of the architect from any record or inscription on the building, it seems to have been John Murdo, from an inscription on Melrose Abbey, of the date 1146. It appears, that he intended the cathedral to assume the form of a cross, from the circumstance of his having formed the south transept; although, for reasons not known to us, that part of the building has been carried no higher than the first tier of arches. The greatest internal length of the cathedral from east to west is 319 feet, the breadth 63 feet; the height of the choir, 90 feet; and of the nave 85 feet. The building is 1090 feet in circumference, measuring round the walls and abutments. The edifice is supported by 147 pillars, and is lighted by 157 windows of various dimensions, many of which are of exquisite workmanship.

The south and north fronts are divided into compartments by square projections, which display two tier of pointed windows with various decorations. The first or undermost range having completed its ornaments, the wall terminates in a battlement, from which the lower roof springs to meet the inner wall, raised so high above this roof as to form space for the second range of windows; this wall then terminates in a battlement similar to the under one, and receives the main roof, which is covered with lead. The succession of windows on the right and left of the transept being interrupted, windows have been formed under the great tower, on each side of the building, 40 feet by 20 feet, divided by mullions and tracery of curious workmanship. About the centre of the building, a square tower rises nearly 30 feet above the roof, supported by four massy pillars, each 29 feet 6 inches in circumference: from this rises a tapering octangular spire, with diminishing battlements. The spaces between the battlements are enlivened by pointed windows, and relieved by mouldings and small spires, the whole terminating in a ball and weather-cock at the height of 225 feet above the floor of the choir. Another square tower, somewhat less ornamented, rises on the west end of the church to a level with the first battlement of the tower above described, and is surmounted with a pyramidal roof covered with lead, and terminated by a ball and vane: this tower contains the bell and clock. The groined arches which support the stone floor of this tower, are of singular workmanship, the middle part of the floor being finished with a circular opening, so large as to admit of a stair going up through it. Prior to the Reformation, and when the rites of the Roman Catholic religion were performed in the cathedral, the grand entrance was by the west end of the building, 17 feet high and 11 feet wide, surmounted by a great window. These openings are formed with beautiful mouldings, terminating in pointed arches. The space which is now occupied as the outer High Church, constituted part of the choir, so that this department of the cathedral extended 152 feet, from the west end of the building to the four steps leading up to the organ gallery and screen of the nave, which was ornamented by a large window and figures of curious workmanship. The nave was what is now used as the inner High Church; the space behind contained the altar: the arched roof of this part of the building, is supported by five massy pillars, over which was a terrace-walk adjoining the large window, in the east wall of the nave.

The vestry, on the north side of the altar, forms a cube of 28 feet: its vaulted ceiling is supported by a pillar 20 feet high. The chapter-house was in the north cross of the cathedral, and had a communication with the nave. The consistory house, in which the bishops held their ecclesiastical courts, projects from the south-west corner of the building, and does not by any means contribute to the general harmony. This court-room is still occasionally used by the commissary of the district: it is 25 feet by 23 feet, and is fitted up with a bench and seats, which evidently bear the marks of antiquity; the royal arms over the bench has the letters C R. II. Immediately above the court-room is a repository for certain official documents connected with the court. The cemetery is of the same dimensions, and is placed immediately under the nave, having entries by a flight of steps, descending on the right and left of that which leads up to the nave at the east end of the choir. The space underneath where the altar stood, is said to have been a repository for relicts, and a cemetery for the bishops. The monument of St Mungo is shewn in this place, in a tolerable state of preservation.

The craftsmen protect the cathedral.

Having thus given a description of the cathedral during the time the rites of the Roman Catholic religion were performed in it, we have now briefly to enumerate the alterations which took place in the buildings when the reformed religion was established. Before entering on this, however, it may be proper to inform our readers, that in 1579, when the fury of fanaticism had nearly reached its height, and while it was thought meritorious to destroy every edifice which had been consecrated for the service of the Roman Catholic religion, the magistrates, at the instigation of certain clerical and lay zealots, determined to raze the cathedral to the ground, and for this purpose had engaged a numerous band of workmen to pull down the stately fabric. When these workmen were assembled by beat of drum, and with their unhallowed hands were about to pull down the carved work, the craftsmen of the city, to their immortal honour, assembled, and swore, that the first man who should pull down one stone of the building should be buried under it; nor would they retire, till they had an assurance from the magistrates that no damage should be done to the fabric. Having thus weathered the storm, the cathedral was altered to contain three places of worship, the choir was divided into two by a stone partition, the west division being formed into a place of worship, under the name of the Outer High Church. The nave of the cathedral was fitted up, and termed the Inner High Church; and the cemetery, although low in the ceiling, when compared with the others, was fitted up into a place of worship for the barony, or Landward parish. In the internal formation of these places of worship, it does not appear that much attention had been paid to taste or ornament; on the contrary, when we observe the great windows and doors, and other admirable decorations then rudely blocked up, we are led to believe, that our early reformers disliked every appearance of show or grandeur in their places of worship.

When it was resolved to fit up the interior of what is called the Inner High Church, in a style which might in some degree correspond with the magnificent external architecture of the cathedral, the magistrates entrusted the arrangements to the late Mr William Stark.

At that time, the entrance from the choir was by small side doors: the centre of the church was entirely filled with pews; the galleries were deep and heavy; the pulpit placed on one side; and the great east window built with stone. The appearance is now completely changed: the entrance is in the centre of the west end; a passage leads from it to the pulpit near the other extremity. The galleries, which were indispensible for accommodation, are placed behind the axis of the pillars of the church; and the east window is opened, and filled with stained glass.

Glasgow. Cathedral.

In repairing the capitals of the pillars, the work is executed so much in the manner of the old carving, that the difference cannot be perceived; and in the small vestibule, the fronts of the galleries, the pulpit, and indeed all the modern parts, the Gothic style is perfectly preserved. The whole is painted of a grey colour, which appears sufficiently neat and clean, without the least glare or tawdriness; and the sober imposing effect of the church is worthy the memory of the architect, who, by the pure and classical taste of his public buildings, has done so much to ornament this city.

About the same time leave was given to a society of sacred music to erect an organ in what is commonly called the choir; and this was executed by Mr David Hamilton, architect, in a manner creditable to his taste.

In 1811, the seats in the outer High Church were completely removed, and the whole of the interior renewed in a manner well suited to the magnificence of the place; the pulpit has been removed from the south side to the west end of the church; and in 1812, the great western window, immediately over the original grand entrance, was opened at an expence upwards of £ 500. This window is 44 feet 6 inches high by 23 feet 6 inches wide.

The heritors of the Barony parish, taking into consideration, the ruinous condition of the seating of their church, and finding the space not large enough for the increased population of the parish, agreed to abandon it as a place of worship. Accordingly, in the year 1801, the seats were removed, and it was again converted into a burying-place, such as it had originally been. This repository for the dead, contains 65 pillars, with capitals of curious workmanship, supporting the groined arches, underneath the stone floor of the Inner High Church; the whole is rendered visible by a glimmering light passing through small apertures retained from the former windows. When a stranger enters this place and examines the monuments of art, and those erected to the memory of departed worth, he is insensibly struck with veneration and awe.

The entrance to the choir is now by the south front. It is 74 feet 6 inches long, 63 feet wide, and 90 feet high, and has a grand imposing effect, the pillars being more than 80, and the windows 40 feet high.

The south transept has long been used as a burying-place for the clergymen of the city: the style and execution of the work in this aisle is much admired. Immediately over this, a flower garden was placed; but in 1812, it was removed, and a stone pavement, concealed by a parapet, substituted in its place. The north transept, formerly the Chapter House, has been fitted up as a private burying-place.

Bishop's palace.

The Bishop's Palace or Castle, erected in 1430, stood somewhat to the south-west of the cathedral, nearly in front of where the Royal Infirmary now stands: it was inclosed with a strong wall of hewn stone by Archbishop Beaton: the ruins of the castle were removed in 1789, to make way for the erection of the Infirmary.

College Church.

The College church is situated on the east side of the High Street, a little below the College. It is a plain building, partaking of the Gothic, with a small steeple in front, containing a clock and bell. It was built in 1699, on the site of a venerable Gothic pile, termed the church of the Black Friars, which was unfortunately destroyed in 1666 during a violent storm. At the Reformation this church was made over to the College, but was some time afterwards conveyed to the community under certain restrictions.

Tron or Laigh Church.

The Tron church, situated on the south side of the Trongate, a little to the eastward of King Street, was founded and endowed by the community in 1484, and dedicated to the Virgin Mary. Prior to the Reformation, a number of chaplainries were founded in it, by pious and wealthy citizens. In the year 1592, this place of worship underwent a thorough repair; and on the 8th February 1793, it was destroyed by fire. The steeple belonging to this church, which is of mixed ancient architecture, projects into the Trongate, and forms a striking feature in that street: it was built in 1637; is 126 feet high, and has a clock and two bells in it. The under part of the steeple being formerly used as a tron, gave to it its present name. In 1794, this church was rebuilt on the site of the old one, from designs by Mr James Adam. It is a plain modern building surmounted by a spacious cupola.

North-west Church.

The north-west church situated in Canon Street, fronting Candleriggs Street, was erected by the community in 1721. Its form is oblong, lying east and west, with a transverse aisle. A steeple 140 feet high, having a clock and bell in it, is placed at the south front of the church. The steeple displays less taste than might have been expected from the period in which it was built.

St Andrew's Church.

St Andrew's church is situated in the centre of St Andrew's Square. It was founded in 1739, but not finished till 1756. It is nearly a copy of St Martin's in the Fields, Westminster, and is allowed to be as complete a specimen of the composite order of architecture as is to be found in Scotland. On the west front a grand portico is formed; the arms of the city are displayed in the pediment in basso relievo; a lofty spire, with a clock and bell in it, is placed at this front of the building: its form and proportions, however, are by no means in unison with the church.

St Enoch's Church.

St Enoch's church, situated on the south side of St Enoch's Square, fronting Buchanan Street, and founded in 1780, is of an oblong form; a portico of the Doric order, is placed at the north end; a lofty and handsome steeple, having a bell and clock in it, is formed at that end of the church.

St George's Church.

The Wynd church, which had been built by a party of Presbyterians during the time of Episcopacy in 1687, was found to be unsuitable for the congregation of the venerable Dr Porteous. Accordingly in 1807, the presbytery, with concurrence of the magistrates, translated the congregation to St George's church, erected on the west side of Buchanan Street, fronting George's Street.

Few things are more difficult than to place a steeple or spire on a modern building, without destroying its effect. A Gothic church is usually proportioned in elevation to its tower; but modern churches, built more for convenience than grandeur, are for the most part so low in their walls, that the spire must either be insignificant in its own dimensions, or appear to crush the building to which it is merely attached, but with which it never seems to be connected. Aware of this, Mr Stark, who gave the plan of this edifice, resolved that the tower should be the principal object of attention, to which the rest of the façade might be considered as an accompaniment. In this view, he was desirous of projecting it from the front of the church, over the side pavement of the street; but this being thought objectionable, the idea was abandoned, and the tower carried back to the line of the front.

The tower itself, both in its general form, and in the variety as well as the proportion of its parts, is uncommonly beautiful; and probably its termination, had the colossal statues intended by the architect been placed on its angles, would have been equally rich and graceful; but many difficulties arose in getting well composed statues for so unusual a situation, without incurring an expence which the magistrates would have thought unjustifiable. Mr Stark accordingly agreed, with reluctance, to substitute obelisks, which it must be confessed appear meagre terminations to the angles of the tower, and scarcely accord with the beautiful little temple which rises from its centre.

ony rch.

The place of worship for the Barony, or Landward parish, in the cathedral, having become insufficient for the purpose, the heritors, in 1798, built a church adjoining, and in complete view of the cathedral and Royal Infirmary, from a design of Mr Adam's. The architecture is of a mixed style, varying from the adjoining specimens of Gothic and Grecian architecture. The outline of the west front of this church has an imposing effect: it is to be regretted, however, that the execution of the whole of the exterior, is so much inferior to that of the adjoining buildings, to which it was intended to assimilate. This extensive parish has chapels of ease, at Shettleston, Calton, and Anderston.

iscopal pel.

The Episcopal chapel is situated to the north of the public green, and immediately behind St Andrew's Square. It is a handsome oblong building, erected by subscription in 1751. The altar, orchestra, and organ gallery, are placed on the east end of the chapel. The whole of the interior is fitted up with great taste, and the window over the altar is beautifully ornamented with scriptural devices.

ian Ca- c Cha- e

A very magnificent Roman Catholic chapel, in chaste Gothic, is at present erecting on the north side of West Clyde Street, from designs by Mr James Gillespie. The towers and pinnacles, the embrazures, the grand entrance, and the magnificent window done up with mullions and tracery, surmounted by a colossal statue of St Andrew on the principal front, are well calculated to gratify the admirers of this venerable style of architecture. The buttresses, embrazures, and ornaments, of the other fronts, which are all executed in polished ashlar, harmonize with the general order. The nave and aisles of the interior are to be fitted up in strict conformity with the style of the exterior. A valuable organ, now building, is to be placed in a gallery over the grand entrance, the altar being at the opposite end of the chapel. This place of worship, which does great credit to the taste of the architect, is to contain 2200 persons, and is calculated to cost about L 13,000, the greater part of which is to be raised by small weekly contributions, from those persons who profess the Roman Catholic religion in this city and neighbourhood.

iges.

Prior to the year 1340, a timber bridge, which had been thrown across the Clyde somewhere to the west of the Saltmarket Street, went into decay; on which William Rae, bishop of Glasgow, in 1345, built a stone bridge across the Clyde, at the foot of what is now called the Stockwell Street, communicating with the barony of Gorbals. This bridge, plain, without even an affectation of ornament, was originally constructed with eight arches. Two of these, on the north side, were built up, when it became necessary to narrow the river, and thereby protect the adjoining houses from the effects of floods. This bridge continued for more than 300 years, without requiring (so far as we have been able to learn) any material repair. In the year 1671, the southmost arch fell at noon of the day on which Glasgow fair is held; and although the concourse of people passing and repassing at the time must have been very great, it is recorded, that no person received injury. This arch was rebuilt with all convenient speed; and the bridge received frequent repairs till the year 1777, when an addition of 10 feet was made to its breadth on the east side, by which the fabric is strengthened, and the passage rendered more convenient for carriages. The bridge, as it now stands, is 415 feet long, by 22 feet wide, within the parapets. The pious and public-spirited Lady Lochow is said to have prevailed on Bishop Rae to allow her to pay the expence of the centre arch.

Jamaica Street Bridge.

In 1768, the foundation of a stone bridge, across the Clyde, was laid at the foot of Jamaica Street, for the more easy communication to the west coast. It has seven arches, is 500 feet long, and 30 feet broad within the parapets. Its general appearance is such, as to combine the idea of strength with elegant simplicity. The plan was given by Mr Milne, the architect who designed Blackfriars bridge, London. The pontage arising from these two bridges, in 1814, was £1529 : 5 : 9, which goes to discharge the existing debt, and keep them in repair.

In the year 1794, the foundation of a stone bridge, to be thrown across the Clyde at the foot of the Saltmarket Street, was laid. During the subsequent year the work was carried on, and so far completed, that the arches were thrown across, and the parapets nearly finished, when, on the 18th November, 1795, the lower part of the city was subjected to an alarming inundation of the river, which, at four o'clock P.M., swept away the northmost arch of the bridge, and, in two hours afterwards, the whole arches gave way. This bridge, which was named Hutchison's, consisted of five arches, was 410 feet long, and 26 feet broad within the parapets.

In 1803, a timber bridge, for foot passengers, justly admired for the simplicity of its construction and light appearance, was thrown across the Clyde at the bottom of the Saltmarket Street, a little eastward of the site of Hutchison's bridge. Its outline is one grand sweep of 340 feet, having eight supports and breakwaters. The breadth within the parapets, which are formed of upright spars, with diagonal braces, is seven feet four inches, the expence of erecting it was £1200. An act of Parliament was procured, authorising certain trustees to levy a halfpenny from every person who passes and repasses the bridge on one day of the week only. The nett pontage, which, in 1814, was £81, goes to discharge the debt incurred in building the bridge, and in keeping it in repair. The design was by Mr Peter Nicholson, architect, author of *The Principles of Architecture, Carpentry, &c.*

Hutchison's Bridge, intended to be rebuilt.

In 1814, the magistrates and council of the city, and others interested in Hutchison's town, obtained an act of Parliament for building a bridge across the Clyde, near the site of the bridge that fell in 1795. They have also procured designs from Mr John Rennie, and are on the eve of contracting for its immediate erection. The cost is supposed to be from £18,000 to £19,000.

College.

The college buildings, and the houses for the accommodation of the professors, are situated on the east side of the High Street, near the Blackfriars church. They are very extensive, having a front of 305 feet to the High Street, and 282 feet from east to west. These buildings, and the four courts, three of which form quadrangles, occupy a space equal to 9556 square yards. The buildings are generally three stories high, of ashlar work, diversified with turrets and appropriate ornaments. There are three entrances in the principal front. The centre gate is ornamented with a species of demi-rusticated work; the royal arms in basso relievo, gilt, are placed over the gate, and consols, supporting a broad balcony, are formed at each side. The entire of the façade, which has a fine effect, is terminated, on the

3

Glasgow.

south, by the principal's house, and, on the north, by that occupied by the professor of oriental languages. At the centre of the east side of the west court, a lofty tower, plain, without any gaudy show of ornament, rises to a considerable height, and terminates in a ballustrade, and semi-curvated roof. The eastmost range of buildings, erected more than 200 years ago, having become unfit for the purposes for which they were intended, were taken down in 1811, and a magnificent range, from designs by Mr Peter Nicholson, erected on their site. The east front is divided into three compartments, the centre projects, and is ornamented with chamfered work, supporting four massy Doric columns, with entablature and pediment; the receding divisions exhibit a range of pannelled pilasters, cornice and ballustrade. This new erection, which is 160 feet long, and 50 feet deep, contains the anatomical theatre; the common hall, 73 feet long; and rooms for the humanity, Greek, logic, chemistry: medical, and mathematical classes. The library is a handsome insulated building, on the south-east extremity, the faculty hall fronting the High Street, is a very spacious room, handsomely wainscoated. The chapel, in which the professors and students attend divine service, is fitted up in a suitable manner. There are some valuable historical pictures, and portraits of eminent literary characters, hung round the walls of several of the apartments. The adjoining ground, on the east of the college, commonly called the college garden, consists of several acres, inclosed by a high stone wall, laid out in walks and shrubberies, for the use of the professors and students: The Macfarlane observatory is erected near the east end of it.

Town-hall and buildings connected with it.

The town-hall buildings, situated on the north side, and at the east end of the Trongate Street, were finished in the year 1636. The basement was originally formed into an arcade, with a rusticated front; the upper part of the building displays the complete range of the Ionic order. The town-hall is fitted up in an elegant manner. The walls are decorated with portraits of the kings and queens of Scotland and Great Britain. Ramsay's Archibald Duke of Argyle, in his robes as Lord Justice-General, is admired as a very valuable picture. The bust of his present Majesty is placed over the mantle-piece; and the statue of his immortal premier, William Pitt, by Flaxman, at the east end of the hall. In 1781, a subscription, by way of tontine, was opened, for building a coffee-room and hotel, in 107 shares, at £50 each. Mr William Hamilton, architect, gave the design, and displayed great professional skill in throwing the arcade of the town-hall into an extensive piazza, retaining the upper part of the cross walls of the superior structure. The coffee-room, on the ground floor, is 74 feet long, of proportional width and height, and is very handsomely fitted up. There are at present 1146 annual subscribers to the room, at 32s. each. It is supplied with Scotch, English, Irish, and Continental newspapers, magazines, reviews, and other periodical publications. In this coffee-room strangers are freely admitted without introduction, and may enjoy all the privileges of subscribers for four weeks without subscription,—a liberality, we believe, not equalled in any of the other great towns in the island.

Prior to 1812, the jail stood contiguous, and at the east end of the town-hall. The jail, from the increased population of the city, having become too small, was taken down in 1812, and an elegant building substituted in its place; the upper part being ornamented with turrets and embrazures, so as to preserve a similarity to the old tower of the prison, which is still preserved. This tower, which is 126 feet high, projects on the High Street, and is only remarkable for its terminating in the shape of an imperial crown. It is furnished with a clock and bell, and a set of musical chimes, so arranged as to play a separate tune at the end of every two hours. A skilful musician performs favourite airs on the musical bells, during Change hours, every lawful day, Saturday excepted.

Merchants or Guild Hall.

The merchant's hall is situated on the south side of the Bridge-gate Street, a little to the east of the Stockwell Street. It was rebuilt in 1659, by Sir Patrick Bell, the then Dean of Guild; it is 80 feet long, and of a proportional width and height. Donation and inscription boards are hung round the walls, containing the names of the Deans of Guild. The building consists of two stories of ashlar work, with little decoration, the basement being fitted up for shops. This building, from its situation and present condition, is by no means suited to the wealth and respectability of Glasgow merchants. The steeple, however, adjoining the south-front of the hall, is considered one of the handsomest in the city; it is 164 feet high; after rising 85 feet in the form of a square tower, a ballustrade is formed, within which a tower of smaller dimensions is again formed, terminating in a ballustrade; this arrangement being repeated, a pyramidal spire is terminated by a gilt ball and ship in full sail.

Town Hospital.

The buildings of the town hospital, which were erected from donations and subscriptions of public bodies and individuals, were so far finished, that the poor were admitted in 1733. The buildings form a quadrangle, the large court in the centre being used as airing ground. The principal front is to Clyde Street; it consists of a centre and two projecting wings of three stories. This range contains the great hall, where the inmates assemble for worship, and other apartments for the use of the charity. The buildings on the other sides of the quadrangle are chiefly fitted up for offices, and the accommodation of sick and fatuous persons, the insane having been removed, in 1814, to the Lunatic Asylum.

Royal Infirmary.

The royal infirmary is situated in the north quarter of the city, partly on the site of the archbishop's palace, near the cathedral. The designs for this building were from Messrs Robert and James Adam; and the general form of it is so imposing, as to command universal approbation. The design partakes of the parallelogram form, with bold projections at each end, having a pediment in the centre, supported by pillars of the Corinthian order, and the royal arms, in alto relievo, cut in the tympan of the pediment. A spacious dome, with vertical lights covering the operation hall, terminates the building, which consists of four stories. The foundation stone of this edifice was laid in 1792; the interior arrangements are well fitted for the purposes of the hospital. Although the Infirmary is calculated to contain 150 patients, it has latterly been found inadequate for the accommodation of increasing applicants; accordingly the managers are at this time making an addition at the back of the buildings, which, without injuring the general appearance, will give more than one third additional accommodation. This addition, which will cost £4000, has been raised by special subscription.

Trades-hall Buildings.

The trades-hall buildings, situated on the west side of Glassford Street, fronting Garthland Street, were erected in 1791, from designs by Mr Robert Adam. The front consists of a centre building, and two wings, the former of two stories, supported by a rusticated basement, with a projection at its centre, on which there are four Doric columns, supporting an entablature. The front is relieved with various mouldings, ornamented with griffins in basso relievo, and terminated in a ballustrade, in the centre of which the city arms are cut in alto relievo, supported by two female figures in a recumbent posture. A dome rising through the roof, terminating in a lantern, gives a happy effect to the whole. The hall, 70 feet long, 35 feet wide, and 24 feet high, exclusive of a magnificent dome, is fitted up with appropriate decorations. Portraits of persons of the trades rank, who had made donations to the house, and the arms of the 14 incorporated bodies, are hung round the walls. Tablets with the names and designations of the conveners of the Trades House, from 1605 down to the present day, are also placed on the walls; the other parts of the building are fitted up as committee rooms, &c. The hall of the Trades House free school adjoins this edifice, which, for extent, light, and ventilation, is justly admired. From a remote period, down to the year 1791, the Trades House and incorporations met in their hall near the cathedral, known by the name of the Alms House, from their chaplain distributing alms to decayed out-door members. This building being found incommodious, and by no means suited to the increasing respectability of the trades rank, has been appropriated to another use.

Assembly rooms. The assembly rooms, erected in 1796 by a tontine subscription of £ 20 shares, are situated on the north side of Ingram Street. From a rusticated basement story, a bold projection is formed at the centre of the building, which supports four Ionic columns, pilastres, and entablature. Various appropriate ornaments are introduced on the front, which terminate in a ballustrade. The interior consists of the assembly-room, card, supper, and retiring rooms, and apartments for the housekeeper, public kitchen, &c. The principal room, 80 feet long, 35 feet wide, and 27 feet high, is finished and fitted up with every requisite, in the most elegant manner. Mr James Adam gave the design of the principal or centre building. The wings, which are separated from the main building by a colonnade wall, were built in 1807, from designs by Mr Henry Holland.

Grammar school. In 1788, the grammar school buildings, in Grey Friars Wynd, were found to be insufficient for the purpose; accordingly a new set were erected on the north side of George's Street in 1789. The front, which has a light cheerful appearance, consists of three compartments, the centre receding from the wings, in which large Venetian windows are formed. The interior is subdivided into a common hall, 70 feet long, and seven large well-aired rooms for the accommodation of the classes. At the back of the building, more than half an acre of ground is enclosed for the use of the students.

Surgeon's hall buildings. In 1791, the Faculty of physicians and surgeons finding that their hall in the Trongate was not sufficiently commodious, erected buildings on the east side of St Enoch's Square. The front consists of two stories; a rusticated basement supports a range of pilasters, entablature, and ballustrade. The interior consists of the faculty-hall, library, committee-rooms, offices, &c.

Barracks. In 1795, government erected very spacious barracks on the north side, and near the east end of the Gallowgate. Exclusive of the guard-house, suttlery, infirmary, and magazine, there are three large buildings for the accommodation of the military: The centre is for officers: it is a handsome building, four stories high, having the royal arms in demi-relief, displayed in the tympan of the pediment. The other two buildings, placed at right angles from the centre one, are for the accommodation of the soldiers; they contain 72 apartments, fitted for 14 men each, exclusive of 24 kitchens. The whole is enclosed with a high wall, forming an extensive parade.

City guardhouse. In 1810, the city guardhouse was removed from Candleriggs Street to the east side of Montrose-street. Its front is formed with arched compartments, surmounted by a cornice and blocking. The interior contains ample accommodation for the officers and soldiers, and the piazza is sufficiently spacious for the relief.

Bridewell. In 1789, a plain building, 106 feet long, 30 feet wide, and 6 stories high, was erected on the north side of Duke-street, for the purposes of a bridewell; it contain 126 cells, 8 feet by 7 feet, exclusive of a chapel and a large work-room. On each side of the bridewell, spacious wings are formed at right angles, which contain the infirmary, public kitchen, keepers' lodgings, and rooms for raw materials for the manufactory, &c. The whole is enclosed within a wall.

Markets and Weigh-house. The principal beef, mutton, and fish markets, are situated in King Street. The former occupies a space of 112 feet by 67 feet, and the latter 173 feet by 46 feet, subdivided around the area into stalls. The courts are paved with free stone, and the fronts formed of ashlar work, with rusticated entries; the beef-market in Bell Street being fitted up in a plainer style. The vegetable market is also done up into stalls, and is so spacious as to occupy the whole site of the former Wynd Church, having its principal entry from King Street. The butter, cheese, and poultry markets, are placed in Montrose Street. The tron, or weigh-house, is a large building, situated at the east end of Ingram Street, and is used for the general purposes of a tron and store-house. Prior to the late erection of markets in the city of Newcastle, the markets in King Street were considered the best in the island. Each stall in the fish-market has a water-pipe in it, and the other markets have a plentiful supply of water.

Slaughter house. The slaughter house, situated a little to the south of the Bridgegate Street, was erected in 1810, and is the largest and most commodious in the island: it contains 77 killing rooms, two cattle-yards and alleys, and accommodation for the searchers and scavengers: it covers 4736 square yards of ground, which is all paved with square stones. Water pipes are placed along the whole of the killing rooms, and extensive sewers carry off every thing which would become offensive.

Theatre. The theatre in Dunlop Street being found inconvenient, and too small for the accommodation of the public, a magnificent one was erected on the west side of Queen Street, in 1804, on the principle of transferable shares, of £25 each. The building is 158 feet long, and 70 feet wide, being considerably larger than any of the provincial theatres. On the east front there are columns of the Ionic order, 30 feet high, with corresponding entablatures, and appropriate devices. The interior is elegantly fitted up with every suitable convenience, to accommodate 1500 persons, from designs by Mr David Hamilton. The building and scenery cost upwards of £18,500.

Hutchison's Hospital. The buildings of Hutchison's Hospital being removed from the Trongate, to make way for Hutchison Street, the patrons, in 1803, erected a hall and offices in Ingram Street, suitable for their accommodation. This building, and the spire of 150 feet high, which rises from the north front, is a great ornament to this part of the town. The great hall and committee rooms are

Glasgow.

fitted up in an elegant manner, from designs by Mr David Hamilton.

Lord Nelson's monument.

The citizens of Glasgow were the first to erect a monument to the memory of the immortal Nelson. Immediately after the hero's fall, a subscription was opened, and on the first of August 1806, the foundation of a solid ashlar obelisk, 142 feet six inches high, of chaste proportions, was laid at the west end of the high green, with great masonic solemnity: the subscription at that time amounted to £2075. On the 5th of August 1810, the upper part of the obelisk was completely shattered, and the greater part of its shaft rent during a violent storm of thunder and lightning. It is very remarkable, that although the ashlars of the upper part were thrown out of their beds, and so suspended that a passenger could see through the obelisk, yet at the present moment, after a lapse of five years, they seem to be still in the same situation.

Hunterian Museum.

The Hunterian museum was erected in 1804, and is situated at the west end of the college garden, in front of the common hall. This was the first public building erected by Mr Stark, who must be considered as singularly fortunate at the commencement of his professional career, in having such an opportunity of displaying his talents and his taste. He was no less fortunate also in being employed by a society, which, from full confidence in his abilities, avoided every interference with his arrangements.

Mr Stark chose the Roman Doric for the portico, as the gravest and most imposing order that could be employed in so confined a situation; and he made its parts as simple and large as that order could properly admit. Behind the portico he formed a recess, divided from it by a second row of columns, like the pronaos of an ancient temple. By this arrangement, securing great depth of shade, without projecting his columns too far into the narrow court, he produced a very rich effect in the angular view, and to so small a portico giving wonderful dignity on a near approach.

The merit of this building, however, is not confined to the portico; its general proportion, the simplicity of its parts, and the elegance of its form, render many views of it from the garden, little if at all inferior to that of the principal front. The interior, likewise, corresponds in a remarkable degree with the exterior appearance. There are, throughout, the same simplicity, the same elegance, and the same attention to picturesque effect. The saloon for paintings, is particularly beautiful in its form, proportions, and decorations, while it is at the same time well contrived for exhibiting to advantage the collection which it contains. With the exception of the staircase, which is too small and too plain, a man of taste will discover, in this elegant building, a unity and consistency rarely to be met with in modern works: no part is neglected, and no part charged.

Gaol and court houses.

The gaol and court houses, situated on the west end of the Green, were built in 1810. The magistrates having resolved to erect a new gaol and court house, applied to several architects, and from their designs, all of which were too expensive, they made a selection and arrangement according to their own ideas. Mr Stark was then desired to adapt his elevation and court hall to the new design. The former has been executed exactly from his drawings; but in the latter, some deviations were afterwards made by order of the committee. Every consideration pointed out the Grecian Doric, as the proper order for such a building, and particularly in so open a situation. But architects have seldom succeeded in adapting this order to a front, in part of which the columns are to give place to a simple wall. Either they have reduced the massiveness of the entablature, on which the magnificence of the order entirely depends, or the cornice, which is admirably proportioned to the immense columns by which it is carried, has appeared heavy and even overwhelming in those parts where it is deprived of their support. This difficulty Mr Stark, by the general simplicity of the arrangement, and the size of the window dressings, has, in as far as possible, overcome; and though in this design there may be somewhat wanting of that unity and symmetry which charm in his other works, the magnificence of the portico rivets the attention, and diverts the mind from what may be less perfect in the other divisions of the facade.

The portico exhibits very nearly the proportions of the Parthenon, and may serve to give some idea of that celebrated temple, divested indeed of the magnificence it derived from the most exquisite sculpture of ancient times. As in the Parthenon, the columns are placed on colossal steps, the dignity of which cannot be conceived without having been seen; and there is a recess divided from the portico by a screen of columns, like the pronaos of the temple, which adds greatly to the richness and grandeur of the effect. It was subject of regret to the architect, that the portico could not be projected farther from the side wall of the building, and the screen of the pronaos. But such a projection would have destroyed all affinity between the centre and the wings, in which porticos, on account of their expense, were inadmissible.

In so flat a situation, it may also be regretted that greater elevation could not be given to the building, consistently with the employment of the Grecian Doric. This defect would probably, however, have passed unnoticed, had it not been rendered much more observable by a parapet and rail, which have been carried along the front since Mr Stark's death, and which, while they sink the building, conceal the colossal steps on which the grandeur of the portico so much depended. Were this obstruction to the view removed, there can be no doubt that the want of elevation in the general form would be far less conspicuous; though to have avoided it entirely was perhaps impossible.

A Grecian Doric portico of six columns is necessarily long in proportion to its height; and to have shortened the compartments, by which the centre is connected with the wings, would have crowded the façade, and destroyed all affinity among the forms and proportions of its several parts.

In contemplating so magnificent a portico, small defects pass unnoticed; and if they could not be remedied without adopting a less imposing order, the most fastidious taste will applaud the architect, for having submitted to what was unavoidable, for the purpose of producing so sublime an effect.

These buildings contain halls for the several courts, and ample accommodation for the civil and criminal establishments. The entry to the gaol is by the west front. This department consists of two spacious courts, 74 fire-rooms, 58 cells, and 2 apartments for prisoners under sentence of death, so completely cased with iron, that it is not necessary to subject the criminals to personal irons, as is done in almost every other jail. There are also a chapel, a military guard-house, and apartments for the keeper of the gaol's family. Four cast-iron cisterns, calculated to contain 14,776 gallons of water, are placed on the top of the prisons, from which the several apartments and water-closets are supplied. Prisoners are received from the counties of

Glasgow.

Lanark, Renfrew, and Dumbarton: They amounted, in 1814, to 1172 persons, viz. 367 debtors, 525 male criminals, 239 female criminals, and 41 deserters: The whole expence of these buildings, viz. £34,811, has been defrayed from the funds of the corporation.

Lunatic Asylum.

The foundation-stone of the Lunatic Asylum, situated between the Royal Infirmary and the Glasgow Observatory, was laid with great masonic solemnity, in 1810. Modern architects seem very generally to have aimed at reputation, rather by the invention than the proportions of their designs. Little aware of the dignity arising from the graceful diminution of columns, from inter-columnations rather narrow than wide, from harmony in the details, and from congruity in all the parts, in reference to each other and to the whole, they must be astonished at Palladio's fame, and unable to comprehend how his buildings, which are for the most part small in their dimensions, and without any pretensions to novelty or singularity in their forms, should so long have charmed the world, and at every repeated inspection afforded increased delight.

In this respect more perhaps than any other, Mr Stark bore a nearer resemblance to an architect of ancient than of modern times. By constant and respectful study of their works, he seemed to have imbibed the spirit of the Greeks, while, by the powers of his genius, he adapted their principles to the wants, manners, and opinions of his countrymen. In the lunatic asylum, he had less opportunity than usual of pleasing, by the proportions of the mouldings, or the richness of the details; for every costly ornament would have been improper, and the situation of the building rendered its effect from a distance much more important, than its beauty on a near approach. Yet even here, he studied the details with the utmost care, convinced that the grandeur of the general form is never independent of a due proportion in the minuter parts.

On considering the interior arrangements of a lunatic asylum, it appeared to him that wards, projected diagonally from a central building, would afford every facility, both for the superintendance and classification of the patients. Such a form had been little attempted, and never executed with a pleasing effect. The difficulties presented by it, Mr Stark has admirably surmounted. By a just proportion of the diagonal wards to the central buildings, by raising over the latter a circular attic, and crowning the whole with a noble dome, he has given the asylum a character of blended elegance and dignity, which perhaps sets it above all his other designs, and, simple and unadorned as it is, entitles it to a most eminent place among the works of art. So noble indeed is this design, that the managers could scarcely persuade the public, that, on erecting it, an extravagant sum of money had not been squandered on external decorations. Its effect is now a little injured by the garden walls, having been raised higher than the architect intended, and still more by a recent building, which interrupts its finest point of view; but wherever it is seen, it must excite feelings of the highest admiration; and even if in course of time all views of it as a whole should be intercepted by the extension of the town, the dome will always remain one of the greatest ornaments of the city.

The asylum and airing grounds cover about three acres and a half. In the distribution, care has been taken to class the higher and lower ranks of both sexes according to the frantic, ordinary, or convalescent state of the disease. The buildings contain 136 apartments for the use of the patients, exclusive of those appropriated for the housekeeper, apothecary, superintendant, physician, and committee; and the whole range of store-rooms, servants' apartments, kitchens, baths, &c. Each class of patients has separate entries to the subdivided airing grounds, which are laid out in gravel walks, flower-plots, and shrubberies. The eating-rooms, parlours, and bed-rooms, for the higher ranks of patients, are spacious and genteelly furnished: the close rooms for that class are 11 feet 6 inches long, 8 feet wide, and 10 feet 6 inches high; and for the paupers, 11 feet 6 inches long, 6 feet 6 inches wide, and 10 feet 6 inches high; each ward having a gallery 70 feet long by 7 feet 6 inches wide, for exercise in bad weather. The several apartments of the asylum are rendered comfortable by the introduction of rarefied air, generated in the sunk storey, and communicated by concealed flues.

Glasgow observatory.

In 1810, the foundation stone of the Glasgow observatory was laid on the south side of Garnet Hill, situated a little to the north-west of George's Square. The funds for this institution were raised by subscription of £20, transferable shares. The building is divided into three compartments: the first contains the instruments for scientific observations; the second those for popular observations; the third is fitted up for the accommodation of the subscribers, where they have the use of astronomical instruments, and treatises connected with the science.

In the Glasgow observatory, there are a great variety of valuable astronomical and meteorological instruments. The most remarkable are, a fourteen and a ten feet telescope by Herschel; a mural, azimuth, and altitude circle, by Troughton; a sidereal and mean time clock by Hardy; and a chronometer by Arnold.

Lyceum.

The Lyceum is situated on the east side of South Albion Street. The saloon is 54 by 33 feet, and the adjoining library 33 by 22 feet, the whole being elegantly fitted up. The saloon is amply supplied with newspapers and periodical publications; and the library is stored with a well-chosen collection of books. Strangers are not admitted to the Lyceum, without being introduced by a subscriber.

Riding school.

The riding-school, which was erected by subscription, is situated on the west side of York Street. It contains two circles of 40 feet each, stables, and a gallery for spectators.

Anderson's Institution Buildings.

The buildings for Anderson's institution are situated on the west side of John Street. The ashlar front is relieved with mouldings, terminating in a ballustrade and pediment: the roof being formed into a dome, has a very fine effect. The great hall is of a spherical form, and seated for 500 persons. The library, laboratory, committee, and apparatus apartments, are fitted up with every convenience.

Post office.

The post office, situated on the east side of South Albion Street, has an ashlar front, relieved in the centre, and terminating in a pediment. At one end of the building there is a covered way, and at the other a spacious lobby, for the accommodation of the public. A range of windows are so placed in the lobby, that persons having boxes in the office, can see if they have letters before the delivery commences.

Magdalene Asylum.

The Magdalene Asylum for the reception of females, who are desirous to return to the paths of virtue, is situated a little to the east of the Lunatic Asylum: It was erected in 1812, and is supported by voluntary contribution. The building consists of three stories; the front is divided into three compartments, the end ones terminating in pediments. This establishment is completed with every suitable accommodation, for the matron, the committee, and 34 penitents. The chapel, exclusive

Glasgow.

of the gallery, contains 150 persons. The managers being aware that the objects of this institution could not be obtained amid the bustle of active life, have inclosed above an acre of ground by a high wall, within which all the buildings for industry and accommodation are placed. As washing and dressing clothes for families form a prominent part of the economy of this establishment, the inclosed ground which is laid down in grass, is well adapted for bleaching, being supplied with pipes from the water companies.

Lock Hospital.

The buildings for the Lock Hospital, situated on the south side of the Rotten-row, are plain, and so completely inclosed, that the patients can only see into the spacious court-yards. Convenient apartments are fitted up for the committee, the housekeeper, and the surgeon.

Charitable institutions.

The public institutions and benefit societies which are established in this city for the relief of the necessitous, are so various and complicated in their nature, that we are under the necessity of briefly mentioning a few of the principal ones, with the sums expended in the year ending December 1814.

The merchants and trades houses, granted annuities to decayed members or their families to the amount of £1620, exclusive of a number of bursaries and apprentice fees, which are placed at their disposal. The 14 incorporations, and the Faculties of Physicians and Surgeons, and Procurators, gave to their poor £3800, exclusive of annuities to widows. Hutchison's and St Nicholas hospital, distributed to outdoor pensioners £1910. The sum raised for the maintenance of the Town's Hospital is £10,273. The ordinary expence of the Royal Infirmary is £3200, and that of the general session £2832. These sums, and what are annually expended for the purposes of the Highland and Humane Societies, Lunatic and Magdalene Asylums, the Lock Hospital, Buchanan and Graham's societies, and those institutions which have for their object the distribution of the scriptures, the education of youth, or the support of old age, amounts to upwards of £35,000 per annum, exclusive of private charities, which are very great. The writer of this article had a recent opportunity of receiving these particulars from the respective secretaries.

Glasgow regiment.

On the breaking out of the war with the United States of America in 1775, the public bodies and spirited individuals of this city raised a battalion of 1000 men, which was named the Glasgow Regiment. The subscription in a few days amounted to £10,000.

In 1795, and at subsequent periods, when government found it necessary to embody volunteer corps, the citizens of Glasgow enrolled themselves into the following corps. The 1st and 2d regiments, the light horse, the sharp-shooters, the armed association, the trades house battalion, the Highland regiment, the grocers' corps, and the Anderston and the canal suburbs corps. The greater part of these regiments found their own uniforms, and served without pay. When the volunteer system gave place to the local militia, this city completed, and has at this time, five regiments in the service of government.

Banks.

In 1695, the Bank of Scotland was established in Edinburgh by charter, with a stock of £100,000; and in 1696, a branch was sent to Glasgow, but recalled in 1697. In the year 1731, a branch was re-established, and again recalled in 1733. In the year 1749, the first Glasgow bank was opened, under the firm of the Ship Banking Company. In 1761, the Thistle Bank commenced business, and some time afterwards, the Glasgow Arms, and Glasgow Merchant Banking companies were formed. In 1729, the Royal Bank of Scotland was constituted by charter, a branch of which was established here in 1783. And in 1809, a company commenced business under the firm of the Glasgow Banking Company.

Exclusive of the above, which are all carrying on business to a very considerable extent, (excepting the Glasgow Arms, and Merchant Bank companies, which have retired,) branches from the following banks have been established, viz. Bank of Scotland, British Linen Company, Paisley and Paisley Union, Greenock, Renfrewshire, Commercial Bank of Scotland, Aberdeen, Air, Stirling, Falkirk, Leith, Perth, Kilmarnock, Fife, and Dundee, &c.

Provident bank.

In 1815, a provident or savings bank was established here for the benefit of the lower orders of the community, wherein deposits of one shilling and upwards are received, bearing interest at the rate of four per cent. when the sum shall amount to 12s. 6d. and have lain one month in the bank. When a contributor's deposit amounts to £10, it is transferred in his or her name to any bank they may desire, and the receipt delivered to them, and they may again pay in their savings, and draw out all, or any part of them, in sums of not less than six shillings. This institution is placed under the management of a governor, deputy-governor, and 28 directors, who all act gratuitously. The necessary charges are defrayed from a subscription fund of upwards of £7,000, and from one per cent. on the deposits, the Royal Bank generously allowing the provident bank five per cent. for money lodged with them, while the contributors only receive four per cent. Although it is little more than four months since the bank commenced business, there have been 785 accounts opened. During the first three months there were 590 accounts, amounting in whole to £2407 : 9 : 6, of which Royal Bank receipts for £750 were given out to contributors, £1550 : 13 : 3 retained in the Royal Bank at the credit of the Provident Bank, and the residue repaid.

Insurance offices against fire.

The Glasgow friendly fire insurance company having been on the decline for a number of years past, was dissolved in 1805. In 1803, a company was formed under the designation of the Glasgow Fire Insurance Company, with a capital of £100,000 divided into 400 shares. This concern, not answering the expectation of the proprietors, was given up in favour of the Phœnix office in 1811. Although there is now no fire insurance office belonging to the town, there are no less than 22 branches of the London and provincial offices established in it. It is worthy of remark, that although the local offices above alluded to have not succeeded, that the annual increase of duty in four years, ending 1814, paid by 15 of the London offices, amounted to £61,175.

Statue of King William.

In 1735, Mr James Macrae, a citizen of Glasgow, and late governor of the presidency of Madras, presented to the town a metallic equestrian statue of King William III. The statue is placed on a pedestal at the cross, bearing an appropriate inscription, and is inclosed by an iron rail.

Mr Pitt.

In 1812, a full length statue in marble of that great minister, who conducted the affairs of Britain during an eventful period of 26 years, was erected in the town hall, by subscriptions from the citizens of Glasgow. This statue, which is executed in parliamentary robes, from the chissel of Mr John Flaxman, London, cost upwards of £1300, and has the following inscription, *Gulielmo Pitt Cives Glasguenses posuerunt* A. D. MDCCCXII.

Sir John Moore.

In 1809, this city lost one of her bravest sons, by the death of Sir John Moore, who, at the head of the British army in Spain, fell gloriously in the arms of victory, on the plains of Corunna, and was buried in the citadel of that town. When the accounts of his victory and death reached his native town, a subscription, amounting to upwards of £4000, was immediately completed, and a bronzed pedestrian statue ordered to be erected to his memory in some conspicuous part of the city, under the direction of Mr John Flaxman, London.

History of the university and other institutions.

The university was founded, as before mentioned, in 1450, in virtue of a bull obtained from Pope Nicholas V. by the solicitation of James II. and William Turnbull, Bishop of Glasgow. This institution, while in its infancy, consisted of a chancellor, rector, dean of faculty, a principal, who taught theology, and three professors of philosophy. At the Reformation, this seminary suffered very materially; and it was not till after James VI. had granted a new charter of erection, and bestowed on it the teinds of the parish of Govan, that it recovered from the shock which it had received. In 1617, the teinds of the parishes of Renfrew and Kilbride were annexed and ultimately conferred on it. In 1630, the temporalities of the bishopric of Galloway were added; and in 1670, the teinds of Cadder, of Old and New Monkland, were conveyed to the college, by charter from Charles II. In 1693, after the Revolution, the sum of £300 per annum was granted to each of the Scottish universities, out of the property of the abolished bishoprics of Scotland; and the better to insure the payment of this sum, this university obtained from the crown a lease for 19 years of the teinds of the archbishopric, which has been periodically renewed ever since. These teinds, and the annual returns from heritable property, and donations received from individuals at various times, constitute the fund from which the professors' salaries, and certain stipends are paid, the college buildings supported, and the other concerns of the university maintained. From its erection down to the present time, the number of professorships have been increased. At present, the establishment consists of a lord chancellor, lord rector, dean of faculty, a reverend principal, a reverend professor of divinity, professors of church history, oriental languages, natural philosophy, mathematics, moral philosophy, logic, Greek, humanity, civil law, medicine, anatomy, practical astronomy, and the regius professors of natural history, surgery, and midwifery. The crown presents to the following chairs, viz. the principality, church history, civil law, medicine, anatomy, astronomy, natural history, surgery, and midwifery. The college elects the chancellor, the dean of faculty, and the professors of divinity, oriental languages, natural philosophy, mathematics, moral philosophy, logic, Greek, and humanity. The rector and dean of faculty are chosen annually. In choosing the former, the mode of election is materially different from that of the other office-bearers. He is elected by what is called the Comitia, that is, a court consisting of the office-bearers and professors, and all the students who have matriculated, by enrolling their names, and stating the place where they were born, and the name of their father and his designation, &c. This court consists nearly of 1000 members, is divided into what is called the four nations, viz. the Glottiana, Transforthana, Loudoniana, and Rothsaiana. The majority of the members of each nation constituting one vote, in case of an equality, the rector has the casting vote. It has been usual to re-elect the rector for one year only. The regius professors have no vote in the faculty, except for the dean; they, however, vote in the Comitia, in common with the matriculated members.

The college has a number of bursaries in its gift. Among others, there are ten for Baliol college, on Mr Snell's mortification, at £70 each, arising from an estate in Warwickshire. This distinguished seminary has produced, at various times, some of the most eminent literary characters of the age in which they lived. Among others, may be ranked the names of the celebrated poet and historian George Buchanan, Archbishop Spottiswood, Principal Leechman, Adam Smith, Hutchison, Reid, Cullen, and Hunter.

Andersonian Institution.

The late celebrated Mr John Anderson, professor of natural philosophy in the university of this city, by his last will, disponed and conveyed his valuable apparatus, museum, and library, and his other effects, to 81 trustees, whereof nine were to be tradesmen, nine agriculturists, nine artists, nine manufacturers, nine physicians and surgeons, nine lawyers, nine divines, nine natural philosophers, and nine kinsmen or namesakes, for the purposes of establishing a college in this city, for the arts, medicine, law, and theology. At the professor's decease, his trustees were incorporated by charter in 1796. Pecuniary and other considerations have hitherto limited the plan to physical science, comprehending natural philosophy, chemistry, materia medica and pharmacy, mathematics, and geography. Popular and scientific lectures, from its commencement, were continued to be delivered to both sexes, in this institution, by Dr Garnet, with great approbation, till in 1799 he received an appointment in the royal institution of London, which had been formed on the model of this primary institution. Dr Garnet was succeeded by Dr Birkbeck, who, in addition to the branches taught by his predecessor, introduced a familiar system of philosophical and mechanical information, to 500 operative mechanics, free of all expence, exclusive of the exhibition of an extensive apparatus; particular models illustrative of the arts, were introduced. A subscription library for the use of this class, has been productive of beneficial effects.

Hunterian Museum.

The late celebrated Dr William Hunter of London, was born in 1718, at East Kilbride, a village about 8 miles south-east from this city, and was educated at this university. By his last will, he left his splendid and very valuable museum in trust to the professors of the college of Glasgow, to be received by them a certain number of years after his death, which happened in 1783. This collection was brought to Glasgow in 1808. It consists of minerals and fossils, plants, shells, fishes, beasts, birds, insects and reptiles, books, rare and valuable manuscripts, anatomical preparations, antiquities, original pictures from the most eminent masters, and many other productions of nature and art. The coins and medals are of the first consideration; the whole is estimated at £150,000. This collection is placed in a building erected in the college garden for the express purpose; and is shewn to the public on application to the trustees.

Royal Infirmary.

The royal infirmary is a noble institution, supported by voluntary contribution. By its charter, the management is placed in the lord-provost, who is, *ex officio*, president; the member of parliament; the dean of guild; the convener of the trades-house; the professors of medicine and anatomy; the president of the faculty of physicians and surgeons; one member from the town-council, merchants and trades-houses, and college; three from the faculty of physicians and surgeons; and ten from the general court of contributors. From 31st December, 1813, to 31st December, 1814, there have been admitted to the hospital 1267 patients, of whom 855 were medical, and 412 surgical; 666 of the gross number were men, and 601 women. Of 104 distinct diseases, with which the patients were afflicted, there were 154 cases of fever, and 52 operations performed; 758 patients were cured, 100 relieved, 102 died, 132 remained in the hospital, and the remainder were either convalescent, improper, or incurable. Since the opening of the infirmary in 1794, there have been admitted 15,036 patients; of which number 10,325 have been cured, and a considerable number of the remainder relieved. During the above period, advice has been given at the infirmary to nearly 40,000 out patients. The subscriptions for 1814 amounted to £1901. 11s. 5d.; contributions, £152 : 11 : 6; legacies, £522, 6s. 9d.; and the fees from medical students for leave to attend the hospital, £597 : 15 : 1.

Town hospital. This institution is supported by fixed contributions from the town council, merchants, and trades houses, and general session; but chiefly from an assessment on the inhabitants, laid on by 15 persons not connected with the town council. The mode is, to assess every person, in proportion to his property and business, within the burgh, who is supposed to be worth £300. In 1814, there were 484 persons in the hospital; 795 out pensioners, who received nursery wages for their children; 738 out pensioners, who received meal from the hospital; making a total of 2017 on the funds. The average cost of each person in the hospital, in 1814, is £9 : 15s. per annum; the quantity of meal used in 1814, is 2302 bolls. The rate of assessment on every £100 of supposed property in the burgh, 3s. 6d.; valuation, £5,830,700; amount of assessment, £10,273.

Lunatic asylum. This institution was opened on the 12th December, 1814, when 23 male and 18 female patients were admitted. Since the opening, a period of only 11 months, 112 patients have been admitted; of whom 24 have been cured, six relieved, one died, six discharged being idiots, and 75 remained in the asylum. The rates for the support of paupers belonging to Glasgow, or those parishes who have contributed £50 for every 1500 persons in the parish, is 8s.; and for those who have no claim, 10s. 6d. per week. The rates for boarders are from 13s. upwards. Although there are at present no boarders in the asylum whose rates are higher than 31s. 6d. per week, every suitable accommodation is provided for the higher ranks.

Magdalene asylum. As a few months have only passed since this institution was opened, no distinct statement of its affairs can be given. There are at present 14 penitents in the asylum, whose conduct gives the managers the happiest presage of future usefulness.

Lock hospital. The affairs of this asylum, for the reception and cure of unfortunate females, are, by its charter, placed under the management of one member from the town council; one from the merchants and trades houses; one from the clergymen; two from the faculty of physicians and surgeons; and eight from the court of contributors. From 31st December, 1813, to 31st December, 1814, there were 128 patients admitted, whereof 118 were cured, one died, and nine remained in the hospital. The expenditure of 1814 was £447 : 14 : 1½. Although no proper patient was refused admittance, the number has this year happily diminished nearly in the proportion of one-third from former years.

Libraries and newspapers. Although it will not be expected that, in a manufacturing and commercial town like Glasgow, there would be libraries on a very extensive scale, there are nevertheless to be found in the collection of the college, the Hunterian museum, the faculties of physicians, and surgeons, and procurators, books of the utmost value and consideration, in every branch of literature. The books in the public subscription and circulating libraries are on a scale suited to the extent of the place. In 1810, the following newspapers were published here:—the Courier, Herald, Journal, Chronicle, Western Star, Clyde Commercial List, and Centinel. The two last, which were weekly papers, are now discontinued.

Water Companies. Prior to 1806, the citizens had no other supply of water than from 28 pump-wells in the streets. As some of these were very limited, and the water often of a bad quality, a number of the inhabitants, in 1806, procured an act of Parliament incorporating them into a company for supplying the city and suburbs with water, under the name of the Glasgow Water Works Company. **Glasgow company.** Accordingly, this corporate body purchased lands at Dalmarnock, on the banks of the Clyde, about three miles above the city, where they erected steam-engines, filtering pits, and reservoirs, &c. and now send river water, in a pure state, in iron pipes, through the streets and lanes of the city and suburbs, for the accommodation of all those who choose to purchase it. The expenditure of the company up to April 1815 is £81,194, 9s. 7d. The produce of water rents for one year, ending at same period, is £5971 : 8 : 7, which is raised in advance from the following rates, viz.—persons occupying a dwelling-house rented under £4, pay 5s. per annum; £4, and under £6, 6s. per annum; £6, and under £8, 7s. 6d. per annum; £8 and upwards five per cent. per annum. Bakers pay 5s. per annum for each man or boy employed in the bakehouse. The keepers of horses and cows, 4s. for each. Counting-houses, shops, and warehouses, pays from 5s. to 10s.; and public works according to the quantity of water used. The cast iron pipes, belonging to the company, laid in the streets and lanes within the royalty, exclusive of the main from Dalmarnock, and pipes in the suburbs of Gorbals, Calton, Bridgetown, &c. amount to seventeen miles, four furlongs, and three poles.

Cranston Hill Company. In 1808, a number of persons, connected with the suburbs, obtained an act of Parliament, incorporating them into a company for supplying the city of Glasgow and its suburbs with water, under the name of the Cranston Hill Water Company. Accordingly, they purchased lands at Cranston Hill, and on the banks of the river, about a mile below the city, and erected steam-engines, filtering beds, reservoirs, &c. and now send river water, in a pure state, in iron pipes, through a number of the streets and lanes of the city and suburbs. The expenditure of the company is £52,000. The water rates are nearly the same as the Glasgow company. The cast-iron pipes belonging to this company, laid in the streets and lanes within the royalty, exclusive of the main from Cranston Hill, and the pipes in the suburbs of Anderston, Gorbals, Calton, and Bridgetown, &c. amount to nine miles, four furlongs, and eleven poles. The total length of pipes within the royalty, belonging to both companies, is 27 miles, and fourteen poles.

Clyde Navigation. The affairs of the river Clyde are placed, by act of parliament, under the management of the magistrates and council. The revenue arising from tonnage, cranage, and harbour dues, collected at the Broomielaw, amounted, in 1814, to £5,920, 2s. 8d. Those dues are kept distinct from the corporation's funds, and are laid out in deepening and improving the river and harbour, and in discharging the debt of the trust.

Police Establishment. Prior to 1800, the police of the city was under the sole management of the magistrates and council, and supported from the corporation funds. In 1800, an act of parliament was obtained, vesting the management in the lord provost, magistrates, dean of guild, convener, and 24 commissioners, to be chosen by the inhabitants.

Glasgow. The commissioners are authorised to assess the inhabitants of houses, shops, and warehouses, &c. for the purposes of the act. The executive power is vested in the magistrates, and the administration of all its other affairs in the magistrates and ward commissioners. The commissioners hold stated weekly and quarterly boards, and numerous committees watch over the particular concerns of every department. This act being in force for seven years, gave the inhabitants an opportunity of observing its beneficial consequences; accordingly, in 1807, a new act was obtained, without requiring any material alteration, other than that the rate of assessment was increased on rents of £4, and under £6, from 4d. to 5d. in the pound; £6, and under £10, from 6d. to 7½d.; £10, and under £15, from 9d. to 11¼d; £15, and upwards, from 1s. to 1s. 3d. The commissioners, under this act, have merited and received the general approbation of the citizens, who have rarely been called on for the maximum rates.

