allies, and unprepared. Prussia then, on 15th June, addressed to the king a summary demand that within twelve hours he should undertake to disband his army, observe neutrality during the war, and enter into an alliance with Prussia. This the king refused to do, contrary to the wishes of the Hanoverian Parliament and the petition of the municipality of the city. The Prussian envoy then declared war, but before he had done so Prussian troops had crossed the frontier. George ordered his army to assemble at Göttingen, and then on 19th June, with a force of 18,000 men, began an adventurous march, hoping to be able to make his way south and join the Bavarians. Owing to the faulty strategy of the Prussians this would probably have been possible had not the king allowed himself to be persuaded to enter into negotiations; the delay enabled fresh troops to be brought up. The king, when he was informed of this, broke off the negotiations. The Hanoverians succeeded in inflicting a severe defeat on the Prussian forces which attacked them at Langensalza on 27th June, but before they were able to continue the march so many fresh Prussian troops had come up that they were obliged to capitulate. The terms of the capitulation determined that the king should not return to Hanover, which was now in the hands of the Prussians. After a few days he proceeded to Vienna, but when, at the conclusion of the war, he addressed a letter to the king of Prussia requesting to know the terms of peace, it was not accepted, and on 20th September a law was introduced in the Prussian Parliament decreeing the annexation of Hanover. It was a step which could only be justified on the ground of political expediency. The king's indignant protest and his appeals for help to France, Great Britain, and Russia were equally in vain. An inquiry whether it would be of any use if the king abdicated in favour of his son was met by the answer that it was too late. His protests were supported by a large party among his subjects, and he began an agitation which for a time caused serious embarrassment to the Prussians. Unfortunately he allowed himself also to be led into fantastic schemes, such as the formation of a Guelph Legion, consisting of Hanoverian officers and soldiers who refused to enter the Prussian service. To the number of 1200 they were maintained at the king's expense in France, and his agents also founded a paper, *La Situation*, and a speculative bank in Vienna. All hopes of being able to bring about a rising in Hanover and recovering the kingdom were destroyed by the war with France, and in 1870 the Guelph Legion was disbanded. None the less George always refused any reconciliation with the Prussian Government. He passed the rest of his life at Gmünden in Austria, but in 1876 went to Paris for medical advice, and died there on the 12th of June 1878. He was buried in St George's Chapel at Windsor.

He had married in 1843 Marie, daughter of the duke of Saxe-Altenburg. He left one son, Ernest Augustus, duke of Cumberland, who married in 1878 Princess Thyra of Denmark, and still maintains the claims of his house to the kingdom of Hanover. (See GERMANY: *History*.)

By the capitulation of Langensalza the enjoyment of his personal property was secured to the king. A large sum, including nearly £1,000,000 in securities, nearly £200,000 in specie, and £100,000 in bank-notes, was safely removed before the Prussians entered Hanover, sent to England, and deposited in the Bank of England. The valuable plate was buried at Herrenhausen, and remained safely hidden till the end of 1867, when it was restored to the king. The Crown jewels were also secretly carried to England during 1866. The rest of the king's property consisted of landed estate. The British Government offered to help in bringing the settlement of his claims to a conclusion, and in 1867 the king agreed to accept 11 million thalers (£1,600,000) in 4½ per cent. Prussian bonds. After the agreement had been signed the Prussian Government, in consequence of the continued acts of hostility on the part of the king, was obliged to sequestrate this property. It was administered by a special commission, and the accounts were not published, and was therefore available as a secret service fund, known as the *Welfenfonds*, or more colloquially the *Reptilienfonds*. In 1892, however, the sequester was removed, and it was arranged to pay the interest derived from the fund to the duke of Cumberland. The palace of Herrenhausen near Hanover is also reserved as the property of the duke, and has been uninhabited since 1866.

See W. v. Hassell. *Geschichte des Königreichs Hannover.* Leipzig, 1897–1901.—Meding. *Memoiren zur Zeitgeschichte*, 3 vols. 1881–84.—O. Klopp. *König Georg V.* (J. W. He.)

George, Henry (1839–1897), American author and political economist, was born in Philadelphia, U.S.A., 2nd September 1839. He settled in California in 1858; removed to New York, 1880; was first a printer, then an editor, but finally devoted all his life to economic and



Henry George.
(From a photograph by Sarony, New York.)

social questions. In 1871 he published *Our Land Policy*, which, as further developed in 1879 under the title of *Progress and Poverty*, speedily attracted the widest attention both in America and Europe. In 1886 he published *Protection or Free Trade.* Henry George had no political ambition, but in 1886 he received an independent nomination as Mayor of New York City, and became so popular that it required a coalition of the two strongest political parties to prevent his election. He received 68,000 votes, against 90,000 for the coalition candidate. His death on 29th October 1897 was followed by one of the greatest demonstrations of popular feeling and general respect that ever attended the funeral of any strictly private citizen in American history. The fundamental doctrine of Henry George, the equal right of all men to the use of the earth, did not originate with him; but his clear statement of a method by which it could be enforced, without increasing state machinery, and indeed with a great simplification of government, gave it a new form. This method he named the *Single Tax.* His doctrine may be condensed as follows: The land of every country belongs of right to all the people of that country. This right cannot be alienated by one generation, so as to affect the title of the next, any more than men can sell their yet unborn children for slaves. Private ownership of land has no more foundation in morality or reason than private ownership of air or sunlight. But the private occupancy and use of land are right and indispensable. Any attempt to divide land into equal shares is impossible and undesirable. Land should be, and practically is now, divided for private use in parcels among those who will pay the highest price for the use of each parcel. This price is now paid to some persons annually, and it is called *Rent.* By applying the rent of land, exclusive of all improvements, to the equal benefit of the whole community, absolute justice would be done to all. As rent is always more than sufficient to defray all necessary expenses of government, those expenses should be met by a tax upon rent alone, to be brought about by the gradual abolition of all other taxes. Landlords should be left in undisturbed possession and nominal ownership of the land, with a sufficient margin over the tax to induce them to collect their rents and pay the tax. They would thus be transformed into mere land agents. Obviously this would involve absolute free trade, since all taxes on imports, manufactures, successions, documents, personal property, buildings, or improvements would disappear. Nothing made by man would be taxed at all. The right of private property in all things made by man would thus be absolute, for the owner of such things could not be divested of his property, without full compensation, even under the pretence of taxation. The idea of concentrating all taxes upon ground-rent has found followers in Great Britain, North America, Australia, and New Zealand. In practical politics this doctrine is confined to the "Single Tax, Limited," which proposes to defray only the needful public expenses from ground-rent, leaving the surplus, whatever it may be, in the undisturbed possession of land-owners.

The principal books by Henry George are: *Progress and Poverty* (1879), *The Irish Land Question* (1881), *Social Problems* (1884), *Protection or Free Trade* (1886), *The Condition of Labor* (1891), *A Perplexed Philosopher* (1892), *Political Economy* (1898). The Single Tax theory is fully discussed on the basis of statistics in Shearman's *Natural Taxation* (1895). (T. G. S.)

Georgia, one of the south Atlantic states of the American Union, bounded on the N. by Tennessee and North Carolina, on the E. by South Carolina and the Atlantic, on the S. by Florida, and on the W. by Alabama. The period of reconstruction after the Civil War—from 1865 to 1870—found everything in an unsettled condition, with the negroes newly enfranchised and the state under military control. The administration of affairs was largely in the hands of "carpet-baggers"—new-comers who had either been left in the state as a heritage of war, or were imported to assist in the distribution of the political loaves and fishes. Many negroes were elected to the Republican legislature and to the constitutional convention which assembled during that period, and the Democrats were practically eliminated from state affairs. In 1870 by compact organization of the whites the Democrats obtained control, and in 1877 the Reconstruction constitution of 1868 was superseded by the new state constitution. Since then the average number of Republican legislators out of a total of 219 has probably not exceeded half-a-dozen. In handling the racial and political problems introduced by the enfranchisement of the negroes Georgia has been fortunate. While there have been occasional outbreaks of popular feeling, they have been sporadic, and have only increased the determination of the whites to bring order out of chaos. Georgia has emphatically refused to join in legislation looking to either disfranchisement of the blacks or discrimination against them. The public funds for education are divided between whites and blacks in just proportion, and in the courts absolute justice prevails. At the same time the whites have upheld Caucasian civilization through moral force, the justice of which has given it victory.

Population.—Under the new constitution the state has advanced rapidly. In 1890 the population was 1,837,353, of whom 978,357 were whites and 858,996 negroes; 919,925 were males and 917,428 females; 1,825,216 native-born and 12,137 foreign-born. In 1900 the population was 2,216,331, showing an increase of 20·6 per cent. for the decade. Three-quarters of the growth of population was made up of white immigrants from other states. The land surface of Georgia is approximately 58,980 square miles, so that the number of persons to the square mile was 37·5 in 1900, as compared with 31·1 ten years before. Of the total population in 1900, 1,103,201 (49·8 per cent.) were males and 1,113,130 (50·2 per cent.) females; 2,203,928 were native-born and 12,403 (0·6 per cent.) foreign-born; 1,181,109 were white and 1,035,222 (46·7 per cent.) coloured, of whom 1,034,998 were negroes, 204 Chinese, 1 Japanese, and 19 Indians. There were 372 incorporated cities, towns, or villages in the state in 1900, of which 13 had a population exceeding 5000, and 3 a population exceeding 25,000. These three are Atlanta with 89,872, Savannah with 54,244, and Augusta with 39,441. In 1890 the urban population — classing as such all persons in cities of 8000 inhabitants or more—was 10·8 per cent.; of the total population in 1900 it was 11 per cent. The death-rate in 1900 was 12·1. The increase of city population in 1900 was due to natural growth, and not to any marked exodus from the country.

Education.—A fund of $1,900,000 per annum for education, furnished from various sources by the state government, is divided among the counties on the basis of school population between the ages of six and eighteen. There are special systems in Atlanta, Savannah, Augusta, Macon, Columbus, Rome, Brunswick, and many other cities and towns, so that the aggregate of annual expenditures for public schools may be placed at $3,000,000. Throughout the entire state the whites and blacks are educated separately, and there is an ascertained division of the funds between them. The number of persons of school age (5 to 20 years inclusive) in 1900 was 885,725. The number in attendance at the grammar and high schools is 423,467. Of these 251,093 are white and 172,374 black. Of the total of illiterates above ten years of age, 93,614 are white and 331,814 are coloured. Out of 500,752 males of voting age (21 years and over) in 1900, 158,247 were illiterate (unable to write), of whom 32,456 were white and 125,712 were negroes. The University of Georgia, situated at Athens, is the recipient of the United States agricultural fund, besides annual appropriations of from $8000 to $25,000 from the state government, and is the centre of other high institutions. Under its patronage there have been established a state normal school in Athens, a normal technical school at Milledgeville for women, and a school of technology in Atlanta for men, to each of which is appropriated from $20,000 to $30,000 a year. In 1900 the legislature inaugurated a large increase of these appropriations, especially to the cause of technological education. There are branch colleges at Dahlonega and Milledgeville for whites, an agricultural college near Savannah for blacks, and a medical college in Augusta of high standing. The Methodist Church South conducts Emory College in Oxford, the Baptist Church maintains Mercer University in Macon, and in almost every considerable town there exist flourishing colleges of lesser grade for young men and women. The total number of undergraduate and graduate students in the institutions of higher education in 1898 was 2177, and of instructors 135. Two-thirds of the religious population, white and black, are about equally divided between Baptists and Methodists. The rest are divided between Protestant Episcopal, Roman Catholic, Presbyterians, and others. The Georgia Sanitarium, for the insane, situated in Milledgeville, accommodates white and black separately, and has an average of 2000 patients. The Georgia Academy for the blind is at Macon; and the Georgia Institute for the deaf and dumb at Cave Spring.

Agriculture.—The commercial and industrial development of the state has been very remarkable. During 1893, 1895, and 1896, $8,000,000 a year were spent for commercial fertilizers, most of which were applied to cotton. In 1897–98 (the cotton year ending 1st September) the crop amounted to 1,536,000 bales, the average gross weight per bale being 506 lb. The average price for middling cotton in New York City during the year was 6·22 cents so the commercial value of that year's crop was $48,337,920. A steadily increasing crop had the effect of lowering the price; in 1885 a crop of 950,025 bales brought the farmers $39,413,825, and in 1893 a crop of 1,250,000 bales brought them only $35,386,875. This compelled attention to other crops. Larger areas were planted in wheat, corn, and oats, and the raising, and especially fattening, of cattle for market was successfully followed. The cotton crop of 1899–1900 was somewhat smaller (1,345,699 bales), but the prices were much more satisfactory, ranging in New York from 6¼ cents for middling upland cotton at the beginning of the season to 9⅝ cents at the close. In 1900 Georgia produced 34,119,530 bushels of Indian corn worth $19,448,132, with an average yield per acre of 10 bushels; 7,010,040 bushels of oats worth $3,434,920, with an average yield per acre of 15 bushels; 5,011,133 bushels of wheat worth $4,760,576, with an average yield per acre of 9·1 bushels. These averages are for the state at large; throughout the wheat belt the average yield is 25 bushels per acre, with a correspondingly increased percentage for the corn and oat belts. On 1st January 1900 the number and value of farm animals was as follows: 109,935 horses, $6,001,626; 157,008 mules, $10,826,032; 294,826 sheep, $518,893; 285,431 milch cows, $6,836,072; 380,716 other cattle, $4,216,054.

Manufactures.—The following table shows the manufacturing and mechanical industries as returned at the censuses of 1890 and 1900, and the percentage of increase for the decade:—

	1890.	1900.	Percentage of Increase.
Number of establishments	4,285	7,504	75·1
Capital	$56,921,580	$89,789,656	57·7
Wage earners, average number	52,298	83,842	60·3
Total wages	$14,623,996	$20,290,071	38·7
Cost of material used	$35,774,480	$68,232,202	62·8
Value of products	$68,917,020	$106,654,527	54·8

The principal products were textiles, especially cotton goods, valued in 1900 at $20,266,712; lumber and timber products, $13,704,923; flour and grist mill products, $8,330,439; turpentine and rosin, $8,110,468; and cotton-seed oil and cake, $8,064,112. The growth of the cotton manufactures has been remarkable. In 1879 the cotton factories were valued at $1,640,000. The spindles in operation in 1890 numbered 445,452, or 28 per cent. of the total in the south. In 1899 they numbered 926,044, or almost one-fourth of the total in the south, namely, 4,057,244. Of the 251,343 spindles in construction, 152,978, or over half, were in Georgia.

Mineral Resources.—Gold occurs in workable quantities in the north-eastern part of the state, usually in belts, from 1 to 5 miles wide, running north-east and south-west. In 1899 a company of capitalists from Ohio erected at Dahlonega a 120-stamp mill, with a capacity of 400 tons of ore per day, and a chlorination plant for treating sulphide ores, which will treat 40 tons of concentrates a day. Magnetic iron ore occurs in several counties. Extensive deposits of aluminum ore, in the form of bauxite, yield a large part of the aluminum produced in the United States. The bauxite is also extensively used for the manufacture of alum. Georgia is also one of the largest producers of manganese in the Union, the ore occurring in extensive masses as pyrolusite and psilomelane. The manganese ore is of high grade, being generally free from impurities. Corundum has been successfully produced. Bituminous coal has been worked continuously for many years, principally for the manufacture of coke for furnace use. There are extensive and very valuable clay deposits, which investigations by the State Geological Survey show to be second to none in the United States. Their fusion-point is exceptionally high, and the amount of impurities included is generally quite small. Abundance of marl and some phosphate rock are found in the southern part of the state. Beds of white, black-and-white mottled, and white-pink-and-grey mottled marbles, of endless variety, are worked on a large scale in Pickens county. Much of the black-and-white mottled marble is used for monumental work, on account of its richness and the sharp outline and contrast of its eccentric figures; and as a building stone this marble is probably not equalled. The Corcoran Art Gallery in the city of Washington, the Rhode Island State Capitol, the Minnesota State Capitol, and many handsome private buildings are constructed of Georgia marble. Large areas of granite and gneiss occur. A dark-green serpentine, of great beauty, has been quarried at Holly Springs, and turned into polished columns, slabs, &c., for interior decoration. A slate of fine texture and easy cleavage has for a long time been quarried at Rockmart. A very good cement has for several years been manufactured from limestone. Yellow ochre, asbestos, pyrite, steatite, and graphite are mined in various parts of the state, and rock crystal, rose quartz, chalcedony, agate, and moonstone exist in considerable quantities.

Railways.—In 1878 a state railway commission was established with mandatory powers for the settlement of all questions.

After consultation the commission fixes tariff, orders betterments, and transacts without appeal all business into which the interests of the public enter. The mileage of the south Atlantic states, consisting of Virginia, West Virginia, North and South Carolina, Florida, and Georgia, is 20,496, of which Georgia has a mileage of 5414, or more than 25 per cent. of the total. The mileage of the principal lines is as follows: Central Railroad, 1581·50; Western and Atlantic, 138; Plant system, 1391; Georgia Pacific, 557; Seaboard Airline, 926; Southern Railroad, about 1000 miles in Georgia. The gross earnings of the Georgia railways for the year ending 30th June 1899 were $21,087,310·36, leaving net earnings of $6,347,554·39. This gives a gross earning per mile of $3,937·85, or a net earning of $1,175·85. *Per contra*, the working expenses absorbed 70·14 per cent. of the gross earnings. There are fifty-one separate companies or systems in the state. During the year ending 30th June 1899 only six companies showed a deficit, the total deficit being $50,962·88. This would make the net earnings $6,296,591·51. Development of railways has resulted in the settlement and building up of considerable towns and manufacturing communities. Along the Georgia and Alabama railway, and especially in the dense pine belt between Montgomery and Savannah, there has been phenomenal growth.

Steamships.—The Central Railway system has a regular tri-weekly steamship service from Savannah to New York and Boston, with well-appointed passenger steamers. Calls are made at Philadelphia. The Merchants and Miners' Line plies regularly between Savannah and Baltimore. There are ship-lines by river: On the Chattahoochee, from Columbus to Apalachicola; on the Coosa, from Rome into the Alabama; on the Altamaha and the Ocmulgee, to their mouths.

Banking.—Charters for state banks are granted by the Secretary of State upon the payment of a fee of $50, which is covered into the state treasury; but $15,000 must first have been subscribed and actually paid, and there must be a capital stock of $25,000. No state banks of issue exist, because of a prohibitory tax of 10 per cent. on circulation medium by the national government. There were in 1900 171 state banks in operation, with a capital of $9,634,659; 22 private banks, with a capital of $605,123; and 11 loan and trust companies, with a capital of $1,194,650. There were 27 national banks, with a capital of $3,556,000. There are clearing houses in Savannah, Atlanta, Augusta, and Macon. Their combined clearings in 1899 aggregated $297,763,629.

Finances.—The total valuation of property in 1880 was $251,424,651; in 1890 it was $415,828,945; in 1900 it was estimated at $435,000,000. Taxation by legislative enactment has been limited to $5 on the thousand, and owing to the absence of a sufficient floating element in all parts of the state, propositions to increase public burdens, by either taxation or bond issues, undergo very strict inquiry. The proceeds of taxation in 1900 were $2,605,569. The state debt amounted to $7,831,500.

Constitutional Reform.—Under the constitution of 1877 the term of the governor was shortened from four years to two; the state was given power to organize a railway commission; the establishment of public schools was made obligatory; municipalities were restricted in the contracting of public debts to an amount not more than 7 per cent. of the value of assessment; all issues of bonds were made subject to a vote of the people; and the power of expending money was limited to certain well-defined public necessities. There are departments of state, treasury, law, agriculture, education, and accounts and insurance. Of the sub-departments the most important are the state railway commission; the penitentiary commission, which has control of the question of pardons as well as of penal matters; and a confederate pension bureau, which has the expenditure annually of $700,000 to the needy wounded veterans and their widows. A new department is that of geology. The state supreme court has been increased from three to six members, and the governing authority of the counties, formerly vested in an inferior court, is now in the hands of a central officer known as the ordinary.

Liquor Laws.—The growth of the anti-liquor sentiment has been marked by the adoption by the counties of local option. Ever since colonial times all matters affecting local government have been referred to the grand jury of each county; and, extending the practice to larger questions of public policy, the state adopted a law by which each county, moving for itself, with the power of biennial reconsideration, can take a vote upon the sale of liquors. One hundred and seventeen out of the one hundred and thirty-seven counties have barred the liquor traffic. The other twenty counties are substantially within prohibition ground, because of a general law which prohibits the sale of liquor in rural districts within three miles of church or school, so that in effect liquor is only sold in the larger cities. (C. Ho.)

Georgievsk, a district town of Russia, North Caucasia, province of Terek, 23 miles north-east of Pyatigorsk railway station. Here the Georgian prince, Heraclius, concluded in 1783 a treaty of federation with Russia. Population in 1897, 10,608.

Georgswalde, a town of Northern Bohemia (Austria), on the borders of Saxony. Together with Rumberg, it is one of the principal centres of the Bohemian linen industry. There are also an iron-foundry, cotton-spinning, brick-making, &c. Population (1900), 8131.

Gera, a town of Germany, capital of the principality of Reuss the Younger, on the White Elster, 45 miles by rail south-south-west from Leipzig. The church of St John's was built in 1885; in front of it stands an equestrian statue of the Emperor William I., unveiled in 1894. There is a municipal museum. Wool-weaving and spinning, iron foundries and machine shops, printing (books and maps), and flower gardening are the distinctive industrial features. Population (1885), 34,152; (1900), 45,640.

Geraldton, the chief port of the northern portion of West Australia, in the district of Victoria, in Champion Bay, about 290 miles north-west from Perth. The chief exports are wool, copper, and lead. The harbour is safe and roomy. The town is the centre of a railway system. The mean temperature for the year is 65·5° F.; for February, 74·6° F.; for July, 57·5° F.; the mean annual rainfall is 17·13 inches. Population (1901), 2593.

Gerasa, now Jerash, one of the cities of Decapolis in Syria, and possibly the Biblical Ramoth Gilead, built on both banks of the Kerwán (Chrysorrhoas), and called in an inscription Γέρασα 'Αντιόχεια. It is now occupied by a colony of Circassians, whose houses have been built with materials from the earlier buildings, and there has been much destruction of the interesting ruins.

German Reed.—The dramatic and musical entertainment, which for so many years was known in London by the title of "German Reed," may be mentioned here in connexion with the principal names of those who made it so successful. Mr THOMAS GERMAN REED (born in Bristol in 1817, died 1888) married in 1844 Miss PRISCILLA HORTON (1818–1895), and in 1855 they started their entertainment at the "Gallery of Illustration," in Waterloo Place, London. From 1860 to 1877 they were assisted by JOHN ORLANDO PARRY (1810–1879), an accomplished pianoforte player, mimic, parodist, and humorous singer; and the latter created a new type of musical and dramatic monologue which became very popular. His tradition was carried on after 1870 by Mr CORNEY GRAIN (1844–1895), who, as a clever, refined, and yet highly humorous society entertainer (originally a barrister), was one of the best-known figures of his day. After the retirement of the elder German Reeds, their son, ALFRED GERMAN REED (1846–1895), himself a capital actor, carried on the business in partnership with Corney Grain. The "German Reed Entertainment"—which was always patronized by a large class of people, many of whom objected on principle to going or taking their children to a regular theatre or a music-hall—retained its vogue for forty years at Waterloo Place and at the St George's Hall, Regent Street. But the death of Mr Corney Grain almost simultaneously with Mr Alfred German Reed, in 1895, together with the changed public attitude towards the regular theatre, ended its career, though more recently Mr Albert Chevalier has to some extent revived this type of entertainment in modified conditions. The success, however, of John Parry and Corney Grain had meanwhile resulted in many others—among them Mr George Grossmith, who had made a reputation in the Gilbert and Sullivan operas at the Savoy Theatre—starting independently as "entertainers" with what were known as "musical sketches."

Germantown, Pennsylvania, a residential district in the northern part of the city of Philadelphia, U.S.A.

GERMANY.

I.—Geography and Statistics.

Geography.—The present German Empire extends from 47° 16′ to 55° 54′ N. lat., and from 5° 53′ to 22° 53′ E. long., therefore the 15th meridian, fixing Central European time, does not divide it in the middle. The difference in time between the most eastern point and the 15th degree E. is 36½ minutes, and between the most western point and the 15th meridian only 31½ minutes. The empire is bounded on the E. by Russia (735 miles according to Strelbitski, 1881), on the S.E. and E. by Austria and Switzerland (together 1647 miles), on the S.W. by France (251 miles), and on the W. by Luxemburg, Belgium, and Holland (together 530 miles). The length of German coast on the North Sea is 460 miles, and on the Baltic (without reckoning the coasts of the "haffs") 735 miles, the intervening land boundary on the north of Schleswig being only 72 miles. The total area of the empire, including rivers and lakes, but not the "haffs" and lagoons on the Baltic (called *Bodden* on the coast of Pomerania) nor other coast waters (together 2590 square miles), is 208,790 English square miles, or 540,743 square kilometres, according to the most recent estimates. As regards the *physical features*, there is little to add to the earlier article (*Ency. Brit.*, x. 447–450).

Area and Population.—Since the constitution of the German Empire in 1871 the territory has been enlarged only by the island of Heligoland (about ¼ square mile), ceded by Great Britain under the treaty of 1st July 1890. The changes in cadastral measurements have been numerous in the several German states, but of small amount.

Table I.—*Population and Growth of the German Empire 1870 to 1900.*

(Population at the beginning of December; 000 omitted.)

Year.	Population.	Increase Percentage Per Annum.	Year.	Population.	Increase Percentage Per Annum.
1870	40,818	0·58	1890	49,428	1·07
1875	42,729	0·91	1895	52,280	1·12
1880	45,236	1·14	1900	56,367	1·50
1885	46,858	0·70			

The following table gives the area and population of the twenty-six states of Germany, in their official order, as returned at the census of 1st December 1900:—

Table II.—*Area and Population of the German Empire.*

States of the Empire.	Area, English Square Miles.	Population.
Kingdoms.		
1. Prussia	134,622	34,472,509
2. Bavaria	29,295	6,176,057
3. Saxony	5,789	4,202,216
4. Würtemberg	7,534	2,169,480
Grand-Duchies.		
5. Baden	5,823	1,867,944
6. Hesse	2,966	1,119,893
7. Mecklenburg-Schwerin	5,069	607,770
8. Saxe-Weimar	1,397	362,873
9. Mecklenburg-Strelitz	1,131	102,602
10. Oldenburg	2,482	399,180
Duchies.		
11. Brunswick	1,418	464,333
12. Saxe-Meiningen	953	250,731
13. Saxe-Altenburg	511	194,914

The population doubled within the period 1825–1900, but there are great differences in the growth. It appears from the following table that the inhabitants of the kingdom of Saxony and the eight old provinces of Prussia have increased three or four times more than those of the South German States and Hanover since 1836.

Table III.—*Increase of Population in States or Provinces.*

(000 omitted.)

Provinces or States.	Population Census, 1831–1900.			Total Increase Per Cent.	
	1831–34.	1875.	1900.	1831–75.	'31–1900
Saxony	('34) 1,596	2,760	4,202	73	169
The eight old Prussian Provinces:	('31) 13,040	21,116	28,528	62	119
Brandenburg (including Berlin)	,, 1,612	3,126	4,997	84	209
Saxony	,, 1,450	2,169	2,832	50	195

Würtemberg	,, 1,573	1,882	2,169	20	38

Of the total population, the females exceed the males in the ratio of 1032 to 1000, as in most European states of Teutonic origin.

According to the occupation census of 14th June 1895, the distribution as regards conjugal condition was as follows (the regular census of 2nd December 1895 did not give such returns):—

Table IV.—*Conjugal Condition*, 1895.

(000 omitted.)

	Males.		Females.		Total.	
	Total.	Per Cent.	Total.	Per Cent.	Total.	Per Cent.
Unmarried	15,784	62·1	15,368	58·3	31,152	60·0
Married	8,849	34·8	8,785	33·3	17,634	33·9
Widowed (and Divorced)	776	3·0	2,209	8·4	2,985	6·1

Table V.—*Marriages, Births, and Deaths*, 1871–99.
(000 omitted.)

Year.	Marriages.	Births (including Still-born).	Deaths.	Still-born.	Surplus of Births.
1871–80 .	369	1744	1233	69	511
1881–90 .	368	1799	1247	67	551
1891–99 . or	426	1953	1226	64	727
1897 . .	448	1991	1206	64	785
1898 . .	459	2030	1183	65	847
1899 . .	472	2045	1250	65	795

The mean number of marriages for each 1000 persons living was, for the whole period, 8·2; the annual number rose (1872) soon after the great war to 10·3, and descended in the period of economic depression (1879–81) to 7·5. Regarding the births, the average annual rate was 38·8. The rate per 1000 ascended slowly to 42·6 (1876), but afterwards decreased (37·1 in 1899). The average death-rate was 26·4. In later years the deaths have regularly diminished, the rates per 1000 from 1894 to 1899 being as follows: 23·5, 23·4, 22·1, 22·5, 21·8, 22·7, still-born included; or 22·3, 22·1, 20·8, 21·3, 20·6, 21·5 without reckoning the still-born. This death-rate is not so favourable as that in Great Britain and Ireland. In Germany, as in most European states, the surplus of females is due to their lower death-rate, for more boys are born than girls.

Table VI.—*Excess of Boys for* 1000 *Girls*.

Year.	Births.	Deaths.
1897 . .	1060	1103
1898 . .	1058	1106
1899 . .	1059	1099

The rate of illegitimacy has generally decreased in the last thirty years from 11 or 12 per cent. (1841–71) to about 9–9¼, but it is still higher than in any other European state, except Denmark, Sweden, and Austria. For the ten years 1889–98 the proportion was 3 to 3·5 per cent. in Western Germany (Rhineland and Westphalia), 6–7 in the north-western and the extreme eastern provinces, 8–10 in the south-western, and 10–12 in most of the provinces round Brandenburg, and 15 per cent. in Bavaria.

The surplus of births over deaths being much greater than the growth of the population, there is a great loss by emigration. Between 1820 and 1900 about 5 or 5½ millions of Germans appear to have emigrated across the sea:—

Table VII.—*Emigration of Germans from German and Foreign Ports.*
(000 omitted.)

Year.	Total.	Average.
1820–70 .	2770	...
1871–75 .	395	79
1876–80 .	231	46
1881–85 .	857	171
1886–90 .	485	97
1891–95 .	403	81
1896–1900 .	127	22

There have been great oscillations in the actual emigration by sea. It first exceeded 100,000 soon after the war (1872, 126,000), and this occurred again in the years 1880 to 1892. Germany lost during these thirteen years more than 1,700,000 inhabitants by emigration. In recent years the emigration has been insignificant. The total number of those who sailed for the United States from 1820 to 1900 may be estimated at more than 4,500,000. The number of German emigrants to Brazil between 1870 and 1900 was about 52,000. The greater number of the more recent emigrants were from the agricultural provinces of Northern Germany — Western Prussia, Posen, Pomerania, Mecklenburg, Schleswig-Holstein, and Hanover. Sometimes the emigration reaches 1 per cent. of the total population of these provinces.

The number of foreigners naturalized during the years from 1872 to 1885 was 65,931; the returns have not been continued. The number of foreign residents in the empire has considerably increased from one census to the other. In 1871 there were 40,852,000 natives and 206,700 foreigners, or 5 per 1000; in 1895, 51,793,711 natives, and 486,185 foreigners, or 9·3 per 1000. The census returns of 1895 show that of these foreigners, 222,952 came from Austria-Hungary, 50,743 from the Netherlands, 44,870 from Switzerland, 28,146 from Denmark, 26,559 from Russia, 22,693 from Italy, 19,619 from France, 15,788 from the United States, 15,290 from Great Britain, 11,755 from Luxemburg, 11,091 from Sweden and Norway, 8947 from Belgium, and 7732 from other countries.

The following table [VIII. (*a*) and (*b*)] shows the density of population. It is not possible to do this properly for the actual states under Table II., but a fairer estimate is obtained if we take into consideration the leading political or natural subdivisions of the whole country.

Table VIII.—*Abstracts for the most important Political or Natural Groups.*
(000 omitted in the Population Returns.)

(*a*) Political Groups.	Area. Sq. Miles.	Population, 1900.	Population per Square Mile.
Prussia, including the minor States of North Germany	147,018	37,695	256
Saxony	5,789	4,200	725
Thuringian States . .	4,762	1,420	298
Bavaria	29,295	6,176	211
Würtemberg . .	7,534	2,169	288
Baden	5,823	1,868	320
Alsace-Lorraine . . .	5,603	1,719	307
Hesse	2,966	1,120	378
Total (1900) . .	208,790	56,367	270

(*b*) Natural Groups.	Area. Sq. Miles.	Population, 1895.	Population per Square Mile.
Baltic Countries . . .	49,624	7,179	145
Middle East Germany .	43,107	11,128	256
North-western Plains . .	17,941	3,693	205
Hills between Weser and Elbe . . .	11,446	3,110	272
Saxony-Thuringia . .	13,724	6,018	438
Hesse	5,593	1,180	228
Lower Rhineland . .	15,756	7,575	479
Western Upper Rhineland .	8,421	2,730	329
Eastern Upper Rhineland .	12,545	3,820	306
Franconia	10,042	2,252	225
Danubian Countries . .	20,552	3,593	174
Total (1895) . .	208,751	52,278	251

The difference in the density of population is much greater than can be seen from the above table if we take the minor districts into consideration. Without mentioning the true mountain circles belonging to the Bavarian Alps, there are some rural districts in the moorlands of Oldenburg and Hanover where the inhabitants number scarcely 50 per square mile. For the purely agricultural districts of the north-eastern lowlands, or those of the Upper German plateau (Danubian plateau), 150 is the number. It seems that a density of about 250 is the highest for a truly rural population in Germany. More thickly populated districts are to be found in the Upper Rhine plain, the Neckar valley, and the plains bordering the midland mountains in the north. But the density attains an extreme degree in the different coal districts. In the Ruhr basin, a district of about 600 square miles, the population equals that of Lancashire, the mean being not under 2500 per square mile.

The number of inhabited houses in 1890 was 5,791,000; in 1871 it was about 5,330,000, so that the average number of inhabitants per house is 8·45 persons. In Great Britain and Ireland in 1891 the average was only 5·28.

Table IX.—*Town and Rural Population.*

Classes of Towns.		Number of Towns.	Population. (000 omitted.)	Per Cent. of Total.
Large Towns of more than 100,000 Inhabitants .	1871	8	1,969	4·8
	1895	28	7,277	13·9
Middle-sized Towns from 20,000 to 100,000 Inhabitants . . .	1871	75	3,147	7·7
	1895	150	5,580	10·7
Small Towns from 5000 to 2000 Inhabitants .	1871	529	4,588	11·1
	1895	796	7,048	13·5
Rural Towns from 2000 to 5000 Inhabitants .	1871	1716	5,087	12·4
	1895	2068	6,158	11·8
Town Population .	1871	2328	14,791	36·1
	1895	3042	26,063	49·9
Rural Population .	1871	...	26,219	63·9
	1895	...	26,217	50·1

The differences in the distribution of the population have become much greater than they were formerly. The mean density has increased from about 120 inhabitants per square mile in 1820 to 150 in 1840, 200 in 1875, and 270 in 1900. In the same period the population of the cities has greatly risen, the natural increase of the inhabitants in the rural districts from the surplus of births being neutralized by the steady migration to the cities. It must be remembered that the official statistics designate all inhabitants of communes with more than 2000 souls as "town population"; the term "rural population" is applied to those of the smaller places. (For further details see *Ency. Brit.*, x. p. 457.)

The figures exhibit the extremely unequal increase of the different groups from 1871 to 1895. In the rural towns it was at the rate of 21 per cent., in the small towns 53·6 per cent., in the middle-sized towns 43·6 per cent., and in the large towns 269 per cent.

The following is a list of the large towns in 1900; the total population of these 33 towns was 9,108,815 in 1900, or 16·2 per cent. of the total population (000 omitted):—

Greater Berlin	2500	Charlottenburg, *see* Berlin.	
Berlin	1884	Königsberg	188
Charlottenburg	189	Stuttgart	176
Hamburg	706	Bremen	163
Altona	162	Altona, *see* Hamburg.	
Munich	500	Elberfeld	157
Leipzig	455	Barmen	157
Breslau	423	Halle-on Saal	157
Dresden	395	Strassburg	150
Cologne	372	Dortmund	142
Hanover	236	Danzig	140
Linden	51	Mannheim	140
Frankfurt-on-Main	288	Aachen (with Burtscheid)	135
Nürnberg	261	Brunswick	128
Magdeburg	230	Essen	119
Düsseldorf	214	Kiel	108
Stettin	211	Crefeld	107
Chemnitz	207	Kassel	106

TABLE X.—*Occupations*, 1882 *and* 1895.
(000 omitted.)

Occupations.	Total.		Engaged in the Several Occupations.		Total in Per Cent.	
	1882.	1895.	1882.	1895.	1882.	1895.
A. Agricultural Class	19,225	18,501	8,236	8,293	42·5	35·7
B. Industrial Class	16,058	20,253	6,396	8,281	35·5	39·1
C. Commercial Class	4,531	5,967	1,570	2,339	10·0	11·5
D. Domestic and other Service	938	887	398	432	2·1	1·7
E. Professions	2,223	2,835	1,031	1,426	4·9	5·5
P. Without Profession or Occupation	2,246	3,327	1,354	2,143	5·0	6·4
Total	45,221	51,770	18,985	22,914	100	100

Germany made a great step in her development as an industrial state between the years 1882 and 1895. The number of persons engaged in agriculture, cattle-rearing, forestry, and fishing was not more in 1895 than the number of those engaged in mining, metal works, and other industries, but with respect to the attendants and other members of families the two branches were in the ratio of 36 to 39 in 1895, while the agricultural class included in 1882 7 per cent. of the total population more than the industrial class.

Constitution and Government.—By the law of 19th March 1888, which came into force in 1890, the members of the Reichstag are elected for the term of five years (previously for three years). The duration of the legislative period is also five years. The average number of inhabitants for each of the 397 electoral districts increased from 103,000 in 1871 to 131,600 in 1898. The total number of electors to the Reichstag inscribed on the lists was 8,523,000 at the general election of 1874 (in 1871 Alsace-Lorraine did not take part in the elections) or 20·8 per cent. of the population of 1871. In 1898 the number of electors was 11,441,000, or 21·9 per cent. of the population according to the census of 1895. In 1874 the number of effective voters was 61·2 per cent. of the whole electoral body, and the rate was about the same in the following elections till 1884. In 1887 the number rose to 78·2 per cent.; in 1898, with 7,787,000 voters (in the first vote), it was 68·1 per cent. The following table shows the number of votes given to the several political parties and the composition of the Reichstag after the elections of 1874, 1887, 1898:—

TABLE XI.—*Number of Votes and Deputies.*

Parties.	Legal Votes (000 omitted)			Deputies.		
	1874.	1887.	1898.	1874.	1887.	1898.[1]
Conservatives	360	1147	859	22	80	52
Reichspartei (Liberal-Conservatives)	430	736	344	36	41	22
National Liberals	1542	1678	971	155	99	47
Freisinnige (Liberals)	447	973	754	49	32	40
Volkspartei (Democrats)	22	89	108	1	...	7
Centrum (Clerical)	1568	1516	1455	101	98	102
Poles	198	220	244	14	13	14
Social Democrats	352	763	2107	9	11	57
Anti-Semites	...	12	284	...	1	10
Welfen, Danes	138	113	105	4	5	9
Alsatians	86	234	107	6	15	10
Other Parties	46	60	413	...	2	23
Total	5189	7541	7751	397	397	393

The multiplicity of parties has been a peculiarity of the German Reichstag from the beginning, and has increased still more since 1874.

Languages.—The number of German-speaking people in the world, including the various branches, such as Dutch and Flemish, may be roughly estimated for the year 1900 at 90,000,000. They are distributed somewhat as follows:—

TABLE XII.—*Distribution of German-speaking People.*

German Empire	51,800,000
Austria-Hungary	11,000,000
Netherlands	5,100,000
Belgium	3,900,000
Luxemburg	200,000
Switzerland	2,300,000
France	500,000
Other European Countries	2,300,000
America	12,000,000
Asia	100,000
Africa	600,000
Australia	100,000

No imperial census relating to the mother tongue yet exists. Apart from the foreigners residing in the various German states, Germans speaking another language than German are found only in Prussia, Saxony, and Alsace-Lorraine. According to the Prussian census of 1st December 1890, there were 29,815,938 persons speaking commonly one language and 137,531 speaking two languages:—

TABLE XIII.—*Languages spoken in Prussia*, 1890.

Germans	26,438,070
Poles	2,816,657
Masurians	105,755
Cassubians	55,540
Moravians and Czechs	66,078
Wends	74,069
Lithuanians	121,345
Danes and Norwegians	139,399
Walloons	11,058
Other Languages, including Frisian (48,828)	125,498
Total	29,953,469

In the kingdom of Saxony, according to the census of 1885, there were 49,916 Wends, most in the Lausitz. With respect to Alsace-Lorraine, detailed estimates (but no census) gave the number of French in the territory of Lorraine at about 170,000, and in that of Alsace at about 46,000. Combining these statistics with those of the foreign residents, it may be estimated that the whole population of the German Empire for 1900 according to language was as follows:—

[1] Composition on 18th January 1900, four seats being vacant.

TABLE XIV.—*Languages spoken in Germany*, 1900.

(000 omitted.)

Languages.	Population.	Per Cent.
Germans	51,900	92·7
Poles, &c.	3,200	5·7
Wends	120	0·2
Czechs, &c.	70	0·1
Lithuanians	120	0·2
Danes	140	0·3
French	250	0·5
Walloons	10	...
All other Peoples	190	0·4
Total	56,000	100

The Poles have increased very much, owing to a greater surplus of births than in the case of the German people in the eastern provinces of Prussia, to immigration from Russia, and to the Polonization of many Germans through clerical influence. The Poles are in the majority in Upper Silesia (Government district of Oppeln, 55 per cent.) and the province of Posen (60 per cent.). They are numerous in West Prussia (34 per cent.) and East Prussia (20 per cent.). In recent years, however, there has been a great emigration of Poles to the western industrial provinces of the empire.

Religion.—The following table gives the results of the religious census of 1890 compared with previous years :—

TABLE XV.—*Religious Statistics.*

(000 omitted.)

Creeds.	1871.	1880.	1890.
Protestants	25,582	28,331	31,027
Roman Catholics	14,868	16,233	17,675
Dissenters	82	78	146
Jews	512	561	568
Other Creeds or not stated	17	31	13
Total	41,061	45,234	49,429

TABLE XVI.—*Religion. Ratio to* 1000 *Inhabitants.*

Year.	Protestants.	Catholics.	Dissenters.	Jews.
1871	623	362	2·0	12
1880	626	359	1·7	12
1890	628	358	2·9	11

Three states in Germany have a decidedly predominant Catholic population—namely, Alsace-Lorraine, Bavaria, and Baden. In four states the Protestant element prevails, but there are from 23 to 33 per cent. of Catholics —namely, Prussia, Würtemberg, Hesse, and Oldenburg. In Saxony and the eighteen minor states the number of Catholics is only from 0·3 to 3·3 per cent. of the population.

TABLE XVII.—*Protestants and Catholics according to the Census of* 1890.

State.	Protestants.	Roman Catholics.	Rate per 1000 of Population.	
			Prot.	Cath.
Alsace-Lorraine	337,476	1,227,225	210	765
Bavaria	1,571,863	3,962,941	281	708
Baden	598,678	1,028,222	361	620
Prussia	19,232,449	10,252,818	642	342
Würtemberg	1,407,176	609,794	691	299
Hesse	666,118	293,651	671	296
Oldenburg	274,410	77,769	773	219
Saxony and Minor States	6,938,640	221,521	961	31
Total	31,026,810	17,673,941	628	358

TABLE XVIII.—*Dissenters.*

The census of 1890 gives the following details about the "Other Christians" :—

Herrnhuters (Moravian Brethren)	6,716
Mennonites	22,365
Baptists	29,074
Church of England	5,249
Methodists and Quakers	10,144
Apostolics (Irvingites)	21,751
German Catholics	5,714
Freethinkers	14,347
Dissidents	23,698
Others	6,482

No official return exists as to the Old Catholics. They are estimated to have numbered not more than 30,000 in 1890.

Education.—School instruction is obligatory upon all, but the administration of all the degrees of instruction is not imperial. An imperial school committee designates those schools which possess the right of granting certificates to pupils entitling them to serve in the army as one-year volunteers.

The number of primary schools is not exactly known; it is about 60,000. The pupils attending them number about 8,000,000, and the teachers 125,000. There were 184 seminaries for the training of teachers in 1900. The progress in education will be seen from the diminishing number of the illiterate army recruits since 1871 :—

TABLE XIX.—*Decreasing Number of Illiterate Recruits.*

Years.	Number of Recruits.	Unable to Read or Write.	
		Total.	Per 1000 Recruits.
1875–76	139,855	3311	23·7
1880–81	151,180	2406	15·9
1885–86	152,933	1657	10·8
1890–91	193,318	1035	5·4
1895–96	250,287	374	1·5
1898–99	252,382	173	0·7

Of the 173 illiterates in 1898–99, 64 were in East and West Prussia, 46 in Posen and Silesia, and 12 in Bavaria. Since 1875 many municipalities have founded schools of a somewhat higher rank for the lower classes, called *Fortbildungsschulen*, or Continuation schools.

The four different classes of schools for higher education have been augmented since 1880. Exact and uniform statistics of the secondary schools for the whole empire do not as yet exist. In 1879 there were 878 schools with the privilege of furnishing pass certificates for the one-year volunteers; in 1900 there were 1286. There were included in this number 170 public seminaries for training teachers in 1879, and 184 in 1900. The number of other secondary schools in 1900 was as follows :—

TABLE XX.—*Number of Schools.*

Gymnasia (classical)	451
Progymnasia (classical)	90
Realgymnasia	121
Oberrealschulen (without Latin)	53
Realschulen	272
Höhere Bürgerschulen	2
Other Public Schools	33
Private Schools	54
Total	1076

The gymnasia, of which the constitution dates back to very remote times, have in Prussia the privilege of giving preparatory training for the universities. Pupils of the realschulen are only allowed to visit the universities for the study of mathematics, natural science, and modern languages. In the southern states the privileges of the upper realschulen are greater. There is now a movement in Germany for extending the privileges of the gymnasia to the other nine-years schools, that is to say, the realgymnasia and the oberrealschulen. The total number of teachers and pupils in the German higher schools is not known, but in 1897 the 578 Prussian schools contained 7683 teachers and about 148,500 scholars.

Universities and Higher Technical Schools.—The attendance of the German youth at the higher schools and the universities has greatly increased since 1880. The number of students at the twenty-one German universities (without taking account of the little academy at Braunsberg) was 16,000 in 1872, the year in which Strassburg university was founded, and 33,500 in 1898–99. At the same time the total population has only increased from 41,000,000 (1871) to 55,000,000, or 34 per cent. For some years women have been allowed to attend, and in 1899 there were from 450 to 500 women at the various universities.

TABLE XXI.—*The German Universities,* 1878 *and* 1899.

Universities.	Professors and Teachers.		Students.		Non-Matriculated Attendants.

Total	1827	2802	16,825	33,463	6697

The number of foreign students is said to have been only 750 in 1860, but in 1899 it was 2092, of whom 126 were from England, 305 from America, and 81 from Asia. In 1898–99 the students were distributed among the different faculties as follows :—

TABLE XXII.—*Number of Students in the different Faculties.*

	1876.	1899.
1. Protestant Theology (17 faculties)	1,595	2,473
2. Catholic Theology (7 faculties)	686	1,548
3. Laws, Politics, and Forestry (20 faculties)	4,862	9,814
4. Medicine, Surgery, Pharmacy (20 faculties)	3,529	8,104
5. Philosophy, Philology, History, Geography, Mathematics, and Natural Science	6,153	11,524
Total	16,825	33,463

The teaching staff was classified in 1899 as follows :—ordinary professors, 1089 (1876, 931); extraordinary professors, 619 (1876, 371); honorary professors, non-salaried, 92 (1876, 45); private teachers (*privatdocenten*), 841 (1876, 431); teachers of languages, 161 (1876, 90). The expenses of all the universities (Braunsberg included) in 1891–92 were 19,912,000 marks, of which 4,872,000 marks were covered by their own revenues, and 15,040,000 marks by state or provincial funds.

The *Technical High Schools* have greatly increased, following on the industrial development of Germany in the last third of the 19th century. The attendance for the winter of 1898–99 is shown in the following table :—

TABLE XXIII.—*The Technical High Schools.*

Technical High School.	Students.	Attendants.
Berlin	2425	1003
Munich	1839	282
Darmstadt	1302	141
Karlsruhe	884	196
Hanover	858	339
Stuttgart	767	171
Dresden	689	134
Aachen	340	141
Brunswick	276	129
Total	9380	2536

The number of foreign students was about 1600.

Among the remaining higher technical schools may be mentioned the three mining academies, with 645 students in Berlin, Clausthal in the Harz, and Freiberg in Saxony; the eight academies of forestry, and the high schools of agriculture, most of them affiliated to the universities, have been named in the earlier article (*Ency. Brit.*, vol. x. p. 472).

Finance.—The most important expenses, in addition to those already mentioned, which the budget of the empire has annually to meet, are the interest on the increasing imperial debt, the charges for the colonies, the subventions for steamer lines, and the charges for workmen's insurance against old age and infirmity. When the revenue is insufficient, assessments are made upon the various states. These *Matrikular Beiträge* pressed so heavily upon the minor states that, after the reorganization of the customs and excise duties in 1887, certain assignments (*Überweisungen*) or repayments to the various states were introduced of the surplus revenue from customs, tobacco, stamps, and spirits above 130,000,000 marks.

The following tables show the increasing requirements of the empire and the respective receipts (in millions of marks). The figures are to be understood as net, as the gross amount of the receipts from the posts and telegraphs, printing office, and imperial railways is not shown. For the same rcason the assignments are deducted for the ordinary expenses and also for the contributions :—

TABLE XXIV.—*Development of the Imperial Finances.*

Years.	Expenditure.			Revenue.			
	Ordinary.	Extraordinary.	Total.	Ordinary (Proper).	Matric. Contributions.	Extraordinary.	Total.
1875	395·8	238·7	634·5	316·7	69·0	185·8	571·5

Total		2,025,670

The chief branches of imperial expenditure, ordinary and extraordinary, have increased as follows (in millions of marks):—

TABLE XXVII.—*Imperial Expenditure.*

Years.	Army.	Navy.	Per Head (Marks). Army.	Per Head (Marks). Navy.	Insurance.	Debt.
1875	364·9	48·6	8·5	1·1	...	...
1885–86	371·6	52·0	7·9	1·1	...	17·4
1895–96	562·7	85·9	10·8	1·6	15·3	71·7
1899–1900	642·9	133·7	11·7	2·4	28·9	75·6
1901–2	673·1	207·5	11·9	3·7	30·4	89·0

Customs Revenue.—The *Zollverein* or German Customs Union, founded in 1828 between Prussia and Hesse, and with progressive territorial extensions during the succeeding fifty years (for details see the earlier article, *Ency. Brit.*, x. 454), had an area of about 209,281 English square miles, with a population of 40,678,000 inhabitants in 1871, when the German Empire was created. The last important addition was in October 1888, when Hamburg and Bremen were incorporated. Outside the *Zollverein* there are now only the two little free-port territories at Hamburg and Bremen, and some districts on the frontier between Baden and Switzerland. These had in 1895 an area of 26·3 square miles, and 13,061 inhabitants. The Grand Duchy of Luxemburg is included in the *Zollverein*, although it is not a part of the German Empire. After having been in general a free-trade country from about 1860 (transit-duties abolished 1861), a more protective system was introduced by the tariff of 15th July 1879, modified to a certain extent by the commercial treaties of 1892. No export duties have been imposed since 1865; but in 1879 raw materials were taxed, and in 1885 the duties on cereals and other foods were raised. The gross amount of customs revenue was as follows (in millions of marks):—

TABLE XXVIII.—*Growth of the Customs Revenue.*

Years.	Total.	Per Head (Marks).	Years.	Total.	Per Head (Marks).
1878	114·7	2·62	1895	415·4	7·94
1880	182·2	4·08	1897	472·0	8·75
1885	235·0	5·08	1899	494·1	8·89
1890	389·4	7·85			

The customs revenue in proportion to the value of the imported taxed merchandise has been calculated as follows (in millions of marks) for 1898:—

TABLE XXIX.—*Ratio of Customs Duties to Imports.*

Articles.	Imports (Value).	Customs Duties.	Per Cent. of the Supposed Value.
Raw Materials for Industry	513·2	34·1	6·6
Manufactures	790·2	116·2	14·7
Articles for Consumption (Animals)	1594·2	355·8	22·3

The principal articles from which duties were received in 1898 were the following: Colonial products, 201·4 million of marks; cereals or agricultural products, 153·7; petroleum, 67·8; timber, &c., 20·7; oils and fats, 20·4; iron and iron manufactures, 9·7; cotton and cotton goods, 9·0.

The following table gives the net amount of the four licensed articles of consumption (totals in millions and per head in marks):—

TABLE XXX.—*Licensed Articles.*

	Spirits. Total.	Spirits. Per Head.	Beer. Total.	Beer. Per Head.	Tobacco. Total.	Tobacco. Per Head.	Salt. Total.	Salt. Per Head.
1875–76	44·3	1·38	...	...	14·5	0·35	...	...
1885–86	50·1	1·35	65·0	1·42	38·5	0·84	...	...
1895–96	149·1	2·84	87·2	1·66	59·9	1·14	48·8	0·93
1898–99	162·1	2·95	94·5	1·73	65·7	1·20	50·4	0·92

There is a great difference between the German beer duty and that of the southern states, where the taxation is much higher. The duty rose in Bavaria to 6·02 marks per head in 1898, in Baden to 4·35, in Würtemberg to 4·27, and in Alsace-Lorraine to 2·05, whereas in the common territory it was only 0·88 mark.

Funds of the Empire.—The Invalid Fund for paying the pensions of the men invalided in the Franco-German war, which amounted originally to 561,000,000 marks, stood at 383,106,600 on 31st March 1900. The imperial war reserve or *Reichskriegsschatz* in coined gold and bullion in Spandau still amounts to 120,000,000 marks. The imperial debt, mainly incurred for military expenses, rose from 2,000,000 marks in 1873 to 2,418,518,000 marks on

31st March 1900. Of this amount 1,240,000,000 marks was at the rate of $3\frac{1}{2}$ per cent., 1,059,000,000 marks at 3 per cent., and 120,000,000 marks in shares (*Reichskassenscheine*) paying no interest.

Defence (see also articles ARMIES and NAVIES).—The strength of the army on a peace footing (*Friedensfuss*) was fixed by the Army Bill of 1874 at 401,659 men (or say 1 per cent. of the population at the census of 1871) for a term of seven years ending 31st December 1881. Other Bills, of 6th May 1880, 11th March 1887, 15th June 1890, and 3rd August 1893, raised the peace footing to 479,229, and the Bill of 25th March 1899 fixed the number at 502,506 men in 1902. Since 1st April 1900 the imperial army has consisted of twenty-three army corps—namely, the Prussian guards corps, sixteen Prussian corps (including the troops of the minor states in military convention with Prussia), three Bavarian corps, two Saxon corps, and one Würtemberg corps. There are now five "army inspections," each comprising from three to five corps. Generally, an army corps consists of two divisions, composed of infantry, cavalry, and artillery, but two corps have three divisions. The guards corps contains two divisions of infantry and one division of cavalry. The army, therefore, has forty-eight mixed divisions and one cavalry division. In 1902 the army consisted of 625 battalions of infantry, 482 squadrons of cavalry, 574 batteries of field artillery, thirty-eight battalions of foot artillery, twenty-six battalions of pioneers, eleven battalions of communication troops (railway and balloon), and twenty-three transport battalions.

The following table shows the strength and the organization of the imperial army on the peace footing according to the budget estimates for 1900 :—

TABLE XXXI.—*The German Army.*

Peace Footing.	Officers.	Rank and File.	Special Service.	Horses.
1. Staff, Non-Regimental Officers	2,604	169	212	...
2. Infantry, 216 regiments	12,056	367,274	2473	...
Rifles (Jäger), 18 battalions	388	11,274	72	...
Bezirkskommandos (293) (Depôts of Landwehr)	870	5,757	15	...
3. Cavalry, 93 regiments	2,406	66.229	817	65,135
4. Field Artillery, 88 regiments	2,980	64,316	962	32,879
Foot Artillery, 17 regiments, 1 battalion	872	23,207	134	43
5. Pioneers, 25 battalions	571	14,814	99	...
6. Communication Troops (Railways, 3 regiments, 1 battalion; Balloon, 2 divisions; Telegraphs, 3 battalions)	237	6,074	47	...
7. Transport, 23 battalions	322	7,963	76	4,872
8. Special Formations	544	4,615	67	...
Total	23,850	571,692	4974	102,929
Grand Total		600,516		

The special service formation includes 2165 military surgeons, 1044 paymasters, 671 veterinary surgeons, and 1094 gunsmiths.

No official returns of the war strength of the army based upon the new formation are published, but no doubt Germany would be able to call up in the last extremity from 2,800,000 to 3,000,000 trained men.

The length of the frontier lines has been already mentioned. Germany has not good natural frontiers on the east or on the west, but the great rivers crossing the country from south to north constitute good lines of defence. These are strengthened by a system of fortresses. There are at present in Germany, which is divided into ten fortress districts, six fortresses of the first class, serving as camps (marked *). In the east we find *Königsberg, with Pillau and Boyen between the lakes in East Prussia; then along the Vistula, Danzig (Weichselmünde), Graudenz, and *Thorn; and farther south, *Posen, Glogau, and Glatz. In the centre, near Berlin, are situated Küstrin, Spandau, and Magdeburg; and along the Donau, Ingolstadt and Ulm. The Franco-German frontier is guarded by Neu-Breisach, *Strassburg, *Metz, and Diedenhofen; and behind by Germersheim, Mainz, Ehrenbreitstein, near Coblenz, *Cologne, and Wesel. Along the coast, besides the great naval ports of *Wilhelmshaven on the North Sea and *Kiel on the Baltic, many points are fortified.

The development of the navy has not until recently kept pace with that of the empire's commercial interests beyond the sea. The navy has also remained behind the marine forces of the other Great Powers. The following table gives the number of ships on 1st April 1901 :—

TABLE XXXII.—*The German Navy.*

	Number.	Displacement.	Indicated Horse-Power.
First-class battleships (*Linienschiffe*)	15	142,503	142,900
Defence armour-clads	8	28,102	38,400
Gunboats, armour-clad	13	13,886	10,700
Large cruisers	11	79,470	114,500
Cruisers	29	59,895	139,250
Gunboats	5	4,441	5,800
School ships	15	29,688	26,000
Vessels for other purposes	8	11,239	17,020
Total	104	369,224	494 750

The *personnel* for 1901 consisted of 1567 officers and surgeons, 526 aspirants, and 29,078 men.

The Navy Bill (*Flottengesetz*) of 14th June 1900 provides for (*a*) a battle-fleet of 2 flag-ships and 4 squadrons, each consisting of 8 first-class battleships, 8 large cruisers, and 24 small cruisers; (*b*) an *Auslands-Flotte* of 3 large cruisers and 10 small cruisers; (*c*) a reserve of 4 battleships, 3 large cruisers, and 4 small cruisers. The total is 38 battleships, 38 large cruisers, and 110 small cruisers. During the seven years ending 1907, 17 battleships, 10 large cruisers, and 29 small cruisers were to be laid down.

The Kaiser Wilhelm Canal, which crosses Schleswig-Holstein, and was opened in 1895, facilitates the transfer of naval forces from one sea to the other.

Agriculture.—In the last quarter of the 19th century there were three official inquiries into the agricultural improvement of the soil—namely, in 1878, 1883, and 1893. The last one gave the area of the different forms of cultivation as follows (in hectares, 000 omitted): —

TABLE XXXIII.—*Area of Different Forms of Cultivation.*

	1000 Hectares.	Per Cent.
(*A*) Cultivable area—		
1. Arable lands (including gardens)	26,243	48·6
Vineyards	133	0·3
2. Meadows	5,916	10·9
Pasture grounds	2,873	5·3
3. Woods and forests	13,957	25·8
Total	49,122	90·9
(*B*) Uncultivable Area—		
1. Houses and courtyards	484	0·9
2. Uncultivable land	2,061	3·8
3. Roads and waters (streams, lakes)	2,382	4·4
Total	4,927	9·1
Grand total	54,049	100

Since 1878 the woodland area has increased by about 20,000 acres. The state forests alone occupy 17,900 square miles, or 33·3 per cent., and are increasing. About 15·6 per cent. of the area belongs to towns or villages, and one-half is in private possession. The greatest attention is paid throughout the empire to forest culture. But the supply of native timber is not sufficient, and much has to be imported. On 14th June 1895 the total number of agricultural and forest holdings was 5,580,358, with an area of 49,627,751 hectares—namely, 22,041 exclusively forest holdings, with 6,343,000 hectares, and 5,558,317 combined holdings, including orchards and vineyards, with an area of 43,284,751 hectares.

The mean growth of the several agricultural holdings—each cultivated by one household—is given in the following table (holdings and hectares in thousands) :—

Table XXXIV.—*Extension of Agricultural Holdings.*

	Holdings.		Area.	
	Total.	Per Cent.	Total.	Per Cent.
1. Holdings (under 2 hectares)	3,236	58·2	1,808	5·6
2. Small farms (from 2 to 5 hectares)	1,016	18·3	3,286	10·1
3. Middle-sized farms (from 5 to 20 hectares)	999	18·0	9,722	29·9
4. Large farms (from 20 to 100 hectares)	282	5·1	9,870	30·3
5. Large properties (100 hectares and more)	25	0·4	7,832	24·1
Total 1895	5,558	100	32,518	100
,, 1882	5,276	...	31,869	...

This table shows that in Germany the farmers (Nos. 2, 3, 4), who held in 1895 70·3 per cent. of the total agricultural area, are still of great importance. There are, besides, many landowners of large estate, but the 4180 holdings of more than 500 hectares each did not cover together more than 4,461,000 hectares, of which there were 572 with more than 1000 hectares (or 2470 acres), holding together 1,169,000 hectares. It appears from the census that 37,270,000 hectares (or 86 per cent. of a total of 43,245,000 hectares) belonged to the holder, and only 14 per cent. was held by tenants. These farms supported in 1895 18,069,000 persons, of whom 8,156,000 were actually working upon the land. If we take the mean of the five years 1895–99, the areas under the principal crops, and the yield of their products, were as follows (in thousands of hectares and thousand metric tons, 1 metric ton or 1000 kilogrammes = 2200 ℔ or ·984 of an English ton).

Table XXXV.—*Acreage under Crops, and Yield per Hectare.*

Crops, 1895–99 (Mean).	Area under Crops. 1000 Hectares.	Yield.	
		1000 Tons.	Tons Per Hectare.
Rye	5,932	8,427	14·0
Wheat	1,953	3,502	17·7
Winter Spelt (Bavaria, Würtemberg, Baden)	328	470	14·3
Oats	4,001	6,314	15·8
Barley	1,647	2,780	16·9
Potatoes	3,076	35,820	116·4
Hay	5,908	23,982	40·7

Though the crops have increased, the yield is not sufficient for the supply of the rapidly increasing population. Nearly all kinds of cereals have to be imported. There were in recent years about 150,000 tobacco planters in Germany, the mean area under plantation being 20,000 hectares in 1894–98, and the mean yield 42,200 tons. The culture of hops is important only in Bavaria, Würtemberg, Baden, and Alsace. The 40,600 hectares planted on an average in 1894–98 with hops gave 27,000 tons, of which 6500 tons were available for export. The culture of the vine is concentrated in the valleys of the Rhine and its confluents (Neckar, Main, and Mosel). The mean area of the cultivated vineyards was 117,000 hectares in 1894–98. The yield has fluctuated enormously in recent years, from 6·3 hectolitres per hectare in 1891 to 43·4 in 1896; the mean from 1888 to 1897 was 21·1. The total yield in 1891 was 748,000, and in 1896, 5,051,000 hectolitres. The mean yield from 1889 to 1891 was 5,200,000 hectolitres.

The Prussian provinces east of the Elbe, including the province of Saxony and Mecklenburg, with a population of about 19,000,000, produced from potatoes in 1898–99 2,800,000 hectolitres of pure spirits, there being 3369 distilleries. The rest of Germany, with a population of 36,000,000, produced only about 1,000,000 hectolitres from 63,500 distilleries, mostly of small size. The mean total annual product of spirits in the twelve years since Bavaria, Würtemberg, and Baden were introduced into the German area of common spirit duty in 1887 was 3,125,000 hectolitres. The number of breweries decreased from 14,000 in 1872 to 7312 in 1898, but they are at present of much larger dimensions. The quantity of beer produced, calculated per head of the population, was enormous in Bavaria and Würtemberg in proportion to the other German states; it has increased also in the latter, but not at all in the same degree as in Northern Germany (German Brewery Union) and Baden.

Table XXXVI.—*Progress of the Production of Beer.*

Year.	Millions of Hectolitres.				Per Head (Hectolitres).		
	Bavaria.	Würtemberg.	German Union.	Empire.[1]	Bavaria.	Würtemberg.	Union.
1872	10·9	4·2	16·1	32·9	256	229	52
1882	12·3	3·2	21·3	38·9	232	165	62
1892	15·1	3·7	33·2	53·6	267	183	84
1899	17·7	4·1	43·2	69·5	292	193	99

The centres of beetroot sugar production are Silesia and Posen, the province of Saxony and Hanover, with Brunswick and Anhalt. But beet is also largely grown in West Prussia, Pomerania, and Mecklenburg.

Table XXXVII.—*Progress of the Production of Beetroot Sugar.*

Year.	Manufactories.	Beetroot consumed.	Sugar (Raw).	Molasses.
		1000 Tons.	1000 Tons.	1000 Tons.
1876–77	328	3,550	289	...
1886–87	401	8,307	986	216
1896–97	399	13,721	1,739	342
1897–98	402	13,698	1,755	344
1898–99	402	12,117	1,627	306

Live Stock.—Since 1873 the number of horses and cattle has increased nearly in the same proportion as the population. But sheep-breeding has declined enormously, as in almost all European countries (from 25 to 10 millions). On the contrary, pig-breeding has spread much in recent years, and the number has doubled since 1873. Germany is still absolutely dependent on foreign countries for live stock.

[1] Including Baden (1872, 927,000 hectolitres; 1898, 2,947,000) and Alsace-Lorraine.

TABLE XXXVIII.—*Live Stock.*

Year.	Live Stock (in Millions).				Per 100 Inhabitants.			
	Horses.	Cattle.	Sheep.	Pigs.	Horses.	Cattle.	Sheep.	Pigs.
1873	3·35	15·78	25·00	7·12	8·2	38·4	60·9	17·4
1883	3·52	15·79	19·19	9·21	7·7	34·5	42·0	20·1
1892	3·84	17·56	13·59	12·17	7·8	35·5	27·5	24·6
1900	4·18	19·00	9·67	16·76	7·3	34·0	17·3	30·0

The number of goats was 3,091,000 in 1892, and 2,320,000 in 1873. Not unimportant is the rearing of bees; there were in 1892 2,034,000 bee-hives.

Fisheries.—The occupation census of 1895 showed that 42,000 persons (members of families included) were occupied in fisheries on lakes, and 34,500 on shore and on the open sea.

Minerals and Mining.—The extraordinary industrial development of the country since 1870 was largely based on its mineral wealth. Having left France much behind in mineral production, Germany now rivals Great Britain and the United States.

Coal.—The six large coalfields rank according to production nearly in the same order as in 1878.

TABLE XXXIX.—*Number and Production of Collieries in* 1900.

Coalfields.	Collieries.	Quantities.	Average No. of Hands.	Value.
		Mill. Tons.		Mill. Marks.
Ruhr	170	60·2	229,000	514·8
Upper Silesia	57	24·8	70,000	184·5
Saar	25	11·1	51,000	129·0
Zwickau, Saxony	31	4·8	23,500	60·3
Lower Silesia	18	4·8	23,000	43·8
Aachen	13	1·8	8,000	16·7
Minor fields	24	1·8	9,500	17·0
Total	338	109·2	414,000	966·1

The following table shows the rapidly increasing development of the coal production. That of lignite is added, the provinces of Saxony and Brandenburg being rich in this product:—

TABLE XL.—*Production of Coal and Lignite.*

Year.	Coal.			Lignite.		
	Quantities.	Value.	Hands.	Quantities.	Value.	Hands.
	Mill. Tons.	Mill. Mks.		Mill. Tons.	Mill. Mks.	
1871	29·4	218·4	...	8·5	26·2	...
1881	48·7	252·3	186,000	12·8	38·1	25,600
1891	73·7	589·5	283,000	20·5	54·2	35,700
1899	101·6	789·6	379,000	34·2	78·4	44,700
1900	109·3	966·1	414,000	40·5	98·5	50,900

This production permits a considerable export of coal to the west and south of the empire (1900, 15,300,000 tons), but the distance from the coalfields to the German coast is such that the import of British coal cannot yet be dispensed with (1900, nearly 6,000,000 tons). Besides this from 7,000,000 to 8,000,000 tons of lignite come annually from Bohemia.

Iron.—The production of iron ores, mostly in Lorraine and Luxemburg, though three times greater than in 1871, does not satisfy the increasing demand. Some fine sorts have to be imported from Sweden and Spain. The following is the production of pig iron. The figures in (*a*) relate to the production exclusive of that of Luxemburg, the figures in (*b*) include this:—

TABLE XLI.—*Production of Iron Ores and Pig Iron.*

Year.	Iron Ores.				Pig Iron.			
	Quantities.		Value.		Quantities.		Value.	
	(*a*)	(*b*)	(*a*)	(*b*)	(*a*)	(*b*)	(*a*)	(*b*)
	Mill. Tons.	Mill. Tons.	Mill. Marks.	Mill. Marks.	Mill. Tons.	Mill. Tons.	Mill. Marks.	Mill. Marks.
1872	4·72	5·90	38·9	42·4	1·82	1·99	211·7	222·3
1881	5·41	7·57	31·1	36·1	2·62	2·91	152·7	164·0
1891	7·55	10·66	33·4	39·4	4·10	4·64	210·1	232·4
1899	11·98	17·99	57·2	70·2	7·15	8·13	410·1	454·7
1900	12·79	18·96	63·8	77·6	7·55	8·52	491·8	551·1

The following table shows the quantities of coal (lignite included) and pig iron which have been produced by the four most important industrial countries of the world (in millions of tons):—

TABLE XLII.—*Production of Coal and Pig Iron.*

States.	Coal.		Pig Iron.	
	1871.	1897.	1871.	1897
	Mill. Tons.	Mill. Tons.	Mill. Tons.	Mill. Tons.
Great Britain	125 5	205·4	6·7	8·9
United States	41·5	181·6	1·9	9·7
Germany	42·3	120·4	1·7	6·9
France	15·9	30·7	1·2	2·5

The production of other important minerals or metals is combined in a single table, showing similar progress to that of coal and iron (in thousands of tons and millions of marks):—

TABLE XLIII.—*Production of other Minerals and Metals.*

	1871.		1899.	
	Quantity.	Value.	Quantity.	Value.
	Mill. Tons.	Mill. Mks.	Mill. Tons.	Mill. Mks.
Zinc ore	335	5·4	665	35·4
Lead ore	97	14·4	144	14·1
Copper ore	217	5·5	774	20·9
Silver and gold ore	27·4	5·3	13·5	1·9
Iron pyrites	140	1·5	145	1·0
Rock salt	140	1·1	861	3·8
Potassic salt	375	3·3	2500	32·2

The total product of the mines, including coal and lignite and iron, and some minor ores, was of the value of 314,000,000 marks in 1871, and of 1,263,000,000 marks in 1900.

Manufactures.—The general census of industries, taken on 14th June 1895, gives the following table, showing the number of the different trades and industries and of the persons engaged in them. The census gives twenty-one groups of manufactures combined in three divisions:—

TABLE XLIV.—*Industries*, 1895.

Groups.	Establishments	Persons Engaged.
1. Horticulturists	24,768	74,991
2. Fishermen, &c.	17,553	28,137
Total *A*	42,321	103,128
3. Miners	4,003	536,289
4. Workers in stone, clay, and glass	48,229	558,286
5. Workers in metal	158,618	639,755
6. Workers in machines, instruments, &c.	87,879	582,672
7. Chemical industry	10,385	115,231
8. Workers in lighting materials, soap, fats, oils, &c.	6,191	57,909
9. Textile industry	205,292	993,257
10. Workers in paper	17,631	152,909
11. Workers in leather	47,325	160,343
12. Workers in wood	219,914	598,496
13. Workers in foods and drinks	269,971	1,021,490
14. Workers in dress and washing	848,845	1,390,604
15. Workers in building	198,985	1,045,576
16. Polygraphic industry	14,193	127,867
17. Artistic industry	9,511	19,879
Total *B*—Industry, including mining and building	2,146,972	8,000,563
18. Persons in mercantile business	635,209	1,332,993
19. Persons in assurance business	7,342	22,256
20. Persons engaged in conveyance	78,696	230 431
21. Lodging and boarding	234,437	579,958
Total *C*—Commerce, innkeeping, &c.	955,684	2,165,638
All industries, incl. commerce, 1895	3,144,977	10,269,329
,, ,, ,, 1882	3,005,457	7,340,789

The rate of increase of persons engaged in industries was 40 per cent. from 1882 to 1895. The following table shows the extent of the several establishments (000 omitted):—

TABLE XLV.—*Extent of Industries.*

Year.	Small Establishments. (1 to 5 Persons.)		Middle-Sized Establishments. (6 to 50 Persons.)		Large Establishments. (more than 50.)	
	Establs.	Persons.	Establs.	Persons.	Establs.	Persons.
Total in 1895 .	2,935	4,771	191	2,454	19	3,044
Total in 1882 .	2,883	4,336	113	1 392	10	1,613
Increase per cent.	1·8	10·10	69·7	76·3	90·0	88·7

The number of establishments employing persons in domestic industry was 22,307 in 1895, with 490,711 persons engaged; 151,695 establishments or factories used steam or water, the horse-power produced amounting to 3,300,000.

Commerce.—It has been stated that the *Zollverein* or German Customs Union does not completely coincide with the frontiers of the empire. Included within it are the Grand Duchy of Luxemburg and some small Austrian communes. The following table shows the special trade. It should be remembered that Hamburg and Bremen were included in the *Zollverein* in 1888:—

TABLE XLVI.—*Special Trade* (*in millions of marks*).

Year.	Imports.	Exports.	Year.	Imports.	Exports.
1880	2859·9	2946·2	1897	4864·6	3786·2
1885	2989·9	2915·3	1898	5439·7	4010·6
1890	4272·9	3409·6	1899	5783·6	4368·4
1895	4246·1	3424·1	1900	6043·0	4752·6

The three principal groups of articles which the official returns distinguish were as follows in 1890 and 1899 (in millions of marks):—

TABLE XLVII.—*Specification of the Special Trade,* 1890 *and* 1900.

Articles.	1890.		1899.	
	Imports.	Exports.	Imports.	Exports.
Raw materials for industry	1767·4	708·3	2803·1	1111·4
Manufactures . . .	981·1	2147·5	1199·7	2982·4
Articles of consumption .	1397·0	470·7	1762·8	517·6

The following table gives further details of the special trade in 1899 (in millions of marks). The official returns distinguish the raw materials from the manufactured articles in respect of certain classes of imports and exports:—

TABLE XLVIII.—*Classes of Imports and Exports,* 1899.

	Imports.		Exports.	
Living and other Animals	186·4		19·7	
Animal Products . .	191·2		40·6	
Seeds and Plants . .	68·6		42·6	
Fuel	160·7		235·6	
Railway Waggons, Ships, &c.	12·9		19·1

Shipping and Navigation.—As with all sea-faring nations, the number of sailing vessels in the German merchant service has decreased, but the number and tonnage of steamers have greatly increased. The official returns do not include ships of less than 17⅗ gross tons. Since 1897 a statement of the gross tonnage has taken the place of the net tonnage returns. The following table shows the rapid increase in the number of steamships since 1871:—

TABLE LII.—*The Mercantile Marine of Germany.*

Year. January 1.	Sailing Vessels.		Steamers.		Total.	
	Number.	Tonnage.	Number.	Tonnage.	Number.	Tonnage.
		Net Tonnage.		Net Tonnage.		Net Tonnage.
1871 .	4372	900,000	147	82,000	4519	982,000
1881 .	4246	966,000	414	216,000	4660	1,181,000
1891 .	2757	710,000	896	723,000	3653	1,433,000
1897	2552	598,000	1126	890,000	3678	1,488,000
		Gross Tonnage.		Gross Tonnage.		Gross Tonnage.
1897	2552	632,000	1126	1,428,000	3678	2,060,000
1900	2466	632,000	1293	1,864,000	3759	2,495,000

The total number of sailors required for manning the ships of the mercantile marine in 1899 was 42,661, of whom 29,111 were on steamers. Of the total number of vessels almost half the tonnage belonged to Hamburg.

TABLE LIII.—*Ships according to States.*

	Total.		Steamers only.	
	Number.	Gross Tonnage.	Number.	Gross Tonnage.
Hamburg . . .	846	1,229,500	435	993,700

Prussian Ports . .	2074	407,500	525	314,600
Mecklenburg-Schwerin	65	39,300	32	20,200
Oldenburg . .	228	81,900	14	10,900
Lübeck . . .	26	14,100	14	14,100
Total . .	3759	2,495,300	1293	1,863,500

Much progress has been made in shipbuilding since 1890. The numbers and gross tonnage of ships built in German yards in 1899 were as follows:—

TABLE LIV.—*Ships built in* 1899.

	Total.		Steamers only.	
	Number.	Gross Tonnage	Number.	Gross Tonnage.
A—Ships Building.				
Men of War—				
For H.M. Navy . .	24	65,470	24	65,470

Men of War . . .	9	3,090	9	3,090
Merchant Vessels . .	307	209,901	222	196,738
River Ships . . .	150	22,633	33	2,852

The number and tonnage of registered sailing and steam vessels of the German Empire engaged in home and foreign trade during 1898 are given in the following table, the net tonnage being in millions of tons:—

TABLE LV.—*Trade Voyages.*

	With Cargoes.		In Ballast.	
	Number.	Tonnage.	Number.	Tonnage.
Voyages between German Ports	42,100	3·0	9,086	0·6
Voyages between German and Foreign Ports . .	18,541	10·2	3,398	1·5
Voyages between Foreign Ports	18,564	26·4	3,420	2·1
Total . . .	79,205	39·6	15,904	4·2

The maritime development of the German ports may be seen from the following table, giving the tonnage of the vessels cleared and entered (in millions of net register tons):—

TABLE LVI.—*Clearances and Entries of Ships.*

Years.	Entered.			Cleared.		
	German.	Foreign	Total.	German.	Foreign.	Total.
1873–75	2·97	3·46	6·43	2·94	3·38	6·32
1880–85	4·50	4 67	9·17	4·53	4·69	9·22
1895	7·91	7 28	15·19	8·03	7·25	15·28
1899	10·25	7·74	17·99	10·31	7·72	18·03

The tonnage of the vessels entered in 1899 under the British flag was 4,353,000 tons. Other countries were as follows: Sweden 958,000 tons, Denmark 925,000, Norway 711,000, Netherlands 285,000, Russia 237,000, France 90,700.

The principal ports of the German Empire ranked as follows in 1899 as to the tonnage of ships entered and cleared (in millions of tons):—

TABLE LVII.—*Number of Ships Entered and Cleared in the most important Ports.*

Ports.	Entered.		Cleared.	
	With Cargoes.	In Ballast.	With Cargoes.	In Ballast.
Hamburg . . .	7·17	0·43	5·36	2·36
Stettin	1·43	0·04	0·90	0·55
Bremerhaven . . .	1·15	0·08	1·04	0·24
Bremen	0·80	0·03	0·64	0·20
Danzig	0·54	0·11	0·50	0·16
Lübeck	0·53	0·01	0·38	0·16
Kiel	0·50	0·02	0·36	0·14
Königsberg . . .	0·33	0·01	0·37	0·03

Railways.—The German railway system nearly doubled from 1865 to 1875. Since that time Prussia has followed the southern states, where the building of railways has from the outset been regarded as a Government duty. To-day the great majority of German railways are owned by the state governments.

TABLE LVIII.—*Development of the Railway System.*

Year. January 1.	Length in Miles.		Total. English Miles.
	Government Lines. English Miles.	Lines belonging to Private Companies. English Miles.	
1875	7,493	10,019	17,522
1885	19,823	3,286	23,109
1895	25,811	2,277	28,088
1900	28,087	2,510	30,597

Of the total in 1900, 21,050 miles were trunk-lines and 9547 branch lines. Germany possesses the most extensive network of railways of any country except the United States. The United Kingdom has about 22,000 miles. As regards proportion to the area, Germany had in 1899 144 miles for every 1000 English square miles, but in Great Britain and Ireland the proportion is about 180 per 1000 square miles. Narrow-gauge lines, not comprised in the above figures, measured 1075 miles in 1900. The financial condition of the railways shows, as to broad-gauge lines, that the total capital invested was 12,134 millions of marks at the end of the financial year 1898, or 405,503 marks per mile; the interest is estimated at 6·06 per cent., the excess of receipts (1898, 1840 millions) over the expenditure (111 millions) being 723 millions of marks. The number of men employed was 509,600, including 308,600 workmen. In 1897–98 320·8 millions of metric tons of goods were carried, and the number of passengers conveyed was 756 millions.

Internal Navigation.—The length of navigable rivers in Germany is 5779 miles, that of canalized rivers 1451 miles, and of canals proper 1551 miles. The construction of canals had almost ceased for a long time, but in recent years the Ruhr and the Ems (Dortmund-Ems Canal) and the Elbe and the Trave (near Lübeck) have been joined by canals. The number of vessels engaged in internal navigation was in 1897 22,000, with a tonnage of 3,370,000 tons. Not included in the above figures is the Kaiser-Wilhelm Canal, joining the Baltic and North Sea and traversing Holstein from Kiel Bay to the mouth of the Elbe. The canal was built between 1887 and 1895. The length is 61 miles, its breadth at the bottom is 72 feet, at the surface 213 feet, and the depth 29½ feet. The number of ships passing through the canal has steadily increased from 20,068 vessels of 1,751,000 tons in 1896 to 29,045 of 4,282,000 tons in 1900, men-of-war not included.

Posts and Telegraphs.—With the exception of Bavaria and Würtemberg, which have administrations of their own, all the German States belong to the Imperial Postal District (*Reichspostgebiet*). The following table shows the extension of the net of post offices for the whole empire, and also the estimated number of letters and packets delivered:—

TABLE LIX.—*Post Office Development.*

Year.	Post Offices.	Men Employed.	Letters Entered.	Packets Entered.	Letters. Per Head.
			Millions.	Millions.	
1872	7,518	...	501·2	62·7	12·1
1880	9,460	...	843·2	86·6	18·7
1890	24,952	128 687	1634·4	120·8	33·2
1899	36,388	206,945	2724·3	184·6	49·4

The number of post offices was 18 per 100 English square miles in 1899.

Telegraph statistics are given in the subjoined table:—

TABLE LX.—*Imperial Telegraphs.*

Year.	Telegraph Offices.	Length of Lines.	Length of Wire.	Number of Messages Entered.	
				Total.	Per Head.
		Miles.	Miles.	Millions.	
1872	2,359	23,425	78,022	9·7	0·24
1880	9,980	44,011	158,986	13·5	0·38
1890	17,200	64,194	226,663	21·8	0·45
1899	23,716	79,870	294,900	37·9	0·69

There were 188 places provided with telephone service in 1888, and 13,175 in 1899; the number of towns in telephonic communication with one another was 1964 in 1899. The number of receivers rose from 37,313 in 1888 to 229,391 in 1899, and that of telephonic messages from 155 millions in 1888 to 621 millions in 1899.

The amount of money circulated by means of the post has also much increased.

TABLE LXI.—*Money circulated through the Post.*

	1872.	1899.
	Millions of Marks.	
Value of charged Letters and Parcels .	14,096	17,235
Value of Payments through Post Office.	55	462
Value of Money Orders issued . .	530	8212

Banking and Credit.—The amount of money coined from the foundation of the empire (1871) to the end of March 1900 is shown in the following table (in millions of marks):—

TABLE LXII.—*Coinage.*

Gold	3631·5
Silver	543·4
Nickel	64·6
Copper	14·6
Total	4254·1
Withdrawn	59·6
Surplus	4194·5

The total value of thalers, which are still legal tender, was estimated in 1894 at about 400,000,000 marks.

There are eight note-issuing banks (*Notenbanken*), that is to say, the Imperial Bank (*Reichsbank*) in Berlin, the Frankfort Bank, the Bayrische Notenbank in Munich, the Sächsische Bank in Dresden, the Würtemberger Notenbank in Stuttgart, the Badische Bank in Karlsruhe, the Bank für Süddeutschland in Darmstadt, and the Braunschweiger Bank. The total mean amount of notes in circulation (100, 500, and 1000 marks) was 1322 millions of marks in 1899. *Reichskassenscheine*, or small paper notes for five, twenty, and fifty marks, have been in circulation of recent years to the amount of 120 millions of marks. The following table shows the average financial condition of the above-named eight note-issuing banks in 1899 (in millions of marks):—

TABLE LXIII.—*Note-Issuing Banks.*

	Liabilities.			Assets.	
	Total.	Reichsbank.		Total.	Reichsbank.
Capital . .	219·7	120·0	Coin and Bullion	911·5	825·5
Reserve Fund .	47·6	30·0	Notes (Empire and Banks)	50·8	35·1
Notes in Circulation .	1322·2	1141·7	Bills . . .	1049·4	817·1
Other Liabilities	649·2	554·9	Other Assets .	229·0	168·9
Total . .	2238·7	1846·6	Total . .	2240·7	1846·6

Life Assurance.—There were forty-six companies in 1900 for the insurance of life. The number of persons insured was 1,446,249 at the end of that year, the insurances amounting to 6397 millions of marks. Besides these are sixty-one companies—of which forty-six are comprised in the above life assurance companies—paying subsidies in case of death or of military service, endowments, &c. Some of these companies are industrial. The transactions of all these companies included in 1900 over 4,179,000 persons, and the amount of insurances was 1606 millions of marks.

Insurance for Working Classes.—The speech of the Emperor William I. from the throne on 17th November 1881 inaugurated a great system of public care for the working classes, such as is not to be found in any other great state. A series of Acts passed during the years 1883 to 1892 introduced obligatory insurance for all the working classes in case of sickness, accident, or incapacity, so that now only an insurance of the widows of workmen is required to complete this system. The insurance in case of sickness is carried out by 23,000 local sick funds, and included in 1898 over 9,223,000 workmen. These funds had receipts amounting to 165,800,000 marks in 1898, and possessed property of the value of 163,900,000 marks. The workmen contribute at the rate of two-thirds, the employers at the rate of one-third. The accident insurance embraces 18,246,000 persons, belonging to 5,110,000 establishments, with 522 professional co-operative associations. Contributions are made by employers only. The receipts were 83,380,000 marks in 1898, and the property was valued at 161,500,000 marks at the end of that year. The old age and invalid insurance is carried out by thirty-one large territorial offices, to which must be added nine special unions. The premiums are paid half by employers and half by workmen, but the empire contributes 50 marks to every annuity. The income of the forty establishments was 163,564,000 marks in 1898 (including 24,400,000 marks of imperial contributions). The capital collected was 671,900,000 marks. The number of annuitants—the old age annuities beginning at seventy years of age—was 512,000 in 1898, and the amount of annuities 68,940,000 marks.

Money, Weights, and Measures.—The variety of German coinage was replaced after the creation of the empire by a united one (Act of 4th December 1871, supplemented by that of 9th June 1873). The standard of value is gold. Silver is legal tender only up to 20 marks. One mark of 100 pfennige is equal to 100/279 grammes of fine gold, so that 1 livre gold (500 grammes) has a value of 1395 marks. The gold coins are 20- and 10-mark pieces, called *doppelkrone* and *krone*. The small 5-mark pieces in gold have been withdrawn. The 20-mark piece contains 7·16846 grammes of fine gold, the fineness being 900/1000. The pound sterling is of the value of 20·43 marks. The silver coins are 5-, 2-, and 1-mark pieces and 50-pfennig pieces. The nickel coins are 20-, 10-, and 5-pfennig pieces, and the bronze coins 2- and 1-pfennig pieces.

The metrical system of weights and measures came into force on 1st January 1872, and the people soon became familiarized with it.

II.—HISTORY, 1870–1900.

The new empire.

The foundation of the empire in 1871 begins a new era in the history of Germany. The rivalry of the dynasties to which for so long the interests of the nation had been sacrificed now ceased. By the treaties of Versailles the kingdoms of Bavaria and Würtemberg, and the grand duchy of Baden, as well as the southern provinces of the grand duchy of Hesse, were added to the North German confederation. Henceforward all the German states that had survived the struggle of 1866, with the exception of the empire of Austria, the grand duchy of Luxemburg, and the principality of Liechtenstein, were incorporated in a permanent federal state under the leadership of Prussia. No important alterations were made in the constitution of 1867. The states retained their autonomy except in those matters which were expressly transferred to the imperial authorities; the princes retained their sovereignty; the king of Prussia, though he now took the title of German Emperor, was only *primus inter pares;* he was president of the confederation, but had no suzerainty over the other princes. None the less, from this time the acts of the State Governments and Parliaments have ceased to have more than a local importance; the history of the nation is centred in Berlin, in the *Bundesrath* or Federal Council, in which the interests of the individual states are represented; in the Reichstag, in which the feelings and wishes of the nation are expressed; and above all, in the Prussian Government and imperial executive.

The constitution of the empire.

The constitution, as established in 1867 and revised in 1871, derives its authority from a double source:—the treaties between the sovereign states of which the confederation is composed, and the vote of the constituent assembly of 1867. It created for federal purposes a *Bundesrath* or Council, in which Prussia had 17 votes; Saxony, 4; Mecklenburg-Schwerin and Brunswick, 2 each; all the other states, 1. In 1871 Bavaria received 6 votes; Würtemberg, 4; Baden, 3; and Hesse, 2 additional votes. The Council, the meetings of which are private, exercises a general control over the administration, and all laws require its sanction. In legislation it is assisted by the Reichstag, which is elected by universal suffrage. The Federal Budget has to be passed each year in the form of a law. The office of president of the confederation, to which in 1871 the title of German Emperor was attached, is permanently vested in the king of Prussia. The emperor commands the army and navy; appoints all federal officials; summons the Council and Reichstag; publishes the laws and administers them. All his acts (except orders as commander of the army and navy) must be countersigned by the chancellor, who is the only responsible imperial minister, and is also president of the Council. The federation formed a customs union (except for the free cities of Hamburg and Bremen), and all legislation on customs, as well as excise on salt, tobacco, beer, brandy, and sugar, belongs to the federal authorities. Post-office, navy, and consular service are also federal. The states retain the right of diplomatic representation, but there is also a common diplomatic representation appointed by the president. The subjects on which the imperial authorities were qualified to legislate were, besides naval and military matters and customs, the law of domicile, trade, banking, money, weights and measures, patents and copyright, mercantile marine, railways, rivers and canals, posts and telegraphs, the press, the law of association, medical law, criminal law, legal procedure, and commercial law.

The southern states when they joined the confederation reserved certain privileges: the king of Bavaria kept the command of his army in time of peace, and military jurisdiction; he, as well as the king of Würtemberg, retains the right of appointing officers. Excise duties on beer and brandy in both kingdoms and in Baden were reserved. Both kingdoms retained the separate administration of their own posts and telegraphs. Bavarian railways were exempt from imperial supervision except for military purposes, and Bavaria kept the right to have its own laws on marriage and domicile.

The empire and the states.

The constitution has stood the test. No serious changes have been made, no serious constitutional questions have arisen. The number of states of which the empire consists has remained unaltered;[1] occasional disputes have been settled harmoniously in a legal manner. The special rights reserved to Bavaria and Würtemberg have not proved, as was feared, a danger to the stability of the empire. Much apprehension had been caused by the establishment of a permanent committee for foreign affairs in the Council, over which the Bavarian representative was to preside; but the clause remained a dead letter. There is no record that the committee ever met until July 1900, when it was summoned to consider the situation in China; and on that occasion it probably formed a useful support to the Government, and helped to still apprehension lest a too adventurous policy should be pursued. Another clause determined that in a division in the Reichstag on any law which did not concern the whole empire, the representatives of those states which were not concerned should not vote. This, had it been retained, would have destroyed the coherence of the Reichstag as representative of the whole nation. It was repealed in 1873. The permission to maintain diplomatic missions has been equally harmless: most of the states have recalled all their diplomatic representatives; Saxony, Bavaria, and Würtemberg have maintained only those at Vienna, the Vatican,

[1] The only formal change is that the duchy of Lauenburg, which since 1865 had been governed by the king of Prussia as a separate principality (but without a vote in the *Bundesrath*) was in 1876 incorporated in the Prussian province of Schleswig-Holstein.

and at St Petersburg. Bavaria has even voluntarily adopted many imperial laws from which it was legally exempted; for instance, the laws of settlement.

If the states have been loyal to the empire, the imperial Government has also respected the constitutional privileges of the states. The harmonious working of the constitution depends on the union of policy between the empire and Prussia, for it is the power of Prussia which gives strength to the empire. This was practically secured by the fact that the emperor, who is king of Prussia, appoints the chancellor, and the chancellor is generally president of the Prussian ministry as well as minister of foreign affairs—in his person the Government of the two is identified. For twenty years the double office was held by Bismarck, who, supported as he was by the absolute confidence of the emperor, and also of the allied princes, held a position greater than that ever attained by any subject in modern Europe since the time of Richelieu. For ten months in 1873 he, indeed, resigned the office of minister president to Roon; and in the same way Caprivi, during the years 1893–94, held the chancellorship alone; but in neither case was the experiment successful, and Hohenlohe and Bülow adhered to the older plan. So important is the practical co-operation of the imperial administration and the Prussian Government, that it has become customary to appoint to seats in the Prussian ministry the more important of the secretaries of state who administer imperial affairs under the chancellor. Delbrück, head of the imperial chancery, had held this position since 1868; in 1877 Bülow, secretary of state for foreign affairs, was appointed Prussian minister, and in recent years this has become the ordinary practice. One result of this is to diminish the control which the Prussian parliament is able to maintain over the Prussian ministry.

Prussia and the empire.

In the federal council Prussian policy nearly always prevails, for though Prussia has only seventeen votes out of fifty-eight, the smaller states of the North nearly always support her; practically she controls the vote of Waldeck, and since 1885 those of Brunswick. A definite defeat of Prussia on an important question of policy must bring about a serious crisis; it is generally avoided because, as the meetings are secret, an arrangement or compromise can be made. Bismarck, knowing that nothing would more impede the consolidation of the empire than an outbreak of local patriotism, always so jealous of its rights, generally used his influence to avoid constitutional disputes, and discouraged the discussion of questions which would require an authoritative interpretation of the constitution. It was, however, opposition in the Bundesrath which obliged him to abandon his scheme for imperial railways, and when, in 1877, it was necessary to determine the seat of the new supreme court of justice, the proposal of the Government that Berlin should be chosen was outvoted by thirty to twenty-eight in favour of Leipzig. On this occasion Bismarck accepted the decision, but when important interests were at stake he showed himself as ready to crush opposition as in the older days, as in the case of Hamburg and Bremen (see below).

The great personal qualities of the reigning emperors and the widely-extended family connexions of the house of Hohenzollern have enabled them to hold with ease their position as leaders among the ruling families. So far as is known, with one or two unimportant exceptions, the other princes have loyally accepted their new position. It is only as regards the house of Brunswick that the older dynastic questions still have some political importance.

The other princes who were dispossessed in 1866 have all been reconciled to Prussia. The elector of Hesse and the duke of Nassau have formally relinquished their claims. In 1883 the daughter of the duke of Augustenburg, the former claimant to the duchies of Schleswig and Holstein, married the heir to the Prussian throne, who became Wilhelm II. On the other hand, the royal family of Hanover has never ceased to protest against the acts by which they were deprived of their dominions. King George (*q.v.*) to the end of his days, whether in Austria or in France, still regarded himself as in a state of war with Prussia. As he had used his large personal property to organize a regiment in order to regain his possessions, the Prussian Government had sequestrated that part of his income, amounting to some £50,000, over which they had control, and used it as secret service money chiefly for controlling the press; to this fund the name "Welfen-Fond" was commonly given. After 1870 the Hanoverian regiment was disbanded, but the sequestration continued. The death of the old king in 1878 made no difference, for his son in a letter to the king of Prussia announced that he assumed and maintained all his father's rights, and that he did not recognize the legal validity of the acts by which he was, as a matter of fact, prevented from enjoying them. His protest was supported by a considerable number of his former subjects, who formed a party in the Reichstag. The marriage of the duke of Cumberland (the title by which the king called himself till he could come into his possessions) with Princess Thyra of Denmark in the same year was made the occasion of a great demonstration, at which a deputation of the Hanoverian nobility assured the duke of their continued attachment to his house.

Hanover.

After Bismarck's retirement, the emperor attempted to bring about a reconciliation with the duke and the Hanoverians. His attention had been drawn to the bad moral effect of the use to which the Welfen-Fond was applied, and on the duke of Cumberland writing him a letter, in which, while maintaining his claims to the throne of Hanover, he recognized the empire and undertook not to support any enterprise against the empire or Prussia, with the consent of the Prussian parliament the sequestration of his property was removed. The attitude of passive resistance is, however, still maintained, and has affected the position of the duchy of Brunswick.

In 1884 William, duke of Brunswick, died after a reign of fifty-four years. The younger son of the duke who fell at Quatre Bras, he had been called to the throne in 1831 to take the place of his elder brother Charles, who had been deposed. Duke Charles had died at Geneva in 1873, and as both brothers were childless, the succession went to the duke of Cumberland as head of the younger branch of the house of Brunswick-Lüneburg. Duke William before his death had arranged that the government should be carried on by a council of regency so long as the heir was prevented from actually assuming the government; at the end of a year a regent was to be chosen from among the non-reigning German princes. He hoped in this way to save his duchy, the last remnant of the dominions of his house, from being annexed by Prussia. As soon as he died the town was occupied by the Prussian troops already stationed therein; the duke of Cumberland published a patent proclaiming his succession; the council of state, however, declared, in agreement with the Bundesrath, that the relations in which he stood to the kingdom of Prussia were inconsistent with the alliances on which the empire was based, and that therefore he could not assume the government. The claim of the duke of Cambridge as the only male heir of full age was referred to the Bundesrath, but the duke refused to bring it before that body, and after a year the Brunswick Government elected as regent Prince Albert of Hohenzollern, to hold office so long as the true heir was prevented from entering on his rights.

Duchy of Brunswick.

By this arrangement Brunswick, which hitherto had steadily opposed all attempts to assimilate and subordinate its institutions to those of Prussia, though it retains formal independence, has been brought into very close dependence upon Prussia, as is the case with all the other northern states. In them the armies are incorporated in the Prussian army; the railways are generally merged in the Prussian system; indirect taxation, post-office, and nearly the whole of the judicial arrangements are imperial. None, however, has yet imitated the prince of Waldeck, who in 1867, at the wish of his own subjects, transferred the administration of his principality to Prussia. The local estates still meet, and the principality still forms a separate administrative district, but it is managed by a director appointed by Prussia. The chief reason for this act was that the state could not meet the obligations laid upon it under the new system, and the responsibility for any deficit now rests with Prussia.

Waldeck.

A curious difficulty, a relic of an older state of society, recently arose in the principality of Lippe. On the death of Prince Waldemar in 1895 (his brother and heir the reigning prince Alexander being childless and insane) a dispute as to the succession arose. The nearest agnate was a count of Biesterfeld, but Prince Adolf of Schaumburg-Lippe, the representative of a younger line, claimed the succession on the ground that the marriage of Count Biesterfeld's grandfather with Fraülein von Unruh was not valid for the purposes of transmitting rights of succession. Under the old empire this would have been decided by the imperial courts, for the answer depended on very old-established principles concerning the different grades of nobility. Under the new empire there is no tribunal qualified to give a decision. The estates of Lippe wished to refer it to the Bundesrath, but the council refused to take the responsibility; at last the two claimants agreed to abide by the arbitration of the king of Saxony. The jurists appointed by him decided in favour of the count, who therefore, as next heir, now acts as regent. Some political importance attaches to the case, for it is not impossible that similar difficulties may occur elsewhere, and the open support given by the emperor to the prince of Schaumburg, who had married his sister, caused apprehension of Prussian aggression. It is probable, in fact, that on the death of the present regent the claims of the prince will again be revived, for the validity of the regent's marriage, and therefore the claim of his children to succeed, is also contested.

Lippe.

A much more serious question of principle arose from the peculiar circumstances of Mecklenburg. The grand duchies, which, though divided between two lines of the ducal house, have a common constitution, are the only state in Germany in which the parliament still takes the form of a meeting of the estates—the nobility and the cities—and has not been altered by a written constitution. Repeated attempts of the grand dukes to bring about a reform were stopped by the opposition of the Ritterschaft. Büffing, one of the Mecklenburg representatives in the Reichstag, therefore proposed to add to the imperial constitution a clause that in every state of the confederation there should be a parliamentary assembly. This was supported by all the Liberal party, and carried repeatedly; of course it was rejected by the Bundesrath, for it would have established the principle that the constitution of each state could be revised by the imperial authorities, which would have completely destroyed their independence. It is noticeable that on the last occasion, in 1894, when this motion was introduced it was lost; a striking instance of the decay of Liberalism.

The Mecklenburg constitution.

The public political history naturally centres around the debates in the Reichstag, and also those in the Prussian parliament. The table on page 681 above shows the position of parties in the German Reichstag. In the Prussian parliament are discussed questions of education, local government, religion, and direct taxation, and though of course it is only concerned with Prussian affairs, Prussia is so large a part of Germany that its decisions have a national importance. The two parliaments sit in Berlin at the same time, an inconvenient arrangement which made Bismarck propose the introduction of biennial budgets, a custom which exists in Bavaria and other states. The constitution is very different, for while the Reichstag, which consists of only one House, is elected by universal suffrage, the Prussian parliament (Landtag) consists of two Houses, and the Lower House is chosen by indirect election on a complicated system which gives great influence to wealth. One result of this was that the Socialists, so powerful in the Reichstag, until the year 1900 refused even to contest seats in the Prussian parliament. In the Prussian parliament the members receive payment, but the members of the Reichstag do not. A very large number of the members sit in both, and the parties in the two are nearly identical. In fact, the political parties in the Reichstag are generally directly descended from the older Prussian parties.

Public affairs: Political parties.

The first place belongs to the Conservatives, who for twenty years had been the support of the Prussian Government. The party of the feudal aristocracy in North Germany, they were strongest in the agricultural districts east of the Elbe; predominantly Prussian in origin and in feeling, they had great influence at court and in the army, and desired to maintain the influence of the orthodox Lutheran Church. To them Bismarck had originally belonged, but the estrangement begun in 1866 constantly increased for the next ten years. A considerable number of the party had, however, seceded in 1867 and formed a new union, to which was given the name of the *Deutsche Reichspartei* (in the Prussian House they were called the *Frei Conservativen*). These did not include any prominent parliamentary leaders, but many of the most important ministers and officials, including Moltke and some of the great nobles. They were essentially a Government party, and took no part in the attacks on Bismarck which came from the more extreme Conservatives, the party of the *Kreuzzeitung*.

Conservatives.

The events of 1866 had brought about a similar division among the Progressives. A large section, including the most important leaders, determined to support Bismarck in his national policy and to subordinate to this, though not to surrender, the struggle after Constitutional development. Under the name of *National-liberal-partei* they became in numbers as in ability the strongest party both in Prussia and the empire. Essentially a German, not a Prussian, party, they were joined by the Nationalists from the annexed provinces of Hanover and Hesse; in 1871 they were greatly strengthened by the addition of the National representatives from the southern states; out of fourteen representatives from Baden twelve belonged to them, seventeen out of eighteen Würtemberger, and a large majority of the Bavarians. It was on their support that Bismarck depended in building up the institutions of the empire. The remainder of the Progressives, the *Fortschrittspartei*, maintained their protest against the military and monarchical elements in the state; they voted against the Constitution in 1867 on the ground that it did not provide sufficient guarantees for popular liberty, and in

National Liberals.

1871 against the treaty with Bavaria because it left too much independence to that state. Their influence was strongest in Berlin, and in the towns of East Prussia; they have always remained characteristically Prussian.

These great parties were spread over the whole of Germany, and represented the great divisions of political thought. To them must be added others which were more local, as the *Volkspartei* or People's party in Würtemberg, which kept alive the extreme democratic principles of 1848, but was opposed to Socialism. They had been opposed to Prussian supremacy, and in 1870 for the time completely lost their influence, though they were to regain it in later years.

Of great importance was the new party of the Centre. Till the year 1863 there had been a small party of Catholics in the Prussian parliament who received the name of the *Centrum*, from the part of the House in which they sat. They had diminished during the years of conflict, and disappeared in 1866. In December 1870 it was determined to found a new party which, while not avowedly Catholic, practically consisted entirely of Catholics. The programme required the support of a Christian-Conservative tendency; it was to defend positive and historical law against Liberalism, and the rights of the individual states against the central power. They were especially to maintain the Christian character of the schools. Fifty-four members of the Prussian parliament at once joined the new party, and in the elections for the Reichstag in 1871 they won sixty seats. Their strength lay in Westphalia and on the Rhine, in Bavaria and the Polish provinces of Prussia. The close connexion with the Poles, the principle of federalism which they maintained, the support given to them by the Bavarian "patriots," their protest against the "revolution from above" as represented equally by the annexation of Hanover and the abolition of the Papal temporal power, threw them into strong opposition to the prevailing opinion, an opposition which received its expression when Mallincrodt declared that "justice was not present at the birth of the empire." For this reason they were generally spoken of by the Nationalist parties as *Reichsfeindlich.*

The Centre.