Abstract Statement of the Receipts and Disbursements for the year ending 25th July 1814.

Sum contributed by the city of Glasgow	£800	0	0
Amount of assessment	6734	2	2
Dung of the streets	652	2	9
Amount of fines	157	0	9
Disbursements.	£8343	5	8
Salaries to the master, clerk, collector, treasurer and surveyor	£640	0	0
Wages to 19 officers	793	10	5
78 watchmen, at 11s. per week	2230	16	0
8 patrole, at 2s. per day	249	12	0
15 scavengers, at 11s. per week	429	0	0
1 ditto, 15s. ditto	39	0	0
Carting dung from the streets	455	8	8
Lighting 1264 lamps, from 20th August to 5th May	2569	16	0
10 ditto part of the season,	12	6	10
Oil for watchmen's lamps, clothes to officers and watchmen, rent of office, fire-engines, and secret service money,	923	15	9
	£8343	5	8

Statute labour. In 1807, a renewal of an act of Parliament was obtained, appointing the magistrates and council trustees of statute labour conversion within the city, and authorising them to assess the inhabitants of dwelling-houses, whose rents are under £5, in 2s. yearly; £5, and under £10, 3s. yearly; £10, and upwards, 5s. yearly; horses, 15s. each; and each ploughgate of land, (60 acres,) at 60s.: the following persons being always exempted,—clergymen, parochial schoolmasters, militia men enlisted under the act of 1779 and 1782, and paupers. The nett proceeds of 1814 are £1445, which is all expended on the streets and common sewers.

Education of youth. This city has long been conspicuous for the number and excellence of its seminaries. In 1814, there were more than 1400 students attending the university. Of this number 800 were enrolled as students of philosophy, and of the Greek and Latin languages, . . 1400

In the Andersonian institution there are 280 students instructed in natural philosophy, chemistry, materia medica, and mathematics, . . 280

The principles of natural philosophy and mechanics are explained to 490 operatives, at a moderate fee, ... 490

In the private lecture rooms instruction is given to 210 medical students, ... 210

In the public grammar-school there are four teachers of the Latin, and a rector, who gives instructions in the Greek and Latin languages, and in geography. The number of students in this seminary are 520

Amount, where a full fee is paid, ... 2900

The following are benevolent foundations, in which all the children receive a substantial education, and some of them clothing and money annually:

In Hutchison's school there are	84	boys.
— Trades-house school,	108	
— Wilson's school,	60	
— Town's hospital, with addition of maintenance,	90	boys and girls.
— Miller's school,	60	girls.
The Highland Society educate and put out to apprenticeships,	80	boys.
The Highland Society also educates 60 boys and girls belonging to Highlanders,	60	
In Lennox's school,	52	girls.
— Fleshers school,	55	boys and girls.
— Peddie's school,	45	girls.
— Routledge's school 70 girls, employed at the public works, are taught, in the evenings, to read, sew, knit, and spin,	70	
In the six schools under the patronage of the kirk-sessions, there are 450 boys and girls taught to read and spell,	450	
On benevolent foundations, where no fee is paid,	1214	
In the Lancasterian schools a small fee is exacted,	560	
In the Sunday schools, under the inspection of a committee from the town council and general session, 800 boys and girls are taught to read the Bible, and repeat the Shorter Catechism, gratuitously,	800	
In the Sunday schools, under the joint management of members of session and dissenters, 1740 boys and girls are taught to read the Scriptures gratuitously,	1740	
In 1799, the presbytery of Glasgow ascertained, that there were 60 private schools in the city, wherein the various branches of elementary education are taught, at various rates; in addition to such as are above described. If we suppose, that, during the course of 16 years, the number of these schools have increased to 75, and that each school averages 45 children, the total will be	3375	
Total of persons educated within the city,	10,589	

A number of these schools have juvenile libraries attached to them.

Ecclesiastical state. This city is the chief seat of the synod of Glasgow and Ayr, and of the presbytery of Glasgow. The members of the latter are the ministers of the city, of the

Glasgow. Ecclesiastical state.

barony, Gorbals, Rutherglen, Cumbernauld, Carmunnock, Calder, Campsie, Govan, Kirkintilloch, Kilsyth, Cathcart, and Eaglesham, and their elders. The synod is composed of seven presbyteries, viz. Glasgow, Ayr, Irvine, Paisley, Hamilton, Lanark, and Dumbarton.

At the Reformation, one minister, who was superintendant of the western district of Scotland, officiated in Glasgow, and had the pastoral charge of all its inhabitants: in 1583, the session of Glasgow was regularly constituted, of 1 minister, 35 elders, and 26 deacons. In 1590, although the lay members of session were numerous, we find the minister had summoned an inquest from the neighbourhood, to assist him in judging of matters of scandal. Soon after this period, public worship was performed in three churches: during subsequent periods, commencing about the time of the Revolution, the town has been divided into eight separate parishes. The patronage of the original one is vested in the crown, the town-council electing all the other clergymen.

The places of worship within the city are now as follows:—nine parish churches, including the barony, four chapels connected with the establishment: one covenanted presbyterian, one antiburgher, three burgher and three relief meeting-houses; two tabernacles; one English and one Scotch Episcopalian chapel; one independent, two baptist, and two methodist meeting-houses; one Roman Catholic and one unitarian chapel. The Glassites, Bereans, universalists, &c. have all places of worship. The number of sittings in the whole are 35,550.

Steam Boats.

In the summer of 1811, Mr Henry Bell, an ingenious engineer of this city, constructed and plied between Glasgow and Greenock, the steam boat Comet, performing a voyage of 22 miles in three hours and a half, by means of an engine of three horse power. This vessel was the first which was impelled by steam on a navigable river in Britain. Since the above period, the following vessels have been built by various persons, and are now plying on the river, viz. the Glasgow, the Clyde, the Dumbarton Castle, the Britannia, the Caledonia, the Argyle, the Greenock, the Duke of Wellington, the Prince of Orange, the Princess of Wales, the Trusty, and Industry, the two last mentioned being constructed chiefly for trade, carry each 70 tons of merchandise; the Prince of Orange, and the Princess of Wales, boats, have accommodation for 120, and the others for 220 passengers. These vessels are worked by engines of from 10 to 32 horse power; the average time of performing a passage of 22 miles is reduced to three hours; when the wind and tide are both favourable, the voyage can be completed in little more than two hours; but when adverse, it is prolonged to three and a half, or even four hours: the present fare for the cabin is 4s. and for the forecastle 2s. 6d. Exclusive of the vessels which are at present plying on the Clyde, the Duke of Argyle and Margery steam boats, carrying each 220 passengers, are now on the Thames, they were carried round by the Forth and Clyde navigation, a distance of more than 500 miles; one of these boats encountered and weathered a very heavy sea. Steam boats from the Clyde are also plying on the Mersey and Forth.

Baths.

Some years ago an extensive range of hot and cold baths were erected in Bath Street, a short distance from George's Square. A model has been approved of for floating baths, intended to be erected on the Clyde during the ensuing summer.

Commerce and manufactures.

The situation of Glasgow is singularly favourable for carrying on manufactures and commerce. Placed on the border of one of the richest coal and mineral fields in the island, with which it communicates by the Monkland Canal, while for carrying off its commodities, and receiving returns, the Atlantic is open to it on the one hand, through the river Clyde, and the German and North Sea on the other, through the Forth and Clyde canal and river Forth.

Before the year 1707, there had been different branches of manufacture begun at Glasgow, particularly the manufacture of coarse linens; and a considerable trade had been carried on with Holland. The union of the kingdoms at this period having opened the colonies to the Scotch, the merchants of Glasgow availed themselves of the circumstance, and entering extensively into a trade with Virginia, soon made their city the great mart for tobacco, and Glasgow became the chief medium through which the Farmers General of France received their supplies of that article. To so great a height was this branch of commerce carried, that for several years before the war, which ended in American independence, the annual imports of tobacco into the Clyde were from 35,000 to 45,000 hogsheads; and in the year immediately preceding that event, 57,143 hogsheads were imported. Only from 1200 to 1300 hogsheads of these were sold for home consumption.

The trade, while it continued, engrossed almost the whole capital and commercial enterprise of Glasgow; very little other foreign trade was attempted, and any manufactures that were carried on, were chiefly of articles adapted to the demands of the Virginia market. Supplying that state with European goods, and taking of the produce of its soil in return, became, in a great degree, a monopoly in the hands of the Glasgow merchants.

There had, as early as the year 1732, been a beginning made in a trade with the West India Islands, but up to the year 1775, the business was confined to a few houses, and had not been very beneficial. The imports of West India produce into the Clyde in the year 1775, were as follows: Sugar, 4621 hogsheads and 691 tierces; rum, 1154 puncheons and 193 hogsheads; cotton, 503 bags.

The interruption of the intercourse with America, now forced the traders of Glasgow to turn to other objects, the enterprise and capital which the commerce with that country had nearly wholly engrossed. They began more generally to direct their attention to manufactures; and the discovery then just made by Mr Arkwright, of the improved process of spinning cotton wool, a few years after this period, led to attempts in the different manufacturing towns to bring the manufacture of muslins into this country. The cambric and lawn manufacturers of Glasgow embarked in the undertaking, and, aided by the facility which a similarity of the fabrics afforded, were successful beyond their most sanguine expectation. The progress of the cotton manufacture at Glasgow after this was rapid, a number of spinning works were established, and most of the different fabrics of cotton cloth were executed. Dyeing and printing of linen and cotton cloths, a branch of manufacture which had been going on for some time on a limited scale, was now greatly extended, and furnished employment to a large amount of capital. A number of other manufactures of linen, woollen, iron, and pottery, and of the other articles subsidiary to more important branches, were prosecuted on a smaller or greater scale, and continued to extend as the general commerce of the city advanced. The manufacturers of

...gow.

...mmerce al manu-...tures.

Glasgow, who, till this period, had principally looked for a vent for their goods to the demands of their own export merchants, now began to open a more extensive sale to London and other parts of England, and going over to the continent, formed connections with almost every country of Europe.

...tton ...ls.

The number of cotton mills belonging to Glasgow, situated in the town and different parts of the country, is 52. The spindles in these are calculated at 511,200; and the capital employed in the buildings, machinery, and in carrying on the manufacture, at about £1,000,000. Two of these mills, not yet finished, and now filling with machinery (1816), will cost £50,000 each.

S...nning ...ks.

The first spinning works were established at a distance from town, for the convenience of water for the machinery; as the Badindalloch and Down mills, which are in Stirlingshire, the Catrine mills in Ayrshire, the Lanark mills, and the Rothsay mills in the island of Bute, all the property of houses in Glasgow.

No positive estimate of the amount of the cotton manufacture, in all its branches, can be given; but some facts may be mentioned, from which an idea of its extent will be derived.

...aving ...power.

Belonging to Glasgow there are eighteen works for weaving by power, which contain 2800 looms, producing about 8400 pieces of cloth weekly. The number of hand looms employed by the manufacturers of Glasgow, at this date, appear, upon a pretty careful investigation, to be about 32,000.

...ico ...nting.

There are eighteen calico printing works belonging to Glasgow; and there has lately been added to this branch, an extensive manufacture of Bandana handkerchiefs, introduced by Messrs Henry Monteith, Bogle and Company, the cloth for which, being dyed a fine turkey red, the pattern is afterwards produced, by discharging the colour of the figure by a chemical process.

...endering ...ses.

There are 17 calendering houses in Glasgow, containing 39 calenders moved by steam, which execute more than four times the quantity of work performed by the same machinery when moved by horses. One of these houses employs 119 hands in calendering and folding the goods; and the whole of these establishments are able to calender in a day 118,000 yards, besides dressing 116,000 not calendered, and glazing 30,000.

...foun-...es.

There are nine iron founderies in Glasgow, and several extensive works for making steam engines, with the machines and machinery required for the different processes of manufacturing. It was not before the year 1778 or 1779 that the power of the steam engine, in consequence of Mr Watt's inestimable improvements, was found to be applicable to manufacturing operations; and it was many years after that period, before it was brought into general use. There are now 73 steam engines in Glasgow, and the immediate suburbs, of a power of from four to fifty horses employed in the different processes of manufactures.

...rts of ...t India ...uce.

The war of 1793 having for a time brought into our possession the West India colonies of the other European states, the West India merchants of Glasgow obtained a large share of the trade which this circumstance threw into the hands of this country. The connection with Demerara in particular, which it gave them the means of forming, proved valuable, and is now likely to be lasting. The imports of West India produce into the Clyde, for the three last years, have been as follows.

		1812.	1813.	1814.

The removal of the royal family of Portugal to America, having opened the trade of the Brazils to foreigners, the merchants of Glasgow immediately formed establishments there, and have continued since to have a profitable intercourse with that country. Establishments were also made at Buenos Ayres and the Caraccas, as soon as these parts of America began to assert their independence; but the commerce with these states has hitherto been fluctuating and hazardous, from the situation in which their affairs have been kept.

Trade with America.

Upon the conclusion of the peace of 1783, an intercourse was opened by the merchants of Glasgow with the different states of the American Union; and the introduction of the cultivation of cotton wool, a few years after, into the southern states, furnished the means for a great increase of this trade. Indeed, without this new field to supply the quantity of the article which the growing demands of the manufacturers required, and of the qualities suited to the different fabrics to be made, this important branch of industry never could have reached that high state at which it has arrived. The bringing home this article for the manufactures of Glasgow, and sending out the returns, became a great trade, and led to the formation of establishments for carrying on this part of the business at Charlestown and New Orleans. The imports of cotton-wool into the Clyde, for the last four years, have been as follows.

Imports of cotton wool into the Clyde.

	1812. Bags	1813. Bags.	1814. Bags.	1815. Bags.

Besides the trade with these parts of America which have been mentioned, the merchants of Glasgow have large dealings with Canada and Nova Scotia.

The rapid progress making in the use of mechanical power in manufactures, is particularly favourable to the growing prosperity of Glasgow, from the inexhaustible supply of coal it possesses for working machinery. This, with the advantage of water communication in every direction, renders it, almost more than any other place, fitted for carrying on manufactures of a heavy or bulky nature, and must have the effect to bring many new branches of industry of this description to be added to those which it already has. This city, then, producing thus a great variety of articles for exportation, and carrying on, at the same time, a very extensive foreign trade, seems to combine all the requisites to raise it to the highest commercial eminence. The revenue of the post-office at Glasgow, in the year 1781, was £4344 : 5 : 8; in 1814 it was £34,000.

Chamber of Commerce.

Connected with the commerce of Glasgow is the institution of its Chamber of Commerce and Manufactures, the first establishment of the kind made in the island. This association was incorporated by a royal

Glasgow.

charter in the year 1783, and owes its origin to Dr Patrick Colquhoun, author of the *State of the Police of London*, and other works, and at that time a merchant in Glasgow, and one of its most enlightened and public-spirited citizens.

The chamber consists of the merchants and manufacturers of Glasgow and the neighbourhood, who may become members upon paying five guineas at admission, and 10s. 6d. yearly. The management is vested in thirty directors, six of whom are renewed annually; and their duty is to keep a watchful eye on whatever may be supposed to affect the commercial interests of Glasgow and its neighbourhood, and, at the same time, to serve as the organ of communication between the manufacturing and commercial body of the district, either acting generally or separately, and the legislature or any of the departments of the state.

Population of the city and suburbs.

In 1780, the number was	42,832	In 1791,	66,578
In 1785,	45,889	In 1801,	83,769

Census of 1811.

North parish	11,159	South-west	8193
North-west	9940	St Andrew's	5250
West	4190	St Enoch's	7715
East	6159	Govan	8081
South	5758	Barony or Landward parish	38,216
Gorbals	5799		
Total population			110,460.

In 1815, the number of families in the 24 police wards, who paid taxes on rents under £5 per annum,

was	7455
Do. on rents of £5 and upwards	5272
Number of families in the 24 wards	12,727

On the principle of there being an average of five souls in each family, the number of inhabitants in the 24 wards of the royalty would be 63,635; being an increase of 5271 during the period of four years. If to this number the population of the Gorbals, Govan, and Barony be added, as taken in 1811, the amount will be 115,731; and if we suppose the increase of these suburbs for four years to be 4269, the grand total in 1815 will be 120,000.

Mortality bills.

In 1814, there were interred in the burying-grounds within the royalty, and in the immediate suburbs, 3254

In the year 1813,	2704
Increase of burials in 1814	570

(C. J.)

GLASS.

Glass.

GLASS is the name of an artificial substance, formed by the igneous fusion of siliceous earth with various salts and metallic oxides, and possessing a high degree of transparency, equalled only by the more perfect crystals of the mineral kingdom, and other physical properties, which render it one of the most useful and ornamental substances which the arts have received from the ingenuity of man.

The word glass is of uncertain etymology. It has been derived by some from the word *glessum*, the name which the ancient Gauls and Germans gave to amber, and from which has arisen the German word *gleisser*, "to shine," and the English word *glisten*; while others have traced it to the word *glastum*, the Latin term for woad, either because the ashes of this plant were used in the manufacture of glass, or because glass had commonly that blue tinge which the Britons communicated to their bodies by the use of the woad. Its derivation from the Latin word *glacies*, signifying ice, is not less probable than those which we have mentioned.

Origin and history.

It would be a task as irksome to ourselves, as it would be unprofitable to our readers, to detail the unfounded speculations which have been accumulated respecting the origin of this remarkable substance.

There is some reason to believe that glass was made by the Phenicians, the Tyrians, and the Egyptians. Paw and other antiquarians maintain, that the first glasshouse was constructed at Diospolis, the ancient capital of the Thebais; but it appears from the writings of the ancients, that the Phenicians had made considerable progress in the manufacture of glass; and Pliny informs us that the Phenician colony of Sidon obtained, for some hundred years, the chief ingredients of their glass from the Phenician town Acco, now St John D'Acre, near the place where the small river Belus throws itself into the Mediterranean.

The account of the origin of glass, which Pliny has handed down to us, is extremely plausible. A merchant vessel laden with nitre or fossil alkali, having been driven ashore on the coast of Palestine, near the river Belus, the crew went in search of provisions, and accidentally supported the kettles on which they dressed them upon pieces of fossil alkali. The river sand, above which this operation was performed, was vitrified by its union with the alkali, and thus produced glass. The important hint which was thus accidentally obtained, was soon adopted, and the art of making glass was gradually improved. *

In the time of Pliny, glass was manufactured out of the fine sand which was collected at the mouth of the river Vulturnus. After being ground to powder, it was mixed with three parts of nitrous fossil alkali, or soda, and after fusion it was taken to another furnace, where it was formed into a mass called *ammonitrum*, and converted into a pure glass. A similar method of making glass was used in Spain and Gaul.

Pliny informs us, that in the reign of Tiberius an artist had his house demolished for making glass malleable, while Petronius Arbiter asserts that he was beheaded by the emperor. About the commencement of the Christian era, drinking vessels were commonly made of glass, and glass bottles for holding wine and flowers were in common use. The company at Rome which was engaged in the manufacture of glass, had a particular street assigned to them near the Porta Capena. Alexander Severus imposed a tax upon this company in A. D. 220, which was continued in the time of Aurelian.

The art of making coloured glass seems to have been coeval with the invention of glass itself. Many of the Egyptian mummies, one of which is in the British Museum, are ornamented with beads of variously coloured glass, which could not have been executed without a chemical knowledge of the properties of the metallic oxides. By what processes these coloured glasses were formed, it is not easy to discover, as the ancients were not acquainted with the mineral acids which are now usually employed in the preparation of metallic oxides. Strabo

* "Fama est, adpulsa nave mercatorum nitri, cum sparsi per littus epulas pararent, nec esset cortinis attollendis lapidum occasio, glebas nitri e nave subdidisse. Quibus accensis permixta arena littoris, translucentes novi liquoris fluxisse rivos, et hanc fuisse originem vitri." *Plin.* lib. xxxvi. cap. 65.

story.

was told by the workmen of Alexandria, that their country produced an ingredient for making coloured glass; and Seneca informs us, that Democritus introduced into Europe the art of making coloured glass, and of thus imitating the precious stones. But from whatever source this curious art was derived, it was brought to a high degree of perfection among the Greeks and Romans; and many of the gems were so admirably counterfeited, as to deceive even those who were intimately acquainted with the study of minerals.

ls used mosaic.

In the time of Augustus, the Roman architects made use of glass in their mosaic decorations; and several specimens of this glass have been found among the ruins of the villa of the Emperor Tiberius, in the island of Capri. Some of these specimens have been examined and analysed by Klaproth. They consist of pieces of red, green, and blue glass.

proth's ysis of ent red green

The first of these is of a lively copper red colour, perfectly opaque, and very bright at the place of recent fracture. The green glass has a light verdigris colour, is opaque, and has a scoriaceous shining fracture. Two hundred grains consisted of

The blue glass had a sapphire colour, verging towards that of smelt, and was transparent at the edges only. Some of the plates of it are not coloured throughout the whole of their mass, but only through about two-thirds of their thickness. Each of the strata is so distinct as to give the appearance of a blue and a colourless plate adhering at their broad surfaces.

of forming pictures n colour- d ass.

A still more singular art of forming pictures with coloured glass was known and practised by the ancients. It consists of variously coloured glass fibres, fitted with the utmost exactness, so that a section across the fibres represents the object to be painted. These fibres, when properly joined together, are afterwards cemented by fusion into a homogeneous and solid mass. Specimens of this art seem to have been first discovered about the middle of the last century. Count Caylus first describes them in his *Collection of Antiquities*, and Winkelman in his *Annotations on the History of the Art among the Ancients*, under the name of pictures made of glass tubes. Sulzer, in his *Theory of the Polite Arts*, describes, in the article Mosaic, specimens which he had seen at Dresden; and Klaproth has given drawings of one which he has in his own possession. The following description of two pieces of this kind of glass, which were brought to Rome in 1765, is given by Winkelman:

"Each of them is not quite one inch long, and one-third of an inch broad. One plate exhibits, on a dark ground of variegated colours, a bird representing a duck of various very lively colours, more suitable to the Chinese arbitrary taste, than adapted to shew the true tints of nature. The outlines are well decided and sharp, the colours beautiful and pure, and have a very striking and brilliant effect; because the artist, according to the nature of the parts, has in some employed an opaque, and in others a transparent glass. The most delicate pencil of the miniature painter could not have traced more accurately and distinctly, either the circle of the pupil of the eye, or the apparently scaly feathers on the breast and wings, behind the beginning of which this piece had been broken. But the admiration of the beholder is at the highest pitch, when, by turning the glass, he sees the same bird on the reverse, without perceiving any difference in the smallest points; whence we could not but conclude, that this picture is continued through the whole thickness of the specimen; and that, if the glass were cut transversely, the same picture of the duck would be found repeated in the several slabs; a conclusion which was still farther confirmed by the transparent places of some beautiful colours upon the eye and breast that were observed. The painting has on both sides a granular appearance, and seems to have been formed, in the manner of mosaic works, of single pieces; but so accurately united, that a powerful magnifying-glass was unable to discover any junctures. This circumstance, and the continuation of the picture throughout the whole substance, rendered it extremely difficult to form any direct notion of the process or manner of performing such a work. And the conception of it might have long continued enigmatical, were it not that, on the section of the fracture mentioned, lines are observable, of the same colours which appear on the upper surface, that pervade the whole mass from one side to the other; whence it became a rational conclusion, that this kind of painting must have been executed by joining variously coloured filaments of glass, and subsequently fusing the same into one coherent body. The other specimen is about the same size, and made in the same manner. It exhibits ornamental drawings of green, white, and yellow colours, which are traced on a blue ground, and represent volutes, beads, and flowers, resting on pyramidally converging lines. All these are very distinct and separate, but so extremely small that even a keen eye finds it difficult to pursue the subtle endings, those in particular in which the volutes terminate. Notwithstanding which, these ornaments pass uninterruptedly through the whole thickness of the piece."

History. Art of forming pictures with coloured glass.

Plate CCLXXV. Fig. 4.

One of the two specimens which we have mentionsented as in the possession of M. Klaproth, is represented in Plate CCLXXV. Fig. 4. Both the pieces have a heart-shaped form, their principal front being flat, and the reverse convex. The length of one of them is one inch, its breadth four-fifths, and its thickness, two-fifths. The other specimen is two-thirds of the size of the first; but they are both nearly alike in the colouring and manner of drawing. The principal mass of the large specimen is a dark and perfectly opaque, but the smaller one, which is in some places transparent, has a sapphire blue colour. The blue ground is ornamented with voluted stellular, minute flowers, on such a small scale as to be scarcely imitable by the miniature painter. Their colours are red, green, brown, sky-blue, and white, and are all pure and lively. The delineations pervade the whole mass; and it is obvious from examining a fracture, that those minute ornaments are formed of parallel glassy fibres of various hues, agglutinated by fusion.

Glass used for windows.

About the end of the 3d century, as appears from a passage in Lactantius,* glass was used for windows; and there is reason to believe, from the glass plates

* "Manifestius est, mentem esse, quæ per oculos ea, quæ sunt opposita transpiciat, quasi per fenestras lucente vitro, aut speculari lapide obductas." *De Opificio Dei*, cap. 5.

History.

Glass used for windows.

found in Herculaneum, that window glass had been introduced at a much earlier period. St Jerome, A. D. 422, Paulus Silentiarus, A. D. 534, Gregory of Tours, A.D. 571, and Johannes Philoponus, A. D. 630,* all speak in the most distinct manner of the use of glass in the formation of windows.

Italy was the first modern nation that employed glass in windows. The custom was afterwards introduced into France; and though the art of making glass was brought into England in A. D. 674, by foreign artists sent for by the Abbot Benedict, who glazed the church and monastery of Weremouth in Durham, yet this great invention was so much neglected, that private houses were not lighted through glass till the end of the 10th century. The windows of houses, and even of cathedral churches, were covered with fine linen cloths.

Painting of church windows.

The application of painted glass to the decoration of church windows, was made before the commencement of the 9th century, as we are informed by Anastasius, librarian to Pope Leo III. that painted glass was used in his time. This art made rapid advances to perfection; and all the ingenuity of the art was exhausted in the production of those splendid windows which at present adorn the Gothic cathedrals of Europe. The art of staining glass, though still known and practised, is, however, to a certain extent lost; and we admire, without being able to imitate, some of the rich productions of the middle ages. We have had occasion to see a specimen of glass, brought home by Dr Brewster from the abbey of Konigsfeld, in Switzerland, which consists of *six* different layers of green and purple glass placed alternately. The thickness of the plate is only about the 7th part of an inch; and the different layers have an equality of thickness, and a parallelism, which is truly surprising. The compound colour is a light purple. A section of this plate is shewn in Plate CCLXXV. Fig. 5, the dark layer representing the purple, and the light one the green glass.

Glass made at Venice.

The art of making plate glass by blowing, was carried on to a great extent at the village of Murano, near Venice; and Europe was long supplied from this quarter with the finest and largest mirrors.

In England and France.

We are indebted, however, to the French, for the art of casting large plates of glass, which was introduced in 1688 by Abraham Thevenart. An account of this establishment, and of the glass manufactories in England, will be found in our articles England, vol. ix. p. 10, and France, vol. ix. p. 718.

In Scotland.

Glass appears to have been first made in Scotland in the reign of James VI. and the exclusive right of manufacturing it within the kingdom, was given to Lord George Hay for 31 years, from 1610. This right was transferred in 1627 for a considerable sum, to Thomas Robinson, merchant-tailor in London, who again transferred it for £250 to Sir Robert Mansell, vice-admiral of England. A manufactory of glass was carried on for some time in a cave at Wemyss, in Fifeshire. Regular glass works were afterwards established at Prestonpans; but the principal places where glass is now made in Scotland, are Leith,† Glasgow, and Dumbarton.

Sect. I. *On Glasshouses, Pots, &c.*

Glass-houses.

The glasshouses now in use are commonly large cones, from 60 to 100 feet high, and from 50 to 80 feet in diameter at the base. *The furnace* is erected in the centre, over a large vault, that extends from one side of the cone to the other. The vault or cave is generally made of a sufficient height and width to allow the workmen to wheel a barrow with rubbish out and in. This, however, is not the only purpose of this cave, as it is made to communicate with the furnace by an aperture in the top of it, of such a size as the furnace above may require. Over this aperture a grating of strong iron is placed, so as to be in the centre of the furnace, and upon that grating the fuel is laid and ignition is maintained by the air that issues into it through the caves or vaults underneath.

Crucibles or pots.

The crucibles or pots are the most important article about a glasswork. The clay obtained at Stourbridge is found to answer the purpose better than any other. After carefully picking and brushing the clay, it is ground in a mill, and sifted through a sieve of about 20 passes in an inch: it is then wet with warm water, and well tramped in a large cistern, until it is brought to the consistence of a thick paste. Some manufacturers make up a very large quantity of this paste, and keep it in that state for many months: others, again, work it immediately into pots or crucibles. It is also common to take old crucibles and grind them down to a fine powder, which they add to the crude clay in quantities seldom exceeding a fourth part, from an idea that the burnt clay renders the crucible more refractory, and of course more likely to resist the combined action of the fire and alkali required in the composition for glass. This mixture contracts less than if the pots were made entirely of crude clay, and of course is less liable to break while drying.

Various methods have been tried for working the clay into pots, by using moulds, &c.; but the method that has been most generally practised, is to knead the clay, while in the state of a paste, till it is nearly as tough as the putty used by glaziers. It is then made into rolls, and wrought one layer upon another, and pressed together with the greatest care, so as to make a compact body, quite free of any vacuity, and generally into the shape of an inverted cone, or into a cylindrical form.

The pots used for bottles and window glass are generally made about 40 inches diameter at top by 30 at bottom, and about 40 inches deep, and are termed open pots. Those for flint glass are covered over, and termed capt pots; they are made of various sizes and shapes. Bottle and crown house pots are made from three to four inches thick; and flint house pots from two to three inches thick. After the pots are made, it requires a good deal of attention to bring them to that state of dryness requisite for their being taken to the annealing furnace. Before pots are set into the furnace, they are heated up with the greatest caution, in an arch or vault built for the purpose, to a perfect white heat. This operation requires four or five days, or longer if they are not very dry previous to their being used; and when they are completely annealed, as it is termed, they are carried with the utmost expedition from the annealing arch, and set into the working furnace. The setting of pots is deemed the severest labour about a glass-house, from the great heat attending it; and is described as follows by M. Blancourt. He observes, that the roughest work in this art, is the changing the pots when they are worn out or cracked. In this case, the great working hole must be uncovered, the faulty pot

* Philoponus informs us that the glass was fastened in with plaster.

† The Editor has been indebted to Mr James Geddes, of Leith, for the principal information respecting the manufacture of bottle, crown, and flint glass, contained in Sects. I. II. IV. and V.

must be taken out with iron hooks and forks, and a new one must be speedily put in its place through the flames, by the hands only. For this work, the man guards himself with a garment made of skins, in the shape of a pantaloon, that covers him all but his eyes, and is made as wet as possible. The eyes should be defended with a very thick plate of glass.

Sect. II. *On Bottle Glass.*

Bottle glass. Plate CCLXXV. Fig. 1.

The bottle-house furnace, represented in Plate CCLXXV. Fig. 1, (see description of Plates,) is generally an oblong square chamber, arched over with the same material. Some give it a very flat *crown*, as it is called; and others raise it high and of a barrel shape. This furnace is erected in the centre of the building, on the top of the cave or vault, and is divided into three spaces in the inside by the grate, and on each side of that is the site for the pots or crucibles, which is a bank of the same material as the furnace, generally about a foot high, and three broad.

In this furnace there is a hole about a foot diameter for each pot, called working holes, at which the workmen put in the materials, and take out the liquid glass. At each angle of the furnace there is also a hole about the same size, which communicates with the calcining furnace; and the flame that issues from the main furnace, which otherwise would be lost, reverberates on the materials in this furnace, and calcines them. There are generally eight other furnaces or arches in a bottle-house. Six are used for annealing the bottles after they are made, and two for annealing the pots, previous to setting them into the main furnace.

Materials.

The materials used for bottle glass are of the coarsest kinds. Government will not allow any but the commonest sea or river sand, mixed with soap boiler's waste, which is done in the proportion of three of soap waste to one of sand, according to the quality of the soap-waste: this soap-waste is generally calcined in two of the arches used for that purpose, and termed the coarse arches, which are kept at a red heat from 24 to 30 hours, the time required to melt the materials and work them into glass, which is called a journey; after that the soap-waste, now termed ashes, are taken out and bruised and mixed with the sand in the proportions already mentioned. The mixture is then put into the fine arch, where it is again calcined during the working journey, which is generally 10 or 12 hours more. When the working journey is over, the pots are again filled with the red hot materials out of the fine calcining arch. In about six hours it is melted; the pots are again filled up, and this second filling requires about four hours to melt.

Fusion.

By continuing the heat to as great a degree as possible, in the course of 12, 15, or 18 hours, these materials become a perfect glass fit for making wine bottles. The furnace is then reduced to a working heat, by shutting the cave doors, and excluding the air from the grating. The metal, as it cools in the pots, becomes more dense; and all the heterogeneous matter that was contained in the ashes, and not melted into glass, floats on the top and is skimmed off. The furnace is then filled with coal, in such a way that it will retain what is termed a working heat, for four or five hours, when it is again filled so as to preserve that degree of heat till the working journey is finished. It is impossible to give any correct idea of the process of blowing to a person that never saw glass manufactured. There are six people employed in the making of one bottle, independent of all the men employed in preparing the materials, each person forming a distinct part; and by that division of labour, they are enabled to make a very large quantity in a journey; and although ten men and boys are busily working with long hot irons, and red hot glass metal in a liquid state, in a space not exceeding four square yards, yet such is their regularity in passing one another, and handing back and forward their work, which never fails to strike a stranger with terror, that it is very rarely any of them meet with an accident.

Method of making bottles.

One workman, called a gatherer, dips the end of a tube, heated red hot, and about five feet long, into the pot containing the metal, to which it readily adheres; and after it is cooled a little, he again immerses the end of the tube so as to cover the metal; and, by giving it a turn in his hand, he is enabled to bring out of the pot as much as is required for a common wine bottle. He then hands it to the blower, and prepares another; while the blower, by rolling the metal on a stone or plate, brings it to the end of the pipe or tube: he then holds it in a brass or cast-iron mould, and, by blowing down through the tube, makes the glass, which is now getting cold, retain the shape given to it, which is that of a common wine bottle. It is then handed to the finisher, who, by means of a cold piece of iron with which he touches the neck while still red hot, but cold enough to retain its shape, cuts it off from the blow-pipe, as completely as if done by a diamond.

Sect. III. *Broad or Inferior Window Glass.*

Broad glass.

This species of glass consists of different ingredients, and is manufactured in a different manner from crown window glass. Its ingredients are, soap boiler's waste 6 bushels; kelp 3 do.; sand 4 do.

When these materials have been calcined for from 20 to 30 hours, they are removed with iron shovels, while red hot, to the melting furnance, when the pots are filled with it. By exposure to the heat from 12 or 15 hours, the whole is reduced to a fluid state. It is then taken out upon tubes in the manner described under Sect. IV. and blown into globes of nearly a foot in diameter. These globes being carried to the mouth of the oven, a longitudinal and nearly rectilineal crack is produced, by touching it with a cold iron dipped in water. The globe is then opened on a smooth iron plate at the mouth of the furnace, and then forms a circular sheet of thin transparent window glass. See Parke's *Essays*.

Sect. IV. *Crown Glass.*

Crown glass. Plate CCLXXV. Fig. 2.

The furnace for crown glass, represented in Plate CCLXXV. Fig. 2. (see description of Plates,) is generally constructed for four or six pots of such a size as will contain from 16 to 20 cwts. of glass. There are also several other furnaces required in this manufacture: A reverberatory furnace for calcining the materials; flashing furnace, and bottoming hole, used for the purpose of heating the glass, in order to continue its flexibility till it acquires from the workman the desired shape, with several others called arches, which are used for the purpose of annealing the glass after it is made, and the pots previous to their being set into the furnace. The materials for crown glass, that is the best window glass, are two parts of kelp to one of fine white sand; these are the usual proportions; but the quality of even the best kelp is extremely various, some vitrifying more and some less sand. From six to eight cwt. of these materials, after they are well mixed, are put into a reverberatory furnace, of about six feet

Crown Glass.

square, having an arch thrown over it of about two feet in height. On the one side is a grating to contain the fire, with an ash-pit beneath. The bottom of this furnace is raised about 3½ feet high, so as to be more convenient for the workmen to turn the materials. As the neutral salt contained in the kelp when heated is extremely penetrating, and readily goes through common or even fire bricks, carrying along with it a considerable quantity of alkali, and thereby very much injuring the quality of the glass, various plans have been tried to prevent it, some by making large bricks of fire clay, and others by placing a plate of iron so far under the floor of the furnace, as not to be much affected by the heat, from an idea that when the iron tub or pan is filled with the neutral salt, no more will be lost. Another plan is to have flues for admitting a stream of cold air below the floor of the furnace, which cools it, and keeps the salt from running off. But it would undoubtedly be a much better plan to separate the alkali from all heterogeneous matter previous to mixing it with the sand.

The operation of calcining, or burning *frit*, requires much care. After the materials are put into the furnace, they are stirred frequently, until all the earthy matter in the kelp is burnt away, which generally requires about three hours; the heat is then raised to such a degree, as to bring the materials almost into a state of fusion, which must be prevented by constant stirring, otherwise it would get into what is termed *catches*, or small knots that contain more sand than the rest of the batch, occasioned by the alkali being dissipated, from an excess of heat. If it is continued at that high temperature for about two hours, it will be sufficiently calcined. It is then taken out of the furnace, and spread, while warm, upon a plate, and divided into large cakes; this must be done before it cools, otherwise it would be one hard lump. It is the opinion of many, that frit cannot be too old. All the opulent manufacturers, therefore, lay up great quantities, and seldom use any till it is six months old.

Crown glass is made by filling the pots on the melting furnace with frit, adding about one-eighth part of broken glass. The furnace is then raised to as high a degree of heat as possible, and in about ten or twelve hours the frit is melted. The pots are again filled up in the same manner. The heat is then continued, and if possible increased, till the metal, as it is now called, is completely fine, that is pure liquid glass fit to be made into window glass, altogether requiring from 30 to 36 hours of intense heat.

After the metal is completely fine, the founder, that is the workman who manages the metal making, allows the fire to slacken for about two hours, until it arrives at what is termed a working heat; this is called settling the furnace, and on the proper settling of the furnace the working of the metal in a great measure depends.

Blowing or flashing of crown glass.

For blowing or *flashing* crown glass few tools are required. The principal instrument is an iron tube, the end of which being heated, is dipped into the pot of melted glass, and turned round to collect some glass upon it. This portion of glass is distributed equally upon all sides of the end of the tube, by rolling it upon a flat table of iron. It is then heated, and again dipped into the melted glass, to take up an additional quantity. In this state, by blowing slightly through the tube, the glass is made hollow within; and the workman judges, from the manner in which it enlarges when he blows, if the glass is so arranged round the end of the tube, that it may be afterwards blown out and extend itself equally on all sides, to form a large globe, or hollow vessel of any other circular figure, of a regular thickness. If he perceives any side to be too thin, he corrects this, by rolling it on the marble. This operation is repeated three or four times. He then heats it well in the fire, and rolls the glass with great care, to form it circularly upon the end of the tube, and lengthen it out in the manner represented by Fig. 1. Plate CCLXXVI. Then, by blowing through the tube, he distends the glass into the form of a long hollow pear, resting it all the while upon the iron table, and rolling it round, that it may preserve a correct circular figure, and distend itself equally. To lengthen out the neck of the pear, he rolls it, as it may require, over a smooth iron rod, fixed up horizontally, as in Fig. 2. and the pressure thus caused will lengthen the neck. He then blows again through the tube, supporting the glass, by resting the extreme end of the pear upon the iron rod, and rolling it round at the same time: The pressure upon the iron rod raises a small point or eminence upon the globe, opposite the end of the blowing iron. The blowing being dexterously managed, and assisted by the pressure of the rolling, the glass is enlarged to the form of a sphere, Fig. 3, which remains attached to the tube by a neck.

Plate CCLXXVI. Fig. 1. Fig. 2. Fig. 3.

By the time the workman has proceeded so far, and produced a globe, Fig. 3. of a very regular thickness, the glass is generally so far cooled as to grow firm; and though it will readily yield to a pressure, it will not alter its figure by its own weight. To proceed in the operation, it must be heated again. For this purpose, it is carried to a particular furnace, called the *bottoming hole*, to be exposed to the heat of the flames. A slight wall is erected before one-half of this mouth, to screen the workman from the heat; and the screen is at a sufficient distance from the wall of the furnace, to leave room for the globe to pass between them. A hook is fixed in this wall for the support of the blowing iron, which is rested in the hook, at a few inches from the neck of the globe. This method admits of turning the tube rapidly round as an axis, to which the globe is affixed, and therefore revolves with it. The side of the globe opposite to the end of the blowing iron being exposed to the heat of the fire, is gradually softened; but the neck of the globe, which joins the rod, and all that part of the glass which is more remote from the fire, is not softened in an equal degree. In this situation, the centrifugal force produced by the whirling, causes the equatorial parts of the globe to fly out from the centre, by stretching or enlarging itself; but as this enlargement will be most powerful upon the softest part of the glass, which is the end opposite to the fire, the centrifugal force will cause that end to become flattened almost to a flat plate, or at least to a slightly convex plate, as shewn in Fig. 4. Fig. 4.

In this state the glass is removed from the fire, and the neck is cracked off, by resting the tube across the rod and turning it round, whilst the neck is touched with a piece of iron wetted in cold water. This produces a circular crack round the neck, which is separated from the tube, by laying the glass upon a table, shewn in Fig. 4, which is composed of two planes *d*, inclining towards each other, so as to receive the glass without danger of its rolling off. In this situation, a slight stroke upon the rod breaks off the neck, and leaves the glass upon the table. The workman now dips the end of an iron rod *o* into the melted glass, and takes up as much as will make it adhere firmly to the prominence *c*, so as to serve

Crown Glass.

for a spindle to turn the glass by. The glass being now thin, soon becomes so cool as to require heating, which is done by presenting the open end to the flame, the workman resting the rod in the hook, and turning it slowly round, that the glass may become equally heated. When the open end is sufficiently softened, the workman, supporting the rod over a rest or hook, turns the glass steadily round. The motion opens and enlarges the aperture to the form of Fig. 5; and they take great care, by turning with a regular motion, to preserve the circular figure, such as is represented in Fig. 6. In this state, being whirled rapidly round, the centrifugal force throws it out into a flat circular plate *a b*, of from 3 feet 6 inches to 4 feet diameter.

When the plate is sufficiently cooled, the workman applies a cold iron to crack the neck of the central projection which connects the plate with the rod, and he then lays the plate flat down upon a bed of ashes previously prepared. The rod or spindle is now separated by a gentle stroke, and the plate is taken up upon an iron fork, and conveyed to the annealing oven, where a great number are set up edgewise, and supported by iron frames to keep them flat. The fire of the oven is suffered to burn out, and the heat to diminish as slowly as possible, until the glasses become quite cold: They are then withdrawn from the furnace, by taking down a slight front wall built in the door or arch. The heat of the annealing oven, which is not sufficient to make the glass so soft as to bend by its weight, is allowed to die away.

Window plate, also called German plate, or table glass, is made by the same means of blowing and rolling; but these are managed to produce a cylinder, which is cut open and spread flat upon a table.

In order to form glass plates by the extension of a cylinder, the workman blows the glass into the shape of a pear, as at Fig. 7. The length of this pear must be nearly equal to the length of the plate, and its diameter of such a size, that the circumference, when unfolded, will be equal to the breadth of the plate desired. He now supports the blowing iron over a stool or iron bar, whilst an assistant, with a pointed iron, pierces a hole into the extreme end of the pear, opposite the end of the blowing iron: This opening is enlarged by introducing the blade of a pair of spring tongs, as in Fig. 8. whilst the glass is turned round; and, by a peculiar management of these, the end of the pear is at last opened out to a cylinder, as in Fig. 9. The workman now mounts a stool, and holds the blowing-iron perpendicularly, whilst his assistant cuts open one side of the cylinder with a pair of cutting shears, as in Fig. 9. The blowing iron is next broken off, and a rod *b*, Fig 10. applied to the end of the cylinder, to form a spindle to work the other end by. This rod has a flat circular plate upon the end of it, or three prongs *c*, *c*, *c*, which being dipped in the melted glass, are applied to the end of the cylinder. By this rod the glass is carried to the fire, and the end from which the tube was broken off is heated. It is then opened by the spring tongs, and reduced to a cylinder of the same size as that at the other end. The shears are next used to cut the cylinder open from this end, and leave it in the state of a sheet of paper rolled up. The cylinder is now laid upon a smooth copper table, where the spindle is detached, and the glass spread into a flat sheet, and annealed.

Sect V. *On Flint Glass.*

Flint glass was formerly manufactured from flints calcined, and afterwards ground, well washed, and sifted, to which was added pearl ashes, or an alkali of some kind, to serve as a flux, and a small quantity of arsenic.

The materials now used for the finest flint glass, are, first, a fine white transparent sand, which is termed the body of glass; this is found often mixed with clay, &c. from which it is freed by washing, until the water comes quite clear off; it is then calcined, and afterwards sifted through a very fine sieve of from 40 to 50 passes to the inch. The second article is red lead, or litharge, which serves as a powerful flux, gives greater density to glass, renders it more ductile, less apt to crack from sudden changes of temperature, and imparts to it a high refractive and reflective power. Litharge is preferable to red lead, as it gives a purer glass, is less liable to be adulterated. and acts more powerfully as a flux. The third ingredient is an alkali, either soda or potash; the finest pearl ashes dissolved, and the solution evaporated to drynesss, is considered the best, as it imparts no particular colour to the glass, whereas soda gives it a greenish-blue tinge.

Nitre, the fourth ingredient, is also used as a flux, and serves to correct the imperfections that arise from the lead being insufficiently calcined. A fifth article, viz. arsenic, is sometimes used to aid the fluxing ingredients; but the quantity must be very small, lest the transparency of the glass be hurt by the opake white colour which it imparts when used largely. A sixth, and very important ingredient, is the black oxide of manganese, which is used to destroy any accidental foulness of colour that may arise in the glass, and particularly any tinge given by particles of iron amongst the sand; but while it destroys the green-yellow, or olive colours in glass, by imparting to them a purple tinge, the mixture of colours produces a blacker glass, and of course greatly injures its transparency.

When too much manganese is added, the purple colour may be destroyed by charcoal; but this can only be done partially, as the purple tinge is not visible until a perfect glass is formed, after which the charcoal cannot be mixed with the glass.

When a batch of flint glass is prepared, it is taken from the mixing-house to the glass-house, and then put into the pots in small quantities of ten or a dozen shovelfuls at a time. When this is melted, which it does in two or three hours, more is added till the pot is full. The mouth of the pot is then completely closed, by putting soft clay round the stopper. except a small aperture, which is left to allow the sandover or glass-gall to escape. This substance consists of those salts that are contained in alkalies purified in the common mode, and which have no affinity for silex, and are thrown up to the top. From the glass, or metal as it is termed, being hotter at the back of the pot than it is at the mouth or front, a small declivity takes place on the surface of the glass, and if the pot is full to the brim or mouth, it will be a little higher at the back part, consequently the liquid sandover runs off. Flint glass requires about 48 hours to its complete fusion, although the furnace (Plate CCLXXV. Fig. 3. See Description of Plates) is carried to as intense a heat as possible. After it is *fine*, that is melted into liquid glass, and freed from all air-bubbles, preparation is made for the working of the glass. For this purpose the blower, in order to make a common wine glass, takes a hollow tube of iron about four feet and a half long, which he heats red hot at the one end. He then dips it into the liquid metal contained in the pot, and takes up a quantity of glass, and forms a hollow ball, as described in Sect. III. He then sits down on a chair with two long arms, to one

Flint Glass.

of which there is a plate of iron fastened to prevent the burning of the chair by the hot iron pipe and glass; for the operation must be done with the greatest quickness while the metal is hot. He rests the pipe across the chair arms, and, while he rolls it back and forward with his left hand, he with an instrument similar to a small pair of tongs, catches the solid metal at the end of the hollow ball and draws it out, at the same time giving it the shape required for the stalk of a wine glass; another blower is going on with the same process, and blowing a smaller ball; and after giving it a sharp cut at the end of the blowpipe, he quickly presses it against the point of the stalk of the glass in the other man's hand, to which it readily adheres as firmly as if there had never been a joint; and, by giving the pipe a smart stroke with a small piece of iron, it is separated from the small ball now attached to the stalk of the glass, which is instantly given to the finisher or workman, the others being called blowers or footmakers. This workman then makes the glass just hot enough to keep it from breaking, and sits down on his chair, and with a similar pair of tools, while rolling the pipe rapidly on the arms of the chair, he opens the ball at the stalk of the glass, and forms a foot. A boy then takes a small rod of iron, called a *ponty*, and dips it into the metal in the pot, takes out on the extremity of the rod a small portion of glass, thrusts it immediately against the centre of the foot, to which it instantly unites. The workman then with a piece of iron, which he wets with his mouth, touches the globe intended for the bowl of the glass with the wet part, which is still very hot, although so much chilled as to retain its shape, and this in a second or two cracks it round; and, by giving the pipe a gentle knock, it separates from it, and leaves an open uneven mouth, which the workman instantly heats, and with a pair of shears, clips the heated glass smooth and even in the mouth; but as the shears have put the glass off that circular form, he heats it again, and by a dexterous twirl and swing round his head, he, if an expert workman, gives it the desired shape to a mathematical exactnes, almost without the aid of any tools. The wine glass now finished and chilled a little, by giving the ponty a smart blow, the glass separates from the iron, and is carried by a boy with a long forked iron to the leer, or annealing furnace, where it is placed in a pan already heated for the purpose of annealing.

Method of making wine glasses.

The following is the composition of the finest flint glass: Fine white sand, 300 parts; red lead, or litharge, 200; refined pearl ashes, 80; nitre, 20; arsenic and manganese, a small quantity.

These, all mixed together with the utmost nicety, are termed a flint batch.

Flint glass for optical purposes.

The following results were obtained by M. Zeiher of St Petersburgh, respecting the optical effects of varying the proportions of the ingredients of flint glass.

	Proportion of red lead to flint.		Index of refraction.	Dispersion of the rays in comparison of crown glass.
	Red lead.	Flint.		
1	3	1	2.028	4800 to 1000
2	2	1	1.830	3550 to 1000
3	1	1	1.787	3259 to 1000
4	$\frac{3}{4}$	1	1.732	2207 to 1000
5	$\frac{1}{2}$	1	1.724	1800 to 1000
6	$\frac{1}{4}$	1	1.664	1354 to 1000

From this Table, it is obvious that a greater quantity of lead not only increases the refractive, but also the dispersive powers of the glass. When M. Zeiher mixed alkaline salts with his glass, he found that they diminished the other refraction, without making any change in the dispersion. He then obtained a kind of glass which had three times the dispersive power of crown glass, and a refractive power of only 1.61. See *Mem. Acad. Berl.* 1766, p. 150.

Cazalet's flint glass for telescopes.

M. Cazalet of Bourdeaux, has lately announced a method of making flint glass for telescopes free of all veins and imperfections. It consists of

Red lead, pure and sifted through silk,	100	parts.
Nitre, purified	50	
Very pure and white chalk	1	
Pure white sand	60	

The sand must be calcined and pounded in an iron mortar, and afterwards washed by ebullition with sulphuric acid, and then purified with muriatic acid. These ingredients are put into a platina crucible, capable of holding 12 ounces of flint glass, and then carried to a bottle glass furnace. After 36 hours, it will be melted, and is then poured into water, dried, and reduced to a fine powder. It is then washed and purified in the same manner as sand; again melted and thrown into water; and after being again pulverised and purified with acids, it is melted a third time, and at the end of 48 hours it is poured upon a warm plate of copper, upon which it is allowed to cool gradually. It will then be found free of all imperfections.

A number of interesting experiments on the manufacture of flint glass for optical purposes, has been made by M. D'Artigues. He always found that the excellence of the flint glass depended on the purification of the red lead; that the middle part of a large mass of glass was always the freest from veins; and that it is only good when it is manufactured on a great scale. The middle portion of the pot of glass is blown into cylinders, and afterwards opened into plates. See *Bulletin de la Société d'Encouragement*, N° 83.

Sect. VI. *On the Manufacture of Plate Glass.*

Plate

The materials for making plate glass must be of the finest quality. The principal ingredient is fine white sand, which is caused to vitrify by adding alkali and nitre, or salt, and sometimes other fluxes. The desirable qualities in plate glass are, that it shall be perfectly transparent and colourless, free from bubbles or specks in the casting. To attain this it must melt with a moderate degree of heat; for, without this quality, it is scarcely possible to have it cast so quickly, that it will not cool in some degree during the operation, and thus have specks. The best alkaline substance for the flux is soda extracted from the ashes of barilla by lixiviation. If pearl ashes are used, they should be purified by washing or dissolving them in water, in which the impurities will subside; and the clear liquor which is drawn off must be boiled down in iron pans, till, by the evaporation of the water, the clean ashes are obtained. Borax is very useful to facilitate the fusion, and also the running into plates. Lime has the same quality; but the quantity must be small, otherwise it will affect the transparency.

The composition recommended by the author of the *Handmaid to the Arts*, is 60 parts of white sand washed clean, 25 parts of pearl ashes, 25 parts of nitre, and 7

Plate Glass. Frit furnace.

of borax. To these are sometimes added a small quantity of lime and manganese, according to circumstances.

The sand and alkali, and also the lime and manganese, if any are used, are first well mixed together, and thrown into a reverberatory furnace, represented in section by Fig. 11, where A is the fire-place, situated between two circular ovens or domes B, upon the flat floors of which the materials are laid; and the flame rising from the grate being reflected down by the arched roofs, strikes upon the floors of the ovens with sufficient heat to nearly fuse the materials, and cause the sand to become very white by a semi-vitrification. This calcination is continued for five or six hours, and the materials are constantly stirred and turned over with an iron poker, to expose every part to the heat, until they cease to afford any vapour, or to undergo any farther change.

Furnace. Plate CCLXXVI. Figs. 12, 13.

A plan of the furnaces used by the French is given at Fig. 12. of Plate CCLXXVI. and a vertical section at Fig. 13, the same letters being used in both. The real furnace A, which contains the two large pots *a, a*, and two others on the opposite side, is surrounded by four other furnaces or ovens B, B, B, D, which proceed from the angles, and are heated by the flame of the same fire passing through flues *g, g*. The three ovens marked B, B, B are intended for burning the pots in which the glass is melted and refined, and also the cisterns into which it is put, to be conveyed to the casting tables. The fourth oven D is intended for heating the frit or material, previous to its being put into the pots to be melted down. The four ovens are all of the same form and dimensions, except that the openings *b, b, b* into the three first are larger than the mouth *d* of the latter: all these openings are closed by doors of bricks fitted in iron frames. The fire is made in the bottom of the great furnace at E, Fig. 13, being included between two sloping walls *e, e*, which form the benches or seats for the four pots; two pots *a, a* being placed upon each bench, and likewise two cisterns *m, m*, which are placed at the ends of each bench; and therefore, in the four angles of the furnace, the form of the arched roof FF is intended to reverberate the flame down into and upon the pots, to which it gives the greatest heat, and then passes off by the flues *g, g, g, g*, Fig. 12. into the four ovens B, B, B, D. The fuel is supplied through arches E at the end of the fire-place, which are of sufficient size to introduce a new pot when necessary; but when the furnace is at work, these arches are bricked up, except a small opening at the bottom. On each side of the furnace are three working holes *i, h, h*, to admit ladles, by which the glass is put into the pots *a*, or taken out and transferred to the cisterns *m*; and, in order to withdraw the cistern from the fire, a door or opening is made in the wall before each, as shewn at *l l*, Fig. 12.; and the dotted lines represent a flooring of iron plate at the level of the bench, upon which the cisterns are received when drawn out of the furnace, which is done by a large pair of forceps, Fig. 14. mounted upon wheels.

F. 14.

Pots.

The pots are placed in the ovens B. The flues which admit the fire into them, are provided with dampers, or sliding doors, which are closed until the pots are placed in the oven. The dampers are then opened very little at first, to admit the heat gradually, and avoid the danger of cracking the pots. The cisterns are made and baked in the same manner.

F.

The frit is mixed with the fragments of old glass, which are reduced to powder, by heating them in the oven D to redness, and throwing them into cold water. To this mixture of frit and glass is added the fluxes of nitre or borax, and the composition is baked for some hours in the oven D, until, by the commencement of the vitrification, the materials are reduced to a sort of thick paste. This is taken out of the oven in long ladles, carried to the mouth *i* of the furnace, and put into the great pots *a, a*, which are already heated. Here the great heat vitrifies, and changes the frit into glass. It requires a fusion of 36 or 48 hours to make fine and clear glass, and sometimes more. If it is found thick or opake like porcelain, the heat must be continued for a longer time, or a greater proportion of flux must be added; borax is the best for this additional flux. If it is found to be a perfect substance of glass, but coloured, manganese or the oxide of cobalt is put in. For this purpose, they are tied up in a thick paper at the end of an iron rod, and put down to the bottom of the pot. A mixture of arsenic and manganese is used at other times, according to the nature of the colour, which is intended to be corrected.

Fusion.

When the glass is completely vitrified, it is taken out of the pots in ladles, and poured into the cisterns which stand at the sides of the pots. The cisterns must be introduced into the furnace whilst they are hot, both to save time in heating them in the great furnace, and also to avoid the danger of cracking them by a sudden exposure to so great a heat. For this purpose, a cistern is taken from the oven B, in which it was baked, by drawing it with hooks to the mouth or door; and it is then seized by the tongs, Fig. 14, which are a very large pair of pincers, united by a joint pin *a*, fixed into the axletree of a pair of wheels *b*, upon which the whole runs. The beaks or jaws *d, d*, are properly adapted to receive the cistern between them; and, for this purpose, the cistern has a groove in each side. The opposite ends of the tongs have handles *e, e*, by which the men guide and direct the machine; and also a small arch *g*, with pin holes to make fast the tongs, when they have seized the cistern. Having taken hold of the cistern with this machine, by two men weighing on the handles *e, e*, they can readily take up the cistern off the floor of the oven, and by the wheels transport it to the furnace, into which they introduce it through the lower openings. If it is a cistern which has been used before, they take the opportunity of its being hot to clean out the old glass from its sides. The glass remains five or six hours in the cistern until the whole is brought to a white heat. The door at *l*, Fig. 12, opposite the cistern, is then removed, and the cistern withdrawn by the pincers, aided by long iron hooks. Being then carried to the casting table, represented in Fig. 15, it is taken up by a crane, and its contents poured out upon the table, upon which it spreads into a thin sheet.

Fig. 14.

Casting table. Plate CCLXXVI. Fig. 15.

The table AA is strongly framed in wood, and covered over with a thick plate of copper, made very smooth upon the surface. B is a heavy cylindrical roller of copper, which is used to roll over the fluid glass, and flatten it to the required thickness. To regulate this thickness, two iron rulers *a, a* are laid down upon the table, at such a distance as will include the width of the intended plate; and the thickness of the rulers is equal to that of the plate, because they bear up the roller to that distance from the surface of the table. The roller B has long projecting spindles at each end for two men to roll it along by; and that it may advance steadily, they are counteracted by two other men, who hold rods *c, c*, and regulate the advance of the roller.

The cistern D is taken up in a pair of tongs E, shewn separately in Fig. 16. They open and shut upon the

Plate Glass.

Operation of casting. PLATE CCLXXVI. Fig. 16. Fig. 17.

joint *c*, and are retained by an arch *x* with pin holes. At one end is a cross handle *f*, and at the other end two handles *g*, *g*. These tongs are suspended by four chains, from two levers *h*, *h*, which, as shewn in Fig. 17, are fitted on the ends of a bar of iron *i*, and through the centre of this passes a cylindrical iron pin *l*, which, at the upper end, has an eye to receive the hook of the crane rope, which takes up the whole, as shewn in Fig. 15. An iron plate *k* is fixed on the top of the pin, to preserve the rope from burning.

The operation of casting is performed before the mouth of the annealing oven, into which the glass plate is introduced immediately after casting. These annealing furnaces are arranged round the building, which has the great furnace in the centre, and the table is mounted upon wheels for removing it from one annealing furnace to another. The crane is also moveable as well as a tressel F, formed for the reception of the roller B, when it has travelled over the whole length of the plate. The roller B, which weighs 500 weight, is transported by a carriage on wheels. By these means, the table and all its apparatus can be very quickly prepared for use before any one of the annealing furnaces.

Fig. 15. Fig. 16.

The cistern being brought to the table Fig. 15, is set down at the side, and the tongs (Fig. 16.) being opened, the cistern is included between the blades, which are shut up and fastened. During this time the surface of the glass is skimmed, to remove any scum which may float at the top. By means of the crane the cistern is now drawn up, and conveyed over the table in the situation of Fig. 15. The two workmen, who govern the cistern by its handles *f* and *g g*, now incline it on the centres of the levers *h*, *h*, as shewn in Fig. 17, and pour out a stream of liquid glass upon the table AA. Just before the roller B, an iron ruler R, which is to form the end of the plate, retains the fluid matter from running off at the end of the table; and the workman who manages this by its long handle S, withdraws it as the matter flows forwards upon the table, so as to suffer it to extend itself over the whole table a moment afterwards. When the glass has completely covered the table, the roller B is advanced with great regularity and steadiness. Its great weight presses down and reduces the upper surface of the glass to the level of the side rulers *a*, *a*. In this operation, some glass will often be forced over the edge of the table, in which case it is received into troughs K, placed on the ground for that purpose. The roller having passed over the whole length of the table, is guided into the tressel F at the end. The plate of glass thus cast, is not suffered to remain longer upon the table than to cool itself, so far that it will not warp by its own weight, and it is then shoved off at the end of the table into the annealing furnace, before which the table is placed. This is done by a tool, Fig. 18, which has a very long handle for two or three men to push it forwards, and the cross end is made to receive the end of the plate. The rest of the men guide the plate sidewise with irons, and assist in placing it properly in the annealing oven, which does not require a particular description, as it so nearly resembles the oven used by bakers; but its dimensions must be sufficient to contain the largest glasses, which continue here baking in a moderate heat for fully 14 days, the heat being at last suffered to die away as gradually as possible. When quite cool, the plate of glass is withdrawn and carried to the magazine, where it is examined and cut square by a large diamond, fixed in a wooden handle, and attached to a block of wood to hold it in the proper position, to cut in the same manner as the cutter of a plane. This tool being drawn over the surface of the glass, cuts so far, that very slight blows with a sharp edged hammer on the opposite side of the glass will break it; and if the fracture is very rough, the irregularities are reduced by breaking them off with pincers.

Annealing. Fig. 18.

Squaring the plates.

Grinding.

The glass plate only requires to be ground and polished, which is performed by bedding the plate with plaster of Paris, upon a table covered with a large slate stone, and laying a smaller plate upon it, which is loaded with weights, and drawn backwards and forwards over the great plate: Sand plentifully moistened with water, grinds away all the prominences of the glasses, until the surfaces of both plates become plane or even. The upper or moveable glass is defended by cementing it to a strong plank, and upon the back of this the weights are laid, which cause the pressure. To give the workmen hold of the plate, a large light coach wheel is placed upon a pin, which projects upwards from the centre of the plank, and two or four workmen take hold of the rim of the wheel on opposite sides, alternately pushing and pulling it in all directions. As this action is transferred by the wheel to the centre pin, the plate is at liberty to move in any direction; and the workmen must take care to vary this every instant, to prevent the glasses grinding each other into furrows or channels. The table upon which the grinding is performed, is surrounded by a ledge of about two inches high, to retain the sand and water with which the lower plate is covered. When great nicety is required, the upper plate should be changed for another upper plate which has been ground on a different table; because two plates may grind themselves to a portion of a sphere, one becoming concave and the other convex; but by changing the grinding plates so as to bring two convex or two concave surfaces together, they will correct each other. When the plates are small, the wheel is not used to move the upper one; but the board to which the upper glass is cemented has four small handles projecting up from it, by which the workmen take hold. When, by the grinding, a perfect surface is obtained, a finer sand is used to produce a smoother surface. A succession of emeries, of different degrees of fineness, are used after the fine sand, and with these the operation of grinding is finished.

Polishing.

The grinding of both sides being completed, the glass is polished by bedding it with plaster upon a flat table, and rubbing on the surface with the polisher, which is a block of wood, covered on the lower side with woollen cloth. The workman keeps it supplied with fine polishing powders, as tripoli and putty; at first using the coarsest, and, towards the end of the operation, the finest. The block of the polisher for large plates is about ten inches square, and has two handles projecting from it. But to regulate the pressure, a springing pole is put upon the back of the block, and being bent to a curve, is supported in the ceiling of the workshop. When both surfaces are polished, the glass is laid upon a table covered with a cloth, and any deficiences are removed, by a small polisher applied by the pressure of the hand without a spring.

In the plate glass manufactory at Ravenhead in Lancashire, which we have had occasion to examine, the operation of grinding and polishing is performed by appropriate machinery driven by two large steam engines. There is nothing very peculiar in the nature of this machinery, excepting the ingenious contrivance for changing the path of the polisher in advancing and returning over the plate of glass. See ENGLAND, vol. ix. p. 10.

Coloured Pastes.

Sect. VII. *On the Formation of Coloured Pastes.*

In our article on Gems, p. 128, we have already had occasion to consider the subject of coloured pastes, or fictitious gems. We have described the method of Fontanieu of making a colourless base, and afterwards communicating to it any particular tint by metallic oxides; but as we have followed that ingenious author only in so far as his experiments relate to the imitation of precious stones, such as the oriental topaz, the amethyst, the hyacinth, and the beryl, we shall here resume the subject, and give an account of his method of producing other colours.

Method of obtaining colours from different metals.

1. From *Gold*.—To obtain the purple colour known by the name of precipitate of Cassius, M. Fontanieu employed the following process.

Distil in a glass retort, placed in a bath of ashes, some gold dissolved in aqua regia, made with three parts of nitrous, and one part muriatic acid; when the acid is passed over, and the gold contained in the retort appears dry, leave the vessel to cool, then pour it into some new aqua regia, and proceed to distil as before. Replace the aqua regia twice upon the gold, and distil it. After these four operations, pour by little and little into the retort some oil of tartar per deliquium, which will occasion a brisk effervescence; when this ceases, distil the mixture till it becomes dry, and then put some warm water into the retort. Shake the whole, and put it into a cucurbit, when a precipitate is deposited, the colour of which is either brown or yellow. After having washed this precipitate, dry it.

2. From *Silver*.—The oxide of silver being vitrified, produces a yellowish-grey colour. This oxide enters only into the composition of the yellow artificial diamond and opal. Mr Fontanieu introduces it into the base in the form of horn silver (*luna cornea*). In order to prepare it, he dissolves the silver in nitrous acid, and afterwards pours into it a solution of sea salt: a white precipitate is obtained, which, being washed and dried, melts easily in the fire, and is soon volatilized, if not mixed with vitrifiable matter.

3. From *Copper*.—The oxide of copper imparts to white glass the finest green colour; but if this metal be not exactly in a state of oxidation, it produces a brownish-red colour.

4. From *Iron*.—Though it is commonly believed that the oxides of iron communicate a very fine transparent red colour to white glass, M. Fontanieu could only obtain from it a pale red, a little opaque. The oxide of iron he employed, was in the proportion of the 20th part of the base. There are various ways of preparing the oxide of iron called crocus martis. In general it is necessary that this metal be so far oxidated that the magnet ceases to attract it. Thus one may use the scales of iron found upon the bars of furnaces, which serve to distil aquafortis. By digesting filings of steel with distilled vinegar, then evaporating and replacing the vinegar ten or twelve times upon these filings, and drying them alternately, an oxide of iron is obtained, which must be sifted through a silk sieve, and then calcined. The oxide of iron, thus obtained by the vinegar, only introduced into the bases a green colour inclining to yellow. By the following process, one of the finest red colours is obtained:—Let an ounce of iron-filings be dissolved in nitrous acid, in a glass retort, and distilled over a sand-bath to dryness. After having replaced the acid or the dry oxide, and re-distilled it a second and a third time, it is then edulcorated with spirits of wine, and afterwards washed with distilled water.

5. From *Cobalt*.—The oxide of cobalt is made use of for introducing a blue colour into glass: but as this metal is rarely free from iron and bismuth, it is first necessary to separate them from it. This is done by calcining the cobalt ore in order to disengage the arsenic; and next distilling the oxide in a retort with sal ammoniac, when the iron and the bismuth are found sublimed with this salt. The distillation must be repeated with the sal ammoniac till this salt is no longer coloured yellow. The cobalt which remains in the cornute is then calcined in a potsherd, and becomes a very pure oxide, which being introduced into the base, in the proportion of a 900th part, gives it a very fine blue colour.

6. From *Tin*.—The oxide of tin, which is of a white colour, renders opaque the glass with which it is melted, and forms white enamel. For this purpose, calcine the putty of tin; then wash and dry it, and sift it through a silk sieve. Take six pounds of the second base, (See Gems, p. 128.) the same quantity of the calcined putty of tin, and 48 grains of manganese.

7. From *Antimony*.—Antimony is only susceptible of vitrification in a certain state of oxidation, and then it produces a reddish hyacinth-coloured glass; but if the antimony be in a state of absolute calx, such as the diaphoretic antimony, then it is no longer vitrifiable, and may be substituted for oxide of tin, to make white enamel.

8. From *Manganese*.—Employed in a small quantity, this metallic substance renders the glass whiter; a larger quantity produces a very fine violet colour, and a still larger dose renders the glass black and opaque. There are two ways of preparing manganese. The most simple consists in exposing it to a red heat, and then quenching it with distilled vinegar: it is then dried and powdered, in order to pass it through a silk sieve. The other method of preparing the manganese proper to furnish a red colour, is described by Blancourt, who calls it "fusible manganese." Take of manganese of Piedmont, one pound; torrefy and pulverize it; then mix it with a pound of nitre, and calcine the mixture during 24 hours; afterwards wash it repeatedly in warm water, till the water of the leys has no longer any taste; dry the manganese, and mix with it an equal weight of sal ammoniac; levigate this mixture on a slab of porphyry, with sulphuric acid, diluted with water to the strength of vinegar. Dry the mixture, and introduce it into a cornute: distil by a graduated fire; and when the sal ammoniac is sublimed, weigh it, and add to the mixture an equal quantity. Then distil and sublime as before, and repeat the operation six times, being careful at each time to mix the sal ammoniac and the manganese upon the porphyry with diluted sulphuric acid.

Compositions to imitate the precious stones.

Compositions.—To make the *white diamond*, take the Mayence base. This base is very pure, and has no colour. It is similar to the beautiful white paste, so generally known by the appellation of *Strass*.

For the *Yellow Diamond*.—To an ounce of the fourth base, add, for colour, 24 grains of horn silver, or ten grains of glass of antimony.

For the *Sapphire*.—To 24 ounces of the Mayence base, add two drachms 46 grains of the calx of cobalt.

For the *Oriental Ruby*.—1. To 16 ounces of the Mayence base, add a mixture of 2 drachms 48 grains of the precipitate of Cassius, the same quantity of crocus martis prepared in aquafortis, the same of golden sulphur of antimony and of fusible manganese, with the addition of two ounces of rock crystal: or, 2. To 20 ounces of the base made with flints, add half an ounce of fusible manganese, and two ounces of rock crystal.

For the *Balas Ruby*.—1. To 16 ounces of the May-

Staining of Glass.

ence base, add the above colouring powder, but diminished a fourth part: or, 2. To 20 ounces of the base made with flints, add the same colouring powder, but with a fourth less of the manganese.

For the *Brazil Topaz.*—To 24 ounces of the second or third base, add, for colour, 1 ounce 24 grains of the glass of antimony, and 8 grains of the precipitate of Cassius.

For the *Saxon Topaz.*—To 24 ounces of the first or third base, add six drachms of the glass of antimony.

For the *Emerald.*—1. To 15 ounces of either of the bases, add, for colour, one drachm of mountain blue and six grains of glass of antimony; or, 2. To an ounce of the second base, add, for colour, 20 grains of glass of antimony, and three grains of calx of cobalt.

For the *Common Opal.*—To an ounce of the third base, add, for colour, 10 grains of horn-silver, two grains of calcined magnet, and 26 grains of an absorbent earth.

Sect. VIII. *On the Art of Staining Glass.*

Glass Staining.

Glass staining is the method of ornamenting glass for the windows of churches, or other edifices, by pictures or designs painted in colours, which are made to penetrate into the substance of the glass, by means of fire. Stained glass is frequently called painted glass, but the distinction should always be preserved between the painting with transparent colours upon a surface of glass, and the staining or tinging of the glass itself, with the colours which produce the picture. As pictures in coloured glass are always placed between the spectator and the light, they have an effect altogether different from any other species of painting; and, from the transparent brilliancy of the colouring, the spectator is often struck with admiration, independent of any excellence in the subject of the picture.

Transparent colours painted on glass, either in water or varnish, can never attain the brilliancy of the coloured glass, but from the great difficulty of staining certain colours, it is very common to find, in modern windows, part of the colours painted on the surface, whilst the large tints are stained.

It was not until the 15th century that the stained glass was made to produce the effect of strong lights and shades; but respecting the methods employed by the painters of those superb specimens which we find in cathedrals, we are wholly uninformed; and our information is now chiefly drawn from a Memoir of M. Leviel, published in the *Description des Arts et Metiers*, vol. xiii. This gentleman was himself a painter on glass, and the only one of eminence who has written upon the art.

The glass upon which it is intended to paint should be very hard, without spots, or any colour. Crown window glass is the best; for cast or plate glass has borax in its composition, which would make the colours to run or spread. When the design is too large to be contained on a single piece of glass, several must be fitted to one another, and a bed of some resinous cement prepared, upon which they can be readily put together, and held on one flat surface whilst painted, with proper spaces for the lead frames, and yet be readily separated, to subject the pieces separately to the fire.

In arranging the pieces of glass which are to be painted, care must be taken to dispose the joints so that they may do the least injury to the design by the opacity of the lead frames, by which the pieces must be joined together, in order to form a large window.

The design which is intended to be painted upon the glass, must be accurately drawn upon a sheet of paper in outline; or, if necessary, in its proper colours. In this species of painting, the artist works quite in the dark as to the effect of his picture, because the colours are produced by the fire; and when the preparations are laid on the glass, they are either colourless, or perhaps have colours quite different from that with which they will ultimately stain the glass.

Method of laying on the colour.

The design drawn upon the paper, is placed beneath the plate of glass, or upon the bed, when several separate pieces are used. The upper side of the glass is then brushed or sponged over with a fine clear gum-water. This, when perfectly dry, forms a surface proper to receive the colours, without danger of their running or spreading beyond their intended limits, as they would do if laid upon the smooth surface of the glass. The first operation, is to draw upon the glass with a fine pencil, all the lines which are necessary to produce the shades, and to mark the outlines. This is usually done in a black colour, or at least in some deep colours, such as brown, blue, or green, and sometimes red. In laying on these, the artist is guided by the same principles as the engraver, when he produces the effect of light and shade, by dots, lines, or hatches; and he employs that colour to produce the shades, which will best accord with the colour which is intended afterwards to be laid on; but, in general, black is used in the outline for all the deeper shades. When this is finished, the whole picture will appear represented in lines or hatches similar to an engraving, finished up to the highest effect possible; and afterwards, when it is perfectly dry, the colours are laid on by means of larger pencils. Each colour is spread upon the part of the design which requires it; as the flesh colour upon the faces of the figures, the green for trees, blue for the sky, &c.; but in doing this, the artist labours under the disadvantage of being unable to see the effect of his work, until it has been subjected to the fire. He therefore avails himself of a number of trials made upon small pieces of glass, which he keeps as specimens of the effect of the different colours, properly numbered, to correspond with the preparations which he employs for colouring: he must, therefore, search among these specimens for the tint, and apply the proper preparation.

In laying on the colours, it must be observed, that some preparations which produce beautiful colours, are liable to run or mix with those which are adjacent to them, so as to confound the outlines of each respective colour, by producing a mixture of the two. This is a serious difficulty; the artist must refer himself to his trials; and when he finds it necessary to lay two adjoining colours which will run together, he must lay one of them on the back of the glass. The few principal colours, of which we shall presently give the preparation, are all fast colours such as will not run, except the yellow, which must therefore be laid upon the opposite side. It should be observed, that those colours which will mix or run, are equally useful with the others when applied to produce compound tints; but the artist should not attempt to use them without being well acquainted with their properties, otherwise he may by a very small tint of improper colour destroy all his work.

After colouring, the artist proceeds to produce the very light parts of his subject, by taking off the colour from them by a goose quill, cut like a pen without a slit. By working this upon the glass, he removes the colour from the parts where the lights should be the strongest; such as the hair, eyes, the reflection of bright surfaces, and light parts of draperies. The blank pen may be either employed to make the lights by lines, or hatches and dots, as will be most suitable to the subject, and the part where they are required, in the same manner as the black was used to produce the shades.

Staining of Glass.

The glass is now ready for burning, to fix the colours, or rather stain the glass, by the preparations which have been laid upon it. The furnace most proper for the purpose, is similar to that used by assayers or enamellers. It consists of a muffle, or arch of fire clay or pottery, so placed over a fire-place, and surrounded by flues, as to receive a very considerable heat, but in the most equable and regular manner throughout the whole; for if this is not attended to, some parts of the glass will become too much stained, before the colour takes place in others. The mouth of the muffle, and the entry to the fire through which the fuel is supplied, should be on opposite sides, to prevent as much as possible the entry of dust into the muffle; and the mouth of the muffle should be closed by iron folding-doors, with small openings or peep holes through them, to allow the artist to observe the progress of the burning, by withdrawing small trial slips of glass, which are stained with the principal tints employed in the picture.

Method of burning the colours by fire.

The muffle must be made of very good fire clay, flat at the bottom, and only five or six inches high, being so much arched at the top as is necessary to render the roof strong, and resist falling in by its weight when heated; the muffle must be so close on all sides, as to admit no smoke or flame. Before the plate of glass is introduced into the furnace, a bed is prepared upon the bottom of the muffle. For this purpose, lime is used. It must be previously burned, so as to yield no more gas, and then reduced to a fine powder. In this state, the bottom of the muffle is strewed half an inch deep, and levelled with a feather. The glass is then introduced, and sometimes the muffle is filled up with other glasses laid above the first, having beds of lime between each. The fire is lighted after all is shut up close, and the heat is raised very gradually at first, lest the glass should be broken by it; but after the fire has attained its full heat, it is continued for three or four hours, more or less, according to the appearances observed upon the trial slips of glass, which are withdrawn for that purpose; and the yellow colour is principally attended to, as that is found the best test for the others. The operation of burning being thus finished, the fire is extinguished, or rather suffered to die away, and the heat to subside gradually, to prevent the glass becoming brittle, as it would do without this precaution; for the heat when at the greatest, must be sufficient to make the glass very flexible, as is seen by the trial glasses.

Method of preparing the colours.

We shall conclude this Section with the preparations for a few principal colours.

Preparation for staining glass of a flesh colour.—Take one ounce of minium, and two ounces of red enamel, of that kind which is called Venetian glass enamel; pound them to a fine powder, and grind it with brandy upon a hard stone. This mixture, when slightly baked, will produce a fine flesh colour.

Black colour.—Take 14½ ounces of those scales of iron, which are found round the anvil of a smith's shop; mix with it two ounces of white glass, an ounce of antimony, and half an ounce of manganese; pound and grind them together with strong vinegar. Brilliant black may also be obtained, by a mixture of blue with the oxides of manganese and iron.

Another black colour.—Take equal parts of iron scales and of small beads or fragments of glass; pound them exceedingly fine, and grind them to a consistence to work with a pencil.

Another black is made from three parts of glass of lead, two parts of the scales of copper, and one of antimony, treated as before.

For brown.—Take one ounce of white glass or enamel and half an ounce of good manganese; grind them first very fine with vinegar, and afterwards with brandy.

Method of preparing the colours.

Red, rose, and brown colours, are made from red oxidated iron prepared with nitric acid. Their flux is composed of borax, sand, and minium, in small quantity.

For red.—Take one ounce of red chalk pounded, and mix it with two ounces of white hard enamel, and a small proportion of the scales of copper which fall off when it is much heated in a forge. This will make a very good red, but requires trial if it will support the fire; and if not, add more of the scales of copper.

For another red.—Take one part of red chalk, which is too hard to write with, one part of white enamel, and a fourth of orpiment; grind them together with vinegar. This is a strong poison.

Or a red may be composed of rust of iron, glass of antimony, and yellow glass of lead, such as is used by potters, these three in equal quantities; to which add a little silver, calcined with sulphur. This composition ground fine, produces a very fine red colour on glass.

When the oxide of copper is used to stain glass, it assumes a bright red or a green colour, according as the glass is more or less heated in the furnace.

Bistres and brown reds may be obtained, by mixtures of different proportions of manganese, brown oxide of copper, and the oxide of iron called umber. They are previously fused with their solvents.

For green.—Take two ounces of brass burned until it becomes a calx, two ounces of minium, and eight ounces of fine white sand; reduce them to a fine powder, which inclose in a well luted crucible, heated in an air furnace with a strong fire for an hour. When this mixture is cold, pound and grind it in a brass mortar. Green may often be advantageously obtained, by a yellow on one side, and a pale blue on the other.

For a fine yellow colour.—Take fine silver in thin plates, and dissolve it in nitrous acid, and precipitate it; mix the precipitate with three times the quantity of pipe-clay, well burnt, and pounded. With this the back of the glass must be painted, or it will run into the other colours.

Another yellow can be made by melting silver in a crucible, and whilst in a state of fusion throw into it powdered sulphur in small quantities, and stir it up until the silver is reduced to a calx. Grind this upon a stone, and mix with it as much antimony as the silver, and some yellow ochre, which has been previously calcined in a crucible, until it is changed to a red brown colour. Work all these together with urine, and paint it on the back of the glass.

Another yellow.—Cut thin plates of silver into small pieces, and put them into a crucible with sulphur and antimony. When melted, throw out the contents into clear water, and afterwards pound and grind the preparation, so that it will work with a pencil.

A pale yellow.—Fill a crucible with thin plates of brass, with beds of sulphur and antimony in powder. Burn it till it ceases to smoke, and throw it hot into water. Reduce this to fine powder, and having added six times as much yellow ochre burnt, mix it with vinegar.

A fine yellow, equal in beauty to that of the ancient painters, has been discovered by M. Meraud. He employs muriate of silver, oxide of zinc, white clay, and the yellow oxide of iron. These colours are applied to the glass simply ground, and without flux.

Blue colour.—Take mountain blue, and beads of glass, equal portions; grind them whilst dry to an impalpable powder, and proceed as with the others.

In general, the same colours as are used for painting on porcelain, and many of those used in enamel paint-

Methods of cutting Glass.

ing, may be employed with success upon glass. But after all, the painter must employ no colour without making trial of it upon the slips of glass. The colours in general become more faint by longer continuance in the fire, because they sink deeper into the glass. But every preparation varies in this respect. All the colours are mixed up for the pencil with gum water in sufficient quantity to make them work properly.

Brongniart's experiment on the colours from metallic oxides.

A number of very interesting experiments on the colours obtained from metallic oxides, and fixed by means of fusion either on porcelain or glass, have been made by M. Brongniart, director of the royal porcelain manufactory at Sevrés. In the preceding list, we have already given some of his results; but in our article PORCELAIN, which that celebrated mineralogist has undertaken to furnish for this work, our readers may expect the fullest and most recent information on the subject.

SECT. IX. *On the different Methods of Cutting Glass.*

Method of cutting glass.

A plate of glass may be cut into any shape, either by the diamond, or by a bar of red hot iron.

With the diamond.

A late and intelligent writer (see Parkes' *Chemical Essays*, vol. v. p. 208) remarks, that there is something very mysterious respecting the action of the diamond in cutting glass: and he informs us, that if a sheet of glass, cut with a diamond, be examined before it is actually broken into its intended divisions, it will be seen that it is entirely cut through except at the *uppermost* surface. If this statement be correct, the operation of the diamond might well be pronounced mysterious; but we can assure our readers, that we have had occasion to examine the fissures or clefts produced by a diamond, and we have always found, that they commence on the upper side of the glass where the diamond is applied, and extend gradually downwards. This may be distinctly seen, by reflecting light from the separated faces, and the progress of the fissure downwards will be marked by the change produced upon the reflected light. We conceive, therefore, that there is no mystery whatever in the action of the diamond. A piece of soft and smooth wood will cut a plate of coagulated isinglass without any difficulty; a piece of steel will, with the same ease, cut a plate of wood; and, in like manner, a diamond will cut a plate of glass with the same facility, because it is as much harder than the glass, as the wood is harder than the isinglass, or as the steel is harder than the wood.

In order that the wood may cut the isinglass, or the steel the wood, the cutting point must be smooth, otherwise the surfaces to be cut will be torn up or scratched, instead of being really divided. For the same reason, the diamond must have a smooth natural point, or solid angle; for if a piece broken from a diamond is employed, it will only scratch the glass.

Mr Atwood, in a communication to Mr Parkes, informs us, that a good cutting diamond should be of a regular rhomboidal form, or have one regular smooth edge and rhomboidal point. The least deviation of the diamond from a particular position and inclination will prevent the cut from taking place. The workman, who is guided altogether by his ear, judges by the peculiar creaking of the glass; and if he does not hear this particular noise, he varies the position of the diamond till it occurs, and then draws it onwards. The diamond apparently wears down at the cutting point by long use, though it will last an ordinary glazier for many years.

"When the cut is perfectly good," says Mr Atwood, "it should be an *internal* fracture, unaccompanied with any scratch, or any visible impression on the surface whatever; for in proportion as any such superficial injury is produced, the completeness of the internal fracture is diminished. This fracture, therefore, which is called a *cut*, from its resemblance thereto in its effects, as also in the similarity of its appearance to a real cut, produced on any other substance by a sharp edged instrument, but which has closed again, (the expression being further countenanced, by the sharp form of that part of the diamond which comes in contact with the glass,) is really no cut at all, nor does the diamond so much as enter the surface." If this reasoning be just, it will follow, that a good diamond is not capable of making any impression upon the surface of a plate of glass over which it is drawn, and that it acts where it is not, and does not act where it is. It would require singular ingenuity to support such paradoxes.

Shaw's patent diamond.

Mr Shaw, an ingenious watchmaker in Leicestershire, being desirous of giving some assistance to a relation of his own, who was a glazier, and who, by a paralytic affection, was unable to pursue his trade, invented a method of fitting up a diamond, by which any person can cut glass as perfectly as the most experienced glazier. This invention was made about a year ago, and its advantages have been secured by a patent. "By the use of one of these instruments," says Mr Atwood, "a person not at all accustomed to a diamond, may produce a perfect cut over a table of glass so uneven in its surface, that the most skilful workman, with a common glazier's diamond, would not be able to produce a cut of any kind upon it. This consists in giving the diamond perfect play, and at the same time affording it such guide and support, as effectually prevent it from being affected by the unsteadiness of the hand, or unevenness of surface in respect of its inclination to the plane of the table; whereby the diamond, being well set or mounted in its carriage, becomes equally certain in the hands of every person." Parkes' *Chemical Essays*, vol. v. This patent diamond is represented in Plate CCLXXV. See the description of this Plate at the end of the volume.

Method of cutting glass by hot iron.

When a plate of glass is very thick, it cannot be easily cut by the diamond; but the same effect may be produced by the proper application of a hot iron. The part of the glass where the cut is to commence must be marked by a file, and a hot iron must be applied to the place, and held a little below the groove which the file has made. In a few minutes the glass will give a crack, and the iron must be instantly removed. The iron must be again applied a little below the termination of this crack, sometimes one-tenth or two-tenths of an inch distant from it, and in the line in which the cut is to be made, and the crack will advance in the direction of the iron. By again applying the iron in a similar manner, the crack may be conducted in any required direction. If the glass is to be cut in the form of a curve, then the hot iron must always be held very near the termination of the crack, in order that it may advance by short steps. The fissure is often most complete on the side of the glass where the iron is applied, and it is sometimes advisable to apply the iron to the opposite side. By this means, we have often cut plates of glass four-tenths of an inch thick with the utmost accuracy.

Glass may also be cut under water by a pair of scissars, but in an imperfect manner. If the operation were performed under a thick viscid fluid, the effect would be still more complete.

SECT. X. *Physical Properties of Glass.*

There is perhaps no substance to which the progress of the arts and the sciences has been so much indebted as glass; and there is none which has contributed more to the splendor and the comfort of civilized society.

We do not propose to enter at present into any detailed account of the electrical, the chemical, or the optical properties of glass, which the reader will find fully discussed under our treatises on CHEMISTRY, ELECTRICITY, and OPTICS. We intend merely to enumerate some of the physical properties which either distinguish it from other bodies, or which could not with propriety be noticed under other heads.

Glass possesses the remarkable property of suffering no change by the application of the most intense heat. The effect of great heats is only to melt the glass, or to dissipate it in vapour; but as long as any of the glass remains, it still preserves its transparency, and other distinguishing properties. The conversion of glass into porcelain by long continued cementation with other materials, happens only to that particular kind which is made of alkaline salt and sand.

Of all the solid substances whose expansibility has been accurately examined, glass possesses the property of being the least affected by heat and cold. Its expansion, according to General Roy, with an increase of heat equal to 180° of Fahrenheit's thermometer, is only 0.000776, while that of platina is 0.000856, and that of hammered zinc 0.003011. On account of this property, glass is peculiarly fitted for containing fluids whose expansions are under examination, as its own change of form may in ordinary cases be neglected. For the same reason, it is better than any other substance for the simple pendulum of a clock. See EXPANSION, p. 254, 255.

The great ductility of glass is one of its most remarkable properties. When heated to a sufficient degree, it may be moulded into any possible form with the utmost facility, and it can be drawn out into the finest fibres. The method of spinning glass is very simple. The operator holds a piece of glass over the flame of a lamp with one hand; he then fixes a hook to the melted mass, and withdrawing it, he obtains a thread of glass attached to the hook. The hook is then fixed in the circumference of a cylindrical drum, which can be turned round by the hand; and a rotatory motion being given to the drum, the glass is drawn in the finest threads from the fluid mass, and coiled round the cylindrical circumference. M. Reaumur supposed, with great probability, that the flexibility of glass increased with the fineness of the threads, and he therefore conjectured, that if they were drawn to a sufficient degree of fineness, they might be used in the fabrication of stuffs. He succeeded in making them as fine as a spider's web, but he was never able to obtain them of a sufficient length when their diameter was so much reduced. The circumference of these threads is generally a flat oval, about three or four times as broad as it is thick. By using opake and transparent glass of different colours, artists have been enabled to produce the most beautiful ornaments.

When glass has been annealed or cooled slowly, it is able to resist very considerable force without being broken; but when it has been cooled suddenly, either by exposure in the open air, or by immersion in water, it exhibits very remarkable properties. These properties are shewn in what are called Prince Rupert's drops, and glass cups.

The phenomena and the formation of Prince Rupert's drops, and the theory of their explosion, have already been explained in our article ANNEALING. The earliest experiments upon glass tears were made in 1656, both in London and Paris; but it is not certain in what country they were invented. They were first brought to England by Prince Rupert, third son of the Elector Palatine Frederick V. and the Princess Elizabeth, daughter of James I. and experiments were made upon them by the Right Hon. Sir Robert Moray, in 1661, by the command of his Majesty. An account of these experiments is to be found in the Registers of the Royal Society, of which he was one of the founders.

Physical Properties. Prince Rupert's drops, or glass tears.

The following experiments have been recently made on these drops by Dr Brewster, and published in the *Phil. Trans.* for 1814, Part II. and 1815, page 1.

Dr Brewster's experiments on glass tears. PLATE CCLXXIV. Figs. 1, 2.

"Having ascertained that glass melted and suddenly cooled, possessed all the optical properties of crystallized bodies, I was anxious to determine if it exhibited any other marks of a crystalline structure. Upon examining the bulb of an unannealed drop AB, Plate CCLXXIV. Fig. 1. by holding it between the eye and a sheet of white paper, I observed a number of lines converging to the vertex *a*, as represented in Fig. 2. This structure was more or less apparent in every bulb which I examined, but never appeared in annealed drops. It exhibited itself even on the surface, and seemed to be owing to an imperfect crystalline form, yet it was not marked with sufficient distinctness to entitle me to consider it as the effect of crystallization. In one specimen, however, where the bulb AB remained unshattered, while all the rest of the drop was burst in pieces, the lines diverging from *a* were most distinctly marked, and the bulb was actually cleft in the direction of these lines, so as to produce a real dislocation at the *surface* of the drop. We may therefore consider the drop as possessing that crystalline structure which gives cleavages in the direction of lines diverging from its apex. By examining the fragments of the drop after it is burst, another cleavage is distinctly perceptible: it is parallel to the outer surface, and produces a concentric structure like that of an onion. A third cleavage is visible in the direction of lines inclined to the axis of the drop, as represented in Fig. 3; but it is not so distinct as the two first. These cleavages are represented in section in Fig. 4.

Figs. 3, 4.

As it appeared probable that the glass drops possessed a less degree of density than if they had been annealed, I attempted to ascertain this point by measuring their specific gravities in these two different states. The unannealed drops, however, had always one or more vacuities, such as E, F, Fig. 1. so that I was able to obtain only approximate results by estimating the magnitude of these cavities.

The following specific gravities were measured by my friend Mr Jardine, with his usual correctness.

Unannealed flint glass drop, Fig. 1. . . . 3.20405

Annealed flint glass from the same pot . 3.2763 .

In order to correct the first of these measures, I moulded a piece of bees' wax into the size and form of the cavities E, F, Fig. 1. by examining them under a fluid of the same refractive power as the glass. I then formed the two pieces of wax into a sphere, and thus ascertained, with tolerable accuracy, the weight of a quantity of water of the same magnitude as the cavities. By this means, I obtained the corrected specific gravity of the unannealed drop 3.264.

With the view of obtaining some farther insight into the structure of the crystallized drop, I brought the one, represented in Fig. 1, nearly to a red heat. Its shape suffered no change at this temperature, and the vacuities E, F, still remained; but it had now lost the faculty of depolarisation, and the particles had therefore

Physical Properties.

Dr Brewster's experiments on glass tears.

assumed a new arrangement. By increasing the temperature, the cavities E, F, disappeared: the lower side of the drop, upon which it rested, was indented by the bottom of the crucible; but it had in no other respect lost its external shape, the appearance of the cleavage in Fig. 2. remaining unaltered. In this state Mr Jardine measured the specific gravity of the drop, and found it to be 3.278, which is almost exactly the same as that of the annealed drop.

In order to observe the manner in which the cavities disappeared, I suspended one of the drops by a wire, and viewed it with a telescopic microscope when exposed to a strong heat. Soon after the drop became red hot, the cavities gradually contracted, and at last vanished, the centre of the cavity being the part that was last filled up. The drop had begun to melt at its smaller extremity, but the lines represented in Fig. 2. were still visible, the heat probably not having been sufficiently intense to affect its superficial structure.

As the specific gravity of the crystallized drop is nearly the same as that of the annealed drop, the cavities must be produced by the contraction which the internal part experiences in cooling, for the sudden induration of the outer layer prevents the contraction from taking place in any other way. The manner, too, in which the cavities disappear, is a complete proof that they contain no air, and hence we may consider their magnitude, which increases with the size of the drop, as a measure of the contraction which the glass undergoes in its transition from the temperature at which it melts, to the ordinary temperature of the atmosphere. See Expansion, p. 255.

I am informed by Dr Hope, that he has obtained unannealed drops of crown glass, in which there were no vacuities, and that they all burst spontaneously in the course of a few months." *Phil. Trans.* 1815, p. 1.

Unannealed glass cups. Plate CCLXXIV. Fig. 5.

The unannealed glass cups, which we have mentioned under Annealing, are represented in Fig. 5. Plate CCLXXIV. The lower end B is made very thick, and the bodies, such as a musket ball or a fragment of flint, are dropped into the mouth of it at A. The stroke of the ball upon the thick bottom will produce no effect, while the blow of the small fragment of flint will burst the cup with great violence. The following are the dimensions of the cup represented in Fig. 5:—Length 4½ inches; width at top I; width at bottom 1$\frac{1}{10}$; thickness of glass at top $\frac{1}{10}$; greatest thickness of glass at bottom $\frac{4}{10}$.

The bursting of these cups is effected, when they are even three inches thick at the bottom. In an experiment made by Dr Littleton upon a cup of this magnitude it resisted a blow from a musket ball let fall from a height of nearly three feet, while it was instantly broken by a shiver of flint weighing only two grains. An account of numerous experiments made with these cups will be found in the *Philosophical Transactions* for 1745, vol. xliii. No. 477, p. 505.

Unannealed hollow balls.

The Right Hon. Sir Robert Moray discovered that hollow balls made of unannealed glass, with a small hole in them, would be burst in pieces by the heat of the hand alone, by stopping up merely the small hole with the finger. This obviously arose from the pressure of the expanded air on the interior of the ball.

Rotatory motion of glass tubes.

About the year 1740, when Mr C. Orme, of Ashby de la Zouch, was drying the glass tubes for his diagonal barometers, he observed that they had not only a rotatory motion about their axis, but also a progressive motion towards the fire. These tubes were about four feet long, and half an inch thick, and when placed about 6 or 8 inches from the fire, they moved "not only progressively, but about their axis along the side wall against which they leant, and along the front wall of the chimney, which made an obtuse angle with the other, so that they seemed to move up hill, and against their weight." The Rev. Granville Wheler, to whom Mr Orme shewed these experiments, repeated them with great care, and found that the experiment succeeded best with a moderate fire, and when the tubes were about 20 or 22 inches long, and about one-tenth of an inch in diameter, when they had in each end a pretty strong pin fixed in a cork as an axis, and when they were supported on other glass tubes of nearly the same diameter. When the progressive motion of the tubes was stopped by an obstacle, they still revolved about their axis. When the tubes were placed horizontally on a large fragment of plate glass, instead of advancing towards the fire as formerly, they moved from the fire, and about their axis in a direction contrary to what they had done before. In this case, as formerly, the tubes receded from the fire, even when the plate of glass was a little inclined. Mr Wheler very ingeniously explains these phenomena by the expansion of the parts of the tube nearest the fire, which, by placing the glass at a greater distance from the centre of motion, destroys its equilibrium. The heavy side of the tube therefore descends, and a fresh part of it being exposed to the fire, expands and descends as formerly. A writer in a modern dictionary opposes this explanation on the ground that "the fundamental principle on which it proceeds is false, for though fire, indeed, will make bodies expand, it does not increase them in weight, and therefore the sides of the tube, *though one of them is expanded by the fire, must still remain in equilibrio*, and hence we must conclude that the causes of these phenomena remain yet to be discovered." In this extraordinary reasoning, the author has overlooked the fundamental truth in mechanics, that the force with which any quantity of matter tends to turn round a fulcrum, is proportional to the sum of all the products of each particle of matter multiplied by its distance from the centre of motion. In the case of the glass tube, the number of particles remains the same, and the distance of all of them from the centre of motion is increased. Hence the sum of the products is increased, and consequently the equilibrium destroyed.

When we look at the sun, or any luminous body, through the common coloured glasses, the transmitted light, though tinged with one colour, nevertheless transmits rays of all the other colours, as may be proved by decomposing it with a prism. It was observed, however, by M. Monge, and the observation has been subsequently confirmed by M. Hassenfratz and M. Arago, that the glass of old churches which has been stained either red or green by the oxide of copper, has the surprising property of transmitting nothing but the homogeneous green or the homogeneous red rays. This property will be of the greatest use in solar observations, as it will remove completely the imperfections of telescopes arising from their different refrangibilities. A telescope should be constructed with a compound object glass, to destroy as much as possible the aberration of sphericity. The red or green glass will remove all the heterogeneous rays, and the most perfect image of the sun will thus be obtained.

A series of new experiments have recently been made upon glass by Dr Brewster, and the results which he has obtained are of such a singular nature, as to lay the foundation of a new science, analogous in its general character to the sciences of electricity and magnetism. He has shewn that when radiant heat

Glass, Glastonbury.

is propagated along a plate of annealed glass, its progress may be rendered visible by exposing it to polarised light, a series of beautiful coloured fringes advancing along the glass. The opposite edge of the glass, however, where the radiant heat does not exist in a sensible state, exhibits the same fringes, and consequently it follows, that in its propagation along glass, radiant heat possesses the singular property of *altering the structure or the mechanical condition of those parts of the glass where it does not exist in a sensible state.* When the heat is uniformly diffused over the plate of glass, all the coloured fringes vanish. By a particular process which we have not time to describe, he has succeeded also in communicating a permanent structure to glass, similar to that which it possesses during the propagation of radiant heat. The pieces of glass that have been subjected to this process, exhibit, by exposure to polarised light, the most brilliant and varied colours, arranged in the finest geometrical forms, and infinitely superior, in point of beauty, to any analogous production of art.

These plates of glass have exactly the same relative action upon the particles of light, as a magnet has upon particles of iron. The glass has a polarity as distinct as that of the magnet, and a piece cut from one pole of the glass, acquires a new polarity exactly similar to what takes place by cutting off a part of a magnet. The results which have now been mentioned, lead also to the construction of a *chromatic thermometer,* which measures all differences of temperature, up to the melting point of the glass which is employed in its construction. A full account of these experiments will be found in our articles OPTICS, POLARISATION, and THERMOMETER. For an account of the sounds produced by glass, see HARMONICA.

GLASTONBURY, a town of England in Somersetshire, is situated in a low marshy country, and is almost surrounded by the river Brue and its branches. It consists of two streets, crossing each other in the direction nearly of the four cardinal points, and the houses are built principally of the stones from its celebrated abbey. At the intersection of the two streets stands the cross of Glastonbury, which consisted of a large central column piercing the roof, and sustaining a naked figure; and clustered columns at each angle, with strangely shaped capitals and pinnacles. This singular building has been allowed to fall into ruins, and only a part of the central column now remains. The church of St John the Baptist is a handsome building, with a lofty tower, remarkable for its lightness and beauty. It contains several monuments, and numerous marks of its former splendor. The church of St Benedict, or the Lower Church, is in no respects remarkable.

The ruins of the celebrated abbey of Glastonbury stand on the south side of the High Street. It was originally constructed of wattles and wreathed twigs, and was afterwards built of more substantial materials. Ina, king of the West Saxons, demolished all the old buildings, and erected a splendid monastery in honour of our Saviour; and the chapel which he added to it contained about 2640 pounds of silver plating. The altar was adorned with gold to the amount of 260 pounds weight; and the church plate was set with jewels. The abbey suffered many subsequent changes, and a very small portion of it now remains. The great church is a heap of ruins. The chapel of St Joseph is tolerably entire, and also the abbot's kitchen. Besides the two parish churches, Glastonbury possesses two dissenting meeting-houses, two alms-houses, and a good free-school. A little way to the north-east of the monastery stands the tower of St Michael, situated on the summit of a high hill. The view of the tower from the plain below is much admired. The principal manufactures of the town are those of silk and silk stockings. The following is the statistical abstract of the two parishes of St John and St Benedict for 1811.

Number of houses	448
Number of families	499
Number of do. employed in agriculture	255
Number in trade and manufactures	121
Males	1067
Females	1270
Total population	2337

GLOUCESTERSHIRE, one of the western counties of England, is bounded on the north and north-east by Worcestershire and Warwickshire; on the east, by Oxfordshire; on the south-east, by part of Berkshire and Wiltshire; on the south and south-west, by Somersetshire and the Bristol Channel; and on the west and north-west, by Monmouthshire and Herefordshire. It stretches from north-east to south-west, from the parish of Clifford Chambers, near Stratford upon Avon, to Clifton, beyond the city of Bristol, nearly 70 miles; and in breadth, from Lechlade north-west to Preston, about 40 miles; but its general breadth is not more than 26 miles. In circumference it is about 156 miles. The form of the county is elliptical. Its area has been variously estimated: by Sir Robert Atkyns, in his *History of Gloucestershire,* and by the author of the agricultural report, it is supposed to contain 800,000 acres. According to the returns to parliament of the poor rates, drawn up under the inspection of Mr Rose, its area is estimated at 718,080 acres. According to other statements, it contains only 705,000 acres.

(Extent and boundaries.)

It is divided as follows: 1. Kifsgate division, which comprehends the north and north-east parts; this is subdivided into 8 hundreds; viz. Kifsgate hundred, upper part, which contains 20 parishes, and one market town, Chipping Camden: Kifsgate, lower part, which contains 19 parishes, and one market town, Winchcomb: Slaughter hundred, upper part, which contains 10 parishes, and one market town, Stow; Slaughter hundred, lower part, which contains 13 parishes, but no market town: Tibbaldston hundred, containing 3 parishes, and no market town: Cleeve hundred, which contains only Cleeve with its tythings: Cheltenham hundred, containing 4 parishes, and one market town, Cheltenham: Deerhurst hundred, containing 4 parishes in the upper part, and 7 parishes in the lower part, but no market town in either: Tewksbury hundred, containing in the upper part 10 parishes, and in the lower 9, and one market town, viz. Tewksbury; Westminster hundred, containing in the

(Divisions.)

Gloucestershire.

Political divisions.

upper part 4, and in the lower part 7 parishes. The second division is called Seven Hundreds Division, and contains the following hundreds: Cirencester hundred, in which is only the town of Cirencester: Crowthorne and Minets hundred, containing 19 parishes, but no market town: Brightwell's Barrow hundred, containing 12 parishes and two market towns, Fairford and Lechlade: Bradley hundred, containing 19 parishes, and one market town, Northleach: Rapsgate hundred, containing 11 parishes, but no market town: Bisley hundred, containing 7 parishes, and 2 market towns, Stroud and Painswick: Longtree hundred, containing 11 parishes, and 2 market towns, Minchen Hampton, and Tetbury: Whitstone hundred, containing in the upper part, 9 parishes, and in the lower part 7 parishes, but no market town: Seven hundreds Division lies to the south and south-west of Kifsgate Division. The third is the Forest Division, which is bounded on the west by the river Wye; on the north-west by Herefordshire and Worcestershire; and on the east, partly by the two former divisions, and partly by the Severn: this division contains six hundreds; viz. Botloe hundred, which contains 9 parishes and one market town, Newent: Duchy of Lancaster, which contains 5 parishes, but no market town: Westbury hundred, containing 6 parishes and one market town, Newnham: Bledesloe hundred, containing 3 parishes, but no market town: St Briawl's hundred, which contains 12 parishes and two market towns, Mitchel Dean and Colford: and Dudstone and King's Barton hundred, which in the upper part contains 10 parishes, in the middle part 11, and in the lower 5; the city of Gloucester is in this hundred. The last division of this county is Berkley Division, which is bounded by the Severn on the west, part of Dudstone and King's Barton hundred on the north; Seven hundreds Division on the east, and the Lower Avon and Somersetshire on the south: Berkley division is subdivided into 7 hundreds; viz. Berkley hundred, the upper part of which contains 19 parishes and 2 market towns, Berkley and Wotton under Edge, the lower part contains 6 parishes, but no market town: Grumbald's Ash hundred, the upper part of which contains 11 parishes, and one market town, Wickwar; and the lower part, 10 parishes, and one market town, Sodbury: Pucklechurch hundred, containing 5 parishes, but no market town: Barton Rape's hundred, containing 6 parishes, but no market town: Langley and Swine's Head hundred, the upper part of which contains 4, and the lower part 5 parishes, but no market town: Thornbury hundred, the upper part of which contains only the market town of Marshfield; and the lower part 5 parishes; and one market town, Thornbury; and Hanbury hundred, the upper part of which contains 5, and the lower 2 parishes, but no market town. Gloucestershire contains one city, Gloucester, and part of another, Bristol; it returns eight members to Parliament, viz. two for the county, two for Gloucester, two for Tewksbury, and two for Cirencester. It is in the province of Canterbury and diocese of Gloucester, with the exception of two chapelries. It pays 12 parts of the land tax.

Natural divisions.

Gloucestershire is naturally divided into three longitudinal stripes, or districts, which differ materially from one another. The Coteswold district comprehends the whole tract of hill country, from Chipping Camden northward to Bath, and is often divided into the upper and lower Coteswolds. This is a long tract of high ground, for the most part bleak and bare: the sides of this tract are extremely beautiful as they sink into the vale, from the hills of Stinchcombe and Nibley on the south, to that of Bredon on the north. The Stroudwater-hills form a tract connected with and similar to the Coteswold. The second natural division of this county is the vale, which comprehends the whole of the lowlands from Stratford upon Avon to Bristol: it is usually divided into the Vales of Evesham, Gloucester, and Berkley; but as the Severn and the Avon are the natural boundaries of it, it might more properly be divided into the Vales of Severn and Avon, the former comprehending all the low country between Tewksbury and Bristol, and the latter the lowlands between the upper Coteswold and the Avon from Tewksbury to Stratford. The last natural division, which is by much the shortest of the longitudinal stripes, is wholly varied with hill and dale: it includes the parishes on the west side of the Severn up to Gloucester; and afterwards on the west side of the Leden, till it enters Herefordshire; this natural division is chiefly occupied by the Forest of Dean, once reckoned the principal support of the English navy, and which, it is said, the Armada was expressly commissioned to destroy: it is now thinned very much, though a few solitary deer continue to run wild in its remoter parts.

Climate.

The climate of these different parts of Gloucestershire varies considerably, though perhaps not so much as might have been expected from the difference of their elevation, cultivation, and soil, since the climate of the Coteswold hills, considering their natural elevation and nakedness, is unusually mild. The climate of the vale lands is perhaps as genial as that of any district in England; and that of the forest district is by no means severe, so that Gloucestershire may justly be regarded as highly favoured in this respect. The soil of the Coteswolds is for the most part a shallow calcareous loam, on a stratum of rubble; clay is met with in some parts, especially on the declivities. The soil of the vale is uncommonly rich, being either a fine black loam, or a red loam of equal fertility. In all parts of this district, except where the compact limestone rocks are found, a blue clay forms the under soil. In most of the forest district, the soil inclines to sand, in general not of a fertile quality: in the forest of Dean, a kind of peaty soil prevails. The principal rivers in Gloucestershire are the Severn, the Thames, and the Upper and Lower Avon. The Severn enters the county near Tewksbury, where uniting its waters with those of the Upper Avon, and pursuing a south-west course, it traverses a wide vale of uncommon richness and beauty. About a mile above Gloucester, it divides into two streams, which reunite a little below the city, forming Alney island. Soon afterwards, the breadth and depth of the river are much increased by the streams that fall into it, and its character becomes more bold and picturesque. Near Franiclode it takes a northerly direction, forming nearly a semicircle in the next ten miles of its course; after this it gradually grows wider, till it receives the Wye near Chepstow and the Avon from Somersetshire, thus forming the Bristol Channel. In its passage through Gloucestershire, it receives the Upper Avon, the Chelt, the Leden, the Frome, and the Lower Avon, near Bristol. This river frequently overflows its banks, particularly below Gloucester; in consequence of which, drains, sea-walls, &c. have been made, which are under the superintendance of a society called the commissioners of the sewers. The Severn is remarkable for its tide, which rolls in with an elevation of three or four feet. The Upper Avon divides a small part of Gloucestershire from Warwickshire, at the north extremity, and another small portion from Worcestershire, near Tewksbury.

Soil.

Rivers.

ucester- hire. The Thames has its source in this county, about two miles south-west of Cirencester; it then enters Wiltshire, and again becomes a Gloucestershire river at Kempsford, continuing the southern boundary of it to Lechlade, where it enters Oxfordshire. The Wye divides part of Gloucestershire from Monmouthshire and Herefordshire, and forms the natural western boundary to the forest of Dean. The canals in this county are the Stroudwater, which begins at the town of Stroud, and enters the Severn at Framilode: its width is 42 feet, its length nearly eight miles, and its rise above the level of the Severn 102 feet. The Thames and Severn canal begins at Walbridge, where the Stroud navigation ends, and joins the Thames at Lechlade; its length is 28 miles; its general breadth 40 feet; its fall 130 feet. It runs by a tunnel through Sapertowhill. The Berkley canal, which was intended to open a communication between Gloucester and the Severn at Berkley, has not been completed. The Hereford and Gloucester canal begins at Hertford, and joins the Severn opposite to Gloucester; the total length is 35 miles.

rals. The mineral productions of this county are not very numerous or important, coal only excepted; this is found in abundance in almost every part of Dean forest, where there are not fewer than 150 pits: the lower parts of the vale also abounds in coal, but of a less sulphureous quality than that of the forest. Iron ore abounds in the forest, but only a small quantity is raised. In this district also a good compact limestone is found, but inferior to that which forms vast beds at the southern extremity of the county: the lime made from this stone is uncommonly white and strong. Blue clay-stone is found in the vale, in layers of from four to ten inches thick; it is useful for building: it contains a considerable portion of calcareous matter. Freestone, of excellent quality, is raised from the Coteswold quarries; and paving stones and grits are found in the forest; of the latter, one of extraordinary hardness and durability, deemed superior to any other for cyder mills. Stone tiles are raised in the Coteswold hills; and in the parish of Henbury there is a fine bed of plaster of Paris.

The principal mineral water is at Cheltenham, which, for upwards of 30 years, has been much resorted to. According to the analysis of Dr Fothergill and other chemists, its component parts are Epsom and Glauber salts, a small portion of chalybeate, and some fixed air. It is particularly efficacious in all disorders of the liver. See Cheltenham.

s and m There are no very large estates in this county; but the number of yeomen who possess freeholds is very great. About a fortieth part of the whole land is held under corporations; there is very little copyhold. The average size of farms is small, though there are some large grazing farms in the vale. Before the injudicious rise in the rent of land, the average rent on the Coteswolds was, for arable 15s. for pasture 25s. per acre. In the vale, for arable 20s. for pasture 30s. In the forest district, for arable 20s. for pasture 25s. per acre. Within the last century, more than 90 acts of Parliament have been passed for the inclosure of waste and commonable lands in this county.

…ments …han… Of the implements of husbandry used in Gloucestershire, the waggon deserves particular notice, being, in the opinion of Mr Marshall, the best farm-waggon in the kingdom. Its most striking peculiarity is that of having a crooked side-rail, bending archwise over the hind wheel; the body is wide in proportion to its shallowness; and the wheels run very wide: its advantages therefore, in carrying a top-load, are obvious. The old plough, with one wheel, but shortened in the beam, is mostly used on the Coteswolds; through the greater part of the vale, the old swing plough is retained. There are but few thrashing machines in the county. A very useful cradle scythe is used in the vale for cutting beans.

As the forest of Dean is still comparatively speaking a waste, the agriculture of Gloucestershire must be sought after in the other parts of the county. The vale of Gloucester is a rich vale district, equally abundant in grass and corn; the Coteswold hills is an upland arable district; and the vale of Berkley is a grassland dairy country. It is computed that there are about 300,000 acres under tillage in Gloucestershire. The most striking practice with respect to the tillage land, is followed on the Coteswold hills, where the crops are generally sown after one plowing. Fallowing is practised on the strong vale lands. In the open fields, below Gloucester, two crops and a fallow are the general practice; and three crops and a fallow above that city. On the Coteswold hills turnips are substituted for a fallow, after which barley, grass for two years, wheat, and oats, pease or vetches. Wheat is drilled and planted in some parts of the vale lands; and is carefully hoed while it is growing. The produce on the Coteswolds averages 15 bushels, and in the vale nearly double that quantity per acre. Barley forms an important crop in the Coteswolds, but is seldom sown on the strong lands of the vale. Oats are chiefly grown in the forest district. In the management of all these crops there is nothing particularly striking or commendable; but in the entire management of the bean crop, Gloucestershire may afford a valuable lesson to almost every other part of the kingdom. Beans are principally the produce of the clay soils of the vale. In the ordinary practice of the district, they are planted by women, and hoed by women and children, always twice, and sometimes thrice; they succeed wheat or barley. The ground being ploughed nine or ten inches deep, manure is seldom given. They are planted early in February, by setting pins either across or down the ridges. The quantity of seed is $2\frac{1}{2}$ or 3 bushels. The distance between the rows from 10 to 14 inches; the distance in the rows about two inches; the depth two inches. The produce varies from 20 to 40 bushels per acre. Pease are principally grown on the Coteswolds. Tares, both winter and spring, are grown in all parts of the county, and on all soils. Turnips are pretty extensively cultivated; they are seldom drilled, but always carefully hoed. Swedish turnips are mostly confined to the rich lands of the vale; both kinds are almost exclusively given to sheep. Rye is grown in abundance in that part of the forest district called the Ryelands, but scarcely any where else. Potatoes are particularly attended to in the southern parts of the county. The culture of flax and teasels has much declined within these late years.