This term may be more properly applied to those who still refuse to recognize the legality of the acts by which the empire was founded. First among these are the Guelphs, or, as they call themselves, *Hannoverische Rechtspartei*, members of the old Hanoverian nobility who represent the rural districts of Hanover and still regard the duke of Cumberland as their lawful ruler. They make no attempt at conspiracy or rebellion; that would indeed be useless, but they maintain a protest against what is still felt to have been an act of injustice. Neither the lapse of time nor the death of King George has seriously affected their numbers. They have repeatedly demonstrated their attachment to the exiled house, and it is noteworthy that in the elections of 1898 nine members of the Guelph party were returned. The attachment of the nobility to the exiled house is a quality which neither the present emperor nor his predecessors could afford to look on with disfavour, for it is at least evidence of that strong monarchical sentiment which they value so highly. A pleasant concession to Hanoverian feeling was made in 1899, when the emperor ordered that the Hanoverian regiments in the Prussian army should be allowed to assume the names and so continue the traditions of the Hanoverian army which was disbanded in 1866.

Guelphs.

The Government has also not succeeded in reconciling to the empire the alien races which have been incorporated in the kingdom of Prussia.

From the Polish districts of West Prussia, Posen, and Silesia a number of representatives are sent to Berlin to protest against their incorporation in the empire. Bismarck, influenced by the older Prussian traditions, always adopted towards them an attitude of uncompromising opposition. The growth of the Polish population has caused much anxiety; supported by the Roman Catholic Church, the Polish language has advanced, especially in Silesia, and this is only part of the general tendency, so marked throughout Central Europe, for the Sclavonians to gain ground upon the Teutons. The Prussian Government has attempted to prevent this by special legislation and severe administrative measures. In 1885 and 1886 large numbers of Austrian and Russian Poles who had settled in these provinces were expelled. Windthorst thereupon raised the question in the Reichstag, but the Prussian Government refused to take any notice of the interpolation on the ground that there was no right in the constitution for the imperial authority to take cognizance of acts of the Prussian Government. In the Prussian parliament Bismarck introduced a law taking out of the hands of the local authorities the whole administration of the schools and giving them to the central authority, so as to prevent instruction being given in Polish. A further law authorized the Prussian Government to spend £5,000,000 in purchasing estates from Polish families and settling German colonists on the land. The commission, which was appointed for the purpose, during the next ten years bought land to the amount of about 200,000 acres, and on it settled more than 2000 German peasants. It appears doubtful whether this will have any appreciable effect, for the Poles have founded a society to protect their own interests, and have often managed to profit by the artificial value given to their property. It has, however, caused great bitterness among the Polish peasants, and the effect on the population is also counteracted by the fact that the large proprietors in purely German districts continue to import Polish labourers to work on their estates.

Poles.

In the general change of policy that followed after the retirement of Bismarck an attempt was made by the emperor to conciliate the Poles. Concessions were made to them in the matter of schools, and in 1891 a Pole, Stabelewski, who had taken a prominent part in the Kulturkampf, was accepted by the Prussian Government as Archbishop of Posen. A moderate party arose among the Poles which accepted their position as Prussian subjects, gave up all hopes of an immediate restoration of Polish independence, and limited their demands to that free exercise of the religion and language of their country which was enjoyed by the Poles in Austria. They supported Government Bills in the Reichstag, and won the commendation of the emperor. Unfortunately, for reasons which are not apparent, the Prussian Government did not continue a course of conciliation; administrative edicts still further limited the use of the Polish language, even religious instruction was to be given in German, and an old royal ordinance of 1817 was made the pretext for forbidding private instruction in Polish. A further sum of £5,000,000 was voted for the settlement of German colonists, and the whole influence of the law, of education, and of the army is used to compel the Poles to forget their mother-tongue and the traditions of their country. Further measures are promised to meet the danger to German nationality which is anticipated from the fact that numerous Poles have migrated to the more prosperous districts in the west.

Compared with the Polish question, that of the Danes in North Schleswig is of minor importance; they number less than 150,000, and there is not among them, as among the Poles, the constant encroachment along an extended line of frontier; there is also no religious question involved. These Danish subjects have elected one member to the Reichstag, whose duty is to demand that they should be handed over to Denmark. Up to the year 1878 they could appeal to the Treaty of Prague; one clause in it determined that the inhabitants of selected districts should be allowed to vote whether they should be Danish or German. This was inserted merely to please Napoleon; after his fall there was no one to demand its execution. In 1878, when the Triple Alliance was concluded, Bismarck, in answer to the Guelphic demonstration at Copenhagen, arranged with Austria, the other party to the Treaty of Prague, that the clause should lapse. Since then the Prussian Government, by prohibiting the use of Danish in the schools and public offices, and by the expulsion from Schleswig of residents of Danish nationality, has used the customary means for compelling all subjects of the king to become German in language and feeling.

Danes.

The attempt to reconcile the inhabitants of Elsass-Lothringen to their condition has been equally unsuccessful. The provinces had been placed under the immediate rule of the emperor and the chancellor, who was minister for them; laws were to be passed by the Reichstag. In accordance with the Treaty of Frankfort, the inhabitants were permitted to choose between French and German nationality, but all who chose the former had to leave the country; before 1st October 1872, the final day, some 50,000 had done so. In 1874, for the first time, the provinces were enabled to elect members for the Reichstag; they used the privilege to send fifteen *Elsasser*, who, after delivering a formal protest against the annexation, retired from the House; they joined no party, and took little part in the proceedings except on important occasions to vote against the Government. The same spirit was shown in the elections for local purposes. It seemed to be the sign of a change when a new party, the *Autonomisten*, arose, who demanded as a practical concession that the dictatorship of the chancellor should cease and local self-government be granted. To some extent this was done in 1879; a resident governor or *statthalter* was appointed, and a local representative assembly, which was consulted as to new laws. All the efforts of Manteuffel, the first governor, to win the confidence of the people failed; the anti-German feeling increased; the party of protestors continued in full numbers. The next governor, Prince Hohenlohe, had to use more stringent measures, and in 1888, to prevent the agitation of French agents, an imperial decree forbade any one to cross the frontier without a passport. Since 1890 there has been, especially in the neighbourhood of Strasburg, evidence of a spread of national German feeling, probably to a great extent due to the settlement of Germans from across the Rhine.

Elsass-Lothringen.

The persistence of opposition in these districts is remarkable. In all cases the inhabitants have shared in the great growth of material prosperity; the Reichsland has been treated with great generosity; the taxes are very low. Strasburg has grown rapidly in wealth and numbers. The foundation of a new university, and the great impulse given to trade by the opening up of new railway and water communications, have added greatly to its prosperity. But the national feeling in Germany is so imperious and so intolerant of opposition, it is so constantly put forward as the only legitimate basis for the existence of the state, as naturally to arouse opposition among those who do not share it. The presence of these parties, amounting often to one-tenth of the whole, has added greatly to the parliamentary difficulties of the Government.

The great work since 1870 has been that of building up the institutions of the empire. For the first time in the history of Germany there has been a strong administration ordering, directing, and arranging the life of the whole nation. The work which in England was done by the Plantagenets, which in France was begun by the House of Bourbon and completed by the Revolution, is now proceeding, and the city of Berlin is rapidly acquiring a position similar to that held by London and Paris. The unification of Germany was not ended by the events of 1866 and 1871; it was only begun. The work has throughout been done by Prussia; it has been the extension of Prussian principles and Prussian administrative energy over the whole of Germany. It naturally falls into two periods; the first, which ends in 1878, is that in which Bismarck depended on the support of the National Liberals. They were the party of union and uniformity. The Conservatives were attached to the older local diversities, and Bismarck had therefore to turn for help to his old enemies, and for some years an alliance was maintained, always precarious but full of results.

The period 1870 to 1878.

The great achievement of the first period was legal reform. In nothing else was legislation so much needed. Forty-six districts have been enumerated, each of which enjoyed a separate legal system, and the boundaries of these districts seldom coincided with the frontiers of the states. Everywhere the original source of law was the old German common law, but in each district it had been wholly or partly superseded by codes, text-books, and statutes to a great extent founded on the principles of the Roman civil law. Owing to the political divisions, however, this legislation, which reached back to the 14th century, had always been carried out by local authorities. There had never been any effective legislation applicable to the whole nation. There was not a state, not the smallest principality, in which some authoritative but imperfect law or code had not been published. Every free city, even an imperial village, had its own "law," and these exist down to the present time. In Bremen the foundation of the civil code still were the statutes of 1433; in Munich, those of 1347. Most of the states by which these laws had been published had long ago ceased to exist; probably in every case their boundaries had changed, but the laws remained valid (except in those cases in which they had been expressly repealed) for the whole of the district for which they had been originally promulgated. Let us take a particular case. In 1591 a special code was published for the upper county of Katzellenbogen. More than a hundred years ago Katzellenbogen was divided between the neighbouring states. But till the end of the 19th century (which in Germany meant the end of 1899) this code still retained its validity for those villages in Hesse, and in the Prussian province of Hesse, which in old days had been parts of Katzellenbogen. The law, however, had to be interpreted so as to take into consideration later legislation by the kingdom of Westphalia, the electorate of Hesse, and any other state (and they are several) in which for a short time some of these villages might have been incorporated.

Legal reform.

In addition to these earlier imperfect laws, three great codes have been published, by which a complete system was applied to a large district: the Prussian Code of 1794, the Austrian Code of 1811, and the Code Napoléon, which applied to all Germany left of the Rhine; for neither Prussia, nor Bavaria, nor Hesse had ever ventured to interfere with the French law. In Prussia therefore the older provinces came under the Prussian Code, the Rhine provinces had French law, the newly annexed provinces had endless variety, and in part of Pomerania considerable elements of Swedish law still remained, a relic of the long Swedish occupation. On the other hand, some districts to which the Prussian Code applied no longer belonged to the kingdom of Prussia—for instance, Anspach and Bayreuth, which are now in Bavaria. In other parts of Bavaria in the same way Austrian law still ran, because they had been Austrian in 1811. In two states only was there a more or less uniform system: in Baden, which had adopted a German translation of the Code Napoléon; and in Saxony, which had its own code, published in 1865. In criminal law and procedure there was an equal variety. In one district was trial by jury in an open court; in another the old procedure by written pleadings before a judge. In many districts, especially in Mecklenburg and some of the Prussian provinces, the old feudal jurisdiction of the manorial courts survived.

The constant changes in the law made by current legislation in the different states really only added to the confusion, and though imperial laws on those points with which the central government was qualified to deal superseded the state laws, it is obvious that to pass occasional Acts on isolated points would have been only to introduce a further element of complication.

It was therefore convenient, so far as was possible, to allow the existing system to continue until a full and complete code dealing with the whole of one department of law could be agreed upon, and thus a uniform system (superseding all older legislation) be adopted. Legislation, therefore, has generally taken the form of a series of elaborate codes, each of which aims at scientific completeness, and further alterations have been made by amendments in the original code. The whole work has been similar in character to the codification of French law under Napoleon; in most matters the variety of the older system has ceased, and the law of the empire is now comprised in a limited number of codes.

A beginning had been made before the foundation of the empire; as early as 1861 a common code for trade, commerce, and banking had been agreed upon by the states included in the Germanic Confederation. It was adopted by the new confederation in 1869. In 1897 it was replaced by a new code. In 1869 the criminal law had been codified for the North German Confederation, and in 1870 there was passed the *Gewerbeordnung*, an elaborate code for the regulation of manufactures and the relations of masters to workmen. These were included in the law of the empire, and the work was vigorously continued.

In 1871 a commission was appointed to draw up regulations for civil and criminal procedure, and also to frame regulations for the organization of the law courts. The draft code of civil procedure, which was published in December 1872, introduced many important reforms, especially by substituting public and verbal procedure for the older German system, under which the proceedings were almost entirely carried on by written documents. It was very well received. The drafts for the other two laws were not so successful. Protests, especially in South Germany, were raised against the criminal procedure, for it was proposed to abolish trial by jury and substitute over the whole empire the Prussian system, and a sharp conflict arose as to the method of dealing with the press. After being discussed in the Reichstag, all three projects were referred to a special commission, which after a year reported to the diet, having completely remodelled the two latter laws. After further amendment they were eventually accepted, and became law in 1877. By these and other supplementary laws a uniform system of law courts was established throughout the whole empire; the position and pay of the judges, the regulations regarding the position of advocates, and costs, were uniform, and the procedure in every state was identical. To complete the work a supreme court of appeal was established at Leipzig, which was competent to hear appeals not only from imperial law, but also from that of the individual states.

By the original constitution, the imperial authorities were only qualified to deal with criminal and commercial law; the whole of the private law, in which the variety was greatest, was withdrawn from their cognizance. Lasker, to remedy this defect, proposed, therefore, an alteration in the constitution, which, after being twice carried against the opposition of the Centre, was at last accepted by the Bundesrath. A commission was then appointed to draw up a civil code. They completed the work by the end of 1887; the draft which they then published was severely criticized, and it was again submitted for revision to a fresh commission, which reported in 1895. In its amended form this draft was accepted by the Reichstag in 1896, and it entered into force on the 1st of January 1900. The new Civil Code deals with nearly all matters of law, but excludes those concerning or arising out of land tenure and all matters in which private law comes into connexion with public law; for instance, the position of Government officials, and the police: it excludes also the relations of master and servant, which in most points are left to the control of individual states. It was accompanied by a revision of the laws for trade and banking. This is far the most important measure which has hitherto been carried by the initiative of a private member of the Reichstag, and though Lasker himself was dead and his party broken up long before the new code became law, and though in many ways the contents of the code did not satisfy the expectations of those who had helped to carry it, it remains a lasting memorial of the reforming zeal and the national enthusiasm of the first years of the empire.

Equal in importance to the legal was the commercial reform, for this was the condition for building up the material prosperity of the country. Germany was a poor country, but the poverty was to a great extent the result of political causes. Communication, trade, manufactures, were impeded by the political divisions, and though the establishment of a customs union had preceded the foundation of the empire, the removal of other barriers required imperial legislation. A common system of weights and measures was introduced in 1868. The reform of the currency was the first task of the empire. In 1871 Germany still had seven different systems; the most important was the thaler and the groschen, which prevailed over most of North Germany, but even within this there were considerable local differences. Throughout the whole of the south of Germany and in some North German states the gulden and kreuzer prevailed. Then there were other systems in Hamburg and in Bremen. Everywhere, except in Bremen, the currency was on a silver basis. In addition to this each state had its own paper money, and there were over 100 banks with the right of issuing bank-notes according to regulations which varied in each state. In 1871 a common system for the whole empire was established, the unit being the mark, which was divided into a hundred pfennig: a gold currency was introduced; no more silver was to be coined, and silver was made a legal tender only up to the sum of twenty marks. The gold required for the introduction of the new coinage was provided from the indemnity paid by France. Great quantities of thalers, which hitherto had been the staple of the currency, were sold.

Commercial reform.

The right of coinage was, however, left to the individual states, and as a special concession it was determined that the rulers of the states should be permitted to have their head placed on the reverse of the coins. All paper currency, except that issued by the empire, ceased, and in 1873 the Prussian Bank was converted into the Imperial Bank.

The Bank. The Prussian (now the Imperial) Bank is a society of private capitalists, but the management is in the hands of the State. The extension of the privilege has always been supported by the Liberals, but in 1891 and again in 1900 unsuccessful attempts were made by the Conservatives, supported by the Agrarians and Anti-Semites, to prevent the renewal of the Bank Act.

Bimetallism. The introduction of a gold standard has not been completely carried through. In 1877, owing to the depreciation of silver, the sale of silver was suspended, and thalers to the value of about 400 million marks were reserved. About half of these are in circulation, and are full legal tender. The Conservative reaction which followed deprived of their influence the economists who were more strongly in favour of a gold standard, and the fall in prices caused in Germany, as in other countries, a demand for the adoption of a bimetallic standard, especially among agriculturists; of recent years bimetallism has become one of the chief points in the Agrarian and even in the Conservative programme. In 1895 a motion was carried in the Reichstag requesting the Governments to summon a conference for an international regulation of the currency. The Council, however, refused to do this, on the ground that there was no prospect that a discussion would lead to any practical result, unless the Indian Government would reopen the mints.

Banking laws. Closely connected with the reform of the currency and the codification of the commercial law was the reform of the banking laws. Here the tendency to substitute uniform imperial laws for state laws is clearly seen. Before 1870 there had been over 100 banks with the right of issue, and the conditions on which the privilege was granted varied in each state. By the Bank Act of 1875, which is the foundation of the existing system, the right of granting the privilege is transferred from the Governments of the states to the Bundesrath. The existing banks could not be deprived of the concessions they had received, but unless they submitted to the regulations of the new law their notes were not to be recognized outside the limits of the state by which the concession had been granted. All submitted to the conditions except the Brunswick Bank, which still holds a unique position. The experience of Germany in this matter has been different from that of England, for nearly all the private banks have since surrendered their privilege, and there now remain only six banks (of which only one, the Frankfurter Bank, is in Prussia) which still issue bank-notes. The other five are situated in Bavaria, Saxony, Würtemberg, Baden, and Hesse, and the continuance of their privilege is a natural accompaniment of the political importance which still belongs to these states.

The organization of the imperial post-office was carried out with great success by Herr v. Stephan (*q.v.*), who remained at the head of this department from its creation till his death in 1897. Proposals to Bavaria and Würtemberg to surrender their special rights have not been accepted.

Railways. The unification of the railways caused greater difficulties. Nearly every state had its own system; there was the greatest variety in the methods of working and in the tariffs, and the through traffic, so important for the commercial prosperity of the country, was very ineffective. In Baden, Würtemberg, and Hanover the railways were almost entirely the property of the State, but in all other parts public and private lines existed side by side, an arrangement which seemed to combine the disadvantages of both systems. In 1871 three-quarters of the railway lines belonged to private companies, and the existence of these powerful private corporations, while they were defended by many of the Liberals, was, according to the national type of thought, something of an anomaly. Bismarck always attached great importance to the improvement of the railway service, and he saw that uniformity of working and of tariffs was very desirable. In the constitution of the empire he had introduced several clauses dealing with it. The independent administration of its lines by each state was left, but the empire received the power of legislating on railway matters; it could build lines necessary for military purposes even against the wish of the state in whose territory they lay, and the states bound themselves to administer their lines as part of a common system.

In order to carry out these clauses a law was passed in 1873 creating an imperial railway office which should have a general control over all the railways. It does not appear, however, that this office has ever been able to acquire any real power or influence; it has drafted laws on railway management, but they have never been laid before the Reichstag. Bismarck desired to go farther, and acquire all the railways for the empire. He found, however, that it was impossible to carry any Bill enforcing this. He therefore determined to begin by transferring to the imperial authority the Prussian state railways; had he been able to carry this out the influence of the imperial railways would have been so great that they would gradually have absorbed those of the other states. The Bill was carried through the Prussian parliament, but the opposition aroused in the other states was so great that he did not venture even to introduce in the Bundesrath a law empowering the empire to acquire the Prussian railways. In many of the state parliaments resolutions were carried protesting against the system of imperial railways, and from that time the preservation of the local railway management has been the chief object towards which, in Saxony, Bavaria, and Würtemberg, local feeling has been directed. It was not till a later period that Bismarck was able, though in a modified form, to carry out his plans.

The result of the legal reform and other laws has been greatly to diminish the duties of the State Governments, for every new imperial law permanently deprives the local parliaments of part of their authority. Generally there remains to them the control of education and religion—their most important duty—police, all questions connected with land tenure, local government, the raising of direct taxes, and, in the larger states, the management of railways. The introduction of workmen's insurance, factory legislation, and other measures dealing with the condition of the working classes by imperial legislation, was at a later period still further to limit the scope of state legislation.

Meanwhile the Government was busy perfecting the administration of the national defences. From the war indemnity large sums had been expended on coast defence, on fortifications, and on replacing the equipment and stores destroyed during the war. A special fund, producing annually about a million pounds, was put aside, from which pensions to the wounded, and to the widows and orphans of those who had fallen, should be provided. It was also desirable to complete the military organization. It must be remembered that technically there is no German army, as there is no German minister of war. *Army organization.* Each state, however small, maintains its own contingent, subject to its own prince, who has the right and the obligation of administering it according to the provisions of the treaty by which he entered the federation. Practically they are closely tied in every detail of military organization. The whole of the Prussian military system, including not only the obligation to military service, but the rules for recruiting, organization, drill, and uniforms, has to be followed in all the states; all the contingents are under the command of the Emperor, and the soldiers have to swear obedience to him in addition to the oath of allegiance to their own sovereign. It is therefore not surprising that, having so little freedom in the exercise of their command, all the princes and free cities (with the exception of the three kings) arranged separate treaties with the king of Prussia, transferring to him (except for certain formal rights) the administration of their contingents, which are thereby definitely incorporated in the Prussian army. The first of these treaties was arranged with Saxe-Coburg-Gotha in 1861; those with the other North German states followed at short intervals after 1866. The last was that with Brunswick, which was arranged in 1885; Duke William had always refused to surrender the separate existence of his army. Owing to the local organization, this does not prevent the contingent of each state from preserving its separate identity; it is stationed in its own district, each state contributing so many regiments.

In 1872 a common system of military jurisprudence was introduced for the whole empire except Bavaria (a revised code of procedure in military courts was accepted by Bavaria in 1898); finally, in February 1874 an important law was laid before the Reichstag codifying the administrative rules. This superseded the complicated system of laws and royal ordinances which had accumulated in Prussia during the fifty years that had elapsed since the system of short service had been introduced; the application to other states of course made a clearer statement of the laws desirable. Most of this was accepted without opposition or debate. On one clause a serious constitutional conflict arose. In 1867 the peace establishment had been provisionally fixed by the constitution at 1 per cent. of the population, and a sum of 225 thalers (£33, 15s.) had been voted for each soldier. This arrangement had in 1871 been again continued to the end of 1874, and the peace establishment fixed at 401,659. The new law would make this permanent. If this were done the power of the Reichstag over the administration would be seriously weakened; their assent would no longer be required for either the number of the army or the money. The Government attached great importance to the clause, but the Centre and the Liberal parties combined to throw it out. A disastrous struggle was averted by a compromise suggested by Bennigsen. The numbers were fixed for the next seven years (the so-called *septennat*); this was accepted by the Government, and carried against the votes of the Centre and some of the Progressives. On this occasion the Fortschrittpartei, already much diminished, split up into two sections. The principle then established has since been maintained; the periodical votes on the army have become the occasion for formally testing the strength of the Government. In 1880 the strength was fixed for the next seven years, 1881–88, at 427,274. The arrangement was revised in 1887, and again in 1893 and in 1898, but on the last two occasions the vote was taken for five instead of seven years.

The Septennat.

The influence of Liberalism, which served the Government so well in this work of construction, brought about also the conflict with the Roman Catholic Church which distracted Germany for many years. The causes were, indeed, partly political. The Ultramontane party in Austria, France, and Bavaria had, after 1866, been hostile to Prussia; there was some ground to fear that it might still succeed in bringing about a Catholic coalition against the empire, and Bismarck lived in constant dread of European coalitions. The Polish sympathies of the Church in Germany made him regard it as an anti-German power, and the formation of the Catholic faction in parliament, supported by Poles and Hanoverians, appeared to justify his apprehensions. But besides these reasons of state there was a growing hostility between the triumphant National parties and the Ultramontanes, who taught that the Pope was greater than the Emperor and the Church than the nation. The conflict had already begun in Baden. As in every other country, the control of the schools was the chief object of contention, but the Government also claimed a control over the education and training of the clergy. With the formation of the empire the conflict was transferred from Baden to Prussia, where there had been for thirty years absolute peace, a peace gained, indeed, by allowing to the Catholics complete freedom; the Prussian constitution ensured them absolute liberty in the management of ecclesiastical affairs; in the ministry for religion and education there was a separate department for Catholic affairs, and (owing to the influence of the great family of the Radziwills) they enjoyed considerable power at court.

Kultur kampf.

The latent opposition was aroused by the Vatican decrees. A small number of Catholics, including several men of learning and distinction, refused to accept Papal Infallibility. They were encouraged by the Bavarian court, which maintained the Josephinist tradition and was jealous of any encroachment of the Papacy; but besides this the Protestants throughout Germany and all opponents of the Papacy joined in the agitation. They made it the occasion for an attack on the Jesuits; even in 1869 there had been almost a riot in Berlin when a chapel belonging to a religious order was opened there. During 1870 and 1871 meetings were held by the Gustavus Adolphus Verein, and a great Protestant conference was called, at which resolutions were passed demanding the expulsion of the Jesuits and condemning the Vatican decrees. As the leaders in these meetings were men like Virchow and Bluntschli, who had been lifelong opponents of Catholicism in every form, the result was disastrous to the Liberal party among the Catholics, for a Liberal Catholic would appear as the ally of the bitterest enemies of the Church; whatever possibility of success the Old Catholic movement might have had was destroyed by the fact that it was supported by those who avowedly wished to destroy the influence of Catholicism. No bishop joined it in Germany or in Austria, and few priests, though the Governments were ready to protect them in the enjoyment of the privileges secured to Catholics, and to maintain them in the use of the temporalities. There was no great following among the people; it was only in isolated places that priests and congregation together asserted their rights to refuse to accept the decrees of the Church. Without the help of the bishops, the leaders had no legal basis; unsupported by the people, they were generals without an army, and the attempt to use the movement for political purposes failed.

Old Catholics.

None the less this was the occasion for the first proceedings against the Catholics, and curiously enough the campaign began in Bavaria. The archbishop of Munich had published the Vatican decrees without the *Regium Placetum*, which was required by the constitution, and the Government continued to treat Old Catholics as members of the Church. In the controversy which ensued, Lutz, the chief member of the ministry, found himself confronted by an Ultramontane majority, and the priests used their influence to stir up the people. He therefore turned for help to the imperial Government, and at his instance a clause was added to the penal code forbidding priests in their official capacity to deal with political matters. (This law, which still exists, is popularly known as the Kanzlei or Pulpit-paragraph.) It was of course opposed by the Centre, who declared that the Reichstag had no right to interfere in what was after all a religious question, and the Bavarian Opposition expressed much indignation that their Government should turn for help to the Protestants of the North in order to force upon the Catholics of Bavaria a law which they could not have carried in that state.

For twenty years the Old Catholics continued to be a cause of contention in Bavaria, until the struggle ended in the victory of the Ultramontanes. In 1875 the parliament which had been elected in 1869 for six years came to an end. In order to strengthen their position for the new elections, the Liberal ministry, who owed their position chiefly to the support of the king, by royal ordinance ordered a redistribution of seats. By the constitution this was within their power, and by clever manipulation of the constituencies they brought it about that the Ultramontane majority was reduced to two. It does not appear that this change represented any change of feeling in the majority of the people. The action of the Government, however, caused great indignation, and in a debate on the address an amendment was carried petitioning the king to dismiss his ministry. They offered their resignation, but the king refused to accept it, publicly expressed his confidence in them, and they continued in office during the lifetime of the king, although in 1881 the growing reaction gave a considerable majority to the Ultramontane party. After the death of the king the prince-regent, Luitpold, still retained the old administration, but several concessions were made to the Catholics in regard to the schools and universities, and in 1890 it was decided that the claim of the Old Catholics to be regarded officially as members of the Church should no longer be recognized.

Meanwhile at Berlin petitions to the Reichstag demanded the expulsion of the Jesuits, and in 1872 an imperial law to this effect was carried; this was again a serious interference with the control over religious matters reserved to the states. In Prussia, the Government having determined to embark on an anti-Catholic policy, suppressed the Catholic division in the ministry, and appointed a new minister, Falk, a Liberal lawyer of uncompromising character. A law was carried placing the inspection of schools entirely in the hands of the state; hitherto in many provinces it had belonged to the clergy, Catholic or Protestant. This was followed by the measures to which the name *Kulturkampf* really applied (an expression used first by Virchow to imply that it was a struggle of principle between the teaching of the Church and that of modern society). They were measures in which the State no longer, as in the school inspection law or in the introduction of civil marriage, defended its prerogatives against the Church, but assumed itself a direct control over ecclesiastical matters.

May Laws.

At the end of 1872 and the beginning of 1873 Falk laid before the Prussian Lower House the draft of four laws. Of these, one forbade ministers of religion from abusing ecclesiastical punishment; the second, which was the most important, introduced a law already adopted in Baden, that no one should be appointed to any office in the Church except a German, who must have received his education in a German gymnasium, have studied for three years in a German university, and have passed a State examination in philosophy, history, German literature, and classics; all ecclesiastical seminaries were placed under the control of the State, and all seminaries for boys were forbidden. Moreover, every appointment to an ecclesiastical benefice was to be notified to the president of the province, and the confirmation could be refused on the ground that there were facts which could support the assumption that the appointment would be dangerous to public order. The third law appointed a court for trying ecclesiastical offences, to which was given the right of suspending both priests and bishops, and a fourth determined the procedure necessary for those who wished to sever their connexion with the Roman Catholic Church.

As these laws were inconsistent with those articles of the Prussian constitution which guaranteed to a religious corporation the independent management of its own affairs, it was therefore necessary to alter the constitution. This was done, and a later law in 1875 repealed the articles altogether.

The opposition of the bishops to these laws was supported even by many Protestants, especially by the more orthodox Lutherans, who feared the effect of this increased subjection of all Churches to the State; they were opposed also by the Conservative members of the Upper House. All, however, was unavailing. Bismarck in this case gave the Liberals a free hand, and the laws eventually were carried and proclaimed on 15th May 1873; hence they got the name of the May laws, by which they are always known. The bishops meanwhile had held a meeting at Fulda, at the tomb of St Boniface, whence they addressed a protest to the king, and declared that they would be unable to recognize the laws as valid. They were supported in this by the Pope, who addressed a protest personally to the Emperor. The laws were put into force with great severity. Within a year six Prussian bishops were imprisoned, and in over 1300 parishes the administration of public worship was suspended. The first sufferer was the cardinal archbishop of Posen, Count Ledochowski. He refused to report to the president of the province appointments of incumbents; he refused also to allow the Government commissioners to inspect the seminaries for priests, and when he was summoned before the new court refused to appear. He was then deprived of the temporalities of his office; but the Polish nobles continued to support him, and he continued to act as bishop. Heavy fines were imposed upon him, but he either could not or would not pay them, and in March 1874 he was condemned to imprisonment for two years, and dismissed from his bishopric. The bishop of Treves, the archbishop of Cologne, and other bishops soon incurred a similar fate. These measures of the Government, however, did not succeed in winning over the Catholic population, and in the elections for the Reichstag in January 1874 the party of the Centre increased in number from 63 to 91; 1,443,170 votes were received by them. In Bavaria the Ultramontanes won a complete victory over the more moderate Catholics. The Prussian Government proceeded to further measures. According to the ordinary practice towards parties in opposition, public meetings were broken up on the smallest pretence, and numerous prosecutions for insult to Government officials were brought against members of the party. The Catholic agitation was, however, carried on with increased vigour throughout the whole empire; over a hundred newspapers were founded (three years before there had been only about six Catholic papers in the whole of Germany), and great numbers of pamphlets and other polemical works were published. The bishops from their prisons continued to govern the dioceses; for this purpose they appointed representatives, to whom they transferred their rights as Ordinary and secretly authorized priests to celebrate services and to perform the other duties of an incumbent. To meet this a further law was passed in the Prussian parliament, forbidding the exercise of ecclesiastical offices by unauthorized persons, and it contained a provision that any one who had been convicted under the law could be deprived of his rights of citizenship, ordered to live in a particular district, or even expelled from the kingdom. The result was that in numerous parishes the police were occupied in searching for the priest who was living there among the people; although his habitation was known to hundreds of people, the police seldom succeeded in arresting him. Bismarck confesses that his doubts as to the wisdom of this legislation were raised by the picture of heavy but honest *gens d'armes* pursuing light-footed priests from house to house. This law was followed by one authorizing the Government to suspend, in every diocese where the bishop continued recalcitrant, the payment of that contribution to the Roman Catholic Church which by agreement had been given by the State since 1817. The only result of this was that large sums were collected by voluntary contribution among the Roman Catholic population.

The Government tried to find priests to occupy the vacant parishes; few consented to do so, and the *Staatskatholiken* who consented to the new laws were avoided by their parishioners. Men refused to attend their administration; in some cases they were subjected to what was afterwards called boycotting, and it was said that their lives were scarcely safe. Other laws excluded all religious orders from Prussia, and civil marriage was made compulsory; this law, which at first was confined to Prussia, was afterwards passed also in the Reichstag.

These laws were all peculiar to Prussia, but similar legislation was carried out in Baden and in Hesse, where in 1872 the Ultramontane and Particularist minister, Dalwick, had retired, and after the interval of a year been succeeded by a Liberal ministry. In Würtemberg alone the Government continued to live peaceably with the bishops.

The Government had used all its resources; it had alienated millions of the people; it had raised up a compact party of nearly a hundred members in parliament. The attempt of the Liberals to subjugate the Church had given to the Papacy greater power than it had had since the time of Wallenstein.

The ecclesiastical legislation and other Liberal measures completed the alienation between Bismarck and the Conservatives. In the Prussian parliament seventy-three members broke off from the rest, calling themselves the "old Conservatives"; they used their position at court to intrigue against him, and hoped to bring about his fall; Count Arnim (*q.v.*) was looked upon as his successor. In 1876, however, the party in Prussia reunited on a programme which demanded the maintenance of the Christian character of the schools, cessation of the Kulturkampf, limitation of economic liberty, and repression of social democracy, and this was accepted also by the Conservatives in the Reichstag. This reunion of the Conservatives became the nucleus of a great reaction against Liberalism. It was not confined to any one department of life, but included Protection as against Free Trade, State Socialism as against individualism, the defence of religion as against a separation of Church and State, increased stress laid on the monarchical character of the State, continued increase of the army, and colonial expansion.

Reaction against Liberalism.

The causes of the change in public opinion, of which this was to be the commencement, are too deep-seated to be discussed here. We must note that it was not peculiar to Germany; it was part of that great reaction against Liberal doctrine which marked the last quarter of the 19th century in so many countries. In Germany, however, it more rapidly attained political importance than elsewhere, because Bismarck used it to carry out a great change of policy. He had long been dissatisfied with his position. He was much embarrassed by the failure of his ecclesiastical policy. The alliance with the Liberals had always been half-hearted, and he wished to regain his full freedom of action; he regarded as an uncontrollable bondage all support that was not given unconditionally. The alliance had been of the nature of a limited co-operation between two hostile powers for a definite object; there had always been suspicion and jealousy on either side, and a rupture had often been imminent, as in the debates on the military Bill and the law reform. Now that the immediate object had been attained, he wished to pass on to other projects in which they could not follow him. Political unity had been firmly established; he desired to use the whole power of the imperial Government in developing the material resources of the country. In doing this he placed himself in opposition to both the financial and the economic doctrines of the Liberals.

The new period which now begins was introduced by some alterations in the official organization. Hitherto almost the whole of the internal business had been concentrated in the imperial chancery (Reichskanzeramt), and Bismarck had allowed great freedom of action to Delbrück, the head of the office. Delbrück, however, had resigned in 1876, justly foreseeing that a change of policy was imminent in which he could no longer co-operate with Bismarck. The work of the office was then divided between several departments, at the head of each of which was placed a separate official, the most important receiving the title of secretary of state. Bismarck, as always, refused to appoint ministers directly responsible either to the Emperor or to Parliament; the new officials in no way formed a collegiate ministry or cabinet. He still retained in his own hands, as sole responsible minister, the ultimate control over the whole imperial administration. The more important secretaries of state, however, are political officials, who are practically almost solely responsible for their department; they sit in the Bundesrath, and defend their policy in the Reichstag, and they often have a seat in the Prussian Ministry. Moreover, a law of 1878, the occasion of which was Bismarck's long absence from Berlin, empowered the chancellor to appoint a substitute or representative (*stellvertreter*) either for the whole duties of his office or for the affairs of a particular department. The signature of a man who holds this position gives legal validity to the acts of the Emperor.

Official changes.

This reorganization was a sign of the great increase of work which had already begun to fall on the imperial authorities, and was a necessary step towards the further duties which Bismarck intended to impose upon them.

Meanwhile the relations with the National Liberals reached a crisis. Bismarck remained in retirement at Varzin for nearly a year; before he returned to Berlin, at the end of 1877, he was visited by Bennigsen, and the Liberal leader was offered the post of vice-president of the Prussian Ministry and vice-president of the Bundesrath. The negotiations broke down, apparently because Bennigsen refused to accept office unless he received a guarantee that the constitutional rights of the Reichstag should be respected, and unless two other members of the party, Forckenbeck and Stauffenberg, were given office. Bismarck would not assent to these conditions, and, even if he had been willing to do so, could hardly have overcome the prejudices of the Emperor. On the other hand, Bennigsen refused to accept Bismarck's proposal for a state monopoly of tobacco. From the beginning the negotiations were indeed doomed to failure, for what Bismarck appears to have aimed at was to detach Bennigsen from the rest of his party and win his support for an anti-Liberal policy.

The session of 1878, therefore, opened with a feeling of great uncertainty. The Liberals were very suspicious of Bismarck's intentions. Proposals for new taxes, especially one on tobacco, were not carried. Bismarck took the opportunity of avowing that his ideal was a monopoly of tobacco, and this statement was followed by the resignation of Camphausen, minister of finance. It was apparent that there was no

Period after 1878.

prospect of his being able to carry through the great financial reform which he contemplated. He was looking about for an opportunity of appealing to the country on some question which would enable him to free himself from the control of the Liberal majority. The popular expectations were expressed in the saying attributed to him, that he would "crush the Liberals against the wall." The opportunity was given by the Social Democrats.

Social Democracy.

The constant increase of the Social Democrats had for some years caused much uneasiness not only to the Government, but also among the middle classes. The attacks on national feeling, the protest against the war of 1870, the sympathy expressed for the Communards, had offended the strongest feelings of the nation, especially as the language used was often very violent; the soldiers were spoken of as murderers, the generals as cut-throats. Attacks on religion, though not an essential part of the party programme, were common, and practically all avowed Social Democrats were hostile to Christianity. These qualities, combined with the open criticism of the institutions of marriage, of monarchy, and of all forms of private property, joined to the deliberate attempt to stir up class hatred, which was indeed an essential part of their policy, caused a widespread feeling that the Social Democrats were a serious menace to civilization. They were looked upon even by many Liberals as an enemy to be crushed; much more was this the case with the Government. Attempts had already been made to check the growth of the party. Charges of high treason were brought against some. In 1872 Bebel and Liebknecht were condemned to two years' imprisonment. In 1876 Bismarck proposed to introduce into the Criminal Code a clause making it an offence punishable with two years' imprisonment "to attack in print the family, property, universal military service, or other foundation of public order, in a manner which undermined morality, feeling for law, or the love of the Fatherland." The opposition of the Liberals prevented this from being carried. Lasker objected to these "elastic paragraphs," an expression for which in recent years there has been abundant use. The ordinary law was, however, sufficient greatly to harass the Socialists. In nearly every state there still existed, as survivals of the old days, laws forbidding the union of different political associations with one another, and all unions or associations of working men which followed political, socialistic, or communistic ends. It was possible under these to procure decisions in courts of justice dissolving the General Union of Workers and the coalitions and unions of working men. The only result was, that the number of Socialists steadily increased. In 1874 they secured nine seats in the Reichstag, in 1877 twelve, and nearly 500,000 votes were given to Socialist candidates.

Legislation against the Socialists.

There was then no ground for surprise that, when in April 1878 an attempt was made on the life of the Emperor, Bismarck used the excuse for again bringing in a law expressly directed against the Socialists. It was badly drawn up and badly defended. The National Liberals refused to vote for it, and it was easily defeated. The Reichstag was prorogued; six days later a man named Nobiling again shot at the Emperor, and this time inflicted dangerous injuries. It is only fair to say that no real proof was brought that the Socialists had anything to do with either of these crimes, or that either of the men was really a member of the Socialist party; nevertheless, a storm of indignation rose against them. The Government seized the opportunity. So great was the popular feeling, that a repressive measure would easily have been carried; Bismarck, however, while the excitement was at its height, dissolved the Reichstag, and in the elections which took place immediately the Liberal parties, who had refused to vote for the first law, lost a considerable number of seats, and with them their control over the Reichstag.

The first use which Bismarck made of the new parliament was to deal with the Social Democrats. A new law was introduced forbidding the spread of Socialistic opinions by books, newspapers, or public meetings, empowering the police to break up meetings and to suppress newspapers. The Federal Council could proclaim a state of siege in any town or district, and when this was done any individual who was considered dangerous by the police could be expelled. The law was carried by a large majority, being opposed only by the Progressives and the Centre. It was applied with great severity. The whole organization of newspapers, societies, and trades unions was at once broken up. Almost every political newspaper supported by the party was suppressed; almost all the pamphlets and books issued by them were forbidden; they were thereby at once deprived of the only legitimate means which they had for spreading their opinions. In the autumn of 1878 the minor state of siege was proclaimed in Berlin, although no disorders had taken place and no resistance had been attempted, and sixty-seven members of the party were excluded from the city. Most of them were married and had families; money was collected in order to help those who were suddenly deprived of their means of subsistence. Even this was soon forbidden by the police. At elections every kind of agitation, whether by meetings of the party or by distribution of literature, was suppressed. The only place in Germany where Socialists could still proclaim their opinions was in the Reichstag. Bismarck attempted to exclude them from it also. In this, however, he failed. Two members who had been expelled from Berlin appeared in the city for the meeting of the Reichstag at the end of 1878. The Government at once asked permission that they should be charged with breaking the law. The Constitution provided that no member of the House might be brought before a court of justice without the permission of the House, a most necessary safeguard. In this case the permission was almost unanimously refused. Nor did they assent to Bismarck's proposal that the Reichstag should assume power to exclude from the House members who were guilty of misusing the liberty of speech which they enjoyed there. Bismarck probably expected, and it is often said that he hoped, to drive the Socialists into some flagrant violation of the law, of such a kind that it would be possible for him completely to crush them. This did not happen. There were some members of the party who wished to turn to outrage and assassination. Most, a printer from Leipzig, who had been expelled from Berlin, went to London, where he founded the *Freiheit*, a weekly paper, in which he advocated a policy of violence. He was thereupon excluded from the party, and after the assassination of the Tsar had to leave England for Chicago. A similar expulsion befell others who advocated union with the Anarchists. As a whole, however, the party remained firm in opposition to any action which would strengthen the hands of their opponents. They carried on the agitation as best they could, chiefly by distributing reports of speeches made in the Reichstag. A weekly paper, the *Social-Democrat*, was established at Zürich. Its introduction into Germany was of course forbidden, but it was soon found possible regularly to distribute thousands of copies every week in every part of the country, and it continued to exist till 1887 at Zürich, and till 1890 in London. In August of 1880 a congress of Socialists was held at the castle of Wyden, in Switzerland, at which about eighty members of the party met, discussed their policy, and separated before the police knew anything of it. Here it was determined that the members of the Reichstag, who were protected by their position, should henceforward be the managing committee of the party, and arrangements were made for contesting the elections of 1881. A similar meeting was held in 1883 at Copenhagen, and in 1887 at St Gallen, in Switzerland. Notwithstanding all the efforts of the Government, though every kind of public agitation was forbidden, they succeeded in winning twelve seats in 1881. The law, which had obviously failed, was renewed in 1881; the state of siege was applied to Hamburg, Leipzig, and Stettin, but all to no purpose; and though the law was twice more renewed, in 1886 and in 1888, the feeling began to grow that the Socialists were more dangerous under it than they had been before.

The elections of 1878, by weakening the Liberal parties, enabled Bismarck also to take in hand the great financial reform which he had long contemplated.

Financial reform.

At the foundation of the North German Confederation it had been arranged that the imperial exchequer should receive the produce of all customs duties and also of excise. It depended chiefly on the taxes on salt, tobacco, brandy, beer, and sugar. So far as the imperial expenses were not covered by these sources of revenue, until imperial taxes were introduced, the deficit had to be covered by contributions paid by the individual states in proportion to their population. All attempts to introduce fresh imperial taxes had failed. Direct taxation was opposed by the governments of the states, which did not desire to see the imperial authorities interfering in those sources of revenue over which they had hitherto had sole control; moreover, the whole organization for collecting direct taxes would have had to be created. At the same time, owing to the adoption of free trade, the income from customs was continually diminishing. The result was that the sum to be contributed by the individual states constantly increased, and the amount to be raised by direct taxation, including local rates, threatened to become greater than could conveniently be borne. Bismarck had always regarded this system with disapproval, but during the first four or five years he had left the care of the finances entirely to the special officials, and had always been thwarted in his occasional attempts to introduce a change. His most cherished project was a large increase in the tax on tobacco, which at this time paid, for home-grown tobacco, the nominal duty of four marks per hundred kilo. (about a farthing a pound), and on imported tobacco twenty-four marks. Proposals to increase it had been made in 1869 and in 1878, and on the latter occasion Bismarck for the first time publicly announced his desire for a state monopoly, a project which he never gave up, but for which he never was able to win any support. Now, however, he was able to take up the work. At his invitation a conference of the finance ministers met in July at Heidelberg; they agreed to a great increase in the indirect taxes, but refused to accept the monopoly on tobacco. At the beginning of the autumn session a union of 204 members of the Reichstag was formed for the discussion of economic questions, and they accepted Bismarck's reforms. In December he was therefore able to issue a memorandum explaining his policy; it included a moderate duty, about 5 per cent., on all imported goods, with the exception of raw material required for German manufactures (this was a return to the old Prussian principle); high finance duties on tobacco, beer, brandy, and petroleum; and protective duties on iron, corn, cattle, wood, wine, and sugar. The whole of the session of 1879 was occupied with the great struggle between Free Trade and Protection, and it ended with a decisive victory for the latter.

Protection.

On the one side were the seaports, the chambers of commerce, and the city of Berlin, the town council of which made itself the centre of the opposition. The victory was secured by a coalition between the agricultural interests and the manufacturers; the latter promised to vote for duties on corn if the landlords would support the duties on iron. In the decisive vote the duty on iron was carried by 218 to 88, on corn by 226 to 109.

The principle of protection which was then adopted has been maintained since; considerable alterations have been made from time to time in the tariff; in 1885 the duty on corn was raised; again in 1885 and 1887, considerable duties were levied on most timbers. The finance duties were also with some exceptions adopted, and have since been maintained. The tax on tobacco was increased to 44 marks, and the duty on imported tobacco raised to 85. The monopoly on tobacco was rejected in 1882 by 273 to 43 votes, and in 1886 that on brandy by 181 to 3. In the next year, after the victory of the coalition, an elaborate law imposing fresh duties on brandy was carried, which was of considerable political importance, for it was adopted by the southern states, who thereby gave up one of their chief privileges. All proposals for a reform of the tax on beer, however, failed. The result of these new taxes was that the income from customs and excise rose from about 230 million marks in 1878–79 to about 700 millions in 1898–99, and Bismarck's object in removing a great burden from the states was attained.

State contributions.

The natural course when the new source of income had been obtained would have been simply to relieve the states of part or all of their contribution. This, however, was not done. The Reichstag raised difficulties on the constitutional question. The Liberals feared that if the Government received so large a permanent source of revenue it would be independent of Parliament; the Centre, that if the contributions of the states to the imperial exchequer ceased, the central Government would be completely independent of the states. Bismarck had to come to an agreement with one party or the other; he chose the Centre, probably for the reason that the National Liberals were themselves divided on the policy to be pursued, and therefore their support would be uncertain; and he accepted an amendment, the celebrated *Franckenstein Clause*, proposed by Franckenstein, one of the leaders of the Centre, by which all proceeds of customs and the tax on tobacco above 130 million marks should be paid over to the individual states in proportion to their population. Each year a large sum would be paid to the states from the imperial treasury and another sum as before paid back to meet the deficit in the form of state contributions. This complicated arrangement has since continued.

From 1871 to 1879 the contribution of the states had varied from 94 to 67 million marks; under the new system the surplus of the contributions made by the states over the grant by the imperial treasury was soon reduced to a very small sum, and in 1884-85 the payments of the empire to the states exceeded the contributions of the states to the empire by 20 million marks, and this excess continued for many years; so that there was, as it were, an actual grant in relief of direct taxation. In Prussia, by the Lex Huene, from 1885 to 1895, all that sum paid to Prussia, so far as it exceeded 15 million marks, was handed over to the local authorities in relief of rates. The increased expenditure on the navy since 1897 has again caused the contributions required from the states to exceed the grants to them from the imperial exchequer.

These events were followed by the disruption of the National Liberal party and a complete change in the parliamentary situation. Already the Liberal ministers, Falk and Hobrecht, had resigned, as well as Forckenbeck the president, and Stauffenberg the vice-president of the Reichstag; in their place there was chosen a Conservative, and Franckenstein, a Catholic. The whole party had voted against the Franckenstein Clause, but a few days later fifteen of the right wing left the party and transferred their support to the Government. For another year the remainder kept together, but there was no longer any real harmony or co-operation; in 1880 nineteen, including most of the ablest leaders, Lasker, Forckenbeck, Bamberger, and Bunsen, left the party altogether. The avowed cause of difference was commercial policy; they were the Free Traders, but they also justly foresaw that the reaction would extend to other matters. They took the name of the *Liberale Vereinigung*, but were generally known as the *Secession*; they hoped to become the nucleus of a united Liberal party in which all sections should join together on the principles of Free Trade and constitutional development. At the elections of 1881 they secured forty-seven seats, but they were not strong enough to maintain themselves, and with great reluctance in 1884 formed a coalition with the Progressives, who had gained greatly in strength owing to the breach among the Government parties. They did so reluctantly, because they would thereby condemn themselves to assume that attitude of purely negative criticism which, during the great days of their prosperity, they had looked down upon with contempt, and were putting themselves under the leadership of Eugen Richter, whom they had long opposed. The new party, the *Freisinnige*, had no success; at the election of 1884 they secured only sixty-seven seats, a loss of thirty-nine; they were subjected to all inconveniences which belonged to opposition; socially, they were boycotted by all who were connected with the Court or Government; they were cut off from all hope of public activity, and were subjected to constant accusations for *Bismarck Beleidigung*. Their only hope was in the time when the Crown Prince, who had shown great sympathy with them, should succeed. They were popularly known as the Crown Prince's party. Lasker soon died; others, such as Forckenbeck and Bunsen, retired from public life, unable to maintain their position at a time when the struggle of class interests had superseded the old conflicts of principle. At the election of 1887 they lost more than half their seats, and, as we shall see, in 1893 the party again broke up.

Party changes.

Secessionists.

Freisinnige.

The remainder of the National Liberals only won forty-five seats in 1881, and during the next three years they were without influence on the Government; and even Bennigsen, unable to follow Bismarck in his new policy, disgusted at the proposals for biennial budgets and the misuse of Government influence at the elections, retired from political life. In 1884 a new development took place: under the influence of Miquel a meeting was held at Heidelberg of the South German members of the party, who accepted the commercial and social policy of the Government, including the Socialist law; their programme received Bismarck's approval, and was accepted by the rest of the party, so that they henceforward were taken into favour by the Government; but they had won the position by sacrificing almost all the characteristics of the older Liberalism; the hope of a reunion for all the different sections which had hitherto kept the name of Liberal was at an end.

These events had a very unfortunate effect on the character of the parliament. From 1878 to 1887 there was no strong party on which Bismarck could depend for support. After 1881 the parties of opposition were considerably strengthened. Alsatians and Poles, Guelphs, Clericals, and Radicals were joined in a common hostility to the Government. Parliamentary history took the form of a hostile criticism of the Government proposals, which was particularly bitter because of the irreconcilable opposition of the Free Traders. Few of the proposals were carried in their entirety, many were completely lost; the tobacco monopoly and the brandy monopoly were contemptuously rejected by enormous majorities; even an increase of the tax on tobacco was refused; the first proposals for a subsidy to the Norddeutsche Lloyd were rejected. The personal relations of the chancellor to Parliament were never so bitter. At the same time, in Prussia there was a tendency to make more prominent the power of the king and to diminish the influence of the parliament. A proposal to introduce biennial budgets was for this reason regarded with great suspicion by the Opposition as a reactionary measure, and rejected. The old feelings of suspicion and jealousy were again aroused; the hostility which Bismarck encountered was scarcely less than in the old days of the conflict. After the elections of 1881 a protest was raised against the systematic influence exercised by Prussian officials. Puttkammer, who had now become minister of the interior, defended the practice, and a royal edict of 4th January 1882 affirmed the monarchical character of the Prussian Constitution, the right of the king personally to direct the policy of the state, and required those officials who held appointments of a political nature to defend the policy of the Government, even at elections.

Political reaction.