Gloucestershire.

Tillage.

Beans.

Meadows.

On the banks of the Severn, and the other rivers which flow through the vale, there are very rich natural meadows and pastures; their fertility principally arises from the mud which is deposited upon them during the inundations. The Avon is said to bring down the richest deposit from the hills of Warwickshire. The meadows on the banks of the Severn, considerably below Gloucester, partake of the nature of salt-marshes. For some miles above and below that city, the meadows are mowed every year, and the average produce is two tons per acre, though no manure is ever laid on them. Sainfoin has been cultivated on the Coteswold hills for upwards of 150 years, and is still a very general and useful crop there: its duration, how-

Sainfoin.

Gloucestershire. ever, is short, seldom more than ten years. The only other artificial grass for which this county is remarkable is Peacey's rye grass, which was first selected from the finest meadows in the vallies of the Coteswolds, and is now well known in almost every part of the kingdom. The management of the stall is no where better attended to than in Gloucestershire. The cattle usually fed are of the Herefordshire breed; they are worked till they are 6 or 7 years old: when fat they are sent either to Smithfield or Bristol market. Great attention is also paid to the fattening of calves. The principal breed of sheep in the county is that of the Coteswold, large and coarse in the wool; at three years old weighing from 30 to 45 lbs. per quarter, and affording a fleece of 9 or 10 lbs. The new Leicester and the south Down are also kept in many parts, and the Ryeland in some parts of the forest district. The real forest sheep are nearly extinct; these are very small, finely formed, and with fine wool. There is no peculiar breed of horses in this county. The old Gloucestershire breed of swine are now seldom kept.

Rye-grass. Cattle. Sheep.

Cheese. We now come to the two most important objects of Gloucestershire husbandry, its cheese and cider. Cheese is made both in the vale of Gloucester and in the vale of Berkley; or, as they are sometimes termed, the upper and lower vales: but the management of the two vales differ in one most material article, the quality of the milk. In the lower vale, the milk is run neat from the cow; in the upper vale, the practice is to set the evening's milk for cream in the morning, and to skim it, and then to add it to the new milk of the morning's meal. The cheese made from this mixture is termed two meal cheese; that from the neat milk, milk cheese, or best making. There are other differences in the practices of the two vales. In the vale of Gloucester, rye-grass is the predominant and favourite grass; in the vale of Berkley, the dog's-tail, with a mixture of rye-grass, the poag, and white clover. The Gloucestershire breed of cattle, a variety of the middle horned species, still predominate in both vales for the purposes of the dairy; though in the higher vale, long-horned cows, from the improved stock of Bakewell, are often kept; few dairies, however, in either vales, are without admixture. As soon as a " pack" or stock of cows is formed, the first consideration is to mark out those inclosures, the herbage of which is most favourable to the production of good milk; among the plants which are useless or injurious, are white honeysuckle, crowfoot, and garlic. About the first of May, the pastures are ready to receive the cows, and soon afterwards cheese-making commences: great care is taken in the selection or preparation of the rennet, and most minute and particular attention is paid to the temperature at which the coagulation takes place most kindly and equally. Previous to adding the rennet, the colouring is put in. In some places, the curd is scalded; where this is not done, a handful of salt is commonly thrown on the curd, immediately after the whey has been taken from it. The next operation consists in crumbling the curd, and pressing it fine in the vat, which is done with great nicety, being turned and salted repeatedly. If the cheese is small, this part of the process is continued only three days. The cheese is then removed to the shelf, and turned every day for a fortnight; then every other day for a fortnight more. At the end of this time, it is fit for the cheese loft: here it is turned twice a week, for three weeks; then the coat is scraped and coloured on the outside, or painted with carnation-red, mixed with water, and rubbed on with flannel. About Michaelmas, the cheese-factor examines the cheeses by walking over and treading upon each of them; those which yield to the tread are said to be heaved, and are unfit for the London market. The cheese of the hundred of Berkley is the most celebrated of all the Gloucestershire cheese; what in the kingdom at large is termed Gloucester cheese, particularly double Gloucester, is in Gloucestershire called double Berkley, not more on account of the superior quality of the cheese of this district, than because the principal part of the thick cheese of Gloucestershire is made within this hundred. It is calculated that a cheese of 11lbs. requires 15 gallons of milk, or one gallon and one-third to one pound of two meal cheese. The year's produce of a cow is estimated at three hundred weight. The vale of Berkley contains 50,000 acres, two-thirds sf which are occupied by cows, to the number of 7000 or 8000; and their annual produce of cheese is from 1000 to 1200 tons. As connected with this subject, the whey-butter of the vale of Berkley may be mentioned, which, if well made, and eaten fresh, is superior to the milk-butter of many districts: the produce of whey-butter is estimated at half a pound a cow a week. See Dairy, p. 559.

Cider. There are few orchards on the Coteswold hills, but in the vale and forest districts, they are abundant and valuable. Of the different kinds of cider made in this county, the Stire cider is deemed the best. The fruit from which it is made, flourishes particularly on the thin lime-stone soils on the margin of the forest of Dean. It is remarked, that the cider made from the Stire apple which grows here, is distinguished by richness, sweetness, and fulness of flavour; whereas, the same apple, in the vale of Gloucester, a strong, deep, rich soil, affords a liquor whose predominating qualities are roughness and strength. There is nothing peculiar in the mode of manufacturing cider in this county. Of pears, the squash is in much the highest esteem: in the township of Taynton, on the Gloucestershire side of Mayhill, where the soil is a strong brown clay, squash-pear perry, of a very superior quality, is made. It is said the perry of this district is the basis of most of the wine sold for Champagne in the metropolis.

Perry.

Wood. On the Coteswold hills, beech and ash are the principal trees. In the vale, there are but few tracts of woodland. The quantity of ground in Dean forest, belonging to the crown, is upwards of 23,000 acres. It formerly supplied about 1000 tons of ship timber annually. The forest is under the government of a lord warden. At Totworth, the chesnut tree is still growing, which, according to Evelyn, was 500 years old in the reign of King John. It was measured in 1791, when it was 44 feet and four inches in circumference. Till the year 1790, when it was burned down, there was an oak growing at Bodington, the circumference of which, at the ground, was 18 yards: the stem was hollow, forming a room more than 16 feet in diameter.

Labour. The wages of farm servants in Gloucestershire are not high, but the allowance of drink is enormous; six quarts a day is the common allowance, frequently two gallons, sometimes nine or ten quarts; drinking a gallon bottle full of cider at a draught is said to be no uncommon feat. In the immediate neighbourhood of the forest, coal, being cheap and abundant, is the common fuel: in other parts of the county, the Staffordshire and Shropshire coal is burnt; but on the Coteswolds, all kind of fuel is scarce and dear. The roads of this, like most of the other western counties, are by no means good; on the Coteswolds, the calcareous grit is too soft for durable roads; and there are still greater difficulties in the vale, from

Roads.

Gloucestershire. the nature of the soil, and the extreme scarcity of materials. The compact lime-stone, from St Vincent's rocks, makes the bests roads; but it is very expensive.

Manufactures. The most considerable markets are those of Gloucester, Cirencester, and Tewksbury; they are abundantly supplied with corn, meat, poultry, and the other necessaries of life. The principal manufactures of the county are those of woollen broad cloths, chiefly superfine, made of Spanish wool: there are also fine narrow goods, in the stripe and fancy way, made to a very great amount. The whole of these manufactures are carried on in that district called the Bottoms. Of this district, the town of Stroud may be regarded as the centre, all the surrounding valleys exhibiting a continued range of houses or villages, occupied by manufacturers. The waters of this district are peculiarly adapted to dyeing scarlet, blue, and black. At Cirencester, thin stuffs of worsted are made: carpets are also made here. At Tewksbury, the stocking-frame knitting is the principal manufacture. Rugs and blankets are made at Dursley, &c. Felt hats, for the Bristol trade, are made in several villages. In the forest of Dean, there are extensive iron works: at Framilore, there is a manufactory of tin-plate. The other manufactures of the county are iron and brass wire, wire cards for the clothiers, pins, nails, and writing paper. The articles of agricultural commerce are cheese, bacon, cider, and perry. The salmon of the Severn is now become scarce, but formerly it was caught in great abundance, and sent to London and other places, where it always obtained a very high price.

Poor. By the returns respecting the poor, presented to Parliament in the year 1803, it appears, that in this county at that time, 33,113 persons were relieved in and out of workhouses, at the expence of £3 : 1 : 7¼ per head, or £102,013 : 12 : 8 total; which, at a rental of £1,128,312, gives about 1s. 9½d. in the pound per annum. By the same return, it appears that there were, in 1803, 19,606 persons belonging to friendly societies.

Population. In the year 1810, the number of families employed in agriculture was 20,782; and in trade, manufactures, &c. 29,988. In the year 1700, the population of the county was 128,341; in 1770, 161,693. In the year 1801, 210,267; and in 1811, 295,100. At this last period, the number of people to a square mile was 263; and on an average of years, there had been one baptism to 36 persons; one burial to 61 persons; and one marriage to 120 persons.

History. The ancient Britons seem to have had no peculiar name for this tract of country, designating it and the whole adjoining low lands by the name of *Duffin*, which is said to signify a vale. It was inhabited by the Cattienchlani. When the Romans occupied England, the Dobuni seem to have inhabited Gloucestershire. This county being divided by the Severn, lay partly in Brittania Prima, and partly in Brittania Secunda; that on the south-east side of the river being in the former, and governed by the president residing in London; whereas that part beyond the Severn was in Brittania Secunda, and governed by the president residing at Caerleon. The Saxons called the inhabitants near this part of the Severn, Wiccii, from the Saxon Wic, *a creek*, because the river near its mouth is full of creeks. During the heptarchy, it was a long time subject to the West Saxons, but was afterwards included in Mercia. See *General View of the Agriculture of the County of Gloucester*, by Thomas Rudge, B. D. *Beauties of England and Wales*, vol. v. *The Rural Economy of Gloucestershire*, by W. Marshall. (J. S.)

Gloucester. GLOUCESTER City, is situated in Dudston and King's Barton hundred, Gloucestershire, 105¼ miles west from London. This city is situated in the Vale of Gloucester, on a gentle eminence, rising on the east side from the river Severn. Its situation, however, though it affords a fine object to the hills around, is by no means pleasant, the country round it partaking of little variety; and though its walls are washed by the Severn, that river loses here much of its dignity and interest, by being divided into two small channels, with a long connecting causeway. Gloucestor has lately been much improved. Its four principal streets are admired for the regularity of their junction in the centre of the town.

Cathedral. The cathedral is a fine building; its lofty tower, and 4 transparent pinnacles, adorned with exquisite fret work, make a conspicuous figure. Within, the high roof and Gothic ornaments of the choir, form a noble contrast with the simple grandeur of the ponderous Saxon pillars and arches which support the aisle. Its principal curiosities, are the beautiful painted glass in the chapel of our Lady; the whispering gallery; the tombs of Edward II. who was murdered in Berkley Castle, and of Robert Duke of Normandy, eldest son of William the Conqueror; and the great bell, suspended in the first story of the central tower. The walls surrounding Gloucester, in the time of William the Conqueror, were completely demolished soon after the Restoration, the only remains being the west gate, standing on the banks of the Severn, at the end of a stone bridge of 5 arches, built in the reign of Henry II. This bridge is connected on the west with a causeway of stone, which extends through the low meads and isle of Alney to the distance of about half a mile. The castle of Gloucester, of which the remains were destroyed a few years ago to make room for the county gaol, was probably erected about the time of the Norman invasion, as the Domesday Book mentions, that 16 houses were taken down for its scite. Camden states, that in his time it was for the most part decayed.

County gaol. The county gaol well deserves the inspection of the stranger. It was commenced, from the designs and under the direction of Sir George Onesiphorus Paul, Bart. a gentleman well known for his judicious and indefatigable exertions in the cause of the best interests of society, nowhere better exemplified than in the plan of this structure, and in the code of laws which he drew up for its government. The gaol consists of 3 divisions; the penitentiary house, the bridewell, and the sheriff's prison. These have all their distinct and appropriate regulations. It contains 203 separate cells; 164 for sleep, and 39 for employment. At stated hours during the day, the prisoners are permitted to enjoy the fresh air, in a court-yard 210 feet long and 57 broad. The same class of prisoners only are allowed to associate together. The internal economy is under the management of the chaplain, governor, and surgeon, who act according to fixed rules, and who are themselves subjected to the controul of the county magistrates. There are besides a house of industry, and a county infirmary, under excellent regulations. Gloucester receives its supply of water from springs about two miles to the south; and it appears from ancient records, that an aqueduct was carried thence to the city, upwards of 400 years ago.

Musical festival. Besides the amusements common to all provincial towns, there is in Gloucester, Worcester, and Hereford, a musical festival, established by the choirs of those cities, with the assistance of the first performers in the kingdom. The profits are applied to relieve the widows and orphans of clergymen. The meetings are held yearly, alternately in each city, and continue for three days.

Gloucester, Glover.

Trade.

The principal trade of Gloucester arises from the pin manufacture, and from the navigation of the Severn. This river is navigable to the wharf near the bridge for barges, vessels of larger size being obstructed by the rocks and sand banks in the narrow channel near the city. To remedy this inconvenience, the Gloucester and Berkley canal was begun, which was intended for the passage of ships of 400 tons burden. There has also been a bell foundery here since the year 1500. For the last 150 years, this business has centered in one family, who, in that period, have cast upwards of 3000 bells.

Government.

This city is the see of a bishop. It returns two members to parliament, the number of electors being about 2000. It was anciently regarded as a distinct hundred, and is still privileged as a county within itself. The corporate officers consist of a mayor, 12 aldermen, a high steward, a recorder, a town clerk, 2 sheriffs, 26 common councilmen, and 4 sergeants at mace. The population returns of 1811, give the following results respecting this city:

Population.

Houses inhabited	1509
Families occupying them	1706
Houses building	15
Houses uninhabited	20
Males	3726
Females	4554
Total population	8280

(J. S.)

GLOVER, Richard, an eminent English poet and political character, was born in St Martin's Lane, Cannon Street, London, in the year 1712. His father was a respectable Hamburgh merchant in the city.

Glover was educated entirely at Cheam school, under the Rev. Daniel Sanxay, having never studied at either of the universities. At the seminary above mentioned, he distinguished himself by the rapidity of his progress, and exhibited early specimens of his poetical powers. At the age of sixteen, he wrote a poem to the memory of Sir Isaac Newton, which was prefixed to the *View of Sir Isaac Newton's Philosophy*, published in 1728, by his friend Dr Pemberton. The seductive charms of literature, however, did not allure him from the pursuits of commerce, to which he was destined; for, in due time, he embraced his father's profession, and became a Hamburgh merchant; to which he alludes at the commencement of his poem called *London*.

The talents of Glover soon brought him into distinguished notice. In all matters regarding the interests of commerce, he took a lively and active concern. Nor did the cares and duties of a life of business estrange him from the study of poetry, for which he had shewn an early partiality. He cultivated the society of those men who were eminent in politics, science, and literature, especially such as belonged to the party in opposition to the administration of Sir Robert Walpole; and he enjoyed the esteem and confidence of several persons distinguished for their rank and talents.

On the 21st of May 1737, he married Miss Nunn, who brought him a fortune of £12,000; and in the same month he published his *Leonidas*, an epic poem, in nine books, which established his reputation as a poet. This poem was extremely popular on its first appearance, but was, no doubt, in a great measure, indebted for its favourable reception to the zealous and enthusiastic applause of the party then in opposition to the court. Their extravagant zeal, however, seems to have ultimately proved disadvantageous to the legitimate pretensions of the author, by encouraging exorbitant expectations, which the poem was not calculated entirely to gratify; for although possessing great and obvious beauties, it has since sunk into an unmerited neglect.

Glover

In 1739, he published his *London, or the Progress of Commerce;* upon which there followed soon after, his ballad, intituled, *Hosier's Ghost*. Both these pieces appear to have been written with a view to stimulate the nation to resent the depredations of the Spaniards; and the latter produced a considerable sensation.

During the last mentioned and subsequent years, Glover took a very active part in the politics of the city; and his talents, his political knowledge, and his extensive information in matters regarding trade and commerce, placed him so high in the estimation of his fellow-citizens, that he was appointed to conduct the application of the merchants of London to parliament, in 1741 and 1742, on the subject of the neglect of their trade. He accepted the office, and his exertions were crowned with success. In summing up the evidence, upon that occasion, he exhibited striking proofs of his oratorical powers. On the death of Sarah, Duchess of Marlborough, in 1744, she left, by her will, £500 each to Glover and Mallet, to write the history of the Duke of Marlborough's life. Glover, it is believed, very early renounced his share of the bequest; and Mallet, though he constantly promised, never made the least progress in the performance of the task.

About this period, Glover's affairs became somewhat embarrassed, in consequence of unavoidable losses in trade, and, perhaps, of too zealous an attention to the public interests, to the neglect of his own private economy. For this reason he determined to withdraw himself, for a time, from public notice, until he should be able to put his affairs into a more prosperous state. In the beginning of the month of May 1751, he was drawn from his retreat by the importunity of his friends, and condescended to stand candidate for the office of chamberlain to the city of London, in opposition to Thomas Harrison, Esq. Unfortunately, however, most of the Livery had engaged their votes before he declared himself; and after a few days, finding that his antagonist gained ground upon the poll, he gave up the contest. Upon this occasion, he addressed the Livery in a speech full of eloquence and manly resignation. In his retirement, he finished the tragedy of *Boadicea*, which he had begun many years before; and in 1753, it was brought upon the stage at Drury-Lane, and acted nine nights with great success. In 1761, he published his *Medea*, a tragedy, taken from the dramas of Euripides and Seneca, and professedly constructed upon the ancient plan, each act terminating with a chorus. It was not acted till 1767; and has since been often performed with success.

Having at length surmounted the difficulties of his situation, Glover again relinquished the pleasures of retirement; and in the parliament which met at the accession of his present Majesty, in 1761, he was elected member for Weymouth, and sat till March 1768. In 1770, he published a new edition of *Leonidas*, corrected throughout, and extended from nine books to twelve. In 1772 and the following years, he took a very active interest in winding up the complicated concerns of Douglas, Heron and Company at Ayr. He also undertook to manage the interests of the merchants and traders in London, concerned in the trade to Germany and Holland, and of the dealers in foreign linens, in their application to parliament, in the month of May 1774. In 1775, he assisted the West India merchants in their application to parliament; and examined the witnesses, and summed up the evidence, in the same masterly manner he had done on former occasions. For his assistance upon this occasion, he was complimented with a service of plate of the value of £300. The speech he delivered to the House was printed in the above-mentioned year.

Glover had now arrived at a period of life which demanded relief from the cares of business. He therefore retired to ease and independence, devoting himself principally to the exercise of private virtues and domestic duties, and to the pleasures of literature. He died at his house in Albemarle Street, on the 25th of November 1785, in the 73d year of his age. Among other manuscripts, he left behind him, *The Athenaid*, a sequel to *Leonidas*, which was published in 1788. He also wrote a sequel to his *Medea*, which, however, has never been exhibited on the stage.

In his person and habits, Glover was a finished gentleman of the old school, slow and precise in his manner, grave and serious in his deportment, and always in the highest degree decorous; but although his natural temper was benevolent, he is said to have been at once irritable and violent. He was very strict in his moral conduct; and although he was brought up in the principles of a dissenter, he attended the established church. He appears to have been an accomplished scholar; and it is evident from his life and writings, that his mind was much devoted to political subjects; but he always avoided such topics of discussion in his own domestic circle. As a poet, Glover displays a cultivated mind, a poetical fancy, and a vigorous and harmonious flow of versification; but he appears to have wanted that inventive imagination, and that higher spirit of enthusiasm, which give birth to the noblest productions of art. The chief defect of his *Leonidas* appears to consist in the subject: the historical facts upon which the poem is founded, are too well known, and too sublime and affecting of themselves, to admit of dilatation or embellishment, without diminishing the impression made upon the mind by the simple and unadorned recital.

Glover has been recently brought forward as a candidate for the credit of the *Letters of Junius*. The hypothesis is not without some plausibility; and there are certainly circumstances in his character and situation, which give considerable support to his claim. But the presumptive proofs, we think, have not yet been arrayed in such order, or stated with such force, as to make the conjecture assume the appearance of probability. See *Memoirs by a celebrated Literary and Political Character*, London, 1814; and, *An Inquiry concerning the Author of the Letters of Junius, with reference to the Memoirs*, &c. London, 1814. (z)

GLOW-WORM. Several of the smaller animals are endowed with the remarkable property of emitting light from their bodies as night advances, which becomes imperceptible on the approach of day: the creature can no longer be distinguished from the myriads of beings around it Eight genera of insects are known to be luminous in the dark, in which is included the genus *Lampyris* of Linnæus; the male, a winged animal of the coleopterous order, but the female is in general a worm, entirely destitute of wings, and so unlike the other, that nothing less than the sexual congress has been required to establish its kindred. This is the common glow-worm, to which our attention shall be briefly directed.

The Lampyris noctiluca, or glow-worm, is about three quarters of an inch long, when full grown; dark-brown above, and yellowish-white below. It crawls on six feet, and its body is divided into eleven segments, of which the last eight constitute the abdomen. The head, which is very small, round, and black, is concealed by the thorax, while in a state of repose. The eyes, also black, are large; and the antennæ, which are filiform, to the naked eye consist of eleven articulations, separated by white rings. Neither wings nor their rudiments exist, and the animal advances with a very sluggish motion, frequenting humid places, and living among the grass. Naturalists conjecture, from its conformation, that it is carnivorous. The male of this species, which is exceedingly rare, and which some of the most industrious entomologists have never seen, is said to have brownish elytra covering the wings; but the female is not only more numerous, but well known, from depositing a cluster of eggs on twigs or straws; and the young animals pass through the state of a larva and nymph, between which there is less difference than among insects in general.

The glow-worm, remaining in concealment through the day, crawls abroad at night, when it appears surrounded by a beautiful radiant light of considerable intensity, and of a greenish colour. It is most brilliant two or three hours before midnight; and an elegant and interesting spectacle is presented by collecting several together in a glass vessel. More powerful emanations illuminate the animals; sometimes the light is suddenly extinguished, sometimes it shines at protracted intervals, while the motion of the insects produces perpetual variety: but it always grows fainter and fainter, and at last it almost totally disappears. The observer, in the course of his examination, discovers, that the exhibition and intensity of the light are partly under the controul of the glow-worm; that the place from which it emanates is in the last three rings of the abdomen; and that it ceases entirely with the death of the animal, though a severed portion will continue to be illuminated, and after extinction the light will at a moderate interval be renewed.

The three rings, while illuminated, are of a pale yellowish colour, and their internal surface is spread over, with a layer of a peculiar soft yellow substance, whose consistence resembles paste. The whole interior, however, is not covered, as it is more or less deficient along the inner edges of the rings, where it forms an irregular waving outline. We compare this substance to paste; but, when magnified, it is found to be organised like the common interstitial matter of the animal's body, except that it is of a closer texture and paler yellow; and the segments of the abdomen, behind which it is situated, are thin and transparent, on purpose to expose the internal illumination. Several years ago, Count Razoumousky, a learned Polish naturalist, discovered that, besides the rings, there were luminous points in the abdomen, giving out a more permanent light; and the ingenious experiments of Mr Macartney prove, that two minute bodies, endowed with this property, are lodged in two slight depressions in the shell of the last ring. By the microscope, these are found to consist of two sacs, containing a substance similar to that lining the inner surface of the rings; and the membrane composing the sacs is so strong and elastic, as to resume its figure after the contents are discharged. The light thence proceeding is less under the controul of the insect than that of the luminous substance disseminated over the rings: it is rarely distinguished even through the day, during the season that the glow-worm gives out light. The presence of these two bodies seems alluded to by Mr Waller, in the Philosophical Transactions, so long ago as the year 1684, when speaking of those species of lampyrides, both male and female of which are winged; and Thunberg mentions one found in Japan with two vesicles on the extremity. The former describes their site as under the termination of the tail; and observes, that the winged insects are extremely rare in England.

The luminous substance, when extracted from a dead glow-worm, gives out no light, though the sacs, when cut from the living animals, shine several hours after separation; and, if put into water, they will emit light uninterruptedly for forty-eight hours. Whether they contain greater heat than the other parts of the animal, as a sufficient number have never yet been accumulated to prove the fact by experiment, is not altogether free of doubt. John Templer, one of the earliest English observers of the nature of the glow-worm, says, "If my senses fail me not, she emits a sensible heat in her clear shining." Mr Macartney also thought, that, when shining brilliantly, the luminous rings communicated the sensation of warmth to the hand; but, from remarking that the heat of the surrounding atmosphere, 69°, was not raised more than to 75° or 77°, on introducing a very sensible thermometer among several glow-worms, he concluded, that the actual difference of heat was insufficient to warn him of its presence. Sometimes, however, the luminous portion of the tail seemed to raise the thermometer more quickly than other parts of the body; and on cutting it off several animals, he found, that if the thermometer were immediately applied, it would rise one or two degrees; but that no effect whatever was produced after these parts were dead, though they continued to give out light. It ought to be kept in view, that many erroneously believe insects are entirely destitute of heat, whereas its presence is sufficiently demonstrated by accumulating a number together in a limited space.

Besides the glow-worm properly so called, an insect wanting wings, there are several of the genus provided with them, and then generally denominated *fire-flies*. In the hot climates, thousands shoot across the eye, and sparkle in the woods and bushes during night, with the most beautiful and brilliant illumination. Some, resembling so many specks, are not larger than the common house-fly; others are above half an inch long; and several collected in a glass vessel, emit sufficient light for reading a book. All are of the coleopterous tribe: both sexes have wings, and the emanations proceed from the last segments of the tail.

Some general conclusions have been drawn regarding the nature of luminous animals, most of which apply to the glow-worm: and first, that this property is not constant, but exists only at certain periods, and in particular states of the animal's body. The site of its emanations, also, resides in a particular substance, compared to paste; and the light is differently regulated while that substance is in the animal's living body, or separated from it. In the former case, it is intermitting: it is commonly produced or augmented by a muscular effort, and is sometimes absolutely dependent on the will of the insect. In the latter case of separation, the luminous exhibition is usually permanent, until becoming extinct, after which it may be restored directly by friction, concussion, and the application of warmth. No diminution of the substance follows the exhibition of light, however long it may be protracted. It does not require the presence of pure air, nor is it extinguished by other gases. The luminous appearance of living animals is not exhausted by long continuance, or frequent repetition, nor is it accumulated by exposure to natural light. From these principles, it is inferred, that this property not being dependent on any foreign source, is inherent in a peculiarly organized animal substance, and is regulated by the same laws which govern all the other functions of living beings.

Many conjectures have been indulged regarding the use of the light exhibited by luminous animals. Some have boldly declared, that it is for no specific purpose; others, more prudently, affirm, that it is utterly unknown: while a third class, substituting opinion for experiment, at once decide that, in the glow-worm at least, it is a wise provision of nature for promoting the concourse of the sexes. Undoubtedly this reason at first sight is plausible; but it ought to have been previously ascertained, that the male, while flying through the air, is sensible of the luminous emanations from the body of his grovelling mate. We know little of the different senses of insects; hearing seems altogether denied to certain species, and others are void of any external organs of sight: but what is more extraordinary, neither the number nor size of the eyes apparently increase the acuteness of vision. It ought constantly to be preserved in remembrance, that the beautiful structures of the bee are erected, and all its complicated operations performed, in the dark; but that other organs, and especially the antennæ, are constantly resorted to by them as a guide. Emanations undoubtedly proceed from the bodies of females at certain periods, which produce a lively impression on the sensations of the male, and we should be inclined to admit that there might be some analogous concomitant of the luminous exhibition of the female glow-worm; but the probability of this hypothesis is greatly diminished, on considering, that the emanations of light belong to the earliest period, even when the insect is in the larva state. We must therefore necessarily conclude, that naturalists have not yet discovered the real uses of this remarkable property.

GLUCKSTADT, a word signifying the *Fortunate Town*, is a town of Germany, in the Duchy of Holstein, and belonging to the King of Denmark. The town, which is situated on the Elbe, where it receives a small river called the Rhu, is regularly and neatly built; and the principal streets run into the market-place. The town is intersected by several canals, the principal one of which passes near the market-place, and is there joined by another, which divides the town into two parts. From the marshy nature of the surrounding country, the road from the town towards Krempe, passes over a stone causeway, nearly three-quarters of a mile long. The town, therefore, can be easily laid under water on the land side. As there are no springs here, every good house is provided with a cistern, and the poor are supplied with water from the harbour in the new moat. There is a free grammar school here, a Calvinist church, a Roman Catholic chapel, and a Jewish synagogue.

The foundations of this town were laid in a waste called the Wilderness, in 1617, by King Christian IV.; who, with the view of making it a commercial town, granted it particular privileges. Frederick III. increased these privileges, and made it the entrepot of all the merchandize of Iceland which came into the Elbe. The vessels of Gluckstadt carried their merchandize to Altona and Hamburg. In 1738, Christian VI. founded a commercial college here; and in 1739 a house of correction and a workhouse were founded. In 1750,

1

Glue. Goa.

Frederick V. instituted a commission for clearing and repairing the harbour. The King of Denmark declared Gluckstadt a free port, and abolished the duties which vessels had formerly paid in passing the town. In 1782, a commercial company was formed, to which the king granted an octroi for 30 years. Its capital was 200,000 rix-dollars, and it was chiefly engaged in the coasting trade and the whale fishery. Distance from Hamburg 28 miles north-west.

GLUE, is a tenacious cement, principally used by cabinet-makers, joiners, book-binders, case-makers, and hatters.

The substances from which glue is made, are the shreds or parings of hides; the ears before they are immersed in the tanner's vats; the cuttings and raspings of horn, from the comb-maker, the button-maker, and the horn lanthorn-maker; and the hoofs and horns of oxen, calves, and sheep from the butcher; the pelts of the hare, rabbit, beaver, &c. from the hat makers, beaver-cutters, and furriers; and the parings of vellum and parchment from the white leather dresser, glover, &c.

English method of making glue.

These substances are indiscriminately mixed together, and are purified from all grease and dirt by digestion in lime water, the greatest care being taken to remove every piece that is in the slightest degree putrescent. The materials are next steeped and washed in clean water, with frequent stirring, and are afterwards laid in heaps, and the water pressed out. They are then boiled in a large brass kettle with clear water, the fat and dirt being constantly skimmed off as they rise, and when the whole is dissolved, a little melted alum or finely powdered lime is added. After the skimming has been continued for some time, the whole is strained through baskets, and suffered to settle, in order that the remaining impurities may subside, and the fat rise to the top. The impurities and fat being removed, it is then returned into a clean kettle, and suffers a second evaporation and skimming. When it acquires a clear darkish brown colour, and a sufficient consistence, which is known by the appearances during ebullition, it is lifted out by a scoop, into frames or moulds, about six feet long, one foot broad, and two deep, where it is allowed to cool gradually. It is then cut by a spade into square cakes, and each of these is afterwards divided into three pieces, by an instrument like a bow, having a brass wire for its string. The pieces thus cut are dried in the open air, on a kind of net-work, (generally old herring nets,) fastened in moveable sheds of four feet square, each containing six or eight rows of net-work. When the glue is dry, each piece is rubbed gently with a wet cloth, to give it that glazed appearance which the London glue always possesses. The different pieces are then packed carefully up in separate rows in barrels or hogsheads, and are ready for sale.

The best glue swells considerably, without melting, by three or four days immersion in cold water, and recovers its dimensions and properties by drying. When glue looks thick and black, or has got frost in the drying, it should be melted over again with a sufficient quantity of fresh glue. Good glue is distinguished by its having a strong black colour, and by being free of cloudy and black spots, when held between the eye and the light.

French method of making glue.

In France, glue is made from whole skins, which, when fresh, are steeped 24 hours in large tubs; but a longer time when they dry. They are then placed upon hand barrows, formed of strong basket work, to allow the water to drain off, and are afterwards well washed in a running stream, where they are shaken in baskets with a long toothed rake, till the water runs through them quite clear. The materials are now steeped in weak lime water, the liquor being refreshed every 15 days with a bucket of fresh lime water, and the skins being occasionally turned. By this process, the grease is removed, and the skins converted nearly into the state of parchment. The parts of the materials that still retain the hair, require a stronger lime water. The skins are again steeped and drained in hand barrows, and sometimes the water is squeezed out of them by a press. The skins are now thrown into the kettle, which has sometimes stones at its bottom, and sometimes a wooden grate to prevent the skins from sticking to it. The boiling is carried on very cautiously and gradually, and the evaporation is known to have been sufficiently great by dropping a little upon a plate, and finding it of the proper tenacity. The glue, when hot, is then filtered through a bed of long straw, into a tub, the operation being performed in a warm place, in order to prevent the glue from congealing. In this tub the glue is left to refine for two or three hours, and when still fluid it is run off by stop cocks, at different heights, into wet wooden boxes, where it congeals. The glue which flows from the different stop cocks, has different degrees of fineness, the uppermost being the purest. After lying 24 hours in the boxes, the cakes are taken out, divided, dried, and packed up for sale.

Glue from bones.

Glue has also been successfully prepared from the bones of animals. Parmentier found that 6 pounds of buttonmaker's raspings yielded a pound of glue not inferior to the English glue. Glue from ivory was less transparent. See *Annales de Chimie*, vol. xii. p. 292.

GOA, the principal Portuguese settlement in the East Indies, is situated in 15° 28′ North Latitude, and 72° 45′ East Longitude; and is built upon an island, called by the natives Tissoari, about 25 or 30 miles in circumference. This island is separated from the continent by a navigable river, about three miles broad at its widest part; and, though generally barren and hilly, it contains many level and fertile spots. At the entrance of the harbour is the new city of Goa, where the viceroy and principal Portuguese inhabitants reside, and is defended by several fortresses, particularly one called the Alguarda, which stands close to the shore, and is so situated that every ship sailing up the river must pass near its walls. About eight miles beyond this castle, is the old city of Goa, the seat of the inquisition, and the residence of the ecclesiastics, built in the form of an amphitheatre on several eminences, and almost surrounded by hills, finely clothed with wood. The harbour is a noble basin, presenting on every side the richest and most magnificent scenery. The city of Goa was first taken from the Hindoo Rajahs by the Bhámenee sovereigns of the Deccan, about the year 1469; and was reduced under the power of the Portuguese by the celebrated Albuquerque in the year 1510. It soon became the most flourishing European settlement in India, but the Portuguese never possessed any considerable extent of territory in its vicinity. Its walls inclosed a compass of nearly twelve miles; and few cities in India or Europe were better built, or more strongly defended. It was crowded with monasteries; and at one time, not less than 30,000 ecclesiastics are said to have resided within its district. These, however, soon began to apply themselves more

Goa.

ardently to the acquisition of wealth, than to the instruction of the natives; and established in the place the tribunal of the Inquisition, which continued till very recently to exercise all its cruelties upon the Hindoo converts.* The town has been rapidly falling into decay since the middle of the last century, and presents a most striking instance of ruined grandeur. The banks of the river are still covered with country houses, and many of these, especially the monasteries, from their elevated situation, make a magnificent appearance. The streets are straight and regularly built; the houses are large and handsome; and the number of its churches, palaces, and public buildings, excites, at a distance, the idea of an imperial residence; but a nearer approach disappoints the expectations of the stranger, and exhibits a melancholy picture of wretchedness and ruin. The churches and monasteries, the office of the inquisition, and a few other public structures, are still kept in good repair, particularly the church of San Caitan, which is a beautiful specimen of Italian architecture; the convent of the Augustine monks, which is a handsome edifice; the Jesuits college, which is very large and conspicuous; the church of Francis Xavier, the chapel of which, containing the monument of the saint, is uncommonly splendid, and the tomb is ornamented with basso relievos composed of the choicest marbles by European artists, representing his history and miracles. But more than one half of the houses and adjacent country seats are void of inhabitants; the most magnificent palaces mouldering into ruin; the streets faintly traced by the remains of forsaken mansions; the squares and market-places depopulated and silent, and actually filled with noxious reptiles. The few human inhabitants are priests, monks, half-starved soldiers, and low mechanics; and so great is their poverty, that women of the best families earn their subsistence by working lace or muslin, and making artificial flowers One of the most celebrated productions of Goa is the Alphonso mango, a delicious fruit, superior to all others of the same species. It has long been famed also for its arrack, which is made from the juice of the palm-tree, and for its cocoa-nut oil. Rice, arrack, and oil, indeed, form the principal articles of its now limited commerce. Two or three ships arrive annually from Portugal with military stores, and other articles; and carry back printed cottons from Surat, a few spices, &c. Two or three trading vessels take in cargoes for China; and a few coasters collect the produce of the Malabar ports, in order to supply the ships from Portugal with their home cargoes, and to answer the demands of the inland trade from Goa. There are a few armed vessels for the protection of the traders. Goa is 292 miles from Bombay, 1300 from Calcutta, 575 from Madras, and 325 from Seringapatam. See *Mod. Univ. Hist.* vol. ix.; Parson's *Travels in Asia and Africa*; Forbes's *Oriental Memoirs*; Hamilton's *East India Gazetteer*; and Buchanan's *Christian Researches in Asia.* (q)

GOLCONDA, a province of Deccan, a district in India, comprehends the tract of country between the rivers Kistnah and Godavery in 17° North Latitude; and extends about 200 miles from north to south, and 220 from west to east. It is bounded on the north by Berar, on the south by the kingdom of Mysore, on the west by Visiapour, and on the east by the northern circars. It was formerly a portion of a very extensive empire, which comprised all the peninsula from the north extremity of Orissa to Cape Comorin. It was anciently called Tellingana; and it is some evidence of its original extent, that the Tellinga language is at present in use from the river Pennar in the Carnatic to Orissa along the coast, and to a considerable distance inland. It was reduced under the power of Aurenzebe in 1687; and now forms the principal possession of the Nizam or Soubah of the Deccan. Its ancient capital was Warangole or Oringal, about 400 miles from Madras, the site of which is indicated by an old rampart of great extent, within which a modern fortress is erected; but the present metropolis is Hydrabad, about 50 miles to the south-west, a large walled town, situated in a delightful plain on the banks of the river Moussy, 902 miles from Calcutta, 352 from Madras, and 480 from Bombay: (See Hydrabad.) About six miles north-west from this town stands the celebrated fortress of Golconda, which gives name to the province, and is deemed impregnable. It occupies the summit of a hill, of a conical form, and is of such extent as to deserve the name of a city. It was anciently the residence of the kings of Golconda; and the tombs of many of them are still to be seen in the midst of gardens at a short distance from the fortress.† The country of Golconda is extremely fertile, and produces abundant crops of rice and other grain. Vines are very plentiful, and a white wine is made of the grapes, which are ripe in January. The wet or winter season begins in June, and continues till January; when the great heats commence. But it is chiefly celebrated for its diamond mines, which are generally adjacent to the ridges of rocks running through the country. The principal of these mines are in the neighbourhood of Raolcondo, and Culloor, the last of which places is about 110 miles east of Hydrabad, and is situated in the midst of barren, rocky plains. The diamonds are sometimes found scattered in the earth, within two or three fathoms of the surface; and in other places they are bedded in the body of the rock, at a depth of 40 or 50 fathoms. For a particular account of these mines, see *Philosophical Transactions*, vol. xii. or of the *Abridgment*, vol. ii. See also *Mod. Univ. Hist.* vol. vi; Rennel's *Mem. of a Map of Hindustan*; and Tavernier's *Travels.* (q)

GOLD. See Chemistry, p. 17, Gilding, Gold-Beating, Mineralogy, Money, and Wire-Drawing.

Goat, Gold-beating.

GOLD-Beating is the art of reducing gold to extremely thin leaves, for the purposes of gilding. The gold employed for this purpose must be pure. It should be melted in a crucible, with a small quantity of borax, and cast into small bars, or thin flat ingots, about $\frac{3}{4}$ths of an inch wide, and weighing two ounces each. These are extended to long plates, by rolling them in a flatting-mill, until they become lengthened out like ribbands, and very thin. To effect this, the ingot must be passed between the rollers a great number of times; and to correct the hardness which the repeated rolling at length produces, the metal must be occasionally annealed, by heating it to redness, and suffering it to cool gradually.

Casting the ingot.

The rollers employed for this process should be of a most perfect cylindrical figure, and have a highly po-

Laminating.

* See *Relation de l'Inquisition de Goa*, par Dellon; and Buchanan's *Christian Researches in Asia.*

† Within the fort itself, the principal inhabitants and bankers of Hydrabad are permitted by the Nizam to possess houses, to which, upon any alarm, they retire with their treasures and families.

lished surface. They should be of a large size, that they may not yield or bend; for the ultimate perfection of the gold leaf depends very materially upon the precision with which every part of the ribband is reduced to an equal thickness. Formerly the reduction was wholly effected by hammering: in course of time, a small hand flatting-mill was used to finish the work, after a considerable extension had been produced by the hammer; but at present the most improved practice is to have the rolling done at a flatting-mill, where, by following a similar process to that which we have described under the article COINING, a ribband can be produced which will contain very nearly the exact weight required for a given surface. The gold-beater generally orders this to be at the rate of very nearly 6½ grains to a square inch; and the workman who conducts the rolling, shews his care in coming as near to this as possible. Still much depends upon the goodness of his machinery, and also upon the regularity of the ingots in the first instance.

The moulds for casting the ingots should be made of cast-iron, and the internal surface rather concave, because, in cooling, the metal contracts more in thickness at the centre than at the outside. The moulds are heated, and rubbed with linseed oil, or tallow, on the inside, previous to pouring in the metal.

The ribband being thus prepared, the gold-beater cuts it up with shears into small squares of an inch each, and having previously divided it rather accurately by compasses, the pieces will all be very nearly of an equal weight, which is about 6½ grains for the ordinary gold leaves, but is more or less as the leaves are intended to be thicker or thinner. In order to beat out these squares to greater extent, they are made up into a parcel of about 150, with a leaf of fine calf-skin vellum interposed between each square, and about 20 leaves extra at the top and bottom of the parcel. The vellum leaves are about four inches square, and the plates of an inch square are carefully laid in the centre. In order to retain the packet together, it is thrust into a case of strong parchment, which is open at each end, so that it is only a belt or band, but sufficiently broad to cover the whole packet, except the two ends; and to secure these, a second case is drawn over the packet in the opposite direction. By this means the packet is rendered sufficiently firm and compact to bear beating with a large hammer of 15 or 16 pounds weight, the face of which is circular, nearly four inches diameter, and so much convex as will make it strike more forcibly upon the centre of the square packet, and extend the small square plates regularly.

The beating is performed upon a very strong stool, or bench, framed to receive a block of marble, or other hard stone, which is about nine inches square on the surface, and as heavy as can be procured; the wood-work is carried up round the stone in the form of a ledge, rising on the two sides and at the back; and to the front edge is nailed a kind of apron, which the workman takes before him, to preserve any fragments of gold which may come out of the packet. The handle of the hammer is very short, and the workman manages it with one hand: he strikes fairly upon the middle of the packet, which he frequently turns over to beat the opposite side, but this he does in the interval between two strokes, without losing his blow. He keeps up a constant beating, and when fatigued with one hand he dextrously changes the hammer to the other, whilst the hammer is elevated in the air, and without any loss of time or force. The packet is occasionally bent, or rolled between the hands, to loosen the leaves, and render the extension of the gold more free; and the packet is sometimes taken to pieces to examine the gold, and the centre leaves put at the outside, by which means the spreading of the gold will be equal throughout the packet. The beating is continued until the gold plates are increased to nearly the same size as the pieces of vellum; they are then taken out of the packet, and each cut into four squares, by a knife drawn across them in two directions. This reduces the plates to about the same size as at first, and they are again made up for a second beating, in a packet of about the same thickness as the former; but instead of vellum, skins about five inches square, prepared from the intestines of an ox, are interposed between each. The packet is made up in cases in the same manner as before described. The second beating is performed with a smaller hammer, of about ten pounds weight, and is continued until the leaves are extended to the size of the skins. The folding of the packet must be frequently repeated during this beating, to leave the gold as free as possible between the skins; because the leaves begin now to be very delicate, and are easily broken if the beating is not very carefully performed. The leaves are spread upon a cushion, and again divided into four, by means of two pieces of cane cut to very sharp edges, and fixed upon a board crossing each other at right angles. This cross being applied upon each square leaf, and pressed upon it, will divide it into four equal portions, which are made up into a third packet of convenient thickness, and once more extended to the size of the intended leaves, which is about three inches, or three and a half square. In this state the leaves will be extended to 192 times the surface which the plates had before the beating was begun. As these plates were each an inch square, and 75 of them weighed an ounce, the surface of the ultimate leaves will be $192 \times 75 = 14400$ square inches, or 100 square feet per ounce. This is by no means so thin as they may be made, for it is very practicable to extend an ounce to 160 square feet; but the waste arising from the great number of broken leaves, and the increase of labour, renders it of very little advantage to the gold-beater to reduce them to a greater thinness; and to the gilder such thin leaves are less valuable, both because they make less durable work, and are so liable to break and waste in laying them on.

Second beating between skins.

Third beating.

Thickness of the leaves.

The leaves when finished are put into small books made of single leaves of soft paper folded, but without sewing, and the surface of the paper is rubbed with red chalk to prevent the leaves adhering. Before putting the leaves into these books, they are taken one by one, with a pair of delicate pincers, out of the packet of the last beating, and spread out upon a cushion of leather, by blowing them flat; then to cut them all to the same size, a piece of square board is applied, which has four sharp edges of cane glued upon it. These edges being pressed upon the gold, cut it to the size desired, which is generally 3¼ inches square. The books are made up to contain 25 leaves each, and in this state they are ready for the gilder.

Cutting the leaves.

The extension of the gold during the latter beating depends greatly upon the nature of the membrane or skin, which is interposed between the leaves. The preparation of these skins is kept a secret by the few individuals who furnish them to the gold-beaters. Dr Lewis describes them as being made from the skins of ox-gut, stripped off from the large straight gut cut open. A number of these membranes are laid with the smooth sides together whilst in a moist state, and will adhere together: they are then stretched in a frame, and the fat and loose skin carefully scraped off, so as to leave

Preparation of the skins.

Gold-beating || Goldoni.

only the fine exterior membrane of the gut. Afterwards they are beaten between leaves of soft paper to absorb the grease, moistened with infusions of strong spices, and are lastly dried and pressed flat. Before being used, they are rubbed over with a pounce, composed of plaster of Paris, which is rubbed strongly with a hare's foot, to prevent the gold from adhering to the membrane, which is very thin but tough, and so transparent, that small print may be read through it. The skins will serve for beating seventy or eighty times; but at length the gold will not extend well between them. It is said in the French *Encyclopedie*, that their virtues may be again restored, by placing them between papers wetted with vinegar or white wine, beating them for a whole day, drying them, and then rubbing them again with the pounce. It is also recommended to dry and press the skins every time before they are used.

Gilt-leaf. The Dutch manufacture a false gold leaf, which is made of brass covered with gold. The brass is reduced to a fine thin ribband, by laminating in the same manner as we have described for the gold. The ribband is then gilded by the wash gilding process, and afterwards cut up into pieces, which are beat out into leaves, by the same means that are used for gold beating; but the extension is not carried so far, because there is less inducement to make the leaves thin.

It is difficult to distinguish this Dutch leaf from true gold when new, but it very soon tarnishes and wholly loses its colour, which renders it unfit for any other kinds of gilding than those which are to be varnished over. (J. F.)

GOLD Coast. See Guinea.

GOLDONI, Charles, an eminent Italian dramatic author, was born at Venice in the year 1707. He displayed an early disposition for study, and could both read and write when only four years old. The perusal of the comic writers of his country was his favourite occupation. Of these, his father's small library afforded him a considerable fund; and he made it a practice to transcribe those passages which gave him most pleasure. At the age of eight, he ventured to sketch a comedy of his own invention.

His father having been called to exercise his profession of a physician at Perugia, he placed his son at the college of the Jesuits there, where he studied grammar and rhetoric; and his preceptors were so highly pleased with his proficiency, that when he was about to leave the college, they offered him a situation in their Society, which he, however, thought proper to decline. He thence went to Rimini, to pursue his philosophical studies at the college of the Dominicans. But the dry dogmas of the scholastic philosophy had no attractions for the lively mind of Goldoni, who thought himself much more usefully and agreeably employed in perusing the works of Plautus, Terence, and Aristophanes, and in attending a troop of comedians, who were then performing at Rimini. At the end of their engagement, the players prevailed upon him to accompany them to Chiozza, where his mother resided. His father was a good deal irritated at this foolish step, but soon became pacified; and intending that his son should embrace his own profession, he took him occasionally to visit his patients. The son, however, showed no inclination for the medical profession; and it was then resolved that he should study law. With this view, he was placed for some time as a clerk with his uncle, M. Indric, a respectable practitioner at Venice, and was afterwards removed to the papal college in the university of Pavia; but in the third year of his studies, he was expelled from the college, in consequence of a satirical effusion which he had been prompted to circulate against some of the inhabitants of the town, who had given him offence. After several changes of fortune, he at length engaged in practice at the bar of Venice; where he published an Almanack for the year 1732, and composed a lyrical tragedy, entitled *Amalasonte*, which he afterwards suppressed. Having been obliged to leave Venice in disgust, he removed to Milan, where he became attached to the suite of the Venetian resident. Here he composed a short comic opera, called *The Venetian Gondolier*, which was performed, and afterwards printed among his works. He afterwards returned to Venice, where he employed himself in composing pieces for the theatres. His *Belisarius*, a tragi-comedy, was represented, for the first time, on the 24th of November 1734, and experienced a most brilliant reception, having been repeated every day until the 14th of December.

Goldoni, Goldsmith.

In the spring of the following year, he accompanied the comedians to Genoa, where he married a lady of that place. From this period, he continued to compose dramatic pieces for several of the Italian theatres. In the year 1742, however, he was induced to settle as an advocate at Pisa, and he appears to have practised for some time with considerable success; but the theatre at length seduced him from his legal pursuits, and he again attached himself to a company of comedians. He accordingly returned to Venice, and continued to compose for the theatres of that and other cities of Italy, until the year 1761, when he received and accepted an invitation to Paris. Here he furnished a number of pieces for the Italian opera; and even ventured, although a foreigner, after a nine years residence, to compose comedies in the French language. One of these, *Le Bourru bienfaisant*, experienced a very flattering reception, and was admitted among the number of stock plays. He also attended some of the French princesses in the capacity of Italian teacher; and besides some presents in money, he obtained the grant of a yearly pension of four thousand livres. At the period of the revolution his prospects darkened; his pension was withdrawn; and after passing some years in poverty and distress, he died in the beginning of the year 1793, at the age af 86.

In private life, Goldoni appears to have been amiable, chearful, easy, and artless. As a comic author, he ranks high among the writers of his age and country. Like Lope de Vega, he seems to have possessed an almost miraculous fertility of conception, and rapidity of execution. In one theatrical season at Venice, he furnished no less than sixteen new comedies, besides other pieces. He also composed a great number of operas, both serious and comic; but of these he was not vain, and indeed never thought them worthy of publication. His admirable comic opera, however, entitled *La Buona Figliuola*, set to music by Piccini, and first performed in London on the 9th of December 1766, established the reputation both of the author and composer in this country.

The works of Goldoni are very numerous. The most complete edition, it is believed, is that printed at Leghorn in 1788-91, in 31 volumes 8vo. See *Memoires de Goldoni*, Paris and London, 1814; and *Monthly Magazine*, vol. v. (z)

GOLDSMITH, Oliver, was born in the parish of Forney, and county of Longford, in Ireland. He was the second son of the Rev. Charles Goldsmith, a respectable clergyman of the established church. His early education was limited to reading, writing, and arithmetic, such as could be acquired from the schoolmaster of

Goldsmith.

his native village, and might fit him for some mercantile employment. But having shewn some marks of genius, it was at length resolved to send him to the university; and accordingly having gone through the preparatory studies, he was admitted a sizer of Trinity College, Dublin, in June 1744. While here, an unfortunate quarrel with his tutor, occasioned by the imprudence of the one and the harshness of the other, blasted his hopes of distinction. He engaged in a tumult, and escaped expulsion only by making a humble confession. Nor did he atone for such follies by diligence and progress in learning. He was habitually indolent: he neither stood candidate for the usual premiums, nor did he obtain a scholarship; and it was not till February 1749, two years after the regular time, that he was admitted to the degree of Bachelor of Arts. Having lost his father, he was taken under the protection of his uncle, the Rev. Thomas Contarin, who had all along, indeed, shewn him the utmost kindness, and who persevered in his friendship towards him, notwithstanding the most provoking conduct on the part of young Goldsmith. He was at length, by this worthy relative, sent to Edinburgh about the end of 1752, to study physic. His attendance on the medical classes there was very irregular; his habits of heedlessness and folly grew upon him; and his health, as well as his finances, was greatly injured, by the dissipations in which he freely engaged. Having gone through the usual course of study, he set out for Leyden with the consent of his uncle: after having, by the generosity of two friends at college, been freed from an arrestment for debt, contracted by his thoughtlessly becoming surety for a fellow-student. At Leyden he continued for a year, studying chemistry under Gaudius, and anatomy under Albinus; but more heartily engaged in gambling, to which he was now unhappily addicted, than in the pursuits of science. Stripped of all his money, he determined to quit Holland, and to make the tour of Europe. He supported himself by various means. Sometimes he had recourse to his musical skill, playing on his flute for what the people would give him; sometimes his classical learning procured for him entertainment at the monasteries; and sometimes, by engaging in those public disputations, which were maintained in the universities and convents, he was so successful, as to be allowed a donation of money, a dinner, and a bed for the night. In this manner he travelled through Flanders, some parts of France and Germany, Switzerland, and Italy. It was while in Switzerland, that he first cultivated his poetical talents, part of his beautiful poem the Traveller having been written there, as he himself tells us. When he was in Italy, he received accounts of the death of his uncle; and the pecuniary remittances failing him in consequence of this, he was obliged to travel homeward on foot. He landed at Dover in 1756, having spent about twelve months in this strange and adventurous peregrination. He first became usher in an academy; then assistant in a chemist's laboratory; and at length commenced business as a physician, which procured for him plenty of patients, but almost no fees. In 1758, through the kindness of Dr Milner, a dissenting clergyman, he was appointed physician to one of the factories in India. To equip him for that situation, (into which, after all, he never entered) he composed "The Present State of Polite Literature in Europe." This work was printed in 1759. Before it appeared, he laboured as a contributor to the Monthly Review. His contract with the editor was favourable to Goldsmith; but it was dissolved by mutual consent at the end of seven or eight months. His circumstances continued to be narrow. While under arrest for debt, he produced that inimitable novel, the Vicar of Wakefield, for which he received £60. On May 31st 1761, he received his first visit from the celebrated Dr Johnson. Besides correcting and revising many publications for Mr Newbery, he wrote his Letters on English History, in 2 vols. 12mo, which have been by mistake attributed to Lord Lyttleton, and other noble authors; conducted a Lady's Magazine; contributed to the "Bee;" and produced a periodical paper called "The Ledger." This last work was afterwards collected into 2 vols. 12mo, and entitled the Citizen of the World: It is characterised by fine sentiment, and exquisite humour. But his chief attention was bestowed on The Traveller, which he brought out in 1765, on which he intended to build his poetical fame, and which did procure for him both high reputation, and considerable patronage. His charming ballad the Hermit, recommended him to the Duchess of Northumberland. In 1764, the famous Literary Club was established; Goldsmith was one of its first members, and continued in it till his death. In 1768, his comedy of "The Good-natured Man" was first represented at Covent Garden, and kept possession of the stage for nine nights. And in the year following, he produced his fine and popular poem of the "Deserted Village." While preparing these pieces for the press, he undertook and completed his "Roman History," in 2 vols. 8vo, and his "History of England," in 4 vols. 8vo,—works intended for the perusal of the young, and certainly written in an interesting manner, but almost always superficial, and frequently inaccurate. The History of England was finished in two years, and he received for it £500. He was employed all this time in literary efforts of an occasional and inferior kind; such as prefaces, introductions, and prospectuses. It was one of these that led to the publication of the "History of the Earth and Animated Nature," a production entertaining and well written, but unfortunately abounding in errors. He also wrote a "Life of Parnell," of which Johnson speaks in terms of high approbation. In preparing his "Beauties of English Poetry," he introduced, inadvertently, an indecent tale from Prior, which blasted the success of the selection, as it was chiefly intended for the use of boarding schools. The life of Lord Bolingbroke, prefixed to that nobleman's Dissertations on Parties, was the production of Goldsmith's pen, though his name was not affixed to it in the first edition. When the Royal Academy was established, Sir Joshua Reynolds procured for him the appointment of professor of ancient history,—an appointment without salary or trouble, but in other respects honourable and useful to him.

On the 15th March 1773, his second comedy, "The Mistakes of a Night, or She stoops to Conquer," was produced at Covent Garden, was received by the audience with great applause, kept possession of the stage as a stock play, and increased his literary reputation. A scurrilous paper, occasioned by his success, and inserted in a London paper, so provoked him, that he went to the editor and assaulted him; but the Doctor got himself severely bruised in the scuffle. He was led into this quarrel by the officiousness of a pretended friend. About this time, he wrote "The Retaliation," "The Haunch of Venison," and some other small pieces, which did not appear till after his death. A great project now entered his mind; it was "An Universal Dictionary of Arts and Sciences." He had engaged his literary friends to assist him, and had actually prepared a prospectus of the work. But his plan was interrupted by a fever, which terminated his life on the 4th of April 1744. He was privately interred in the Temple burial ground. A marble monument was afterwards erected to his memory in Westminster Abbey, between those of Gay and the Duke of Argyle, in the poet's corner. The inscription was written by Dr Johnson, and contains a very just though concise delineation of his merits. As a man, he was constitutionally kind, but exceedingly improvident, and acted according to impulse rather than principle. As a writer, he must be regarded as standing in the very foremost rank of the British classics. In both views, simplicity may be considered as his leading characteristic. (τ)

GOLF, is an ingenious field game, played with bats or clubs, and balls, and a favourite amusement in Scotland. When or by whom it was first introduced, is not ascertained; but we find, that as early as the fifteenth century, it was so much in vogue as to be an object of attention to the legislature. The parliament of Scotland, assembled under James II. in 1457, passed an act prohibiting golf and foot-ball, as being found to interfere too much with the acquisition of dexterity in archery, an accomplishment in those days of such consequence to the safety of the state. "It is decreed and ordained," says the act, "that the foot-ball and golf be utterly cried down, and not to be used, and that the bow-marks be made at ilk (*each*) parish kirk a pair of butts, and shooting be used. And that ilk man shoot six shots at the least, under the pain of being raised upon them that comes not, at the least two pennies, to be given to them that comes to the bow-marks to drink." This shows that golf was at that period known and much practised. And as in the former reign, viz. of James I. anno 1424, we have a similar act of parliament, prohibiting foot-ball, without any mention being made of golf, we think the probability is, that golf was not then known:—certainly it was not much practised.

In both the subsequent reigns of James III. and James IV. we have similar acts of parliament against foot-ball and golf. Under the first of these monarchs, in 1471, it is enacted, "that foot-ball and golf be abused, (that is disused) in time coming; and that the buts be made up, and shooting used, after the tenor of the act of parliament made thereupon." In the reign of James IV. 1491, it is statute and ordained, "that in no place of the realm there be used foot-ball, golf, or other such unprofitable sports," under the penalty of forty shillings. All these statutes were evidently framed, not from a conviction that there was, in the manly and athletic exercises of foot-ball and golf, any thing injurious either to the health, the morals, or the loyalty of the subject; but because they drew the attention too much from the attainment of skill in martial exercises, at a time when the situation of the country so eminently required it.

The ground over which golf is played, is in Scotland called links, and is usually a particular sort of sandy soil in the neighbourhood of the sea-shore, its surface mostly covered with short close grass, here and there interrupted by breaks, pits, and inequalities. These interruptions are necessary to impart interest to the game.

The track along which the players proceed, is denominated the course, and may be either rectilinear, or a figure of any number of sides. Holes are made in the ground of about four inches diameter, and at the distance of four hundred yards, or a quarter of a mile from each other; and the object of the game is to strike a ball from one of these holes into the next with as few strokes as possible. A game may be said to terminate at each of these holes, and their number is not limited, but depends on the nature of the ground.

Balls are used of about $1\frac{1}{4}$th of an inch in diameter, and weighing from 26 to 30 drachms avoirdupois. They are made of strong alumed leather, and stuffed with feathers. The feathers are forced in at a small hole left in the covering, by a blunt pointed iron instrument, which the maker applies to his shoulder, and the operation is continued till the ball acquires a surprising degree of hardness and elasticity. A good workman makes about nine balls in a day. When dry, they are painted with white oil-paint, to exclude the water, and render them easily seen. In playing, they are struck with a bat or club, four feet in length, having a small tapering elastic shaft, with a crooked head, into which is run a quantity of lead to render it heavy, and it is fortified by a piece of horn before. A good player, with one of these clubs, will strike a ball to the distance of 180 or 200 yards. Every golfer has a variety of clubs, differently formed, and adapted for playing in different situations of the ball, and in different stages of the game. A set consists of four at least, viz. the common or play-club, the spoon, the putter, and the iron; but most golfers have ten or a dozen different sorts. The common club is used when the ball lies fair on the ground; the spoon, when in a hollow; the iron, when among sand, gravel, or stones; and the putter, when near the hole.

A match may consist of two or more players; but no proficient at golf every plays in one exceeding four, that number being allowed to be the most elegant and convenient. Each party has a ball, and the rule is, that at the beginning of a hole or game, the player may elevate his to what height he chooses for the convenience of striking, and this is done by means of a little sand or earth, and is called *teeing*; but after the first stroke has been made, the ball must be played from the spot where it chances to lie. And whichsoever of the balls lies farthest back, or at the greatest distance from the hole to which the players are proceeding, must be always played till it get before the other.

Thus, suppose A and B to be engaged in a match. A plays off, and then B. A's ball lies farthest behind, and therefore, by the rules of the game, he is obliged to play again. This is called playing *one more*, or *the odds*. But A misses his ball, or sends it only to so short a distance, that it is not yet so near the mark as B's. A must therefore play a third time, and this is called playing two more; and should it so happen, that, even at this stroke he does not get his ball laid nearer to the hole than that of B, he must then play three more, and so on.

When B then plays, he is said to play *one off three*; and if he plays a second time in order to get before A's ball, he is said to play one off two; and if a third time, one off one, or *the like*. Then whoever of the two plays first, again plays the odds. But if when B played one off two, or one off three, A had been to play next, he would then have played two more, or three more, respectively. If the party consists of four, the rule is the same, except that the two partners on each side play alternately. If the ball be struck into the hole at *the like*, or an equal number of strokes on both sides, the hole is said to be halved, and goes for nothing.

To play this game, will require more dexterity and practice than is commonly imagined. But an idea of its difficulty may be formed by considering the smallness of the object struck, compared with the largeness of the circle described in the swing round with the club; the accuracy required to keep the course, and to measure the force applied in such a manner as to avoid hazards and over-driving the ball when approaching the end of the range; also the judgment requisite to determine the most advantageous club to be used in any given situation of the ball; as well as the allowance to be made for the force and direction of the wind when there happens to be any, and the nature and inequalities of the ground. (*)

GOMBROON, or Bender Abassi, the Harmozia of the ancients, is a town of Persia, in the province of Kerman. It is situated in a barren country, on a bay of the gulf of Ormuz. The town is large, and the houses more commodious than in other parts of Persia. It is fortified with double walls, and is defended by the fort of Minah, which stands partly on a hill, and is divided into the upper, the centre, and the lower, forts. A small river breaks through the hills, and forms a pass from the east, and its water, diffused by means of canals, serves as ditches to the fort. The country, for about 45 miles round, is covered with villages, and supplies all the neighbouring districts with grain and dates. The cattle of the adjoining districts are sent here in great numbers to feed during the hot season.

Gombroon was formerly the first sea-port in Persia, and it is still a place of considerable trade. The English settled here in 1613. In 1620, the Dutch followed their example; and, upon the taking of Ormuz, in 1622, merchants flocked here in great numbers. In 1759, it was taken by the French; but though the English factory was afterwards re-established, yet, from the heaviness of the expence, and the unhealthiness of the climate, it has long ago been withdrawn. Gombroon is now subject to the Imam of Muskat. The customs amount to 20,000 rupees annually; and for this, as well as the tribute of Minah, the Imam is accountable to the King of Persia. East Long. 56° 12′, North Lat. 27° 81′. See Milburn's *Oriental Commerce*, vol. i. p. 131; and Kinneir's *Memoir of the Persian Empire*, p. 201.

GOMERA, one of the Canary Isles, is situated about six leagues S. W. from Teneriffe, and is about 20 miles long, and 10 broad. The chief town in the island is St Sebastian, or La Villa de la Palma, which stands upon the shore in the bottom of a bay on the south-east side of the island, where shipping is secure from all winds except the south-east. Ships of any burthen may heave down and repair at the cove, hauling close to the shore, which is a high and perpendicular cliff. A battery, with several pieces of cannon, are placed on the summit, for the defence of the harbour. At a short distance from the beach the town commences, the principal street running straight inland. The houses, to the number of 150, are small and mean; the only public buildings are a church and a convent. It is supplied with good water. An account of the trade, &c. of this place, will be found under our article Canary Isles. Population 7000. West Long. of the harbour 17° 7′ 45″, North Lat. 28° 5′ 40″.

GONDAR, the capital city of Abyssinia, is situated in 12° 34′ 30″ North Latitude, and 37° 33′ East Longitude from Greenwich. It is placed upon a hill of considerable height, the top of which is nearly plain, and which is surrrounded on every side by a deep valley. The river Kahha, which comes from the Mountain of the Sun, runs through the valley on the south side of the town, and the river Angrab, falling from Woggora, surrounds it on the north and north-east. These two rivers unite their waters at the bottom of the hill, about a quarter of a mile south of the city. The houses of Gondar are constructed chiefly of clay, and the roofs are of a conical form, covered with thatch. The principal public building is the palace, at the west end of the town, which is said to have been built in the time of Facilidas, by masons from India, and by such Abyssinians as had been instructed in architecture by the Jesuits. It had been originally a square building, four stories high, and flanked with square towers; but having been burnt at different times, great part of it was in ruins during Mr Bruce's residence in Abyssinia. Some of the apartments, however, still exhibited proofs of their ancient magnificence. In one chamber the walls had been covered with plates of ivory, stained with stars of various colours; and in another the skirting was finished with ivory, four feet from the ground; and over it were arranged, around the room, three rows of Venetian mirrors, fixed in frames of copper, while the roof was formed of split painted cane, disposed in Mosaic figures, in the gayest style. There was still ample lodging in its two lowest floors, and the audience chamber alone was above 120 feet in length. Successive sovereigns have built apartments by the side of the original edifice, which are formed of clay, and according to the fashion of the country; but the whole structure, and these contiguous buildings, are surrounded with a substantial stone wall, 30 feet high, and the four sides of which are above an English mile and a half in circumference. There are battlements upon the outer wall, but no appearance of embrazures for cannon; and a parapet roof between the outer and inner wall forms a gallery, by which a person can go along the whole, and look into the street. In times of peace, Gondar contains above 10,000 families, or 50,000 souls. One of its principal manufactures is a kind of coarse carpet made of the wool of the sheep and hair of the goat dyed red or light blue. See Bruce's *Travels in Abyssinia*, vols. iv. and v. 8vo; Valentia's *Travels*, vol. ii. and Salt's *Travels*. (*q*)

GONG, is the name of an instrument used among the Chinese for producing loud sounds by percussion. It is a large circular instrument, somewhat resembling a tambourine. It is entirely made of metal, and has its face somewhat convex. The metal, which resembles bronze, bears numerous marks of the hammer in every part. A string passes though a hole in the rim, and when the gong is suspended by this string, it is beaten on the centre by repeated gentle strokes of a spherical mallet, covered with folds of woollen cloth. When it is properly struck, it emits an overpowering sound, which may be heard at more than the distance of a mile. Gongs are manufactured openly in Canton; and the largest kinds are made in one of the interior provinces of China. They are generally carried on a pole by two men, and beaten by the hindmost, and are commonly used at processions and at festivals, and also for the purpose of regulating the steps of the soldiers.

The metal of which the gong is composed is brittle, and very elastic, and has a granular texture. Dr Wollaston found it to be quite malleable at a temperature considerably below that of red heat. He determined the composition of the metal, and having made a quantity of similar alloy, he mended a crack in a gong belonging to Sir Joseph Banks, and restored the tone of the instrument. Klaproth found that the specific gravity of the gong was 8.815, and that it consisted of

Copper	78
Tin	22
	100

Dr Thomson found that its specific gravity was 8.953, that its thickness varied from one-fifteenth to one-twentieth of an inch, and that it was composed of

Copper	80.427
Tin	19.573
	100.000

Mr Murdoch has recently discovered not only the proper composition, but also the mode of manufacturing gongs; and in the course of his investigation has obtained several interesting results, which we hope to be able to communicate in a subsequent article. See Gehlen's *Journal, Second Series*, vol. ix. p. 408; and Thomson's *Annals of Philosophy*, vol. ii. p. 208. 315, 316.

GONIOMETER, from γωνια *an angle*, and μετρειν *to measure*, is the name of a class of instruments for measuring the inclination of one plane surface to another. As the principal use of these instruments is to measure the angles of crystallised bodies, they were first introduced, and are now principally used, by mineralogists; although those which depend on the principle of reflexion, are of the most essential utility in many branches of physics, particularly in optical experiments.

Common goniometers.

In our article CRYSTALLOGRAPHY, p. 454, we have already described the goniometer used by Romé de Lisle, and M. Hauy, and invented by M. Carangeau, (see Plate CCXXIII. Fig. 34.) and in the same article we have given drawings and descriptions of the new reflecting goniometers invented by Dr Wollaston and Dr Brewster. See Plate CCXXIV. Figs. 1. and 2. The present article will therefore embrace some additional remarks on the applicacion of the principle of reflexion, and an account of some other goniometrical instruments which could not with propriety have been introduced under the head of CRYSTALLOGRAPHY.

The reflecting goniometers of Dr Wollaston and Dr Brewster were invented nearly about the same time, without any communication between their respective authors; but though these instruments resemble one another in so far as they both make use of the principle of reflexion, yet they differ very widely in the application of that principle, and in the mode of measuring the angles of crystals.

Reflecting goniometers by Wollaston and Brewster.

Plate CCLXXVII. Fig. 1, 2, 3.

One of the advantages which Dr Brewster's goniometer possesses over that of Dr Wollaston's, is, that the former is capable of measuring a hollow angle, such as *a b c*, represented in Plate CCLXXVII. Fig. 1. and 2. or one in which the crystal *a b c*, Fig. 3. is imbedded in a stony mass from which it cannot easily be detached. The case represented in Fig. 2. is one which actually occurs in measuring the angle which the edge of the interrupting stratum, or crystallised vein of some specimens of Iceland spar, forms with the surfaces of the rhomboid. The determination of this angle is of the utmost importance, and is incapable of being measured by any goniometrical instrument with which we are acquainted, excepting that of Dr Brewster's. See *Philosophical Transactions* for 1815, p. 277.

This goniometer will measure the angles of crystals with great accuracy, and little trouble, if the surfaces are moderately smooth, and reflect the smallest quantity of light. When the surface has the appearance of being perfectly rough and irregular, the oblique reflection generally gives a very distinct image of a vertical bar, when the image of a horizontal line or of any other object could not possibly be obtained. It frequently happens, however, that the crystal does not reflect sufficient light to form an image, or is so irregular in its surface, or is so inconveniently placed in the specimen, that a variety of different contrivances must be adopted for measuring its angles. In a specimen of Allanite, for example, belonging to Mr Allan, the crystals are situated in such a manner, that their angles could not be measured by any goniometer without breaking off some of the projecting parts of the mineral.

Brewster's goniometer.

Plate CCLX[illegible] Fig. 4.

When the planes of the crystal are smooth, but unpolished, a small piece of parallel glass AB, Fig. 4. or any other reflecting substance, with parallel sides, is successively placed upon the surfaces of the crystal CDE; the coincidence of the direct image of a rectilineal object with the image reflected from the piece of glass, is observed as before, and the angle found in precisely the same manner. If the two surfaces of the reflector should not be parallel, the aberration will be corrected by reversing its position on the second surface of the crystal.

Fig. 5.

When the planes of the crystal are covered with asperities which prevent the piece of glass from lying parallel to these planes, we must make use of the reflector AB, Fig. 5. supported by three slender feet, and so formed that the reflecting plane *m n* is exactly parallel to the plane *o p*, passing through the extremities of the three feet. The three feet are then placed upon those points of the surface where there are no asperities, and the coincidence of the images is observed in the reflector: It is then transferred to the other surface of the crystal, the coincidence of the images again observed, and the angle of the planes measured as before. As the surface of the crystal may always be brought into a horizontal position when the coincidence of the object and its image is observed, the reflector will stand steadily on the planes of the crystal; but, in order to secure it from sliding, a drop of varnish or melted bee's wax may be placed round each of its feet. It might be proper to have two or three of these reflecting tripods of different sizes, and with their feet at different distances, in order to accommodate themselves to the smooth parts of the crystal. One of the reflectors might be fixed on each surface with bee's wax, in the way represented in Fig. 6. where C is the crystal, and A, B the two reflecting tripods. If the position of the crystal should prevent us from adopting either of these methods, which was the case in the specimen of Allanite already mentioned, we must have recourse to the goniometrical microscope, which is intended to measure the angles formed by two lines when the eye is perpendicular to the plane of the angle.

Fig. 6.

If we conceive the two surfaces of a crystal to be cut by a plane perpendicular to their common section, the apparent angle contained by the two lines which form the boundary of the section, when the eye is perpendicular to the section, is evidently the inclination of the planes. But if the cutting plane is not perpendicular to the common section, the apparent angles of the lines which form the boundaries of the section when viewed by an eye perpendicular to it, is evidently greater or less than the real angle of the crystal, according to the position of the cutting plane. If the observer, however, places himself in such a manner, that the common section of the planes is parallel to the axis of his eye, then the apparent angle formed by the bounding lines of the section, whatever be the position of the cutting-plane, is the real angle of the crystal. By placing the crystal therefore, in this position, in the focus of the goniometrical microscope, which shall be hereafter described, and measuring the apparent angle formed by the bounding lines, we obtain, by a very simple process, the inclination of the planes.

Fig. 7.

This will be understood from Fig. 7. in which ABCDEF is a crystal, ABC a section of it perpendicular to AD, and A *b c* an oblique section. Now, though BAC is the real angle of the crystal, yet, when the oblique section A *b c* is viewed by the observer at O, its bounding lines A *b*, A *c* are apparently coinci-

Goniometer. Brewster's goniometer. PLATE CCLXXVII.

dent with the lines AB, AC, whose inclination is the real angle of the planes; and therefore, if we measure by a proper instrument, the apparent angle contained by the oblique lines A b, A c, we obtain a measure of the real angle of the crystal.

The angles of the crystal may also be advantageously deduced, from the plane angles by which any of the solid angles is contained. The plane angles are first measured with great accuracy by the goniometrical microscope, or the angular micrometer adapted to a microscope, and the inclination of the planes is deduced from a trigonometrical formula. Whatever be the number of plane angles which contain the solid angle, we can always reduce the solid angle to one which is formed by three plane angles, and determine by the formula the inclination of any two of them. Thus, if the solid angle at A, Fig. 8. is contained by five plane angles, and if it is required to find the inclination of the planes ABC, ACD, we first measure the plane angles CAB, CAD, and also the angle contained by the lines AB, AD; so that we have now reduced the solid angle contained by five plane angles, into one contained by three plane angles, CAB, CAD, BAD.

Fig. 8.

Legendre, in his Elements of Geometry, has given a very elegant solution of this problem by a plain construction; and it is easy, from his solution, to form an instrument for shewing the angles of the planes without the trouble of calculation. Thus let the angles BAC, CAD, DAE, Fig. 9. be made equal to the three plane angles by which the solid angle is contained. Make AB equal to AE, and from the points B, E let fall the perpendiculars BC, ED on the lines AC, AD, and let them meet at O. From the point C, as a centre with the radius CB, describe the semicircle BFG. From the point O draw OF at right angles to CO, and from F, where it meets the semicircle, draw FC. The angle GCF is the inclination of the two planes, CAD, CAB. In order to construct an instrument on this principle, to save the trouble of projection or calculation, we have only to form a graduated circle BHEG, with three moveable radii, AC, AD, AE, and a fixed radius AB. The moveable radii must have vernier scales at their extremities, that they may be set so as to contain the three plane angles which form the solid angle. Two moveable arms BG, EO, the former of which is divided into any number of equal parts, turn round the extremities B, E; and, by means of a reflecting mirror on their exterior sides, they can be set in such a position as to be perpendicular to the radii AC, AD. When this is done, the number of equal parts between C and O, divided by the number between B and C, is the natural co-sine of the angle GCF; and therefore, by entering a table of sines with this number, the inclination of the two planes will be found.

Fig. 9.

In order to obtain a more accurate result, however, we must have recourse to a trigonometrical formula. Let A, Fig. 10. be the solid angle, and let it be required to determine, by means of the three plane angles, the inclination of the surfaces ACB, ACD. Draw AM, AN in the planes ACB, ACD, and perpendicular to the common section AC; join BM, DN. Then it is obvious, that the angle MAN is the inclination of the planes required, and that the angle BAD, which is an oblique section of the prism BM, will be equal to MAN when it is reduced to the plane AMN. By considering that the inclinations of the bounding lines of the oblique section of the prism, to the bounding lines of the perpendicular section, are measured by the angles DAN, BAM, the complements of the two given plane angles CAD, CAB, we shall obtain, by spherical trigonometry, the following formula:

Fig. 10.

$$\text{Sin.}\,\frac{\text{MAN}}{2} = \frac{\text{R}\sqrt{\left(\text{Sin.}\,\frac{\text{BAD}+\text{CAD}-\text{CAB}}{2}\,.\ \text{Sin.}\,\frac{\text{BAD}+\text{CAB}-\text{CAD}}{2}\right)}}{\text{Sin. CAB. Sin. CAD}}$$

Or, calling φ the angles of the surfaces of the crystal, B, C the plane angles at the vertex of these surfaces, and A the other plane angle, then we shall have

$$\text{Sin.}^2\,\frac{\varphi}{2} = \text{Rad}^2\frac{\left(\text{Sin.}\,\frac{\text{A}+\text{B}-\text{C}}{2}\,.\ \text{Sin.}\,\frac{\text{A}+\text{C}-\text{B}}{2}\right)}{\text{Sin. B. Sin. C.}}$$

a formula from which the value of φ may be obtained by a very simple calculation.

Let the angle BAD, for example, be 62° 56′, the angle CAD = 100° 2′, and the angle CAB = 106° 10′, then we shall have, by the preceding formula,

$$\text{Sin.}^2\,\frac{\varphi}{2} = \text{Rad.}^2\,\frac{\text{Sin. } 28^\circ\, 24'\ \ \text{Sin. } 34'\, 32''}{\text{Sin. } 106^\circ\, 10'\ \ \text{Sin. } 100^\circ\, 2'};$$

Now we have,

Log. sin. 28° 24′ . .	9.6772640
Log. sin. 34° 32′ . .	9.7534954
	19.4307594
Add 2 Log. of Rad. .	20.0000000
	39.4307594
Log. sin. 106° 10′ . .	9.9824774
Log. sin. 100° 2′ . .	9.9933068
	19.9757842
From	39.4307594
Subtract	19.9757842
2 Log. sin. $\frac{\varphi}{2}$ . . .	19.4549752
Log. sin. $\frac{\varphi}{2}$ . . .	9.7274876

Hence $\frac{\varphi}{2} = 32^\circ\, 16'\, 18''$

and $\varphi = 64^\circ\, 32'\, 36''$

the angle of the surfaces of the crystal.

A goniometer, upon another principle, has recently been invented by the Rev. E. J. Burrow, fellow of Magdalene College, Cambridge. The following is the description of it given by himself:

Burrow's goniometer.

"BG (Fig 11.) is a steel bar, of about $\frac{1}{12}$ of an inch square, chamfered off to the point B. On BG is taken exactly an inch, BA, and A is made the centre of motion of the legs DE and de, of which DE is also brought to a point at D to correspond with B. To the other end of these legs is attached by the pin F, a moveable quadrant, passing through the bar BG at C, and graduated to read towards the side of the shorter leg de. The handle GH is made to project on the opposite side to that on which the legs move, that it may not interfere with the use of a brass degree divided into minutes, to be attached to the centre A upon longer radii. The leg AB is divided accurately into tenths, and the two nearest the point B into twentieths, and these again into fortieths. The whole instrument is about four inches and a half long.

Fig. 11.

Now if the crystal, the angle of which is to be mea-

Goniometer. Burrow's goniometer. PLATE CCLXXVII. Fig. 11.

sured, be detached, it is obvious, that, if an acute one, by applying it to the angle BAD, the vertical and equal angle EAC will be given on the quadrant; if obtuse, by applying it to the angle E and B, we obtain its supplement EAC. But if the crystal be imbedded in the matrix, so that with the common goniometers having the moveable vertex, it is difficult to procure a mechanical measurement of the protruding angle, we take any distance from the vertex of the crystal measured upon the scale of tenths, &c.; and placing one point of the instrument, (*ex. gr.*) on x (Fig. 12.) and the other on z, so as to make the triangle $x\,y\,z$ isosceles, we get upon the quadrant the angle which the base $x\,z$ subtends at the radius one inch; and we have the side $x\,y$ measured. As, therefore, when the object is given, the angle it subtends, and $\frac{1}{\text{rad.}}$, we have the proportion $x\,y$: AB : : angle found : angle sought. And as the whole radius is one inch divided into tenths, this proportion is easily made in the head.

Fig. 12.

The short bar is added for the better carrying of the quadrant, and renders the instrument useful in geological observations, to ascertain the inclination of strata. This is done by hanging a small plummet to a hook at A, and having made the angle which it forms at BC a right angle, and moving the outer bars, till their upper line coincides with the stratum, the angle of inclination will be given on the quadrant."

We shall now conclude this article with the description of a goniometrical telescope, and a goniometrical microscope, invented by Dr Brewster, and described in his *Treatise on New Philosophical Instruments.*

Brewster's goniometrical telescope. Fig. 13.

This instrument is represented in Fig. 13, where TT is the eye-tube of the telescope, which carries the graduated circle AB, divided into 360 degrees. By means of the milled head which surrounds the eye-glass at E, this circle has a motion of rotation about the axis of the eye-tube. The vernier V has likewise a motion round the axis of the instrument, and may be set to the zero of the scale, when the level L, fixed to the plane surface of the graduated circle, is adjusted to a horizontal line. On the same surface, parallel to the axis of the level, there are fixed two screws, (one of them is seen at s,) on which the arm DF may slide to or from the eye-glass E. This arm is bent into a right angle at D, and carries a frame, in which the small reflecting plane O, made of black glass, is fitted so as to have a rotatory motion about the axis $a\,b$.

When an angular object appears in the field of the telescope, the arm DF is pushed backwards or forwards, till the mirror O is near the centre of the eye-glass, and it is then turned round its axis $a\,b$, by means of the lever h, till the observer, by looking through the eye-glass, and into the mirror at the same time, perceives a distinct reflected image of the field of view, and the angular object which it contains. The graduated circle AB is then moved round its centre, till the reflected image of one of the lines which contains the angle is continuous with the line itself, and the degree pointed out by the index is noted down. The circle is again made to revolve till the image of the other line is continuous with the line itself, and the place of the index is again marked. The arch of the circle intercepted between these positions, is the measure of the angle required. To save the trouble of reading off a second line, the vernier may be placed at the zero of the scale, when the first coincidence has been observed.

In order to explain the theory of this instrument, let ABC, Fig. 14. be a plane angle seen in the field of the telescope, and MN the section of a reflecting mirror, which moves along with the graduated circle. When the side BC is in the same straight line with its image CE, BC is perpendicular to MN; and when, by the motion of the divided circle, the mirror MN is brought into a position $m\,n$ perpendicular to the other side AB, the arch described by the moveable circle is evidently a measure of the angle formed by the lines AB, BC. The angular motion of the mirror, in passing from the position MN to $m\,n$, is not measured by the angle AOC, formed at the centre O by AO and CO, but by the angle FOG, which is equal to ABC. This will be evident from considering, that the lines AB, CB are parallel to FO, GO, and that the same angle would have been obtained, by taking the reflected image of the lines FO and GO.

Goniometer. Goniometer. PLATE CCLXXVII. Fig. 14.

When the instrument is required to measure the apparent angle which any right line makes with the horizon, the index of the vernier should point to zero when the level is adjusted to the horizon; and then, by turning round the graduated circle till the coincidence between the direct and reflected image of the right line is observed, the index will point out the angle required.

Goniometrical microscope. Fig. 15.

The goniometrical microscope is represented in Fig. 15, and is nothing more than the application of the preceding contrivance to a microscope. See Nicholson's *Journal*, Jan. 1809, vol. xxii. p. 1. and Brewster's *Treatise on New Phil. Instruments*, p. 97—106, 110.

GONORRHŒA. See MEDICINE and SURGERY.

GOREE, is an island in the Atlantic, on the west coast of Africa. It is about 30 leagues from Senegal, about 1 league from the Terra Firma of Cape Verd, and about 3 leagues from that Cape itself. The island is about 800 yards long and 240 broad, and is surrounded on all sides by inaccessible rocks, excepting in one small place to the east-north-east, contained between two points, one of which is high and the other flat, and covered with a bank of sand. This place forms a natural and secure harbour. A late director of the island, M. de St Jean, erected a new fort, and several buildings, discovered springs of good water, and planted a variety of vegetables and fruit trees. The air is cool and temperate during the whole of the year; and the inhabitants are refreshed by alternate breezes from the land and sea.

This island was ceded to the Dutch in 1617, by Biran, king of Cape Verd. It was immediately strengthened by Nassau Fort on the north-west, and afterwards by Orange Fort, a little nearer the shore. In 1663, Admiral Holmes took it from the Dutch. In 1665, it was retaken by Ruyter; but in 1677 it was taken, after some resistance, by the French under the Count D'Estrées. The English took the island from the French in 1692, and restored it in 1693. Since that time, it continued in the possession of the French with a few interruptions, and was guaranteed to them by the treaty of 1783. It was taken by the British in the late war. West Long. 17° 24′ 45″, and North Lat. 14° 40′ 10″. Those who wish for very particular information respecting Goree, may consult Prelong's *Memoire sur Goree*, in the *Annales de Chimie* for 1793.

GORITZ, GORZ, or GORITIA, is a town of Germany, situated in a district of the same name. The town is handsome, and is picturesquely situated on the river Lisonzo. A great number of the houses are good, and belong to noble families. It has seven convents, nine chapels, and a college. The opera-house, though not very neat without, is elegant and commodious within. The fort commands an extensive view over the surrounding country. On the north side of the town are eminences of moderate height, affording all the characteristics of the finest Swiss scenery; while on the south, the plain country exhibits all the beauties of an Italian climate.

The district of Goritz contributes annually along with Gradisca, an insignificant town, 41,502 florins to the maintenance of the army. The country produces wine, fruits, silk, and corn. Population 12,000.

GORLITZ is a town of Germany in Upper Lusatia. It is situated on the river Neisse. Besides the cathedral, there are two churches within the walls, and three without. The organ is reckoned the finest in Europe, next to that of Haarlem. The great spire, the chapel of St George cut out of the rock, the public library, and the collections of the Society of Sciences of Upper Lusatia, are worthy the notice of strangers. The mountains of Gorlitz near the village of Konigshayn, about 4 miles from the town, are composed of vast masses of granite; on one of which, a lofty granite column has been erected to the memory of M. Von Schachman, the proprietor of Konigshayn. Numerous fragments of granite are scattered around these mountains. On the road from Gorlitz to Konigshayn, is situated the once celebrated holy sepulchre. It is an exact representation of that which was shewn in Palestine in the 15th century. The baths of Liebwerda, about five miles from Gorlitz, are generally visited by strangers. Gorlitz has long been celebrated as a flourishing manufacturing town. Cloth is fabricated here in great quantities; and during the last 20 years, considerable improvements have been made, particularly in the quality of that article, by the attention which is paid to the breed of sheep, and the importation of Spanish rams. Linen and cotton stuffs are also manufactured here. Population 8500.

GOSPORT, is a seaport town of England, in Hampshire, situated on the west side of Portsmouth Harbour. This town, which flourishes particularly in times of war, consists of a principal street extending westward from the harbour to the fortification, with the obstruction only of the market-house, and of other streets parallel to the principal one, and crossed by various streets of a smaller size. Different ranges of buildings stretch also along the shore and near the fortification. Gosport is fortified on the land side by a line of bastions, counterscarps, &c. which extend from Weovil to Alverstoke Lake. The king's brewery and cooperage, with storehouses for wine, malt, and hops, are within the works on the Weovil side. The new barracks are also on the Weovil side. Gosport is a chapelry to the village of Alverstoke. The chapel stands to the south of the town, in a well-wooded cemetery. It is a large building, neatly fitted up. There is also here a Roman Catholic chapel, and a meeting-house for the Dissenters, who have an academy for the education of young clergymen, under the management of Dr Bogue. There are at Gosport several charity-schools, an alms-house, and a large and airy work-house for the poor. The principal manufactures here are an iron foundery, and several breweries. A neat theatre has been erected at Gosport.

This town communicates with the sea by means of a large bason and canal, with extensive quays, where vessels of considerable size can take in their stores. Ferry-boats are constantly passing and repassing across the harbour between Gosport and Portsmouth.

Near Gosport is situated the royal hospital at Hasler, for the reception of sick and wounded seamen, which was erected between 1746 and 1762. It stands within 400 yards of the extremity of the point of land which lies to the west of the entrance to Portsmouth harbour. The front is about 567 feet long, and it has two wings, each of which is about 552 feet long. It can accommodate 2000 patients, and has an annual expenditure of £5000. The following is an abstract of the population of the town of Gosport for 1811.

Inhabited houses	1439
Number of families	1614
Families employed in trade	385
Males	3483
Females	4305
Total population	7788

See Warner's *Topographical Remarks relating to the South-western parts of Hampshire;* and the *Beauties of England and Wales*, vol. vi. p. 310.

GOSSLAR, is a large town of Westphalia, situated on the river Gose. The magnitude of this town forms a very singular contrast with its population, which does not exceed 6000, the number of houses being no fewer than about 1500. The cathedral church of Gosslar is the only remarkable building which the town contains. It possesses the altar of Crothos, one of the deities of the ancient Saxons, who sacrificed to it infants. It was brought from Harzburg, and is considered as a genuine piece of antiquity by the antiquarians of the town. It is a brass chest, perforated on every side, so that the flames could strike through to consume the victims which lay upon it. There is also here a Christian altar, encircled with large metallic columns. It was found at Harzburg, and is regarded as a monument of the heathen ages in Saxony. This town is celebrated for its excellent beer called Gose. There are seven different species of it, the best of which is called Beste-Krug. It is a very spirituous drink, and tastes more of wine than of beer. There are here also manufactories for vitriol, paper, and fishing-nets.

GOTHA, anciently *Grimmestein,* and afterwards *Friedenstein,* is a town of Germany in Upper Saxony, situated on an eminence near the Leine, which supplies the town with water, conveyed to it in stone canals. Gotha is one of the handsomest towns of Thuringia. The Ducal Palace stands on a height above the town, and contains a museum of natural history, a library, a cabinet of medals, and a splendid collection of prints, paintings, geographical charts, and mathematical and physical instruments. This excellent collection, which has been recently enlarged by that of M. Lichtenberg, has been long ago minutely described by Keysler. At that time the Ducal library consisted of about 80,000 printed volumes, and 2000 manuscripts. The cabinet of medals, which is particularly valuable, has been long ago described by M. Liebe, in his *Gothæ nummaria,* and more recently by M. Schlichtegroll, in his *Historia Numothecæ Gothanæ.* Gotha, 1799. The Ducal Palace has recently undergone great improvement, particularly in the grand terrace, which has been compared to that of Windsor The English garden of the Duke is worthy of being visited, and the small island, planted with weeping willows and birches, which contains the tombs of Ernest and Charlotte, the children of the reigning Duke. A column of granite, surmounted by an urn of white marble, is placed near the tomb. The garden of the Duchess, containing the monument of Madame de Buchwald, and busts of Newton, Leibnitz, and Kepler; the buildings of the Orangerie; and the hotel of Prince Augustus, the brother of the Duke, are also objects of some interest. The other public buildings are the arsenal, the two churches, called *Kloster und Neumarkts Kirchen,* the last of which contains the tombs of several of the Saxe-Gotha princes; an hospital for soldiers, two schools for the children of soldiers, a public college, a gymnasium with a good library, the public library, the house of correction, and an hospital for widows, and another for orphans.

The principal manufactures in Gotha are those of woollen goods, ribbands, muslin, and porcelain. There are no fewer than six periodical papers published in this town. Near the village Siebeleben, about half a league from Gotha, upon the insulated mountain of Seeberg, is an excellent observatory, under the charge of Baron Zach, an able and active astronomer. Population of the town, 11,500.

GOTTENBURG, or GOTHEBORG, is a sea port town on the west coast of Sweden, and the second town in the kingdom. This town is situated on the banks of the most easterly branch of the Gotha, a large river which issues from the lake Wenner. About ten miles from Gottenburg it divides into three branches, two of which are soon reunited, after passing a rock upon which the old fort of Bohus is situated. The other two branches discharge themselves, by separate mouths, into the sea, and form a large island called Hisingen. The town is nearly three miles in circumference, exclusive of the suburbs called Hoga, and is regularly fortified with a ditch and wall.

Gottenburg consists of a principal street, called Great Harbour Street, consisting of houses three stories high, built of stone or brick, resting upon piles, and covered with white plaster, the roofs being in general concealed. A canal on the river Ham, crossed occasionally by wooden bridges, two of which only are for carriages, runs along the middle of this street. This street is crossed at right angles by North Harbour Street and South Harbour Street, and a few others; and parallel to it there are other streets of inferior note. These streets are ill paved with round stones, and have no side pavement. At the west end of the town is a hill about 100 feet high, upon which are several streets. This part is called the upper town, and the other part the lower town. In the upper town, the rows of buildings rise above one another like the seats of an amphitheatre. The exchange, and the extensive building belonging to the East India company, stand in the principal street. There are in this town two Swedish churches, and a German church. In 1812, a very magnificent church was building with stones brought from Scotland.

The harbour of Gottenburg is about one-fourth of a mile in breadth, and is formed by two chains of rocks. Its entrance is defended by the small fort of New Elfsborg, situated upon a rocky island, and garrisoned with 250 men.

Gottenburg formerly carried on a very great commerce in herrings, but, for several years past, they have entirely left the coast, and the fishing has of course declined. Formerly, they obtained about 600,000 barrels of herring annually, of which they salted 200,000; train oil being obtained from the remainder, at the rate of one barrel from 15 barrels of herring. In the year 1790, there was exported from Gottenburg 104,797 schips of iron in bars; 9,033 schips of other iron; 1142 schips of steel; 36,900 planks; 195,482 tons of salt herrings; and East India commodities, consisting of tea, silken stuffs, cinnamon, rhubarb, sago, fans of bamboo, porcelain, &c. to the amount of 599,471 rix dollars. A Royal Society of Sciences and Literature has been established here, and has published some volumes of its memoirs in 8vo.

The population of Gottenburg was in

1791	15,000
1804	17,760
1811	24,858

The country about Gottenburg consists of low precipitous ridges of naked rocks of gneiss, stretching in various directions. They vary in height from 100 feet to 310, which was the highest, as measured by Dr Thomson. Tolerably cultivated vallies, about a mile wide, separate these ridges. The west side of the island of Hisingen is composed almost entirely of naked rocks; and it protects the town against the north sea, and the west winds. See Coxe's *Travels in Sweden*, vol. iv.; Catteau de Calleville's *Voyage en Allemagne et en Suede*, vol. ii. p. 300; Kuttner's *Travels through Denmark, Sweden, &c.* sect. vi.; Thomson's *Travels in Sweden*, chap. i.; and INLAND NAVIGATION, for an account of the great canal of Trolhatta.

GOTTINGEN, or GOETTINGEN, is a city of Lower Saxony, in the electorate, (now kingdom,) of Hanover, and principality of Calenberg. It is situated on the small river Leine, in longitude 9° 53′ east, and latitude 51° 32′ north.

The university was founded by George II. in the year 1734, and soon became one of the most celebrated and best frequented seminaries on the continent. It is believed to have suffered considerably during the oppressive occupation of Hanover by the French, and the military operations in the north of Germany, subsequent to the disastrous battle of Jena; but it will probably recover, in some degree, its former prosperity, under the present favourable circumstances. The university possesses a noble library, consisting, it is said, of more than 150,000 volumes, a museum of natural history, an observatory, and other institutions for the advancement of science. Connected with the university, are the Royal Society, the Philological Seminary, and other scientific and literary institutions. Gottingen boasts of having cherished many individuals, eminent in different departments of learning; among whom may be reckoned Mosheim, Michaelis, Mayer, Lichtenberg, Kästner, Bürger, Beckmann, Pütter, Heyne, Blumenbach, Martens, and many others whose names are familiar to those who are conversant with continental literature.

The town contains about 12,000 inhabitants, including the garrison and university. It was formerly a place of some strength; but the fortifications have been demolished, and the rampart converted into a public walk. The woollen and hat manufactures are, besides the university, the principal support of the inhabitants.

Those who wish for a more particular description of Gottingen, and more minute information on the subject of its literary history, may consult Pütter's *Versuch einer Academ. Gelehrten-Geschichte von der Univ. zu Gottingen*, 2 vols. 8vo. 1788; and Rintel's *Versuch einer skizz. Beschreib. von Gottingen*, Berlin, 1791, 8vo. (z)

GOUDA, or TERGOUW, is a town of Holland, advantageously situated on a branch of the Rhine, called the Issel, where it receives the Gouw. The town is well fortified, and has five gates; but it is principally celebrated for the painted windows of its magnificent cathedral. These paintings were executed principally by Theodore, and Walter Crobeth of Gouda, and they have been preserved with singular care. The principal trade of the place consists in cordage, and tobacco pipes, and cheese. In the neighbourhood of the town great quantities of bricks and tiles are made. Peuchet informs us that there were once in Gouda 350 breweries, which supplied with beer Zealand and a great part of Flanders. This trade is now greatly diminished.

GOVERNMENT, in political science, sometimes signifies the act of carrying the national affairs into execution; sometimes the person or persons who, as a separate branch of the constitution, are lawfully charged with that function; and sometimes it imports the whole frame of the civil polity. In this latter and more comprehensive sense, it is synonymous with *constitution;* and it is in this sense we purpose here to employ it.

In endeavouring to simplify a subject so infinitely varied and complex, Aristotle and other ancient writers have reduced all systems of government to the primary and elementary forms of Democracy, Aristocracy, and Despotism. Under the first, the whole body of the people are at once the sovereign and the subject; laws are enacted by them alone, and the whole business of the commonwealth, whether it be the command of armies, the judiciary and ecclesiastical functions, negotiations with foreign states, or any other department of affairs, is transacted by officers appointed by them, and responsible to their authority. Under the second form, the many are subject to the few,—on whom superior wealth, talent, and, it may be, virtue, have originally conferred power, and in whose descendants a still further accumulation of wealth,—ambition,—and the popular sentiment in favour of illustrious birth, even where talent and virtue have no place, have, by a natural and easy transition, confirmed it. Under a Despotism, no orders are issued, no measures adopted, no affairs transacted, but with an exclusive reference to the personal gratification of the prince, or the security of his power. Laws which, under a Democracy, are enacted by the people themselves, and, under an Aristocracy, by the nobles, as the rule of public and private conduct, and the measure of public and private right, have no existence under a Despotism. The will of the tyrant is the sole law,--which, therefore, fluctuates every moment, and the people, their children, and their property, exist only in subservience to his passions, his caprices, and his crimes.

Modern writers, and particularly the President Montesquieu, have regarded this arrangement of the elementary forms of government as inaccurate. According to the well known division of that eloquent philosopher, these forms are, in like manner, *three;* the Republican, the Monarchical, and the Despotic. Under the first, he comprehends the Democratical and Aristocratical of the ancients; his description of which, as well as of the Despotic form, corresponds with theirs. The description of the Monarchical form differs in nothing from that of the Aristocratical, except that, in the latter, the supreme power is exercised by a combined plurality, but, in the former, by a single individual. As in the Aristocratical too, the administration of the nobles is controlled by the laws which they have themselves enacted; so, in the Monarchical, that of the prince is restrained, however imperfectly, by the rules of his own sovereign appointment; and this, as in both the Republican forms, constitutes the elementary difference between it and the Despotic.

But, according to this distribution, the ancient arrangement is not so properly inaccurate, as *incomplete.* The arrangement of Montesquieu is precisely that of the Greek philosophers, with the addition of the Monarchical form. The inaccuracy, it would seem, is rather chargeable upon him, since, in his enunciation of the elementary or simple forms of government, he limits, after the ancients, the number to three, whilst, in his description, he enumerates, (as they appear to us,) four essentially different systems. For though he has combined the Democratical and Aristocratical forms under the general term *republican*, it is difficult to perceive in what sense the latter is more republican than the Monarchy of his enumeration. The characteristic difference, according to his own description, between an Aristocracy and such a Monarchy, consists in the individuality in the one case, and, in the other, in the plurality of persons by whom the sovereign power is exercised. The people are absolutely excluded alike under both, from all share in the public authority; alike under both, the concerns of the state, its interests, its property, and its rights, are in no respect subject to their control or interference. In what sense therefore can these rights, interests, and concerns, or (which is here the same thing) the power by which they are regulated and controlled, be denominated *republican*, when applied to the Aristocratical form, which will not be equally applicable to the Monarchical?

Whether this enumeration of the elementary governments, as enlarged by Montesquieu, be complete, we shall not at present stop to inquire;—that it is chargeable with the inaccuracy we have alluded to, can scarcely, we think, be questioned. We rather proceed to observe, (what must likewise be well known to most of our readers,) that the same writer, besides describing the *nature* of the different simpler forms of government, has, with no less elegance than, as it appears to us, sound philosophy, indicated the *principle* upon which they chiefly depend for their respective support.

Under the Democratical form, *public virtue*, pervading the hearts and conduct of the whole body of the people, is the animating and sustaining principle. Every selfish and exclusive purpose must be relinquished by the individual; and his country, its glory, and its happiness, must take entire possession of his breast. Proud distinction for popular government! and happy the people among whom it is established, if the principle were a sure consequence of the form!

Under an Aristocracy, (and as a distinct principle is ascribed to it, we have here a further indication that it constitutes a *fourth* form, altogether different from a Democracy with which the celebrated writer we have alluded to, had classed it,) *moderation*, as well on the part of the few who govern, as of the many who obey, is the principle. If, among the former, any individual aspire to an over-ruling share of power, a tendency to the Monarchical or to the Despotic form, immediately arises; and if, among the latter, a sense of public rights, a spirit of patriotism, a disposition to interfere with the government, should appear, a tendency emerges in favour of Democracy.

Under the Monarchical form, the preserving principle is said to be *honour*. The word is abundantly vague and illusory, because the thing signified is commonly so also; but here it seems to import, that each individual of a numerous nobility, (for a Monarchy, in the sense of Montesquieu, implies a nobility,—*no nobles, no king,*) as well as the whole order considered as a separate body, and even each individual of the people, as well as the separate classes of which they may be composed, are constantly actuated by a jealousy for their respective and exclusive interests and consequence. Ever jostling in the pursuit of these objects; ever suspicious of mutual encroachments; and, at the same time, alike intent upon securing a portion of the royal favour, through one or other of the many channels in which, in a Monarchy so nearly absolute, it always abundantly flows, they become at once the vigilant instruments of their own controul, and the vain-glorious yet submissive dependants of the sovereign. Without a suffrage in the enactment of laws, and deriving from the constitution little power of restraint over the direction of affairs, they are almost necessarily unconscious of any principle of a pure and disinterested patriotism. The envied distinction of the prince's approbation,—preferment, emoluments, honours, become the chief incitement to their public exertions: and if thus they are not the legitimate objects of moral approbation, they often achieve deeds at once illustrious in themselves and beneficial to their country, as the proper means of acquiring the royal distinctions to which they aspire.—The government which has been so lately annihilated in France, as well as the more ancient monarchy, and several of the other governments of the continent of Europe, sufficiently illustrate and justify this description.

Fear, on the part of the people, is the dismal principle by which a Despotism must be maintained: nor need any thing further be added to indicate that system of sanguinary and incessant cruelty, which, on the part of the prince, becomes necessary to uphold his unhallowed empire.

These observations, as well on the primary forms of government, as on the principles on which they chiefly depend for their maintenance, are elementary, and could not with propriety, in a work of this nature, be passed over in silence. But, in contemplating the subject further, we are at a loss to determine under what particular aspect to regard it. When the various combinations of which these primary forms are susceptible, both with one another, and with their respective principles, are considered; the infinite varieties in the modification of the most simple as well as complex system of government,—arising from a narrower or more extended territory,—from insular or continental, maritime or inland situation,—a thinly scattered or crowded population,—the religious ceremonies and dogmas of the people, and the nature of their ecclesiastical establishment,—the constantly progressive or retrograde state of their morals, manners, and intellectual habits,—their warlike or peaceful, commercial or agricultural genius,—the character of the political institutions of the neighbouring states with which they have their principal intercourse,—the accidents of talent or imbecility, disinterested purpose or selfish emolument and aggrandisement, which may influence alike the conduct of the executive and legislative members of the government,—and the innumerable other circumstances which conspire to the same infinite variety of modification,—thought is bewildered in the complexity of the subject, and finds all attempt at detail utterly overwhelming and impracticable. To deduce, with any degree of exactness, the particulars which truly and accurately characterize even the most celebrated governments of ancient or of modern times, would be an undertaking sufficiently appalling from its magnitude, and sufficiently hazardous from the obscurity in which the information to be derived on such subjects seems inevitably to be involved. Nay, to attempt a clear and satisfactory delineation of our own government, on the nature of which full and accurate information might be supposed to be the most accessible, would be bold, perhaps presumptuous. For how has it fluctuated, by a thousand minute or more extensive gradations, throughout the greater period of its history! and though, since the days of William III. it has acquired a more balanced motion, and assumed an infinitely more regular and majestic form, yet how great the diversity of parts of which it is composed! how varied, and often delicate, the machinery by which it is impelled! and how numerous the interfering considerations necessary for giving it a safe and steady direction! *

But amidst a speculation so complex and embarrassing, some general views present themselves of a more manageable nature, and of a universal and paramount interest. Of these, an investigation of the rule by which *the legitimacy of all governments shall be tried*, which shall serve at once as the measure of lawful authority on the part of the sovereign, and of obedience on that of the people, seems the most important. It is a subject unquestionably of some delicacy, but infinitely less so than, in some countries, the mercenary partizans of usurped power,—and, in others, the mistaken and narrow-sighted zeal of many sincere friends to order,—would represent it; whilst the advantages to liberty of preserving it constantly in the public view, are incalculable. Under arbitrary governments, such discussions (when, indeed, they can be avowed at all) are justly alarming to the existing authorities; but under a constitution like that of Great Britain, they are its worst enemies, and but little acquainted with its real nature, who would regard the subject as dangerous.

In pursuing this inquiry, we will avoid, as much as possible, the metaphysical abstractions of mere general reasoning. We will endeavour, rather, to consider the subject through the medium of some of the principal events in the history of our own government; and with these we will at the same time combine, (whilst we shall take care to indicate sufficiently our own sentiments,) the opinions which the nation at large, as well as some of the most distinguished individuals in it, have from time to time entertained on a topic so interesting. We shall thus, besides blending historical fact with the less edifying deductions of bare general discussion, present also the outlines, at least, of the political branch of our literary history.

Except the close of the eighteenth century, no period in the British history appears to have been more productive of political discussion than about the time of the civil wars, in the reign of Charles I. Before that period, political inquiry had made little progress among the people. Opposite claims to the crown had divided their efforts in favour of the different competitors, and changes in the religious establishment had very deeply engaged their attention; but no question had arisen calculated to lead the public mind, by an easy and obvious connection, to an investigation of the original principles upon which all government is founded, or to a comparison of one species of government with another. The two Houses of Parliament were the only place in which political discussion was at all to be found; and, even there, it had scarcely ever dared to trespass the safe boundaries prescribed to it by the executive authority. A few speculative and learned men alone had indulged in inquiries of this nature To them exclusively the fragments of political science which the general ruins of antiquity presented, were accessible; and, fired with the seemly ideas which these had excited, they were naturally led to emulate their own conceptions of the superstructure. The performances, however, which some of these men thus produced, were

* We could not with propriety, under this general article, have introduced even the outlines of our own goveroment, the theory of which, the more it is studied cannot fail to be the more admired. The reader may coosult the more appropriate article, ENGLAND, p. 25. and, for still more detailed information, Blackst. *Comm.* b. i.; Montesq. *De L'Esprit des Lois,* l. xi. c. 6. &c; and De Lolme. For other individual governments, see their appropriate articles, SPARTA, ROME, &c.

either expressed in a language with which the people were utterly unacquainted, or conceived in so subtle and scholastic a manner as was little fitted to engage public attention.

But in proportion as the disputes between Charles and his parliament drew to a crisis, in proportion were the minds of the people directed to a bolder range of political discussion. At first, *the limits of the prerogative* formed the only subject of inquiry. By degrees, as the fortunes of Charles darkened, *the circumstances which constituted a total forfeiture of the throne* began to be examined. And at last, when the sovereign was destroyed, and the peers voted useless, the question assumed the broadest form of which it was susceptible. The inquiry now was into the *best form of civil polity*; and in this enquiry, the whole extent of political science was developed to the people.

That all lawful authority was derived from them, and was co-existent only with the just and impartial administration of it, were considerations of no mean importance, and accordingly received a share of the public attention; but the opportunity was now arrived when the British people, freed from their ancient government and all its deformities, might, as they conceived, erect a new superstructure which, while it secured their own and their descendants felicity, might for ever serve as a model to the rest of mankind. On this wider subject, therefore, every mind was occupied. All other conversation was naturally without interest. Every press was employed in furnishing the various publications which might inform the ignorant, convince the doubting, or excite the enthusiastic. The blemishes of the former government needed no exaggeration from the pen of the political writer, to create a general abhorrence of every form of polity which bore any resemblance to it. The people themselves had too recently felt its imperfections, even while its administration was yet unexasperated by opposition, and had smarted too severely under the consequences it admitted when its chief magistrate chose to be offended. The most opposite form, therefore, was the most favourite. Every publication, accordingly, consisted either of arguments in support of a democracy, or detailed some new and rival plan of government for the approbation and choice of the people. Nor in this competition of speculative politics, then deemed so glorious, do we find such names only as are ever ready to serve the purposes of ambition, or of avarice. Warmed with the love of ancient liberty, and proud to avow their admiration of it, the fairest schemes of republican government, and the strongest arguments in support of it, which the minds of a Harrington and a Milton could devise, or their energetic eloquence recommend, afford interesting specimens both of the manner in which the public mind was then occupied, and of the ability employed in giving it a direction.

But these delusive prospects soon disappeared. The hope of establishing a republican government became daily fainter and fainter; and with it, those schemes which had been so eloquently detailed, and so fondly contemplated, quickly fell into neglect. The views of Cromwell, which had always been suspected by some, now began to be understood by many; and the vigorous administration by which he confirmed his usurped power, by and by convinced the people that they still possessed a monarchy in every thing but the name. The death of the Protector, and the incapacity of his son, replunged the nation in all the miseries of anarchy. The partizans of the royal family were not slack to improve the opportunity they so much desired. By their efforts, and the concurrence of a full tide of circumstances, the proscribed monarch was received into the bosom of the kingdom, without any limitation of his authority, and with an ardour of popular affection, proportionate to the interruption it had suffered, and to the calamities and confusion to which the nation had been exposed.

It was accordingly during the reign of Charles II. that the public mind seems to have been disposed to admit the exercise of the royal prerogative in as unlimited and dangerous an extent as had ever been possessed by any former monarch. Still smarting under the desolating consequences of the civil wars, and still remembering the odium with which they had regarded the tyrannical, though energetic, administration of the Protector, it is not surprising if the people began to indulge the opinion, that an uncontrolled prerogative in the crown was necessary to order and good government.

The court does not seem to have been insensible to this favourable state of men's minds for promoting its views. The nation, it was easy to perceive, had now acquired a taste for political speculation which it would be more practicable to lead in a safe or advantageous course, than altogether to obstruct. And though the reigning monarch had little reason to apprehend any immediate opposition to his power, yet a theory in support of it, would at once gratify the public mind, and might lessen the chance of future resistance. There was now no demand for plans of government. These had had their day. They had fallen into neglect with all, and contempt with many. Monarchy, the resumed, uncontrouled monarchy, was the idol; and nothing was wanting but a systematic detail of the justice and rationality of the principles upon which it rested.

About this time, accordingly, several writers appeared who, either hired immediately by the court, or impelled by general hopes of reward, endeavoured to perform so acceptable a service. Among these, the most celebrated was Sir Robert Filmer. His book, entitled *Patriarcha*, seems to have been by far the most daring and specious attempt to assign a legitimate and rational origin to absolute monarchy. It was daring, not so much because it was an express and avowed endeavour to establish that form of government in exclusion of every other that had ever been set up in the world, but to establish it upon the basis of *a divine appointment*; and it was specious, because the mode of argument, and the style of writing adopted, were such as, in those times, were likely to make considerable impression,—the former being chiefly, or altogether, founded in texts of scripture, and the latter made up of expressions sufficiently vague and unmeaning to elude detection in an age when literature was yet but little diffused, or accurately studied. If not the first to assert the *jus divinum* of kings, Filmer seems to have been the first, at least, who ventured to account for its origin, to develope its nature, and to establish it avowedly and expressly, upon the basis of argument.

Aware of the futility of that sort of reasoning which, while it founded the legitimacy of the sovereign power in the general or providential arrangements of the Supreme Being, would at the same time have justified every form of government, and even every species of crime, (since these also fall out, or are permitted in the general arrangements of Providence), Filmer had recourse, if not to a more logical, at least to a more specious, mode of argument. Texts of scripture, he conceived, could be found, in which might be traced the legitimacy of modern kings to the appointment of God himself at the creation of the world. If so, his object was accomplished—infidelity in that age not having yet dared to erect his unhallowed standard among the people.

Government.

Filmer accordingly maintained that God, at the creation of Adam, endowed him with a right of fatherhood, (as he termed it), absolute and unlimited; or, in other words, with a right of arbitrary dominion over all his offspring. *Second,* That he was endowed in like manner with a right of absolute dominion over Eve: "Thy desire shall be unto thy husband, and he shall rule over thee:"—in which text he seriously assures us we have very expressly, the original grant of monarchical government. *Third,* That the whole material globe, with all the brute creation, was his property by right of donation from the same Almighty Being And, *fourth,* That these rights, upon Adam's death, descended to his next heir; that thence they descended, in direct succession, to the patriarchs; and from them, in similar succession, to modern kings. These principles he partly asserted, and partly endeavoured to prove, sometimes by producing garbled passages of scripture, and sometimes by giving to other passages an unlimited, or, as it would seem, a sophisticated meaning.

It would be frivolous to occupy much time in examining a theory so ridiculous. It could scarcely, one would think, have drawn the attention of the Sidneys and the Lockes to its refutation. Yet however easy the task, it will not appear unworthy even of such men, when we consider the bias of the times, and the impression which Filmer's book appears to have made upon the public mind. The philosopher and the patriot felt alike indignant at the insult which had been offered to their country; and the employment of their talents upon a subject so far beneath their powers, they deemed a sacrifice well due to public virtue.