One result of the new policy was a reconciliation with the Centre. Now that Bismarck could no longer depend on the support of the Liberals, it would be impossible to carry on the Government if the Catholics maintained their policy of opposition to all Government measures. They had supported him in his commercial reform of 1878, but by opposing the Septennate in 1880 they had shown that he could not depend upon them. It was impossible to continue to treat as enemies of the state a party which had supplied one of the vice-presidents to the Reichstag, and which after the election of 1881 outnumbered by forty votes any other single party. Moreover, the Government, which was now very seriously alarmed at the influence of the Social Democrats, was anxious to avail itself of every influence which might be used against them. In the struggle to regain the adherence of the working men it seemed as though religion would be the most valuable ally, and it was impossible to ignore the fact that the Roman Catholic priests had alone been able to form an organization in which hundreds of thousands of working men had been enlisted. It was therefore for every reason desirable to remedy a state of things by which so many parishes were left without incumbents, a condition the result of which must be either to diminish the hold of Christianity over the people, or to confirm in them the belief that the Government was the real enemy of Christianity. It was not easy to execute this change of front with dignity, and impossible to do so without forsaking the principles on which they had hitherto acted. Ten years were to pass before the work was completed. But the cause of the conflict had been rather in the opinions of the Liberals than in the personal desire of Bismarck himself. The larger political reasons which had brought about the conflict were also no longer valid; the fears to which the Vatican decrees had given rise had not been fulfilled; the failure of the Carlists in Spain and of the Legitimists in France, the consolidation of the new kingdom in Italy,

End of the Kulturkampf.

and the alliance with Austria, had dispelled the fear of a Catholic League. The growth of the Catholic democracy in Germany was a much more serious danger, and it proved to be easier to come to terms with the Pope than with the parliamentary Opposition. It would clearly be impossible to come to any agreement on the principles. Bismarck hoped, indeed, putting all questions of principle aside, to establish a *modus vivendi;* but even this was difficult to attain. An opportunity was given by the death of the Pope in 1878. Leo XIII. notified his accession to the Prussian Government in a courteous despatch; the interchange of letters was followed by a confidential discussion between Bismarck and Cardinal Franchi at Kissingen during the summer of 1878. The hope that this might bring about some agreement was frustrated by the sudden death of the cardinal, and his successor was more under the influence of the Jesuits and the more extreme party. Bismarck, however, was not discouraged.

The resignation of Falk in July 1879 was a sign of the change of policy; he was succeeded by Puttkammer, who belonged to the old-fashioned Prussian Conservatives and had no sympathy with the Liberal legislation. The way was further prepared by a lenient use of the penal laws. On 24th February 1880 the Pope, in a letter to the ex-bishop of Cologne, said he was willing to allow clerical appointments to be notified if the Government withdrew the obnoxious laws. In 1880 a provisional Bill was submitted to Parliament giving the Crown discretionary power not to enforce the laws. It was opposed by the Liberals on the ground that it conceded too much, by the Clericals that it granted too little, but, though carried only in a mutilated form, it enabled the priests who had been ejected to appoint substitutes, and religious worship was restored in nearly a thousand parishes. In the elections of 1881 the Centre gained five more seats, and in 1883 a new law was introduced prolonging and extending that of 1881. Meanwhile a Prussian envoy had again been appointed at the Vatican; all but three of the vacant bishoprics were filled by agreement between the Pope and the king, and the sequestrated revenues were restored. Finally, in 1886, a fresh law, besides other concessions, did away with the *Kultur Examen*, and exempted seminaries from state control. It also abolished the Ecclesiastical Court, which, in fact, had proved to be almost unworkable, for no priests would appeal to it. By this, the real Kulturkampf, the attempt of the state to control the intellect and faith of the clergy, ceased. A further law of 1887 permitted the return to Prussia of those orders which were occupied in charitable work.

As permanent results of the conflict there remain only the alteration in the Prussian Constitution and the expulsion of the Jesuits; the Centre have continued to demand the repeal of this, and to make it the price of their support of Government measures; in 1897 the Bundesrath permitted the return of the Redemptorists, an allied order. With these exceptions absolute religious peace resulted; the Centre to a great extent succeeded to the position which the National Liberals formerly held; in Bavaria, in Baden, in Prussia, they obtained a dominant position, and they became a Government party.

Nationalization of railways.

Meanwhile Bismarck, who was not intimidated by the parliamentary opposition, irritating and embarrassing though it was, resolutely proceeded with his task of developing the material resources of the empire. In order to do so the better he undertook, in addition to his other offices, that of Prussian minister of commerce. He was now able to carry out, at least partially, his railway schemes, for he could afford to ignore Liberal dislike to state railways, and if he was unable to make all the lines imperial, he could make most of them Prussian. The work was continued by his successors, and by the year 1896 there remained only about 2000 kilometres of private railways in Prussia; of these none except those in East Prussia belonged to companies of any great importance. More than this, Bismarck was able to obtain Prussian control of the neighbouring states; in 1886 the Brunswick railways were acquired by the Prussian Government, and in 1895 the private lines in Thuringia. The imperial railways in Elsass-Lothringen are managed in close connexion with the Prussian system, and in 1895 an important step was taken towards extending Prussian influence in the south. A treaty was made between Prussia and Hesse by which the two states together bought up the Hesse-Ludwig railway (the most important private company remaining in Germany), and in addition to this agreed that they would form a special union for the joint administration of all the lines belonging to either state. What this means is that the Hessian lines are now managed by the Prussian department, but Hesse has the right of appointing one director, and the expenses and profits are divided between the two states in proportion to their population. Thus a nucleus and precedent has been formed similar to that by which the Customs Union was begun, and it was hoped that it might be possible to arrange similar agreements with other states, so that in this way a common management for all lines might be established. There is, however, strong opposition, especially in South Germany, and most of the states cling to the separate management of their own lines. Fearful that Prussia might obtain control over the private lines, they have imitated Prussian policy and acquired all railways for the state; there is now a separate railway administration in Saxony, Bavaria, Würtemberg, Baden, Mecklenburg, and Oldenburg. The management of the railways plays an important part in local politics, and occupies much of the attention of Parliament; much of the old opposition to Prussia is revived in defence of the local railways.

Bismarck's policy has been fully justified by results. In nothing has there been so great an increase in practical efficiency as in the working of the railways. And now that the tariffs are fixed by the state, it is possible to use them so as to support the fiscal and commercial policy of the Government. In the early years of the empire it happened that the railway companies fixed the tariffs so as to give an advantage to foreign imports over home industries; now they can be fixed so as to afford, if desirable, an additional protection to home produce.

Canals.

A natural supplement to the nationalization of railways was the development of water communication. This is of great importance in Germany, as all the chief coalfields and manufacturing districts—Silesia, Saxony, Westphalia, and Elsass—are far removed from the sea. The most important works which have been executed in recent years are the canal from Dortmund to the mouth of the Ems, and the Jāhde canal from the Ems to the Elbe, which enables Westphalian coal to reach the sea, and so to compete better with English coal. In addition to this, however, a large number of smaller works have been undertaken, such as the canalization of the Main from Frankfort to the Rhine, and a new canal from the Elbe to Lübeck. The traffic on the great waterways increased fourfold during the period 1870–1900, and so great has been the growth of industry and enterprise that the increased use of water communication does not prevent the railway traffic from increasing with equal rapidity. The great ship canal from Kiel to the Elbe, which was begun in 1887 and completed in 1896, has perhaps even more importance for naval than for commercial purposes.

The change which has taken place in the Rhine is characteristic of modern Germany. This great river, so long the home of romance, has become one of the great arteries of traffic, and while lines of railways on both sides have caused small villages to become large towns, the river itself is navigated by more than 400 steamers. The Prussian Government also planned a great scheme by which the Westphalian coalfields should be directly connected with the Rhine in one direction and the Elbe in the other by a canal which would join together Minden, Hanover, and Magdeburg. This would give uninterrupted water communication from one end of the country to the other, for the Elbe, Oder, and Vistula are all navigable rivers connected by canals. This project, which was a natural continuation of Bismarck's policy, was, however, rejected by the Prussian parliament in 1894. The opposition came from the Agrarians and extreme Conservatives, who feared that it would enable foreign corn to compete on better terms with German corn; they were also jealous of the attention paid by the Government to commercial enterprise in which they were not immediately interested. The proposal continued to be repeatedly discussed, but without success, and it was the rejection of this Bill in 1901 which led to a ministerial crisis and the resignation of Miquel.

Equally important was the action of the Government in developing foreign trade. The first step was the inclusion of Hamburg and Bremen in the Customs Union; this was necessary if German maritime enterprise was to become a national and not merely a local concern, for the two Hansa cities practically controlled the whole foreign trade and owned three-quarters of the shipping; but so long as they were excluded from the Customs Union their interests were more cosmopolitan than national. Both cities, but especially Hamburg, were very reluctant to give up their privileges and the commercial independence which they had enjoyed almost since their foundation. As a clause in the Constitution determined that they should remain outside the Customs Union until they voluntarily offered to enter it, there was some difficulty in overcoming their opposition. Bismarck, with characteristic energy, proposed to take steps, by altering the position of the imperial customs stations, which would practically destroy the commerce of Hamburg, and some of his proposals which seemed contrary to the Constitution aroused a very sharp resistance in the Bundesrath. It was, however, not necessary to go to extremities, for in 1881 the senate of Hamburg accepted an agreement which, after a keen struggle, was ratified by the citizens. By this Hamburg was to enter the Union; a part of the harbour was to remain a free port, and the empire contributed two million pounds towards rearranging and enlarging the harbour. A similar treaty was made with Bremen, the free port of that city being situated near the mouth of the Weser at Bremerhaven; and in 1888, the necessary works having been completed, the cities entered the Union. They have had no reason to regret the change, for no part of the country profited so much by the great prosperity of the following years, notwithstanding the temporary check caused by the serious outbreak of cholera at Hamburg in 1896.

Hamburg and Bremen.

During the first years of the empire Bismarck had occasionally been asked to interest himself in colonial enterprise. He had refused, for he feared that foreign complications might ensue, and that the country might weaken itself by dissipation of energy. He was satisfied that the Germans should profit by the commercial liberty allowed in the British colonies. Many of the Germans were, however, not contented with this, and disputes regarding the rights of German settlers in Fiji caused some change of feeling. The acquisition of German colonies was really the logical and almost necessary sequel of a Protective policy. For that reason it was always opposed by the extreme Liberal party.

Colonies.

The failure of the great Hamburg house of Godefroy in 1879 threatened to ruin the growing German industries in the South Seas, which it had helped to build up. Bismarck therefore consented to apply to the Reichstag for a state guarantee to a company which would take over its great plantations in Samoa. This was refused, chiefly owing to the influence of the Liberal party. Bismarck therefore, who took this rebuff much to heart, said he would have nothing more to do with the matter, and warned those interested in colonies that they must depend on self-help; he could do nothing for them. By the support of some of the great financial firms they succeeded in forming a company, which carried on the business and undertook fresh settlements on the islands to the north of New Guinea. This event led also to the foundation of a society, the *Deutscher Kolonial Verein*, under the presidency of the prince of Hohenlohe-Langenburg, to educate public opinion. Their immediate object was the acquisition of trading stations.

The year 1884 brought a complete change. Within a few months Germany acquired extended possessions in several parts both of Africa and the South Seas. This was rendered possible owing to the good understanding which at that time existed between Germany and France. Bismarck therefore no longer feared, as he formerly had, to encounter the difficulties with Great Britain which would be the natural result of a policy of colonial expansion.

The first acquisition was made in South-West Africa. On several occasions missionaries had applied to the German Government for protection. In 1883 Herr Luderitz, a Bremen tobacco merchant, had acquired by purchase from the natives and half-breed chiefs a trading-station on the Bay of Angra Pequeña and considerable territory in the neighbourhood. He then asked for the protection of the empire. A correspondence between the British and German Foreign Offices showed that the British Government had not hitherto exercised rights of sovereignty over this district, and had refused to undertake the responsibility for the protection of German settlers. In the month of June, therefore, the German flag was hoisted at Angra Pequeña, and shortly afterwards the whole coast from the river Orange to the Portuguese colonies, with the exception of Walfisch Bay, was taken under German protection. During the same year, in consequence of a dispute which had arisen between German traders and natives on the Gulf of Guinea, a gunboat was despatched, and Dr Nachtigal was instructed to proclaim a protectorate over Cameroon. Dr Nachtigal, however, on his own authority, found it desirable to take Togoland also under German rule. Encouraged by this action of the Government, a company, the *Gesellschaft für deutsche Kolonization*, was founded by Dr Peters, who at once went off to the east coast of Africa and succeeded in negotiating treaties with twelve chiefs on the coast off Zanzibar; at the beginning of 1885 these also were taken over by the Government.

Africa.

Similar events took place in the South Seas. The acquisition of Samoa, where German interests were most extensive, was prevented by the arrangement made in 1879 with Great Britain and the United States. But in 1884 and 1885 the German flag was hoisted on the north of New Guinea (to which the name Kaiser Wilhelmsland has been given), on several parts of the New Britain Archipelago (which afterwards became the Bismarck Archipelago), and on the Caroline Islands. The last acquisition was not kept. The Spanish Government claimed the islands, and Bismarck, in order to avoid a struggle which would have been very disastrous to monarchical government in Spain, suggested that the Pope should be asked to mediate. Leo XIII. accepted the offer, which was an agreeable reminiscence of the days when Popes determined the limits of the Spanish colonial empire, all the more gratefully that it was made by a Protestant power. He decided in favour of Spain, Germany being granted certain rights in the islands. The loss of the islands was amply compensated for by the political advantages which Bismarck gained by this attention to the Pope, and, after all, not many years elapsed before they became German.

The Pacific.

Bismarck in his colonial policy had repeatedly explained that he did not propose to found provinces or take over for the Government the responsibility for their administration; he intended to leave the responsibility for their material development to the merchants, and even to entrust to them the actual government. He avowedly wished to imitate the older form of British colonization by means of chartered companies, which had been recently revived in the North Borneo Company; the only responsibility of the Imperial Government was to be their protection from foreign aggression. In accordance with this policy, the territories were not actually incorporated in the empire (there would also have been constitutional difficulties in doing that), and they were officially known as Protectorates (*Schutzgebiete*), a word which thus acquired a new signification. In 1885 two new great companies were founded to undertake the government. The *Deutsch Ost Afrika Gesellschaft*, with a capital of £200,000, took over the territories acquired by Dr Peters, and for the South Seas the *Neu Guinea Gesellschaft*, founded by an amalgamation of a number of firms in 1884, received a charter in 1885. It was not, however, possible to limit the imperial responsibility as Bismarck intended. In East Africa the great revolt of the Arabs in 1888 drove the company out of all their possessions, with the exception of the port of Dar-es-Salam. The company was not strong enough to defend itself; troops had to be sent out by the Emperor under Captain Wissmann, who as imperial commissioner took over the government. This, which was at first a temporary arrangement, was afterwards made permanent.

The New Guinea Company had less formidable enemies to contend with, and with the exception of a period of three years between 1889 and 1892, they maintained a full responsibility for the administration of their territory till the year 1899, when an agreement was made and ratified in the Reichstag, by which the possession and administration was transferred to the empire in return for a subsidy of £20,000 a year, to be continued for ten years. The whole of the colonies have therefore now come under the direct administration of the empire. They are administered under a special department of the Foreign Office, and in 1890 a council of experts on colonial matters was instituted, who should help the director and the chancellor by their advice. It is one of the complaints of the colonial party that a separate Office for colonial affairs has not been created. In 1887 the two chief societies for supporting the colonial movement joined under the name of the *Deutsche Kolonialgesellschaft*. This society, which in 1901 had over 25,000 members, takes a great part in forming public opinion on colonial matters.

This new policy inevitably caused a rivalry of interests with other countries, and especially with Great Britain. In every spot at which the Germans acquired territory they found themselves in opposition to British interests. The settlement at Angra Pequeña caused much ill-feeling in Cape Colony, which was, however, scarcely justified, for it was the reluctance of the Cape ministry to undertake responsibility for the administration of Namaqualand which prevented the British Government from anticipating the Germans in the acquisition of this district. In Togoland and Cameroon British traders had long been active, and the proclamation of British sovereignty was impending when the German flag was hoisted. The settlements in East Africa menaced the old-established British influence over Zanzibar, which was all the more serious because of the close connexion between Zanzibar and the rulers of the Persian Gulf; and the colony of Queensland saw with much concern the German settlement so near their shores. As soon as the acquisitions had been made, however, a period followed during which by a series of treaties the boundaries of German, French, and British possessions were determined in the way of peaceful negotiation. The overthrow of Jules Ferry and the danger of war with France made a good understanding with Great Britain of more importance. Bismarck, by summoning a conference to Berlin to discuss African questions, secured for Germany, though the youngest of colonial powers, a European recognition which was very grateful to the colonial parties; and in 1888, by lending his support to the anti-slavery movement of Cardinal Lavigerie, he won the support of the Centre, who had hitherto opposed the colonial policy. At the same time the anti-slavery agitation was of use in another way, for the proclamation of a general blockade on the east coast of Africa was of considerable assistance to the Germans in their difficult struggle against the Arabs.

Germany and Great Britain.

This period is concluded by the general agreement for the demarcation of Africa which was made in 1890. A similar agreement had been made in 1886 regarding the South Seas. It was made after Bismarck had retired from office, and he, as did the colonial party, severely criticized the details; for the surrender of Zanzibar and Witu cut short the hopes which had been formed of building up a great German empire controlling the whole of East Africa. Many of the colonial party went further, and criticized not only the details, but the principle. They were much offended by Caprivi's statement that no greater injury could be done to Germany than to give her the whole of Africa, and they refused to accept his contention that "the period of flag-hoisting was over," and that the time had come for consolidating their possessions. It must, however, be recognized that a continuation of the ambitious policy of the last few years might easily have involved Germany in dangerous disputes.

It appeared a small compensation that Great Britain surrendered to Germany the island of Heligoland, which she had taken from the Danes in the Napoleonic wars. It was annexed to Prussia; the natives born before the year 1880 were exempted from military service, and till the year 1901 no additional import duties were to be imposed. It has been strongly fortified and made a naval station.

Heligoland.

It was easy for the Opposition to criticize the colonial policy. They could point out that in no case had territory been acquired in which any large number of German emigrants could live and rear families. As late as 1896 the total number of Germans living in the protectorates was less than 2000, and of these more than half were officials and soldiers. The colonies are therefore, and will probably continue to be, useless as a means of providing homes for surplus population. As in the old days, emigrants go to the United States and South America. As markets for German products the colonies still are of the smallest importance; in 1901 the whole value of the trade, import and export, between Germany and her colonies was less than £1,000,000, and the cost of administration, including the grant to the shipping companies, has often exceeded the total trade. Many mistakes have been made in the administration, and cases of misconduct by individual officials have formed the text for attacks on the whole system. Dr Karl Peters, one of the founders of the East African dominion, was in 1897 dismissed from the service. It is noticeable that the colonial party complained of what, on the evidence, was a mere act of justice, as a political blunder, and thereby appeared to identify themselves with his offence and justify the criticisms of the Socialists. Generally, however, these criticisms were premature. Many years must elapse before prosperous plantations can be made in new countries. The colonial policy was one essentially of the future; but whatever the issue be, it was surely wiser, while the opportunity was still open, to take care that Germany, in the partition of the world among European races, should not alone go entirely without a share.

It would be little use acquiring colonies and creating manufactures if the foreign trade was to be in the hands of other nations. As early as 1881 the Government had published a proposal for a subvention to German shipping; it was criticized with peculiar energy by Bamberger and the Free Traders; a Bill introduced in 1884 was abandoned, but in 1885 Bismarck succeeded in carrying a vote by which, for fifteen years, four million marks could annually be devoted to helping a line of mail steamers to the Pacific and Australia and a branch line in the Mediterranean. An agreement was made with the North German Lloyd, one clause of which was that all the new steamers were to be built in Germany; in 1890 a further vote was passed for a line to Delagoa Bay and Zanzibar.

Grants to shipping companies.

This far from exhausts the external activity of the nation and the Government: the establishment of studentships for the study of Oriental languages enabled Germans to make their way in the Turkish and Persian empires, and to open up a fresh market for German goods; by the great excavations at Pergamum and Olympia Germany entered with great distinction on a field in which the way had been shown by France and Great Britain. The progress of technical studies and industrial enterprise enabled Germany to take a leading place in railway and shipbuilding, in the manufacture of military weapons, in chemical experiments, and in electrical work.

It was a part of the new policy not only to combat Social Democracy by repression, but to win the confidence of the working men by extending to them the direct protection of the state. Recent legislation, culminating in the *Gewerbeordnung* of 1869, had, in accordance with the principles of the Liberal Economists, or, as the Germans called it, the Manchester School, instituted freedom from state control in the relations between employers and workmen. The old guilds had been destroyed, compulsory apprenticeship had ceased; little protection, however, was given to the working men, and the restrictions on the employment of women and children were of little use, as there was no efficient system of factory inspection. It was difficult for the men by their own exertions to improve their condition, for the masters had full liberty of association, which the law refused to the workmen. Even before 1870 a protest was raised against this system among the Roman Catholics, who were chiefly concerned for the preservation of family life, which was threatened by the growth of the factory system and also by the teaching of the Social Democrats. Baron von Ketteler, archbishop of Mainz, had maintained that it was the duty of the state to secure to working men work and provision during sickness and old age. The general interest of the Church in the social question was recognized by a congress of the bishops at Fulda. Ketteler's work was continued by Canon Moufang, and Catholics brought forward motions in the Reichstag demanding new factory legislation. The peculiar importance of the Catholic movement is that it alone was able to some extent to meet the Socialists on their own ground. The Catholics formed societies which were joined by large numbers of workmen. Originated by Father Kolping on the Rhine, they soon spread over the whole of Catholic Germany. Herr von Schorlemer-Ast, a Catholic landed proprietor from Westphalia, formed similar associations among the peasants. The result of this has been that the Social Democrats have failed to conquer the Catholic as they have the Protestant districts. A similar movement began among the Protestants after the commercial crisis of 1873, which forms an epoch in German thought, since it was from that year that men first began to question the economic doctrines of Liberalism, and drew attention to the demoralization which seemed to arise from the freedom of speculation and the influence of the stock exchange —a movement which in later years led to some remarkable attempts to remedy the evil by legislation. A minister, Rudolph Todt, and Rudolph Meyer criticized the moral and economic doctrines of Liberalism; his writings led to the foundation of the *Christlich-Social Arbeiter Verein*, which for a few years attained considerable notoriety under the leadership of Adolph Stöcker. The Protestant movement has not succeeded in attaining the same position as has the Catholic among the working men; but it received considerable support among the influential classes at court, and part of the programme was adopted by the Conservative party, which in 1876 demanded restriction of industrial liberty and legislation which would prevent the ruin of the independent artizans.

Social reforms.

Christian Socialism.

In a country where learned opinion has so much influence on public affairs it was of especial importance that several of the younger teachers separated themselves from the dominant Manchester School and asserted the duty of the state actively to promote the well-being of the working classes. At a congress held in Erfurt in 1873, Schmoller, Wagner, Brentano, and others founded the *Verein für Social Politik*, which by its publications has had much influence on German thought.

The peculiar social conditions brought it about that in many cases the Christian Social movement took the form of Anti-Semitism (*q.v.*). In Germany nearly all the bankers and stockbrokers are Jews. Many of the leaders of the Liberal parties, *e.g.*, Bamberger and Lasker, were of Jewish origin; the doctrines of Liberalism were supported by papers owned and edited by Jews; hence the wish to restore more fully the avowedly Christian character of the state, coinciding with the attack on the influence of finance, which owed so much to the Liberal economic doctrines, easily degenerated into attacks on the Jews. The leader in this was Stöcker. During the years 1879 to 1881 the anti-Semite agitation gained considerable importance in Berlin, Breslau, and other Prussian cities, and it culminated in the elections of that year, leading in some cases to riots and acts of violence.

Anti-Semites.

So long as the Government was under the influence of the National Liberals, it was indifferent if not hostile to these movements. The Peasants' Union had actually been forbidden by the police; Bismarck himself was violently attacked for his reputed connexion with a great Jewish firm of bankers. He had, however, kept himself informed regarding these movements, chiefly by means of Hermann Wagener, an old editor of the *Kreuzzeitung*, and in the year 1878 he felt himself free to return in this matter to his older opinions. The new policy suggested in that year was definitely announced at the opening of the session in the spring of 1881, and at the meeting of the new Reichstag in November 1881. It was explained in a speech from the throne, which, as the Emperor could not be present, became an imperial message. This is generally spoken of as the beginning of a new era. The help of the Reichstag was asked for "healing social evils by means of legislation . . . based on the moral foundation of Christianity." Compulsory insurance, the creation of corporate unions among working men under the protection of the state, and the introduction of indirect taxes, were the chief elements in the reform.

The condition of parties was such that Bismarck could not hope to win a majority for his schemes, especially as he could not obtain the monopoly on tobacco on which he depended to cover the expense. The first reform was the restoration of the guilds, to which the Conservatives attached great importance. Since 1869 they continued to exist only as voluntary associations with no public duties; many had been dissolved, and this is said to have brought about bad results in the management of lodging-houses, the condition of apprentices, support during illness, and the maintenance of labour bureaus. It was supposed that, if they could be restored, the corporate spirit would prevent the working men from falling under the influence of the Socialists. The law of 1881, while it left membership voluntary, gave to them many duties of a semi-public nature, especially that of arbitration between masters and men. These were extended by a further law in 1884.

Compulsory insurance.

The really important element was the scheme for a great imperial system by which all working men and women should be provided for in case of sickness, accident, or old age. Bismarck hoped by this to relieve the parishes of the burden of the poor-rate, which would be transferred to the empire; at the same time the power of the Government would be greatly extended. The first proposal in March 1881 was for compulsory insurance against accidents. Every one employed on railways, mines, and factories was to be insured in an imperial office; the premium was to be divided equally between masters, workmen, and the state. It was bitterly opposed by the Liberals, especially by Bamberger; all essential features were altered by the Reichstag, and it was withdrawn by the Government after it had passed the third reading.

In 1882 a fresh scheme was laid before the newly-elected Reichstag dealing with insurance against accident and against sickness. The two parts were separated by the Reichstag; the second, which was the necessary prelude to the other, was passed in 1883. The law was based on an old Prussian principle: insurance was made compulsory, but the state, instead of doing the work itself, recognized the existing friendly and other societies; they were still to enjoy their corporate existence and separate administration, but they were placed under state control, and for this purpose an imperial insurance department was created in the office of the secretary of state for the interior. Uniform regulations were to be followed in all trades and districts; one-third of the premium was paid by the employer, two-thirds by the workmen.

The Accident Law of 1883 was rejected, for it still included the state contribution to which the Reichstag would not assent, and also contributions from the workmen. A new law, drafted according to their wishes, was passed in 1884. It applied only to those occupations, mines and factories, in which the use of machinery was common; it threw the whole burden of compensation on to the masters; but, on the other hand, for the first thirteen weeks after an accident the injured workman received compensation from the sick fund, so that the cost only fell on the masters in the more serious cases. The masters were compelled to insure themselves against the payments for which they might become liable, and for this purpose had to form trades associations, self-governing societies, which in each district included all the masters for each particular trade. The application of this law was subsequently extended to other trades.

It was not till 1889 that the greatest innovation, that of insurance against old age, was carried. The obligation to insure rests on all who are in receipt of wages of not more than two pounds a week. Half the premium, which varies according to the wages received, is paid by the master. The pension begins at the age of seventy, the amount varying by very complicated rules, but the state pays a fixed sum of two pounds ten shillings annually in addition to the pension.

These measures worked well. They were regarded with satisfaction by masters and men alike. Alterations have been made in detail, and further alterations demanded, but the laws have established themselves in practice. The large amount of self-administration has prevented an undue increase of bureaucratic power. The co-operation of masters and men in the administration of the societies has a good effect on the relations of the classes. The expense of administration is, however, considerable. The existence of the separate funds causes much waste of money and labour. The latest proposals are for simplification by establishing a common administration of the sick funds and the old age pensions, and abolishing the separate administration of the different trade benefit societies. It is to be expected that as time goes on the administration will fall more completely into the hands of the state, and that the authority of the imperial insurance department will absorb the older societies.

So far had the social reform gone during this period; except in the matter of insurance, the total result was small. The demands repeatedly made by the Centre and the Conservatives for effective factory legislation and prohibition of Sunday labour were not successful. Bismarck did not wish to lay heavier burdens on the capitalists, and it was not till a later period that they were carried out.

Foreign affairs: the Triple Alliance.

During all this period Bismarck's authority was so great, that in the conduct of foreign affairs he was freed from the criticism and opposition which so often hampered him in his internal policy, and he was able to establish that system of alliances on which for so many years the political system of Europe depended. The close union of the three empires which had existed since the meeting of the Emperors in 1872 did not survive the outbreak of disturbances in the East. Bismarck had maintained an attitude of neutrality, but after the Congress of Berlin he found himself placed between the alternatives of friendship with Austria or Russia. Movements of Russian troops on the western frontier threatened Austria, and the Tsar, in a letter to the German Emperor, stated that peace could only be maintained if Germany gave her support to Russia. Bismarck, now that the choice was forced upon him, determined in favour of Austria, and during a visit to Vienna in October, arranged with Count Andrassy an alliance by which in the event of either being attacked by Russia the other was to assist; if either were attacked by any Power other than Russia, the other was to preserve benevolent neutrality unless the attacking Power was helped by Russia. The effect of this was to protect Austria from attack by Russia, and Germany from the danger of a combined attack by France and Russia. Bismarck with some difficulty procured the consent of the Emperor, who by arranging a meeting with the Tsar had attempted to preserve the old friendship. From that time the alliance with Austria has continued. In 1883 it was joined by Italy, and was renewed in 1887, and in 1891 for six years, and if not then denounced, for twelve.

In 1882, after the retirement of Gortchakoff, the relations with Russia again improved. In 1884 there was a meeting of the three Emperors, and at the same time Bismarck came to a close understanding with France on colonial questions. The period of quiet did not last long. The disaster in Tongking brought about a change of ministry in France, and Bulgarian affairs again alienated Austria and Russia. Bismarck with great skill used the growing foreign complications as a means of freeing himself from parliamentary difficulties at the same time that he secured the position of Germany in Europe.

To meet the increase in the French army, and the open menaces in which the Russian press indulged, a further increase in the German army seemed desirable. The Septennate would expire in 1888. In the autumn of 1886 a proposal was laid before the Reichstag to increase the peace establishment for the next seven years to 468,409 men. The Reichstag would not assent to this, but the opposition parties offered to vote the required increase for three years. Bismarck refused to accept this compromise, and the Reichstag was dissolved. Under his influence the Conservatives and National Liberals formed a coalition or *Cartel* by which each agreed to support the candidates of the other. The elections caused greater excitement than any which had taken place since 1870. The numbers who went to the poll were much larger, and all the opposition parties, except the Catholics, including even the Socialists, suffered severe loss. Bismarck, in order to win the support of the Centre, appealed directly to the Pope, but Windthorst took the responsibility of refusing to obey the Pope's request on a matter purely political. The National Liberals again became a Government party, but their position was much changed. They were no longer, as in the old days, the leading factor. They had to take the second place. They were subordinate to the Conservatives. They could no longer impose their will upon the Government. In the new parliament the Government proposals were accepted by a majority of 223 to 48 (seven members of the Centre voted for it, the others abstained). The opposition consisted chiefly of Socialists and Freisinnige.

Elections of 1887.

The fall of Boulanger removed the immediate danger from France, but for the rest of the year the relations with Russia caused serious apprehensions. Anti-German articles appeared in Russian newspapers. The growth of the Nationalist party in Russia led to measures injurious to German trade and German settlers in Russia. German vessels were forbidden to trade on the Niemen. The increase of the duties on iron injured German trade. Stringent measures were taken to stamp out German nationality in the Baltic provinces, similar to those used by the Germans against the Poles. Foreigners were forbidden to hold land in Russia. The German Government retaliated by a decree of the Reichsbank refusing to deal with Russian paper. Large accumulations of troops on the western frontier excited alarm in Germany and Austria. During a short visit paid by the Tsar to Berlin in November Bismarck discovered that forged despatches misrepresenting the policy of Germany in the Eastern Question had been communicated to the Tsar. This did not seem to remove all danger, and in February 1888 the Government introduced an amendment to the imperial Military law extending the obligation for service from twelve to eighteen years. In this way it was possible to increase the war establishment, excluding the Landsturm, by about half a million men without adding to the burden in time of peace. Another law authorized a loan of £14,000,000 for military equipment. At the same time the text of the Triple Alliance was published. The two laws were adopted without opposition. Under the effect of one of Bismarck's speeches, the Military Bill was unanimously passed almost without debate.

Relations with Russia.

It was probably at the meeting of 1884 that a secret treaty, the existence of which was not known for many years, was arranged between Germany and Russia. The full text has never been published, and the exact date is uncertain. Either state pledged itself to observe benevolent neutrality in case the other were attacked by a third Power. Apparently the case of an attack by France on Germany, or by Austria on Russia, was expressly mentioned. The treaty lapsed in 1890, and owing to Bismarck's dismissal was not renewed. Caprivi refused to renew it because it was doubtful whether by increasing the number of treaties the value of them was not diminished. Under this system it was to be apprehended that if war broke out between Austria and Russia, Austria would claim the support of Germany under the Triple Alliance, Russia neutrality under this treaty. The decision of Germany would theoretically have to depend on the question which party was the aggressor—a question which notoriously is hardly ever capable of an answer. (For this treaty see the debate in the Reichstag of 16th November 1896; the *Hamburger Nachrichten* of 24th October in the same year; and Schulthess, *Europäisches Geschichts-kalendar*, 1896.)

Secret treaty with Russia.

The Emperor William died on 9th March 1888. He was succeeded by his son, who took the title of Frederick III. In Italy, the older title of King of Piedmont has been absorbed in the newer kingdom of Italy; this is not the case in Germany, where the title German Emperor is merely attached to and not substituted for that of King of Prussia. The events of this short reign, which lasted only ninety-nine days, have chiefly a personal interest, and are narrated under the articles FREDERICK and BISMARCK. The illness and death of the Emperor, however, destroyed the last hope of the Liberals that they might at length succeed to power. For a generation they had waited for his accession, and bitter was their disappointment, for it was known that his son was more inclined to follow the principles of Bismarck than those of his own father. The Emperor, crippled and dying though he was, showed clearly how great a change he would, had he lived, have introduced in the spirit of the Government. One of his first acts was severely to reprimand Puttkammer for misusing Government influence at elections. The minister sent in his resignation, which was accepted, and this practice, which had been deliberately revived during the last ten years, was thereby publicly disavowed. Bismarck's own position would naturally have been seriously affected by the fall of a colleague with whom he was closely connected, and another point of internal policy showed also how numerous were the differences between the chancellor and the Emperor. Laws had been passed

Reign of Frederick III.

prolonging the period of both the Prussian and Imperial parliaments from three to five years; when they were laid before the Emperor for his signature he said that he must consider them. Bismarck then pointed out that the constitution of the empire did not authorize the Emperor to withhold his assent from a law which had passed both the Reichstag and the Bundesrath; he could as king of Prussia oppose it by his representatives in the Council, but when it had been accepted there, it was his duty as Emperor to put the law into execution. The Emperor accepted this exposition of the constitution, and after some delay eventually gave his consent also to the Prussian law, which he was qualified to reject.

William II.

He was succeeded by his eldest son, William II. (*q.v.*). The first year of the new reign was uneventful. In his public speeches the Emperor repeatedly expressed his reverence for the memory of his grandfather, and his determination to continue his policy; but he also repudiated the attempt of the extreme Conservatives to identify him with their party. He spent much time on journeys, visiting the chief courts of Europe, and he seemed to desire to preserve close friendship with other nations, especially with Russia and Great Britain. Changes were made in the higher posts of the army and civil service, and Moltke resigned the office of chief of the staff, which for thirty years he had held with such great distinction.

Fall of Bismarck.

The beginning of the year 1890 brought a decisive event. The period of the Reichstag elected in 1887 expired, and the new elections, the first for a quinquennial period, would take place. The chief matter for decision was the fate of the Socialist law; this expired 30th September 1890. The Government at the end of 1889 introduced a new law, which was altered in some minor matters, and which was to be permanent. The Conservatives were prepared to vote for it; the Radicals and Centre opposed it; the decision rested with the National Liberals, and they were willing to accept it on condition that the clause was omitted which allowed the state governments to exclude individuals from districts in which the state of siege had been proclaimed. The final division took place on 25th February 1890. An amendment had been carried omitting this clause, and the National Liberals therefore voted for the Bill in its amended form. The Conservatives were ready to vote as the Government wished; if Bismarck was content with the amended Bill, they would vote for it, and it would be carried; no instructions were sent to the party; they therefore voted against the Bill, and it was lost. The House was immediately dissolved. It was to have been expected that, as in 1878, the Government would appeal to the country to return a Conservative majority willing to vote for a strong law against the Socialists. Instead of this, the Emperor, who was much interested in social reform, published two proclamations. In one addressed to the chancellor he declared his intention, as Emperor, of bettering the lot of the working classes; for this purpose he proposed to call an international congress to consider the possibility of meeting the requirements and wishes of the working men; in the other, which he issued as king of Prussia, he declared that the regulation of the time and conditions of labour was the duty of the state, and the Council of State was to be summoned to discuss this and kindred questions. Bismarck, who was less hopeful than the Emperor, and did not approve of this policy, was thereby prevented from influencing the elections as he would have wished to do; the coalition parties, in consequence, suffered severe loss; Socialists, Centre, and Radicals gained numerous seats. A few days after the election Bismarck was dismissed from office. The difference of opinion between him and the Emperor was not confined to social reform; beyond this was the more serious question as to whether the chancellor or the Emperor was to direct the course of the Government. The Emperor, who, as Bismarck said, intended to be his own chancellor, required Bismarck to draw up a decree reversing a cabinet order of Frederick William IV., which gave the Prussian minister-president the right of being the sole means of communication between the other ministers and the king. This Bismarck refused to do, and he was therefore ordered to send in his resignation.

Chancellorship of Count von Caprivi.

Among those more immediately connected with the Government, his fall was accompanied by a feeling of relief which was not confined to the Opposition, for the burden of his rule had pressed heavily upon all. There was, however, no change in the principles of Government or avowed change in policy; some uncertainty of direction and sudden oscillations of policy showed the presence of a less experienced hand. Bismarck's successor, General von Caprivi, held a similar combination of offices, but the chief control passed now into the hands of the Emperor himself. He aspired by his own will to direct the policy of the state; he put aside the reserve which in modern times is generally observed even by absolute rulers, and by his public speeches and personal influence took a part in political controversy. He made very evident the monarchical character of the Prussian state, and gave to the office of emperor a prominence greater than it had hitherto had.

One result of this was that it became increasingly difficult in political discussions to avoid criticizing the words and actions of the Emperor. Prosecutions for *lèse-majesté* became commoner than they were in former reigns, and the difficulty was much felt in the conduct of parliamentary debate. The rule adopted was that discussion was permitted on those speeches of the Emperor which were officially published in the *Reichsanzeiger*. It was, indeed, not easy to combine that respect and reverence which the Emperor required should be paid to him, with that open criticism of his words which seemed necessary (even for self-defence) when the monarch condescended to become the censor of the opinions and actions of large parties and classes among his subjects. The attempt to combine personal government with representative institutions was one of much interest; it was more successful than might have been anticipated, owing to the disorganization of political parties and the absence of great political leaders; in Germany, as elsewhere, the parliaments had not succeeded in maintaining public interest, and it is worth noting that even the attendance of members was very irregular. There was below the surface much discontent and subdued criticism of the exaggeration of the monarchical power, which the Germans called *Byzantinismus*; but after all the nation seemed to welcome the government of the Emperor, as it did that of Bismarck. The uneasiness which was caused at first by the unwonted vigour of his utterances subsided, as it became apparent how strong was his influence for peace, and with how many-sided an activity he supported and encouraged every side of national life. Another result of the personal government by the Emperor was that it was impossible, in dealing with recent history, to determine how far the ministers of state were really responsible for the measures which they defended, and how far they were the instruments and mouthpieces of the policy of the Emperor.

The first efforts of the "New course," as the new administration was termed, showed some attempt to reconcile to the Government those parties and persons whom Bismarck had kept in opposition. The continuation of social reform was to win over the allegiance of the working men to the person of the Emperor; an attempt was made to reconcile the Guelphs, and even the Poles were taken into favour; Windthorst was treated with marked distinction. The Radicals alone, owing to their ill-timed criticism on the private relations of the imperial family and their continued opposition to the army, were excluded. The attempt, however, to unite and please all parties failed, as did the similar attempt in foreign policy. Naturally enough, it was social reform on which at first activity was concentrated, and the long-delayed factory legislation was now carried out. In 1887 and 1888 the Clerical and Conservative majority had carried through the Reichstag laws restricting the employment of women and children and prohibiting labour on Sundays. These were not accepted by the Bundesrath, but after the International Congress of 1890 an important amendment and addition to the *Gewerbeordnung* was carried to this effect. It was of even greater importance that a full system of factory inspection was created. A further provision empowered the Bundesrath to fix the hours of labour in unhealthy trades; this was applied to the bakeries by an edict of 1895, but the great outcry which this caused prevented any further extension.

Factory laws.

These acts were, however, accompanied by language of great decision against the Social Democrats, especially on the occasion of a great strike in Westphalia, when the Emperor warned the men that for him every Social Democrat was an enemy to the empire and country. None the less, all attempts to win the working men from the doctrinaire Socialists failed. They continued to look on the whole machinery of government, emperor and army, church and police, as their natural enemies, and remained completely under the bondage of the abstract theories of the Socialists, just as much as fifty years ago the German bourgeois were controlled by the Liberal theories. It is strange to see how the national characteristics appeared in them. What began as a great revolutionary movement became a dogmatic and academic school of thought; it often almost seemed as though the orthodox interpretation of Marx's doctrine were of more importance than an improvement in the condition of the working men, and the discussions in the annual Socialist Congress resembled the arguments of theologians rather than the practical considerations of politicians. The party, however, prospered, and grew in strength beyond all anticipation. The repeal of the Socialist law was naturally welcome to them as a great personal triumph over Bismarck; in the elections of 1890 they won thirty-five, in 1893 forty-four, in 1898 fifty-six seats. Their influence was not confined to the artizans; among their open or secret adherents were to be found large numbers of Government *employés* and clerks. In the autumn of 1890 they were able, for the first time, to hold in Germany a general meeting of delegates, which has been continued annually. In the first meetings it appeared that there were strong opposing tendencies within the party which for the first time could be brought to public discussion. On the one side there was a small party, *die Jungen*, in Berlin, who attacked the parliamentary leaders on the ground that they had lent themselves to compromise and had not maintained the old *intransigeant* spirit. In 1891, at Erfurt, Werner and his followers were expelled from the party; some of them drifted into anarchism, others disappeared. On the other hand, there was a large section, the leader of whom was Herr von Vollmar, who maintained that the social revolution would not come suddenly, as Bebel and the older leaders had taught, but that it would be a gradual evolution; they were willing to co-operate with the Government in remedial measures by which, within the existing social order, the prosperity and freedom of the working classes might be advanced; their position was very strong, as Vollmar had succeeded in extending Socialism even in the Catholic parts of Bavaria. An attempt to treat them as not genuine Socialists was frustrated, and they continued in co-operation with the other branch of the party. Their position would be easier were it not for the repeated attempts of the Prussian Government to crush the party by fresh legislation and the supervision exercised by the police. It was a sign of most serious import for the future that in 1897 the electoral law in the kingdom of Saxony was altered with the express purpose of excluding the Socialists from the Saxon Landtag. This and other symptoms caused serious apprehension that some attempt might be made to alter the law of universal suffrage for the Reichstag, and it was policy of this kind which maintained and justified the profound distrust of the governing classes and the class hatred on which Social Democracy depends. On the other hand, there were signs of a greater willingness among the Socialists to co-operate with their old enemies the Liberals in opposition to the commercial policy of the Government, and every step is welcomed which will break down the intellectual isolation in which the working classes are kept.

Progress of Socialism.

In foreign affairs a good understanding with Great Britain was maintained, but the Emperor failed at that time to preserve the friendship of Russia. The close understanding between France and Russia, and the constant increase in the armies of these states, made a still further increase of the German army desirable. In 1890, while the Septennate had still three more years to run, Caprivi had to ask for an additional 20,000 men. It was the first time that an increase of this kind had been necessary within the regular period. When, in 1893, the proposals for the new period were made, they formed a great change. Universal service was to be made a reality; no one except those absolutely unfit were to escape military service. To make enlistment of so large an additional number of recruits possible, the period of service with the colours was reduced to two years. The parliamentary discussion was very confused; the Government eventually accepted an amendment giving them 557,093 for five and a half years instead of the 570,877 asked for; this was rejected by 210 to 162, the greater part of the Centre and of the Freisinnige voting against it. Parliament was at once dissolved. Before the elections the Freisinnige party broke up, as about twenty of them determined to accept the compromise. They took the name of the *Freisinnige Vereinigung*, the others who remained under the leadership of Richter forming the *Freisinnige Volkspartei*. The natural result of this split was a great loss to the party. The Liberal opposition secured only twenty-three seats instead of the sixty-seven they had held before. It was, so far as now can be foreseen, the final collapse of the old Radical party. Nothwithstanding this the Bill was only carried by sixteen votes, and it would have been thrown out again had not the Poles for the first time voted for the Government, since the whole of the Centre voted in opposition.

Military legislation.

This vote was a sign of the increasing disorganization of parties and of growing parliamentary difficulties which were even more apparent in the Prussian Landtag. Miquel, as minister of finance, succeeded indeed in carrying a reform, by which the proceeds of the tax on land and buildings were transferred to the local government authorities, and the loss to the state exchequer made up by increased taxation of larger incomes and industry. The series of measures which began in 1891, and were completed in 1895, won a more general approbation than is usual, and Miquel in this successfully carried out his policy of reconciling the growing jealousies arising from class interests.

A School Bill for Prussia was less successful, and aroused conflicts of principle, which afterwards divided the country. It is remarkable that up to this time there is no general law existing in Prussia regulating the management of the elementary schools. In every province there are different rules as to the age at which attendance is compulsory, as to school management, the regulation of religious education, and the relation of the Church to the schools.

Education proposals.

A clause in the Constitution states that these matters are to be regulated by law, but no law has yet (1902) been carried. In November 1890 a general law was introduced, but it was opposed by the Centre on the ground that it would adversely affect the religious teaching, and Gossler, minister of education, had to resign; he was succeeded by Count Zedlitz, who, in 1892, introduced a new law so drawn up as greatly to strengthen the influence of the Church. This led to a violent agitation; all the Liberal parties joined in opposing it; the agitation spread to the learned classes, and the cry was raised that culture and learning were being handed over to the priests. Caprivi defended the law as part of the great struggle between Christianity and Atheism, but the Ministry was nearly equally divided; the Emperor was dissatisfied with the manner in which it had been introduced, and on 16th March the law was withdrawn. The next day Zedlitz resigned; Caprivi also sent in his resignation, but, at the special request of the Emperor, continued in office as chancellor; he was succeeded by Count Eulenburg as president of the Prussian ministry.

Caprivi's administration was further remarkable for the arrangement of commercial treaties. In 1892 treaties with Austria-Hungary, Italy, Belgium, and Switzerland for twelve years bound together the greater part of the

Commercial treaties.

Continent, and opened a wide market for German manufactures; the idea of this policy was to secure, by a more permanent union of the middle European states, a stable market for the goods which were being excluded owing to the great growth of Protection in France, Russia, and America. These were followed by similar treaties with Rumania and Servia, and in 1894, after a period of sharp customs warfare, with Russia. In all these treaties the general principle was a reduction of the import duties on corn in return for advantages given to German manufactures, and it is this which brought about the struggle of the Government with the Agrarians, which after 1894 took the first place in party politics.

The agricultural interests in Germany had during the middle of the 19th century been in favour of Free Trade. The reason of this was that, till some years after the foundation of the empire, the production of corn and foodstuffs was more than sufficient for the population; as long as they exported corn, potatoes, and cattle, they required no protection from foreign competition, and they enjoyed the advantages of being able to purchase colonial goods and manufactured articles cheaply. Mecklenburg and Hanover,

Agrarians.

the purely agricultural states, had, until their entrance into the Customs Union, followed a completely Free Trade policy. The first union of the Agrarian party, which was formed in 1876 under the name of the Society for the Reform of Taxation, did not place protection on their programme; they laid stress on bimetallism, on the reform of internal taxation, especially of the tax on land and buildings, and on the reform of the railway tariff, and demanded an increase in the stamp duties. These three last points were all to some extent attained. About this time, however, the introduction of cheap corn from Russia began to threaten them, and it was in 1879 that, probably to a great extent influenced by Bismarck, they are first to be found among those who ask for protection.

After that time there was a great increase in the importation of foodstuffs from America. The increase of manufactures and the rapid growth of the population made the introduction of cheap food from abroad a necessity. In the youth of the empire the amount of corn grown in Germany was sufficient for the needs of its inhabitants; the amount consumed in 1899 exceeded the amount produced by about one quarter of the total. At the same time the price, making allowance for the fluctuations owing to bad harvests, steadily decreased, notwithstanding the duty on corn. In twenty years the average price fell from about 235 to 135 marks the 1000 kilo. There was therefore a constant decrease in the income from land, and this took place at a time when the great growth of wealth among the industrial classes had made living more costly. The agriculturists of the north and east saw themselves and their class threatened with loss, and perhaps ruin; their discontent, which had long been growing, broke out into open fire during the discussion of the commercial treaties. As these would inevitably bring about a large increase in the importation of corn from Rumania and Russia, a great agitation was begun in agricultural circles, and the whole influence of the Conservative party was opposed to the treaties. This brought about a curious situation, the measures being only carried by the support of the Centre, the Radicals, and the Socialists, against the violent opposition of those classes, especially the landowners in Prussia, who had hitherto been the supporters of the Government. In order to prevent the commercial treaty with Russia, a great agricultural league was founded in 1893, the *Bund der Landwirthe*; some 7000 landowners joined it immediately. Two days later the Peasants' League, or *Deutsche Bauernbund*, which had been founded in 1885 and included some 44,000 members, chiefly from the smaller proprietors in Pomerania, Posen, Saxony, and Thuringia, merged itself in the new league. This afterwards gained very great proportions. It became, with the Social Democrats, the most influential society which had been founded in Germany for defending the interests of a particular class; it soon numbered more than 200,000 members, including landed proprietors of all degrees. Under its influence a parliamentary union, the *Wirthschaftsvereinigung*, was founded to ensure proper consideration for agricultural affairs; it was joined by more than 100 members of the Reichstag; and the Conservative party fell more and more under the influence of the Agrarians.

Having failed to prevent the commercial treaties, Count Kanitz introduced a motion that the state should have a monopoly of all imported corn, and that the price at which it was to be sold should be fixed by law. On the first occasion, in 1894, only fifty members were found to vote for this, but in the next year ninety-seven supported the introduction of the motion, and it was considered worth while to call together the Prussian Council of State for a special discussion. The whole agitation was extremely inconvenient to the Government. The violence with which it was conducted, coming, as it did, from the highest circles of the Prussian nobility, appeared almost an imitation of Socialist methods; but the Emperor, with his wonted energy, personally rebuked the leaders, and warned them that the opposition of Prussian nobles to their king was a monstrosity. Nevertheless they were able to overthrow the chancellor, who was specially obnoxious to them. In October 1894 he was dismissed suddenly, without warning, and almost without cause, while the Emperor was on a visit to the Eulenburgs, one of the most influential families of the Prussian nobility.

Fall of Caprivi.

Caprivi's fall, though it was occasioned by a difference between him and Count Eulenburg, and was due to the direct act of the Emperor, was rendered easier by the weakness of his parliamentary position. There was no party on whose help he could really depend. The Military Bill had offended the prejudices of conservative military critics; the British treaty had alienated the colonial party; the commercial treaties had only been carried by the help of Poles, Radicals, and Socialists; but it was just these parties who were the most easily offended by the general tendencies of the internal legislation, as shown in the Prussian School Bill. Moreover, the bitter and unscrupulous attacks of the Bismarckian press to which Caprivi was exposed made him unpopular in the country, for the people could not feel at ease so long as they were governed by a minister of whom Bismarck disapproved. There was therefore no prospect of forming anything like a stable coalition of parties on which he could depend.

The Emperor was fortunate in securing as his successor Prince Chlodwig von Hohenlohe. Though the new chancellor once more united with this office that of Prussian minister-president, his age, and perhaps also his character, prevented him from exercising that constant activity and vigilance which his two predecessors had displayed. During his administration even the secretary of state for foreign affairs, Baron Marschall von Bieberstein, and afterwards Count von Bülow, became the ordinary spokesman of the Government, and in the management of other departments the want of a strong hand at the head of affairs was often missed. Between the Emperor, with whom the final direction of policy rested, and his subordinates, the chancellor often appeared to evade public notice. The very first act of the new chancellor brought upon him a severe rebuff. At the opening of the new buildings which had been erected in Berlin for the Reichstag, cheers were called for the Emperor. Some of the Socialist members remained seated. It was not clear that their action was deliberate, but none the less the chancellor himself came down to ask from the House permission to bring a charge of *lèse-majesté* against them, a request which was, of course, almost unanimously refused.

Chancellor Prince v. Hohenlohe.

The Agrarians still maintained their prominent position in Prussia. They opposed all Bills which would appear directly or indirectly to injure agricultural interests. They looked with suspicion on the naval policy of the Emperor, for they disliked all that helps industry and commerce. They would only give their support to the Navy Bills of 1897 and 1900 in return for large concessions limiting the importation of margarine and American preserved meat, and the removal of the Indemnitäts Nachweis acted as a kind of bounty on the export of corn. They successfully opposed the construction of a canal from Westphalia to the Elbe, on the ground that it would facilitate the importation of foreign corn. They refused to accept all the compromises which Miquel, who was very sympathetic towards them, suggested, and thereby brought about his retirement in May 1901.

The opposition of the Agrarians was for many reasons peculiarly embarrassing. The franchise by which the Prussian parliament is elected gave the Conservatives whom they controlled a predominant position. Any alteration of the franchise was, however, out of the question, for that would admit the Socialists. It was, moreover, the tradition of the Prussian court and the Prussian Government (and it must be remembered that the Imperial Government is inspired by Prussian traditions) that the nobility and peasants were in a peculiar way the support of the Crown and the State. The old distrust of the towns, of manufacturers and artizans, still continued. The preservation of a peasant class was considered necessary in the interests of the army. Besides, intellectual and social prejudices required a strong Conservative party. In the south and west of Germany, however, the Conservative party was practically non-existent. In these parts, owing to the changes introduced at the revolution, the nobility, who hold little land, are, comparatively speaking, without political importance. In the Catholic districts the Centre had become absolutely master, except so far as the Socialists threaten their position. Those of the great industrialists who belonged to the National Liberals or the Moderate Conservatives did not command that influence which men of their class generally hold in Great Britain, because the influence of Social Democracy banded together the whole of the working men in a solid phalanx of irreconcilable opposition, the very first principle of which was the hostility of classes. The Government, therefore, were compelled to turn for support to the Centre and the Conservatives, the latter being almost completely under the influence of the old Prussian nobility from the north-east. But every attempt to carry out the policy supported by these parties aroused an opposition most embarrassing to the Government.

The Conservatives distrusted the financial activity which centred round the Exchanges of Berlin and other towns, and in this they had the sympathy of Agrarians and Anti-Semites, as well as of the Centre. The Agrarians believed that the Berlin Exchange was partly responsible for the fall of prices in corn; the Anti-Semites laid stress on the fact that many of the financiers were of Jewish extraction; the Centre feared the moral effects of speculation. This opposition was shown in the demand for additional duties on stamps (this was granted by Bismarck), in the opposition to the renewal of the Bank Charter, and especially in the new regulations for the Exchange which were carried in 1896. One clause in this forbade the dealing in "futures" in corn, and at the same time a special Prussian law required that there should be representatives of agriculture on the managing committee of the Exchange. The members of the Exchanges in Berlin and other towns refused to accept this law. When it came into effect they withdrew and tried to establish a private Exchange. This was prevented, and after two years they were compelled to submit and the Berlin Bourse was again opened.

Exchange regulations.

Political parties now came to represent interests rather than principles. The Government, in order to pass its measures, was obliged to purchase the votes by class legislation, and it bought those with whom it can make the best bargain—these being generally the Centre, as the ablest tacticians, and the Conservatives, as having the highest social position and being boldest in declaring their demands. No great parliamentary leader took the place of Windthorst, Lasker, and Bennigsen; the extra-parliamentary societies, less responsible and more violent, grew in influence. The Anti-Semites gained in numbers, though not in reputation. The Conservatives, hoping to win votes, even adopted an anti-Semite clause in their programme. The general tendency among the numerous

Political bargaining.

societies of Christian Socialism, which broke up almost as quickly as they appeared, was to drift from the alliance with the ultra-Conservatives and to adopt the economic and many of the political doctrines of the Social Democrats. The *National-Socialer Verein* defended the union of Monarchy and Socialism. Meanwhile the extreme spirit of nationality was fostered by the *All-deutscher Verein*, the policy of which would quickly involve Germany in war with every other nation. More than once the feelings to which they gave expression endangered the relations of Germany and Austria-Hungary. The persecution of the Poles in Prussia naturally aroused indignation in Austria, where the Poles had for long been among the strongest elements on which the Government depended; and it was not always easy to prevent the agitation on behalf of the Germans in Bohemia from assuming a dangerous aspect.

In the disintegration of parties the Liberals suffered most. The unity of the Conservatives was preserved by social forces and the interests of agriculture; the decay of the Liberals was the result of universal suffrage. Originally the opponents of the landed interest and the nobility, they were the party of the educated middle class, of the learned, of the officials, and finance. They never succeeded in winning the support of the working men. They had identified themselves with the interests of the capitalists, and were not even faithful to their own principles. In the day of their power they showed themselves as intolerant as their opponents had been. They resorted to the help of the Government in order to stamp out the opinions with which they disagreed, and the claims of the artizans to practical equality were rejected by them, as in earlier days the claims of the middle class had been by the nobles.

The Centre alone maintained itself. Obliged by their constitution to regard equally the material interests of all classes—for they represent rich and poor, peasants and artizans—they were the natural support of the Government when it attempted to find a compromise between the clamour of opposing interests. Their own demands were generally limited to the defence of order and religion, and to some extent coincided with the wishes of the Emperor; but, as we shall see, every attempt to introduce legislation in accordance with their wishes led to a conflict with the educated opinion of the country, which was very detrimental to the authority of the Government. In the state parliaments of Bavaria, Baden, and Hesse their influence was very great. There was, moreover, a tendency for local parties to gain in numbers and influence—the Volkspartei in Würtemberg, the Anti-Semites in Hesse, and the Bauernbund (Peasants' League) in Bavaria. The last demanded that the peasants should be freed from the payment to the state, which represented the purchase price for the remission of feudal burdens. It soon lost ground, however, partly owing to personal reasons, and partly because the Centre in order to maintain their influence among the peasants adopted some features of their programme.

Another class which, seeing itself in danger from the economic changes in society, agitated for special legislation was the small retail traders of the large towns. They demanded additional taxation on the vast shops and stores, the growth of which in Berlin, Munich, and other towns seemed to threaten their interests. As the preservation of the smaller middle class seemed to be important as a bulwark against Socialism, they won the support of the Conservative and Clerical parties, and laws inspired by them were passed in Bavaria, Würtemberg, and Prussia. This *Mittelstand-politik*, as it is called, was very characteristic of the attitude of mind which was produced by the policy of Protection. Every class appealed to the Government for special laws to protect itself against the effects of the economic changes which had been brought about by the modern industrial system. Peasants and landlords, artizans and tradesmen, each formed their own league for the protection of their interests, and all looked to the state as the proper guardian of their class interests.

Mittel-stand-politik

Moral and religious policy.

After the fall of Caprivi the tendency of the German Government to revert to a strong Conservative policy in matters of religion, education, and in the treatment of political discussions became very marked. The complete alienation of the working classes from Christianity caused much natural concern, combined as it was with that indifference to religion which marks the life of the educated classes in the large towns, and especially in Berlin. A strong feeling arose that social and political dangers could only be avoided by an increase in religious life, and the Emperor gave the authority of his name to a movement which produced numerous societies for home mission work, and (at least in Berlin) led to the erection of numerous churches. Unfortunately, this movement was too often connected with political reaction, and the working classes were inclined to believe that the growth of religion was valued because it afforded an additional support to the social and political order. The situation was somewhat similar to that which existed during the last years of Frederick William IV., when the close association of religion with a Conservative policy made orthodoxy so distasteful to large sections of society. The Government, which had not taken warning by the fate of the School Bill, attempted to carry other measures of the same kind. The Emperor had returned to Bismarck's policy of joining social reform with repressive legislation. In a speech at Königsberg in November 1894, he summoned the nobles of Prussia to support him in the struggle for religion, for morality, for order, against the parties of *Umsturz*, or Revolution, and shortly afterwards an amendment of the Criminal Code, commonly called the *Umsturz Vorlage*, was introduced, containing provisions to check attempts to undermine the loyalty of the soldiers, and making it a crime punishable with three years' imprisonment to attack religion, monarchy, marriage, the family, or property by abusive expressions in such a manner as to endanger public peace. The discussion of this measure occupied most of the session of 1895; the Bill was amended by the Centre so as to make it even more strongly a measure for the defence of religion; and clauses were introduced to defend public morality, by forbidding the public exhibition of pictures or statues, or the sale of writings, which, "without being actually obscene, might rudely offend the feeling of modesty." These Clerical amendments aroused a strong feeling of indignation. It was represented that the freedom of art and literature was being endangered, and the Government was obliged to withdraw the Bill. The tendency towards a stricter censorship was shown by a proposal which was carried through the Prussian parliament for controlling the instruction given at the universities by the Privatdocenten. Some of the Conservative leaders, especially Baron von Stumm, the great manufacturer (one of Bismarck's chief advisers on industrial matters), demanded protection against the teaching of some of the professors with whose economic doctrines they did not agree; pastors who took part in the Christian-Social movement incurred the displeasure of the Government; and Professor Delbrück was summoned before a disciplinary court because, in the *Preussische Jahrbücher*,

Umsturz Vorlage.

which he edited, he had ventured to criticize the policy of the Prussian Government towards the Danes in Schleswig. All the discontent and suspicion caused by this policy broke out with greater intensity when a fresh attempt was made in 1900 to carry those clauses of the old *Umsturz Vorlage* which dealt with offences against public morality. The gross immoralities connected with prostitution in Berlin had been disclosed in the case of a murderer called Heinze in 1891; and a Bill to strengthen the criminal law on the subject was introduced but not carried. The measure continued, however, to be discussed, and in 1900 the Government proposed to incorporate with this Bill (which was known as the *Lex Heinze*) the articles from the *Umsturz Vorlage* subjecting art and literature to the control of the criminal law and police. The agitation was renewed with great energy. A *Goethe Verein* was founded to protect *Kultur*, which seemed to be in danger. In the end the obnoxious clauses were only withdrawn when the Socialists used the forms of the House to prevent business from being transacted. It was the first time that organized obstruction had appeared in the Reichstag, and it was part of the irony of the situation that the representatives of art and learning owed their victory to the Socialists, whom they had so long attacked as the great enemies of modern civilization.

Lex Heinze.

These were not the only cases in which the influence of the parties of reaction caused much discontent. There was the question of the right of combination. In nearly every state there still existed old laws forbidding political societies to unite with one another. These laws had been passed in the years immediately after the revolution of 1848, and were quite out of place under modern conditions. The object of them was to prevent a network of societies from being formed extending over large districts, and so acquiring political power. In 1895 the Prussian police used a law of 1850 as a pretext for dissolving the Socialist organization in Berlin, as had been done twenty years before. A large majority of the Reichstag demanded that an imperial law should be passed repealing these laws, and establishing the right of combination, and they refused to pass the revised Civil Code until the chancellor promised that this should be done. Instead of this course being adopted, however, special laws were introduced in most of the states, which, especially in Prussia and Saxony, while they gave the right of combination, increased the power of the police to forbid assemblies and societies. It was apparent that large and influential parties still regarded political meetings as something in themselves dangerous and demoralizing, and hence the demand of the Conservatives that women and young persons should be forbidden to attend. In Prussia a majority of the Upper House and a very large minority of the Lower House (193 to 206) voted for an amendment expressly empowering the police to break up meetings in which anarchistic, socialistic, or communistic doctrines were defended in such a manner as to be dangerous to society; the Saxon Conservatives demanded that women at least should be forbidden to attend socialistic meetings, and it remained illegal for any one under twenty-one years of age to be present at a political meeting. In consequence of the amendments in the Upper House the Prussian law was lost; and at last, in 1899, a short imperial law was carried to the effect that "societies of every kind might enter into union with one another." This was at once accepted by the chancellor; it was the time when the Navy Bill was coming on, and it was necessary to win votes. The general feeling of distrust which this prolonged controversy aroused was, however, shown by the almost contemptuous rejection in 1899 of a Bill to protect artizans who were willing to work against intimidation or violence (the *Zuchthaus Vorlage*), a vote which was the more significant as it was not so much occasioned by the actual provisions of the Bill, but was an expression of the distrust felt for the motives by which the Government was moved and the reluctance to place any further powers in their hands.

Law of combination.

In these cases the Government depended on the support of the Conservatives and Clericals, assisted sometimes by a few National Liberals. This combination of the Conservatives, moved by political and economic motives, and the Clericals, who wished to defend religion and morality, with the Prussian Government, inspired by its traditional aversion from liberty, introduced into the political situation a line of cleavage which cut across the grouping of parties on commercial questions. The result was an attempt to check by legislation the action of those moral and intellectual forces which were embodied partly in the Radical but chiefly in the Socialist party—forces which threatened to undermine the authority of Crown and Church, but were vital to the whole intellectual growth of the country. The learned classes still count for much in German life, and it is dangerous to revive that kind of intellectual discontent which prevailed when, in the 'seventies, the Governments were trying in the same way to crush the rising power of Liberalism. A generation earlier, modern thought attempted to use the whole power of the State so as to mould even the teaching of the Church; now there seemed some danger of an alliance with the Church against modern thought. Politically the power of the Church depends on universal suffrage, and so it came about more than once that an agitation among the intellectual classes was necessary in order to defeat measures inimical to liberty which secured a majority in a parliament elected by universal suffrage. There is no doubt that the restrictive policy of the Government caused much intellectual discontent. When the official teaching is that the maintenance of order and society requires restrictions on thought, and even criminal laws which are repugnant to the general feeling of the community, a moral scepticism is produced which makes a nation restless. The forces of reaction were stronger in Prussia and Saxony than in the south of Germany; and this undoubtedly strengthened the position of the southern states, for it enabled them to appear to some extent as defenders of liberty. There was therefore some increase in particularism, which during Bismarck's government nearly disappeared, and this was helped by the suspicion with which the great personal activity of the Emperor was regarded. Altogether, a good deal of disappointment and dissatisfaction existed with the management of internal affairs. Between the disintegration of parliamentary parties, the growth of Socialists and Catholics, and the increasing number of small groups, a contrast was inevitable with the state of things during the first years of the empire, when there was a strong party guiding national thought and able by the capacity of its leaders to check and assist the Government. The result, however, was, while diminishing the interest in parliamentary debate, to make the nation look with increased interest and satisfaction at the great advances made in practical affairs—commerce and industry, engineering and shipping.

Increase of Prussian autocracy.

The Emperor set himself the task of doing for the German fleet what his grandfather had done for the army. The acquisition of Heligoland enabled a new naval station to be established off the mouth of the Elbe; the completion of the canal from Kiel to the mouth of the Elbe—an old plan of Bismarck's which was begun in 1887 and completed in 1895—by enabling ships of war to pass from the Baltic to the North Sea greatly increased the strategic strength of the fleet. In 1890 a change in the organization separated the command of the fleet from the office of secretary of state, who was responsible for the representation of the Admiralty in the Reichstag, and the Emperor was brought into more direct connexion with the navy. During the first five years of the reign four line-of-battle ships were added and several armoured cruisers for the defence of commerce and colonial interests. With the year 1895 began a period of expansion abroad and great naval activity. The note was given in a speech of the Emperor's on the twenty-fifth anniversary of the foundation of the empire, in which he said, "the German empire has become a world empire." The ruling idea of this new *Welt-Politik* was that Germany could no longer remain merely a Continental power; owing to the growth of population she depended for subsistence on trade and exports; she could not maintain herself amid the rivalry of nations unless the Government was able actively to support German traders in all parts of the world. The extension of German trade and influence has, in fact, been carried out with considerable success. There was no prospect of further territory in Equatorial Africa, and the hopes of bringing about a closer union with the South African Republic were not fulfilled. On the Pacific, however, there were great gains; long-established plans for obtaining a port in China which might serve as a base for the growing trade at Tientsin were carried out at the end of 1897; the murder of two Catholic missionaries was made the pretext for landing troops in the bay of Kiao-chow; and in amends China granted the lease of some fifty square miles of territory, and also a concession for building railways. The Emperor showed his strong personal interest by sending his brother, Prince Henry, in command of a squadron to take possession of this territory, and the visit of a German prince to the Emperor of China strongly appealed to the popular imagination. The Emperor's characteristically rhetorical speeches on this occasion—particularly his identification of his brother with the "mailed fist" of Germany—excited considerable comment. In Turkey the Government, helped again by the personal interest of the Emperor, who himself visited the Sultan at Constantinople, gained important concessions for German influence and German commerce. The Turkish armies were drilled and commanded by German officers, and in 1899 a German firm gained an important concession for building a railway to Baghdad. In Brazil organized private enterprise established a considerable settlement of German emigrants, and though any political power was for the time impossible, German commerce increased greatly throughout South America.

Welt-Politik.

The "mailed fist."

Encouraged by the interest which the events in China had aroused, a very important project was laid before the Reichstag in November 1897, which would enable Germany to take a higher place among the maritime Powers. A completely new procedure was introduced. Instead of simply proposing to build a number of new ships, the Bill laid down permanently the number of ships of every kind of which the navy was to consist. They were to be completed by 1904; and the Bill also specified how often ships of each class were to be replaced. The plan would establish a normal fleet, and the Reichstag, having once assented, would lose all power of controlling the naval budget. The Bill was strongly opposed by the Radicals; the Centre was divided; but the very strong personal influence of the Emperor, supported by an agitation of the newly-formed *Flotten Verein* (an imitation of the English Navy League), so influenced public opinion that the opposition broke down. A general election was imminent, and no party dared to go to the country as the opponents of the fleet.

Naval programme, 1897.

Scarcely had the Bill been carried when a series of events took place which still more fully turned public attention to colonial affairs, and seemed to justify the action of the Government. The war between the United States and Spain showed how necessary an efficient fleet was under modern conditions, and also caused some feeling of apprehension for the future arising from the new policy of extension adopted by the United States. The Government was, however, enabled to acquire by purchase the Caroline Islands from Spain. This was hardly accomplished when events in South Africa occurred which made the nation regret that their fleet was not sufficiently strong to cope with that of Great Britain. The Government used with great address the bitter irritation against Great Britain which had become one of the most deep-seated elements in modern German life. This feeling had its origin at first in a natural reaction against the excessive admiration for English institutions which distinguished the Liberals of an older generation. This reaction was deliberately fostered during Bismarck's later years for internal reasons; for, as Great Britain was looked upon as the home of parliamentary government and Free Trade, a less favourable view might weaken German belief in doctrines and institutions adopted from that country. There also existed in Germany a curious compound of jealousy and contempt, natural in a nation the whole institutions of which centred round the army and compulsory service, for a nation whose institutions were based not on military, but on parliamentary and legal institutions. It came about that in the minds of many Germans the whole national regeneration was regarded as a liberation from British influence. This feeling was deliberately fostered by publicists and historians, and was intensified by commercial rivalry, since in the struggle for colonial expansion and trade Germans naturally came to look on Great Britain, who held the field, as their rival. The sympathy which the events of 1896 and 1899 awakened for the Boers caused all these feelings, which had long been growing, to break out in a popular agitation more widespread than any since the foundation of the empire. It was used by the Nationalist parties, in Austria as well as in Germany, to spread the conception of Pan-Germanism; the Boers as Low Germans were regarded as the representatives of Teutonic civilization, and it seemed possible that the conception might be used to bring about a closer friendship, and even alliance, with Holland. In 1896 the Emperor, by despatching a telegram of congratulation to President Kruger after the collapse of the Jameson Raid, had appeared to identify himself with the national feeling. When war broke out in 1899 it was obviously impossible to give any efficient help to the Boers, but the Government used the opportunity to make an advantageous treaty by which the possession of Samoa was transferred to Germany, and did not allow the moment to pass without using it for the very practical purpose of getting another Bill through the Reichstag by which the navy was to be nearly doubled. Some difficulties which arose regarding the exercise by the British Government of the right of search for contraband of war were also used to stimulate public feeling. The Navy Bill was introduced in January 1900. There were some criticisms of detail, but the passing of the Bill was only a matter of bargaining. Each party wished in return for its support to get some concessions from the Government. The Agrarians asked for restrictions on the importation of food; the

Pro-Boer movement.

Navy Bill, 1900.

Centre for the Lex Heinze and the repeal of the Jesuit law; the Liberals for the right of combination.

The murder of the German ambassador, Baron von Ketteler, at Peking in 1900 compelled the Government to take a leading part in the joint expedition of the Powers to China. A force of over 20,000 men was organized by voluntary enlistment from among the regular army; and the supreme command was obtained by the Emperor for Count von Waldersee, who had succeeded Moltke as chief of the staff. The Government was, however, sharply criticized for not first consulting the Reichstag in a matter involving the first military expedition since the foundation of the Empire. It was desirable in such circumstances that a younger and more vigorous statesman than Prince Hohenlohe should be placed at the head of affairs before the Reichstag met; and on 17th October he resigned, and was succeeded as Chancellor by Count von Bülow, the Foreign Secretary.

AUTHORITIES.—*Das deutsche Reich zur Zeit Bismarcks*, by HANS BLUM (1893), and ONCKEN, *Das Zeitalter des Kaiser Wilhelm*, vol. 2 (Berlin, 1890), give a connected history of the empire.—SCHULTHESS's *Europäischer Geschichtskalendar*, Nordlingen (a work similar to the *Annual Register*), is invaluable as a book of reference for recent German history; see also *Die politische Geschichte der Gegenwart*, by MÜLLER (continued by WIPPERMANN, 1871–1900). For constitutional questions see the parts dealing with Germany in MARQUARDSEN'S *Handbuch des öffentlichen Rechts der Gegenwart* (Leipzig, 1896, &c.), and LOWELL, *Governments and Parties in Continental Europe* (Longmans, 1896). For economic and statistical information the most useful work is the *Handwörterbuch der Staatswissenschaften*, edited by CONRAD and ELSTER (Jena, 1890–97, new edition, 1898, &c.); as also the *Statistisches Jahrbuch des deutschen Reichs*. For political history and party politics the reader must refer to the special works issued by the different parties as *Die National-Liberale Partei, 1867–1892* (Leipzig, 1892); *Politisches A B C-Buch*, by EUGEN RICHTER; *Conservatives Handbuch; Geschichte des Kultur-kampfes*, by MAJUNKE (Münster, 1896); *Geschichte der deutschen Social-democratie*, by F. MEHRING, Part II. (Stuttgart, 1898). GERMAN LITERATURE SINCE 1870.

I. In the years immediately following the Franco-German war the conditions existing in Germany were unfavourable to literary production, and the re-establishment of the German Empire left little or no trace on the national literature. All minds were for a time engrossed by the "Kulturkampf," which broke out in 1872 between the state and the papal authority; by the financial difficulties—the so-called "Gründertum"—due to unscrupulous speculation in Berlin; and, finally, by the rapid rise of social democracy as a political force. The first volume of Karl Marx's (1818–1883) *Das Kapital*, the chief text-book of the party, had appeared in 1867. But even if these disturbing factors had been wanting, the general atmosphere of German intellectual life was not buoyant enough to inspire a literary revival. The influence of Hegel, and the various schools which had gone out from him, was still paramount, and the "historical" method, which found characteristic expression in D. F. Strauss's (1808–1874) *Der alte und der neue Glaube* (1872), had spread over all fields of intellectual activity. To many, H. Lotze's (1817–1881) compromise between science and metaphysics was a relief from the oppression of Hegelian tradition, but, in literature and art, the dominant force was still, as before the war, the philosophy of Schopenhauer; and in his *Philosophie des Unbewussten* (1869) E. von Hartmann (born 1842) endeavoured to bring pessimism into harmony with idealism.

Philosophy.

In lyric poetry the dull monotony was broken by the victory at Sedan, the singers of the Revolution of 1848 being among the first to welcome the triumph of German arms and the unification of the nation. F. Freiligrath (1810–1876), E. Geibel (1815–1884), O. von Redwitz (1823–1891), and even G. Herwegh (1817–1875) regarded the establishment of the empire with enthusiasm; but at the same time these older revolutionists could ill conceal a certain disappointment: the united Germany of 1871 was not what they had dreamed of in their youth, when all hopes were set on the Frankfort Parliament. Geibel, whose *Heroldsrufe* appeared in 1871, was a favourite poet with all classes, and his shallow, musical verses are characteristic of the period.

Lyric of the war.

The group of writers whom Maximilian II. of Bavaria gathered round him in Munich, between 1852 and 1860, and of whom Geibel was the centre, gave the tone to German letters at the beginning of the new era. J. V. von Scheffel (1826–1886), author of *Der Trompeter von Säckingen* (1854), was the undisputed master of the story in verse, a form of poetry particularly associated with this school. *Till Eulenspiegel redivivus* (1874), J. Wolff's (born 1834) first verse-romance, was followed by *Der Rattenfänger von Hameln* (1875), *Der wilde Jäger* (1877), and *Tannhäuser* (1880)—the sentiment of the last-mentioned poem forming a striking contrast to the pessimism and satire of *Der neue Tannhäuser* (1869), an epic by E. Grisebach (born 1845). With Wolff it is usual to class R. Baumbach (born 1841), author of a number of charming tales in verse, such as *Zlatorog* (1877) and *Frau Holde* (1880). *Die Völkerwanderung* (1866–68) is an ambitious epic by H. Lingg (born 1820), while *Dreizehnlinden* (1878), by a Catholic poet, F. W. Weber (1813–1894), depicts the struggle between Christianity and Saxon heathendom in the early centuries of German history. R. Hamerling (1830–1889) also gave new vitality to the epic in his grandiose poems, *Ahasver in Rom* (1860) and *Der König von Sion* (1869). Among the older lyric poets of the Munich circle, F. von Bodenstedt (1819–1894), the author of *Mirza Schaffy*, shared Geibel's popularity, while the pessimism of the age is deeply engrained in the verse of H. Lorm (born 1821), H. Leuthold (1827–1879), and F. von Schmid (pseudonym "Dranmor," 1823–1888).

The Munich School.

The most important writer of the group is Paul Heyse (born 1830), who made his reputation with a volume of "Novellen" as far back as 1855. Since then Heyse has written more than a hundred short stories, all of which are characterized, if not by invariable truth to nature, at least by beauty of form and grace of style. In 1873 Heyse published his first novel, *Kinder der Welt*, which is one of the representative works of the period, reflecting admirably the pessimism and religious scepticism on the one hand, and on the other the jubilant hopefulness of the German capital after the war. *Im Paradiese* (1875), a romance of art-life in Munich, was followed in 1876 by *Der Roman einer Stiftsdame.* Heyse's recent novels, such as *Merlin* (1892) and *Über allen Gipfeln* (1895), continue the conflict which this author has always carried on against modern realism, but they are inferior to *Kinder der Welt.* As a lyric poet Heyse also occupies an important place, but his dramas have failed to maintain a hold upon the stage. The historical plays of Martin Greif (born 1839) have met with a similar fate, Greif's talents being lyric rather than dramatic.

P. Heyse.

The novel continued to be what it was before the war, the most vigorous form of German literature, but the novelists who were popular in 1871 were almost all past middle age. H. Laube (1806–1884) and K. Gutzkow (1811–1878) were still writing fiction, and B. Auerbach (1812–1882) expressed his enthusiasm for German unity in a novel called *Waldfried* (1874). Fritz Reuter's (1810–1874) masterly "plattdeutsch" stories remained universal favourites, while another North German, Theodor Storm (1817–1888), in his *Chroniknovellen* (1877–1886), put the crown to his work as a prose-writer. Storm and Heyse were acknowledged masters of the "Novelle" in an age which was not ripe for the manlier art of Gottfried Keller. The most widely read novelists at this time were Spielhagen and Freytag. Ten years before the war Friedrich Spielhagen, who was born in 1829, had established himself in the first rank of

The novel.

German novelists, and in 1876, as a worthy successor to *Problematische Naturen* (1860) and *In Reih' und Glied* (1866), he published *Sturmflut*, a novel in which the financial instability of Berlin was brought into parallelism with a great storm on the Baltic coasts. Among the best of Spielhagen's later books are *Plattland* (1878), *Quisisana* (1879), *Angela* (1881), *Noblesse oblige* (1888), *Sonntagskind* (1893), and *Freigeboren* (1900), but they are not to be compared with the masterpieces of his first period.

Historical fiction.

In 1872 Gustav Freytag (1816–1884) commenced the most ambitious work which the Franco-German war inspired, *Die Ahnen* (1872–81), a cycle of romances which follows the fortunes of a German family from prehistoric times to the Revolution of 1848. Generally speaking, however, the historical novel was a weak feature of the literature of this period; the example set by Scheffel in *Ekkehard* (1857) found no worthy imitators. G. Ebers (1837–1898) made the antiquarian novel fashionable with *Eine ägyptische Königstochter* (1864), which he followed up with similar works of small literary value; F. Dahn's (born 1834) historical romances, especially *Ein Kampf um Rom* (1876), found many readers, though Dahn is a scholar and historian rather than an artist; and other historical novelists, such as G. Taylor (pseudonym for A. Hausrath, born 1837) and E. Eckstein (born 1845), were hardly more successful than Dahn or Ebers. An original figure in the literature of this period is W. Jordan (born 1819), whose alliterative epic, *Die Nibelunge* (1867–1874), has a certain rugged grandeur. But although neither poetry nor fiction showed much promise, Germany was in those years making solid contributions to her intellectual possessions in other fields.

Historians.

L. von Ranke (1795–1886), still the dominant force in German historical science, published between 1881 and 1888 nine volumes of his crowning work, *Weltgeschichte;* while H. von Sybel (1817–1895) described *Die Begründung des deutschen Reichs durch Wilhelm I.* (1889–1894). But the historian who identified himself most completely with the new order of things, whereby Prussia assumed the leading rôle in the united empire, was H. von Treitschke (1834–1896); the trenchant vigour of Treitschke's lectures and of his *Deutsche Geschichte im neunzehnten Jahrhundert* (1879–1894) made him one of the most influential teachers of the younger generation. Hardly less important as an educative force was the Swiss historian, J. Burckhardt (1818–1897), whose masterly *Kultur der Renaissance in Italien* appeared in 1860. But the determining factor in this essentially unliterary era was Bismarck (1815–1898), the record of whose life and work is to be found in his *Reden* (16 vols., 1885–1891), his *Gesammelte Werke* (4 vols., 1890), and *Politische Briefe* (3 vols., 1890), as well as in the personal records of H. Kohl and M. Busch.

II. Towards the end of the first decade of the period under consideration signs of a change became visible.

Philosophy and criticism.

The philosophy of Schopenhauer, it is true, still dominated the intellectual life of the nation, but natural science and materialism had many adherents, and were appreciably weakening the influence of Schopenhauer. At the universities Hegelianism was giving way to a new movement, the motto of which was "Zurück zu Kant," and on the basis of this movement German theology, as represented by A. Ritschl (1822–1889) and his disciples—notably A. Harnack (born 1851)—entered upon a new period of development. Of the older Hegelians, Kuno Fischer (born 1824) was the most eminent, and his *Geschichte der neueren Philosophie*—especially in its latest edition, 1889–1901—is one of the outstanding achievements of recent German philosophy. People now began to have leisure to revise their opinions of the German classical poets. Schiller, it was found, no longer occupied the place that had once been his, and a number of (mostly unfinished) biographies by J. Minor, O. Brahm, R. Weltrich, and O. Harnack endeavoured to form a conclusive estimate of that writer. On the other hand, a marked change came over the nation's attitude towards Goethe, a poet to whom neither the era of Hegel nor that of Schopenhauer had been favourable. Indications of a warmer appreciation of Goethe were the lectures on the poet delivered by Herman Grimm (1828–1901) in 1877, the foundation of the Goethe Archive and the Goethe Society at Weimar in 1885, and the issue of a monumental edition of the poet's works (1887 ff.). The increased attention which has been paid to Goethe in recent years has also resulted in a large number of popular biographies, the best of which are by R. M. Meyer (published 1894) and A. Bielschowsky (vol. i., 1896). In general criticism, the chief writer between 1870 and 1880 was Karl Hillebrand (1829–1884), while, at the universities, Wilhelm Scherer (1841–1886), whose masterly *Geschichte der deutschen Litteratur* appeared in 1883, had and still has many followers.

The drama.

In the summer of 1876 Richard Wagner's (1813–1883) long struggle for his art ended with the inauguration of the "Festspielhaus" at Bayreuth and the first complete representation of *Der Ring des Nibelungen; Tristan und Isolde*, it may be noted, was performed in 1865, *Die Meistersinger von Nürnberg* in 1868, while his last work, *Parsifal*, was produced in 1882. Since about 1880 Wagner's music-dramas, which give artistic expression to the pessimism of the time, have held the chief place in the repertory of the German theatres. To Wagner on the one hand, and to the careful and artistic work of the Court Theatre of Meiningen on the other, was due the revival of German dramatic art which began in the 'eighties. The classical iambic tragedy was cultivated by the Munich School, by A. Wilbrandt (born 1837), whose *Arria und Messalina* appeared in 1874, and A. Lindner (1831–1888), author of *Brutus und Collatinus* (1867) and *Die Bluthochzeit* (1871); and it was also characteristic of the time that Halm was popular, while Hebbel and Grillparzer were neglected. Superior to Wilbrandt's iambic tragedies were his comedies, *Die Maler* (1872), *Jugendliebe* (1873), and his dramas of a later period, *Die Tochter des Herrn Fabricius* (1883) and *Der Meister von Palmyra* (1889). The really popular playwrights at this date, however, were R. Benedix (1811–1873) and his successors, A. L'Arronge (born 1833), G. von Moser (born 1825), F. von Schönthan (born 1849), and O. Blumenthal (born 1852); and social dramas on French models, such as P. Lindau's (born 1839) *Ein Erfolg* (1874) and *Gräfin Lea* (1879), were more to the taste of the public than the verse-dramas of H. Kruse (1818–1902), of the Austrian F. Nissel (1831–1893), or a tragedy like A. Fitger's (born 1840) *Die Hexe* (1876). Apart from Wagner, the only German dramatist of importance between 1870 and 1880 was Ludwig Anzengruber (1839–1889), an Austrian, whose first play, *Der Pfarrer von Kirchfeld* (1870), reflected the liberal ideas that were then in the air; and this was followed by a series of masterly dramas, mostly in dialect, such as *Der Meineidbauer* (1871), *Die Kreuzelschreiber* (1872), *Der G'wissenswurm* (1875), *Der Doppelselbstmord* (1876), and *Das vierte Gebot* (1878).

L. Anzengruber.

Compared with the peasant-literature of the middle of the century, Anzengruber marks an advance, in so far as his peasants are less violently adapted to artificial literary ideals: in this respect he is to some extent a forerunner of the realistic school. The North German theatre had no writer who could be compared with Anzengruber, but in 1882 hopes were raised by Ernst von Wildenbruch's historical tragedy, *Die Karolinger.* Wildenbruch, who was born at Beirut in Syria in 1845, first attracted attention by two "Heldenlieder," *Vionville* (1874) and *Sedan* (1875), on the war of 1870–71, in which he had himself taken part. His dramas, *Die Karolinger*, *Harold* (1882), *Der Menonit* (1882), *Christoph Marlowe* (1884), and *Das neue Gebot* (1886), were followed in 1888 by *Die Quitzows*, with which the author touched the height of his popularity. This play was the first of a series of dramas, including *Der Generalfeldoberst* (1889), *Der neue Herr* (1891), *Der Junge von Hennersdorf* (1896), on subjects borrowed from the history of Prussia. Wildenbruch has also written *Die Haubenlerche* (1891), a realistic drama of modern life, and, more recently, *Heinrich und Heinrichs Geschlecht* (1896), a double drama on Emperor Heinrich IV., and *Die Tochter des Erasmus* (1900). As a dramatist Wildenbruch combines a keen sense of stage effect with strong patriotism and a somewhat effusive pathos, but higher dramatic or poetic qualities are only sparingly present in his work.

E. von Wildenbruch.

The writers of fiction, who took a leading place before the realistic movement set in, were, like their predecessors, influenced by mid-century traditions, but, in the novel as in the drama, the younger generation was beginning to make more exacting artistic demands. Since 1869 the North German, A. Wilbrandt, whose work as a dramatist has already been mentioned, had been known to the public as a novelist, but *Adams Söhne*, his first book worthy of note, only appeared in 1892. It was succeeded by *Hermann Ifinger* (1892), *Der Dornenweg* (1894), *Die Osterinsel* (1895), *Die Rothenburger* (1895), and *Hildegard Mahlmann* (1897), novels which, although old-fashioned in style and technique, discussed themes of actual interest, such as Böcklin's art and Nietzsche's philosophy. This somewhat factitious interest in Wilbrandt's books is wanting in the novels of Wilhelm Jensen (born 1837); it is unfortunate, however, that the delicate poetic talent revealed in some of Jensen's earlier "Novellen" is entirely lost amidst the diffuseness and formlessness of the many volumes he has published since 1866. A novelist whose style is more in accordance with modern taste is Hans Hopfen (born 1835), while the humourist of the group is Wilhelm Raabe (born 1831), who wrote his early work under the pseudonym of "Jakob Corvinus." Raabe combines with a sentimentalism not unlike Jean Paul's a very modern pessimism, and has a clearer sense for the actual aspect of what he describes than either Wilbrandt or Jensen; his most characteristic novels, however, such as *Der Hungerpastor* (1865) and *Abu Telfan* (1867), appeared before the period under discussion. Other humorous writers are H. Seidel (born 1842), who since 1871 has published a series of charming sketches (*Leberecht Hühnchen*, 1880), which are true to the best traditions of German humour, and W. Busch (born 1832), author of *Max und Moritz* (1858), *Die fromme Helene* (1871). Hans Hoffmann (born 1848) is seen to more advantage in the *Geschichten aus Hinterpommern* (1891), in which he is a disciple of Storm and Reuter, than in his ambitious novels on Prussian history. A humorist who stands somewhat alone is the Hegelian professor of æsthetics, F. T. Vischer (1807–1887), who in 1878 brought out an admirable satirical novel, *Auch Einer*, and in 1882 his collected lyrics as *Lyrische Gänge.* Younger writers of fiction, whose style has more in common with the group of novelists under consideration than with the realistic school presently to be discussed, are Ernst von Wildenbruch, E. Wichert (1831–1902), A. Stern (born 1835), Isolde Kurz (born 1853), and Ricarda Huch (born 1864). The two most eminent Austrian novelists of the period are Marie von Ebner-Eschenbach (born 1830) and Ferdinand von Saar (born 1833). The former of these wrote in 1876 an excellent novel, *Bozena*, but her "Novellen" first made her name known outside Austria; the genial humour and the light ironical touch of *Neue Erzählungen* (1881), *Dorf und Schlossgeschichten* (1883)—above all, of the excellent story, *Zwei Comtessen* (1885)—are unique of their kind. Frau von Ebner-Eschenbach is also the author of several longer novels, *Das Gemeindekind* (1887), *Unsühnbar* (1890), *Glaubenslos?* (1893), and a collection of subtle *Aphorismen* (1880); she is unquestionably the most gifted woman writer in recent German literature. Ferdinand von Saar has written comparatively little—a few dramas, several volumes of short stories (*Novellen aus Oesterreich*, 1876; *Herbstreigen*, 1897), a handful of *Gedichte* (1882), and *Wiener Elegien* (1892), but his delicacy, his lightness of touch, and the deep undercurrent of pessimism in all his work place him in the front rank of modern poets and prose-writers. The story in dialect bulks largely in recent Austrian literature, a typical novelist of this class being Peter Rosegger (born 1843 in Styria). Rosegger's *Schriften des Waldschulmeisters* appeared in 1875, and have been followed by a large number of similar stories, all sentimental in tone. An Austrian, too, is K. E. Franzos (born 1848), whose early novels and sketches describe Galician life (*Aus Halbasien*, 1876; *Die Juden von Barnow*, 1877), while L. von Sacher-Masoch (1835–1895) has written a series of vivid *Galizische Geschichten* (1876–81) and *Judengeschichten* (1878). But the two masters of German prose at this epoch, Gottfried Keller and Konrad Ferdinand Meyer, were neither Austrians nor Germans.

The novel.

Austrian writers.

Gottfried Keller was born at Zurich in 1819, and died there in 1890. His ambition was to be an artist, and, with this object, he spent two years in Munich; in 1848 a bursary allowed him to study at the University of Heidelberg, and two years later he went to Berlin with a view to becoming a dramatist. From 1861 to 1876 Keller was town-clerk in his native town. Meanwhile, in 1846 and again in 1851, he published volumes of poetry, and in 1854, after a protracted delay, his fine autobiographical novel, *Der grüne Heinrich.* This work was followed by a volume of short stories, entitled *Die Leute von Seldwyla* (1856). Although both *Der grüne Heinrich* and the "Novellen"—above all, such stories as *Romeo und Julia auf dem Dorfe* and *Die drei gerechten Kammmacher*—were unrivalled in the literature of their time, Keller's importance was not generally recognized until the appearance of a second edition and an additional volume (1874) of *Die Leute von Seldwyla.* In 1872 he published a cycle of *Sieben Legenden*, and in 1879–80 a revised edition of *Der grüne Heinrich.* The *Züricher Novellen*, including the masterpieces, *Der Landvogt von Greifensee* and *Das Fähnlein der sieben Aufrechten*, appeared in 1878, *Das Sinngedicht* in 1882, and a less successful novel, *Martin Salander*, in 1886. Original and inspired although much of Keller's lyric poetry is, his genius could only move at ease in prose. He is, without question, the most eminent German novelist of the century. Of all modern German writers, he alone was endowed with that *naïveté* which Schiller regarded as characteristic of the highest form of genius. (*Cf.* J. Baechtold, *Gottfried Kellers Leben*, 3 vols., Berlin, 1894–97.)

G. Keller.

K. F. Meyer (1825–1898), who turned to literature comparatively late in life, was also a native of Zurich. Two volumes of verse, which appeared in 1864 and 1871, attracted little attention, but his epics, *Huttens letzte Tage* (1871) and *Engelberg* (1872), were widely read; and these were followed by the novels on which his reputation rests—*Das Amulet* (1873), *Jürg Jenatsch* (1876), *Der Heilige* (1880), *Plautus im Nonnenkloster* (1882), *Die Hochzeit des Mönchs* (1884), *Die Versuchung des Pescara* (1887), *Angela Borgia* (1890). In the choice of his subjects Meyer shows a preference for the virile personalities of the Renaissance, whom he describes with an objectivity unusual in German writers; above all, his novels are masterpieces in form and style. (*Cf.* A. Frey, *K. F. Meyer*, Stuttgart, 1900.)

K. F. Meyer.

III. The last fifteen years of the 19th century were distinguished in Germany by a remarkable literary activity. Since about 1885 Berlin has unmistakably asserted itself as the intellectual and artistic metropolis, and the leadership in literature has passed into the hands of a new generation of writers, who have grown up as citizens of the empire. An all-important condition, however, for any healthy revival of literature in Germany was that it should be freed from the clogging elements of mid-century tradition—above all, from the levelling influence of Hegelianism and the collective ideals of socialism. The liberator from tradition, the writer who embodies most completely the spirit of the period, is Friedrich Nietzsche.

F. W. Nietzsche. Friedrich Wilhelm Nietzsche was born at Röcken, near Lützen, on 15th October 1844. He was educated at Pforta, and subsequently studied classical philology at Bonn and Leipzig. In 1870 Nietzsche was appointed professor of classical literature at Basel, but in 1879 was obliged to resign this position owing to ill-health. The next ten years were spent partly in Italy, partly at high altitudes in Switzerland, until in 1889 he became insane. He died at Weimar on 25th August 1900. *Die Geburt der Tragödie aus dem Geiste der Musik* (1872), Nietzsche's first book, was written under the influence of Schopenhauer and Wagner, and discussed the Dionysiac origin of the Greek drama. In the *Unzeitgemässen Betrachtungen* (4 vols., 1873-76) he laid, in a trenchant, polemical style, a foundation for the new ideas of the time. The first of these *Betrachtungen* was an attack on Strauss's *Der alte und der neue Glaube;* the second gave definite form to Nietzsche's attack on the Hegelian ideals of a "historical" culture. The third *Betrachtung, Schopenhauer als Erzieher*, expressed the writer's indebtedness and that of his time to the great thinker of the previous generation; while the last, devoted to his friend and master, Richard Wagner, was written at a time when Nietzsche was already struggling to free himself from Wagner's influence. The writings of the next period of Nietzsche's life, *Menschliches, Allzumenschliches* (1878–1880), *Morgenröte* (1881), and *Die fröhliche Wissenschaft* (1882), show his philosophic ideas in the process of crystallization; these books represent a preliminary, positive stage, in which their author was casting aside traditional prejudices. The full development of his thought is to be found in *Also sprach Zarathustra* (1883-91)—the most original philosophic and poetic masterpiece of modern German literature—in *Jenseits von Gut und Böse* (1886), and *Zur Genealogie der Moral* (1887). Finally, *Der Fall Wagner* (1888) and *Nietzsche contra Wagner* (1889), gave full expression to the breach between Nietzsche and Wagner. Of a comprehensive work, *Der Wille zur Macht, Versuch einer Umwertung aller Werte*, which was intended to contain a summary of his whole philosophy, only fragments were completed, which have been published in posthumous volumes. So far as it is possible to speak at present, Nietzsche represents the final stage of the revolt against Hegelianism. Individualism here takes the place of collectivism, and pessimism gives way to a vigorous optimism. The individual, not the race; the "Herrenmensch," not the slave; self-assertion, not self-less renunciation—these are the chief ideas round which Nietzsche's ethics turn. Above all, he looks forward to the human race emerging from an effete culture, and re-establishing itself on a new basis, in harmony with primitive instincts. Nietzsche follows in Schopenhauer's footsteps by being not only a philosopher, but also a stylist; his musical language and clear, finely balanced sentences are a marked advance on the superficiality and clumsiness that have lain heavy on German prose since the days of "Young Germany." (*Cf.* E. Forster-Nietzsche, *Das Leben Friedrich Nietzsche's*, I.-II., Leipzig, 1895-97; H. Lichtenberger, *La Philosophie de Nietzsche*, Paris, 1898; T. Ziegler, *Friedrich Nietzsche*, Berlin, 1900.)

The full import of this individualistic philosophy—which was to some extent foreshadowed by a work like *Der Wert des Lebens* (1865), by E. Dühring (born 1833)—was not understood until Nietzsche himself could no longer appreciate his recognition; but the antagonism which he expressed to conventional ideals of culture early met with an enthusiastic response. The influence of the *Unzeitgemässen Betrachtungen* is to be seen in J. Langbehn's *Rembrandt als Erzieher*, a book which, appearing in 1890, was for some years extraordinarily popular. Under the auspices of realism, which had taken root not only in France, but also in Russia and Scandinavia, the German people began to take a more serious interest in literature. The inspirers of the German movement were Flaubert, the brothers Goncourt, Zola and Maupassant, Tolstoi and Dostoieffski, while, as regards the drama, the chief stimulus came from Norway; plays by both Björnson and Ibsen were seen on the German stage before 1880. The new movement was accompanied by a corresponding change in the spirit of German criticism, which is to be observed in the work of O. Brahm (born 1856), P. Schlenther (born 1854)—both of whom studied under Wilhelm Scherer—and the brothers Heinrich and Julius Hart (born 1855 and 1859). M. G. Conrad (born 1846), K. Bleibtreu (born 1859), and Arno Holz (born 1863) formulated the principles of German realism, while, under the guidance of the Viennese critic, Hermann Bahr (born 1862), contemporary Austrian literature at an early date abandoned realism in favour of symbolism and decadence. Max Nordau (born 1849) has written several volumes of vigorous and independent criticism, while, of the older writers, Spielhagen and Fontane welcomed every new development with encouragement. The Danish critic, Georg Brandes, who in his own literature created a literary school on the basis of realism, has also exerted very considerable influence on recent German criticism.

The realistic movement. Criticism.

Fiction. The new school in German fiction virtually began with the novels of a writer who was well known as poet and journalist long before the Franco-German war; in 1878 Theodor Fontane (1819–1898) brought out his first romance, *Vor dem Sturm*, and this was followed by several other more or less successful stories, such as *Grete Minde* (1880) and *Schach von Wuthenow* (1883). Fontane's realism was not, however, pronounced until he wrote *L'Adultera* (1882) and *Graf Petöfy* (1884). In the following years appeared *Irrungen, Wirrungen* (1887), *Stine* (1890), *Frau Jenny Treibel* (1892), *Effi Briest* (1895), and *Der Stechlin* (1898). *Effi Briest*, one of the masterpieces of modern fiction, marks the culminating point of Fontane's work. The strictly realistic novels of the period were written by H. Conradi (1862–1890), Max Kretzer (born 1854), M. G. Conrad, H. Heiberg (born 1840), K. Bleibtreu, K. Alberti (born 1862), and H. Sudermann. In his early work, *Meister Timpe* (1888), Kretzer gave promise of being the leading German realist, but his subsequent books were disappointing. A want of stability was characteristic, however, of the whole movement in Germany; the idealistic trend of the German mind proved ill adapted for the uncompromising realism of the French writers, and the German adherents of the school ultimately sought to escape from the consequences of their theories—Kretzer, for example, in the supernaturalism of his novel, *Das Gesicht Christi* (1897), Hauptmann in *Hanneles Himmelfahrt* (1893) and *Die versunkene Glocke* (1896). Even Sudermann, whose *Frau Sorge* (1887), *Die Geschwister* (1888), *Der Katzensteg* (1889), and the brilliant, though sensational romance, *Es war* (1894), are among the best novels of this period, has never been consistently realistic. Novelists whose work, although popular, has little abiding value, are T. H. Pantenius (born 1843), E. von Wolzogen (born 1855), J. C. Heers (born 1859), G. von Ompteda (born 1863), and F. Holländer (born 1867). Of the large number of women engaged in writing fiction, the most distinguished are—besides Isolde Kurz and Ricarda Huch, already mentioned—I. Frapan (born 1852), G. Reuter (born 1859), Clara Viebig (born 1860), and Helene Böhlau (born 1859). The last-mentioned is the author, amongst other works, of an admirable story of Munich art-life, *Der Rangierbahnhof* (1896), *Ratsmädelgeschichten* (1888–1897), and *Das Recht der Mutter* (1897).

At no period in Germany were literature and the theatre in such close touch as at the end of the 19th and opening of the 20th centuries: more than ever before, the theatre became the arena in which all literary battles were fought out. Since about 1875 the German theatre and German acting had undergone a steady improvement, and E. von Wildenbruch has already been mentioned as a pioneer of the new drama. With Wildenbruch is to be associated Richard Voss (born 1851), who, in such plays as *Alexandra* (1888), *Eva* (1889), and *Die neue Zeit* (1891), stands nearer the younger writers than in his verse tragedy, *Luigia San Felice* (1882). But, as far as the drama is concerned, the new movement did not set in definitely until the end of 1889. In October of that year G. Hauptmann's play, *Vor Sonnenaufgang*, was produced on the recently founded "Freie Bühne" in Berlin; and a month later *Die Ehre*, by H. Sudermann, met with a more enthusiastic reception than had fallen to the lot of a German play for many years.

The drama.

Gerhart Hauptmann, who was born in 1862, at Salzbrunn in Silesia, is the most original modern German writer. His earliest work was an epic, *Promethidenlos* (1885), written in the style popular at the middle of the century; and in 1889 and 1890 his two first social dramas, *Vor Sonnenaufgang* and *Das Friedensfest*—both of which show the influence of Holz's realistic theories—were performed. They were followed in 1891 by *Einsame Menschen*, for which Ibsen's later plays served as models. Hauptmann's genius found a more congenial subject in *Die Weber* (1892)—originally in Silesian dialect as *De Waber*—a powerful play on the sufferings of the Silesian weavers in 1844. Slighter pieces were *College Crampton* (1892), an admirable study of an artist fallen upon evil days, and a "thieves' comedy," *Der Biberpelz* (1893). In 1893 Hauptmann also brought out another work which attracted general attention, *Hanneles Himmelfahrt*, in which a sordid realism is contrasted with the poetic mysticism of a child's dream. *Florian Geyer* (1895) is a tragedy of the 16th century, but on so large a scale and so historically realistic that it found little favour on the stage. Most popular of all Hauptmann's works is the allegorical dramatic poem, *Die versunkene Glocke* (1896), which did not, however, afford his peculiar genius the same scope as the plays of actual life, and to this form of drama he returned in his next work, *Fuhrmann Henschel* (1898), perhaps the finest tragedy that the German realistic movement has produced. A humorous poetic fantasy, *Schluck und Jau*, appeared in 1900, *Michael Kramer* also in 1900, and in the following year *Der rote Hahn*, a sequel to *Der Biberpelz*. (*Cf.* P. Schlenther, *Gerhart Hauptmann*, Berlin, 1898). As a dramatist, Hermann Sudermann has been more influenced than Hauptmann by the traditions of the German theatre. A native of East Prussia, where he was born in 1857, Sudermann passed through a severe apprenticeship to literature before *Frau Sorge* and *Die Ehre* brought him fame. The popularity of *Die Ehre* was due partly to its satire on conventional ideas of honour, partly to the realism with which the stock figures of the "bürgerliche Drama" were described. *Sodoms Ende* (1891), Sudermann's next play, although it met with less success, showed a marked advance in dramatic construction, while *Heimat* (1893), the theme of which is similar to that of *Die Ehre*, carried its author's reputation beyond the boundaries of Germany. Since then Sudermann has added to his dramas of contemporary life *Schmetterlingsschlacht* (1895), *Das Glück im Winkel* (1896), *Johannisfeuer* (1900), and *Es lebe das Leben!* (1902). Although a keen observer, and never deficient in interesting ideas, Sudermann is, in the first instance, a practical playwright, and the theatrical element in his work occasionally overshadows its finer literary qualities. In the one-act plays, grouped under the titles *Morituri* (1896), in *Johannes* (1898), and *Die drei Reihersfedern* (1899), Sudermann has abandoned the drama of modern life for fields in which he is less at home; most important of these is the second, a prose tragedy on John the Baptist, in which the psychological conflict is treated with a refinement that recalls Hebbel. (*Cf.* W. Kawerau, *Hermann Sudermann*, Magdeburg, 1897).