As Filmer had found it expedient to have recourse to the standard of public faith for the arguments by which he had supported his system, so the writers to whom we have just alluded, found it necessary to resort to the same standard for the arguments by which they were to overturn it. They denied that there was any text of scripture that asserted a right of absolute fatherhood, or unlimited paternal jurisdiction in Adam; but, on the contrary, maintained, that neither Adam, nor any other man, ever had a right to any further paternal jurisdiction than was necessary for the protection, improvement, and welfare of his children, during those years of minority when they were unable to protect, improve, or provide for themselves; and that this paternal jurisdiction was more properly termed *parental,* since it implied duties that belonged equally to Eve, and every other mother, as to Adam, and every other father,—the nature of the duties requiring such common jurisdiction. *Second,* The jurisdiction granted to Adam over Eve, could not be understood to mean a *political* jurisdiction, or the right of life and death; but merely such a right of control as, in matters regarding their common interest and property, would enable the husband, in the event of opposite opinions, to decide, and so prevent that endless contention which would arise had no superior authority been conferred upon either. *Third,* As the donation which God is said to have given to Adam of the earth, with all the animals upon it, is nowhere to be found in scripture, so, had it been given, it could not have been absolutely and exclusively, but only so far as his own use might require,—it being absurd to suppose, that God would give to one man an exclusive right to what, from its extent, was infinitely beyond his power of enjoyment, and would, at the same time, call other rational beings into existence, who should be at this favoured person's mercy for a foot of ground to stand upon, or a morsel of food to support life. But *fourth,* Although Filmer had succeeded in establishing these premises, it did not follow that such absolute rights were to descend to his *next heir.* If it did so follow, who was his next heir? for God has neither by scripture, nor by human reason, pointed out a natural and invariable line of succession in the person of any individual. Granting however this also, it was still incumbent on Filmer to shew, not only that the patriarchs possessed this absolute authority, and that they possessed it from Adam through this invariable line, but that it has also come down from them to modern kings through the same invariable line,—an attempt, which only requires to be stated to evince its extravagance. But still granting even this extravagance, there must be only one legitimate monarch in the world, only one king who reigns *jure divino* derived in this direct line from Adam, and all the rest must be usurpers and interlopers, against whom every honest man and sound Christian should raise his arm, never to be pacified till all the nations of the globe should be reduced to the arbitrary and exclusive dominion of this lineal descendant, and true heir of Adam!

These writers having thus demonstrated the absurdity of this theory *jure divino* of Sir Robert Filmer, they conceived it necessary to substitute another, more friendly to liberty, and more consistent with truth. They proceeded, accordingly, to point out what they regarded as the only foundation and just limits of *legitimate* government; and this, they maintained, was the *consent of the people.**

That the *consent of the people,* they contended, is necessary to all legitimate government, seems not to admit of argument; for the very notion of such a government implies the notion of a contract between those that govern and those that obey. By what other right, or upon what other foundation, can any form of government which is to be regarded as *legitimate,* that is, binding upon the people to preserve and obey it, be either originally established, or afterwards exercised? Various other foundations of legitimate government indeed, have been pointed out and defended; but all of them appear to be sufficiently irrational. The doctrine of the right of conquest, where such conquest has been occasioned by the repeated and aggravated hostility of the party conquered, is perhaps the least exceptionable. But besides that the arbitrary form of government established in consequence of conquest, involves the innocent with the guilty, it is a punishment disproportionate to the crime. The victor, in such a case, has no other right than to indemnify himself sufficiently for the injury he may have sustained, either by former provocations, or the actual war. He can only demand *compensation for the past, and security for the future.* And this he may, in most instances, sufficiently obtain, by making it a losing bargain to his enemies to offer him injury. This

* As Filmer appears to have been the first, if not to suggest the doctrine of absolute monarchy *jure divino,* at least the first avowedly and systematically to explain and argue it; so Mr Locke, if not the first to suggest the consent of the people, as the only foundation of lawful government, seems to have been the first who entered, at any length, into a developement and defence of the principle. For although the celebrated Discourses of Algernon Sidney were written previously to Mr Locke's Treatises, and embrace the same principle, yet they were not given to the public by Mr Toland till after Locke's Treatises had appeared, and accordingly do not seem to have been known to that philosopher.

We may here observe, that the opinions of the Tories approximated to the extravagance of Filmer's system; those of the Whigs consisted, it would seem, of most of the reasonings and inferences of Mr Locke's.—We may add, that, by *the people,* Locke and his followers evidently meant the nation at large, in contradistinction to the sovereign magistracy, of whatever nature that may be;—not that needy and desperate class of men, who, in every country, and most of all under the freest constitutions of government, are always found opposed to the orderly, industrious, and fortunate.

loss indeed, must be proportionate to the circumstances of the case; but no case can be figured, where it ought to amount to *absolute authority* on the part of the conqueror; that is, to *slavery* on the part of the people. A few captives taken in actual war may be reduced to that unhappy state, where the law of retaliation, and only where such law demands it; but no *national* offence can infer the punishment of *national* slavery. It is possible to imagine cases, where *security for the future* may require the conquered to submit to the government of the conqueror; but such government cannot be *legitimate*, unless it be as free as is compatible with that security.

It would seem, therefore, they argued, that the doctrine of the *consent of the people*, as forming the only foundation for legitimate government, requires only to be sufficiently explained, in order to be acknowledged.

This consent they conceived to be of two kinds. First, that which is *implied* in consequence of certain acts of the people; and, second, that which is *direct*, and *expressly conventional*.

First, The greater part of the governments, as well ancient as modern, to which the epithet of *legitimate* can with any propriety be applied, have been of the first description. They have all been originally constituted, and afterwards exercised, in consequence of the implied consent of the people; an implication by no means doubtful in its nature, or feeble in its conventional effects; but, on the contrary, more generally, as well as more powerfully binding, perhaps, than that consent which is direct and express.

These governments have been the same in their origin, and similar in the first periods of their progress; but, for the most part, sufficiently varied in the subsequent and concluding eras of their history. At first, the savage who roamed the desert, was at once the father and supreme civil governor of his family. Convenience, and the ties of blood, soon united a certain number of families into a tribe, village, or horde. The same natural sentiment of confidence and respect, which had impelled the children of a family to admit the father's authority, impelled the several families of the same tribe or village to admit, *in time of peace*, the authority of those individuals amongst them who were most celebrated for wisdom and experience; and, *in time of war*, of that single individual who was most renowned for his martial skill and achievements. But as war among rude nations (alas! in more civilized periods also) ever occupies much more of the public attention than peace, and as, from its nature, there can be only one supreme leader at a time, sufficient opportunity is then afforded him of acquiring a greater share of public respect, and of being regarded as of greater national importance, than those individuals in whose authority he is only a sharer in time of peace. Hence the consideration which the leader or king, in civilized as well as in rude periods, acquires over the other individuals of the civil administration, whether that consist of a senate, (as it comes afterwards to be termed,) a popular assembly, or both. This leader or king, as well as the other members of the civil administration, are not, in the earlier periods of the history of political government, expressly elected by the concurring voice, by the majority, or by any other avowedly conventional act of the people. Their experience, their wisdom, and their virtues—such virtues as men in those ruder periods can understand and admire—invest them with authority, and render them the natural objects of respect and obedience. The people soon perceive the beneficial effects of submission, and, by a thousand different acts, testify their concurrence in a government so naturally formed, and so advantageously administered. As the king, or any of the other rulers, dies, or from any other cause becomes unfit for discharging the duties of his station, another, of similar accomplishments, succeeds him by the same natural means, and receives the same natural obedience. For obvious reasons, the successor is commonly the immediate descendant, or intimate friend, of the deceased, unless a striking deficiency of capacity disqualify him. As the ideas, however, of property extend and improve, and as other alterations take place in the progress of society, men come to acquiesce in that *hereditary* succession to civil authority for which kings and rulers now begin to struggle. The people perceive its tendency to exclude rival and tumultuary pretensions to power, and, in this respect, soon actually experience its advantageous consequences. Their original acquiescence is confirmed by their voluntary obedience, and their acknowledgment of the legitimacy both of the constitution, and of the administration, of the government, is sufficiently declared by their reiterated acts of co-operation, as well in forming as in executing the laws, and in modifying, when necessary, the form itself of the civil polity.

But this natural and just order of things is too often interrupted and broken. Usurpation may either occupy the place of those rulers, whether supreme or subordinate, whom alone the people acknowledge as lawful; or tyranny may characterise the conduct of those rulers themselves. In both cases, the administration of government, and, as an usual, or rather almost necessary consequence, the form of government itself, have undeniably become *illegitimate*; and the people, if they can yet command sufficient force, or whenever they choose to risk the attempt, may, with perfect justice, endeavour to displace and punish the usurper and tyrant. Should they neither command sufficient force, nor choose to risk the attempt, the government of the *usurper* may *become* legitimate, by the justice with which it is afterwards administered, and by reiterated acts of sufficiently implied consent on the part of the people; but that of the *tyrant* can never become so. He may hold his people in a precarious subjection, if they choose to remain in his territory, by the principle of fear; but none of his enactments, or of their involuntary compliances, can ever render his authority legitimate, or deprive the people of the right to displace and punish him when they can, and to substitute another governor, as well as to appoint another form of government more equitable and friendly to liberty.

Second, That consent of the people, they further maintained, which is *direct* and *expressly conventional*, although by no means of such frequent occurrence in the history of civil government as the former species of consent, is yet sufficiently frequent to prove its existence, and give an idea of its nature. Among rude tribes, we find instances of general assemblies of the people, met for the express purpose of electing their rulers by a majority of suffrages. The great civil magistrates of several of the states of Greece, and particularly the archons and other civil officers of Athens, together with the consuls and most of the other magistrates of Rome, were appointed periodically by the act of the people. Most of the ancient colonies also, whether they originated from Greece, Rome, or Carthage, were left at liberty to establish such a form of civil polity, and to choose such rulers, as the colonists themselves thought best; the respective mother countries claiming no authority over them, but only soliciting from their

Government.

friendship, consanguinity, or bounty, assistance in times of general difficulty and danger. The government established by the United Provinces in the reign of Philip III. of Spain, by America in 1782, and, proud reflection! by Great Britain herself in 1688, may be quoted as further examples, in which this *direct* and *expressly conventional* consent of the people was exercised.

But as the theory of Filmer was fated to fall before the opposition of Sidney and Locke, so the system which these distinguished men had set up in its stead, was, in its turn, exposed to an attack, which, if less efficacious, proceeded notwithstanding from a quarter not less respectable. About the middle of the last century, Mr Hume and some other writers undertook to shew, that the doctrine of the consent of the people, as the only basis of legitimate government, was altogether erroneous and visionary.

If it be meant, said they, that the contract, implied or direct, between the sovereign and the people, is the agreement by which men in a savage state form the social union, and from which every community is originally derived, we admit the accuracy of the fact, but deny its obligation on men in the advanced stages of society: Every government that has endured for any period, has undergone the most entire changes since its first establishment; nor can a consent or voluntary acquiescence, which was given some centuries ago, be binding under a totally different aspect of the political arrangement.

Again, in those instances, they further observed, which seem the most favourable to the doctrine of the consent of the people, the real exercise of the right has been altogether imperfect or illusory. In the most perfect and extensive republics of antiquity, not a tenth part of the people voted either for the original establishments, or on the enactment of any subsequent law; and even at the boasted Revolution of 1688 itself, the Prince of Orange was brought over, and seated on the throne, by a mere junto of the English people. But, it was further said, if, even in these instances, the principle has in fact no place, how much less shall we find it realized in any of the other governments, which either actually exist, or which history has recorded? In perhaps all of them, it is not difficult to trace the sovereign authority to conquest, usurpation, donation by testament, or some other mode of fraud or violence. Hereditary descent prevails the most generally; yet it would be bold to affirm that none of these governments were lawful, or that the people were never sensible of any obligation to submit to their authority. In fine, "though an appeal," says Mr Hume, in the concluding part of his Essay on the Original Contract, "though an appeal to general opinion may justly, in the speculative sciences of metaphysics, natural philosophy, or astronomy, be deemed unfair and inconclusive, yet in all questions with regard to morals, as well as criticism, there is really no other standard by which any controversy can ever be decided; and nothing is a clearer proof that a theory of this kind is erroneous, than to find that it leads to paradoxes repugnant to the common sentiments of mankind, and to the practice and opinion of all nations and all ages. The doctrine which founds all lawful government on an original contract, or consent of the people, is plainly of this kind; nor has the most noted of its partizans, in prosecution of it, scrupled to affirm, *that absolute monarchy is inconsistent with civil society, and so can be no form of civil government at all, and that the supreme power in a state, cannot take from any man by taxes and impositions any part of his property, without his own consent, or that of his representatives.** What authority," continues Mr Hume, "any moral reasoning can have which leads into opinions so wide of the general practice of mankind in every place but this single kingdom, it is easy to determine."

In the remarks which we have already made, when detailing what we conceive to be the just and fair state of the doctrine of the consent of the people, we have already, perhaps, anticipated the proper answer to some of these objections. We shall, therefore, only very briefly take further notice of them.

1. It would be improper to say, that so candid a mind as Mr Hume's is represented to have been, has intentionally sophisticated the doctrines of Locke, or that so great a philosopher was not always eager to discover truth, whether it agreed with his own political opinions or not. Yet we cannot but think, that the careful peruser of Mr Locke's book, can have no difficulty in reconciling the passage in question to the "general practice of mankind." For it is most obvious, as well from the whole scope of the work, as from the undeniable and notorious nature of the facts themselves, that Mr Locke could never mean to deny the *actual existence* of absolute monarchy in the world, or that the supreme power in a state did not often *actually take* part of a man's property without his own consent, or that of his representatives. It is plain that he only meant to affirm, that absolute monarchy was inconsistent with such a state of society, as, from its internal security, and the innumerable advantages thence arising, might with propriety be termed *civil*; and that the supreme power in a state could not *lawfully* take any part of a man's property without his own consent, or that of his representatives. Indeed, the opposers of this doctrine seem always to have taken it for granted, that its advocates maintained its applicability to all the different governments which have ever actually appeared in the world. Neither was Locke nor Sidney so little conversant with the history of mankind, as not to know the various sources of fraud and violence from which political establishments had, *in point of fact*, too often proceeded. All that they meant to affirm was, that no government could be regarded as *lawful*, that is, exercising its functions upon any obligatory principle, where the unequivocal, though it might be tacit, consent of the people actually existing under it, was not interposed.

2. It is true, that in none of the instances in which the consent of the people was most directly exercised, did it arise from the universal suffrage, or even, perhaps, from a fair and totally unbiassed majority of the people. It is sufficient if this conventional consent was given in as perfect a manner, or as nearly so, as the nature and structure of human society will admit. An abstractedly perfect expression of the popular consent is impossible. Nor can they be accused of supporting an illusory principle, who would rest the legitimacy of government upon that consent of the people which is expressed by such a majority as, from the very nature of society, it is reasonable to expect, or practicable to obtain.

3. We grant that it is impossible, in every instance, to ascertain the precise period when this consent of the people may be considered as fully and unequivocally expressed, or to distinguish between that apparent consent which a tyrant or usurper may exact, and that which is voluntary and free. But the principle is not, therefore, the less real. Pirates, or banditti, may seize

* "Locke on Government, chap. vii. sect. 90."

a man's person, and carry him into captivity. In that situation he may find it his interest to serve his masters with alacrity and zeal. Yet nobody would thence infer, that the authority exercised over him was lawful, or that the assent which he gave to it was voluntary and free. None will deny, that those unhappy men who, in different parts of the world, exist in a state of slavery, have a right to revolt whenever they can; yet, from the circumstances of their birth, and the manner in which they have been brought up, this right is but imperfectly understood by many of them, and perhaps, for the most part, not recognised at all. But that it belongs to them, is not the less certain. The case is the same in reality, though not in degree, with any people whose government exists otherwise than by their consent alone. The neutral observer may be uncertain, whether or not they are a free people, and they may themselves have employed little thought upon the matter; but that *the right*, notwithstanding, to adapt the government to their own views of national felicity, is inherent in them, seems unquestionable.—Again, though it be impossible, in most instances, precisely to fix the period when the national consent may *first* be regarded as fully and unequivocally expressed in favour of the government, yet, when it is once actually interposed, little doubt of its reality can exist. It may safely be affirmed, that the government of the American States is free; that is, *that the people are sensible* that it is co-existent only with their consent, and that the obligatory nature of its acts proceeds from the same source. The like, for a similar reason, may be confidently affirmed of our own government. That the governments of Spain and Turkey are not free, may as safely be affirmed, since it is impossible that this consciousness of consent can, in these instances, exist on the part of the people. We may add, that it is precisely for this reason that these governments seem ready to receive any new form, and that so many of the governments of Europe lately expired without one popular effort to save them.

It will not, we apprehend, be alleged, that, after all, this principle of the consent of the people is of little influence in the actual conduct of nations, and that men, for the most part, submit to their respective governments, and regard them as lawful, from habit, prejudice, or education. It would be difficult, we readily admit, to estimate, with any precision, the effects which the principle has produced, either in ancient or modern times. But from what source, we would inquire, did all the energy of the Greek and Roman character, in the best days of these states, proceed? Whence was each individual conscious of a degree of political importance of which most modern nations seem to have little conception? It obviously arose from the conviction with which every man was impressed, that not only each act, but the very existence of the government, depended, in some measure, upon his individual concurrence. It was this conviction that made him proud of his country: it was the principle that incited him to every effort for her prosperity, or exposed him to every danger for her glory. Nor in modern times has the principle been altogether inefficient. The policy, indeed, has prevailed of discountenancing it as much as possible; and as most of the feudal governments of Europe arose in utter violation of it, so their subsequent aim has been to suppress it as seditious and criminal. Yet it is to this sentiment chiefly, as the unfailing and copious fountain of all her exertions, that our own country has so long owed, and still so eminently maintains, her splendid distinction among nations. The latter periods also of the history of America and of Europe afford eventful instances of its more general diffusion, and seem yet to support the hope of its further progress. It does not appear idle, therefore, to speculate upon this principle. Let us, besides the example of our own political institutions,—of which when it ceases to be the actuating spirit, they will cease to be worth preserving,—expressly divulge its nature and effects. Let us impress it on the general mind. We shall thereby create a perpetually living motive to liberal action, which, in proportion as it is diffused, will control despotism, and extend the triumphs of liberty.*

But as those philosophers who overturned the system of Filmer erected another in its place, did Mr Hume and his followers offer, in their turn, a substitute for that which they had opposed? We think not. In comparing the History of that great writer with his Political Essays, it is not easy, we believe, to discover any distinct and consistent principle by which he would try the lawfulness of any form of civil government. At one time, he would seem to have regarded as legitimate every government which was once established, and, *from whatever motive*, acquiesced in by the people; a doctrine which appears to lead, without any circuit, to the encouragement of usurpation, and the exercise of tyranny. At another time, he appears to have reposed in the very principle he had been combating. "The observation," says he, "of our general and obvious interests, is the source of all allegiance, and of that moral obligation which we attribute to it. What necessity, therefore, he continues, "to found the duty of allegiance or obedience to magistrates, on that of fidelity, or a regard to promises; and to suppose, that it is the *consent of each individual* which subjects him to government, when it appears that both *allegiance and fidelity* stand precisely on the same foundation, and are both submitted to on account of the apparent interests and necessities of human society." The interests which are here meant, must be those advantages which appear to the mind of the people as well worthy of preservation; and, consequently, their adherence and consent to the government from which these advantages proceed, or by which they are protected, is implied; since, were they to withdraw this consent, the government would become precarious, or actually perish, and with it, consequently, those interests for whose sake alone they had formerly supported it. The question, therefore, in this case, seems to resolve itself into the mere propriety of the appellation by which the principle has been distinguished;—a point of too little importance to merit consideration. Call it the consent of the people, or *a sense of their own interests*, it is of no consequence, provided they be made sufficiently sensible that there can be no legitimate government that is not established for their good, and co-existent only with their opinion that it is so.

The philosophical scepticism in which Mr Hume indulged, necessarily arose, perhaps, from the very nature of several of the subjects upon which he employed his exquisite powers; yet we need not extend the remark to the principle we have been considering. It would seem to lie too near the surface, to elude a penetration much feebler than that of Mr Hume. In fact, at the time that philosopher wrote, † a coalition of parties was the wish of every good man in the commu-

* Any endeavour to fix *prospectively* the exact amount of disorder in the constitution, or actual administration, of a government, which would warrant a renunciation of the national allegiance, would be sufficiently absurd, nor is here contemplated. All we mean is, an unceasing recognition of *the principle*.

† The first part of Mr Hume's *Political Essays* was published in 1742, and the second in 1752.

Government.

nity. The friends of the exiled family were still numerous in the nation. A junto favourable to their interests had recently been discovered in the cabinet itself; and a rebellion, countenanced and supported by the power of France, had actually broken out for the purpose of restoring them to the throne. It is not therefore to be wondered, if such men as Mr Hume, who might be supposed capable of influencing, in some measure, the public mind, should endeavour, if not by reconciling, at least mitigating, the principles by which the opposite parties were actuated, to moderate their passions, and encourage unanimity.—Philosophy may sometimes preserve silence in the cause of truth; but can she, consistently with her obligations to the moral interests of mankind, ever actually raise her voice in opposition to her real sentiments? Can she ever delight to sacrifice the sternness of her dictates, even on the altar of public peace? (J. B.)

GRADUATION.

Graduation.

GRADUATION is the name given to the most delicate, difficult, and important branch of mathematical instrument making: it gives to the instrument the means of ascertaining the dimensions of objects, or their distance from each other, according to its nature, whether linear or angular measure is required.

History.

The substance of this article was intended to have been placed under the equally appropriate title of DIVIDING, and was partly written with that intention. Our having indiscriminately used both these terms, is owing not only to this circumstance, but also because the latter is exclusively used by the workmen.

Graduation first practised amongst clockmakers.

We believe that in every country in Europe, clock-making was the earlier art, and that clock-makers were the first who fabricated mathematical instruments. But as the excellence of the time-piece depends not at all upon the accuracy of the division of its dial-plate, we may suppose that instruments, the perfection of which rests principally upon the correctness of division, came from their hands in a very rude state.

As clocks, however, must at first have raised clock-makers out of brasiers, smiths, or other workers in metal nearest allied to the nature of the work; so instruments must have made instrument-makers, and for this purpose the clock-maker was more than half formed. One would think, indeed, that makers of compasses, dials, rules, astrolabes, &c. from the great usefulness of these instruments, must have existed prior to clock-makers, and of course the graduation of them; but however that might be, if there was about the middle of the 17th century any such distinct trade in this country, those who practised it were little thought of by men of science; for the instruments invented by Hook were made by Tompion; and both Tompion and Graham in succession made instruments for the royal observatory.

Abram Sharp.

It was the opinion of the late Mr Smeaton, that Mr Abram Sharp, the assistant of Flamstead, was the first who cut accurate divisions upon astronomical instruments: he having, about the year 1689, constructed and graduated for the royal observatory, a mural sextant of $6\frac{1}{2}$ feet radius, which in the hands of Flamstead rendered essential service to astronomy. Whether Mr Sharp was bred up to any mechanical business, or whether the whole was the effort of his own genius, is now unknown.

There were, however, instrument-makers in the early part of the 18th century, who, in the art of dividing, might at least have equalled those celebrated clock and watch-makers, whose names have been mentioned. Some of the works of Rowley are still extant, and bear such evident proofs of neatness and accuracy, that many a workman of the present day might be proud to own them. The elder Sisson, contemporary with, or a little later than Rowley, like him, constructed and graduated large instruments with success; but neither the manner of performing the work of graduation, when beyond the limits of their dividing-plates, nor the method pursued by Sharp, has been recorded. It was in the workshop of Sisson, that the eight feet mural quadrant, several large zenith sectors, &c. of Graham, were executed. That the latter should be employed in the construction of them, rather than any one who was exclusively an instrument-maker, was owing, no doubt, to his superior abilities as a general mechanician, his knowledge in astronomy, and his proficiency in making observations, as well as to his sound judgment, and nice execution of the most essential parts of whatever he undertook to construct.

Rowley. Sisson the elder. Graham.

Bird.

About the year 1727, the late Mr Bird, then a rustic lad of Bishop Aukland, observing the unequal divisions and coarse-engraving of a clock dial-plate, determined upon doing one himself. The success of this attempt was the first step that led to the developement of powers, which, during a long life, proved beneficial to science, and rendered his name an honour to his country. It was from the elder Sisson, to whom he served a short apprenticeship, and his acquaintance with Graham, that Bird learned every thing that was not derived from his own resources. Bird and the younger Sisson were contemporaries and rivals for fame, were both men of considerable abilities and application. But the superior ingenuity of the latter lost its effect with the best informed, when brought into competition with the accurate execution and sound judgment of the former.

Sisson younger.

Ramsden.

Mr Ramsden followed the next in time; and perhaps gained greater credit in his line of business, than any preceding artist. The dividing-engine, which he invented, by rendering small instruments almost as accurate as large ones had been before, will shed lasting and well-merited honour upon his name. In his larger works, however, he was not so happy, although they were graduated better than any previous to his day. Too vain of invention, he despised the patterns left by his predecessors, and gave to his works complex and unsteady forms.

Mr John Troughton.

The late Mr John Troughton, about twelve years younger than Ramsden, was equal, if not superior, to him in the graduation of instruments. But his chief works, performed in his own attic, were destined to shed honour upon the names of the first mathematical instrument sellers in London; and by the time his merit became known to the public, his younger brother had taken the lead. But we must close these short biographical sketches with the labours of the dead.

We are aware that these desultory remarks will ill supply the place of a regular history of the art; a thing which we cannot attempt, and which is perhaps impossible. To describe things as they are, and to give the methods as hitherto practised by eminent men, will certainly be more useful: and in doing this, as often as ommon Graduation.

they have written upon the subject, their different modes of practice shall be given in their own words.

Of those numerous contrivances, which have neither ingenuity of conception, nor have been found useful in their day, we shall say nothing; for it would be idle to obstruct their natural passage to oblivion.

ision of subject.

For the sake of perspicuity, we shall divide this article into three Sections, containing, 1. *Common graduation*, 2. *Engine graduation*, and 3. *Original graduation.*

Sect. I. *Common Graduation.*

mon duation.

In this Section of our article will be shewn the method of taking copies from a pattern, which has already been laid down originally; or, as indeed is now generally practised, taking copies from a copy. This part also includes original dividing, in cases where the usual patterns do not apply, and where the utmost degree of accuracy is not required.

 divid- plate.

It will here be necessary to describe the apparatus or tools used by the person who divides in common. And first the dividing-plate must be noticed. Its dimension varies from 14 to 30 inches in diameter. It is either an entire plate, or a broad rim, connected with the centre by four or more radii, and rendered inflexible by circular rings, or edge bars underneath. The extreme border is divided into degrees and quarters; and just within this another circle, into degrees and third parts. Within are usually put such numbers as are required for the dial of the perambulator; Gunter's line of numbers arranged in a circle, and other logarithmic lines, are sometimes inserted. There are also often to be found tangents in hundredth parts of the radius, and the difference of the hypothenuse and base, as applied to the theodolite; also the equation of time for dialling; the points of the compass, &c.

There is always in the centre of the plate a circular hole, which should be truly perpendicular to the surface. Into this is nicely fitted a pin or arbor, which also fits the centre hole in the circle or arc to be divided; and while the operation is carried on, is the principal connexion between them. Fig. 1. Plate CCLXXVIII. shews the dividing plate, and its connection with a compass ring; also a pair of *holdfasts* for keeping the work from turning round. One of these fastenings would be sufficient, were it not necessary to remove one of them, when its position obstructs the work. An index of tempered steel, usually made of a saw blade, has one of its edges made very straight: At one end a plate of brass, as at A, is rivetted fast to this index, having at its extremity a right angular notch, reaching a little beyond the blade: the angular point should be exactly in a line with the edge of the index. This notch receiving the arbor of the plate, will always direct its edge to the centre. The length of the index should be equal to the radius of the plate. To the exterior end, and below it, is fixed a secondary index B, reaching as far inwards as the original lines of the plate extend, which also must have its edge directed to the centre; but it need not be exactly in the line of the other, and will be better seen if it is placed a little to the right. The figure shews this, and also an arrangement of nuts and screws, by which the distance of the two parts is to be adjusted, according to the thickness of the work, so that the secondary one may be flat upon the plate. The generality of dividers, instead of this contrivance, bend the index to suit the different planes of the work and plate; but this is a very bungling method; indeed, when the borders of instruments are required to be divided on feather edges, as is the case with protractors, bending is necessary: a very flexible index should, in such cases be employed, in order that the pressure of the hand may bring it in contact with the inclining plane. But even here a secondary index might be employed to advantage, having its position adjustable to the plane which is to receive the divisions.

ATE CLXXVIII. Fig. 1.

The dividing-knife. Fig. 2.

The dividing-knife must next be described. This little implement is represented, in full size, by Fig. 2. It consists of a blade and handle; the former should be made of the very best steel, and the latter of beech-wood. The cutting edge should be exactly of the same thickness that the divisions are intended to be; it should be quite straight, and in a line with the handle. This edge must not be sharp like that of a common knife, but rounding, so as to present to the surface to be divided a small semicircle, whose radius is equal to half the breadth of the line it is to make. At the back the blade should be about a fifteenth of an inch in thickness. The left side, which is the front and downwards in the figure, should be ground flat; but the opposite side must be chamfered in a faint curve from back to edge. The extreme end of the blade makes with the line of the edge, an angle of about 70°. A small chamfer on the side to the right, broad at the back, but vanishing at the edge, reduces the end to an equal thickness. A semicircular recess is made in the edge of the blade, near the handle, which affords a relief when the tool is sharpened, and is farther useful by receiving the inner side of the end of the middle finger. For the accommodation of this finger also, a part of the ferrule of the handle is cut away, as represented in the Figure. There is a convenience in the back of the blade being formed into a curve so as to make it narrow at the point, for without diminishing its strength, it enables the operator to see his work better. Such is the form of the dividing knife, an important tool in every branch of the art, as in the hands of the best workmen it has continued unaltered since the time of Bird. Had we, indeed, been inclined to describe it as found in the workshop of an ordinary divider of the present time, we should only have had occasion to say, that it exactly resembles the butcher's cleaver; and, perhaps, we might add, is commonly directed with about equal science.

Mode of using the dividing-knife.

The action of the dividing knife is directly the reverse of the graver; the latter being pushed outwards, cuts away a fibre in the line of its course, leaving the rest of the surface of the metal undisturbed; but the former is drawn inwards, and without producing chips, ploughs a furrow, and the metal displaced rises in a bur on each side. The knife is held very much like a pen, only the handle must be quite home between the thumb and fore-finger, which being placed upon the ferrule, directly over the back, is, by its pressure, the chief agent in giving depth to the divisions, the thumb and middle finger acting as supporters, while the other two fingers, as in writing, prop the hand. The knife is held at an angle of about 45° with the plane to be divided, and is used with the flat side in contact with the index before described. If it has an inclination of its own to deviate either to the right or left, it is not in a condition fit to be used; for in the former case it would require too hard a pressure of the hand to keep it in contact with the index, and in the latter would undermine it, and in either case it would make crooked lines. It is therefore necessary to try it in this respect, before the commencement of dividing. If, on drawing a line without an index, it deviates to the right, then is the vertex of the semicircular edge too near that side; but when that vertex is too near the left, the knife will deviate the contrary way. The use of the small chamfer before described is to make the two sides of the knife exactly similar at the point; were it not for this

Common Graduation.

contrivance, the bur would not rise equally on both sides, and the strokes, where they meet the bounding lines, would have an appearance of crookedness.

Method of drawing the circular line.

Preparatory to making the divisions, the circular lines must be drawn for limiting the length of the strokes: these are made with the well known apparatus called a beam-compass; but it is only necessary to trace the lines with it. They are to be made of sufficient breadth and depth by the dividing-knife, which, when sharpened as above directed; and guided by the hand alone, will aptly follow the slightest mark.

Scraper.

The bur is generally taken off the lines with a tool called a scraper, and then cleared with the knife. After this the surface is rubbed with charcoal (that from the willow is best) and water, which leaves the surface smooth, without producing a gloss that would be unpleasant to the eye.

Having been thus minute in the description of the tools, that of their application will be short indeed.

Method of dividing circles.

A compass ring, for instance, as before mentioned, is attached to the dividing plate, for the purpose of being graduated; its *zero*, or N, being placed so, that the index, when set to it, may agree also with the *zero* of the plate. In this position of things, the operator must drop the point of the dividing knife into the line on the plate, and, pressing the index to prevent its moving, cut the corresponding stroke upon the ring. He must be careful to hold the knife steady, and in exactly the same position, while he sets and cuts. His eye must be directed to the left side of the knife, in order that he may see that he holds it in contact with, and parallel to, the edge of the index. The index is now drawn forwards something more than the value of a division, and the knife being fixed in a second line, it is then pushed back into contact with it, and a second stroke cut as before; thus proceeding from right to left until the circle is completed. In dividing upon metals, this work is laborious for the hands, which will require frequent intervals of rest: during these the divider should examine his work with a magnifying glass. In cases where the hand has not power to cut the strokes deep enough at once, which does not unfrequently happen, instead of cutting twice, the operator will proceed with more ease and expedition, if he goes round by single cutting, and afterwards completes his work; for, in the latter part, he will not have occasion for either the dividing plate, or the index; the knife, if well set, will follow the former strokes with accuracy and neatness. The bur must be worn off the divisions by rubbing the surface with charcoal and water, as was before done with the circular lines; but the scraper must not be employed.

Method of dividing straight lines.

Plate CCLXXVIII Fig. 3. & 4.

Common dividing, as it applies to straight lines, is so similar to circular dividing, that little need be said about it. Figs. 3. and 4. represent the necessary apparatus; the dividing knife is common to both. AA is the pattern, and B is a scale to be divided into inches and tenths: CCC represents what is called the dividing square. This tool consists of a thin tempered piece of steel, extending, in the line of the pattern, about six inches, and at right angles somewhat more, and a stock about two-tenths of an inch shorter and narrower than the parallel part. This latter is formed of two pieces of brass; one above the steel, and the other below it, to which they are securely rivetted. The stock and blade are even with each other at the outside and left end; the projecting part of the steel, in the line of the pattern, lies upon the latter, preventing the square from tilting, and that at the end places the stock out of the way when the edge of the blade requires to be repaired. As it is, in some cases, necessary that the square should be used when placed upon the farther side of the work, the two parts of the stock should both be accurately at right angles to the blade; the best way to secure which property is this:—After having made the holes which are to receive the rivets, remove the steel, and pin the two branches of the stock together; then, with the *plane*, make the inner edges straight and even with each other. In order to prove that the blade is at right angles with the stock, take a broad scale of brass, having its edges truly straight and parallel, a thing by no means difficult to procure, and, first applying the square to one edge, draw a line across the scale with the dividing knife, and then, applying it to the other edge of the scale, with the same side uppermost, draw another line extremely near the former. If the parts are right, it is evident the two lines will be parallel to each other; but if they are inclined, half their inclination is the error of the tool, which must be altered by grinding the edge of the steel blade. It is almost unnecessary to observe, that the use of the square, in parallel dividing, is precisely the same as that of the index in angular dividing.

Beam-compass.

We omitted to describe the beam-compass, for tracing the circular lines which limit the length of divisions, on account of that apparatus being well known; for the opposite reason, we now proceed to give a description of the *gauge*, (See Fig. 4.) an implement which performs the same office in tracing parallel lines. It consists of a brass beam A, about six or eight inches long; a socket B, of the same material, with a steel front to the left, which, sliding along the beam, may be set fast on any part of it by the finger screw S on the upper side, and a tracer of tempered steel fixed to the end of the beam by a wedge and screw. The tracer has its point of action brought close to the inner edge, in order that it may draw a line extremely near to the edge of the scale; its great length, as shewn in the Figure, being in no respect incommodious, is designed for the purpose that it should be lasting. The steel front of the socket extends in the line of its action about two inches, which enables the operator to keep the beam without deviation at right angles to the edge of the scale; and there is a projecting part in the front, of the same length, which, bearing upon the surface, keeps the tracer perpendicular; this is discontinued in the middle, for the purpose of admitting the tracer to be brought into contact with the front. The tracing point should be so adjusted as to be a very small quantity below the projecting part. The end of the socket to the right is on every side chamfered to a thin edge, and the beam has divided upon its different sides many lines, suited to the most common work, such as drawing the parallel lines of diagonal scales, &c. By dropping the dividing knife into these, pushing up the socket into contact with it, and there fastening it, the operator places the steel front and the tracer at the proper distance for the performance of his work. In cases of less frequent occurrence, he clamps the socket by trial, so as to make the tracer pass through points previously laid down with the spring-dividers, a tool to be described presently.

Dividing gauge. Plate CCLXX Fig. 4.

The process of dividing from straight line patterns being exactly similar to that from the dividing plate, it must be quite unnecessary to repeat it. We may, however, observe, that in the former the errors go undiminished to the work, while those of the dividing plate are contracted in the ratio of the radius of the plate and work. Clockmakers pursue the contrary process; they fix a small dividing plate upon the centre of their dials, and transfer the divisions outwards. It is not, however, now uncommon for them, in their very best work, to send the dial plates to the instrument maker to be divided.

In straight line dividing, the operator has frequent occasion to divide lines to which none of his patterns will apply; but there is an expedient that he ought not to be unacquainted with, which will enable him, to a certain extent, to overcome this difficulty. Suppose he were required to set off French inches; that he knows the proportion they bear to English inches, which are shorter; and that he has marked off upon the scale to be divided, according to this proportion, the total length of French inches required: he may divide it from his English inch pattern. In this case his work must be placed at an angle with his pattern. The proper inclination is readily found by trial; and as the square must run along the pattern, its blade will not be at right angles with his work. On this account he will have to perform two distinct operations. In the first he is to go through his work, only making slight notches in the hypothenusal, or inclined line, with the dividing knife; in the second, with the square applied to the edge of the instrument which is to receive the divisions, he must, by seeing and feeling those notches, cut the corresponding perpendicular strokes.

Suppose, again, that Spanish inches were to be divided from the same pattern: These are shorter than English inches, and will require but one operation. In this case the square must be applied to the work, and the parts taken from the inclined pattern. We might here annex the rule for finding the angle of inclination, according to the proportion between the pattern and work to be divided, but we do not see its use. Those who handle the dividing-knife, especially in this department of the art, are seldom versed in computation; and as the lines upon the pattern, as well as those upon the work to be divided, are often remote from the edge, the angular point would seldom be found upon either, and would often fall beyond the limits of the room in which the work is to be performed. We have already said, that cutting divisions upon metal is laborious to the hand; but in ivory and wood it is not so; for in either of these a divider will keep pace with a dexterous seamstress, a division for a stitch, for any length of time. The common carpenter's rule is divided in this manner, and, small as is the price of the finished instrument, the dividing bears but a small proportion to it. As a farther proof of the celerity with which this kind of work is performed, it may be mentioned, that the writer of this part of our article being once in want of a good piece of boxwood, exactly similar to that of the common Gunter, but without slider or divisions, the artist who provided it charged sixpence more than he would have done for the finished instrument; and, upon being asked the reason, gave a good one: "the little order had put him out of his common track."

When box, or any other kind of wood, is divided upon, the bur is first well rubbed off the divisions, and then the whole surface brought to a polish with a dry rush; the surface is next burnished by rubbing it hard both ways, in the direction of the grain of the wood, with a clean piece of old hat, which produces an agreeable gloss; and, lastly, to blacken the divisions, a mixture of powdered charcoal and linseed oil being laid on quickly, rubbed hard and cleared away, finishes the process. In ivory, the divisions are, in the first place, filled with a composition of lamp-black and hard tallow, or, which is rather better, of bees-wax and olive oil: when this is hard rubbed into the strokes, the whole surface should be well rushed, and then polished with chalk and water laid upon a linen rag. It has already been said, that the bur of dividing on metal should be taken off with charcoal and water; but in brass, the surface will have a much better appearance if the finishing stroke is given with wet blue-stone, which is a very soft slate, or the same substance that slate pencils are made of. Divided gold and silver, however, look best when they receive their finish from the charcoal. The divided surface of all the metals is improved in appearance by being rubbed with the hand, after a little oil has been applied. No other blacking is required.

Division of diagonal lines.

In dividing diagonal scales, the beginnings and endings of the inclining lines are marked off with the dividing-knife from a pattern of equal parts, and afterwards those lines are traced by means of a straight edge, similar to the blade of the square. The knife being dropped into one of the marks, the ruler is brought into contact with it, and very nearly up to the other mark; the thumb of the left hand is placed exactly over the ruler at the former, and the knife being dropped into the latter, the ruler is brought into contact with it, being turned under the thumb as on a centre. Instead of drawing the diagonal lines by hand, some use the bevel; and as by this the whole is done at once from the pattern, it would seem to be the more methodical way, but it requires a very nice adjustment to make the bevel agree with the square which had been previously used to draw the perpendicular lines. But which ever method is used, to do it with sufficient exactness is one of the most difficult operations of this department of the art.

In the sector, and every other instrument, where the lines, which bound the length of the dividing strokes, are not parallel to the edge, so as to be traced with the gauge, the straight-edge and dividing-knife are used: The beginning and ending of the lines are set off in their proper positions by the spring-dividers: a tool so important in every branch of the art, that a description of it might have sooner claimed a place.

The spring dividers. Plate CCLXXVIII. Fig. 5.

This is a kind of compasses formed altogether of fine steel. It consists of a circular bow and two legs, all in one piece, as represented in full dimensions by Fig. 5. Plate CCLXXVIII. The bow is strong and well tempered, and, without danger of breaking, allows a motion of the points from the distance of about an inch to their contact. This is their range for use, but the elasticity is not exhausted until the points are separated nearly twice as far. At about three-fifths, reckoning from the bow, the adjusting screw has its place: It is at right angles with the legs when the distance between the points is small, because short lengths are most commonly taken. The screw, throughout its whole length, has a fine deep thread of about sixty turns to an inch; is fastened to one of the legs by a pin passing through it, and upon which it turns as on a centre, in order to obey the circular spring of the bow; and the other leg is perforated, in order that, at every distance of the points, it may pass freely through it. A nut, the female screw of which is nicely fitted to the former, by its action overcomes the expansive force of the bow, and regulates the distance between the points: But this nut does not come in contact with the leg; there is interposed between them a saddle-piece, which exterior to the screw is made conical, and this is received by a hollow conical part in the nut, which it exactly fits. The saddle-piece next the leg is formed into a knife-edge, or sharp angle, which, resting upon the sharp bottom of a notch in the leg, keeps the former from turning round with the nut, at the same time that it allows the angular change, as the distance of the points is varied. By this contrivance, freedom of action of the screw is preserved, and the possibility of its change

Common Graduation.

The spring-dividers. PLATE CCLXXVIII Fig. 5.

of place, and consequent alteration of the distance between the points, prevented. The legs are bored in the direction of their length, to a depth of about three quarters of an inch; they have each, near their extremities, a part which projects outwards. These parts, as well as the length bored, are cut open on the outer edge by a saw. A screw, in each of the projecting parts, passes freely through one-half, but acting in the other, brings the parts nearer together, and furnishes the means of securing the points firmly in their places. The points themselves are cylinders, exactly filling the bore of the legs, and their ends are worked to the requisite sharpness; and, in order that they may measure the shortest possible distance, are brought very near the inner extremity of the diameter. At the very point, however, they should be round, and in every direction the sides must make equal angles with the perpendicular; for, were they not so, a distance set off with them, it is obvious, would be altered by pressure.

In using this instrument, the fore-finger is pressed upon the bow, the thumb and middle-finger keeping it upright while the other fingers prop the hand; but where a distance is to be set off many times in succession, the dividers are to be twirled round in the same direction, making a dot at every half turn. This is the manner of handling the tool for common purposes; but for the accurate bisection of a distance, they must not be touched by any other part than the leg near the point, which is lodged in one extremity, while with the other a faint arc is described: the same thing being done from the other end of the distance, the middle point is secured by making a dot with a fine conical pointril. In every use of the dividers, a magnifying glass is to be held in the left hand.

Exemplification of their use in the division of common thermometers.

In *dividing* a common thermometer, several points, 12 or 15 degrees a part, are marked off, according with a standard one; these, always unequal, are filled up with equal parts. The use of the dividers cannot be better exemplified than in this case: Say the distance from one mark to the next is 15°, the operator knows the value of his time better than to do this at two operations; instead of first dividing the space into three or five, he guesses or estimates the distance of 1°, and running the tool over the space almost as quick as he can count its steps, sees how much he has erred; a second or third trial never fails to give him the proper distance. The dots in these trials, two of which should never be made in the same line, are barely to be seen by the glass, and he wants the last, that, by repeating the steps with a greater pressure, he may make the dots sufficiently large to receive the point of the dividing-knife. It may be mentioned, that the operator does not draw a line in the direction of his work: without such help, he learns by practice to plant his points in the direct course.

Division of sectors and plane scales.

Sector and plane scale patterns are divided from a diagonal scale, with the square and dividing-knife: the whole length of the scale is equal to the radius of the sector, and is divided into 1000 parts, and a lower subdivision is obtained by estimation. The value of each division is picked up among the diagonals, according to tables of natural or logarithmic sines, tangents, &c. Whoever wishes for full information upon this subject, may consult the *Select Mechanical Exercises* of the late celebrated James Ferguson; every table is there given, and not a figure more or less than what is required. The practical part of what is here referred to, Mr Ferguson learned from the first of the three Troughtons, to whom his youngest son James was apprentice, a youth of considerable promise, who died at the early age of 23 years.

If it should be thought that we have been unnecessarily diffuse in this department of the art, we would observe, that should any one, before he is fully acquainted with it, and habituated to the use of the tools, attempt to practise the higher branches, he will most probably find himself unqualified for the task.

Sect. II. *Engine Graduation.*

Engine Graduation. Hindley's dividing engine.

The late Mr Henry Hindley of York, about the year 1740, was the first who constructed an engine for graduating instruments, and which also served the purpose of cutting the teeth in clock wheels. We have it not in our power to give a particular account of this engine, but the late Mr Smeaton, in the *Phil. Trans.* for 1785, informs us that the plate was turned round by an *endless screw*, which having been cut with a tool that turned upon a centre at a distance equal to the radius of the plate, made it of smaller diameter in the middle, so that the screw throughout its whole length, acted in contact with the convex edge of the plate. Smeaton informs us, that both the screw and the teeth in the plate, were produced from the original graduation of the plate. Mr Smeaton's paper here alluded to, is replete with general information upon the graduation of instruments; but Hindley's method of original dividing, and his own improvements thereon, form the main subject. These will be briefly noticed in the next Section.

Hindley, far removed from the metropolis, and perhaps knowing little how, in his time, the useful arts were cultivated there, was, by dint of his own native powers, making considerable progress in the improvement of his double profession of clock and instrument making. In the latter, however, he must have wanted that constant employment which alone can ripen experience, and give full effect to execution. He died in the year 1771, at the age of 70 years.

The Duc de Chaulnes' dividing engine, 1768.

An account of the next attempt to make a dividing engine was published at Paris in 1768, by the Duke de Chaulnes; every part of which is described with the utmost minuteness, and illustrated by 15 folio plates, all full of figures. It will not, however, be to our purpose to give even an abstract of this ingenious work, on account of its having been superseded by better contrivances, a due attention to which will occupy as many of our pages as can be appropriated to this subject. We may however observe, that the wheel of this engine is not turned round by an *endless screw*; itself, together with the work to be graduated, is acted on by a clamp and screw for slow motion; by the latter, a divison of the limb is brought to be bisected by the vertical wire of a fixed microscope, and then the corresponding division upon the work cut with a point and frame adapted to the purpose. We do not know that any small instruments were ever divided by the Duke de Chaulnes' engine, or that any large ones were done according to the original method by which it was graduated. The method, highly interesting, and at that time altogether new, will find the notice it deserves in that Section of our present article to which it belongs.

Ramsden's dividing engine, 1766.

It is, however, to the ingenuity of the late Mr Ramsden, that the world is indebted for engine dividing in its full effect. That artist, about the year 1766, produced an engine which, although it fell far short of his expectations, exceeded, in accuracy, the best dividing plate. It was fully competent to the division of common instruments for surveying of land, &c. but was deemed insufficient to produce that accuracy which is required for the purpose of finding the longitude at sea. This engine, about 30 inches in diameter, after Ramsden had, about 1775, made another of nearly four feet, was sold to a nobleman in France for the purpose of being lodged in his cabinet.

Mr Ramsden, in his second effort to make an engine, was completely successful, insomuch that a sextant divided by it, being subjected to the examination of Bird, was by him reported to be fit for every purpose of nautical astronomy.* Ramsden's account of this engine, was in 1777 published by the Board of Longitude, who rewarded his ingenuity with the sum of £300. For a further sum of £315, he made over to the public the property of the engine itself, on condition, that at stated prices he should divide any instruments that might be sent to him by other makers, so long as the engine should be allowed to remain in his possession.

Previous to the account of Ramsden's being published, and before its construction was generally known, Messrs Dollond made an engine, differing materially we believe from the former; but as it was never used except in the graduation of instruments made by them, the only judgment we can form of its quality, arises out of the high respectability of that well known house.

In the year 1778, the late Mr John Troughton completed a graduating engine, which at the full stretch of his pecuniary means had occupied him for three years. In its general construction, this differs in no material respect from Ramsden's, though it is generally, we believe, thought to be superior in point of accuracy. The trade were so ill satisfied with Ramsden, on account of his keeping their work for an unreasonable length of time, as well as for the careless manner in which it was often divided by his assistants, that Troughton immediately, at augmented prices, found full employment for his; and he has been heard to say, that by the care and industry of himself and his young brother, he soon found himself as well remunerated for making his engine, as Mr Ramsden had been by public rewards.

It was about 1788, that Mr John Stancliffe finished a dividing engine. This accurate artist had been apprentice to Hindley of York, and for many years a foreman to Ramsden. The latter derived much information from him in the construction of his second engine, in which the cutting-frame of Hindley was adopted. In the first, the divisions were cut with the beam-compass, which, compared with Hindley's apparatus, is tedious and inaccurate. Mr Stancliffe's practice has almost exclusively been confined to making sextants, and their being held in the highest estimation, furnishes the most certain proof of the excellence of the engine by which they were divided.

It would be useless particularly to enumerate all the engines that have been made for angular dividing; perhaps there may be ten or twelve in London, generally copies of Ramsden's second engine. The greatest novelty that has appeared in this way, was given a few years ago by Mr James Allen, an industrious workman, which he stiles a *self-correcting method of racking the plate*, and which, with the usual good nature of the Society of Arts, &c. was honoured with their gold medal. Those who wish to know more of it, may, by consulting the journals of that Society, gain full information, and have an opportunity to examine whether or not it deserves its title.

As in our article, we have not room for more than the description of one circular engine;—as Ramsden's has been copied into more than one work similar to our own; and as that of the present Mr Troughton has not yet met the public eye, we give the preference to the latter, which at our request he has lately communicated, in the following letter to Dr Brewster:

"Dear Sir, I remember that in a late conversation between us, you gave me to understand, that a description of my circular dividing engine would be acceptable to you, in order to form a part of the article in your Encyclopædia to which it belongs. For that purpose, I have at length drawn it up, not to my own satisfaction indeed, for I wished it to have been done well; but such as it is I have the honour of presenting it to you.

The excellent engine of my late brother being fully four feet in diameter, gave to the operator, when at work near the centre, a position so painful, that it had done no good to either his health or my own, and had materially injured that of a worthy young man then my assistant; it was evident that, by making one of smaller dimensions, this evil would in a great measure be removed, and I foresaw that by employing my own method of original dividing from which to rack the plate, a considerable reduction might be effected without any sacrifice of accuracy. I also perceived, that by contriving the parts with more simplicity than Ramsden had done, I could get through the work at less than two-thirds of the labour and expence.

Such were my motives for making an engine, and the work was accomplished in the year 1793.

"The principal parts of this engine are represented by Fig. 1 a plan, and Fig. 2 an elevation, in Plate CCLXXIX. It is mounted upon a strong frame of wood, the upper part serving as a box to preserve it, and which at certain places opens for use. This stand does not, like those of engines hitherto made, form a part of the machine; it only serves to support it at a convenient height, and is not, excepting the platform EE, at all represented in the Plate. The lowest part of the engine is a heavy tripod of cast brass, nearly in the same state in which it came from the mould. Two of its branches are denoted at A, A, in the plan; the third is similar, but mostly covered by the work above. In Fig. 2. the tripod is also represented by AA, below which three finger-screws that support it upon the platform are seen. These screws, marked B in the elevation, serve the purpose of levelling the engine. They work in the tripod with their heads downwards, and are planted in the broad part where the two branches meet. At about two inches from the centre of the tripod, and at equal distances from each other, are fixed three conical tubes, extending downwards nearly three feet. Two of them appear at C, C, the other is hidden behind the axis of the engine plate. They are connected at the lower ends by a strong piece of brass F, forming together with the centre of the tripod a frame wherein the axis revolves.

The engine plate itself, represented by G*s* in Figs. 1, 2, and 5, was cast in one piece of brass, all except the circular limb. The form of the twelve radii respecting depth is seen in the elevation, and a central part of four inches diameter, equal in thickness to their greatest depth, connects them; but the broad circular centre-piece seen in the plan, as well as the circular ring shewn in the middle, are no thicker than the limb. The limb, three inches broad and half an inch thick, is formed without soldering of one piece of fine plate brass. It is rabbetted upon the extremities of the radii, so as to bring its upper surface into the same plane with them, and there by rivets made permanently fast.

The axis of the plate is a strong conical tube D, four inches in diameter at the upper end, and half as much below. Its length is determined by the three cones of the tripod. At the upper end it is immoveably fixed to the centre of the plate; the lower end terminates in an obtuse point of steel. There is fastened in the up-

Margin notes: Engine Graduation. — Dollond's engine. — Mr John Troughton's dividing engine, 1778. — Stancliffe's dividing engine, 1788. — Letter to the Editor, containing a description of Mr E. Troughton's dividing engine, completed in 1793. — Plate CCLXXIX. Fig. 1. & 2. — Fig. 5.

Description of Mr E. Troughton's circular dividing engine.

per end of the axis an arbour of hardened and tempered steel, which, having passed through the plate from below, stands full two inches above its surface, and ends in an obtuse point similar to that below. Upon the two points when revolving in the lathe, the surface of the plate was generated, and its outer edge made perfectly circular.

A screw for making the teeth in the limb had previously been made. It had 20 threads in an inch; and as it was intended that by one of its revolutions it should carry the plate through an angle of 10′, it followed, that the circumference of the plate should be 108 inches. From the measure of the screw, therefore, the dimension of the exterior border of the plate was derived, first by computation nearly, and afterwards by trial with the screw itself.

A strong collar of bell-metal had been soldered upon the axis, and, when the limb was turned, made concentric with it. The position of this collar is, respecting height, coincident with the body of the tripod. The centre of the tripod is hollow, in order that the collar should pass through, but does not form a socket for it to work in. Instead of that, two narrow pieces of steel are fixed vertically at an angle of 120° with each other. Against these, the collar is pressed by a steel spring planted at 120° distance from them. In this triangular bearing the axis is supported at top, while the piece F receives the point at the lower end, and supports the whole weight.

To that branch of the tripod which is in front, a strong plate of brass is screwed fast, as represented in the plan. It extends inwards half way to the centre, and outwards somewhat beyond the border of the wheel. Its breadth is rather more than the length of the screw arbor. Immediately above this, and in contact with it, is an exactly similar plate. To the under side of the latter are screwed three oblong pieces, the thickness of which is equal to that of the lower plate. These, one of them at the middle of the inner end of the plate, and the other two at the outer end near the edges, are received by slits cut in the lower plate, which are about one-eighth of an inch longer than the pieces, and allow a motion of the upper plate, in the direction of the radius equal to that quantity, but afford it no lateral play.

The dividing screw is fastened to the upper plate, and partakes of its motion, the use of which is occasionally to disengage the screw from the teeth of the limb. Two pieces, which connect the screw with the upper plate, are seen, one or both of them, in all the figures, and marked with H; they extend towards the centre, as far as the plate, and form edge-bars to strengthen it. The shape of these pieces is best shewn in Fig 4. especially as to the manner how they are brought from below, for placing the screw even with the edge of the wheel, and how the screw arbor is centered in them. The arbor of the screw is cylindrical; and a portion of each end forms a cylinder of smaller diameter. The shoulders, which near each end of the arbor, limit those parts, prevent lateral play in the pieces last described; for the smaller parts work freely in the holes of those pieces, the shoulders being in contact with their inner edges.

Plate CCLXXIX. Fig. 4.

The engine, so far described, is ready to receive the original graduation of its limb; and as this operation was done, while work to be described hereafter was preparing, I will here explain by what means this most important part of the work was accomplished: to do this, however, within moderate bounds, I must suppose that the reader is already acquainted with my method, as published in the *Phil. Trans.* for 1809, or that he will turn over to the last Section of this article, where it is fully explained.

In the first step, a roller was placed horizontally, in a frame attached to the tripod, having free and steady motion round its own axis; this was adjusted so as to be carried exactly 16 times round, while the engine plate made one revolution, and was itself near the edge upon its upper surface, divided into 16 parts. Now, upon turning the plate round, these 16 divisions 16 times told = 256, came in succession to the wire of a fixed microscope, and were, by a proper apparatus, transferred to the surface of the plate, in five dots, at a sufficient distance within the edge to prevent their being disturbed by making the teeth. To accomplish the next step, an index was made to revolve upon the arbor of the plate; it was composed of two branches, each of which carried at its extremity a microscope with a micrometer; these had a range of angular motion respecting each other, from a right line to a very small angle. By this index, and these microscopes, the 256 fine dots were examined by a certain bisectional process, from which their individual errors were investigated by computation, and formed into a table. By the help of the table of errors, the future work of racking the limb was prosecuted with as much certainty as could have been done, had the original divisions been inserted without error.

It has already been said that the value of a tooth of the limb should be 10′, and consequently their whole number will be 2160; now $\frac{2160}{256} = 8\frac{7}{16}$, and just so many revolutions and parts of the dividing screw will be commensurate with a mean space from dot to dot = an angle of 1° 24′ 22″.5. In order, therefore, that a comparison between the plate and the screw might be made at every original dot, it became necessary to provide means to ascertain the position of the former at every 16th part of a revolution. To this end a micrometer head, as large as could be admitted, divided into 16 equal parts, was fixed upon the left end of the screw arbor; and contiguous to this, was placed a fixed index bearing a fiducial line. For the purpose mentioned above, these were all that could be wanted; but as our dots were erroneous, in order from their apparent, to determine their true places, a lower subdivision of the head became necessary. Each of the 16 spaces, therefore, was divided into 10 by actual division, and as an eye, practised in such matters, can by estimation accurately obtain the value of the next decimal figure, it was into the last denomination of subdivision that the table of errors had been reduced, the value of an unit of which, in angular measure, is $\frac{3}{8}$ths of a second.