G. Hauptmann.

H. Sudermann.

Since the production of *Die Ehre*, the drama has occupied the foreground of interest in Germany. It is true that the permanent repertory of the German theatre has, so far, been but little enriched by the activity in this form of literature, but it is at least a healthy sign that German playwrights are unwilling to rest content with their successes, and are constantly experimenting with new forms. Besides Hauptmann and Sudermann, the most talented dramatists of the present day are Max Halbe (born 1865), whose *Jugend* (1893) and *Mutter Erde* (1897), are, however, better than any plays he has since published; O. E. Hartleben (born 1864), author of *Hanna Jagert* (1893), *Rosenmontag* (1900), and other plays; W. Kirchbach (born 1857); and G. Hirschfeld (born 1873). The most consistently realistic dramatist is Johannes Schlaf (born 1862), whose first drama, *Familie Selicke* (1889), written in collaboration with Arno Holz, is typical of the movement. E. Rosmer (pseudonym for Elsa Bernstein, born 1866) has written, besides several realistic pieces, a drama in verse, *Königskinder* (1895), which may be compared with Hauptmann's *Versunkene Glocke*. A lighter vein is exemplified by the graceful comedies (*Der Talisman*, 1893; *Jugendfreunde*, 1897, &c.) of Ludwig Fulda (born 1862); by the plays of Max Dreyer (born 1862), especially *Der Probekandidat* (1899), and of Otto Ernst (pseudonym for O. E. Schmidt, born 1862). In Austria the drama still retains the specifically national character it has possessed throughout the century. The most eminent writers for the stage here are Arthur Schnitzler (born 1862), whose *Anatol* (1893) and *Liebelei* (1896) show an almost French lightness of touch; Hermann Bahr and Philipp Langmann (born 1862); while J. J. David (born 1859), best known as a novelist, has also written plays. Lastly, Hugo von Hofmannsthal's (born 1874) *Theater in Versen* (1899) reveals a poetic talent of extraordinary delicacy.

The most characteristic expression of German literature in every period is to be found in the lyric. The present epoch is no exception, although, apart from Liliencron, it is not possible to point to a single poet of the first order. But, regarded as a whole, the modern German lyric shows a remarkable variety of new tones and pregnant poetic ideas; it has been more influenced by the individualism and optimism of Nietzsche—himself a lyric poet of considerable gifts—than has either novel or drama. Detlev von Liliencron, who, born in 1844, belongs to the older generation, was the first to break with the traditions of the German lyric as handed down from the Romantic epoch; in his *Adjutantenritte* (1883) he opposed to the melancholy and sentimentality of the Munich school a vigorous and healthy delight in life. While the lyric of Keller, Meyer, Saar, the Prince of Schönaich-Carolath (born 1852), Isolde Kurz, and Ricarda Huch is essentially conservative in character, A. Holz, J. Schlaf, and W. Arent (born 1864) made, to some extent under the influence of Walt Whitman, a complete break with the past. Since the appearance of Arent's lyric anthology, *Moderne Dichtercharaktere*, in 1885, the number of essentially modern poets has greatly increased; among the more characteristic are Richard Dehmel (born 1863), K. Henckell (born 1864), J. H. Mackay (born 1864, at Greenock), G. Falke (born 1853), F. Avenarius (born 1856), L. Jacobowski (1868–1900), F. Evers (born 1871), F. Dörmann (born 1870), and K. Busse (born 1872). The latest development of the German lyric—a return to the mystic and symbolic—is to be seen in the work of Stefan George (born 1865). Epic poetry, although little in harmony with the spirit of the time, is not altogether neglected; the brothers Hart have published the first volumes of *Das Lied der Menschheit* (1887 ff.), an epic planned on an ambitious scale; and in Austria Marie delle Grazie (born 1864) has followed in Hamerling's footsteps with *Robespierre* (1894), an epic in two volumes. Lastly, the extraordinary popularity of the *cabaret*, or so-called "Ueberbrettl," in recent years has not been without some effect on literature. Particularly associated with this movement are E. von Wolzogen (born 1885) and O. J. Bierbaum (born 1865), and it is significant that a collection of Bierbaum's lyrics (*Irrgarten der Liebe*, 1901)

The modern lyric.

has been the most popular volume of poetry published in Germany since the days of Bodenstedt and Geibel.

Gérôme, Jean Léon (1824– ——), French painter, was born 11th May 1824 at Vesoul (Haute-Saône). He went to Paris in 1841 and worked under Paul Delaroche, whom he accompanied to Italy (1844–45). On his return he exhibited "The Cock-fight," which gained him a third-class medal in the Salon of 1847. "The Virgin with Christ and St John" and "Anacreon, Bacchus, and Cupid" took a second-class medal in 1848. He exhibited "Bacchus and Love, Drunk," a "Greek Interior," and "Souvenir d'Italie," in 1851; "Pæstum" (1852); and "An Idyll" (1853). In 1854 Gérôme made a journey to Turkey and the shores of the Danube, and in 1857 visited Egypt. To the exhibition of 1855 he contributed a "Pifferaro," a "Shepherd," "A Russian Concert," and a large historical canvas, "The Age of Augustus and the Birth of Christ." The last was somewhat confused in effect, but in recognition of its consummate ability the State purchased it. Gérôme's reputation was greatly enhanced at the Salon of 1857 by a collection of works of a more popular kind: the "Duel: after a Masquerade" (see Plate), "Egyptian Recruits crossing the Desert," "Memnon and Sesostris," and "Camels Watering," the drawing of which was criticized by Edmond About. In "Cæsar" (1859) Gérôme tried to return to a severer class of work, but the picture failed to interest the public. "Phryne before the Areopagus," "Le Roi Candaule," and "Socrates finding Alcibiades in the House of Aspasia" (1861), gave rise to some scandal by reason of the subjects selected by the painter, and brought down on him the bitter attacks of Paul de Saint-Victor and Maxime Ducamp. At the same Salon he exhibited the "Egyptian chopping Straw," and "Rembrandt biting an Etching," two very minutely finished works. Gérôme's best paintings are of Eastern subjects; among these may be named the "Turkish Prisoner," and "Turkish Butcher" (1863); "Prayer" (1865); "The Slave Market" (1867); and "The Harem out Driving" (1869). He often illustrated history, as in "Louis XIV. and Molière" (1863); "The Reception of the Siamese Ambassadors at Fontainebleau" (1865); and the "Death of Marshal Ney" (1868). Gérôme has also been successful as a sculptor; he executed, among other works, "Omphale" (1887), and the statue of the duc d'Aumale which stands in front of the Château of Chantilly (1899). His "Bellona" (1892), in ivory, and metal, precious stones, which was also exhibited in the Royal Academy of London, attracted great attention. The artist then began an interesting series of "Conquerors," wrought in gold, silver, and gems—"Bonaparte entering Cairo" (1897); "Tamerlane" (1898); and "Frederick the Great" (1899). Gérôme was elected member of the Institut in 1865.

Gerona, a maritime frontier province in the extreme north-east of Spain, with an area of 2272 square miles. The population in 1877 was 299,702, and in 1897 298,497. The proportion of illegitimate births (1·50 per cent.) is the lowest in Spain. The province is divided into six administrative districts and 249 parishes. Its general aspect is mountainous, especially in the western districts. Most of the lower chains are covered with splendid forests of oak, pine, and chestnut. More than a hundred mineral springs are scattered over the province. The climate is generally temperate and rainy during several months in the valleys and near the coast, cold in the Cerdana and Rivas districts during eight months, whilst Gerona, La Bisbal, and Santa Coloma are quite Mediterranean in their hot summers and mild winters. The principal local industry is fishing, which in 1898 occupied 2653 hands and 518 boats, the fish being valued at £28,000; there are thirty-one factories for salting fish. Next in importance is the cork industry, occupying 8000 hands at San Feliu de Guixols, Palafrugell, and Cassa. There are also important hydraulic cement, estealite, and ochre works, and no fewer than twenty-two of the towns are centres of manufactures of linen, cotton, woollen stuffs, paper, iron foundries, cloth, leather, steel, copper, and furniture. The commerce of the province is important, Port Bou being, after Irun, the most active outlet for the trade not only with France but with the rest of the Continent by land and railway. The main railway from Barcelona to France runs through the province, and there is another line from Gerona to Olot; there are besides several good steam tramways connecting industrial centres. There are sixteen productive coal mines, turning out some 40,000 tons a year. Agriculture is in a backward state. Official data (1898) show that 78,000 acres produce wheat; 42,352 acres barley, oats, rye, maize; 18,000 acres vines; 38,500 acres olives. The capital, Gerona, has greatly developed its local industries. It is still a fortified and walled town, with a citadel used as a state prison. Population, 16,000.

Gers, a department in the south of France, watered by the river Gers.

Area, 2429 square miles. From 274,391 in 1886 the population decreased to 236,204 in 1901. There were in 1896 832 schools, with 27,000 pupils, and 6 per cent. of the population was illiterate. The area under cultivation amounted in 1896 to 1,393,700 acres, 751,200 of which were plough-land and 256,990 vineyards. There are few industries beyond the manufacture of the esteemed brandy of Armagnac, the distillation of which in 1898 amounted to 178,000 gallons. Auch, the capital, has a population of 11,500.

Gettysburg, capital of Adams county, Pennsylvania, U.S.A., on the Philadelphia and Reading and the Western Maryland railways. It was the scene of one of the most important battles in the Civil War. This took place on 1st, 2nd, and 3rd July 1863, between the Union forces, numbering 78,043, under General Meade, and the Confederates, numbering from 70,000 to 77,000, under General Lee, and resulted in the defeat of the latter. The former lost in killed, 3072; wounded, 14,497; missing, 5434; total, 23,003. The latter lost in killed, 2592; wounded, 12,709; missing, 5150; total, 20,451. The site of the battle has been acquired by the general Government and made a national cemetery, in which the bodies of 3580 Union soldiers have been buried. It was at the dedication of this cemetery in November 1863 that President Lincoln delivered his celebrated "Gettysburg Oration." Population (1890), 3221; (1900), 3495, of whom 58 were foreign-born and 234 negroes.

Ghadames. Ghat. See Tripoli.

Ghazipur, a town and district of British India, in the Benares division of the North-West Provinces. The town is on the left bank of the Ganges, 44 miles east of Benares. Population (1881), 32,885; (1891), 44,970; (1901), 39,186. Municipal income (1897–98), Rs.38,979. Death-rate (1897), 60·31 per thousand. The District of Ghazipur has an area of 1462 square miles. It had a population in 1881 of 1,014,099, and in 1891 of 1,077,909, giving an average

"THE DUEL AFTER THE BALL." By J. L. GÉRÔME.

(From a Photograph by Goupil and Co.)

density of 737 persons per square mile. In 1901 the population was 914,148, showing a decrease of 11 per cent. The land revenue and rates were Rs.11,81,745, the incidence of assessment being R.1–2–8 per acre; the cultivated area in 1896–97 was 558,410 acres, of which 188,348 were irrigated, mostly from wells; the number of police was 2191; the number of vernacular schools in 1896–97 was 88, with 4336 pupils; the registered death-rate in 1897 was 27 per thousand. There are 84 indigo factories, employing 2501 persons, with an annual outturn valued at Rs.1,55,000, and three printing-presses. The main line of the East Indian Railway traverses the southern portion of the district, with a branch to the Ganges bank opposite Ghazipur town, 35 miles in all.

Ghazni, a city of Afghanistan, 78 miles south-west of Kabul. Its position, as determined by recent surveys, is in 33° 33′ N. and 68° 28′ E., its altitude above sea-level being 7280 feet. It is still in the condition of decay which was described by Yate in 1875, and nothing substantially was added to our information regarding its condition or history by the investigations of the officers with Stewart's force, which passed upwards from Kandahar to Kabul in 1879, or with Roberts's force, which passed downwards in 1880. A very considerable trade in fruit, wool, skins, &c., is carried on between Ghazni and India by the povindah Khafilas, which yearly enter India in the late autumn and pass back again to the Afghan highlands in the early spring. The povindah merchants belong chiefly to Nasir, Suliman Khel, and other Ghilzai clans. They invariably make use of the Gomul pass route which leads to the British frontier at Dera Ismail Khan. The opening up of this pass and the British occupation of Wana, by offering protection to the merchants from Waziri blackmailing, largely increased the traffic. In 1890 the estimated value of imports and exports on the Gomul trade route was about 20 lakhs of rupees annually.

Gheel, a town of Belgium, in the province and 25 miles east of the town of Antwerp, with a station on the railway line between Herenthals and Moll. It is chiefly notable for its unique system of treatment for the insane, which dates from the 13th century. The asylum, a large structure flanked by the residences of the medical staff, stands in well-kept grounds. The village proper, and each of ten neighbouring villages, is divided into two portions, for each of which a doctor and his assistant (a fully qualified practitioner) are appointed, with four *surveillants*, all being subordinate to the medical director of the colony. Patients on arrival enter the asylum, where for five days they are under observation. If at the end of that time it is judged advisable for them to enter a private family, great care is exercised in choosing a home for them. The local keepers, or *nourriciers*, are people of known good character, and the sanitary condition of their houses is closely inspected, the *surveillants* being authorized to enter them at any hour of the day or night. The *pensionnaires* (private patients) are provided with regular occupation and recreation suited to their tastes and social position. There is an excellent Harmonic Society, in which sane and insane alike take part. No person with a tendency to suicide, homicide, or vicious habits is admitted into the colony. The cost of maintenance varies from 300 francs per annum for a pauper patient (defrayed by the district or parish to which he belongs), which includes his clothing, to 3000 or 4000 francs for patients of a higher class. The sum paid by patients to the inhabitants amounts to over 800,000 francs a year. Population (communal, 1899), 13,151.

Ghent (Flemish, *Gent*; French, *Gand*), capital of the Belgian province of East Flanders, at the confluence of the Lys and the Scheldt, which by their ramifications form many islands, 30 miles west-south-west of Antwerp. Since 1875 the narrow and unhealthy lanes in which the population was crowded together have given way to well-aired streets and elegant squares. Ancient buildings, such as the Hôtel de Ville (14th century) and the Cathedral of St Bavon (12th century), have been partially restored. The vast ruins of the Count's Castle, of the 9th and the 12th centuries, covering 43,000 square feet, have been cleared of all the houses that abutted on it. The glacis of the citadel, erected by the Dutch in 1822, has been converted into a public park. New public buildings have been raised, such as the Hôtel du Gouvernement Provincial and the Institute of Sciences, comprising the laboratories of the Faculté des Sciences and technical schools in connexion with the university. The canal connecting Ghent with Terneuzen, on the Scheldt, in Holland (1827), has been widened and deepened (to a depth of 21·3 feet), and united with three basins in the city and an outer harbour, to which in 1897 there entered as many as 1000 vessels. The two chief branches of industry are, first, textiles—cotton and linen spinning and weaving, employing 17,000 workers, 540,232 spindles for cotton, and 195,000 spindles for linen weaving. The second branch is the cultivation of ornamental plants—orchids, ferns, azaleas, &c. The grounds of a single establishment of this kind cover 49½ acres. The population, 131,000 in 1875, amounted to 163,000 in 1899, an increase in twenty-five years of 32,000, or 24 per cent.

Ghika, Dimitrie (1816–1897), Rumanian statesman, son of the Wallachian Hospodar (or Prince) Gregor Ghika, was born on 31st May 1816. As a youth he studied at Vienna and Berlin, and obtained a commission in the Russian Imperial Guard. After extensive travels through Europe he returned to Bucarest, and became a member of the Court of Appeal. He distinguished himself as prefect of police at Bucarest under Prince Stirbeĭ, was a member of the Divan of 1857, and in 1859 had attained prominence enough to offer himself as a candidate for the princedom of Wallachia. He retired, however, in favour of Couza, under whom he held, in 1860, the office of minister of public instruction. In the following year he was minister of finance under Catargi, on the fall of whose ministry he became president of the council and minister of the interior. Under the rule of Charles of Hohenzollern, Ghika was soon called to office again as minister of the interior, and in 1868 formed a cabinet in which he held the portfolio of finance, and for a time that of foreign affairs. Going out of office in 1870, he was from 1871 to 1875 president of the Chamber. Hitherto he had been identified with the Conservatives, but he now combined with others to form a "central" party; and when this was dissolved in 1879, he joined the Liberals, under whom he was president of the Senate till 1888. In that year the Liberal coalition broke up: Ghika made an unsuccessful attempt to form a Liberal and Dissident Liberal cabinet, and held no further office till the return of the Liberals to power in 1895. He then became once more president of the Senate, and held this post till his death, which took place at Bucarest on 27th February 1897. An adroit politician and a capable administrator, he played a leading part in the making of Rumania and in its development as a constitutional monarchy, but left no great measure to keep alive his reputation as a statesman. (See RUMANIA.) (H. SY.)

Ghika, Helene (1828–1888), Rumanian novelist, better known under her literary pseudonym "Dora d'Istria," was born at Bucarest on 22nd January 1828, being the daughter of Prince Michael (brother of Gregor) Ghika. Carefully educated under a Greek master, Grigor Pappadopulos, she showed herself such an apt pupil that, at the early age of fifteen, she commenced a translation of the *Iliad* into German. After continuing her education in Dresden, Venice, and Berlin, she married, in 1849, the Russian prince Kolzow Massalski, and settled with him in St Petersburg. After a few years of unhappy union, however, she separated from him and removed, in 1855, to Florence, which was her home until her death in 1888. During all the years of her residence in that city she was very busy with her pen, and published a number of works characterized by depth of research and brightness of description. Chief among them may be noted *La vie monastique dans l'église Orientale* (1855); *La Suisse allemande* (1856); *Pélerinage au tombeau du Dante*, describing the festival in honour of the anniversary of Dante's birth, to which she received an official invitation; *Les Lacs Helvétiques* (1864). One of the last, and not least important, of her works was *Gli Albanesi in Rumenia, Storia dei principi Ghika nei secoli, xvii., xviii., xix.* (Florence, 1873). She also wrote largely for the *Revue des Deux Mondes*, and was a contributor to *Scribner's Magazine.*

Ghika, Ion (1817–1897), Rumanian statesman and diplomatist, was born at Bucarest in 1817. From 1837 to 1840 he was a student in Paris, where he fell under the influence of the Liberal and Romantic movement, then at its height. Returning to Bucarest, he joined the ranks of the Opposition, and in 1841 was concerned in the conspiracy of Ibraila. From 1843 to 1845 he was professor of mathematics and political economy in the university of Jassy, and in 1844 helped his lifelong friend Vasilie Alecsandri to found the Liberal journal *Progresul*, which was speedily suppressed by the Government. He took a prominent part in the Revolution of 1848, and was sent by the provisional Government as *chargé d'affaires* to Constantinople. Here he won the confidence of Lord Stratford de Redcliffe, on whose recommendation he received from the Sultan in 1854 the appointment of governor of Samos. The neighbouring seas, at that time infested with pirates, were swept clear by the untiring energy of Ghika, who thus rendered an important service to the Allied forces at the time of the Crimean War. He received in 1856 the title of prince of Samos, and continued to rule the island with conspicuous success till 1857. After a brief tenure of ministries in Moldavia and Wallachia, he returned to Bucarest, and became the leader of the Liberal party. As president of the council and minister for foreign affairs in the provisional Government of 1866, he played the chief part in the nomination of Charles of Hohenzollern as prince of Rumania, and became the first prime minister of the new *régime.* Forced to resign in 1867 by a vote of want of confidence, he joined the Opposition, and took part in the Republican movement of 1870. In December of that year he again became prime minister, but in the following March, being implicated in the attempt to overthrow Prince Charles, was dismissed from office. After repeatedly holding the vice-presidency of the Senate, he was in 1881 appointed Rumanian minister in London, where his brilliant powers of intellect and profound sympathy with Western culture gave him a distinguished place in society. He retired in 1890, and died at his estate Gherganĭ on 4th May 1897. Prince Ion Ghika ranks high among Rumanian authors for his charm of style and power of graphic representation—qualities best displayed in his correspondence with Vasilie Alecsandri. Many of these letters are of prime importance to the student of Rumanian economic problems. Equally noteworthy are his *Convorbiri Economici*, and his work in collaboration with D. Sturza, *Ajutorul Comerciantlui.* His position as a writer was recognized by his election to the presidency of the Rumanian Academy. The ability he displayed in so many different fields of activity entitles him to be called the most remarkable man Rumania has yet produced; and, if he did not always keep clear of the intrigues and inconsistencies of Balkan politics, he yet was in no small degree the author of his country's prosperity. (See RUMANIA.) (H. SY.)

Giant's Causeway, a promontory of columnar basalt on the north coast of county Antrim, Ireland. In 1883 an electric railway, the first in the United Kingdom, was opened for traffic, connecting the Causeway with Portrush and Bushmills. After a protracted lawsuit the Causeway, and certain land in the vicinity, have been declared to be private property, and a small charge is now made for admission.

Gibara, one of the old fortified north-coast cities of the eastern province of Cuba, 80 miles north by west of Santiago de Cuba. It has an extensive banana export trade, and lays claim to have been originally discovered by Columbus. Population about 7000.

Gibbons, James (1834– ——), cardinal of the Roman Catholic Church and American archbishop, was born in Baltimore, Md., 23rd July 1834, and baptized in the cathedral over which he was afterwards destined to preside. Entering St Charles College, Md., he completed there his classical studies in 1857, and passed to St Mary's Seminary, Baltimore, where he finished his theological training and was ordained priest 30th June 1861. After a short time spent on the missions of Baltimore, he was called to be secretary to Archbishop Spalding and assistant at the cathedral. When, in 1866, the Second Plenary Council of Baltimore considered the matter of new diocesan developments, he was selected to organize the new Vicariate Apostolic of North Carolina, and was consecrated bishop in August 1868. He devoted four years to missionary work, preaching, lecturing, and organizing with great success. During the years spent in North Carolina he wrote, for the benefit of his mission work, *The Faith of our Fathers*, a simple, scholarly presentation of the doctrines and principles of the Catholic Church. He was transferred to Richmond, Va., in 1872, and in 1877 was made coadjutor to Archbishop Bayley of Baltimore. In October of the same year he succeeded to the archbishopric. Pope Leo XIII. in 1884 selected him to preside over the Third Plenary Council of Baltimore, and in June 1886 created him a cardinal priest, with the title of Santa Maria Trastevere. His simplicity of life, foresight, and prudence have made him a power in the Church. Thoroughly American, and a lover of the people, he is in close touch with all that tends to benefit the nation and to ennoble its citizenship, and his public utterances manifest the true instincts of a popular leader. He has contributed frequently to the leading magazines. As an author he is known principally by his works on religious subjects. *The Faith of our Fathers* has passed through forty editions; his other books are *Our Christian Heritage* and *The Ambassador of Christ.* He had been for many years an ardent advocate for the establishment of a Catholic University, but it was not until the Third Plenary Council of Baltimore, 1884, that he saw the realization of his desires in the establishment of the Catholic University of America at Washington. He enjoyed the distinction of being its first chancellor and president of the board of trustees.

Gibraltar, a British fortress and Crown colony at the western entrance to the Mediterranean. The southern point of the rock is known as Europa Point, in longitude 5° 21′ 0″ W., latitude 36° 6′ 30″ N., and 11½ nautical miles distant from the opposite African coast. The town is crowded together at the north-west angle, and covers about one-ninth of the whole area; a small part only of the town is on level ground, and those of its narrow streets and lanes which run away from the shore of the bay are for the most part little more than ramps and rough stairs formed of rubble stones, which contract in places into mere stone steps. The climate of Gibraltar is pleasant, mild in winter and only moderately hot in summer; the heat, however, though not excessive is lasting, and rain seldom falls in the five months from May to September; from October to May the climate is generally delightful, warm sunshine prevailing, tempered by cool breezes; the periods of bad weather, although blustering enough at times, are seldom of more than a few days' duration. The thermometer in summer rarely reaches 90° in the shade; from 83° to 85° may be taken to be the average maximum for July and August, which are the hottest months. The average annual rainfall is 37·56 inches, and in twenty years, from 1880 to 1899, the heaviest recorded rainfall was 59·35 inches, and the lightest 16·75. Although the number of persons employed in and dependent upon Gibraltar has of late considerably increased, especially since the new dockyard works were begun in 1895, the population actually resident has not grown. As Crown leases, of which there are many, fall in they are often not renewed; and as houses are rebuilt they are adapted for a better class of tenant, and so the poorer classes are being gradually driven out, and go to live in the adjoining Spanish town of Linea de la Concepcion, which, itself a mere suburb of Gibraltar, is said to contain some 40,000 inhabitants, or nearly twice the population of the mother city. It has been estimated that some ten thousand workers come daily from Linea to Gibraltar. The population (1900) was estimated at 24,701; the garrison and its families account for nearly 6000, the civil population numbers not quite 17,000, and there are about 2400 resident aliens, chiefly working men, domestic servants, and professional men. Aliens, who are not duly accredited consuls, are not allowed to reside without a special permit signed by the chief of police, which has to be renewed every three months; and by an Order in Council, taking effect from November 1900, like disabilities were extended to British subjects not previously resident. When Gibraltar was taken by the British most of the Spanish inhabitants left. The bulk of the present inhabitants are of Italian or Genoese descent; there are a fair number of Maltese, and two or three thousand Jews: these never intermarry with other races, and form a society of their own. The language is Spanish, spoken not very correctly. English is in every case an acquired language, and is hardly, if ever, spoken by the people in their own homes.

The recorded births, marriages, and deaths are as follows:—

	Births.	Marriages.	Deaths.
1883 . .	640	190	525
1888 . .	645	163	474
1893 . .	651	149	404
1899 . .	657	208	511

Gibraltar is a Crown colony. Of local government, properly so called, there is none. There is a sanitary commission, which is vested with large powers over buildings and streets, like those of local authorities in England. Its members are for the most part nominees of the Government, with little or no knowledge of the rights of owners of property. An appeal from their decisions lies to the supreme court, but as their decisions are not always made known to those injuriously affected by them within the time limited for appeal, the protection is of no special value. Apart from the garrison and the civil officials, there are comparatively few members of the Anglican Church; the great majority of the inhabitants belong to the Roman communion. The Jews have four synagogues. The Protestant dissenters have two places of worship, Presbyterian and Wesleyan. Education is not compulsory for the civil population, but most if not all children receive a fair education at private or private-aided schools. The number of children on the roll of the private-aided schools was, in 1899, 1086 boys and 732 girls; total, 1818. There is no direct taxation. The main sources of revenue are: (i.) duties upon wines, spirits, malt liquors, and tobaccos; (ii.) port and harbour dues; (iii.) tavern and other licenses; (iv.) posts and telegraphs; (v.) ground and other rents; (vi.) stamps and miscellaneous. The returns prior to 1898 are given in pesetas (5 = $), which have been converted in the following table into sterling at an average of exchange 30 = £1.

	(i.)	(ii.)	(iii.)	(iv.)	(v.)	(vi.)	Total Revenue.
	£	£	£	£	£	£	£
1883 .	8,092	15,404	4,842	737	7,079	4,479	40,634
1888 .	9,732	18,446	5,288	6,444	6,472	3,004	49,386
1893 .	9,050	12,843	4,474	7,382	6,268	10,745	50,762
1899 .	18,245	6,179	4,053	9,191	5,931	16,355	59,954

Before 1886 the colony derived no revenue from the post office, which was administered from London as a branch of the General Post Office. The depreciation of the Spanish currency during the war with the United States led, in 1898, to the reintroduction of British currency as the legal tender money of Gibraltar. An indirect result of this was a large increase in the revenue of the post office, the old issues of postage stamps in Spanish currency being largely bought by stamp dealers and collectors. Notwithstanding the legal change of currency, the Spanish dollar still remains the current coin in everyday use; much of the retail business of the town being done with people living in Spain, the dollar more than holds its own.

Great changes have been made in the defences of Gibraltar during recent years. Guns of the older types have been removed and replaced by those of the latest pattern. The heaviest pieces, instead of being at or near the sea-level, are now high up, many of them upon the very crest-ridge of the rock, 1200 or 1300 feet above the sea. Guns so placed have a great advantage over an enemy's ships, the decks, the weakest part of the ship, being exposed to the plunging fire of the higher-placed guns. Guns on the crest-line have the further advantage of being able to fire all round the horizon; an elaborate system of range-finding has been carefully worked out. With the completion of the new docks and works (see DOCKYARDS) the importance of Gibraltar as a naval base will be greatly increased. The new dockyard will be able to undertake all the repairs of a squadron. There will be an enclosed harbour, in which a fleet can anchor secure from the attacks of torpedo boats. As part of the same scheme commercial wharves are being constructed for coaling steamers alongside, and the loading and discharging of cargo. There will be from 30 to

35 feet of water over the enclosed area at low water ordinary spring tides. Three dry docks, from 450 to 850 feet in available length, will provide for the simultaneous repair of three or four vessels; these will be at the south end of the harbour. At the north end will be the commercial wharves, at which a considerable number of vessels will be able to coal or load and unload at one time in 30 feet of water. With the defences the food and water supply is in close connexion. Cold stores have been erected, in which frozen meat can be kept for an indefinite period. The water supply has also been largely increased. There are very few good wells in Gibraltar; nearly all the water used for drinking and cooking consists of rain water stored in tanks underground; most of the better class of houses have their own rain-water tanks, and there are large tanks belonging to the war department for the supply of the garrison. Large additional storage tanks have been constructed by the sanitary commission, with specially prepared collecting areas high up the rock. The collecting areas have been enlarged from 3 to 16 acres, and the capacity of the storage tanks from $1\frac{1}{3}$ to $6\frac{1}{3}$ million gallons. The tanks are excavated from the solid rock; the water will thus be kept in the dark and cool, and secure from the effects of an enemy's fire.

The general trade of Gibraltar has undergone little change of late years: one must go a long way back to find a time when there was much active business. At the point of contact of two continents, on the direct line of ocean trade with the Far East, in regular steam communication with North and South America, Gibraltar is by its position fitted to be a trade centre of the world; but the dead hand of Islam upon Morocco and protection in Spain have strangled commerce. There are no trustworthy statistics of the trade: up to the year 1898 wine, beer, and spirits were the only goods which paid duty. In that year a duty of 1d. per pound was for the first time put upon tobacco, and produced £1444. This duty was in force during part only of the year 1898; in 1899 the duty at the same rate produced £7703. The chief business is the coaling of passing steamers; this gives work to several thousand men. Goods are also landed for re-export to Morocco, but the bulk of the Morocco trade, much of which formerly came to Gibraltar, is now done by lines of steamers trading to and from Morocco direct to British, German, or French ports. A fair amount of retail business is done with the passengers of ocean steamers which call on their way to and from the East and from North and South America. The steam tonnage cleared is shown in the following table:—

	British.	Foreign.	Total.
	Tons.	Tons.	Tons.
1883 . .	3,771,075	859,711	4,630,786
1888 . .	5,033,088	876,489	5,909,577
1893 . .	3,521,164	1,036,696	4,557,860
1899 . .	3,214,965	1,048,536	4,263,501

The money, weights, and measures in legal use are British. Before 1898 Spanish money only was used, and though no longer legal it keeps its hold on the people, so that there is practically a double coinage.

(H. M*.)

Giers, Nicholas Karlovitch de (1820–1895), Russian minister for foreign affairs, was born on the 21st of May 1820. Like his predecessor, Prince Gortchakoff, he was educated at the lyceum of Tsarskoe Selo, near St Petersburg, but his career was much less rapid, because he had no influential protectors, and was handicapped by being a Protestant of Teutonic origin. At the age of eighteen he entered the service of the Eastern department of the ministry of foreign affairs, and spent more than twenty years in subordinate posts, chiefly in South-eastern Europe, until he was promoted in 1863 to the post of minister plenipotentiary in Persia. Here he remained for six years, and, after serving as a minister in Switzerland and Sweden, he was appointed in 1875 director of the Eastern department and assistant minister for foreign affairs under Prince Gortchakoff, whose niece he had married. No sooner had he entered on his new duties than his great capacity for arduous work was put to a severe test. Besides events in Central Asia, to which he had to devote much attention, the Herzegovinian insurrection had broken out, and he could perceive from secret official papers that the incident had far-reaching ramifications unknown to the general public. Soon this became apparent to all the world. While the Austrian officials in Dalmatia, with hardly a pretence of concealment, were assisting the insurgents, Russian volunteers were flocking to Servia with the connivance of the Russian and Austrian Governments, and General Ignatieff, as ambassador in Constantinople, was urging his Government to take advantage of the palpable weakness of Turkey for bringing about a radical solution of the Eastern question. Prince Gortchakoff did not want a radical solution involving a great European war, but he was too fond of ephemeral popularity to stem the current of popular excitement. Alexander II., personally averse from war, was not insensible to the patriotic enthusiasm, and halted between two opinions. M. de Giers was one of the few who gauged the situation accurately. As an official and a man of non-Russian extraction he had to be extremely reticent, but to his intimate friends he condemned severely the ignorance and light-hearted recklessness of those around him. The event justified his sombre previsions, but did not cure the recklessness of the so-called patriots. They wished to defy Europe in order to maintain intact the treaty of San Stefano, and again M. de Giers found himself in an unpopular minority. He had to remain in the background, but all the influence he possessed was thrown into the scale of peace. His views, energetically supported by Count Schuvaloff, finally prevailed, and the European congress assembled at Berlin. He was not present at the congress, and consequently escaped the popular odium for the concessions which Russia had to make to Great Britain and Austria. From that time he was practically minister of foreign affairs, for Prince Gortchakoff was no longer capable of continued intellectual exertion, and lived mostly abroad. On the death of Alexander II. in 1881 it was generally expected that M. de Giers would be dismissed as deficient in Russian nationalist feeling, for Alexander III. was credited with strong anti-German Slavophil tendencies. In reality the young Tsar had no intention of embarking on wild political adventures, and was fully determined not to let his hand be forced by men less cautious than himself. What he wanted was a minister of foreign affairs who would be at once vigilant and prudent, active and obedient, and who would relieve him from the trouble and worry of routine work while allowing him to control the main lines, and occasionally the details, of the national policy. M. de Giers was exactly what he wanted, and accordingly the Tsar not only appointed him minister of foreign

"The Return of the Victors." By Sir John Gilbert, R.A.

(By permission of the Corporation of Birmingham.)

affairs on the retirement of Prince Gortchakoff in 1882, but retained him to the end of his reign in 1894. In accordance with the desire of his august master, M. de Giers followed systematically a pacific policy. Accepting as a *fait accompli* the existence of the Triple Alliance, created by Bismarck for the purpose of resisting any aggressive action on the part of Russia and France, he sought to establish more friendly relations with the cabinets of Berlin, Vienna, and Rome. To the advances of the French Government he at first turned a deaf ear, but when the *rapprochement* between the two countries was effected with little or no co-operation on his part, he utilized it for restraining France and promoting Russian interests. In private life M. de Giers had none of the brilliancy of his illustrious predecessor. To the outside world he seemed a taciturn, solemn, and rather commonplace person, who had few human sympathies, and whose idea of happiness was to sit in his chancellery surrounded with heaps of official documents. Those who knew him well were aware that his somewhat uncouth exterior covered many amiable qualities, and that his habitual careworn expression concealed a good deal of quiet humour. He died on 26th January 1895, soon after the accession of Nicholas II. (D. M. W.)

Giessen, a town and important railway junction of Germany, grand-duchy of Hesse-Darmstadt, on the Lahn, 41 miles by rail north from Frankfort-on-Main. The town hall contains the collections of the Upper Hessian Historical Association; the arsenal is now used as barracks. There is a new Evangelical church (1891). In 1889 new buildings were erected for the university, and in 1887–90 new medical schools. In 1900 the university was attended by 855 students, and had 82 professors. The old university buildings have been appropriated to the library, containing about 200,000 volumes. Giessen is the seat of an agricultural college. It has also a monument to von Liebig, the chemist, who was professor here from 1824 to 1852. There is a large lignite mine in the vicinity, and large tobacco and cigar factories in the town. Population (1885), 18,836; (1900), 25,564.

Gifu, or IMAÏZUMI, a city of Japan, capital of the ken (government) of Central Nippon, which comprises the two provinces of Mino and Hida. It lies east by north of Lake Biwa, on the Central Railway, about 172 miles from Tôkyô and 64 miles from Kyôtô, on a tributary of the Kiso, which flows to the Bay of Mia Uro. Population (1880), 12,500; (1898), 31,000. The ken has an area of about 4000 square miles, and is thickly peopled, with a population of over 1,000,000 in 1900. The whole district is subject to frequent earthquakes, and Gifu was nearly ruined during the disturbances which lasted from October 1891 to March 1892, when as many as 2588 shocks were registered at this place.

Gijon, a Spanish seaport on the Bay of Biscay, in the province of Oviedo. Population (1897), 43,392. Important works have been in progress since 1892 to create an excellent harbour of refuge at Musel, at the extremity of the bay of Gijon, which will also be a mineral loading port, capable of accommodating vessels of any size. More than a quarter of the works have been completed, and they have already attracted much trade. The value of the import trade was £384,440 in 1898, Great Britain figuring for £160,743. The principal imports were machinery, iron, and metal work, and iron ore for the works at Mieres, Duro, and Moreda. The exports in 1898 were valued at £122,200, the United Kingdom taking £28,349. With the increasing output of coal in the province, Gijon exported 302,217 tons of coal in 1898, being an increase of 25,826 tons since 1897. The shipping in 1898 numbered 1980 vessels of 313,000 tons. The town has grown apace, not only with the movement of the port, but with the summer influx of people, who come for the bathing. New suburbs have sprung into existence, broader streets have been built, the public gardens improved, statues raised to the memory of Jovellanos and Pelayo, duke of Asturias, and a new town hall, theatre, and markets erected. The bull-ring, recently restored, can hold 12,000 persons. Besides the institute, Gijon has a nautical school, a school of arts and handicrafts, and numerous primary schools educating large numbers of children. The glass factory is the best in Spain; porcelain factories, iron works, and petroleum refineries are in a flourishing condition; manufactures of preserves, soap, candles, chocolate, and liqueurs are among the rising local industries.

Gílán (*Ghilan*), one of the northern provinces of Persia, on the south-west shore of the Caspian, between 36° 20′ and 38° 30′ N., and 48° 50′ and 50° 30′ E. It is divided into the following administrative districts:—Rasht (with the capital of the province and its immediate neighbourhood), Fúman (with Tulam and Masúlah, where are iron mines), Gesker, Tálesh (with Tálesh, Dúláb, Shandarmán, Asalom, Gíl Dúláb, Kargánrúd, Masal, Enzeli, the port of Rasht), Sheft, Manjíl (with Rahmatábád and Amarlú), Langarúd (with Rúdsar and Ránehkúh), Dilmán, and Lashtnishah (on the lower Safíd rúd). Gílán means "land of the Gíl," and the Gíl were an old tribe which the ancient Greeks mentioned as the Gelae. A man of Gílán is called a "Gílek," and the dialect which he speaks is "Gílekí." The land-tax paid by the province is £48,840, or £14,560 less than in 1876. The value of the exports and imports from and into Gílán, much of them in transit, is about £1,860,000. The Government abolished the farm system in Gílán in March 1900, in the hope that the customs dues would yield a considerably higher revenue. The Crown lands of Gílán have been much neglected, and the revenue derived from them is stated to amount to no more than 153,500 krans, or a little over £3000. The fisheries of the whole Persian littoral of the Caspian, having been conceded to a Russian firm for an annual payment of £16,000, which is paid direct into the Treasury, cannot be considered as revenue of Gílán.

Gilbert, Sir John (1817–1897), English painter and illustrator, was one of the eight children of George Felix Gilbert, a member of a Derbyshire family. He was born at Blackheath on the 21st of July 1817, went to school there, and even in childhood, without any instruction whatever, displayed an extraordinary fondness for drawing and painting. Nevertheless, his father's lack of means compelled him to accept employment for the boy in the office of Messrs Dickson & Bell, estate agents, in Charlotte Row, London. It was even then clear that he possessed, as if by nature, an amazing power of dramatically realizing subjects the pictorial qualities of which he intuitively recognized, and that "the young Gilbert thought in pictures." Yielding to his natural bent, his parents agreed that he should take up art in his own way, which included but little advice from others, his only teacher being Haydon's pupil, George Lance, the fruit painter. This artist gave him brief instructions in the use of colour. Gilbert, who studied in none of the schools, worked indefatigably, in a somewhat florid mood, from nature, and thus like an old master attained such skill that no artistic methods came amiss to him, while, like Millais, "he thought out his subjects by instinct." In 1836 Gilbert appeared in public for the first time. This was at the gallery of the Society of British Artists, where he sent drawings, the subjects of which were characteristic, being "The Arrest of Lord Hastings," from Shakespeare, and "Abbot Boniface," from *The Monastery* of Scott. "Inez de Castro" was in the same gallery in the next year; it was the first of a long series of works in the same medium, representing similar themes, and was accompanied, from 1837, by a still greater number of works in oil which were exhibited at the British Institution. These included "Don Quixote giving advice to Sancho Panza," 1841; "Brunette and Phillis," from *The Spectator*, 1844; "The King's Artillery at Marston Moor," 1860; and "Don Quixote comes back for the last time to his Home and Family," 1867. In that year the Institution was finally closed. Gilbert exhibited at the Royal Academy from 1838, beginning with the "Portrait of a Gentleman," and continuing, except between 1851 and 1867, till his death to exhibit there many of his best and more ambitious works. These included such capital instances as "Holbein painting the Portrait of Anne Boleyn," "Don Quixote's first Interview with the Duke and Duchess," 1842; "Charlemagne visiting the Schools," 1846. "Touchstone and the Shepherd," and "Rembrandt," a very fine piece, were both there in 1867; and in 1873 "Naseby," one of his finest and most picturesque designs, was also at the Royal Academy. Gilbert was elected A.R.A. 29th January 1872, and R.A. 29th June 1876. Besides these mostly large and powerful works, the artist's true arena of display was undoubtedly the gallery of the Old Water Colour Society, to which from 1852, when he was elected an Associate exhibitor, till he died forty-five years later, he contributed not fewer than 270 drawings, most of them admirable because of the largeness of their style, massive coloration, broad chiaroscuro, and the surpassing vigour of their designs. These qualities won for him the title of "The Rubens of his time," and, taken with the great distinction of his works on larger scales, induced the leading critics to claim for him opportunities for painting mural pictures of great historic themes as decorations of national buildings. "The Trumpeter," "The Standard-Bearer," "Richard II. resigning his Crown" (now at Liverpool), "The Drug Bazaar at Constantinople," "The Merchant of Venice," and "The Turkish Water-Carrier," are but examples of that wealth of art which added to the attractions of the gallery in Pall Mall. There Gilbert was elected a full Member in 1855, and president of the Society in 1871, shortly after which he was knighted. Gilbert, as an illustrator of books, magazines, and periodicals of every kind, including newspapers, produced an astounding number of designs, all of which possessed extraordinary value, nor did he repeat himself in any. Energy, abundance of invention, and picturesqueness existed in all of them; yet their multitude did not affect his painting pictures, nor exhaust his powers in the least degree. To the success of the *Illustrated London News* his designs lent powerful aid, and he was eminently serviceable in illustrating the *Shakespeare* of Mr Howard Staunton. He illustrated a great proportion of the dramatic literature and poetry of England, and of other countries besides. Sir John Gilbert died 6th October 1897. He was a member of many artistic societies besides those mentioned above, and was a Knight of the Legion of Honour. (F. G. S.)

Gilbert, Sir Joseph Henry (1817–1901), English chemist, was born at Hull on 1st August 1817. He studied chemistry first at Glasgow under Thomas Thomson, then at University College, London, in the laboratory of A. T. Thomson, also attending Graham's lectures, and finally at Giessen under Liebig. On his return to England from Germany he acted for a year or so as assistant to his old master A. T. Thomson at University College, and in 1843, after spending a short time in the study of calico dyeing and printing near Manchester, accepted the directorship of the chemical laboratory at the famous experimental station established by Sir J. B. Lawes at Rothamsted, near St Albans, for the systematic and scientific study of agriculture. This position he held for fifty-eight years, until his death on 23rd December 1901. The work which he carried out during that long period in collaboration with Sir John Lawes was of a most comprehensive character, involving the application of many branches of science, such as chemistry, meteorology, botany, animal and vegetable physiology, and geology; and its influence in improving the methods of practical agriculture extended all over the civilized world. Some account of the results obtained will be found in the article AGRICULTURE. Sir Joseph Henry Gilbert was chosen a fellow of the Royal Society in 1860, and in 1867 was awarded a Royal medal jointly with Sir John Lawes. In 1880 he presided over the Chemical Section of the British Association at its meeting at Swansea, and in 1882 he was president of the Chemical Society, of which he had been a member almost from its foundation in 1841. For six years from 1884 he filled the Sibthorpian chair of rural economy at Oxford, and he was also an honorary professor at the Royal Agricultural College, Cirencester. He was knighted in 1893, the year in which the jubilee of the Rothamsted experiments was celebrated.

Gilbert, William Schwenk (1836– ——), English playwright and humorist, son of William Gilbert (a descendant of Sir Humphrey Gilbert), was born in London on the 18th of November 1836. His father was the author of a number of novels, the best known of which were *Shirley Hall Asylum* (1863) and *Dr Austin's Guests* (1866). Several of these novels — which were characterized by a singular acuteness and lucidity of style, by a dry, subacid humour, by a fund of humanitarian feeling, and by a considerable medical knowledge, especially in regard to the psychology of lunatics and monomaniacs—were illustrated by his son, who developed a talent for whimsical draughtsmanship. Young Gilbert was educated at Boulogne, at Ealing, and at King's College, graduating B.A. from the University of London in 1856. The termination of the Crimean war was fatal to his project of competing for a commission in the Royal Artillery, but he obtained a post in the Education Department of the Privy Council Office (1857–61). Disliking the routine work, he left the Civil Service, entered the Inner Temple, was called to the bar in November 1864, and joined the northern circuit. His practice was inconsiderable, and his military and legal ambitions were eventually satisfied by a captaincy in the volunteers and appointment as a magistrate for Middlesex (June 1891). In 1861 the comic journal *Fun* was started by H. J. Byron, and Gilbert became from the first a valued contributor. Failing to obtain an *entrée* to *Punch*, he continued sending excellent comic verse to *Fun*, with humorous illustrations, the work of his own pen, over the signature of "Bab." A collection of these lyrics, in which deft craftsmanship unites a titillating satire on the deceptiveness of appearances with the irrepressible nonsense of a Lewis Carroll, was issued separately in 1869 under the title of *Bab Ballads*, and was followed by *More Bab Ballads*. The two collections and *Songs of a Savoyard* were united in a volume issued in 1898, with many new illustrations. The best of the old cuts, such as those depicting the "Bishop of Rum-ti-Foo" and the "Discontented Sugar Broker," were happily preserved intact.

While remaining a staunch supporter of *Fun*, Gilbert was soon immersed in other journalistic work, and his position as dramatic critic to the *Illustrated Times* turned his attention to the stage. He had not to wait long for an opportunity. Early in December 1866 T. W. Robertson was asked by Miss Herbert, lessee of the St James's Theatre, to find some one who could turn out a bright Christmas piece in a fortnight, and suggested Gilbert; the latter promptly produced *Dulcamara*, a burlesque of *L'Elisire d'Amore*, written in ten days, rehearsed in a week, and duly performed at Christmas. He sold the piece outright for £30, a piece of rashness which he had cause to regret, for it turned out a commercial success. In 1870 he was commissioned by Buckstone to write a blank verse fairy comedy, based upon *Le Palais de la Vérité*, the novel by Madame de Genlis. The result was *The Palace of Truth*, a fairy drama, poor in structure but clever in workmanship, which served the purpose of Mr and Mrs Kendal in 1870 at the Haymarket. This was followed in 1871 by *Pygmalion and Galatea*, another three-act "mythological comedy," a clever and effective but artificial piece. Another fairy comedy, *The Wicked World*, written for Buckstone and the Kendals, was followed in March 1873 by a burlesque version, in collaboration with Gilbert à Beckett, entitled *The Happy Land*. Gilbert's next dramatic ventures inclined more to the conventional pattern, combining sentiment and a cynical humour in a manner strongly reminiscent of William Gilbert the novelist. Of these pieces, *Sweethearts* was given at the Prince of Wales's Theatre, 7th November 1874; *Tom Cobb* at the St James's, 24th April 1875; *Broken Hearts* at the Court, 9th December 1875; *Dan'l Druce* (a drama in darker vein, suggested to some extent by *Silas Marner*) at the Haymarket, 11th September 1876; and *Engaged* at the Haymarket, 3rd October 1877. The first and last of these proved decidedly popular. *Gretchen*, a verse drama in four acts, appeared in 1879. A one-act piece, called *Comedy and Tragedy*, was produced at the Lyceum, 26th January 1884. Two dramatic trifles of later date were *Foggerty's Fairy* and *Rozenkrantz and Guildenstern*, a travesty of *Hamlet*, performed at the Vaudeville in June 1891. Several of these dramas were based upon short stories by Gilbert, a number of which had appeared from time to time in the Christmas numbers of various periodicals. The best of them have been collected in the volume entitled *Foggerty's Fairy, and other Stories*. In the autumn of 1871 Gilbert commenced his memorable collaboration (which lasted over twenty years) with Sir Arthur Sullivan. The first two comic operas, *Thespis; or The Gods grown Old* (26th September 1871) and *Trial by Jury* (Royalty, 25th March 1875) were merely essays. Like one or two of their successors, they were, as regards plot, little more than extended "Bab Ballads." Later (especially in the *Yeomen of the Guard*), much more elaboration was attempted. The next piece was produced at the Opera Comique (17th November 1877) as *The Sorcerer*. At the same theatre were successfully given *H.M.S. Pinafore* (25th May 1878), *The Pirates of Penzance; or The Slave of Duty* (3rd April 1880), and *Patience; or Bunthorne's Bride* (23rd April 1881). In October 1881 the successful *Patience* was removed to a new theatre, the Savoy, specially built for Gilbert and Sullivan by Richard D'Oyly Carte. *Patience* was followed, on 25th November 1882, by *Iolanthe; or The Peer and the Peri*; and then came, on 5th January 1884, *Princess Ida; or Castle Adamant*, a re-cast of a charming and witty fantasia which Gilbert had written some years previously, and had then described as a "respectful perversion of Mr Tennyson's exquisite poem." The impulse reached its fullest development in the operas that followed next in order—*The Mikado; or The Town of Titipu* (14th March 1885); *Ruddigore* (22nd January 1887); *The Yeomen of the Guard* (3rd October 1888); and *The Gondoliers* (7th December 1889). After the appearance of *The Gondoliers* a temporary misunderstanding occurred between the composer and librettist. Gilbert wrote several more librettos, and of these *Utopia Limited* (1893) and the exceptionally witty *Grand Duke* (1896) were written in conjunction with Sullivan. Yet there were many to whom it seemed that the old spell was broken. The plan of paradox and musical theme upon which the partners had hitherto relied was becoming too well worn, and no ingenuity could disguise the repetition of devices and methods, tricks of jest and of rhythm, which they had taught their sincerest admirers to anticipate. As a master of metre Gilbert had shown himself consummate, as a dealer in quips and paradoxes and ludicrous dilemmas, unrivalled. Even for the music of the operas he deserves some credit, for the rhythms were frequently his own (as in "I have a Song to Sing, O"), and the metres were in many cases invented by himself. One or two of his librettos, such as that of *Patience*, are virtually flawless. Enthusiasts are divided only as to the comparative merit of the operas. *Princess Ida* and *Patience* are in some respects the daintiest and the most idyllic. There seems a genuine, if limited, vein of poetry in *The Yeomen of the Guard*. Some of the drollest songs are in *Pinafore* and *Ruddigore*. *The Gondoliers* has the most charming *légèreté*, while with the general public *The Mikado* proves the most popular.

Gilgit, an outlying province in the extreme north-west of India, over which Kashmir has reasserted her sovereignty. Only a part of the basin of the river Gilgit is included within its political boundaries. There is an intervening width of mountainous country, represented chiefly by glaciers and ice-fields, and intersected by narrow sterile valleys, measuring some 100 to 150 miles in width, to the north and north-east, which separates the province of Gilgit from the Chinese frontier beyond the Muztagh and Karakoram. This part of the Kashmir borderland includes Kanjut (or Hunza) and Ladak. To the north-west, beyond the sources of the Yasin and Ghazar in the Shandur range (the two most westerly tributaries of the Gilgit river) is the deep valley of the Yarkhun or Chitral. Both Kanjut (or Hunza) and Chitral are included within the sphere of the Gilgit Agency, which, as a branch of the Kashmir Agency, extends British influence over the whole borderland south of Afghanistan and China. Chitral, Yasin, Panyal, the Gilgit valley, Hunza and Nagar, Astor, and the Indus valley from Bunji to Batera, together with the hills of the upper Panjkora and Swat, all fall within the political sphere of the British Agency at Gilgit, although the political boundaries of Kashmir administration only enclose the lower Gilgit valley and a portion of the Indus valley bordering Chilas.

Within these wider limits of the Agency are many mixed races, speaking eleven different languages, which have all been usually classed together under the name Dard. The Dard, however, is unknown beyond the limits of the Kohistan district of the Indus valley to the south of the Hindu Koh, the rest of the inhabitants of the Indus valley belonging to Shin republics, or Shinaka. The great mass of the Chitral population are Kho (speaking Khowar), and they may be accepted as representing the aboriginal population of the Chitral valley. (See HINDU KUSH.) Between Chitral and the Indus the "Dards" of Dardistan are chiefly Yeshkuns and Shins, and it would appear from the proportions in which these people occupy the country that they must have primarily moved up from the valley of the Indus in successive waves of conquest, first the

Yeshkuns, and then the Shins. No one can put a date to these invasions, but Biddulph is inclined to class the Yeshkuns with the Yuechi who conquered the Baktrian kingdom about 120 B.C. The Shins are obviously a Hindu race (as is testified by their veneration for the cow), who spread themselves northwards and eastwards as far as Baltistan, where they collided with the aboriginal Tatar of the Asiatic highlands. But the ethnography of "Dardistan," or the Gilgit Agency (for the two are, roughly speaking, synonymous), requires further investigation, and it would be premature to attempt to frame anything like an ethnographical history of these regions until the neighbouring provinces of Tangir and Darél have been more fully examined. No material exists on which even an approximate estimate of the population of that rough tract of country which is comprised within the Gilgit Agency can be based. The area of the Gilgit valley falling directly under Kashmir administration is about 2000 square miles, but the total area of those border districts over which British political influence extends cannot be less than 30,000.

In general appearance and dress all the mountain-bred peoples extending through these northern districts are very similar. Thick felt coats reaching below the knee, loose "pyjamas" with cloth "putties" and boots (often of English make) are almost universal, the distinguishing feature in their costume being the felt cap worn close to the head and rolled up round the edges. They are on the whole a light-hearted, cheerful race of people, but it has been observed that their temperament varies much with their habitat—those who live on the shadowed sides of mountains being distinctly more morose and more serious in disposition than the dwellers in valleys which catch the winter sunlight. They are, at the same time, bloodthirsty and treacherous to a degree which would appear incredible to a casual observer of their happy and genial manners, exhibiting a strange combination (as has been observed by a careful student of their ways) of "the monkey and the tiger." Addicted to sport of every kind, they pursue no manufacturing industries whatsoever, but they are excellent agriculturists, and show great ingenuity in their local irrigation works and in their efforts to bring every available acre of cultivable soil within the irrigated area. Gold washing is more or less carried on in most of the valleys north of the river Gilgit, and gold dust (contained in small packets formed with the petals of a cup-shaped flower) is an invariable item in their official presents and offerings. Gold dust still constitutes part of the annual tribute which, strangely enough, is paid by Hunza to China, as well as to Kashmir.

Routes in the Gilgit Agency.—One of the oldest recorded routes through this country is that which connects Mastuj in the Chitral valley with Gilgit, passing across the Shandur range (12,250). It now forms the high-road between Gilgit and Chitral, and has been engineered into a passable route. From the north three great glacier-bred affluents make their way to the river of Gilgit, joining it at almost equal intervals, and each of them affords opportunity for a rough passage northwards. (1) The Yasin river, which follows a fairly straight course from north to south for about 40 miles from the foot of the Darkôt pass across the Shandur range (15,000) to its junction with the river Gilgit, close to the little fort of Gupis, on the Gilgit–Mastuj road. Much of this valley is cultivated and extremely picturesque. At the head of it is a grand group of glaciers, one of which leads up to the well-known pass of Darkôt. (2) Twenty-five miles (by map measurement) below Gupis the Gilgit receives the Ashkuman affluent from the north. The little Lake of Karumbar is held to be its source, as it lies at the head of the river. The same lake is sometimes called the source of the river Yarkhun or Chitral; and it seems possible that a part of its waters may be deflected in each direction. The Karumbar, or Ashkuman, is nearly twice the length of the Yasin, and the upper half of the valley is encompassed by glaciers, rendering the route along it uncertain and difficult. (3) Forty miles or so below the Ashkuman junction, and nearly opposite the little station of Gilgit, the river receives certain further contributions from the north which are collected in the Hunza and Nagar basins. These basins include a system of glaciers of such gigantic proportions that they are probably unrivalled in any part of the world. The glacial head of the Hunza is not far from that of the Karumbar, and, like the Karumbar, the river commences with a wide sweep eastwards, following a course roughly parallel to the crest of the Hindu Kush (under whose southern slopes it lies close) for about 40 miles. Then striking south for another 40 miles, it twists amidst the barren feet of gigantic rock-bound spurs which reach upwards to the Muztagh peaks on the east and to a mass of glaciers and snow-fields on the west, hidden amidst the upper folds of mountains towering to an average of 25,000 feet. The next great bend is again to the west for 30 miles, before a final change of direction to the south at the historical position of Chalt and a comparatively straight run of 25 miles to a junction with the Gilgit. The valley of Hunza lies some 10 miles from the point of this westerly bend, and 20 (as the crow flies) from Chalt. Much has been written of the magnificence of Hunza valley scenery, surrounded as it is by a stupendous ring of snow-capped peaks and brightened with all the radiant beauty that cultivation adds to these mountain valleys; but such scenery must be regarded as exceptional in these northern regions.

Glaciers and Mountains.—Conway and Godwin Austen have described the glaciers of Nagar which, enclosed between the Muztagh spurs on the north-east and the frontier peaks of Kashmir (terminating with Rakapushi) on the south-west, and massing themselves in an almost uninterrupted series from the Hunza valley to the base of those gigantic peaks which stand about Mount Godwin Austen, seem to be set like an ice-sea to define the farthest bounds of the Himalaya. From its uttermost head to the foot of the Hispar, overhanging the valley above Nagar, the length of the glacial ice-bed known under the name of Biafo is said to measure about 90 miles. Throughout the mountain region of Kunjut (or Hunza) and Nagar the valleys are deeply sunk between mountain ranges which are nowhere less than 15,000 feet in altitude, and which must average above 20,000 feet. As a rule, these valleys are bare of vegetation. Where the summits of the loftier ranges are not buried beneath snow and ice they are bare, bleak and splintered, and the nakedness of the rock scenery extends down their rugged spurs to the very base of them. On the lower slopes of tumbled débris the sun in summer beats with an intensity which is unmitigated by the cloud drifts which form in the moister atmosphere of the monsoon-swept summits of the Himalaya. Sun-baked in summer and frost-riven in winter, the mountain sides are but immense ramps of loose rock débris, only awaiting the yearly melting of the upper snow-fields, or the advent of a casual rainstorm, to be swept downwards in an avalanche of mud and stones into the gorges below. Here it becomes piled and massed together, till the pressure of accumulation forces it out into the main valleys, where it spreads in alluvial fans and silts up the plains. This formation is especially marked throughout the high level valleys of the Gilgit basin.

Passes.—Each of these northern affluents of the main stream is headed by a pass, or a group of passes, leading either to the Pamir region direct, or into the upper Yarkhun valley from which a Pamir route diverges. The Yasin valley is headed by the Darkôt pass (15,000 feet), which drops into the Yarkhun not far from the foot of the Baroghil group over the main Hindu Kush watershed. The Ashkuman is headed by the Gazar and Kora Bohrt passes, leading to the valley of the Ab-i-Punja; and the Hunza by the Kilik and Mintaka, the connecting links between the Taghdumbash Pamir and the Gilgit basin. They are all about the same height—15,000 feet. All are passable at certain times of the year to small parties, and all are uncertain. In no case do they present insuperable difficulties in themselves, glaciers and snow-fields and mountain staircases being common to all; but the gorges and precipices which distinguish the approaches to them from the south, the slippery sides of shelving spurs whose feet are washed by raging torrents, the perpetual weary monotony of ascent and descent over successive ridges multiplying the gradient indefinitely—these form the real obstacles blocking the way to these northern passes.

Gilgit Station.—The pretty little station of Gilgit (4400 feet above sea) spreads itself in terraces above the right bank of the river nearly opposite the opening leading to Hunza, almost nestling under the cliffs of the Hindu Koh which separates it on the south from the savage mountain wilderness of Darél and Kohistan. It includes a residency for the local political officer, with about half a dozen homes for the accommodation of officials, barracks suitable for a battalion of Kashmir troops, and a hospital. Evidences of Buddhist occupation are not wanting in Gilgit, though they are few and unimportant. Such as they are, they appear to prove that Gilgit was once a local Buddhist centre, and that the old Buddhist route between Gilgit and the Peshawar plain passed through the gorges and clefts of the unexplored Darél valley to Thakot under the northern spurs of the Black Mountain.

Connexion with India.—The Gilgit river joins the Indus a few miles above the little post of Bunji, where an excellent suspension bridge spans the river. The valley is low and hot, and the scenery between Gilgit and Bunji is monotonous; but the road is now maintained in excellent condition. A little below Bunji the Astor river joins the Indus from the south-east, and this deep pine-clad valley indicates the continuation of the high-road from Gilgit to Kashmir *viâ* the Tragbal and Burzil passes. Another well-known route connecting Gilgit with the Abbottabad frontier of the Punjab lies across the Babusar pass (13,000 feet), linking the lovely Hazara valley of Kaghán to Chilas; Chilas (4150 feet) being on the Indus, some 50 miles below Bunji. This is a more direct connexion between Gilgit and the plains of the Punjab than that afforded by the Kashmir route *viâ* Gurais and Astor, which latter route involves two considerable passes—the Tragbal (11,400) and the Burzil (13,500); but the intervening strip of absolutely independent territory (independent alike of Kashmir and the Punjab), which includes the hills bordering the road from the Babusar pass to Chilas, renders it a risky route for travellers unprotected by a military escort. Like the Kashmir route, it is now defined by a good military road.

Gilly, a town of Belgium, in the province of Hainaut, 2 miles north-east of Charleroi by rail. It has coal-pits and numerous factories, which include glass and nail works. Population (communal, 1899), 23,298.

Gilman, Daniel Coit (1831-——), American educationalist, was born in Norwich, Connecticut, 6th July 1831. He graduated at Yale in 1852, studied in Berlin, and between 1856 and 1870 was professor of physical geography at Yale, in 1872 becoming president of the University of California, at Berkeley, near San Francisco. In 1875 he was chosen first president of Johns Hopkins University at Baltimore, a post which he filled until 1901. His influence upon higher education in America has been great. Under his direction Johns Hopkins became the first university in the United States to develop a strong graduate department under competent professors, in which holders of bachelors' degrees pursued non-professional and advanced work (leading to the degree of Doctor of Philosophy) in philology, biology, physics, and other subjects. Johns Hopkins retains its superiority, in this respect, among the institutions of the old southern states; and its methods have been widely spread by the work of the recipients of its higher degrees. Some of Dr Gilman's papers and addresses are gathered in a volume, entitled *University Problems in the United States* (1898), representing his mature conclusions on many educational themes. He is also the author of a work on *James Monroe in his Relations to the Public Service during Half a Century* (1883) in the American Statesmen Series, and a *Life of James D. Dana*, the geologist (1899).

Ginsburg, Christian David (1831-——), Hebrew scholar, was born at Warsaw, 25th December 1831. Coming to England shortly after the completion of his education in the Rabbinic College at Warsaw, Dr Ginsburg continued his study of the Hebrew Scriptures, with special attention to the Megilloth. The first result of these studies was a translation of the Song of Songs, with a commentary historical and critical, published in 1857, and containing a careful elucidation of the text in accordance with the established laws of historico-grammatical exegesis. A similar translation of Ecclesiastes, followed by treatises on the Karaites, on the Essenes, and on the Kabbalah, kept the author prominently before Biblical critics while he was preparing the first sections of his *magnum opus*, the critical study of the Massorah. Beginning in 1867 with the publication of Jacob ben Chajim's Introduction to the Rabbinic Bible, Hebrew and English, with notices, and the Massoreth Ha-Massoreth of Elias Levita, in Hebrew, with translation and commentary, Dr Ginsburg at once became an authority on Biblical Hebrew criticism. In 1870 he was appointed one of the first members of the committee for the revision of the English version of the Old Testament. His life-work culminated in the publication of the Massorah, in three volumes folio (1880–86), followed by the Masoretico-critical edition of the Hebrew Bible (1894), and the elaborate introduction to it (1897). In attempting to appreciate the value of Dr Ginsburg's work, and the vast labour it has entailed, it is necessary to bear in mind the character and peculiarities of the Massorah itself. This elaborate code of marginal references and exhaustive notes, collating and calling attention to the minutest peculiarities of style, grammar, or spelling, originated in the wise forethought of the Jewish scribes, who thus endeavoured to guard against even the most trivial variation in copying the Holy Scriptures. After being, as its name signifies, an oral tradition, the Massorah was reduced to writing, probably about the 3rd century before Christ, by the Jewish scholars of Palestine.

The growing vastness of the work soon rendered it impossible to transcribe the whole of the Massorah in any single manuscript of the Bible, and consequently portions only were copied. Gradually these portions were written in a contracted form and purposely rendered difficult by the copyists, who expended their ingenuity in the fantastical transcription of words which they had long ceased to understand. Such are the MSS. which Dr Ginsburg has deciphered, transcribed, and collated. He had one predecessor in the field, the learned Jacob ben Chajim, who in 1524–25 published the second Rabbinic Bible, containing what has ever since been known as the Massorah; but neither were the materials available nor was criticism sufficiently advanced for a complete edition. It was reserved for Dr Ginsburg to take up the subject almost where it was left by those early pioneers, and to collect portions of the Massorah from the countless MSS. scattered throughout Europe and the East. Dr Ginsburg's latest contribution to the branch of learning which he has made so peculiarly his own is a critical treatise "on the relationship of the so-called Codex Babylonicus of A.D. 916 to the Eastern Recension of the Hebrew Text." In this work he proves that the St Petersburg Codex, for so many years accepted as the genuine text of the Babylonian School, is in reality a Palestinian text carefully altered so as to render it conformable to the Babylonian recension.

Giolitti, Giovanni (1842– ——), Italian statesman, was born at Mondovì on 27th October 1842. After a rapid career in the financial administration he was, in 1882, appointed councillor of state and elected to parliament. As deputy he chiefly acquired prominence by attacks on Magliani, treasury minister in the Depretis cabinet, and on 9th March 1899 was himself selected as treasury minister by Crispi. On the fall of the Rudinì cabinet in May 1892, Giolitti, with the help of a Court clique, succeeded to the premiership. His term of office was marked by misfortune and misgovernment. The building crisis and the commercial rupture with France had impaired the situation of the state banks, of which one, the Banca Romana, had been further undermined by maladministration. A bank law, passed by Giolitti, failed to effect an improvement. Moreover, he irritated public opinion by raising to senatorial rank the director-general of the Banca Romana, Signor Tanlongo, whose irregular practices had become a byword. The Senate declined to admit Tanlongo, whom Giolitti, in consequence of an interpellation in parliament upon the condition of the Banca Romana, was obliged to arrest and prosecute. During the prosecution Giolitti abused his position as premier to abstract documents bearing on the case. Simultaneously a parliamentary commission of inquiry investigated the condition of the state banks. Its report, though acquitting Giolitti of personal dishonesty, proved disastrous to his political position, and obliged him to resign. His fall left the finances of the state disorganized, the pensions fund depleted, diplomatic relations with France strained in consequence of the massacre of Italian workmen at Aigues-Mortes, and Sicily and the Lunigiana in a state of revolt, which he had proved impotent to suppress. After his resignation he was impeached for abuse of power as minister, but the supreme court quashed the impeachment by denying the competence of the ordinary tribunals to judge ministerial acts. For several years Giolitti, while retaining his seat in the Chamber, was compelled by public opinion to play a passive part, but later he took the leadership of a group of deputies, with whose help he succeeded by degrees in regaining some portion of his former influence.

Girgeh, or Girga, a town and former capital of Upper Egypt, on the left bank of the Nile. It is an important railway station on the Nile valley line, 336 miles from Cairo, with a population in 1900 of about 15,000, and probably occupies the site of This (Tini), one of the oldest places in Egypt. It stood formerly at some distance from the river, but is now on the bank, the intervening space having been washed away, together with a large part of the town, by the stream continually encroaching on its left bank.

Girgenti, a town, episcopal see, and capital of the province of Girgenti, Sicily, Italy, about midway on the south coast, but 3 miles from the sea and 58 miles south from Palermo. A new aqueduct from Poltano, 23 miles distant, has been made since 1897. Population (1881), 20,391; (1901), 25,069.

Gironde, a department in the south-west of France, bathed by the Atlantic Ocean, and watered by the Garonne and the Dordogne, which unite under the name of the Gironde.

Area, 4141 square miles. The population increased from 775,845 in 1886 to 820,781 in 1900. Births in 1899, 14,908, of which 1817 were illegitimate; deaths, 16,216. There were in 1896 1280 schools, with 93,000 pupils, and the illiterate formed 4 per cent. of the population. The area under cultivation comprised in 1896 1,974,400 acres, of which 499,000 acres were arable and 336,000 acres vineyard. Woods and forests occupy more than 740,000 acres, principally in the region of the Landes. In 1899 the produce of wheat amounted to the value of £980,000; rye yielded £21,000; oats, £38,000; maize, £40,000. The natural pastures returned a value of £607,000. A little tobacco also is cultivated. The great source, however, of the wealth of the Gironde is its wine, which in 1899 yielded a value of more than 3½ millions sterling. Gironde has no great industries except those connected with alimentation. Gironde in 1899 owned 50,160 horses, 139,330 cattle, 236,710 sheep, and 67,800 pigs. The distilleries of alcohol have, however, assumed large proportions, turning out in 1898 no less than 1,282,000 gallons. Bordeaux, the capital, had in 1901 a population of 257,471.

Girvan, a police burgh, market and fishing town of Ayrshire, Scotland, at the mouth of the river Girvan, 21½ miles south-south-west of Ayr by rail. The harbour has been improved by the building of a pier and breakwater, and a sewage scheme has been carried out. There is a Roman Catholic church and convent. Population (1881), 4505; (1901), 4019.

Gitschin (Czech, *Jičin*), the chief town of a government district in Bohemia, Austria. It has a garrison of 834 men, and an important corn trade, together with large sugar refineries, and the manufacture of paper, soda-water, beer, &c. Population, mostly Czech (1890), 8457; (1900), 9790.

Giurgevo, or Giurgiu, a town in Rumania, on the left bank of the Danube opposite Rustchuk in Bulgaria. It is the seat of a court of first instance, has four Rumanian churches, one Greek church, and two synagogues. Its port is at Smarda, 2½ miles east of the town. Giurgevo is the terminus of the first railway constructed in Rumania (Bucarest–Giurgiu), and is a town of considerable commercial importance. The export trade in 1898 was valued at £591,660. Population (1900), 13,977.

Givet, a town and important railway junction in the arrondissement of Rocroi, department of Ardennes, France, 40 miles by rail north of Mézières. The fortifications, with the exception of the citadel of Charlemont, were demolished in 1892. In the new quarter is a statue of the musician Méhul (1892). The town has considerable river traffic; total tonnage entered 1900, 32,332, consisting chiefly of coal, copper, and stones. Population (1881), 4932; (1901), 7011.

Gladbach, or MÜNCHEN-GLADBACH, a town of Prussia, in the Rhine province, 16 miles by rail west by south from Düsseldorf. There are monuments to the Emperor William I. (1897) and to Bismarck (1900). The cotton and other industries still flourish vigorously, and there is also manufacture of account books, cloth, stove tiles, paper, hosiery, linen, shoes, and breweries. Population (1885), 44,230; (1900), 58,014.

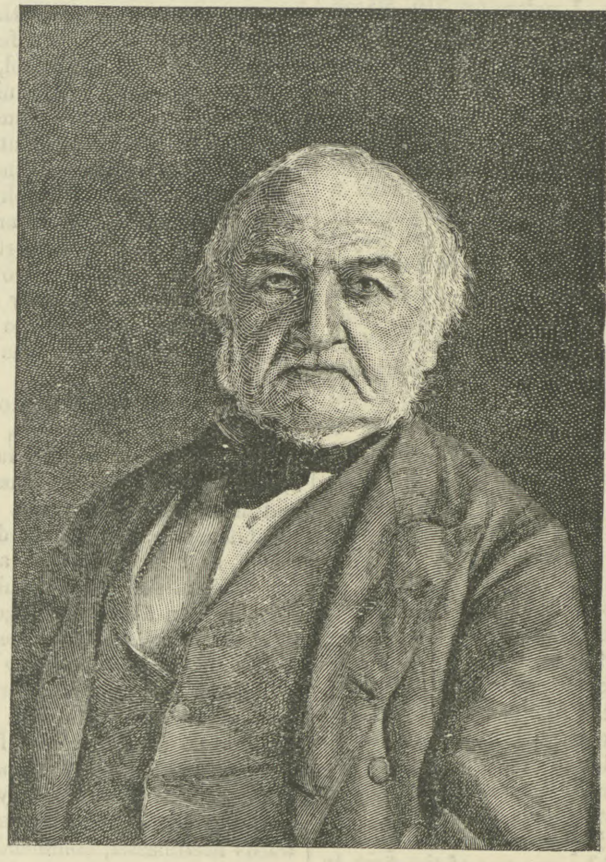
Gladstone, John Hall (1827– ——), English chemist, was born at Hackney, London, on 7th March 1827. From childhood he showed great aptitude for science; geology was his favourite subject, but since this in his father's opinion did not afford a career of promise, he devoted himself to chemistry, which he studied under Graham at University College, London, and Liebig at Giessen. In 1850 he became chemical lecturer at St Thomas's Hospital, and three years later was elected a fellow of the Royal Society at the unusually early age of twenty-six. From 1858 to 1861 he served on the Royal Commission on Lighthouses, and from 1864 to 1868 was a member of the War Office committee on gun-cotton. From 1874 to 1877 he was Fullerian professor of chemistry at the Royal Institution, in 1874 he was chosen first president of the Physical Society, and in 1877–79 he was president of the Chemical Society. In 1897 the Royal Society recognized his fifty years of scientific work by awarding him the Davy medal. Dr Gladstone's researches have been large in number and wide in range, dealing to a great extent with problems that lie on the border-line between physics and chemistry—with that physical chemistry which was the creation of the latter part of the 19th century. Thus a number of his inquiries, and those not the least important, have been partly chemical, partly optical. He determined the optical constants of hundreds of substances, with the object of discovering whether any of the elements possesses more than one refractive equivalent. Again, he investigated the connexion between the optical behaviour, specific gravity, and chemical composition of ethereal oils, and the relation between molecular magnetic rotation and the refraction and dispersion of nitrogenous compounds. So early as 1856 he showed the importance of the spectroscope in chemical research, and he was one of the first to notice that the Fraunhofer spectrum at sunrise and sunset differs from that at midday, his conclusion being that the earth's atmosphere must be responsible for many of its absorption lines, which indeed have been subsequently traced to the oxygen and water-vapour in the air. Another portion of his work was of an electro-chemical character. His studies, with Hibbert, in the chemistry of the storage battery have added largely to our knowledge, while the "copper-zinc couple," with which his name is associated together with that of Tribe, among other things afforded a simple means of preparing certain organo-metallic compounds, and thus promoted research in branches of organic chemistry where those bodies are especially useful. Mention may also be made of his work on phosphorus, on explosive substances such as iodide of nitrogen, gun-cotton, and the fulminates, on the influence of mass in the process of chemical transformations, and on the effect of carbonic anhydride on the germination of plants. Dr Gladstone has always taken a great interest in educational questions, and from 1873 to 1894 he was a representative for Chelsea on the London School Board, of which for three years he acted as vice-chairman.

Gladstone, William Ewart (1809–1898), British statesman, was born on 29th December 1809 at No. 62 Rodney Street, Liverpool. His forefathers were Gledstanes of Gledstanes, in the upper ward of Lanarkshire; or, in Scottish phrase, Gledstanes of that Ilk. As years went on their estates dwindled, and by the beginning of the 17th century Gledstanes was sold. The adjacent property of Arthurshiel remained in the hands of the family for nearly a hundred years longer. Then the son of the last Gledstanes of Arthurshiel removed to Biggar, where he opened the business of a maltster. His grandson, Thomas Gladstone (for so the name was modified), became a corn-merchant at Leith. He happened to send his eldest son, John, to Liverpool to sell a cargo of grain there, and the energy and aptitude of the young man attracted the favourable notice of a leading corn-merchant of Liverpool, who recommended him to settle in that city. Beginning his commercial career as a clerk in his patron's house, John Gladstone lived to become one of the merchant-princes of Liverpool, a baronet, and a member of parliament. He died in 1851, at the age of eighty-seven. Sir John Gladstone was a pure Scotsman, a Lowlander by birth and descent. He married Anne, daughter of Andrew Robertson of Stornoway, sometime Provost of Dingwall. Provost Robertson belonged to the Clan Donachie, and by this marriage the robust and business-like qualities of the Lowlander were blended with the poetic imagination, the sensibility, and fire of the Gael.

Childhood and Education.

John and Anne Gladstone had six children. The fourth son, William Ewart, was named after a merchant of Liverpool who was his father's friend. He seems to have been a remarkably good child, and much beloved at home. In 1818 or 1819 Mrs Gladstone, who belonged to the Evangelical school, said in a letter to a friend, that she believed her son William had been "truly converted to God." After some tuition at the vicarage of Seaforth, a watering-place near Liverpool, the boy went to Eton in 1821. His tutor was the Rev. Henry Hartopp Knapp. His brothers, Thomas and Robertson Gladstone, were already at Eton. Thomas was in the fifth form, and William, who was placed in the middle remove of the fourth form, became his eldest brother's fag. He worked hard at his classical lessons, and supplemented the ordinary business of the school by studying mathematics in the holidays. Mr Hawtrey, afterwards headmaster, commended a copy of his Latin verses, and "sent him up for good"; and this experience first led the young student to associate intellectual work with the ideas of ambition and success. He was not a fine scholar, in that restricted sense of the term which implies a special aptitude for turning English into Greek and Latin, or for original versification in the classical languages. "His composition," we read, "was stiff," but he was imbued with the substance of his authors; and a contemporary who was in the sixth form with him recorded that "when there were thrilling passages of Virgil or Homer, or difficult passages in the *Scriptores Graeci* to translate, he or Lord Arthur Hervey was generally called up to edify the class with quotation or translation." By common consent he was pre-eminently God-fearing, orderly, and conscientious. "At Eton," said Bishop Hamilton of Salisbury, "I was a thoroughly idle boy, but I was saved from some worse things by getting to know Gladstone." His most intimate friend was Arthur Hallam, by universal acknowledgment the most remarkable Etonian of his day; but he was not generally popular or even widely known. He was seen to the greatest advantage, and was most thoroughly at home, in the debates of the Eton Society, learnedly called "The Literati" and vulgarly "Pop," and in the editorship of the *Eton Miscellany*. He left Eton at Christmas 1827. He read for six months with private tutors, and in October 1828 went up to Christ Church, where, in the following year, he was nominated to a Studentship.

At Oxford Gladstone read steadily, but not laboriously, till he neared his final Schools. During the latter part of his undergraduate career he took a brief but brilliant share in the proceedings of the Union, of which he was successively Secretary and President. He made his first speech on 11th February 1830. Brought up in the nurture and admonition of Canning, he defended Roman Catholic emancipation, and thought the Duke of Wellington's Government unworthy of national confidence. He opposed the removal of Jewish disabilities, arguing, we are told by a contemporary, "on the part of the Evangelicals," and pleaded for the gradual extinction, in preference to the immediate abolition, of slavery. But his great achievement was a speech against the Whig Reform Bill. One who heard this famous discourse says: "Most of the speakers rose, more or less, above their usual level, but when Mr Gladstone sat down we all of us felt that an epoch in our lives had occurred. It certainly was the finest speech of his that I ever heard." Bishop Charles Wordsworth said that his experience of Gladstone at this time "made me (and I doubt not others also) feel no less sure than of my own existence that Gladstone, our then Christ Church undergraduate, would one day rise to be Prime Minister of England." In December 1831 Gladstone crowned his career by taking a double first-class. Lord Halifax (1800–1885) used to say, with reference to the increase in the amount of reading requisite for the highest honours: "My double-first must have been a better thing than Peel's; Gladstone's must have been better than mine."



William Ewart Gladstone (1895).
(From a photograph by Elliott and Fry, London.)

Now came the choice of a profession. Deeply anxious to make the best use of his life, Gladstone turned his thoughts to Holy Orders. But his father had determined to make him a politician. Quitting Oxford in the spring of 1832, Gladstone spent six months in Italy, learning the language and studying art. In the following September he was suddenly recalled to England, to undertake his first parliamentary campaign. The fifth Duke of Newcastle was one of the chief potentates of the High Tory party. His frank claim to "do what he liked with his own" in the representation of Newark has given him a place in political history. But that claim had been rudely disputed by the return of a Radical lawyer at the election of 1831. The Duke was anxious to obtain a capable candidate to aid him in regaining his ascendancy over the rebellious borough. His son, Lord Lincoln, had heard Gladstone's speech against the Reform Bill delivered in the Oxford Union, and had written home that "a man had uprisen in Israel." At his suggestion the Duke invited Gladstone to stand for Newark in the Tory interest against Mr Serjeant Wilde, afterwards Lord Chancellor Truro. The last of the Unreformed Parliaments was dissolved on the 3rd December 1832. Gladstone, addressing the electors of Newark, said that he was bound by the opinions of no man and no party, but felt it a duty to watch and resist that growing desire for change which threatened to produce "along with partial good a melancholy preponderance of mischief." The first principle to which he looked for national salvation was, that the "duties of governors are strictly and peculiarly religious, and that legislatures, like individuals, are bound to carry throughout their acts the spirit of the high truths they have acknowledged." The condition of the poor demanded special attention; labour should receive adequate remuneration; and he thought favourably of the "allotment of cottage grounds." He regarded slavery as sanctioned by Holy Scripture, but the slaves ought to be educated, and gradually emancipated. The contest resulted in his return at the head of the poll.

Entry into Parliament.

The first Reformed Parliament met on 29th January 1833, and the young member for Newark took his seat for the first time in an assembly which he was destined to adorn, delight, and astonish for more than half a century. His maiden speech was delivered on the 3rd June, in reply to what was almost a personal challenge. The Colonial Secretary, Mr Stanley, afterwards Lord Derby, brought forward a series of resolutions in favour of the extinction of slavery in the British colonies. On the first night of the debate Lord Howick, afterwards Lord Grey, who had been Under-Secretary for the Colonies, and who opposed the resolutions as proceeding too gradually towards abolition, cited certain occurrences on Sir John Gladstone's plantation in Demerara to illustrate his contention that the system of slave-labour in the West Indies was attended by great mortality among the slaves. Gladstone in his reply—his first speech in the House—avowed that he had a pecuniary interest in the question, "and, if he might say so much without exciting suspicion, a still deeper interest in it as a question of justice, of humanity, and of religion." If there had recently been a high mortality on his father's plantation, it was due to the age of the slaves rather than to any peculiar hardship in their lot. It was true that the particular system of cultivation practised in Demerara was more trying than some others; but then it might be said that no two trades were equally conducive to health. Steel-grinding was notoriously unhealthy, and manufacturing processes generally were less favourable to life than agricultural. While strongly condemning cruelty, he declared himself an advocate of emancipation, but held that it should be

The question of slavery.

effected gradually, and after due preparation. The slaves must be religiously educated, and stimulated to profitable industry. The owners of emancipated slaves were entitled to receive compensation from Parliament, because it was Parliament that had established this description of property. "I do not," said Gladstone, "view property as an abstract thing; it is the creature of civil society. By the legislature it is granted, and by the legislature it is destroyed." On the following day King William IV. wrote to Lord Althorp: "The King rejoices that a young member has come forward in so promising a manner as Viscount Althorp states Mr W. E. Gladstone to have done." In the same session Gladstone spoke on the question of bribery and corruption at Liverpool, and on the temporalities of the Irish Church. In the session of 1834 his most important performance was a speech in opposition to Hume's proposal to throw the Universities open to Dissenters.

On 10th November 1834 Lord Althorp succeeded to his father's peerage, and thereby vacated the leadership of the House of Commons. The Prime Minister, Lord Melbourne, submitted to the King a choice of names for the Chancellorship of the Exchequer and leadership of the House of Commons; but His Majesty announced that, having lost the services of Lord Althorp as Leader of the House of Commons, he could feel no confidence in the stability of Lord Melbourne's Government, and that it was his intention to send for the Duke of Wellington. The Duke took temporary charge of affairs, but Peel was felt to be indispensable. He had gone abroad after the session, and was now in Rome. As soon as he could be brought back he formed an administration, and appointed Gladstone to a Junior Lordship of the Treasury. Parliament was dissolved on 29th December. Gladstone was returned unopposed, this time in conjunction with the Liberal lawyer whom he had beaten at the last election. The new Parliament met on 19th February 1835. The elections had given the Liberals a considerable majority. Immediately after the meeting of Parliament Gladstone was promoted to the Under-Secretaryship for the Colonies, where his official chief was Lord Aberdeen. The administration was not long-lived. On 30th March Lord John Russell moved a resolution in favour of an inquiry into the temporalities of the Irish Church, with the intention of applying the surplus to general education without distinction of religious creed. This was carried against ministers by a majority of thirty-three. On 8th April Sir Robert Peel resigned, and the Under-Secretary for the Colonies of course followed his chief into private life.

Released from the labours of office, Gladstone, living in chambers in the Albany, practically divided his time between his parliamentary duties and study. Then, as always, his constant companions were Homer and Dante, and it is recorded that he read the whole of St Augustine, in twenty-two octavo volumes. He used to frequent the services at St James's, Piccadilly, and Margaret Chapel, since better known as All Saints', Margaret Street. On 20th June 1837 King William IV. died, and Parliament, having been prorogued by the young Queen in person, was dissolved on the 17th of the following month. Simply on the strength of his parliamentary reputation Gladstone was nominated, without his consent, for Manchester, and was placed at the bottom of the poll; but, having been at the same time nominated at Newark, was again returned. The year 1838 claims special note in a record of Gladstone's life, because it witnessed the appearance of his famous work on *The State in its Relations with the Church.* He had left Oxford just before the beginning of that Catholic revival which has transfigured both the inner spirit and the outward aspect of the Church of England. But the revival was now in full strength. The *Tracts for the Times* were saturating England with new influences. The movement counted no more enthusiastic or more valuable disciple than Gladstone. Its influence had reached him through his friendships, notably with two Fellows of Merton — Mr James Hope, who became Mr Hope-Scott of Abbotsford, and the Rev. H. E. Manning, afterwards Cardinal Archbishop. *The State in its Relations* was his practical contribution to a controversy in which his deepest convictions were involved. He contended that the Church, as established by law, was to be "maintained for its truth," and that this principle, if good for England, was good also for Ireland.

Literary work.

On 25th July 1839 Gladstone was married at Hawarden to Miss Catherine Glynne, sister, and in her issue heir, of Sir Stephen Glynne, ninth and last baronet of that name. In 1840 he published *Church Principles considered in their Results.*

Parliament was dissolved in June 1841. Gladstone was again returned for Newark. The General Election resulted in a Tory majority of eighty. Sir Robert Peel became Prime Minister, and made the member for Newark Vice-President of the Board of Trade. An inevitable change is from this time to be traced in the topics of Gladstone's parliamentary speaking. Instead of discoursing on the corporate conscience of the State and the endowments of the Church, the importance of Christian education, and the theological unfitness of the Jews to sit in Parliament, he is solving business-like problems about foreign tariffs and the exportation of machinery; waxing eloquent over the regulation of railways, and a graduated tax on corn; subtle on the monetary merits of half-farthings, and great in the mysterious lore of *quassia* and *cocculus indicus.* In 1842 he had a principal hand in the preparation of the Revised Tariff, by which duties were abolished or sensibly diminished in the case of 1200 duty-paying articles. In defending the new scheme he spoke incessantly, and amazed the House by his mastery of detail, his intimate acquaintance with the commercial needs of the country, and his inexhaustible power of exposition. In 1843 Gladstone, succeeding Lord Ripon as President of the Board of Trade, became a member of the Cabinet at the age of thirty-three. He has recorded the fact that "the very first opinion which he ever was called upon to give in Cabinet" was an opinion in favour of withdrawing the Bill providing education for children in factories, to which vehement opposition was offered by the Dissenters on the ground that it was too favourable to the Established Church.

Enters the Cabinet.

At the opening of the session of 1845 the Government, in pursuance of a promise made to Irish members that they would deal with the question of academical education in Ireland, proposed to establish non-sectarian colleges in that country and to make a large addition to the grant to the Roman Catholic College of Maynooth. Gladstone resigned office, in order, as he announced in the debate on the Address, to form "not only an honest, but likewise an independent and an unsuspected judgment," on the plan to be submitted by the Government with respect to Maynooth. His subsequent defence of the proposed grant, on the ground that it would be improper and unjust to exclude the Roman Catholic Church in Ireland from a "more indiscriminating support" which the State might give to various religious beliefs, was regarded by men of less sensitive conscience as only proving that there had been no adequate cause for his resignation.

Maynooth grant: resignation.

Before he resigned he completed a second Revised Tariff, carrying considerably farther the principles on which he had acted in the earlier revision of 1842.

In the autumn of 1845 the failure of the potato crop in Ireland threatened a famine, and convinced Sir Robert Peel that all restrictions on the importation of food must be at once suspended. He was supported by only three members of the Cabinet, and resigned on 5th December. Lord John Russell, who had just announced his conversion to total and immediate repeal of the Corn Laws, declined the task of forming an administration, and on 20th December Sir Robert Peel resumed office. Lord Stanley refused to re-enter the Government, and his place as Secretary of State for the Colonies was offered to and accepted by Gladstone. He did not offer himself for re-election at Newark, and remained outside the House of Commons during the great struggle of the coming year. It was a curious irony of fate which excluded him from Parliament at this crisis, for it seems unquestionable that he was the most advanced Free Trader in Sir Robert Peel's Cabinet. The Corn Bill passed the House of Lords on the 28th June 1846, and on the same day the Government were beaten in the House of Commons on an Irish Coercion Bill. Lord John Russell became Prime Minister, and Gladstone retired for a season into private life. Early in 1847 it was announced that one of the two members for the University of Oxford intended to retire at the General Election, and Gladstone was proposed for the vacant seat. The representation of the university had been pronounced by Canning to be the most coveted prize of public life, and Gladstone himself confessed that he "desired it with an almost passionate fondness." Parliament was dissolved on 23rd July 1847. The nomination at Oxford took place on 29th July, and at the close of the poll Sir Robert Inglis stood at the head, with Gladstone as his colleague.

Free Trade.

The three years 1847, 1848, 1849 were for Gladstone a period of mental growth, of transition, of development. A change was silently proceeding, which was not completed for twenty years. "There have been," he wrote in later days to Bishop Wilberforce, "two great deaths, or transmigrations of spirit, in my political existence—one, very slow, the breaking of ties with my original party." This was now in progress. In the winter of 1850–51 Gladstone spent between three and four months at Naples, where he learned that more than half the Chamber of Deputies, who had followed the party of Opposition, had been banished or imprisoned; that a large number, probably not less than 20,000, of the citizens had been imprisoned on charges of political disaffection, and that in prison they were subjected to the grossest cruelties. Having made careful investigations, Gladstone, on 7th April 1851, addressed an Open Letter to Lord Aberdeen, bringing an elaborate, detailed, and horrible indictment against the rulers of Naples, especially as regards the arrangements of their prisons and the treatment of persons confined in them for political offences. The publication of this letter caused a wide sensation in England and abroad, and profoundly agitated the Court of Naples. In reply to a question in the House of Commons, Lord Palmerston accepted and adopted Gladstone's statement, expressed keen sympathy with the cause which he had espoused, and sent a copy of his Letter to the Queen's representative at every court of Europe. A second Letter and a third followed, and their effect, though for a while retarded, was unmistakably felt in the subsequent revolution which created a free and united Italy.

Naples prisons.

In February 1852 the Whig Government was defeated on a Militia Bill, and Lord John Russell was succeeded by Lord Derby, formerly Lord Stanley, with Mr Disraeli, who now entered office for the first time, as Chancellor of the Exchequer and Leader of the House of Commons. Mr Disraeli introduced and carried a makeshift Budget, and the Government tided over the session, and dissolved Parliament on 1st July 1852. There was some talk of inducing Gladstone to join the Tory Government, and on 29th November Lord Malmesbury dubiously remarked, "I cannot make out Gladstone, who seems to me a dark horse." In the following month the Chancellor of the Exchequer produced his second Budget. The Government redeemed their pledge to do something for the relief of the agricultural interest by reducing the duty on malt. This created a deficit, which they repaired by doubling the duty on inhabited houses. The voices of criticism were heard simultaneously on every side. The debate waxed fast and furious. In defending his proposals Mr Disraeli gave full scope to his most characteristic gifts; he pelted his opponents right and left with sarcasms, taunts, and epigrams. Gladstone delivered an unpremeditated reply, which has ever since been celebrated. Tradition says that he "foamed at the mouth." The speech of the Chancellor of the Exchequer, he said, must be answered "on the moment." It must be "tried by the laws of decency and propriety." He indignantly rebuked his rival's language and demeanour. He tore his financial scheme to ribbons. It was the beginning of a duel which lasted till death removed one of the combatants from the political arena. "Those who had thought it impossible that any impression could be made upon the House after the speech of Mr Disraeli had to acknowledge that a yet greater impression was produced by the unprepared reply of Mr Gladstone." The House divided, and the Government were left in a minority of nineteen. Lord Derby resigned.

Gladstone and Disraeli.

The new Government was a coalition of Whigs and Peelites. Lord Aberdeen became Prime Minister, and Gladstone Chancellor of the Exchequer. Having been returned again for the University of Oxford, he entered on the active duties of a great office for which he was pre-eminently fitted by an unique combination of financial, administrative, and rhetorical gifts. His first Budget was introduced on 18th April 1853. It tended to make life easier and cheaper for large and numerous classes; it promised wholesale remissions of taxation; it lessened the charges on common processes of business, on locomotion, on postal communication, and on several articles of general consumption. The deficiency thus created was to be met by a "succession-duty," or application of the legacy-duty to real property; by an increase of the duty on spirits; and by the extension of the income-tax, at 5d. in the pound, to all incomes between £100 and £150. The speech in which these proposals were introduced held the House spell-bound. Here was an orator who could apply all the resources of a burnished rhetoric to the elucidation of figures; who could sweep the widest horizon of the financial future, and yet stoop to bestow the minutest attention on the microcosm of penny stamps and post-horses. Above all, the Chancellor's mode of handling the income-tax attracted interest and admiration. It was a searching analysis of the financial and moral grounds on which the impost rested, and a historical justification and eulogy of it. Yet, great as had been the services of the tax at a time of national danger, Gladstone could not consent to retain it as a part of the permanent and ordinary finances of the country. It was objectionable on account of its unequal incidence, of the harassing investigation into private affairs which it entailed, and of the frauds to which

Chancellor of the Exchequer.

it inevitably led. Therefore, having served its turn, it was to be extinguished in 1860. The scheme astonished, interested, and attracted the country. The Queen and Prince Albert wrote to congratulate the Chancellor of the Exchequer. Public authorities and private friends joined in the chorus of eulogy. The Budget demonstrated at once its author's absolute mastery over figures and the persuasive force of his expository gift. It established the Chancellor of the Exchequer as the paramount financier of his day, and it was only the first of a long series of similar performances, different, of course, in detail, but alike in their bold outlines and brilliant handling. Looking back on a long life of strenuous exertion, Gladstone declared that the work of preparing his proposals about the succession-duty and carrying them through Parliament was by far the most laborious task which he ever performed.

War between Great Britain and Russia was declared on 27th March 1854, and it thus fell to the lot of the most pacific of ministers, the devotee of retrenchment, and the anxious cultivator of all industrial arts, to prepare a war-budget, and to meet as well as he might the exigencies of a conflict which had so cruelly dislocated all the ingenious devices of financial optimism. No amount of skill in the manipulation of figures, no ingenuity in shifting fiscal burdens, could prevent the addition of forty-one millions to the national debt, or could countervail the appalling mismanagement at the seat of war. Gladstone declared that the state of the army in the Crimea was a "matter for weeping all day and praying all night." As soon as Parliament met in January 1855 J. A. Roebuck, the Radical member for Sheffield, gave notice that he would move for a select committee "to inquire into the condition of our army before Sebastopol, and into the conduct of those departments of the Government whose duty it has been to minister to the wants of that army." On the same day Lord John Russell, without announcing his intention to his colleagues, resigned his office as President of the Council sooner than attempt the defence of the Government. Gladstone, in defending the Government against Roebuck, rebuked in dignified and significant terms the conduct of men who, "hoping to escape from punishment, ran away from duty." On the division on Mr Roebuck's motion the Government was beaten by the unexpected majority of 157.

Lord Palmerston became Prime Minister. The Peelites joined him, and Gladstone resumed office as Chancellor of the Exchequer. A shrewd observer at the time pronounced him indispensable. "Any other Chancellor of the Exchequer would be torn in bits by him." The Government was formed on the understanding that Mr Roebuck's proposed committee was to be resisted. Lord Palmerston soon saw that further resistance was useless; his Peelite colleagues stuck to their text, and, within three weeks after resuming office, Gladstone, Sir James Graham, and Mr Sidney Herbert resigned. Gladstone once said of himself and his Peelite colleagues, during the period of political isolation, that they were like roving icebergs on which men could not land with safety, but with which ships might come into perilous collision. He now applied himself specially to financial criticism, and was perpetually in conflict with the Chancellor of the Exchequer, Sir George Cornewall Lewis.

In 1858 Lord Palmerston was succeeded by Lord Derby at the head of a Conservative administration, and Gladstone accepted the temporary office of High Commissioner Extraordinary to the Ionian Islands. Returning to England for the session of 1859, he found himself involved in the controversy which arose over a mild Reform Bill introduced by the Government. They were defeated on the second reading of the Bill, Gladstone voting with them. A dissolution immediately followed, and Gladstone was again returned unopposed for the University of Oxford. As soon as the new Parliament met a vote of want of confidence in the ministry was moved in the House of Commons. In the critical division which ensued Gladstone voted with the Government, who were left in a minority. Lord Derby resigned. Lord Palmerston became Prime Minister, and asked Gladstone to join him as Chancellor of the Exchequer. To vote confidence in an imperilled ministry, and on its defeat to take office with the rivals who have defeated it, is a manœuvre which invites the reproach of tergiversation. But Gladstone risked the reproach, accepted the office, and had a sharp tussle for his seat. He emerged from the struggle victorious, and entered on his duties with characteristic zeal. The Prince Consort wrote: "Gladstone is now the real leader in the House of Commons, and works with an energy and vigour altogether incredible."

Budget of 1860.

The Budget of 1860 was marked by two distinctive features. It asked the sanction of Parliament for the commercial treaty which Cobden had privately arranged with the Emperor Napoleon, and it proposed to abolish the duty on paper. The French treaty was carried, but the abolition of the paper-duty was defeated in the House of Lords. Gladstone justly regarded the refusal to remit a duty as being in effect an act of taxation, and therefore as an infringement of the rights of the House of Commons. The proposal to abolish the paper-duty was revived in the Budget of 1861, the chief proposals of which, instead of being divided, as in previous years, into several Bills, were included in one. By this device the Lords were obliged to acquiesce in the repeal of the paper-duty, or else to incur the responsibility of rejecting the whole financial scheme for the year. The Budget became law, and Gladstone was triumphant.

During Lord Palmerston's last administration, which lasted from 1859 to 1865, Gladstone was by far the most brilliant and most conspicuous figure in the Cabinet. Except in finance, he was not able to accomplish much, for he was met and thwarted at every turn by his chief's invincible hostility to change; but the more advanced section of the Liberal party began to look upon him as their predestined leader. In 1864, in a debate on a private member's Bill for extending the suffrage, he declared that the burden of proof lay on those "who would exclude forty-nine fiftieths of the working-classes from the franchise." In 1865, in a debate on the condition of the Irish Church Establishment, he declared that the Irish Church, as it then stood, was in a false position, inasmuch as it ministered only to one-eighth or one-ninth of the whole community. But just in proportion as Gladstone advanced in favour with the Radical party he lost the confidence of his own constituents. Parliament was dissolved in July 1865, and the University elected Mr Gathorne Hardy in his place.

Gladstone at once turned his steps towards South Lancashire, where he was returned with two Tories above him. The result of the General Election was to retain Lord Palmerston's Government in power, but on the 18th October the old Prime Minister died. He was succeeded by Lord Russell, and Gladstone, retaining the Chancellorship of the Exchequer, became for the first time Leader of the House of Commons. Lord Russell, backed by Gladstone, persuaded his colleagues to consent to a moderate Reform Bill, and the task of piloting this measure through the House of Commons fell to Gladstone. The speech in which he wound up the debate on the second reading was one of

Leader of House of Commons.

the finest, if not indeed the very finest, which he ever delivered. But it was of no practical avail. The Government were defeated on an amendment in committee, and thereupon resigned. Lord Derby became Prime Minister, with Disraeli as Chancellor of the Exchequer and Leader of the House of Commons. On the 18th March 1867 the Tory Reform Bill, which ended in establishing Household Suffrage in the boroughs, was introduced, and was read a second time without a division. After undergoing extensive alterations in committee at the hands of the Liberals and Radicals, the Bill became law in August. Lord Cranborne (afterwards Lord Salisbury) declared that it had been remodelled at the dictation of Gladstone.

At Christmas 1867 Lord Russell announced his final retirement from active politics, and Gladstone was recognized by acclamation as Leader of the Liberal party. Nominally he was in Opposition; but his party formed the majority of the House of Commons, and could beat the Government whenever they chose to mass their forces. Gladstone seized the opportunity to give effect to convictions which had long been forming in his mind. Early in the session he brought in a Bill abolishing compulsory Church-rates, and this passed into law. On the 16th March, in a debate raised by an Irish member, he declared that in his judgment the Irish Church, as a State Church, must cease to exist. Immediately afterwards he embodied this opinion in a series of resolutions concerning the Irish Church Establishment, and carried them against the Government. Encouraged by this triumph, he brought in a Bill to prevent any fresh appointments in the Irish Church, and this also passed the Commons, though it was defeated in the Lords. Parliament was dissolved on the 11th November. A single issue was placed before the country—Was the Irish Church to be, or not to be, disestablished? The response was an overwhelming affirmative. Gladstone, who had been doubly nominated, was defeated in Lancashire, but was returned for Greenwich. He chose this moment for publishing a *Chapter of Autobiography*, in which he explained and justified his change of opinion with regard to the Irish Church Establishment.

Leader of Liberal party.

On the 2nd December Disraeli, who had succeeded Lord Derby as Premier in the preceding February, announced that he and his colleagues, recognizing their defeat, had resigned without waiting for a formal vote of the new Parliament. On the following day Gladstone was summoned to Windsor, and commanded by the Queen to form an administration. The great task to which the new Prime Minister immediately addressed himself was the disestablishment of the Irish Church. The Queen wrote to Archbishop Tait that the subject of the Irish Church "made her very anxious," but that Mr Gladstone "showed the most conciliatory disposition." "The Government can do nothing that would tend to raise a suspicion of their sincerity in proposing to disestablish the Irish Church, and to withdraw all State endowments from all religious communions in Ireland; but, were these conditions accepted, all other matters connected with the question might, the Queen thinks, become the subject of discussion and negotiation." The disestablishing Bill was drawn on the principle, and piloted on the lines, thus indicated. Gladstone brought it in on the 1st March 1869. Its progress through the House of Commons was easy. In committee in the House of Lords there was some risk of serious conflict, but moderate counsels prevailed, and the Bill became law on the 26th July. In the session of 1870 Gladstone's principal work was the Irish Land Act, of which the object was to protect the tenant against eviction as long as he paid his rent, and to secure to him the value of any improvements which his own industry had made. In the following session Religious Tests in the Universities were abolished, and a Bill to establish Secret Voting was carried through the House of Commons. This was thrown out by the Lords, but became law a year later. The House of Lords threw out a Bill to abolish the purchase of commissions in the army. Gladstone found that purchase existed only by royal sanction, and advised the Queen to issue a royal warrant declaring that, on and after 1st November following, all regulations authorizing the purchase of commissions should be cancelled.

Prime Minister: Irish Church disestablishment.

In 1873 Gladstone set his hand to the third of three great Irish reforms to which he had pledged himself. His scheme for the establishment of a University which should satisfy both Roman Catholics and Protestants met with general disapproval. The Bill was thrown out by three votes, and Gladstone resigned. The Queen sent for Disraeli, who declined to take office in a minority of the House of Commons, so Gladstone was compelled to resume. But he and his colleagues were now, in Disraelitish phrase, "exhausted volcanoes." Election after election went wrong. The Government had lost favour with the public, and was divided against itself. There were resignations and rumours of resignations. When the session of 1873 had come to an end Gladstone took the Chancellorship of the Exchequer, and, as high authorities contended, vacated his seat by doing so. The point was obviously one of vital importance; and we learn from Lord Selborne, who was Lord Chancellor at the time, that Gladstone "was sensible of the difficulty of either taking his seat in the usual manner at the opening of the session, or letting . . . the necessary arrangements for business in the House of Commons be made in the Prime Minister's absence. A dissolution was the only escape." On 23rd January 1874 Gladstone announced the dissolution in an address to his constituents, declaring that the authority of the Government had now "sunk below the point necessary for the due defence and prosecution of the public interest." He promised that, if he were returned to power, he would repeal the income-tax. This bid for popularity failed, the General Election resulting in a Tory majority of forty-six. Gladstone kept his seat for Greenwich, but was only second on the poll. Following the example of Disraeli in 1868, he resigned without meeting Parliament.

Dissolution of 1874.