The roller was removed when the 256 dots had been transferred to the plate, as were the double index and microscopes from the central arbor, when the position of those dots had been ascertained. Now, the dividing screw was placed in its frame; a micrometer, with a moveable wire, fixed to the tripod for viewing the primitive dots, and a winch for turning the screw attached to its arbour on the right: this change of parts being effected, the screw with its frame having free motion in the line of radius, and capable of being, by the force of a spring, pressed into contact with the edge of the plate, or by a screw drawn backwards at pleasure; and the plate itself having free motion round its axis, the important operation of forming the teeth, or racking the circle, was commenced.

It should be premised, that to prevent mistakes, by beginning an interval at a wrong 16th of the head, which, by making false marks, would occasion much

Method of graduating the limb in Mr Edward Troughton's circular dividing engine.

trouble, those parts were numbered 1, 2, 3, &c. to 16, in the order of turning the screw forwards. Corresponding numbers were marked in ink upon the plate opposite to the dots, the order of which, from right to left, was 0, 7, 14, 5, 12, 3, 10, 1, 8, 15, 6, 13, 4, 11, 2, 9, which, repeated 16 times, completed the circle. These enabled me to proceed with confidence; for, in beginning any interval, it was only required that the number upon the head should be that, which distinguished the dot under the wire of the microscope. In the table of errors, I marked those dots, which were too forwards, with the sign —, and those that were too backward +, because it is evident that a + position of the screw will effect the correction of a — error of the dot, and the contrary.

The *zero*, or first dot, being without error in the table, is, by turning the plate round, to be brought exactly under the wire of the microscope, and the division of the head marked 0 made to coincide exactly with the fiducial line. The spring must now be allowed to press up the screw into contact with the edge of the plate, and then, by means of the winch, the screw is to be turned through $8\frac{7}{16}$ revolutions, which will make impressions upon the edge of the plate, and bring up another dot to the wire of the microscope. The screw must now be released, and the plate turned backwards, so as to bring that dot to the wire which precedes the one that the former interval began from, which dot is marked 9, and the division of the head marked 9 must be brought to the fiducial line, but not exactly; for in this, as well as in every future interval, the tabular error of the dot must be allowed for, according to the subdivisions of the head: the screw being again pressed up, and turned with the winch, as was done before, this interval will be indented. Thus proceeding in a retrograde course, from one interval to another, until the whole circle has been gone over, we shall have a slight impression of the screw at each of its 2160 revolutions.

The marks formed in the manner just described are laid on, as it were, in patches, the beginnings of which are agreeable to the original corrected dots, but at every other point subject to the error of mismeasurement of the screw, as well as to that of its uncertain action.

It is evident that the backward process in making the first impression, was to prevent accumulated error, which must have taken place, had the screw been turned forwards through successive intervals; but as the impressions already made are sufficiently deep for the screw in its future action to follow them, and by its own equalizing action to produce agreement, if necessary, between the beginning of one interval and the end of another, it would be useless to pursue that process any farther.

A continued forwards motion of the screw with the winch was therefore kept up, until the plate had made two more complete revolutions, when an examination at several places was made as to the agreement between the original dots and the impressions of the screw, which was highly satisfactory.

Hitherto the threads of the screw had not been made to cut; they indented the edge merely by their sharpness and pressure; and, without making either dust or chips, ploughed a furrow, on each side of which the metal rose in *bur;* and it was easy to see, that already four or five of the middle threads had been worn into action.

But to prosecute the operation of racking from these slight indentations to the full tooth, required that the screw should cut like a saw; and for that purpose, the spiral notches, which in opposite directions are represented in the Figures as crossing the threads of the screw, were made with a sharp-edged file; and, in order to preserve sharpness through long-continued action, those notches were from time to time filed deeper and broader.

In the account which Mr Ramsden gives of racking his engine, it is stated, that, after following step by step the retrograde process described above, through three or four revolutions of the wheel, without regarding any more the original divisions, he turned round by continued motion, until he had produced the full tooth.

I have, however, to give a very different description of a method of doing the same thing; an operation which occupied me nearly a month, and turned out one of the most troublesome I was ever engaged in: it was a continued process of *coaxing* from beginning to end. My brother, who had performed a similar task before, had, from his own experience, warned me of what I might expect; but, without that caution, I should not, any more than he had done, have trusted, without examination, to the blind operation of the screw. The chief cause of the embarrassment was, that the threads of the notched screw cut sharper with one edge than with the other, and consequently the indentations gained or lost upon the original divisions. By frequently sharpening the screw opposite various parts of the limb, the error arising from this source was sometimes + and sometimes —, and that to the amount of 7″ or 8″ in some parts of the circle. These errors were corrected from time to time, as they were found to exist, by pressing the wheel forwards or backwards, so as to force the screw, in its revolution, to remove more metal on one side of the indentation than on the other.

Those who dream of a self-correcting method of racking an engine, will do well to open their eyes to the above circumstance; and for their use it may be remarked, that, in mechanical matters at least, faith is but a poor substitute for good works, and ought never to supersede the use of the senses.

My brother had told me that he had experienced considerable inconvenience from having made the notches in the screw parallel to the axis, as Ramsden had done before; for the whole length of each cut, coming into action at once, and going out at once, caused an irregular jerking motion; this inconvenience I avoided by making the notches in spirals, which crossing each other at equal angles, gave in one set the preceding edge, and in the other the following edge the most advantageous cutting angle: this expedient was not only productive of dispatch, but also afforded an important advantage altogether unforeseen. In all the engines hitherto made, the racking screw, by frequent sharpening, had been completely cut up, and in every case a second had been provided for working with. I also had provided a duplicate; but the spiral cuts, by coming into and going out of action continually and imperceptibly, rendered its application quite unnecessary. The notched screw to be worked with, requires a much less pressure than that which would make it cut, but the working pressure is quite sufficient to cause the notches to rake off every impurity from the teeth of the wheel, and keep them perfectly clean: this last, together with the economy of using but one screw, constitutes the advantage above alluded to.

Fig. 3. is designed to shew in perspective the apparatus for carrying the wheel forwards by the screw, the manner how the latter is connected with the foot, Plate CCLXXIX. Fig. 3.

Engine Graduation.

Method of graduating the limb in Mr Edward Troughton's circular dividing engine.

Plate CCLXXIX.

and how it is stopped at every division. The chief parts of which this apparatus consists, are more or less seen in all the Figs.; but the manner of its being supported upon the platform of the stand by the intervening block I, is seen only in Fig. 2. The principal piece is a cock J, the horizontal part of which has two branches, (one shewn in the Figure,) between which the strings pass. The vertical part supports a cylinder of steel, which, when the screw is in action, forms a right line with its arbor; but there is left between their ends a space of about half an inch: this affords easy means of changing the ratchet-wheels, which are placed upon the screw-arbor, and move round or stop with it. A barrel about 2 inches long, and $1\frac{1}{4}$ diameter, is fitted upon the cylinder, but so as to admit of its being turned round and moved upon it with perfect freedom from end to end. The middle part of the barrel is formed into a spiral worm or screw, the groove of which receives a cord or cat-gut of one-tenth of an inch in diameter. There is a slight frame dove-tailed upon the horizontal branches of the cock, as shewn in front of Fig. 3. which has steady and free motion in the direction of the cylinder; to each side of this frame is attached a pallet, one of which enters in front, and the other behind into the spiral worm of the barrel, by which means, when the latter is turned round, rectilinear motion is given to the frame. The barrel to the right is large, and excavated, so as to admit the ratchet-wheel, which latter is driven by a catch and spring, planted in the edge of the cavity in the former. The end of the barrel to the left is embraced by a ring, which is capable of being turned round or set fast at pleasure. A stopping piece is fastened to the frame by a finger-screw, and by means of a slit, through which the screw passes from the ring of the barrel, varied through a considerable extent. The elevated part of the stopping-piece resembles an anvil, and the hither side of the ring of the barrel, a hammer: the contact of these determines the point from which divisions begin: each division is terminated by similar means; an anvil is found in the elevated part of the frame behind, and a hammer in a screw-head, projecting from the enlarged end of the barrel: a string occupying four or five turns of the groove of the barrel, at one end is attached to a treadle near the floor, and at the other, after passing over two pullies, to a weight behind. When the treadle is pressed down with the foot, the hammer in front leaves its anvil; and as the barrel is carried round, the frame is moved forwards by the pallets; so that in the second turn they pass clear of each other, and the motion is continued until the anvil behind is struck by the other hammer: during this time the catch, by the pressure of its spring, has hold of the perpendicular side of a tooth of the ratchet-wheel, carries the screw round along with it, and moves also the engine plate through the proper angle. On the pressure of the foot being gradually withdrawn from the treadle, so as to let the weight prevail, the barrel will be brought round in a contrary direction; the hammer and anvil on the farther side leave and pass each other, and then those on this side pass and meet as at first, ready for a second tread. During the time that the barrel runs backwards, the screw and engine-plate stand still; for the sloping sides of the ratchet-wheel allow the catch to escape freely over them. As things stand in Fig. 3. a tread gives only two revolutions of the screw, but the number may be varied at pleasure as far as six; for let the anvil in front be placed by its finger-screw so much to the right as will allow the hammer to escape it, the weight will then draw the barrel back through another revolution, and the parts will meet again. Parts of a revolution are obtained with equal ease. It was said before, that the ring of the barrel, to which is attached the hammer in front, might be turned round and fixed at pleasure; now it is evident, that if the hammer were brought down so as to meet the anvil sooner, the tread would be shortened; and, if shifted the contrary way, it would be lengthened. Thus, by changing the position of the anvil, we can vary the number of complete revolutions; and as parts of a revolution are obtained by shifting the hammer, we have the power of varying the angular value of a tread from six revolutions of the screw, down to a single tooth of the ratchet-wheel. The most useful number for the teeth in this wheel is 120, for it answers to the division of the vernier that gives 5″ of the usual degree, or 10″ in instruments of reflexion, as well as to many others. To divide the vernier of a reflecting one that shews 15″, requires a ratchet-wheel of 80 teeth; and this number, were it of any use, which it is not, would give the usual subdivision of the 96° arc. To divide the centesimal degree of the French, and its first decimal subdivision, requires a wheel of 100 teeth. To the division of odd and prime numbers, a near approximation may be made by an artifice contrived by myself, and I believe unknown to any except those who have been my assistants: an example will be the best way of teaching it to those to whom it may be useful. Let the number to be divided be 331, and let the ratchet-wheel with 80 teeth be chosen; if we divide 2160, the whole number of turns the screw makes in one revolution of the plate, by 331, we shall have a quotient of 6, with a remainder of 174, which latter being multiplied by 80, to reduce revolutions of the screw into teeth of the ratchet-wheel, gives 13920, and this also being divided by 331, quotes 42 with a remainder of 18; that is, a division will be equal to 6 revolutions of the screw, and 42 teeth of the ratchet-wheel nearly. But as we cannot at one tread exceed 6 revolutions, we must be content with half of it = 3.21, and tread twice for one division; but as in our arithmetical operation we had a remainder of 18 teeth, in order to *make ends meet*, these must, as we proceed, be disposed of in their proper places: now, as 18 is the 20th part of 360, if at every 20° of the circle we set the screw one tooth forward by hand, the thing will be accomplished, and no greater error than 1 tooth = 7″.5 will enter the work; a precision fully sufficient for any purpose that such numbers can require, and in my opinion greater than can be come at by any other means.

Fig. 5.

On the end of the screw arbor to the right, as exhibited in Fig. 5. is attached a milled-head and divided micrometer; the latter, like the rachet-wheel, is changeable at pleasure, and carrying the same number of divisions that the wheel does teeth; the micrometer turns round with the screw, and a cock, fixed to the frame, bearing a fiducial line, serves as an index for counting the divisions. By the help of this we are enabled at once to set the stopping apparatus to any part of a revolution of the screw, without the trouble of a second trial; and by it, in case of a false tread or other accident, we can adjust the parts again to due position.

Apparatus for cutting the divisions.

The frame and apparatus for cutting the divisions, and their connection with the engine, remain to be described. Upon the two remote branches of the tripod, and beyond the border of the wheel, are erected two pillars, the upper parts of which are formed into screws. Four screw nuts work, two and two, upon the screw part of these pillars, and embracing the ends of a strong bar of brass KK which they support, enable us to ad-

Engine Graduation.

just its height, to suit the thickness of the work to be divided.

Apparatus for cutting the divisions.

To the near branch of the tripod, a cross piece L, Fig. 2, nearly the length of the screw arbor, and parallel to it, is firmly fastened. This carries upon its extremities two pillars similar to, but smaller than, the others. Upon the strong bar KK, at equal distances from the middle, are two other bars fixed by finger screws. They extend from the strong bar to the pillars in front, to which they are secured by double nuts like the former. These two bars, marked M, M in the plan, are bound together by a cross brace at the remote end, and by another a little way beyond the centre. But in no other part can crossing pieces be admitted; for as they form the support for the apparatus that cuts the divisions, uninterrupted motion along the whole line of the radius is required.

The cutting apparatus consists of three principal pieces, marked in the plan *a*, *e*, *o*. The first is a bridge, which crosses the space between the bars M, M, and to which it is attached at either end by sliding sockets. The latter run along the bars, to any part of which the apparatus may be clamped, according to the length of the radius of the instrument to be graduated. Two steel screws having conical points, are tapped through the perpendicular ends of the bridge above the sockets, and by working in holes of the second piece, form an axis or joint, round which the latter has a free and steady motion. The third piece, the form of which, as well as that of the second, is seen in the plan, has, like the first, steel screws with conical points tapped through its ends, and these like the others act in the middle piece, forming another horizontal axis parallel to the former, and in every respect like it. In Fig. 1, the parts are extended, for the purpose of being more distinctly represented, into a position in which they cannot work. The best effect is produced, when the middle piece is vertical, and the third horizontal. Sufficient freedom of action, however, is found in this contrivance of Hindley's, to produce a rectilinear motion of the pointril of at least one-third of an inch, a quantity fully adequate to the purposes required. The part of the third piece next the centre, is that in which the pointril is placed. It is so contrived, that its length below the piece may be varied at pleasure, that it may be turned round upon a horizontal axis, so as to make any angle with the plane to be divided upon, and that its action may be viewed by a properly attached magnifying-glass.

There is one part, which might either have been mentioned sooner, or, as the performance of the engine in point of accuracy is not at all promoted by its introduction, might have been altogether omitted; but as it bears rather a conspicuous appearance in Fig. 2, it may as well be noticed. A bar attached to the same pieces that support the screw arbor, to which it is parallel, and placed below it, together with a cock behind, bear the axis of a vertical friction wheel N. This wheel is placed so, as to roll in contact with the under side of the limb of the engine immediately below the dividing screw. Without this, the action of the screw in the teeth of the wheel would occasionally produce a very harsh jarring sound, but which is rendered mute by this contrivance.

Fig. 2.

A hardened and tempered steel arbor rises full two inches above the surface of the plate, in the axis of which it is immoveably fixed. In other engines the axis is hollow, into which may be dropped differently sized arbors, suitable to the centre holes of the instruments to be graduated; but as I never intended with this engine to divide any other instruments than those of my own construction, and as it was easy to make them, whether great or small, to suit my arbor, by fixing it, I avoided one source of uncertainty and error. This arbor is the principal connection between the engine and work to be graduated, and requires the most exact fitting; and tapped holes, arranged variously through the length of the 12 radii, furnish the means of applying holdfasts, to prevent accidental circular derangement.

I will now conclude this long description with observing, that with this engine, and indeed the observation applies equally well to those of Ramsden's construction, the operator can cut about 24 strokes in a minute of time; for one single minute indeed, he will be able to make 30; but including short and frequent intervals of rest, the former rate may be kept up for hours together. The vast importance of this expedition, needs no comment with those who know the value of accurately graduated nautical instruments, and the great demand for them. Yours, &c. EDWARD TROUGHTON."

We are well aware, that engines for dividing straight lines, are of much less importance than those for graduating circles and arcs; yet we should not think that justice was done to our article, were we to omit an account of one for the former purpose.

Account of Ramsden's straight line engine.

Encouraged by his former success, and having in prospect farther rewards, of which he was not disappointed, Mr Ramsden constructed the first right-line engine, an account of which was published in 1779, by order of the Board of Longitude. Of this, the following is a copy, accompanied by reduced drawings of the original figures.

"Experience having evinced the great utility of the engine for graduating circles, it encouraged me to attempt a similar method, whereby lines of equal parts, sines, tangents, secants, &c. might be divided with equal ease and correctness.

By the engine hereafter described, any line of equal parts, &c. may be divided without an error of the $\frac{1}{4000}$th part of an inch; and, as this can be done by any indifferent person, and so very expeditiously, its uses for dividing all sorts of navigation scales, sectors, &c. must be obvious; especially when it is considered, that from the incorrectness of the present method of dividing, these valuable instruments are of less use than they might be.

This engine consists of a strong plate of brass, moveable on two edges of an iron frame. To facilitate its motion, the friction is considerably diminished by the application of three rollers to the under-side of the plate: the iron frame is supported on a strong mahogany stand.

One edge of the brass plate is ratched or cut into teeth, of which there are exactly twenty in an inch, and it is moved along the iron frame by an endless screw, having exactly the same number of threads in an inch; these threads fit into the teeth on the brass plate. Each revolution of the endless screw round its axis will move the plate $\frac{1}{20}$th of an inch along the iron frame.

A small wheel is fixed on one end of the screw, having its circumference divided into 50 parts, which are again subdivided into five parts by a vernier; therefore, when the screw is turned on its axis, one of the primary divisions, the plate will be moved $\frac{1}{1000}$th of an inch along the iron frame; if the screw be turned to the coincidence of one division on the vernier, the plate will be moved $\frac{2}{10000}$th of an inch, and so of the rest; and the line on the plate to be divided, which terminates the spaces moved by the brass plate, may be

Engine Graduation.

Account of Ramsden's straight line engine.

drawn on it, or on any instrument fastened on the plate, with the greatest accuracy, by a point or tracer fixed in a proper frame, whereby it has a rectilinear motion, without any lateral shake.

Sometimes it may be necessary to lay down lines on instruments which are not commensurable with English inches; such as are the feet, inches, &c. of most other countries: this is done by inclining the line to be divided to make an angle with the direction of motion of the plate, by an apparatus to be described hereafter; if the tracer be set to draw lines at right angles to the direction of motion, or to the side of the plate, then the line to be divided will be as much longer than the space the plate has moved, as the secant of the angle of inclination is longer than the radius; but if the tracer be set to draw lines at right angles to the line to be divided, then divisions on that line will be shorter than the space the plate has moved along the iron frame, as much as the cosine of the angle of inclination is shorter than the radius.

Plate CCLXXX. Figs. 1—5.

Fig. 1. Represents a plan of the dividing engine.

Fig. 2. An elevation.

Fig. 3. A section on the line AB.

Fig. 4. A section on the line DE.

Fig. 5. The underside of the plate A, represented in Fig. 1.

Note. Like parts are marked with the same letter in each of the Figures.

Fig. 1. A represents a strong brass plate, 27 inches long, four inches broad, and $\frac{7}{10}$ths of an inch thick; worked exceeding flat, and of the same thickness throughout, with its two edges exactly parallel.

B is a strong iron frame, 48 inches long, having two edges *a*, *b* rising half an inch above its surface; these two edges are made very straight, and in the same plane; the inside of the edge *a* is also made as straight as possible.

Fig. 5. The plate A slides on the two edges of the iron frame; beneath it are two springs *c*, *c*, each fastened at the extreme ends to the plate A by the screws *s*; at the other end of each spring is a roller *c* of tempered steel, turning on an axis in these springs; there is also a third roller *d* of tempered steel, let into the iron frame near where the threads of the endless screw act; this roller hath a long axis, one end turning in the iron frame at *g*, and the other in the lever *h*; this lever turns on a centre at *i*, and with it the roller *d* may be raised or depressed, by turning the capstan-head screw *o*, which presses on a strong spring.

Fig. 3. Figs. 2, 3.

The use of the rollers is to diminish the friction of the plate A, when moving on the iron frame B: for this purpose, the strength of the springs is regulated by turning the two screws *n*, *n*, and of the roller *d* by the capstan-head screw *o*, till the weight of the plate A be very nearly carried on these rollers.

Fig. 2. C is the endless screw, which is of tempered steel, and has its pivots formed in the shape of two frustums of cones joining each other at their smaller end by a cylinder, as shewn in the description of the circular engine, p. 5, Plate III. of that work. These pivots turn in half holes of the same form in the pieces of brass DD, which are firmly screwed to the iron frame; the half holes are kept together by the screws *m*, *m*, which may be tightened at any time to prevent the endless screw from shaking.

Fig. 1. On one end of the screw arbour is a wheel *h*, having its circumference divided into 50 parts, and numbered at every tenth division with 1, 2, to 5; and these divisions are again subdivided into five parts by the vernier *t*.

G, G represent two frames of steel; each of these frames turn on centres K, fastened to the under-side of the plate A, and equi-distant from the edge of it. In each frame is a roller *y* of tempered steel, turned very concentric to their pivots, and exactly of the same diameter.

Plate CCLXXX. Fig. 5.

The frames G, G are connected together by the brass plate E, which turns on a stud in each frame; the studs must be at equal distances from the centres K on which the frames turn, and the distance between the holes in the plate E in which the studs act, must be the same with the distance between the centres *k*, so that the plate E may always move parallel to itself, and that the circumference of the rollers may be always equidistant from that edge of the plate A, which is intended to be ratched. This apparatus serves to press the edge of the plate A, with a motion parallel to itself, against the threads of the endless screw.

Figs. 1. On the end of the plate A is a spring of tempered steel, which acts as a bent lever. The spring end of this lever has a ketch, which passes under the head of the stud I, that is on the end of the connecting piece E. While the other end of the lever is pressed gradually down towards the plate A, by turning the finger screw F, the connecting piece E is drawn forward, so that the steel rollers pressing against the edge *a* of the iron frame, may force the side of the plate against the endless screw.

Then having two screws of tempered steel exactly of the same diameter and number of threads, viz. 20 in an inch, one of these screws was notched across the threads, so as to cut in the manner of a saw; this screw was put in the half holes in the pieces D, D; on the opposite end of the screw arbor to that whereon the wheel is, there is attached a long rod, of such length, that the winch on the end of it, by which the rod and endless screw are turned round, may be clear of the iron frame. Fig. 2

Fig. 1. Z is a narrow slip of brass, having its edges exactly parallel, which is screwed on the plate A, and steady pinned.

The edge of this slip is parallel to the edge of the plate A; a distance of 25.6 inches was set off on a line on the slip parallel to its edge; this distance was bisected continually, till the distance between each bisection was $\frac{8}{10}$ths of an inch.

A brass cock was fastened to the iron frame, which passing over the endless screw, applied itself to the slip on the brass plate A, a small silver wire was stretched across a hole of half an inch diameter in the end of the cock. The coincidence of the bisections with this wire was examined by a small magnifier in a brass tube fixed exactly over it.

The plate A being on the iron frame, the bisection marked I, towards the right hand, was set to coincide with the wire, and the division numbered 50 on the wheel, was set to the first division on the nonius.

The plate A was then pressed against the endless screw, by turning the finger screw F; then, by means of the winch, the endless screw was turned towards the left sixteen revolutions, till the bisection marked *o*, was brought to the wire; this done, the plate was detached from the endless screw, by unturning the finger screw F, and the division numbered 2 was set to coincide with the wire, the division 50 on the wheel being previously set to its index, and the edge of the plate was pressed against the screw by turning the finger screw F; then, by means of the winch, the endless screw was again turned round its axis 16 revolutions

4

Engine Graduation.

Account of Ramsden's straight line engine.

Plate CCLXXX.

towards the left hand, till the bisection I was brought to coincide with the wire. The plate was again detached as before, and the bisection marked 3 was set to coincide with the wire, and in this manner the edge of the plate was ratched from end to end three or four times, till the threads had made a good impression, which afterwards was ratched from end to end, without ever disengaging the plate from the screw, till the teeth were entirely finished.

The notched endless screw, with the rod and winch, were then removed, and the plain screw was put in its place; having the divided wheel on one end of the screw arbor, and two sets of ratchet wheels on the other end. These sets are each composed of three wheels, having teeth round their circumference; one in each set hath 32 teeth, another 48, and the third 50. These two sets being one for turning the screw, and the other for stopping it, they have, for this purpose, their ratchet teeth cut in opposite directions.

Figs. 1, 2.

I, represents a cylinder of brass, having on one end two steel rings *a* and *b*, with their edges that are towards each other cut into ratchet teeth; these teeth are cut in contrary directions, so as to fit into each other; on one of these rings is an index, and the other hath its teeth numbered with 10, 20, up to 50. The other end of the cylinder is made hollow, and contains one of the sets of ratchet wheels. There are two slits opposite each other, pierced through the hollowed part of the cylinder W. In each of these slits is a click turning on an axis, and is pressed into the teeth of the ratchet wheel by a small spring. The clicks may be moved along their axis, so as to catch in any one of the three ratchet wheels, and may be fastened at that place, by tightening the small screw S.

Figs. 1, 2. 4.

The cylinder I, with the clicks, &c. turns on a steel axis X, firmly attached to the piece K, and in a line with the axis of the endless screw. Motion is given to this cylinder round its axis by a piece of cat-gut, which hath one end fastened to the ratchet ring *b*; and the other end, after passing four or five times round the cylinder, is fastened to a treadle; and on pressing the treadle downwards, the clicks S catch in the teeth of one of the ratchet wheels, by which means the cylinder I, together with the endless screw, are turned round their axis, which moves the plate along the iron frame, and at the same time winds up the spiral spring *u*. On releasing the treadle, the spring *u* unbends itself, the clicks quit the ratchet wheel, and leave the endless screw at rest, while the cylinder I turns in an opposite direction, and raises the treadle to where it was before.

Figs. 2, 4.

V is a small square bar of steel, having both its extremities cylindric. These cylinders move in holes lined with hardened steel, one in the piece D, and the other in the piece K. This bar carries three different pieces, which are of tempered steel; the middle one *t*, is made to lie in the interval between the threads of the screw cut on the cylinder, and passes nearly half round its circumference; it is kept in the threads by a spring *e*, which presses on a piece *q*, screwed to the iron frame. This piece being attached to the bar V, by the screw *p*, turning the cylinder I on its axis, will give a longitudinal motion to the bar V.

Fig. 2.

The upper end of the piece *f* is formed into a hook, and may be set to catch in the teeth of any of the ratchet wheels, and then fastened to the bar *v* by the screw *i*. Towards the other end of the bar is a piece *j*, which serves to stop the cylinder in turning back, so as to limit the number of revolutions or parts. It is fastened to any required place on the bar *v*, by the finger screw *f*.

When the engine is used, the treadle is pressed downwards, which, by means of the cat-gut string, turns the cylinder I round its axis; and the piece *t* moves along the thread, till a stud *r* on the cylinder, striking on the top of the curved piece *t* bends the spring *e*, till that piece rests on the piece *q*. By bending this spring, the square bar is turned a little on its axis, and pulls the hook *f* into the teeth on the ratchet wheel R. Then releasing the treadle, the spiral spring turns back the cylinder, till the piece *j* is brought under the stop on the ratchet ring *b*.

Engine Graduation.

Account of Ramsden's straight line engine.

Plate CCLXXX. Figs. 2, 4.

The parts of a revolution are regulated, by setting the number required on the ratchet ring *b*, to the index on the fixed ring *a*. Each of the teeth answers to a motion of $\frac{1}{1000}$ of an inch of the plate A; and the number of revolutions, each of which moves the plate A $\frac{1}{20}$ inch, is regulated by setting the piece *j* on the bar. Figs. 1, 2.

L represents the steel frame, in which the tracer is fixed. This frame turns between the conical points of two screws *n*, *n* of tempered steel, which are screwed in the frame Q. There are also two similar screws in the same frame at *m*, *m*. The points of these screws, which are also of tempered steel, turn in conical holes in the piece P. By means of this parallel motion, the tracing point, by which the divisions are cut, will always describe the same line without any lateral bending. The tracer is put in the hole in the axis *b*, and is fixed there by tightening the four screws *f*, which presses the piece *c* against the flat part of the axis. Figs. 1, 2, 3.

This axis, which hath its pivots formed in double cones, turns between the half holes at *d*, and may be fixed when the tracer is set to any required inclination, by tightening the screw S.

S is a brass ruler, having its edges very straight and parallel. It hath two thin pieces of steel *g* attached to it, which turn on joints at *h*, exactly equi-distant from the edges of the ruler. The interval between the pieces *g*, *g*, is exactly the same with the width of the steel frame L. There are angular notches on the lower edge of the pieces *g*, similar and equi-distant from their centres; so that when any two corresponding notches are put on the screws *n*, *n*, between the frames Q and L, the screws being on that part made cylindric, and both of the same diameter, then the edge of the ruler will always be at right angles to a line drawn by the tracer. The ruler S, in this manner attached to the cutting frame, may be set parallel, or to any required inclination with the edge of the plate A, by turning the handle T, which moves the piece P with the cutting frame and ruler on the centre *x*, and may be fixed there by tightening the nut P. Fig. 6.

From a centre J, on the plate A, are drawn two circular arcs. The outer one is divided into degrees, and numbered from 1 to 9. Each degree is again subdivided into six parts, or every ten minutes. The inner circle is divided in the proportion, that the cosines of the angles of inclination with the edge of the plate A bears to the radius, supposing the radius 10,000, and the divisions are numbered every 10th with 10, 20, to 140. But the use of this apparatus may be perhaps better understood by an example.

Let it be required to divide a line of the length of 9 $\frac{900}{1000}$, into the same number of divisions, and in the same manner as if it were 10 inches long. Put the ruler S to the cutting frame L, and turn the handle T till the same edge of the ruler cuts the centre J, and the first division from the O of the inner arc. Then screw the instrument to be divided firmly on the plate A, so that the line to be divided may be parallel to the edge of the ruler, which may be now removed. When the plate has moved 10 inches in its own direction, the

Engine Graduation.

whole length of the divisions on the line divided will only be $9\frac{999}{1000}$ inches."

On the formation of the screw of dividing engines.

The screw of a dividing engine, whether for right lines or circles, must be considered as a most essential part, and should be of the most perfect workmanship. Probably from knowing, that there are several good methods of producing a screw now well known to artists, Troughton omitted to send an account of that by which his was made, at the time he transmitted to us the description of his engine. We will, however, annex the method of making one; and as that employed by Ramsden for his straight line engine, may, for aught we know, be as good as any, it has been selected. The following is Mr Ramsden's own directions for making the screw, and the Plate is a copy from his original.

Ramsden's method of making a screw.

"The exactness of the above described engine, depends very much on the correctness of the endless screw, which here is required to have some properties, that were not absolutely necessary in the endless screw for the circular engine. In that, as there were but a few threads of the endless screw engaged in the teeth of the wheel, it only required that those threads should have an equal inclination to the axis of the screw; but in this engine, where the whole length of the screw is engaged in the teeth of the moveable plate, it is necessary also that the distance between the threads should be the same throughout the whole length of the screw. This is effected by the screw engine hereafter described.

Plate CCLXXXI.

Fig. 7. Represents the plan;

Fig. 8. The elevation; and

Fig. 9. A section on the line BO. The same letter refers to the same part in each of the figures. A represents a strong circular plate of brass, having its edge ratched by the method given in the description of the circular engine. On its centre is firmly fixed the pulley B by four screws; a groove is turned on the cylindric part of the pulley, perfectly concentric to the plate A.

Figs. 8, 9. C is a steel axis two feet long, terminating in a point whereon it rests. The upper part of the axis is firmly screwed to the plate A, and turns in the collar D.

Fig. 7. E represents an endless screw, which, being turned on its axis, moves the plate A round its centre. F, a divided circular plate, which may be turned with or without turning the endless screw. On the other end of the screw arbor is a wheel *a*, having its outer edge cut into teeth. X is a winch whereby the endless screw is turned round.

Figs. 7, 8, 9. G represents a triangular bar of steel, which passes over the circular plate A, and is firmly screwed to the frame at H and I.

K, a piece of steel whereon the screw is intended to be cut, having its pivots formed in the manner before described. On one end of this steel is a wheel L, having teeth round its circumference, which take into those on the wheel *a*, on the arbor of the endless screw.

Figs. 7, 8. M and N represent two strong pieces of brass, in which the steel whereon the screw is to be cut turns. They are firmly fixed to the triangular bar G, by tightening the piece I by the screw *n*.

Figs. 7, 8, 9. O is a piece of brass, which slides on the triangular bar G. Its two extremities are made to fit the bar, it slides regularly thereon, and is prevented from rising by the two springing pieces *c*, *c*. (Fig. 8.) Near one end of the piece O, is an angular groove *q*, (Fig. 7.) that holds the tool by which the threads are cut. As it was necessary to cut the screw after the steel was hardened and tempered, therefore the tool was pointed with a diamond. The cock W serves to fasten the tool, which may be set to take proper hold on the steel, by turning the finger screw S, and is fixed there by the screw V.

Ramsden's method of making screw. Plate CCLXXXI. Figs. 7, 8.

To make a screw perfect, it is only required to give the point which cuts the threads an uniform motion parallel to itself, and to the axis of the intended screw, and that this motion be proportioned to the revolution of the intended screw, as the number of threads may require.

To effect this, a piece of thin tempered steel, exactly of the same thickness throughout, is fastened to the slide O at *r*; the other end of the spring is fastened to the pulley B, in the groove. Now, while the circle A, (Fig. 7.) with the pulley, is turning round its centre, by turning the endless screw towards the right hand, the spring *t* draws the slide O with the cutter *q*, along the triangular bar; at the same time the steel K, whereon the screw is to be cut, is turned round its axis by the communication of the wheel *a*, on the endless screw with the wheel L.

It hath already been mentioned, that the screw of the engine before described hath 20 threads in an inch; therefore, if the number of teeth on the wheel *a* be to the number on the wheel L, as the number of teeth on the wheel A, is to the number of twentieths of an inch round the circumference of the pulley B, allowing for part of the thickness the spring *t*, the spaces between each of the threads of the screw to be cut will be twentieths of an inch.

The size of the pulley was determined in this manner: the endless screw being disengaged from the wheel A, the slide O was drawn back till the end of it came nearly to the piece M; the endless screw was again engaged in the wheel A; then having two very small dots on the slide O set off parallel to one side, and exactly five inches distant from each other; the slide was moved by turning the endless screw, till one of the dots was bisected by a small silver wire fixed across a hole in a thin piece of brass attached to the piece N; then the O on the divided wheel F was set to its index, without moving the endless screw, and the pulley was reduced, till 600 revolutions of the endless screw brought the other dot to be exactly bisected by the fixed wire. These bisections were examined by a lens of half an inch focus, set in a small brass tube, which was fixed perpendicularly over the wire."

Remarks on Ramsden's straight line engine.

We believe that the above described right-line engine, has been chiefly employed in dividing such scales as surveyors use for mapping their work, barometer plates, &c. But contrary to what Mr Ramsden has stated, it should be remarked, that, for unequal parts, (sines, tangents, &c.) its performance must be tedious, and of course expensive; for after every tread, the screw would require to be put forward by hand, to the amount of at least one significant figure of the Tables for every division from which they are gathered.

Mr Ramsden states the accuracy of this engine to be equal to the 4000th part of an inch, which it certainly ought to be; this exceeds in precision, by a small degree, what may generally be expected from Bird's standard measures; yet, as we know that Sir George Shuckburgh Evelyn sought in vain when he examined our national standards, for some work of Ramsden's to place in his list; and as in the apparatus for our great trigonometrical survey, otherwise made entirely by himself, a 42 inch scale of Bird's was used, it may be presumed he never executed any thing of the kind.

Soon after the above described engine was finished, and before the description was published, another right-line engine appeared. This, with the assistance of an

Engine Graduation.

Harrison's dividing engine.

ingenious workman, was made by the late Mr Harrison, a son of the celebrated artist, who gained the great reward for finding the longitude at sea by means of time-keepers. There is reason to believe, that this engine possesses great merit, and that, in its construction, it is materially different from Ramsden's; but we are not sufficiently acquainted with it to point out those differences, or to offer any description of it. We know, however, that this engine is not idle; it is in the possession of John Barton, Esq. a relation of Harrison, who, we think, is now deputy comptroller of his Majesty's mint. But the avocations of office cannot suppress his natural inclination to mechanical exercises, for which his ingenuity, as well as his nice hand and eye, so eminently qualify him.

Coventry's micrometers.

There was a man of the name of Coventry, a glazier, who for many years rendered himself useful by dividing with wonderful minuteness and accuracy upon glass and other substances, the micrometer scales for microscopes and other purposes. His engine consisted of a very long beam compass, nicely balanced, having at one end a socket moveable by a micrometer screw, and furnished with a fine diamond point. The death of this man, which only happened a few years ago, would have been more regretted, had not Mr Barton, with the engine of Harrison, produced in similar works, still more exquisite specimens of art. The mother-of-pearl scales (Cavallo's micrometer) come from his hand almost miracles of neatness and accuracy.

Barton's micrometers.

It is, however, comparatively easy, to produce equality among neighbouring divisions in short measures, to what is required in larger works, where the most distant parts would occupy their relative places as correctly as adjacent ones. The latter, indeed, is the great difficulty of the art in all its branches, but more particularly so, in that which is the subject of the next Section.

SECT. III. *Original Graduation.*

Original graduation the most difficult of the mechanical arts.

WE now come to treat of the art in its highest order; the importance of which may be inferred from considering with what attention it has been cultivated, during a succession of ages, by men of science as well as artists. A modern journalist has designated it, "one of the nicest operations of manual labour;" the truth of which may be evinced from the very limited number of those who have performed it with success, and the high consideration in which they are held by all who are qualified to appreciate their labours. But the exactness required in the art may be drawn from still more certain sources. In a circle of three feet radius, which is that of the mural circle at Greenwich, a minute of a degree is little more than the 100th part of an inch, and this quantity, respecting latitude, is the measure of about a mile upon the surface of the earth; but if we speak of longitude, as derived from lunar and solar tables, the minute represents upon a mean no less than about 30 miles; while some of the elements of astronomy respecting their maxima, are by observation brought down from heaven to earth under an infinitely greater disparity.

Astronomers formerly divided their own instruments.

There was a time when astronomers graduated their own instruments. Tycho Brahe and Hevelius are said to have done so; but neither the methods used by them, nor by any of the more ancient astronomers, have come down to us; nor perhaps need this, excepting from mere curiosity, be regretted, if the statement of the errors of their instruments, given by Sir George Shuckburgh Evelyn (*Phil. Trans.* for 1793) be tolerably correct. Sir George says, "With respect to the precision of astronomical instruments in general, I may notice, by the way, that from the time of Hipparchus and Ptolemy, before and at the commencement of the Christian æra, to the age of Walther and Copernicus, in the beginning of the 16th century, few observations can be depended on to less than five, eight, or perhaps ten minutes; those of Tycho Brahe, indeed, that princely promoter of astronomy, to within one minute. The errors of Hevelius' large sextant of six feet radius, towards the middle of the 17th century, might amount to 15 or 20 seconds; Flamstead's sextant to 10 or 12 seconds; and lastly, those of Graham's quadrant, of eight feet radius, with which Dr Bradley made so many observations from 1742, might amount to seven or eight seconds." It should, however, be remarked, that the above statement, being derived from inspection of the observations made with the several instruments, exhibits errors not strictly imputable to graduation; a part may have been produced by other defects in the instruments, and also by imperfect observation.

Original Graduation. — Errors of the old astronomical instruments.

Sir George Shuckburgh's comparison of standard measures.

Sir George (*Phil. Trans.* for 1798) examined the errors of division in several of the old British standard measures, and compared their length with his own, made by Troughton in 1796. The first in his list is the standard yard of Henry VII. about the year 1490, which is said to have been taken from the length of the arm of that monarch; but as history is silent respecting this trait of his greatness, it may be presumed that the surveyors of his Majesty's person took for the purpose half the distance between the extreme finger ends of out-stretched hands and arms. Upon this standard the greatest measured interval exceeds the least, by no less a quantity than .132 of an inch; and the whole yard is .076 of an inch shorter than Sir George's. In the standard yard of Elizabeth, about 1588, the greatest interval exceeds the least by .185, and the entire yard is .015 longer. For the standard ell of Elizabeth, of the same date, the greatest difference of intervals is .072, and the whole length exceeds the modern standard by .016 of an inch.

Many of our standard measures bear no subdivisions, being simply finished to the length. Of these, nothing but their whole extent could be examined; and this was done by Graham in the four following instances. The yard-bed of Guildhall, about 1660, too long by .032. Ell-bed of Guildhall, same date, .018 too long. A standard belonging to the clock-makers' company, about 1671, too short by .028 on 36 inches. And the standard of the tower of London, about 1720, made by Rowley, was .004 too long.

Graham's own standard, made by Sisson, in 1742, with which it is supposed the above comparisons were made, was itself examined by Sir George, and found to be as follows: line E, .0013 longer, and line Exch. .0067 shorter, upon 36 inches than his own.

Many of the above measures exhibit miserable work; a neat hand by doubling, tripling, &c. a string, and making notches with a file, would subdivide better. But it is likely, and indeed the list indicates as much, that greater attention was paid to the whole length, than was done to the intermediate parts; yet are the yard-bed of Guildhall, and the standard of the clock-makers company, exceptions, and differ from each other by no less than .06 of an inch. Indeed, it seems difficult to suppose that the makers of those measures did their very best. It is more probable, that, according to their own judgment, or that of the times in which they lived, they

Original Graduation.

thought their works sufficiently correct for the purpose; or, as the ancient astronomers graduated their own instruments,—might not the magistrates of old make their own standard measures?

Hevelius, and the astronomers who preceded him, made their observations without the assistance of telescopes, and the result of the well-known controversy between Hevelius and Dr Hook speaks highly in favour of the division of his sector; for men of science decided the dispute in favour of the Dantzig astronomer, from the superior accuracy of his observations; whereas, had the instruments of Hook been equal in other respects, the telescopic sights, as is now well known, must have given him the advantage.

Hook's method of graduation.

Dr Hook, in his animadversions upon the *Machina Cœlestis* of Hevelius, published in 1674 the first method of graduation that has been described. It consisted of indenting the edge of an arc by the rotation of a screw about its axis, in the manner that has since been practised with success in the dividing engine; the indentations themselves stood for the divisions of the instrument, the angular value of which were to be found by other means. A screw similar to that which cut the teeth, was connected with the telescope; and the number of teeth, and parts of a tooth, as shewn upon the micrometer head of the screw, gave the observed angle.

As the inventor of this method describes no means for correcting distant divisions, it may fairly be concluded, that he did not foresee the necessity of any. And his own words bear out this supposition. Dr Hook entitles it, *An explication of the new way of dividing:* and says, that *the perfection of his instrument is in the way of making the division;* that *it excels all the common ways of division;* and that *it does not at all depend upon the care and diligence of the instrument-maker, in dividing, graving, or numbering the divisions, for the same screw makes it from end to end.*

With such screws as may be supposed to have been in use at that time, their want of truth could have had no good effect upon the run from end to end of the arc; yet as the same error would recur at every complete revolution, no material mischief might arise. But it is evident that the parts of a revolution would be affected by the whole amount of such error. The method was put in practice by Tompion, Sharp, Rowley, the Duc de Chaulnes, and perhaps many others; but in every recorded instance it completely failed; and such instruments as bore this graduation, before they could be depended on to any useful degree, were furnished with hand dividing.

Mr Smeaton seems to ascribe the failure of Hook's method to the different resistance which the different hardness in parts of the metal presented to the action of the screw; and undoubtedly this afforded one source of error. But we are of opinion, that much greater errors arose from the screw not being so sharp at the end of the arc, as it was at the beginning; and that notching the screw, in order to produce the full tooth, made it cut sharper with the preceding edge of the threads in some parts, and the following edge in others; a fact which is mentioned by Troughton as having embarrassed him in racking his engine.

Both Hook and Hevelius, in their controversy, pretended, in measuring an angle, to come at the exactness of a single second; but as they flourished upon the verge of an age when most things relative to science were taken upon credit, perhaps their works should not be too severely criticised by those who live at a time when every thing is tried by the test of experiment.

Flamstead's polar sector.

The polar sector of Flamstead, made by Tompion, with which he made so many observations from 1676 to 1689, bore the screw division; but its gross errors obliged Mr Flamstead himself to perform an original diagonal graduation upon its limb. It was about the latter date that a mural arc was completed for the royal observatory, which, under the direction of Flamstead, was altogether constructed by his assistant Mr Sharp. This also had the division of Hook, but it does not appear to have succeeded better than that executed by Tompion: however, Sharp's instrument was at first furnished with a diagonal graduation more accurate than any that had preceded it.

Roemer's mural arc.

The celebrated astronomer of Denmark, Olaus Roemer, about the year 1715, finished a mural arc. Probably knowing of the failure of the screw method in England, he performed his graduation in a very different way. Mr Smeaton, in the paper before alluded to, introduces his account of Roemer's method with the following remark: "Though it is a very simple problem by which geometricians teach how to divide a given right line into any number of parts required; yet it is still a much more simple thing to set off upon a given right line, from a point given, any number of equal parts required, where the total length is not exactly limited; for this amounts to nothing more than assuming a convenient opening of the compasses, and beginning at the given point, to set off the opening of the compasses as many times in succession, as there are equal parts required; which process is as applicable to the arch of a circle, as it is to a right line. Of this simple principle Roemer endeavoured to avail himself." To this end he took two finely pointed pieces of steel, and bound them firmly together at a distance which, as nearly as he could calculate, would give him divisions upon his arc of 10′ each. This contrivance was to avoid the spring of long-legged compasses, and was, for the purpose intended, much better than the best spring-dividers of the present day. With this distance between the points of the tool, set off in succession 450 times, Roemer divided his arc of 75°. This way of dividing has appropriately been denominated *stepping*, and Hook's can be considered in no other light. Neither of them could give exactness in the total arc, even within moderate limits; but this defect, great as it is, would have been amply compensated for, had they secured the grand desideratum of equal parts. Smeaton is of opinion, that of those two methods, Hook's is the best, because the screw, in making the teeth, has hold of several at a time; and, as far as neighbouring divisions are concerned, it certainly is so: but with respect to distant ones, as well as general accuracy, we feel inclined to give the preference to Roemer's. The astronomer of Uraniburg was the first who read off the angles observed with instruments, by means of a double microscope; not indeed by a wire put in motion by a micrometer screw, as is now done. Instead of this, 10 equidistant parallel lines of single silk were stretched across the field of view, and being adjusted so as to fill the space between two of his dots, gave him single minutes: the seconds were obtained only by estimation.

Tycho Brahe reads off his divisions by a double microscope.

Soon after the death of Flamstead, the royal observatory was unfurnished. It has been said, that his executors demanded a higher price for the instruments than government thought it right to pay. This was the more excusable in the latter, as it is probable that it was in contemplation to procure new ones, in which case the old ones were intrinsically of no more value than the materials of which they were composed; yet it

Original Graduation.

Graham constructs the eight feet mural quadrant.

is a pity that those venerable and solid records of art should have left the spot where they had been so useful in their day.

Graham undertook, about the year 1725, to construct for our national establishment an eight feet mural quadrant. This magnificent instrument still occupies its place; and though great part of a century has elapsed since its erection, it seems not to have suffered at all from either use or time. Its frame is made of iron: the arc which bears the graduation, as also the telescope and centre work, are of brass. The contrivance and execution of the whole are admirable; but it should be remembered, that its division alone is applicable to our present article.

To Graham, in the graduation of this quadrant, has been ascribed the rejection of the diagonal method; but certainly he was not the first; for Hook and Roemer did the same. He has also the credit of being the first who discontinued the practice of cutting the divisions by the edge of a ruler with the dividing-knife, instead of which he substituted the beam-compass. His strokes cut in this way, of course, were circular arcs; but as they were short in comparison with the length of the beam, the bend was scarcely perceptible; and as the resting point was set in a line that made a tangent to the arc where the strokes were cut, the latter would stand nearly in the direction of the radius. With respect to making divisions with the beam-compass, it may be doubted whether it was not a practice among instrument-makers, particularly upon chamfered edges, before the time that the Greenwich quadrant was finished; and we have seen old works that indicated it. But there was another improvement of much more importance than either of the above, which was indisputably the invention of Graham; that is, the division of the quadrant into 96, which precludes altogether the practice of stepping, and has rendered essential service to astronomy.

Graham's quadrant is described at length in Smith's *Optics*, and we have availed ourselves of the process pursued in its graduation, by copying the following account from that celebrated work.

Account of Graham's method of graduating this quadrant.

"There are 2 arches struck upon the brass limb; one with a radius of 8 feet, or more exactly of 96.85 inches; and the other with a radius of 95.8 inches. This inner arch is divided into degrees, and 12th parts of a degree; and the outward arch into 96 equal parts, which are severally subdivided into 16 equal parts. The beam of the compass which struck these arches, was secured from bending, by several braces fastened to it; and when an arch was struck, 60 degrees of it was determined, by placing one point of the compass at *a*, (Fig. 1. Plate CCLXXXII.) and by making a stroke with the other at *b*. This arch *a b*, was bisected in *c*, by drawing two small arches upon the centres *a* and *b*, with such a radius as to cross the arch *a c b*, in two points as near together as possible, without touching each other; then the small interval between them was bisected at *c*, by estimation of the eye, assisted by a magnifying glass. After this, the interval between the points *a* and *c*, or *c* and *b*, was taken with the beam compass, and was transferred from *b* to *d*, which determined the length of the quadrantal arch *a c b d*. Every one of the three arches being bisected in the same manner, the quadrant became divided into six equal parts, containing 15 degrees a piece; and every one of these was divided into three equal parts, as follows. To avoid making any false or superfluous points in the quadrantal arch, with its radius unaltered, but upon any other centre, there was struck another

Plate CCLXXXII. Fig. 1.

faint arch, upon which the chord of 15 degrees, already found, was transferred from the quadrantal arch; and the third part of 15 degrees, being determined by trials upon the faint arch, was transferred back again upon the quadrantal arch; which then was divided into 18 equal parts, containing 5 degrees a piece; and the 5th part of these was found by trials, as before, in dividing a separate arch, drawn upon a new centre for this purpose only. The subdivisions of the degrees into 12 equal parts, were made by bisections and trisections, as before. Thus was the whole quadrant divided without any false or superfluous points.

The outward quadrantal arch was divided into 96 equal parts, by no other method than that of bisection, till 60 degrees, or two thirds of the quadrant, became divided into 64, and the remaining third into 32 equal parts, which make 96 in the whole. And every one of these was also divided into 16 equal parts by continual bisections. These two sorts of divisions are a check upon each other, being in effect two different quadrants; and the divisions in one being reduced into the divisions of the other, by a table made for that purpose, they are never found to differ above five or six seconds in any place of the limb, and when they do, the preference ought to be given to the bisected divisions, as being determined by a simpler operation.

The divisions hitherto mentioned being only very fine points in a fine arch *a b d*, scarce discernible by the naked eye, it was necessary, as usual, to strike lines perpendicular to the arch, through every one of them. But since it is very difficult, and tedious too, to draw lines exactly through every point by the edge of a ruler, the following method was judged more accurate and expeditious. It was proposed then to divide any other concentric arch, *f h t*, by cross strokes, into similar parts to those in the given arch *a c g e b d*. Take a small beam compass, and having once fixed its points at any convenient interval; upon the centres *e*, *g*, &c. being the given points of the divided arch, strike the small arches *f i*, *h k*, &c. cutting the undivided arch in *f*, *h*, &c.; then will the intercepted arches, as *f*, *h*, &c. be similar to the arches *e*, *g*, &c. that is, they will subtend the same angles at their common centre *o*. For joining *e f*, *g h*, and also *o f*, *o h*, *o e*, *o g*, the triangles *e o f*, *g o h*, will be similar and equal to each other; every side in one being respectively equal to every side in the other. Therefore, by taking away the common angle *e o h*, from the equal angles, *e o f*, *g o h*, the angles *e o g*, *f o h*, that remain, will also be equal.

If the triangles *e f o*, *g h o*, &c. be right angled at *f* and *h*; the dividing strokes *f i*, *h k*, &c. will cut the quadrantal arch *f h t*, at right angles also, at *f* and *h*, &c."

Remarks on Graham's method.

Respecting the means employed by Graham in the division of the arc of 90°, there is nothing in them, except what has already been noticed, that evinces superior contrivance; it is to his accurate execution, and the invention of the continually bisectional arc, that he owes the well-deserved reputation which he holds among those who have distinguished themselves in the art of graduating astronomical instruments.

Before the time that Bird flourished, there is not a word to be found in the history of graduation about the dilatation and contraction of metals in different temperatures; and it may be supposed, that as Graham made his quadrant of iron, and the limb of brass, he was unacquainted with the different expansions of those metals. Our doubts, however, respecting the accuracy of that instrument, from this circumstance, have been partly removed by the writer of this part of our article

Original Graduation.

having heard Troughton say, that he had looked at it with an eye to this matter; that he is of opinion, from estimating the elasticity of those metals at 8 or 10 times their difference of expansion, in such temperatures as they are exposed to in the observatory, that the iron will command the brass, and little or no error will ensue. The same artist also observes, that as the iron quadrant has long borne an additional arc of 96°, divided by Bird, and as there is no proof of its having changed its figure, since that arc was put on, as the brass one has certainly done to the amount of 7 or 8 seconds, for aught that is known to the contrary, the iron one may be the better instrument; but as both of them are now superseded by the new mural circle, this question may, perhaps, remain for ever at issue, and its discussion is now rendered of far less interest than it would have been 30 years ago.

Graham laid it down as a principle or maxim, "that it is possible, practically, to bisect an arch or a right line, but not to trisect quinquisect, &c." Bird not only acted upon this maxim, to the full scope of what had been done by the artist who conceived it, but extended it even to the division of the arc of 90°. We will not, however, anticipate the method of Bird, which is in many respects original and ingenious; for every one who dips into these matters, will derive the most satisfactory information from perusing his own account of it, as published by order of the Board of Longitude in 1767, the whole of which is subjoined.

Bird's method of graduation.

"The following method of dividing astronomical instruments, &c. is collected principally from the experience which I have gained in the space of thirty-four years; and, in some parts, from the instructions which I received from the late Mr Jonathan Sisson.

What I call my own, I have distinguished by Italic characters. If any other instrument-makers have used the same method, it is unknown to me; and shall, therefore, pay no regard to any pretensions unsupported by evidence;—I mean, pretensions, without producing astronomical instruments superior, or, at least, equal to those which I have made.

How far the lunar theory hath been improved by the observations of the late Dr Bradley and Mr Mayer, I leave to the decision of those who have tried it by observations, in order to find the longitude at sea, &c. I cannot help, however, being fully of opinion, that a still more perfect knowledge of the motion of the heavenly bodies may be obtained by future observations, skilfully made, with accurate instruments.

I have been favoured with so distinguished a mark* of approbation from the Commissioners of Longitude, that nothing on my part shall be wanting, that may, in the least, contribute to so desirable an end:"—So far the preface.

"It will be sufficient, for my purpose, to make use of no more lines and arcs than are represented in Fig. 2. Plate CCLXXXII.

Plate CCLXXXII. Fig. 2.

The requisites for the performance of this work are as follow:—A scale of equal parts, by which the radius may be measured to 0.001 *of an inch, must be provided. My scale is* 90 *inches long, each inch divided into* 10, *contiguous to which are nonius divisions, viz.* 10.1 *inches divided into* 100 *equal parts, shewing* 0.001 *of an inch; and, by the assistance of a magnifying glass, of one inch focal length, a third of* 0.001 *may be taken off by estimation.*

Provide five beam compasses, to which magnifying glasses, of not more than one inch focal length, should be applied. Let the longest beam be sufficient to draw the arcs, and measure the radius; the 2d, to measure the chord of 42° 40′; *the 3d, to measure the chord of* 30°; *the 4th,* 10° 20′; *the 5th,* 4° 40′; *and if a 6th, to measure* 15°, *be made use of, so much the better.*

I have, for the sake of a round number, mentioned above, that the radius of the mural arc in the Royal Observatory at Greenwich is eight feet; but, as I shall here put down the lengths of the several chords made use of in the dividing, it will be necessary to note the exact radius in inches and decimal parts.

The radius of the arc of 90°, *at the points,* = 95.938 *inches, from which the following numbers were computed, viz.* 49.6615 *inches = chord of* 30°, — 25.0448 *inches = chord of* 15° — 17.279047 *inches, = chord of* 10° 20′— 7.81186 *inches, = chord of* 4° 40′, *and* 69.80318 *inches, = chord of* 42° 40′. *Having drawn the several arcs, between which the divisions were to be cut, the radius and the lengths of the above chords were taken by the beam compasses, which, together with the scale, were laid upon the quadrant, where they remained till the next morning, during which time the door of the room was kept locked. Before sun-rise I remeasured the radius, which required some correction; the beam being of white fir, and the scale of brass, which probably contracted, while the beam remained unaltered. The other beam compasses also required correction.*

Now the quadrant and scale being of the same temperature, the faint arc *b*, *d*, was struck, and, with a very fine prick-punch, the point *a* was made. With the same beam compass, unaltered, I laid off, from *a* to *e*, the chord of 60°, making also a fine point. *With the chord of* 30°, a e *was bisected in* c. *Now, one point of the beam compass, containing* 60°, *was fixed in* c; *and with the other was marked the point* r, *or* 90°. *Next, with the beam compass, containing* 15°, *was bisected* e r *in* n, *or* 75°. *From* n *was laid off the chord of* 10° 20′, *and from* r, 4° 40′; *which two last chords joined exactly in* g, *being the point of* 85° 20′. Now each degree being to be divided into 12 parts, or every 5′, *therefore* $\overline{85 \times 12} + 4 = 1024$, *a number divisible by continual bisections. The last chord computed was* 42° 40′, *with which* a g *was bisected in* o; a o *and* o g *were bisected by trials. But whoever undertakes to divide a large quadrant, will do well to compute also the chord of* 21° 20′; *but for this chord any of the beam compasses already provided, which will take in the length, may be used. The point* g *being found as above, I proceeded, by continual bisections, till I had the number required, viz.* 1024. *To fill up the space between* g *and* r, *containing* 56 *divisions, the chord of* 64 *divisions was laid off from* g *towards* d, *and divided, like the rest, by continual bisections, as was also from* a *towards* b. *The points* 30°, 60°, 75°, *and* 90°, *fell in without any sensible inequality.*

Here it is necessary to mention in what manner the bisecting and pointing were performed. Having the chord of 42° 40′ in the beam compass, and one point placed in *a*, with the other a faint arch of about $\frac{1}{20}$ of an inch in length was made in *o*. Again, one point of the beam compass was placed in *g*, and with the other the aforesaid faint arch was intersected. Here, as in all other places, great care was used to make the points exactly in the arc to be divided, and also in the intersection.