For some years he had alluded to his impending retirement from public life, saying that he was "strong against going on in politics to the end." He was now sixty-four, and his life had been a continuous experience of exhausting labour. On 12th March 1874 he informed Lord Granville that he could give only occasional attendance in the House of Commons during the current session, and that he must "reserve his entire freedom to divest himself of all the responsibilities of leadership at no distant date." His most important intervention in the debates of 1874 was when he opposed Archbishop Tait's Public Worship Bill. This was read a second time without a division, but in committee Gladstone enjoyed some signal triumphs over his late Solicitor-General, Sir William Harcourt, who had warmly espoused the cause of the Government and the Bill. At the beginning of 1875 Gladstone carried into effect the resolution which he had announced a year before, and formally resigned the leadership of the Liberal party. He was succeeded by Lord Hartington, afterwards Duke of Devonshire. The learned leisure which Gladstone had promised himself when released from official responsibility

Temporary retirement.

was not of long duration. In the autumn of 1875 an insurrection broke out in Bulgaria, and the suppression of it by the Turks was marked by massacres and outrages. Public indignation was aroused by what were known as the "Bulgarian atrocities," and Gladstone flung himself into the agitation against Turkey with characteristic zeal. At public meetings, in the press, and in Parliament he denounced the Turkish Government and its champion, Disraeli, who had now become Lord Beaconsfield. Lord Hartington soon found himself pushed aside from his position of titular leadership. For four years, from 1876 to 1880, Gladstone maintained the strife with a courage, a persistence, and a versatility which raised the enthusiasm of his followers to the highest pitch. The county of Edinburgh, or Midlothian, which he contested against the dominant influence of the Duke of Buccleuch, was the scene of the most astonishing exertions. As the General Election approached the only question submitted to the electors was—Do you approve or condemn Lord Beaconsfield's foreign policy? The answer was given at Easter 1880, when the Liberals were returned by an overwhelming majority over Tories and Home Rulers combined. Gladstone was now member for Midlothian, having retired from Greenwich at the dissolution.

Midlothian Campaign.

When Lord Beaconsfield resigned the Queen sent for Lord Hartington, the titular leader of the Liberals, but he and Lord Granville assured her that no other chief than Gladstone would satisfy the party. Accordingly, on 23rd April he became Prime Minister for the second time. His second administration, of which the main achievement was the extension of the suffrage to the agricultural labourers, was harassed by two controversies, relating to Ireland and Egypt, which proved disastrous to the Liberal party. Gladstone alienated considerable masses of English opinion by his efforts to reform the tenure of Irish land, and provoked the Irish people by his attempts to establish social order and to repress crime. A Bill to provide compensation for tenants who had been evicted by Irish landlords passed the Commons, but was shipwrecked in the Lords, and a ghastly record of outrage and murder stained the following winter. A Coercion Bill and a Land Bill passed in 1881 proved unsuccessful. On the 6th May 1882 the newly-appointed Chief Secretary for Ireland, Lord Frederick Cavendish, and his Under-Secretary, Mr Burke, were stabbed to death in the Phoenix Park at Dublin. A new Crimes Act, courageously administered by Lord Spencer and Sir George Trevelyan, abolished exceptional crime in Ireland, but completed the breach between the British Government and the Irish party in Parliament.

The bombardment of the forts at Alexandria and the occupation of Egypt in 1882 were viewed with great disfavour by the bulk of the Liberal party, and were but little congenial to Gladstone himself. The circumstances of General Gordon's untimely death awoke an outburst of indignation against those who were, or seemed to be, responsible for it. Frequent votes of censure were proposed by the Opposition, and on 8th June 1885 the Government were beaten on the Budget. Gladstone resigned. The Queen offered him the dignity of an earldom, which he declined. He was succeeded by Lord Salisbury.

The General Election took place in the following November. When it was over the Liberal party was just short of the numerical strength which was requisite to defeat the combination of Tories and Parnellites. A startling surprise was at hand. Gladstone had for some time been convinced of the expediency of conceding Home Rule to Ireland in the event of the Irish constituencies giving unequivocal proof that they desired it. His intentions were made known only to a privileged few, and these, curiously, were not his colleagues. The General Election of 1885 showed that Ireland, outside Ulster, was practically unanimous for Home Rule. On 17th December an anonymous paragraph was published, stating that if Mr Gladstone returned to office he was prepared to "deal in a liberal spirit with the demand for Home Rule." It was clear that if Gladstone meant what he appeared to mean, the Parnellites would support him, and the Tories must leave office. The Government seemed to accept the situation. When Parliament met they executed, for form's sake, some confused manœuvres, and then they were beaten on an amendment to the Address in favour of Municipal Allotments. On 1st February 1886 Gladstone became, for the third time, Prime Minister. Several of his former colleagues declined to join him, on the ground of their absolute hostility to the policy of Home Rule; others joined on the express understanding that they were only pledged to consider the policy, and did not fetter their further liberty of action. On the 8th April Gladstone brought in his Bill for establishing Home Rule, and eight days later the Bill for buying out the Irish landlords. Meanwhile two members of his Cabinet, feeling themselves unable to support these measures, resigned. Hostility to the Bills grew apace. Gladstone was implored to withdraw them, or substitute a resolution in favour of Irish autonomy; but he resolved to press at least the Home Rule Bill to a second reading. In the early morning of 8th June the Bill was thrown out by thirty. Gladstone immediately advised the Queen to dissolve Parliament. Her Majesty strongly demurred to a second General Election within seven months; but Gladstone persisted, and she yielded. Parliament was dissolved on 26th June. In spite of Gladstone's skilful appeal to the constituencies to sanction the principle of Home Rule, as distinct from the practical provisions of his late Bill, the General Election resulted in a majority of considerably over 100 against his policy, and Lord Salisbury resumed office. Throughout the existence of the new Parliament Gladstone never relaxed his extraordinary efforts, though now nearer eighty than seventy, on behalf of the cause of self-government for Ireland. The fertility of argumentative resource, the copiousness of rhetoric, and the physical energy which he threw into the enterprise, would have been remarkable at any stage of his public life; continued into his eighty-fifth year they were little less than miraculous. Two incidents of domestic interest, one happy and the other sad, belong to that period of political storm and stress. On 25th July 1889 Gladstone celebrated the fiftieth anniversary of his marriage, and on the 4th July 1891 his eldest son, William Henry, a man of fine character and accomplishments, died, after a lingering illness, in his fifty-second year.

First Home Rule Bill.

The crowning struggle of Gladstone's political career was now approaching its climax. Parliament was dissolved on 28th June 1892. The General Election resulted in a majority of forty for Home Rule, heterogeneously composed of Liberals, Labour Members, and Irish. As soon as the new Parliament met a vote of want of confidence in Lord Salisbury's Government was moved and carried. Lord Salisbury resigned, and on 15th August 1892 Gladstone kissed hands as First Lord of the Treasury. He was the first English statesman that had been four times Prime Minister. Parliament reassembled in January 1893. Gladstone brought in his new Home Rule Bill on the 13th February. It passed the House of Commons, but was thrown out by the House of Lords on the second reading on 8th September 1893. Gladstone's political work was

Second Home Rule Bill.

now, in his own judgment, ended. He made his last speech in the House of Commons on the 1st March 1894, acquiescing in some amendments introduced by the Lords into the Parish Councils Bill; and on the 3rd March he placed his resignation in the Queen's hands. He never set foot again in the House of Commons, though he remained a member of it till the dissolution of 1895. He paid occasional visits to friends in London, Scotland, and the south of France; but the remainder of his life was spent for the most part at Hawarden. He occupied his leisure by writing a rhymed translation of the Odes of Horace, and preparing an elaborately annotated edition of Butler's *Analogy* and *Sermons.* He had also contemplated some addition to the Homeric studies which he had always loved, but this design was never carried into effect, for he was summoned once again from his quiet life of study and devotion to the field of public controversy. The Armenian massacres in 1894 and 1895 revived all his ancient hostility to "the governing Turk." He denounced the massacres and their perpetrators at public meetings held at Chester on 6th August 1895, and at Liverpool on 24th September 1896. In March 1897 he recapitulated the hideous history in an Open Letter to the Duke of Westminster, which in its masterly handling of facts and its resonant eloquence may rank with the best of his writings.

But the end, though not yet apprehended, was at hand. Since his retirement from office Gladstone's physical vigour, up to that time unequalled, had shown signs of impairment. Towards the end of the summer of 1897 he began to suffer from an acute pain, which was attributed to facial neuralgia, and in November he went to Cannes. In February 1898 he returned to England and went to Bournemouth. There he was informed that the pain had its origin in a disease which must soon prove fatal. He received the information with simple thankfulness, and only asked that he might die at home. On 22nd March he returned to Hawarden, and there he died on 19th May 1898. During the night of 25th May his body was conveyed from Hawarden to London, and the coffin was placed on a bier in Westminster Hall. Throughout the 26th and 27th a vast train of people, officially estimated at 250,000, and drawn from every rank and class, moved in unbroken procession past the bier. On the 28th May the coffin, preceded by the two Houses of Parliament and escorted by the chief magnates of the realm, was carried from Westminster Hall to Westminster Abbey. The Heir-Apparent and his son, the Prime Minister and the Leader of the House of Commons, were among those who bore the pall. The body was buried in the north transept of the abbey, where, on the 19th June 1900, Mrs Gladstone's body was laid beside it.

Death.

After a careful survey of Mr Gladstone's life, enlightened by personal observation, it is inevitable to attempt some analysis of his character. First among his moral attributes must be placed his religiousness. From those early days when a fond mother wrote of him as having been "truly converted to God," down to the verge of ninety years, he lived in the habitual contemplation of the unseen world, and regulated his private and public action by reference to a code higher than that of mere prudence or worldly wisdom. A second characteristic, scarcely less prominent than the first, was his love of power. His ambition had nothing in common with the vulgar eagerness for place and pay and social standing. Rather it was a resolute determination to possess that control over the machine of State which should enable him to fulfil without let or hindrance the political mission with which he believed that Providence had charged him. The love of power was supported by a splendid fearlessness. No dangers were too threatening for him to face, no obstacles too formidable, no tasks too laborious, no heights too steep. The love of power and the supporting courage were allied with a marked imperiousness. Of this quality there was no trace in his manner, which was courteous, conciliatory, and even deferential; nor in his speech, which breathed an almost exaggerated humility. But the imperiousness showed itself in the more effectual form of action; in his sudden resolves, his invincible insistence, his recklessness of consequences to himself and his friends, his habitual assumption that the civilized world and all its units must agree with him, his indignant astonishment at the bare thought of dissent or resistance, his incapacity to believe that an overruling Providence would permit him to be frustrated or defeated. He had by nature what he himself called a "vulnerable temper and impetuous moods." But so absolute was his lifelong self-mastery that he was hardly ever betrayed into saying that which, on cooler reflection, needed to be recalled. It was easy enough to see the "vulnerable temper" as it worked within, but it was never suffered to find audible expression. It may seem paradoxical, but it is true, to say that Mr Gladstone was by nature conservative. His natural bias was to respect things as they were. In his eyes, institutions, customs, systems, so long as they had not become actively mischievous, were good because they were old. It is true that he was sometimes forced by conviction or fate or political necessity to be a revolutionist on a large scale; to destroy an established Church; to add two millions of voters to the electorate; to attack the parliamentary union of the kingdoms. But these changes were, in their inception, distasteful to their author. His whole life was spent in unlearning the prejudices in which he was educated. His love of freedom steadily developed, and he applied its principles more and more courageously to the problems of government. But it makes some difference to the future of a democratic state whether its leading men are eagerly on the look-out for something to revolutionize, or approach a constitutional change by the gradual processes of conviction and conversion.

Character.

Great as were his eloquence, his knowledge, and his financial skill, Gladstone was accustomed to say of himself that the only quality in which, so far as he knew, he was distinguished from his fellow-men was his faculty of concentration. Whatever were the matter in hand, he so concentrated himself on it, and absorbed himself in it, that, for the time being, nothing else seemed to exist for him.

A word must be said about physical characteristics. In his prime Gladstone was just six feet high, but his inches diminished as his years increased, and in old age the unusual size of his head and breadth of his shoulders gave him a slightly top-heavy appearance. His features were strongly marked; the nose trenchant and hawk-like, and the mouth severely lined. His flashing eyes were deep-set, and in colour resembled the onyx with its double band of brown and grey. His complexion was of an extreme pallor, and, combined with his jet-black hair, gave in earlier life something of an Italian aspect to his face. His dark eyebrows were singularly flexible, and they perpetually expanded and contracted in harmony with what he was saying. He held himself remarkably upright, and even from his school days at Eton had been remarked for the rapid pace at which he habitually walked. His voice was a baritone, singularly clear and far-reaching. In the Waverley Market at Edinburgh, which is said to hold 20,000 people, he could be heard without difficulty;

and as late as 1895 he said to the present writer: "What difference does it make to me whether I speak to 400 or 4000 people?" His physical vigour in old age earned him the popular nickname of the Grand Old Man.

(G. W. E. R.)

Glaisher, James (1809– ——), English meteorologist and aeronaut, was born in London on 7th April 1809. After serving for a few years on the Ordnance Survey of Ireland, he acted as an assistant at the Cambridge and Greenwich observatories successively, and when the department of meteorology and magnetism was formed at the latter, he was entrusted with its superintendence, which he continued to exercise for thirty-four years, until his retirement from the public service. In 1845 he published his well-known dew-point tables, which have gone through many editions. In 1850 he established the Meteorological Society, acting as its secretary for many years, and in 1866 he assisted in the foundation of the Aeronautical Society of Great Britain. He was appointed a member of the Royal Commission on the Warming and Ventilation of Dwellings in 1875, and for twelve years from 1880 acted as chairman of the executive committee of the Palestine Exploration Fund. But his name is best known in connexion with the series of balloon ascents which he made between 1862 and 1866, mostly in company with Coxwell. Many of these ascents were arranged by a committee of the British Association, of which he was a member, and were strictly scientific in character, the object being to carry out observations on the temperature, humidity, &c., of the atmosphere at high elevations. In one of them, that which took place at Wolverhampton on 5th September 1862, Mr Glaisher and his companion attained what is probably the greatest height ever reached by a balloon carrying passengers. As no automatically recording instruments were available, and Mr Glaisher was unable to read the barometer at the highest point owing to loss of consciousness, the precise altitude can never be known, but it is estimated at about 7 miles from the earth. An authentic account of this and other ascents undertaken by him may be found in the article AERONAUTICS (*Ency. Brit.*, 9th edition, vol. i.), which came from his pen.

Glamorgan, a maritime county of South Wales, bounded on the N.W. by Carmarthen, on the N. by Carmarthen and Brecon, on the E. by Monmouth, from which it is separated by the Rhymney, and on the S. and the S.W. by the Bristol Channel.

Area and Population.—The area of the ancient county is 516,959 acres, or 808 square miles, with a population in 1881 of 511,433, and in 1891 of 687,218, of whom 360,260 were males and 326,958 females; the number of persons per square mile being 851, and of acres to a person 0·75. The area of the administrative county, according to the census returns of 1891, was 505,815 acres, with a population of 467,954, or with the county boroughs of Cardiff and Swansea, 516,966 acres, with a population of 687,218; but in 1895 the acreage of the combined area was slightly altered by transferences in the case of the county borough of Cardiff to and from Monmouth. The area of the registration county is 576,308, with a population in 1891 of 693,072. Within this area the percentage of increase between 1881 and 1891 was 33·70. The excess of births over deaths between 1881 and 1891 was 97,222, but this was much exceeded by the increase of the population, which was 174,689. In 1901 the population of the ancient county was 860,022. The following table gives the number of marriages, births, and deaths, with the number and percentage of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				No	Per cent
1880	4088	18,345	11,076	597	3·3
1890	6575	24,245	13,646	680	2·9
1898	6112	29,347	14,732	812	2·8

In 1891 there were in the county 3289 natives of Scotland, 11,256 natives of Ireland, and 5856 foreigners, while 326,481 persons could speak English, 142,346 Welsh, and 177,726 English and Welsh.

Constitution and Government.—The county is divided into five parliamentary divisions, and it also includes the Cardiff district of boroughs (consisting of Cardiff, Cowbridge, and Llantrisant), greater part of the borough of Merthyr Tydfil, and Swansea, comprising Swansea town and Swansea district (consisting of the boroughs of Aberavon, Kenfig, Loughor, and Neath). There are five municipal boroughs:—Aberavon (7553), Cardiff (164,420), Cowbridge (1202), Neath (13,732), and Swansea (94,514). Cardiff and Swansea are county boroughs. The following are urban districts:—Aberdare (43,357), Barry (27,028), Bridgend (6063), Briton Ferry (6961), Caerphilly (15,835), Glyncorrwg (6450), Maesteg (15,013), Margam (9014), Merthyr Tydfil (69,227), Mountain Ash (31,093), Ogmore and Garw (19,912), Oystermouth (4483), Penarth (14,227), Pontypridd (32,319), Porthcawl (1871), and Rhondda (113,735). Glamorganshire is in the South Wales and Chester circuit, and assizes are held at Cardiff and Swansea. The boroughs of Cardiff, Swansea, and Aberavon have separate commissions of the peace, and the former two have also separate courts of quarter sessions. The ancient county—which is partly in the diocese of Llandaff and partly in that of St Davids—contains 140 entire ecclesiastical parishes and districts and part of five others.

Education.—Cardiff is the seat of the University College of South Wales and of a technical school. At Swansea are the Government schools of science and art. In connexion with the University College of Cardiff there is a day training college for schoolmasters and mistresses. At Swansea there is a residential college for mistresses (British and Foreign School Society's) which also takes day students. In Cardiff there are two school board blind schools and one school board deaf school; in Swansea are the Royal Cambrian Institution for the deaf and the Swansea and South Wales Institution for the blind; at Pontypridd is a school board deaf school, and there is also one at Ystradyfodwg. The number of elementary schools in the county on 31st August 1899 was 382, of which 253 were board and 129 voluntary schools, the latter including 100 National Church of England schools, 24 Roman Catholic, and 5 "British and other." The average attendance at board schools was 108,320, and at voluntary schools 16,400. The total school board receipts for the year ended 29th September 1899 were over £513,702. The income under the Technical Instruction Act was over £669, and that under the Agricultural Rates Act over £2467.

Agriculture.—More than half of the total area of the county is under cultivation, and of this about seven-ninths is in permanent pasture, cattle, especially cows for milk-selling, and sheep being largely kept. There are in addition over 121,000 acres of mountain pasture, and about 27,000 acres under woods. Since 1880 the acreage under corn crops has decreased by about a third, there being a considerable decrease even in the acreage under oats, and a decrease of about two-fifths in the acreage under wheat, and only a little less than two-fifths in the acreage under barley. The acreage under green crops has decreased more than a sixth, the decrease being chiefly in that under turnips, which, however, still occupy about three-fourths of the green crop area.

The following table gives the larger main divisions of the cultivated area at intervals from 1880:—

Year.	Total area under Cultivation.	Corn Crops.	Green Crops	Clover.	Permanent Pasture.	Fallow.
1880	272,215	36,685	15,013	26,088	190,514	3911
1885	279,659	31,455	14,606	27,570	203,889	2128
1890	282,774	28,661	14,176	23,195	215,072	1573
1895	279,416	26,191	13,299	21,358	217,149	1266
1900	274,410	25,205	11,851	21,824	214,375	1026

The following table gives particulars regarding the principal live stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	14,206	51,972	21,863	253,321	13,020
1885	15,362	57,256	23,957	283,939	17,660
1890	16,125	55,849	25,138	303,507	18,024
1895	17,284	52,203	24,285	292,786	18,892
1900	16,468	56,485	25,697	330,060	16,406

Industries and Trade.—According to the annual report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 54,859, as compared with 53,313 in 1896. Of these 47,358 persons were employed in non-textile factories, there being an increase of 2·2 per cent. between 1895 and 1896, and of 3·3 per cent. between 1896 and 1897. In metal founding and conversion 19,298 persons were employed, in the extraction of metals 3695, in the manufacture of machines, appliances, conveyances, and tools 11,846, in pottery, &c., 1684, in the manufacture of paper, &c., 1916; there is considerable manufacture of chemicals. Workshops employed 7266 persons, of whom 4430 were employed in clothing industries. The fishing industry is of some importance: by lines, draught nets, dredging, trawling, fixed nets, and hand. The principal fish are cod, herring, pollard, whitings, fluke, brill, plaice, soles, turbot, oysters, mussels, limpets, winkles, cockles, shrimps, crabs, and lobsters. The total quantity landed at the ports of Cardiff and Swansea in 1899 was 29,242 cwts., valued at £19,983. The total number of persons employed in mines and quarries in 1899 was 96,017, rather more than the number employed in Lancashire, and exceeded among British counties only by the numbers of Durham and Yorkshire. In the same year 681,910 tons of limestone were raised and 292,137 tons of sandstone. Tin and copper ore are imported from Cornwall for smelting purposes, and most of the iron for the special industries of the county is also imported. There are many large blast-furnaces—at Dowlais, Merthyr Tydfil, Cardiff, Pontypridd, Bridgend, Landore, Port Talbot, and Briton Ferry—the amount of pig iron produced in 1885 being 354,692 tons, in 1890 416,874 tons, in 1895 447,715 tons, and in 1899 578,790 tons. The following table gives particulars regarding the principal minerals in 1890 and 1899:—

Year.	Clay.		Coal.		Iron Ore.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.
1890	144,767	£28,804	21,426,415	£11,451,913	21,363	£9613
1899	217,147	£23,364	28,116,941	£10,967,247	6,817	£3068

A PARTIAL LIST OF THE CONTRIBUTORS

TO

THE NEW VOLUMES

OF

THE ENCYCLOPÆDIA BRITANNICA

WITH THE INITIALS WHICH HAVE BEEN AFFIXED TO THEIR RESPECTIVE ARTICLES.

THE LIST OF CONTRIBUTORS here given is necessarily incomplete, inasmuch as the later Volumes are still in course of preparation, and all the Contributors have not yet been selected. On the other hand, the present List may contain a few names which ultimately will not appear in the final List of Contributors. Death or other cause may prevent certain writers who have undertaken the preparation of Articles from completing the contributions which they were to furnish. A full List, compiled when the final Volume goes to press, will be given later. The present List includes the names of all who have written signed Articles for the Volumes which have so far appeared.

After the few words of description which accompany the names are given the initials of the different authors as they have been affixed to the Articles contributed by them.

The Publishers congratulate themselves that in this List of a thousand names are to be found not only the most famous scholars and writers of Great Britain, but of the whole world.

A

ABBE, Prof. Cleveland, A.M., Ph.D., LL.D.; Meteorologist, U.S. Weather Bureau; author of 'Atmospheric Radiation,' etc.; editor of 'Monthly Weather Review'; Lecturer on Meteorology, Johns Hopkins University. (C. A.)

T. C.)

CURRAN, Rev. J. Milne; author of 'Geology of Sydney and the Blue Mountains,' 'A Contribution to the Geology and Petrography of Bathurst,' etc. (J. M. Cu.)

D

DABNEY, Charles William, Ph.D.; Pres. Univ. of Tennessee; assistant U.S. Secretary Agriculture, 1893-97, etc. (C. W. D.)

DABNEY, Richard Heath, A.M., Ph.D.; Professor of Historical and Economical Science, University of Virginia; author of 'The Causes of the French Revolution,' 'John Randolph: a Character Sketch.' (R. H. D.)

DALBY, W. Ernest, M.A., B.Sc., M.I.C.E., M.I.M.E., Assoc. M.I. Nav. Architects; Professor of Mechanical Engineering and Applied Mathematics, City and Guilds Technical College, Finsbury. (W. E. D.)

DALE, T. F.; author of 'The Game of Polo, part-editor of 'Riding and Polo.' (T. F. D.)

DALL, Hon. William Healey, A.M.; naturalist, U.S. National Museum; author of 'Alaska and its Resources,' 'Tribes of the Extreme North-west,' etc. (W. H. D.)

DALLAS, J. M. M.; late Secretary of the Edinburgh Draughts Club. (J. M. M. D.)

DANNREUTHER, Edward, Professor Royal Coll. Mus.; author of 'Musical Ornamentation,' 'Liszt's Études,' 'Richard Wagner.' (E. Da.)

DARWIN, George Howard, M.A., LL.D., D.Sc., F.R.S.; Plumian Professor of Astronomy and Experimental Philosophy, Cambridge; Fellow of Trin. Coll. Camb.; author of 'Tides,' in Ninth Edition of 'Ency. Brit.' 'Reports to B.A. on Harmonic Analysis of Tidal Observations,' 'Memoirs on the Effects of Tidal Friction on the Earth and on the Moon,' Phil. Trans. Roy. Soc., 'The Tides and Kindred Phenomena in the Solar System,' etc. (G. H. D.)

DARWIN, Leonard, Major, late R.E.; Intelligence Dept. War Office, 1885-90; served on several scientific expeditions, including Transit of Venus of 1874 and 1882; author of 'Bi-metallism.' (L. D.)

DAVENPORT, Cyril James H., F.S.A.; British Museum; silver medal Society of Arts, 1900; binding editor to the Anglo-Saxon Review; author of 'The English Regalia,' 'Royal English Bookbindings,' 'Cantor Lectures on Decorative Bookbindings,' 'English Embroidered Bookbindings,' 'Life of T. Berthelet.' (C. D.)

DAVEY of Fernhurst, Lord, D.C.L., F.R.S.; Lord of Appeal in Ordinary; Solicitor-General, 1886; Lord Justice of Appeal, 1893. (D.)

DAVIDS, T. W. Rhys, LL.D., Ph.D.; Secretary and Librarian Royal Asiatic Society; Professor of Pali and Buddhist Literature, Univ. Coll. London; author of 'Buddhism,' 'Jains,' 'Lamaism,' in Ninth Edition of 'Ency. Brit.,' 'Buddhism,' 'Buddhist Birth Stories,' 'Buddhist Suttas from the Pali,' 'Hibbert Lectures,' 1881, etc. (T. W. R. D.)

DAVIDSON, William Leslie, M.A., LL.D.; Professor of Logic and Metaphysics, Aberdeen University; author of 'English Words Explained,' 'Theism as grounded in Human Nature,' 'A Philosophical Centenary: Reid and Campbell,' 'Christian Ethics.' (W. L. D.)

DAVIES, A. Llewelyn, B.A.; Barrister, Inner Temple; Assistant Reader in Common Law under the Council of Legal Education. (A. Ll. D.)

DAVIES, Henry Walford, Mus. Doc. (Camb.), A.R.C.M. (Lond.); organist and director of the choir, Temple Church, London; formerly organist and choirmaster, St Anne's, Soho; teacher of counterpoint, R.C.M., 1895. (H. W. D.)

DAVIS, John Patterson, Ph.D., A.M.; assistant in History and Economics, University of Michigan, 1894-1895; now Attorney-at-Law, Nampa, Idaho; author of 'The Union Pacific Railway,' etc. (J. P. D.)

DAVIS, William Morris, Professor Physical Geography, Harvard University; author of 'Physical Geography' and numerous scientific publications. (W. M. D.)

DAWKINS, William Boyd, M.A., D.Sc., F.R.S., F.S.A., F.G.S., A.M.I.C.E.; Professor of Geol. and Palæontology in Owens College, Manchester; geologist on Geological Survey of Great Britain, 1861-69; author of 'Cave' in Ninth Edition of 'Ency. Brit.,' 'Cave Hunting,' 'Early Man in Britain,' 'British Pleistocene Mammalia.' (W. B. D.)

DAWSON, George Mercer, LL.D., F.R.S., the late; Director Geological Survey of Canada; Geologist and Naturalist to H.M. North American Boundary Commission, 1873-75; one of

H.M. Behring Sea Commissioners, 1891, and under the Behring Sea Joint Commission Agreement, 1892; author of numerous scientific and technical reports printed by the Canadian Government, and scientific and other papers. (G. M. D.)

DAY, Lewis F.; English Designer and Art Lecturer; Med. Paris Exhibition (1900); Examiner for Art, Board of Education; author of 'Windows—Stained and Painted Glass,' 'The Anatomy of Pattern,' 'The Distribution of Ornamental Design,' 'Nature in Ornament,' etc. (L. F. D.)

DAYOT, Armand; Inspector of Fine Arts, Ministry of Fine Arts, France; author of 'Un siècle d'art,' 'La Révolution Française, d'après des peintures, sculptures, etc.,' 'Les maîtres de la caricature Française au XIXe siècle,' etc. (A. Da.)

DEACON, George Frederick, M.I.M.E.; Member of Council of Institution of Civil Engineers, London; investigated schemes for water-supply of Liverpool; projected the Vyrnwy scheme; carried out part of it in conjunction with the late Thomas Hawksley; President Association of Municipal and County Engineers, 1878; President Engineering Section Sanitary Institute, 1894; President Mechanical Science Section, British Association, Toronto, 1897. (G. F. D.)

DEANS, Richard Storry, LL.B.; Barrister-at-Law, Gray's Inn. (R. S. D.)

DENNING, W. F., F.R.A.S.; Gold Medal, R.A.S.; President Liverpool Ast. Society, 1877-78; author of 'Telescopic Work for Starlight Evenings,' 'The Great Meteoric Shower,' etc. (W. F. D.)

DE VILLIERS, John Abraham J.; British Museum. (J. A. J. de V.)

DE VINNE, Theodore Low, printer and typographist, New York; head of the firm of Theodore L. de Vinne and Co.; author of 'Printers' Price List,' 'Invention of Printing,' 'Historic Types,' etc. (T. L. de V.)

DEWAR, James, M.A., Hon. LL.D. (Glasgow, St Andrews, Edin.), D.Sc. (Victoria), F.R.S., F.R.S.Ed., F.I.C., F.C.S.; Professorial Fellow of Peterhouse, Camb.; Jacksonian Professor of Experimental Philosophy, Cambridge; Fullerian Professor of Chemistry, Royal Institution, London; Vice-President of the Royal Society; a Director of the Davy-Faraday Research Laboratory; President British Association for 1902; co-inventor with Sir Frederick Abel of cordite; late member of the Government Explosives Committee; author of 'Alum,' etc. in Ninth Edition of 'Ency. Brit.,' numerous papers contributed to the proceedings of the Royal Societies of London and Edinburgh, the Royal Institution, the British Association, the Chemical Society, etc. (J. Dr.)

DIBDIN, Charles, F.R.G.S., A.V.I.; Knight of St John of Jerusalem in England; Hon. Corresponding Member of Institutions de Prévoyance, France; Secy. of the Royal National Lifeboat Institution, England; Hon. Secy. of the Civil Service Lifeboat Fund. (C. Di.)

DIBDIN, Lewis Tonna, K.C., D.C.L. (Durham), F.S.A.; author of 'Church Courts,' 'City Livery Companies,' 'Brewer's Endowment and Establishment,' 'Monasticism in England,' 'Hanson's Death Duties.' (L. T. D.)

DICEY, Edward, C.B., B.A.; editor of 'The Observer' (London), 1870-89; author of 'Rome in 1860,' 'Cavour,' 'The Morning Land,' 'England and Egypt,' 'Victor Emmanuel,' 'Bulgaria, the Peasant State,' 'The Story of the Khedivate,' etc. (E. D.)

DICKEY, Rev. Charles A., D.D.; President of the Presbyterian Hospital in Philadelphia; Moderator of the General Assembly of the Presbyterian Church in the U.S., 1900. (C. A. D.)

DICKSON, Henry Newton, B.Sc., F.R.S.E., F.R.G.S.; late Vice-President Royal Meteorological Society; Lecturer in Physical Geography, Oxford; author of 'Meteorology: the Elements of Weather and Climate,' etc. (H. N. D.)

DIXON, Capt. J. Whitly, R.N.; conservator of the river Humber; late Staff Commander of the Medway Fleet Reserve; author of 'Mariner's Compass in an Iron Ship,' etc. (J. W. D.)

DOBSON, George; Petersburg; author of 'Russia's Railway Advance and Central Asia,' etc. (G. D.)

DOBSON, Henry Austin, Principal, H.M. Board of Trade, to 1901; author of 'Hogarth' in Ninth Edition of 'Ency. Brit.'; 'Proverbs in Porcelain,' 'Old-World Idylls,' 'At the Sign of the Lyre,' 'Collected Poems,' 'Thomas Bewick and his Pupils,' Lives of Fielding, Steele, Goldsmith, Horace Walpole, William Hogarth, 'Four Frenchwomen,' 'Eighteenth Century Vignettes,' 'A Paladin of Philanthropy,' etc. (A. D.)

DODD, Lieut.-Col. John Richard, M.B., F.R.C.S., R.A.M.C.; Medical Officer, Royal Arsenal, Woolwich. (J. R. D.)

DOUGLAS, James, LL.D.; member and Vice-President Am. Inst. of Mining Engineers; member Am. Philosoph. Soc., Am. Geolog. Soc., Society of Arts, London, etc.; formerly Professor of Chemistry, Morrin College, Quebec; author of 'Canadian Independence,' 'Imperial Federation and Annexation,' numerous technical articles and reports, etc. (J. Ds.)

DOUGLAS, Robert Kennaway, Keeper of Oriental Printed Books and MSS. at the British Museum; Professor of Chinese, King's Coll. London; appointed China Consular Service, 1858; retired, and appointed assistant in charge of Chinese Library, British Museum, 1865; author of 'Canton,' 'China,' 'Jenghiz Khan,' 'Manchuria,' etc., in Ninth Edition of 'Ency. Brit.,' 'The Language and Literature of China,' 'Confucianism and Taoism,' 'China,' 'A Chinese Manual,' 'The Life of Li Hung-Chang,' 'China.' (R. K. D.)

DOUGLASS, William Tregarthen, M.I.C.E., M.I.M.E., M.I.E.E.; late Consulting Engineer to the Trinity House; Con. Eng. to Govts. of W. Australia, N. S. Wales, Victoria, Cape of Good Hope, etc.; erected the Eddystone, Bishop Rock Lighthouses, etc.; author of 'The New Eddystone Lighthouse,' 'On the More Efficient Lighting of Estuaries and Rivers,' etc. (W. T. D.)

DOWSON, J. Emerson, M.I.C.E., M.I.M.E.; Inventor of the Dowson Gas Plant; part author of 'Tramways,' 'Decimal Coinage,' etc. etc. (J. E. Do.)

DREYER, John Louis Emil, Director Armagh Observatory; assist. Astronomer at Dublin University Observatory, 1878-82; author of 'Observatory,' 'Sextant,' 'Time,' 'Transit Circle,' in Ninth Edition 'Ency. Brit.,' 'Second Armagh Catalogue of 3300 Stars,' 1886, 'New General Catalogue of Nebulæ and Clusters of Stars,' 'Tycho Brahe'; co-editor 'Copernicus: an International Journal of Astronomy,' 1881-84. (J. L. E. D.)

DRIESCH, Hans A. E., Ph.D. Jena; Stazione Zoologica, Naples; author of 'Analytical Theory of Organic Development,' 'Biology,' etc. (H. A. E. D.)

DRIVER, Rev. Samuel Rolles, D.D., D.Litt.; Regius Professor of Hebrew, and Canon of Christ Church, Oxford; member of Old Testament Revision Company; author of 'Isaiah,' 'Notes on the Hebrew Text of the Books of Samuel,' 'An Introduction to the Literature of the Old Testament,' various commentaries; joint-editor of the 'Holy Bible, with various renderings and readings from the best authorities,' 'A Hebrew and English Lexicon of the Old Testament.' (S. R. D.)

DUFF, Rt. Hon. Sir Mountstuart Elphinstone Grant, P.C., M.A., D.L., G.C.S.I., F.R.S.; Under-Secretary of State for India, 1868-74; Under-Secretary for the Colonies, 1880-81; Governor of Madras, 1881-86; Member of Senate University of London, 1891; President Royal Geographical Society, 1889-93; President Royal Historical Society, 1892-99; author of 'Miscellanies, Political and Literary,' 'Memoir of Sir H. S. Maine,' 'Ernest Renan,' 'Memoir of Lord de Tabley,' 'Notes from a Diary.' (M. G. D.)

DUFFIELD, William Bartleet; of the Inner Temple, Barrister-at-Law. (W. B. Du.)

DU FIEF, J.; Secrétaire, Société Royale Belge de Géographie, Bruxelles; author of 'Atlas du Belgique,' 'Les decouvertes maritimes des Portugais au XVe siècle,' 'Les Expeditions Belges au Katenga,' etc. (J. du F.)

DUNCAN, Louis, Ph.D.; sometime President of the American Institute of Electrical Engineers, and Associate Professor of Electricity, Johns Hopkins University, Baltimore. (L. Du.)

DUNCAN, P.; Secretary's Department, Inland Revenue Office, London. (P. D.)

DUNNING, William Archibald, Ph.D.; Professor of History, Columbia University, New York; member of The American Historical Association; author of 'Essays in Reconstruction,' etc.; editor 'Political Science Quarterly.' (W. A. D.)

DUTT, Romesh Chunder, C.I.E.; Lecturer Indian History, Univ. Coll. London; Fellow of the Calcutta Univ.; Divisional Commissioner, 1894 and 1895, being the only native of India who attained that position in the last century; author of a series of historical and social novels in Bengali, and a translation of the Rig Veda and other Sanscrit religious works into that language; in English, 'Civilization in Ancient India,' 'Lays of Ancient India,' 'Maha-bharata,' condensed into English verse, 'Ramayana,' condensed into English verse, 'England and India, 1785-1885'; 'Famines in India.' (R. C. D.)

EDGINGTON, Charles, M.A.; President Oxford University Speed Skating Club; holder since 1898 of the world's speed record for the hour (19 m. 348 yds.). (C. E.)

EDGEWORTH, Francis Ysidro, M.A.; D.C.L.; Professor of Political Economy, Oxford, Fellow of All Souls' Coll. Oxford; Fellow of King's Coll. London; editor of the 'Economic Journal'; author of 'Mathematical Psychics,' etc. (F. Y. E.)

EDWARDS, William Seymour, Attorney and Counsellor-at-law, U.S.A.; author of 'Coals and Cokes in West Virginia.' (W. S. E.)

EGERTON, H. E.; author of 'A Short History of British Colonial Policy,' 'Sir Stamford Raffles,' 'Essays on Christ's Hospital,' etc. (H. E. Eg.)

ELIOT, Charles William, LL.D., D.C.L.; President of Harvard University; author of 'American Contributions to Civilization,' 'Educational Reform,' etc. (C. W. E.)

ELIOT, Whately, M.I.C.E.; conducted survey of the coast of New Zealand; late Engineer to Peterhead Harbour Board; Resident Engineer Eastham section of the Manchester Ship Canal; Superintendent Civil Engineer, Keyham Dockyard Extension, etc. (W. E.)

ELLINGTON, E. B., M.I.C.E.; Member of the Council M.E.; Member of the Société des Ingénieurs Civils de France; Chief Engineer London and Liverpool Hydraulic Power Companies, etc.; inventor of numerous improvements in hydraulic machinery. (E. B. E.)

ERNST, Gen. Oswald Herbert; Brigadier-General U.S.A.; member of the U.S. Isthmian Canal Commission; Engineer in charge of Western River Improvements, 1878-86, and of Harbour Improvements on Texas Coast, 1886-89; Superintendent U.S. Military Academy, 1893-98; author of 'Manual of Practical Military Engineering,' etc. (O. H. E.)

EVANS, Hon. Henry Clay; U.S. Commissioner of Pensions, Washington. (H. C. E.)

EVERETT, Commander Allan F., R.N.; Signal School, H.M.S. 'Victory,' Portsmouth. (A. F. E.)

EVERETT, Joseph David, M.A., D.C.L., D.Sc., F.R.S.; late Professor of Natural Philosophy, Queen's Coll. Belfast; Assist. to Professor of Mathematics, Glasgow, 1864-67; author of 'Centimètre-Gramme-Second System of Units,' English edition of 'Deschanel's Physics,' 'Elementary Text-Book of Physics,' 'Outlines of Natural Philosophy.' (J. D. E.)

EWART, James Cossar, M.D., F.R.S.; Regius Professor of Natural History, Edinburgh; Professor Natural History, Aberdeen, 1878-82; member Fishery Board for Scotland; author of 'The Locomotor System of the Echinoderms' (with the late G. J. Romanes), 'On the Progress of Fish Culture in America,' 'On Whitebait,' 'On the Preservation of Fish,' 'The Development of the Limbs of the Horse.' (J. C. E.)

EWING, James Alfred, M.A., B.Sc., F.R.S., M.I.C.E.; Professor of Mechanism and Applied Mechanics, Cambridge; Fellow of King's College, Cambridge; Professor of Mechanical Engineering at the Imperial University, Tokyo, Japan, 1878-83; author of 'Pneumatic Despatch,' 'Seismometer,' 'Sewerage,' 'Siemens,' 'Steam Engine,' 'Strength of Materials' in Ninth Edition of 'Ency. Brit.,' 'Treatise on Earthquake Measurement,' 'Magnetic Induction in Iron and other Metals,' 'The Steam Engine and other Heat Engines,' etc. (J. A. E.)

EXETER, Bishop of, Right Rev. Herbert Edward Ryle, D.D., B.A.; Warburton Lecturer 1899-1903; Fellow King's College, Cambridge, 1881; Divinity Lecturer at

Emmanuel College, Cambridge, 1881-84; at King's College, 1882-86; Principal of St David's College, Lampeter, 1886-88; Professorial Fellow of King's College, Cambridge, 1888; examining chaplain to late Bishop of St Asaph, 1887-89, and to Bishop of Ripon, 1889; Hon. Canon of Ripon, 1895; Chaplain to the Queen, 1898-1901; Hulsean Professor of Divinity, Cambridge University, 1887-1901, and President of Queens' College, Cambridge, 1896-1901; author of 'The Canon of the Old Testament,' 'The Early Narratives of Genesis,' 'Commentary on Ezra and Nehemiah,' 'Philo and Holy Scripture,' etc. (H. E. E.)

F

FAIRBAIRN, Andrew Martin, M.A., D.D., LL.D.; Principal Mansfield Coll. Oxford; Principal of Airedale Coll. 1877-1886; Chairman of Congregational Union of England and Wales, 1883; Member of Royal Commission on Secondary Education, 1894-95; author of 'Arminius,' 'Independents,' in Ninth Edition of 'Ency. Brit.,' 'Studies in the Life of Christ,' 'The City of God,' 'Religion in History and in Modern Life,' 'Catholicism, Roman and Anglican,' 'The Philosophy of the Christian Religion,' etc. (A. M. F.)

FAIRBROTHER, William Henry, M.A., Lecturer in Philosophy, Lincoln College, Oxford; author of 'Philosophy of Thomas Hill Green.' (W. H. F*.)

FAIRLIE, John A., Ph.D.; Asst. Prof. of Administrative Law, Univ. of Michigan; author of 'Municipal Government.' (J. A. Fa.)

FARRAR, Very Rev. Frederic William, D.D., F.R.S.; Dean of Canterbury; Hulsean Lecturer at Cambridge; Bampton Lecturer at Oxford; Chaplain to the Speaker of the House of Commons, 1890-95; author of 'Jesus Christ' in Ninth Edition of 'Ency. Brit.,' 'The Life of Christ,' 'The Life of St Paul,' 'The Early Days of Christianity,' 'Darkness and Dawn,' 'The Bible, its Meaning and Supremacy,' etc. (F. W. F.)

FAUNCE, W. H. P., A.M., D.D.; President of Brown University, Providence, R.I. (W. H. P. F.)

FAUR, G., of the Egyptian Hall, London. (G. Fa.)

FERGUSON, J.; editor of the 'Ceylon Observer,' 'Tropical Agriculturist,' etc.; author of 'Handbook to Ceylon,' manuals on Coffee, Tea, Gold, Gems, etc. (J. F.)

FERRERO, Baron Augusto; editor of 'La Tribuna,' Rome; author of 'Nostalgie d'Amore'; edited 'From Florence to Rome: A Political Diary of 1870-71,' etc. (A. Fe.)

FFOULKES, Miss C. Jocelyn; translator of Morelli's 'Italian Painters,' etc. (C. J. F*.)

FIDLER, H.; Civil Engineer, head of Technical Staff Department of Civil Engineer-in-Chief, Admiralty; editor of 'A Manual of Construction,' etc. (H. F.)

FIELD, Capt. A. Mostyn, R.N.; F.R.A.S., F.R.G.S., F.R.Met.S.; has worked for the Hydrographic Survey in various parts of the world. (A. M. F*.)

FILON, Pierre Marie Augustin; agrégé ès lettres; French Critic; tutor to the late Prince Imperial; literary editor of the 'Revue Bleue'; author of 'Le Mariage de Londres,' 'Histoire de la Littérature Anglais,' 'English Profiles,' and works on the French and English drama. (A. Fi.)

FISHER, Alexander; English teacher and specialist in the art of enamelling; author of technical articles in the 'Magazine of Art,' the 'Studio,' etc. (A. Fi*.)

FISHER, George Park, D.D., LL.D.; Professor of Ecclesiastical History, Yale; author of 'The Reformation,' 'History of the Christian Church,' 'The Colonial Era,' etc. (G. P. F.)

FISKE, John, LL.D., the late; author of 'Discovery of America,' 'American Revolution,' 'The Mississippi Valley in the Civil War,' 'Cosmic Philosophy,' etc. (J. Fi.)

FITCH, Charles H., in charge of the Indian Territory Section, U.S. Geological Survey. (C. H. F.)

FITCH, Sir Joshua Girling, M.A., LL.D.; Chief Inspector of Training Colleges, retired 1894; H.M. Inspector of Schools, 1863; Chevalier of the Legion of Honour; Governor of St Paul's School, London, and Girton College, Cambridge; author of 'Lectures on Teaching,' The Arnolds and their Influence on English Education,' 'Educational Aims and Methods.' (J. G. F.)

FITZGERALD, Vice-Adml. Charles Cooper Penrose; Superintendent, Pembroke Dockyard; second in command of the China Station, 1898-1899; author of 'Boat Sailing,' 'Life of Sir George Tryon.' (C. C. P. F.)

FITZGERALD, J. D.; Barrister-at-Law of N.S.W., Journalist, and Alderman of the Corporation of Sydney. (J. D. F.)

FITZMAURICE-KELLY, James; corresponding member of the Spanish Academy; author of 'A History of Spanish Literature,' 'The Life of Miguel de Cervantes Saavedra,' etc. (J. F.-K.)

FLANNERY, Sir Fortescue, M.Inst.C.E., M. Inst. Marine Engineers; Consulting Engineer; sometime President of the Institution of Marine Engineers. (F. F*.)

FLEMING, C. J. N., B.A.; Scottish International Football Player; member of Committee of Scottish Rugby Football Union. (C. J. N. F.)

FLEMING, John Ambrose, M.A., D.Sc., F.R.S.; Pender Professor of Electrical Engineering, Univ. College, London; Fellow of Univ. Coll. London; author of 'Treatise on the Alternate Current Transformer,' 'Electric Lamps and Electric Lighting,' 'Magnets and Electric Currents,' 'A Handbook for the Electrical Laboratory and Testing Room.' (J. A. F.)

FOOTE, Arthur De Wint; Superintendent of North Star Mining Company, California; Member of the American Society of Civil Engineers. (A. De W. F.)

FORBES, Dr H. O., LL.D., F.R.G.S.; Director of Museums, Liverpool; author of 'A Naturalist's Wanderings in the Eastern Archipelago,' etc. (H. O. F.)

FORD, Worthington Chauncey, Public Library, Boston, U.S.A.; Chief of Bureau of Statistics, U.S. Department of State, 1885-89, and of Bureau of Statistics, U.S. Treasury Department, 1893-98; author of 'American Citizen's Manual,' etc. (W. C. F.)

FORD, W. J., M.A.; author of 'A Cricketer on Cricket.' (W. J. F.)

FORTIER, Alcée, Litt.D.; Professor of Romance Language, Tulane University, New Orleans; sometime President of the Modern Language Association of America, and of the American Folk-Lore Society; President of the Louisiana Historical Society since 1894; author of 'Louisiana Studies,' 'Louisiana Folk Tales,' etc. (A. Fo.)

FOSTER, Clement Le Neve, B.A., D.Sc., F.R.S.; Professor of Mining at Royal School of Mines, London; Examiner in Mining for the Board of Education; Geological Survey of Great Britain, 1860-65; H.M. Inspector of Mines, 1873-1901; author of 'Mining' in Ninth Edition of 'Ency. Brit.,' 'Ore and Stone Mining,' etc. (C. L. N. F.)

FOSTER, Hon. John Watson, LL.D.; ex-U.S. Minister to Mexico, Russia, and Spain; U.S. Secretary of State 1892-93, and Agent of the United States in the Behring Sea Arbitration. (J. W. Fo.)

FOSTER, Sir Michael, D.C.L., D.Sc., LL.D., K.C.B., F.R.S., M.P.; Professor of Physiology, Cambridge; secretary R.S.; President British Ass., 1899; author of 'Physiology' in Ninth Edition of 'Ency. Brit.,' 'Text-Book of Physiology,' 'Lectures on History of Physiology'; joint-editor of 'Scientific Memoirs of Thomas Henry Huxley,' etc. (M. F.)

FOWLER, G. H., Ph.D. Leipsic; late Hon. Secretary, Marine Biological Association, Plymouth; edited 'The Hydromedusa,' and 'The Leptomedusa,' Marshall's 'The Frog,' Erichson's 'Scientific Progress in Entomology.' (G. H. Fo.)

FOX, Francis, M.I.C.E.; author of 'On the Results of Trials of Varieties of Iron Permanent Way,' and various papers on 'Ventilation, Tunnelling,' etc. (F. Fo.)

FOX, Major Charles James; head of London Salvage Corps. (C. J. F.)

FRANKLIN, Fabian, Ph.D.; editor of 'Baltimore News,' Baltimore, U.S.A.; formerly Professor of Mathematics, Johns Hopkins University. (F. Fr.)

FRANTZ, Henri; art critic, 'Gazette des Beaux Arts,' Paris. (H. Fr.)

FREAM, William, LL.D., F.G.S. F.L.S., F.S.S.; Lecturer on Agricultural Entomology, Edin. Univ.; author of 'Elements of Agriculture,' 'Soils and their Properties,' 'The Complete Grazier,' etc. (W. Fr.)

FREEMANTLE, Commander S., R.N.; part author of 'Nautical Terms and Phrases in French and English,' etc. (S. Fr.)

FRERE, Rev. Walter Howard, M.A.; Superior of the Community of the Resurrection; author of 'A New History of the Book of Common Prayer,' 'Notes on the Early History of the Use of Incense'; editor 'Bibliotheca Musico-Liturgica,' 'The Marian Reaction,' etc. (W. H. F.)

FRY, Rt. Hon. Sir Edward, B.A., D.C.L., LL.D., F.R.S., F.S.A., F.L.S.; Judge of High Court, Chancery Division, 1877-83; Lord Justice of Appeal, 1883-92; Fellow University of London and Univ. Coll. London; Hon. Fellow of Balliol Coll. Oxford; presided over the Royal Commission on the Irish Land Acts, 1897-98; author of 'Quakers' in Ninth Edition of 'Ency. Brit.,' 'The Specific Performance of Contracts,' 'British Mosses,' 'James Hack Tuke,' etc. (E. F.)

FULTON, Robert Burwell, A.M., LL.D.; Chancellor of the University of Mississippi; author of 'Mississippi, State' in Ninth Edition of 'Ency. Brit.' (R. B. F.)

G

GADOW, Hans Friedrich, Ph.D., Hon. M.A. Cambridge, F.R.S.; Strickland Curator and Lecturer on Zoology, Cambridge; British Museum, Natural History Department, 1880-82; author of 'In Northern Spain,' 'A Classification of Vertebrata,' 'Aves in Bronn's Animal Kingdom,' 'Amphibia and Reptiles,' and papers in Royal Society Philosophical Transactions and other scientific periodicals. (H. F. G.)

GALLWEY, Lt.-Col. Henry Lionel, C.M.G., D.S.O.; Deputy Commissioner and Consul, Niger Coast Protectorate; Acting Consul-General, 1896-98, Oil Rivers Protectorate; in command of a Haussa company during operations in Benin country, including capture of Benin City, 1897, etc. (H. L. G.)

GAMBLE, F. W., editor of 'Junior Course of Practical Zoology,' 'Flatworms and Mesozoa,' etc. (F. W. Ga.)

GANNETT, Henry; Chief Geographer U.S. Geological Survey; Chief Geographer 10th, 11th, and 12th U.S. Censuses; author of 'Idaho,' etc., in Ninth Edition of 'Ency. Brit.,' 'Dictionary of Altitudes,' 'Statistical Atlas of the U.S.,' etc. (H. G*.)

GARCKE, Emile, M.I.E.E., F.S.S.; Manager of the Brush Electrical Engineering Co.; Chairman Elect. Sect. London Chamber of Commerce, 1884-88; Member of Council, Tramways and Light Railways Assoc.; author of 'Manual of Electrical Undertakings,' joint-author of 'Factory Accounts.' (E. Ga.)

GARDNER, Ernest Arthur; Yates Professor of Archæology, University College, London; Director of British School of Archæology at Athens, 1887-95; author of 'Handbook of Greek Sculpture,' 'Journal of Hellenic Studies,' many articles on Greek art, archæology, and excavations, from 1882; joint-editor of the 'Journal of Hellenic Studies' since 1897. (E. Gr.)

GARDNER, J. Starkie, English Iron Worker and Expert; author of 'English Enamels,' 'Ironwork,' 'Armour in England,' etc. (J. S. G.)

GARDNER, Percy, Litt.D., F.S.A.; Linc. and Merton Professor of Classical Archæology, Oxford University; Corresp. Member of the Academy of Sciences, Göttingen; Member of the Archæological Institutes of Germany, Austria, America, Greece, etc.; Assistant at British Museum, 1871; Fellow of Christ's College, Cambridge, 1872; Disney Professor of Archæology, Cambridge, 1880; editor of 'Journal of Hellenic Studies'; author of 'Corinth,' 'Ephesus,' in Ninth Edition of 'Ency.