* Bird received the sum of £560, by certificate, from the Commissioners of Longitude, for his method of graduation, together with that of constructing mural quadrants; the latter of which was published soon afterwards.

Original Graduation. Bird's method of graduation. Plate CCLXXXII. Fig. 2.

In the following pages, I shall not only describe the farther process in dividing the mural arc in the Royal Observatory, but endeavour, also, to make the description general.

If the chord should be taken a little too long, or too short, so that the intersection be made on one side or the other of the arc to be divided, it will not occasion an inequality, provided the point be made in the middle between the two short lines, *except at the point of 85° 20′, where great care must be used in taking the chords from the scale. Great care must also be used in pointing intersections in general, being more difficult than a single line. But here I must not be understood to mean a single line made by one point of the compass; for, in all bisections, the place to be* pointed must be laid off from left to right, and from right to left; and if any error arises from an alteration of the beam compass, it will be shewn double.

In dividing, the points of the beam compass should never be brought nearer together than two or three inches, except near the ends of the arch or line to be divided; and there spring-dividers, having round points, which may be put in and taken out occasionally, will best answer the purpose.

The next thing to be considered is, the method of making the points. The prick-punch, for this purpose, must be extremely sharp and round, the conical point to make a pretty acute angle; and as the points herewith to be made, *should not exceed 0.001 of an inch, when linear divisions are to be cut from them, a magnifying glass of ½ inch focal length should be used;* by the assistance of which, the impression, or scratch, made by the points of the beam compass, will be very conspicuous; *and, if the said impression be not too faint, feeling, as well as seeing, will greatly contribute to make the points properly.*

It is scarce necessary to say any thing about the arc of 96°. I shall only mention, that it contains 1536 divisions; is to be divided into three equal parts, in the same manner as the arc of 90°. Each third contains 512 divisions; which number is divisible continually by 2, and gives 16 in each 96th part of the whole arc.

This arc of 96, (so far as I know,) was first applied to the iron quadrant in the Royal Observatory, in the year 1725, by my late worthy friend, Mr George Graham. It was not only a severe check upon that great mechanic, but will be so to all others, who divide the two arcs, upon one and the same instrument; yet, if the above instructions be strictly followed, the agreement between the two will be surprising, and differ very little from the truth.

The next step is to cut the linear divisions from the points. The best instrument for this purpose is the beam compass, *having both its points conical, and* very sharp. Draw a tangent to the arc *b d*, suppose at *e*, it will intersect the arc *x y* in *q*; this will be the distance between the points of the beam compass to cut the divisions (nearly at right angles to the arc *b d*.)

Lodge that point of the beam compass next your right hand, in the point r; *let the other fall freely into the arc,* x y; *press gently with your finger upon the screw-head, which fastens the socket* (this screw-head must be *convex*, and right over the point;) *and, with the point towards the right hand, cut the divisions.—In this manner you must proceed with the rest.*

Having finished the divisions of the limb, the nonius divisions are next to be divided. Chuse any part of the arch, where there is a coincidence of the 90 and 96 arches, which let be at e: Draw the faint arcs *s t* and *i k*, which may be continued to any length towards A, upon which the nonius divisions must be divided in points; a tangent line, as before, intersecting this arc, gives the distance of the points in the beam-compass. Now as the nonius divisions of the arc 90° subdivide the divisions of the limb of the mural arc at Greenwich to half a minute, 11 divisions of the limb being equal to 10 upon the nonius plate (a number which only 5 and 2 will divide,) *recourse must again be had to computation. Measure the radius of the arc, and compute the chord of 16, or rather 32, of the nonius divisions; the quantity of an arc equal thereto, may be easily had by the following proportion: As 10 div. : 55′ (the number of minutes in 11 divisions of the limb) : : 32 div. : 2° 56, the chord of which must be computed, and taken from the scale of equal parts:* But as different subdivisions by the nonius may be required, *let* n = *number of nonius divisions,* m = *number of minutes taken in by the nonius,* b = 16, 32 or 64, *and* x=*arc sought; then as* n : m : : b : x.

Lay off with the beam-compass, having the length of the tangent between the points, the point q *from* e, *and the chord of 32 from* q, *towards the left hand,* and divide by continual bisections, 10 *of those divisions, counting from* q *to the left, will be the points required.* As the number of nonius divisions for the 96 arch should always be 16, 32, &c. I need only mention, that the extremes may be laid off from the divisions of the limb, without computation.

Now the place upon the chamfered edge of the nonius plate, where the nonius is to begin, may be found in the following manner. *Measure the distance of the quadrant centre, from the axis of the telescope; this distance from the axis of the telescope at the eye-end, will be the place for the first division of the nonius, where draw a faint line from the centre. The greater accuracy with which this is laid off, the nearer to the axis of the tube will be the intersection of the wires, in the common focus of the object and eye-glasses.*

I will suppose that no instrument-maker will fix to the telescope the nonius, and centre-plates, without steady-pins, as well as screws. Screw the centre-plate of the telescope very fast: put the nonius plate upon the steady-pins, without screws, and put the telescope upon the quadrant: make fast the nonius plate to the arch with two pair of hand-vices, and take the telescope away. *Now with one point of a beam-compass, in the centre of the quadrant, and the other at the middle of the nonius plate, draw a faint arch from end to end: Where this arch cuts the faint line before-mentioned, make a fine point: From this point lay off on each side another, which may be at any distance in the arch; only care must be taken, that they be equally distant from the middle point: From the two last make a faint intersection as near as possible to either of the chamfered edges of the nonius plate: Through this intersection, the first division of the nonius must be cut.*

Put the telescope again upon the centre of the quadrant, the steady-pins into the nonius plate as before; unscrew the hand-vices, and bring the last-mentioned intersection to e *or 60° upon the limb, where fasten it again with the hand vices, and take away the telescope.* Now, from the point before divided, the nonius divisions must be cut; by lodging the left hand point of the beam-compass in the point upon the arch, and cutting with the right.

Here great care must be taken, to cut the first division of the nonius through the point of *intersection;* which may be done by altering the distance of the points in the beam-compass, if necessary: This will not sensibly affect the perpendicularity of the divisions, provided the intersection be placed very near to *e*, or 60°.

Having cut the nonius divisions, suppose of the 90 arc, take up the plate, polish off the bur, and fasten it to the limb, as before; but here great care must be taken to make the first division of the nonius coincide with the 60th deg. so as to appear one line; and the nonius of the 96 arc may be cut in the same manner, making the first division coincide with 64 = 60° upon the limb.

Now, take up the plate, and draw a tangent at the point in the faint arc in the middle of the nonius plate; and with a distance about a quarter of an inch longer than the nonius, lay off from the tangent point another in the tangent line; also lay off this distance from the centre of the collar at the object end of the telescope, and make a fine point: Then extend the beam-compass nearly the whole length of the nonius, or centre plate (which should reach, at least, half an inch beyond the telescope, on the contrary side), and lay off other points in the tangent line before mentioned, and in a line passing through the centre of the quadrant, at right angles to the telescope.

Now screw the two plates to the telescope, and draw lines by the edge of a steel-ruler through the correspondent points, to which lines the plates must be carefully filed. Then the ends of the plates will be in lines parallel to each other, and to the axis of the tube, which affords an excellent mechanical method of finding the line of collimation of the telescope.

The apparatus used for this purpose by the late Mr Graham, was a box equal in length to the telescope, having deep sides, to prevent its bending by its own weight. The ends were of hard wood. *Instead of which, I use two flat pieces of brass, which I can move according to different lengths required; and by the help of a small spirit-level, these pieces of brass may be fixed in one and the same plane.* This apparatus should stand firm upon the ground, where a distant and distinct object can be seen. Rest the ends of the nonius and centre plates upon the two pieces of brass, and observe what point of the object is cut at the intersection of the horizontal and vertical wires. Invert the telescope, and if the horizontal wire does not cut the same point of the object, it must be altered by the screws for that purpose, half the difference. By repeating this, you may approximate extremely near the truth.

In the middle, between the 90 and 96 arches of the mural quadrant, in the royal observatory, is an arch of points (96), which are used with a silver wire, of about 600 in an inch, carried by a small frame, screwed to the end of the nonius plate. When the wire, in an observation, falls between two points, it must, by the micrometer screw, be made to bisect the nearest point to the left hand, the instrnment shewing the zenith distance; and the minutes and seconds shewn by the micrometer added. If the next point to the right hand be bisected, the minutes and seconds must be subtracted. This arch of points was divided in every respect like the other arch of 96.

Having gone through the whole process of dividing the mural arc, &c. it will be necessary to shew some reasons why this kind of management hath succeeded better than any other, as far as I either know or have heard.

After I had found by experience, that the expansion of the instruments to be divided, occasioned by the increasing heat of the sun, or a contraction by a decrease thereof, was the grand difficulty with which I had to struggle, especially when two or three hours were required to lay off the principal points; I immediately set about contriving how to lay them off in the least time possible, i. e. *before any expansion or contraction could take place; and as the heat of three or four persons in the room may produce the same effect as the sun, I never admit more than one as an assistant. Neither must any fire be suffered in the room, till the principal points are done.*

The above being understood, it was easy to conceive, that, having all the chords before-mentioned computed and measured, the evening before they were to be laid off, I should be enabled to perform in a few minutes, what by trials would require some hours; and as too much caution cannot be used, it is proper to lay off the principal points before sun-rise, or else chuse a cloudy morning.

The method of cutting the divisions as described above, is to prevent any inequality that would arise from the expansion of the beam compass by the heat of the hands, especially if the beam be of metal. Wooden beams will also alter, probably from a small bending; *but in this method, if the beam should alter $\frac{1}{10}$ of an inch or more, it would not cause any sensible inequality.* As the points of the nonius divisions cannot be divided upon the nonius plate without inconvenience, it is best to use the method formerly described, *holding the beam compass a small while in the hand* previous to the cutting. The points being but few in number, the divisions may be cut, before any expansion can sensibly take effect.

Sextants, or octants, for observing the distance of the moon from the fixed stars, should be divided by the foregoing method, great accuracy being required. *If instead of dividing sextants to every 20′ upon the limb, as is commonly done, they should be divided to 15′, a chord of 64° might be laid off, and divided by continual bisections.* This would, in some measure, crowd the limb with divisions; but it would shorten the nonius; for 15, instead of 20, would shew one minute.

In dividing either arches or straight lines, a number (which will divide continually by 2) greater than is required upon the arc or line, is the best to begin with, and may be used in dividing a circle, by laying off the chord of the difference. Suppose it was required to divide a circle into 54 equal parts, it would be 64—54 = 10 = 10° 30′; the chord of which laid off must be added to 360°, and it will be 360° + 10° 30′, to be divided into 64 equal parts, 54 of which will complete the circle. If the arc of 10° 30′ be laid off from a dividing plate, it will answer the same purpose.

Analogous to the foregoing method, my scale of equal parts was divided. I took $\frac{512}{10}$ of an inch in a beam compass, laid the scale which I took it from, the brass scale to be divided, and the beam compass in a room facing the north, where they lay the whole night. Early next *morning, after correcting the lengths, the above* $\frac{512}{10}$ were laid off three times (the brass being long enough to take it in); then, having in other compasses 256, 128, and 64, I bisected the three spaces of 512 with all the expedition I could. Having now only 64 inches in the last beam compass, any partial or unequal expansion was not to be feared; therefore worked by continual bisections till I had done. *The linear divisions were cut from the points with a beam compass, as before described.*

The nonius divisions of this scale contains $\frac{101}{10}$ of an inch, which were divided into 100 in the following manner: *As* 100 : 101 :: 256 : 258.56 *tenths of an inch, the integer in this case being* $\frac{1}{10}$. Suppose the scale to be numbered at every inch from left to right; then exactly against $\frac{1}{10}$, to the left of 0, was made a fine point, *from which was laid off* 258.56 to the right hand. This was taken from a scale 3 feet in length, which was divided after the common method; but the error was so small as to vanish at the other extremity of the nonius, when divided continually by 2.

Original Graduation.

Whoever undertakes to divide a scale of the above kind, not being furnished with one long enough to lay off 258.56, *may take* $\frac{250}{10}$ *from that before him, to which he may add* 8.56 *taken from a diagonal scale, that may be made at a small expence.*

To prove the expedience of the above methods of dividing astronomical instruments, &c. I need only to mention the following particulars, taken from the Nautical Almanac for this present year 1767, page 152.

"Mr Mayer made his observations with his six-foot mural arch, from the year 1756 to the time of his decease: with it he settled the mean obliquity of the ecliptic, to the beginning of the year 1756, at 23° 28′ 16″; which Dr Bradley settled by his observations, made in the years 1750 and 1751, at 23° 28′ 18″. The difference is agreeable to what ought to arise from the gradual diminution of the obliquity of the ecliptic at the rate of about ½ a second in a year," &c. That two different observers, with instruments of different radii, and in different parts of Europe, should so nearly agree, is matter of no small astonishment, and sufficiently proves, that a mean of several observations, made by good observers, with accurate instruments, properly adjusted, will always lead us either to the truth itself, or extremely near to it.

Remarks on Bird's method of graduation.

Excepting the means of rendering the common subdivision of the circle bisectional, and his care in avoiding errors from expansion, Bird's method of cutting the strokes was its most important deviation from the practice of Graham. The latter made his dots in the tangential line, which supported the resting point of the compass, while the other point, at a considerable distance, traced the divisions. Bird, by making his dots extremely near to the outer ends of the strokes, and resting the point in an undivided tangential line, avoided any error that might arise from an alteration of the length of the beam during the operation, which was a serious objection to Graham's way of proceeding. We should, however, have been afraid that the resting point, on being simply dropped into the line, and having apparently nothing to hold it there, might have been in danger of slipping, did not we know that artists themselves, provided the metal be sound, are apprehensive of little or no error on this account.

The Duke de Chaulnes' method of graduation.

Soon after the publication of Bird's method, that of the Duke de Chaulnes' made its appearance, which has in the preceding Section been noticed as applicable to a dividing engine. He was the first who employed double microscopes in the graduation of the circle; a practice which, in the hands of others, the Duke's work, known or unknown to them, has essentially improved the art. There are also two more peculiarities in De Chaulnes' method, that deserve to be noticed. One is its being purely visual. The whole is done by the eye, except cutting the real divisions; and even this, to prevent the errors of the hand, is performed by machinery. The other is, that, to avoid superfluous marks upon the limb, he had provided, ready for his purpose, a competent number of thin pieces of brass, about one-third of an inch long, and one-sixth broad, with a fine line upon the surface of each, drawn perpendicular to its length. To make these pieces adhere to the surface that was to receive the divisions, their under planes were thinly coated with wax, and thereby made capable of being easily adjusted to their places, and of retaining that position until the divisions represented by them were inserted.

The circle to be divided moves round horizontally upon a vertical axis, within a strong frame of wood, to which the microscopes are fixed, and applicable to any part of it.

The first step is to bisect the circle. To this end one of the brass pieces is to be made fast with screws, at the place which is intended to be zero, the line upon its surface being directed towards the centre. A microscope is affixed to the frame, with its radial wire coincident with the line, and its cross one a tangent to the circle. Another microscope is secured on the frame, by estimation or any better way, diametrically opposite to the first, and one of the waxed pieces placed under it, so that the line and wires may have to each other, and to the circle, the same relation as above. Let the circle be turned half round within the frame, so as to bring the zero line coincident with the radial wire of the other microscope. If now the line of the waxed piece be found exactly under the wire of the first microscope, it is evident that the circle is bisected; but as this can hardly happen in the first instance, the apparent error must be corrected one half, by sliding the waxed piece towards the wire, and the other half by moving the microscope to it. The circle must again be turned half round, to verify the correction, or, if necessary, to afford means for a second correction, and the operation repeated until the lines exactly coincide with the wires in both positions of the circle. This being done, the microscope which has under it the zero piece should be regarded as fixed, and let its name be A; the other, which we will call B, is to be taken off, and reserved for future use. In the room of B there is to be fixed the tracer or cutting point, so that if the piece were taken off, which it must not be, the tracer would cut a line exactly in its place, or diametrically opposite to the zero line. By this contrivance, it becomes necessary only to divide half the circle; for if the divisions of one semicircle are brought successively to the wire of A, the tracer will cut their opposites in the other.

The second step is to trisect the semicircle, which is to be done by two more of the adjustable pieces, and the two microscopes. With *zero* under A, place B as nearly at an angle of 60° from it as can be done by estimation or otherwise, and put a waxed piece under it; move back the circle so as to bring the waxed piece to A, and put another under B; again move the circle so as to bring the second piece under A, when, if B should happen to coincide with the line opposite to *zero*, the thing is done; but if not, as most likely will be the case, then B must be moved towards the line one-third of the quantity of apparent error, and the operation repeated, as was done for bisecting the circle. The third step is to bisect the three equal arcs of the semicircle, which is done by similar means; and at the fourth step by which those last are trisected, arcs of 10° are obtained.

The Duke de Chaulnes' microscopes could not be brought near enough to each other to bisect the arcs of 10°; he therefore had recourse to that of 9°, which he found and used in the following manner. He obtained it by taking ten steps with nine additional waxed pieces for each of the two quadrants, which he brought to their places by frequent trial and adjustment. With this opening between the microscopes, from the tens he set off all the nines forwards, and all the ones backwards. He then resumed the former opening of 10°; and as the operation for ascertaining the arc of 9° had left a waxed piece in every interval of 10°, which would in their respective places represent 8°, 7°, 6°, &c. to 2° in each quadrant, with the opening of 10° from eight, he set of all the eights, from seven he set off all the sevens, &c. and in this manner put in every single degree of the semicircle.

Original Graduation.

The Duke de Chaulnes' method of graduation.

As all the waxed pieces had their opposites cut in the other, it was not necessary to have 180 of them; for it is evident from the mode of procedure, that after the ones and nines had been put in, neither these nor the tens could be wanted. The semicircle of trial has yet upon it no divisions, and how (the waxed pieces being removed) it was divided from the other, has already been mentioned.

It is observed, that when a circle is large enough to allow the microscopes to come so near each other as to bisect the arc of 10°, the numbers four and five may with advantage be substituted for nine and ten; and when half degrees are required, it is proposed to bisect the arc of 15°, and with this opening to put in all the half degrees.

To subdivide the degree into five-minute spaces, the Duke de Chaulnes proposes to mount a telescope with a vertical wire in its focus, upon the centre arbor of the circle, so that it may either revolve with the circle, or concentric to it by itself, as the case may require; and let a long beam of wood be provided, accurately divided into 12 equal parts, and placed at such a distance as to subtend an angle of one degree; a thin piece of brass is to be fixed upon the circle under the tracer; and as the telescope and circle are turned round together, and the wire made successively to coincide with the divisions of the beam, the corresponding strokes are to be drawn upon the piece of brass: and lastly this piece is to be placed under the fixed microscope, in order that by means of it and the tracer, every degree may be filled up.

Remarks on the Duke de Chaulnes's method.

The ingenious inventor of the above method, like those who preceded Bird, has made no provision against the errors arising from expansion; indeed, his tracer being fixed opposite to the point of trial, subjects his work to the greatest possible error in that respect; and under this disadvantage, his division of the first semicircle is no more than a copy of the wax-work; and, again, the second semicircle is, under the same disadvantage, a copy from the first.

Hindley's method of graduation.

The method of Hindley having been in part communicated to Smeaton in 1741, and fully in 1748, might in our article have preceded some of the methods already noticed, but as he received it under the seal of secrecy, it was unknown to the public until 1785, in which year Mr Smeaton's paper, before referred to, concerning it, was read to the Royal Society.

Smeaton introduces this method under the full persuasion that vision, even when assisted by glasses, cannot command a greater degree of accuracy than to the 4000th part of an inch; and maintains, that by contact, the 60,000th becomes equally sensible. Were this true, and contact applicable to the graduation of instruments without *drawback*, a fine field of improvement would have been opened to the artist through the paper under consideration.

Mr Smeaton says, " It now comes to be time to open a principle, upon which there is a prospect of effecting such an improvement. I have shewn that a 4000th part of an inch is the ultimatum that we are to expect from sight, though aided by glasses, when observing the divisions of an instrument. But in the 48th volume of the *Philosophical Transactions*, (p. 149 of this volume), I have shewn the mechanism of a new pyrometer, and experiments made therewith; whereby it appears, that, upon the principle of contact, a 24,000th part of an inch is a very definite quantity. I remember very well that I did not then go to the extent of what I might have asserted, being willing to keep within the bounds of credibility; but on occasion of the present subject, I have re-examined this instrument, and find myself very well authorised to say, that a 60,000th part of an inch, with such an instrument, is a more definite and certain quantity than a 4000th part of an inch is to the sight, conditioned as above specified. The certainty of contact is, therefore, fifteen times greater than that of vision, when applied to the divisions of an instrument: and if this principle of certainty in contact did not take place, even much beyond the limit I have now assigned, we never should have seen those exquisite mirrors for reflecting telescopes that have already been produced.

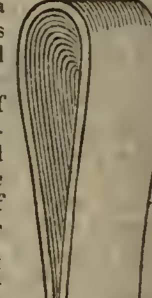
These reflections apply immediately to my present subject, as Hindley's method of division proceeds wholly by contact, and that of the firmest kind; there being scarcely need of magnifying glasses in any part of the operation.

In the year 1748, I came to settle in London; and the first employment I met with was that of making philosophical instruments and apparatus. In this situation, my friend Hindley, from a principle the reverse of jealousy, fully communicated to me, by letter, his method of division; and though I was enjoined secrecy respecting others, (for the reasons already mentioned), yet the communication was expressly made with an intention that I might apply it to my own purposes.

The following are extracts from two letters, which contain the whole of what related to this subject; and since I have many things to observe thereon, so that the paraphrase would be much greater than the text, I think it best not to interrupt the description with any commentary, as perhaps his own mode of expression will more briefly and happily convey the general idea of the work, than any I can use instead of it.

" My Dear Friend, " York, 14th Nov. 1748.

" As to what you was mentioning about my brother's knowing how I divided my engine plate, I will describe it as well as I can myself; but you will want a good many things to go through with it. The manner is this: first choose the largest number you want, and then choose a long plate of thin brass; mine was about one inch in breadth, and eight feet in length, which I bent like a hoop for a hogshead, and soldered the ends together, and turned it of equal thickness, upon a block of smooth-grained wood, upon my great lathe in the air, (that is, upon the end of the mandrel); one side of the hoop must be rather wider than the other, that it may fit the better to the block, which will be a short piece of a cone of a large diameter: when the hoop was turned, I took it off, cut, and opened it straight again.



The next step was to have a piece of steel bended into the form as per margin; which had two small holes bored in it, of equal bigness, one to receive a small pin, and the other a drill of equal size. I ground the holes after they were hardened, to make them round and smooth. The chaps formed by this steel plate were as near together as just to let the long plate through. Being open at one end, the chaps so formed would spring a little, and would press the long plate close, by setting in the vise. Then I put the long plate to a right angle to the length of the steel chaps, and bored one hole through the long plate, into which I put the

Original Graduation.

Hindley's method of graduation.

small pin; then bored through the other hole; and by moving the steel chaps a hole forward, and putting in the pin in the last hole, I proceeded till I had divided the whole length of the plate.

The next thing was to make this into a circle again. After the plate was cut off at the end of the intended number, I then proceeded to join the ends, which I did thus: I bored two narrow short brass plates, as I did the long one, and put one on the inside, and the other on the outside of the hoop, whose ends were brought together; and put two or three turned screw pins, with flat head and nuts to them, into each end, which held them together till I rivetted two little plates, one on each side of the narrow plate, on the outside of the hoop Then I took out the screws, and turned my block down, till the hoop would fit close on; and by that means my right line was made into an equal divided circle of what number I pleased.

The engine plate was fixed on the face of the block, with a steel hole fixed before it, to bore through; and I had a point that would fall into the holes of the divided hoop; so by cutting shorter, and turning the block less, I got all the numbers on my plate.

I need not tell you, that you get as many prime numbers as you please; nor that the distance of the holes in the steel chaps must be proportioned to the length of the hoop.

You may ask my brother what he knows about my method of dividing; but need not tell him what I have said about it; for I think neither he nor John Smith knows so much as I have told you, though I believe they got some knowledge of it in general terms. I desire you to keep the method of dividing to yourself, and conclude with my best wishes. And am, dear sir, yours, &c. HENRY HINDLEY.

Though the above letter was in itself very clear and explicit as to the general traces of the method, yet some doubts occurring to me, a farther explanation became necessary. A copy of my letter not being preserved, the purport of it may be inferred from the answer, which was as follows:

Dear Friend, *York*, 13*th March*, 1748-9.

I think, in your last, you seem to be apprehensive of some difficulties in drilling the hoop for dividing: First, that the centre of the hole in the hoop might not be precisely in the centre of the hole of the steel chaps it was drilled in; but if I described fully to you the method I used, I can see no danger of error there; for my chaps were very thick, and the two corresponding holes were a little conical, and ground with a steel pin; first one pair, and then the other, alternately, till the pin would go the same depth into each. Then for drilling the hoop, I took any common drill that would pass through and bore the hole. After that I took a five-sided broach, which opened the hole in the brass betwixt the steel chaps, but would not touch the steel; so, consequently, the centre of the holes in the brass must be concentric with the holes in the chaps; and for alterations by air, heat, cold, &c. I was not above two or three hours in drilling a row of holes, as far as I remember.

2*dly*, For drilling, in a right line, I had a thin brass plate, fastened between the steel chaps, for the edge of the hoop to bear against, whilst I thrust it forward from hole to hole. What you propose of an iron frame with a lead outside, will be better than my wooden block; but considering the little time that past betwixt transferring the divisions of the hoop to the divisions of my dividing plate, I did not suffer much that way. It was when I drilled the holes in my dividing plate that I used a frame for drilling, which had one part of it that had a steel hole; that in lying upon the plane of the dividing plate, was fixed fast in its place for the point of the drill to pass through; then, at the length of the drill, there was another piece of steel, with a hole in it, to receive the other end of the drill to keep it at right angles to the plane of the plate. This piece was a spring, which bended at the end, where it was fastened to the frame of the lathe, at about 18 inches from the end of the drill; so it pushed the drill through with any given force the drill would bear; and though that end of the drill moved in the arch of a circle, it was a very small part of it, being no more than equal to the thickness of the dividing plate. My good wishes. Conclude me yours, HEN. HINDLEY.

Remarks on Hindley's method of dividing.

Nothing ever surpassed in originality the method described in the above letters, which is in no respect like any other. There is not a tool employed in it, except the lathe, but what may either be found in the shop of the most common worker in metals, or made by him. It is, however, like Hook's and Roemer's, a system of uncontroulled stepping; and, like theirs, if only applied to an arc, would have ended in the same uncertainty; but being extended to the whole circle, it secures the intended number of divisions, and closes without a remainder, which is what theirs never could have done.

Mr Smeaton's method of dividing.

To avoid errors occasioned by expansion, which Hindley seems not to have been aware of, Smeaton recommends that the work should be done when the air is of a moderate temperature; and that, to prevent the materials from being heated, it should be carried on at short intervals; but his chief improvement was directed to correct the effect of long continued stepping. Mr Smeaton would divide his circle into 1440 parts, or quarters of a degree. To effect the correction last mentioned, two pieces of brass must be provided, in every respect like that which is to be the hoop, except that they need not be longer than is required to contain 30°; these pieces, which are called *straps*, he would drill in the manner that Hindley prescribes, and it should be mentioned, that the first hole in each must be made in a short piece of hardened steel, which in the first instance had been soldered to the ends of the straps. For the purpose of obtaining the total length, the straps are drilled from end to end; but no more than the first, middle, and last holes are used. The zero hole being made in the long, or hoop-piece, the middle holes of the straps are to be pinned to it on opposite sides, and the steel pieces directed forwards; the three pieces extended in a right line are to be pressed together, and the 60th hole in the hoop-piece bored coincident with those of the straps. The straps are now taken off, and the 59 intermediate holes drilled by means of the chaps only. Again, the extreme holes of the straps are to be pinned to the zero holes of the hoop-piece, and arranged as before, when the 120th hole of the latter is to be bored agreeable to the steel holes in the former; and recourse again had to the chaps for the next 59 holes. As the process described above fills up as much of the hoop-piece as is equal to 30°, eleven similar double operations will complete the whole length; and, as Smeaton observes, produce 12 master checks, and 12 subordinate ones. The next thing to be done is to fasten the ends of the long piece together, so as to form

Original Graduation.

it into a hoop, by pressing it upon the edge of a *chock*, as directed by Hindley.

Farther than this, Smeaton's paper cannot be considered as describing an original method of graduation, the remainder being directed to the forming it into an engine, of which, in its proper place, we declined giving a description, and here it would be inapplicable. We may however observe, that Smeaton has improved upon Hindley in every part, with his usual ingenuity and ability; and provided the foundation were good, so would be the superstructure. Smeaton was no advocate for large astronomical instruments, and therefore would have an engine constructed of sufficient magnitude to graduate any that ought to be made.

Mr Smeaton's paper was not well received by the instrument makers; but he predicted, that when half a century had worn off the prejudice against it, the method would be adopted and improved to the advantage of astronomy. But as Mr Troughton, in a paper to be noticed hereafter, ventures to make a quite contrary prediction concerning it, and gives his reasons for it; we decline entering into the question.

Ramsden's method of dividing.

Considering the celebrity of Mr Ramsden, his long career and extensive practice in making instruments that required the nicest graduation, we have in this department of our article comparatively little to say of him. Excepting the descriptions of his engines, we believe he never wrote upon the subject; nor has any one else, so far as we know, described how he proceeded. Troughton has indeed pointed out the manner in which he adjusted erroneous dots to their places; a practice which it is said was suggested to Ramsden by the adjustable waxed pieces of the Duc de Chaulnes. A pupil of Ramsden informs us, that in an early part of his practice he had used the scale of equal parts, agreeably to the manner of Bird, but that he soon abandoned it; and that he had often varied his apparatus and method. At what time the method of coaxing, as it is called, was first applied in the works of Ramsden, is perhaps known to no one except Mr Berge: this artist, who at his death succeeded him, had long been his able and indefatigable assistant, and in the graduation of instruments had honoured the name of his employer,

"By patient touches of unwearied art."

That the coaxing could not have been in practice so early as the time when the dividing engine was made, may be inferred from the circumstance, that the description of the engine was given in upon oath, and nothing said about it.

For many years previous to the publication of the following method by Troughton, the art of graduation had been carried on in secrecy and silence; every artist had, or pretended to have a method of his own, of which astronomers could only judge, perhaps indeed the best way, by the comparative exactness of the work that came from their hands. Mr Troughton's paper was read to the Royal Society in February 1809, and appeared in the first part of the volume of the *Phil. Trans.* for that year.* It contains not only an account of a method invented by himself, and which he had successfully practised for many years, but also remarks upon other methods, which had been, or were then in use. To abridge this work, after giving Bird's at length, is what we will not attempt; for we think our readers may not be displeased to see Troughton's ideas upon the subject in general, expressed in his own way; we therefore give the whole, notwithstanding a few repetitions, that will thus be introduced into our article.

"It would ill become me, in addressing myself to the members of this Society upon a subject which they are so well enabled to appreciate, to arrogate to myself more than may be assigned as my due, for whatever of success may have been the result of my long continued endeavours, exerted in prosecuting towards perfection *the dividing of instruments immediately subservient to the purposes of astronomy.* A man very naturally will set a value upon a thing on which so much of his life has been expended; and I shall readily, therefore, be pardoned for saying, that, considering some attainments which I have made on this subject as too valuable to be lost, and being encouraged, also, by the degree of attention which the Royal Society has ever paid to practical subjects, I feel myself ambitious of presenting them to the public through what I deem the most respectable channel in the world.

It was as early as the year 1775, being then apprentice to my brother, the late Mr John Troughton, that the art of dividing had become interesting to me; the study of astronomy was also new and fascinating; and I then formed the resolution, to aim at the nicer parts of my profession.

At the time alluded to, my brother, in the art of dividing, was justly considered the rival of Ramsden; but he was then almost unknown beyond the narrow circle of the mathematical and optical instrument makers, for whom he was chiefly occupied in the division, by hand, of small astronomical quadrants, and Hadley's sextants of large radius. Notwithstanding my own employment at that time was of a much inferior nature, yet I closely inspected his work, and tried, at leisure hours, on waste materials, to imitate it. With as steady a hand, and as good an eye, as young men generally have, I was much disappointed at finding, that, after having made two points, neat and small, to my liking, I could not bisect the distance between them, without enlarging, displacing, or deforming them with the points of the compasses. This circumstance gave me an early dislike to the tools then in use; and occasioned me the more uneasiness, as I foresaw, that it was an evil which no practice, care, or habit, could entirely cure;—beam-compasses, spring-dividers, and a scale of equal parts, in short, appeared to me little better than so many sources of mischief.

I had already acquired a good share of dexterity as a general workman. Of the different branches of our art, that of *turning* alone seemed to me to border on perfection. This juvenile conceit, fallacious as I afterwards found it, furnished the first train of thoughts which led to the method about to be described; for it occurred to me, that if I could, by any means, apply the principle of turning to the art of dividing instruments, the tools liable to objection might be dispensed with. The means of doing this were first suggested by seeing the action of the perambulator, or measuring wheel; the surface of the Earth presenting itself as the edge of the instrument to be divided, and the wheel of the perambulator as a narrow roller acting on that edge; and hence arose an idea, that some easy contrivance might be devised, for marking off the revolutions and parts of the roller upon the instrument. Since the year above-mentioned, several persons have proposed to

* The Royal Society voted to Mr Troughton the gold medal on Sir Godfrey Copley's Donation, for his valuable Paper.—ED.

Original Graduation.

me, as new, dividing by the roller, and I have been told, that it also occurred long ago to Hook, Sisson, and others; but, as Hatton on watch-making says, "I do not consider the man an inventor, who merely thinks of a thing. To be an inventor, in my opinion, he must act successfully upon the thought so as to make it useful." I had no occasion, however, to have made an apology for acting upon a thought, which, unknown to me, had been previously conceived by others; for it will be seen in the sequel, how little the roller has to do in the result, and with what extreme caution it is found necessary to employ it.

hen most urate, de-uive.

When a roller is properly proportioned to the radius of the circle to be divided, and, with its edge, made a small matter conical, so that one side may be too great, and the other side too little, it may be adjusted so exactly, that it may be carried several times around the circle, without the error of a single second; and it acts with so much steadiness, that it may not unaptly be considered as a wheel and pinion of indefinitely high numbers. Yet, such is the imperfection of the edges of the circle and roller, that, when worked with the greatest care, the intermediate parts, on a radius of two feet, will sometimes be unequal to the value of half a minute or more. After having found the terminating point of a quadrant or circle so permanent, although I was not prepared to expect perfect equality throughout, yet I was much mortified to find the errors so great, at least ten times as much as I expected; which fact indicated, beyond a doubt, that if the roller is to be trusted at all, it must only be trusted through a very short arc. Had there been any thing slippery in the action, which would have been indicated by measuring the same part, at different times, differently, there would have been an end of it at once; but this not being the case in any sensible degree, the roller becomes a useful auxiliary to fill up short intervals, the limits of which have been corrected by more certain means.*

ust be ufined short arcs.

rd's me-od of divi-n.

Bird, who enjoyed the undisputed reputation of being the most accurate divider of the age in which he lived, was the first who contrived the means how to render the usual divisions of the quadrant bisectional; which property, except his being unusually careful in avoiding the effects of unequal expansion from change of temperature, chiefly distinguished his method from others who divided by hand. This desirable object he accomplished by the use which he made of a finely divided scale of equal parts. The thing aimed at was, to obtain a point upon the arc at the highest *bisectional number of divisions* from 0, which in his eight feet quadrants was 1024 = 85° 20′. The extent of the beam compasses, with which he traced the arc upon the limb of the instrument to be divided, being set off upon that arc, gave the points 0° and 60°; which being bisected, gave 30° more to complete the total arc. A second order of bisections gave points at 15° distance from each other: but that which denoted 75° was most useful. Now, from the known length of the radius, as measured upon the scale, the length of the chord of 10° 20′ was computed, taken off from the scale, and protracted from 75° forwards; and the chord of 4° 40′, being ascertained in the same manner, was set off from 90° backwards, meeting the chord of 10° 20′ in the continually bisectional arc of 85° 20′. This point being found, the work was carried on by bisections, and the chords, as they became small enough, were set off beyond this point, to supply the remainder of the quadrantal arc. My brother, whom I mentioned before, from mere want of a scale of equal parts upon which he could rely, contrived the means of dividing bisectionally without one. His method I will briefly state as follows, in the manner in which it would apply to dividing a mural quadrant. The arcs of 60° and 30° give the total arc as before; and let the last arc of 30° be bisected, also the last arc of 15°, and again the last arc of 7° 30′: the two marks next 90° will now be 82° 30′ and 86° 15′, consequently the point sought lies between them. Bisections will serve us no longer; but if we divide this space equally into three parts, the most forward of the two intermediate marks will give us 85°, and if we divide the portion of the arc between this mark and 86° 15′ also into three, the most backward of the two marks will denote 85° 25′. Lastly, if we divide any one of these last spaces into five, and set off one of these fifth parts backwards from 85° 25′, we shall have the desired point at 1024 divisions upon the arc from 0°. All the rest of the divisions which have been made in this operation, which I have called marks, because they should be made as faint as possible, must be erased; for my brother would not suffer a mark to remain upon the arc, to interfere with his future bisections.

Mr John Troughton's method of dividing bisectionally without a scale.

Smeaton's preference of division by the computed chord.

Mr Smeaton, in a paper to be more particularly noticed presently, justly remarks the want of a unity of principle in Mr Bird's method; for he proceeds partly on the ground of the protracted radius, and partly upon that of the computed chord; which, as Smeaton ob-

* There are two things in the foregoing account, of the action of the roller, which have a tendency to excite surprise. The first is, that the roller should, in different parts of its journey round the circle, measure the latter so differently. One would not wonder, however, if in taking the measure across a ploughed field, it should be found different to a parallel measure taken upon a gravel walk; and, in my opinion, the cases are not very dissimilar. Porosity of the metal, in one part of the circle more than in the other, must evidently have the same effect. Brass unhammered is always porous; and the part which has felt the effect of two blows, cannot be so dense as other parts which have felt the effect of three; and, should the edge of the circle be indented by *jarring turning*, it would produce a visible similitude to ploughed ground. Every workman must be sufficiently upon his guard against such a palpable source of error; yet, perhaps, with our greatest care, we may not be able to avoid it altogether. The second is, that, notwithstanding the inequality above-mentioned, the roller having reached the point upon the circle from which it set out, should perform a second, third, &c. course of revolutions, without any sensible deviation from its former track. This is not, perhaps, so easily accounted for. It must be mentioned, that the exterior border of the circle should be *turned rounding*, presenting to the roller a convex edge, the radius of curvature of which is not greater than one-tenth of an inch. Now, were the materials perfectly inelastic and impenetrable, the roller could only touch the circle in a *point*, and, in passing round the circle, it could only occupy a *line* of contact. This, in practice, is not the case; the circle always marks the roller with a broad list, and thereby shows, that there is a yielding between them to a considerable amount. The breadth of this list is not less than one-fiftieth of an inch; and it follows, that at least 12° of the circle's edge must be in contact at the same time; that the two surfaces yield to each other in depth, by a quantity equal to the *ver. sin.* of half that arc, or $\frac{1}{1800}$th of an inch; and that the circle has always hold of the roller by nearly 1° of the edge of the latter. Whoever has examined the surfaces of metals, which have rolled against each other, must have observed that peculiar kind of indentation that always accompanies their action; and there can be no doubt, that the particles of a roller, and those of the surface on which it acts, which mutually indent each other, will, upon a second course begun from the same point, indent each other deeper. This is not, however, exactly the case in question; for whatever of fitting might have taken place between the surfaces of our roller and circle, in the first revolution of the former, we should imagine would be obliterated by the fifteen turns which it must repeat over fresh ground. Experience shows, however, as every one will find who tries the experiment with good work, that on coming round to the point of commencement, the roller has the disposition to regain its former track; for, were this not the case, although the commensurate diameters were adjusted so exactly as to be without sensible error in one course, yet a less error than that which is so would become visible, when repeated through many courses.

Original Graduation.

serves, may or may not agree. Bird, without doubt, used the radius and its parts, in order to secure an exact quadrant; but Smeaton, treating exactness in the total arc as of little value to astronomy, would, in order to secure the more essential property of equality of division, reject the radius altogether, and proceed entirely upon the simple principle of the computed chord. The means pursued by my brother, to reach the point which terminates the great bisectional arc, is the only part in which it differs from Bird's method; and I think it is without prejudice that I give it the preference. It is obvious, that it is as well calculated to procure equality of division as the means suggested by Smeaton, at the same time that it is equal to Bird's in securing the precise measure of the total arc. It proceeds entirely upon the principle of the protracted chord of 60° and its subdivision; and the uncertainty which is introduced into the work, by the sparing use which is made of subdivision by 3 and 5, is, in my opinion, likely to be much exceeded by the errors of a divided scale, * and those of the hand and eye in taking off the computed chords, and applying them to the arc of the instrument to be divided.

Advantages of Mr John Troughton's method.

Ramsden's method by the engine.

Ramsden's well known method of dividing by the engine unites so much accuracy and facility, that a better can hardly be wished for; and I may venture to say, that it will never be superseded in the divisions of instruments of *moderate radii.* It was well suited to the time in which it appeared; a time, when the improvements made in nautical astronomy, and the growing commerce of our country, called for a number of reflecting instruments, which never could have been supplied, had it been necessary to have divided them by hand; however, as it only applies to small instruments, it hardly comes within the subject of this paper.

Hindley's method.

The method of Hindley, as described by Smeaton, † I will venture to predict, will never be put in practice for dividing astronomical instruments, however applicable it might formerly have been for obtaining numbers for cutting clockwork, for which purpose it was originally intended. It consists of a train of violent operations with blunt tools, any one of which is sufficient to stretch the materials beyond, or press them within their natural state of rest; and, although the whole is done by contact, the nature of this contact is such, as I think ought rather to have been contrasted with, than represented as being similar to, the nature of the contact used in Smeaton's Pyrometer, which latter is performed by the most delicate touch; and is represented, I believe justly, to be sensible to the $\frac{1}{60000}$ part of an inch. Smeaton has, however, acquitted himself well, in describing and improving the method of his friend; and the world is particularly obliged to him for the historical part of his paper, as it contains valuable information, which perhaps no one else could have written.

London practice of dividing large instruments.

The only method of dividing large instruments now practised in London, that I know of beside my own, has not yet, I believe, been made public. It consists in dividing by hand with beam compasses and spring dividers, in the usual way; with the addition of examining the work by microscopes, and correcting it, as it proceeds, by pressing forwards or backwards by hand, with a fine conical point, those dots which appear erroneous; and thus adjusting them to their proper places. The method admits of considerable accuracy, provided the operator has a steady hand and good eye; but his work will ever be irregular and inelegant. He must have a circular line passing through the middle of his dots, to enable him to make and keep them at an equal distance from the centre. The bisectional arcs also, which cut them across, deform them much; and what is worse, the dots which require correction (about two-thirds perhaps of the whole) will become larger than the rest, and unequally so in proportion to the number of attempts, which have been found necessary to adjust them. In the course of which operation, some of them grow insufferably too large, and it becomes necessary to reduce them to an equality with their neighbours. This is done with the burnisher, and causes a hollow in the surface, which has a very disagreeable appearance. Moreover, dots which have been burnished up are always ill defined, and of a bad figure. Sir George Shuckburg Evelyn, in his paper on the Equatorial, ‡ denominates these 'doubtful or bad points;' and (considering the few places which he examines) they bear no inconsiderable proportion to the whole. In my opinion, it would be a great improvement of this method, to divide the whole by hand at once, and afterward to correct the whole; for a dot forced to its place as above, will seldom allow the compass-point to rest in the centre of its apparent area; therefore other dots made from these will scarcely ever be found in their true places. This improvement also prevents the corrected dots from being injured or moved by the future application of the compasses, no such application being necessary.

Its defects.

Its tediousness.

I will now dismiss this method of dividing, with observing, that it is tedious in the extreme; and did I not know the contrary beyond a doubt, I should have supposed it to have surpassed the utmost limit of human patience. § When I made my first essay at subdividing with the roller, I used this method, according to the improvement suggested above, of correcting a few primitive points; but even this was too slow for one who had too much to do. Perhaps, however, had my instruments been divided for me by an assistant, I might not have grudged to have paid him for the labour of going through the whole work by the method of adjustment; nor have felt the necessity of contriving a better way.

Mr E. Troughton's method.

I might now extend the account of my method of dividing to a great length, by relating the alterations which the apparatus has undergone during a long course of years, ‖ and the various manner of its application, before I brought it to its present state of improvement; but I think I may save myself this trouble, for truly I do not see its use. I will, therefore, proceed immediately to a disclosure of the method, as practised on a late occasion, in the dividing of a four feet meridian circle, now the property of Stephen Groombridge, Esq. of Blackheath.

* That Bird's scale was not without considerable errors, will be shewn towards the end of this paper.

† Phil. Trans. for 1788.

‡ Phil. Trans. for 1793.

§ At the time alluded to, the double microscopic micrometer was unknown to me, and I did not learn its use, for these purposes, till the year 1790, from General Roy's description of the large theodolite. Previous to that time, I had used a frame, which carried a single wire very near the surface to be divided. This wire was moveable by a fine micrometer screw, and was viewed by a single lens inserted in the lower end of a tube, which, for the purpose of taking off the parallax, was four inches long. The greatest objection to this mode of constructing the apparatus is, that the wire, being necessarily exposed, is apt to gather up the dust; yet it is preferable to the one now in use, in cases where any doubt is entertained of the accuracy of the plane which is to receive the divisions.

‖ The full conception of the method had occupied my mind in the year 1778; but, as my brother could not be readily persuaded to relinquish a branch of the business to me in which he himself excelled, it was not until September 1785 that I produced my first specimen, by dividing an astronomical quadrant of two feet radius.

1

riginal Graduation. Dcribed.

The surface of the circle which is to receive the divisions, as well as its inner and outer edges, but especially the latter, should be turned in the most exact and careful manner; the reason for which will be better understood, when we come to describe the mode of applying the roller: and, as no projection can be admitted beyond the limb, if the telescope, as is generally the case, be longer than the diameter, those parts which extend farther, must be so applied, that they may be removed during the operation of dividing. Fig. 1. and 2. Plate CCLXXXIII. represent the principal parts of the apparatus; Fig. 1. showing the plan, and Fig. 2. the elevation; in both of which the same letters of reference are affixed to corresponding parts, and both are drawn to a scale of half dimensions. AA is a part of the circle, the surface of which is seen in the plan, and the edge is seen in the elevation. BBB is the main plate of the apparatus, resting with its four feet *a*, *a*, *a*, *a* upon the surface of the arc; these feet, being screws, may be adjusted to as to take equal shares of the weight, and then are fastened by nuts below the plate, as shown in Fig. 2. CC and DD are two similar plates, each attached to the main plate, one above and the other below, by four pillars; and in them are centred the ends of the axis of the roller E. F and G are two friction wheels, the latter firmly fastened to B, but the former is fixed in an adjustable frame, by means of which adjustment these wheels and the roller E may be made to press, the former on the interior, and the latter on the exterior edge of the circle, with an equal and convenient force.* At the extremities of the axis of the roller, and attached to the middle of the plates C and D, are two bridges *c*, *c*, having a screw in each; by means of which an adjustment is procured for raising or lowering the roller respecting the edge of the circle, whereby the former, having its diameter at the upper edge about .001 of an inch greater than at the lower edge, (being, as before described, a little conical,) it may easily be brought to the position where it will measure the proper portion of the circle.

Apparatus. Plate CCLXXXIII Figs. 1, 2.

The roller.

Much experience and thought upon the subject have taught me, that the roller should be equal to one sixteenth part of the circle to be divided, or that it should revolve once in 22° 30′; and that the roller itself should be divided into sixteen parts; no matter whether with absolute truth, for accuracy is not at all essential here. Each of such divisions of the roller will correspond with an angle upon the circle of 1° 24′ 22″.5, or $\frac{1}{256}$th part of the circle. This number of principal divisions was chosen, on account of its being capable of continual bisection; but they do not fall in with the ultimate divisions of the circle, which are intended to be equal to 5′ each.

Microscopes.

The next thing to be considered is, how to make the roller measure the circle. As two microscopes are here necessary, and those which I use are very simple, I will in this place give a description of them. Fig. 6. is a section of the full size, and sufficiently explains their construction, and the position of the glasses; but the micrometer part and manner of mounting it, are better shown at H, in Fig. 1. and 2. The micrometer part consists of an oblong square frame, which is soldered into a slit, cut at right angles in the main tube; another similar piece nicely fitted into the former, and having a small motion at right angles to the axis of the microscope, has at one end a cylindrical guide pin, and at the other a micrometer screw; a spring of steel wire is also applied, as seen in the section, to prevent play, by keeping the head of the micrometer in close contact with the fixed frame. This head is divided into one hundred parts, which are numbered each way to 50; the use of which will be shown hereafter. A fine wire is stretched across the moveable frame, for the purpose of bisecting fine dots. Two of these microscopes are necessary; also a third, which need not have the divided head, and must have in the moveable frame two wires crossing each other at an angle of about 30°: this miscroscope is shown at I, Fig. 1. In the two first micrometers, a division of the head is of the value of about 0″.2, and the power and distinctness such, that when great care is taken, a much greater error than to the amount of one of these divisions cannot well be committed in setting the wire across the image of a well made dot. The double eye-glass has a motion by hand, for producing distinct vision of the wire; and distinct vision of the dots is procured by a similar adjustment of the whole microscope.

Micrometer.

Original Graduation.

Adjustment of the size of the roller.

The first step towards sizing the roller, is to compute its diameter according to the measure of the circle, and to reduce it agreeably thereto, taking care to leave it a small matter too large. The second step is, after having brought the roller into its place in the plate BB, to make a mark upon the surface of the circle near the edge, and a similar one upon the roller, exactly opposite each other; then carrying the apparatus forward with a steady hand, until the roller has made sixteen revolutions. If now, the mark upon the roller, by having over-reached the one upon the circle, shows it to be much too large, take it out of the frame and reduce it by turning accordingly: when, by repeating this, it is found to be very near, it may be turned about .001 of an inch smaller on the lower edge, and so far its preparation is completed. The third and last step is, the use and adaptation of the two microscopes; one of these must take its position at H in Fig. 1. viewing a small well-defined dot made for the purpose on the circle; the other, not represented in the Figure, must also be fixed to the main plate of Fig. 1. as near to the former as possible, but viewing one of the divisions on the roller. With a due attention to each microscope, it will now be seen to the greatest exactness, when, by raising or depressing the roller, its commensurate diameter is found.

Use and adaptation of the two microscopes.

Apparatus for making the dots in the circle.

Fig. 3. is a representation of the apparatus for transferring the divisions of the roller to the circle. It consists of two slender bars, which, being seen edgewise in the figure, have only the appearance of narrow lines; but, when looked at from above, they resemble the form of the letter A. They are fastened to the main frame, as at W and Z, by short pillars, having also the off leg of the angle secured in the same manner; Y is a fine conical steel point for making the dots, and X is a feeler, whereby the point Y may be pressed down with a uniform force, which force may be adjusted, by bending the end of the bar just above the point, so as to make the dots of the proper size. The point Y yields most readily to a perpendicular action; but is amply secured against any eccentric or lateral deviation.

Primary dots.

The apparatus, so far described, is complete for laying our foundation, *i. e.* making 256 primary dots; no matter whether with perfect truth or not, as was said respecting the divisions of the roller; precision in either

* Sufficient spring for keeping the roller in close and uniform contact with the edge of the circle is found in the apparatus, without any particular contrivance for this purpose. The bending of the pillars of the secondary frames, and of the axis of the roller, chiefly supplies this property.

Original Graduation.

is not to be expected, or wished; but it is of some importance, that they should be all of the same size, concentric, small, and round. They should occupy a position very near the extreme border of the circle, as well to give them the greatest radius possible, as that there should be room for the stationary microscope and the other mechanism, which will be described hereafter.

It must be noticed, that there is a clamp and adjusting screw attached to the main plate of Fig. 1; but, as it differs in no respect from the usual contrivances for quick and slow motion, it has been judged unnecessary to incumber the drawing with it.

Method of making the dots.

Now the roller having been adjusted, with one microscope H upon its proper dot on the circle, and the other microscope at the first division on the roller; place the apparatus of Fig. 3. so that the dotting point Y may stand directly over the place which is designed for the beginning of the divisions. In this position of things, let the feeler X be pressed down, until its lower end comes into contact with the circle; this will carry down the point, and make the first impression, or primary dot, upon the circle; unclamp the apparatus, and carry it forwards by hand, until another division of the roller comes near the wire of the microscope; then clamp it, and with the screw motion make the coincidence complete; where again press upon the feeler for the second dot: proceed in this manner until the whole round is completed.

Method of ascertaining the errors of the dots.

From these 256 erroneous divisions, by a certain course of examination, and by computation, to ascertain their absolute and individual errors, and to form these errors into convenient tables, is the next part of the process, and makes a very important branch of my method of dividing.

The apparatus must now be taken off, and the circle mounted in the same manner as it will be in the observatory. The two microscopes, which have divided heads, must also be firmly fixed to the support of the instrument, on opposite sides, and their wires brought to bisect the first dot, and the one which should be 180° distant. Now, the microscopes remaining fixed, turn the circle half round, or until the first microscope coincides with the opposite dot; and, if the other microscope be exactly at the other dot, it is obvious that these dots are 180° apart, or in the true diameter of the circle; and if they disagree, it is obvious that half the quantity by which they disagree, as measured by the divisions of the micrometer head, is the error of the opposite division; for the quantity measured is that by which the greater portion of the circle exceeds the less. It is convenient to note these errors + or —, as the dots are found too forward or too backward, according to the numbering of the degrees; and for the purpose of distinguishing the + and — errors, the heads, as mentioned before, are numbered backwards and forwards to fifty. One of the microscopes remaining as before, remove the other to a position at right angles; and, considering for the present both the former dots to be true, examine the other by them; *i. e.* as before, try by the micrometer how many divisions of the head the greater half of the semicircle exceeds the less, and note half the quantity + or —, as before, and do the same for the other semicircle. One of the micrometers must now be set at an angle of 45° with the other, and the half differences of the two parts of each of the four quadrants registered with their respective signs. When the circle is a vertical one, as in the present instance, it is much the best to proceed so far in the examination with it in that position, for fear of any general bending or spring of the figure; but, for the examination of smaller arcs than 45°, it will be perfectly safe, and more convenient, to have it horizontal; because the dividing apparatus will then carry the micrometers, several perforations being made in the plate B for the limb to be seen through at proper intervals. The micrometers must now be placed at a distance of 22° 30′, and the half differences of the parts of all the arcs of 45° measured and noted as before; thus descending by bisections to 11° 15′, 5° 37′ 30″, and 2° 48′ 45″. Half this last quantity is too small to allow the micrometers to be brought near enough; but it will have the desired effect, if they are placed at that quantity and its half, *i. e.* 4° 13′ 7″.5; in which case the examination, instead of being made at the next, will take place at the next division but one to that which is the subject of trial. During the whole of the time that the examination is made, all the dots, except the one under examination, are for the present supposed to be in their true places; and the only thing in this most important part of the business, from first to last, is to ascertain with the utmost care, in divisions of the micrometer head, how much one of the parts of the interval under examination exceeds the other, and carefully to tabulate half of their difference.

The instrument to be engraved before dividing.

I will suppose that every one, who attempts to divide a large astronomical instrument, will have it engraved first. Dividing is a most delicate operation, and every coarser one should precede it. Besides, its being numbered is particularly useful to distinguish one dot from another: thus, in the two annexed tables of errors, (see p. 380, 381.) the side columns give significant names to every dot, in terms of its value to the nearest tenth of a degree, and the mistaking of one for another is rendered nearly impossible.

Table of apparent errors.

The foregoing examination furnishes materials for the construction of the table of half differences, or apparent errors.* The first line of this table consists of two varieties; *i. e.* the micrometers were at 180° distance for obtaining the numbers which fill the columns of the first and third quadrant; and at 90° for those of the second and fourth quadrant. The third variety makes one line, and was obtained with a distance of 45°: the fourth consists of two lines, with a distance of 22° 30′: the fifth of four lines, with a distance of 11° 15′: the sixth of eight lines, with a distance of 5° 37′ 30″: the seventh of sixteen lines, with a distance of 2° 48′ 45″: and the eighth and last variety, being the remainder of the table, consist of thirty-two lines, and was obtained with a distance of 4° 13′ 7″ 5.

Table of errors.

The table of apparent errors, or half differences, just explained, furnishes data for computing the table of real errors. The rule is this: let a be the real error of the preceding dot, and b that of the following one, and c the apparent error, taken from the table of half differences, of the dot under investigation; then is $\frac{a+b}{2}+c=$ its real error. But, as this simple expression may not be so generally understood by workmen as I wish, it may be necessary to say the same thing less concisely. If the real errors of the preceding and following dots are both +, or both —, take half their sum, and prefix thereto the common sign; but if one of them is + and the other —, take half their difference,

* If the table of real errors be computed as the work of examination proceeds, there will be no occasion for this table at all; but I think it best not to let one part interfere with another, and therefore I examine the whole before I begin to compute.

Original Graduation.

prefixing the sign of the greater quantity: again, if the apparent error of the dot under investigation has the same sign of the quantity found above, give to their sum the common sign for the real error; but if their signs are contrary, give to their difference the sign of the greater for the real error. I add a few examples.

Example 1.

For the first point of the second quadrant.	
Real error of the first point of the first quadrant	— 0.0
Real error of the first point of the third quadrant	— 6.9
Half sum or half difference	— 3.4
Apparent error of the dot under trial .	+ 12.2
Real error	+ 8.8

Example 2.

For the point 45° of the second quadrant.	
Real error of the first point of the quadrant	+ 8.8
Real error of the last point of the quadrant	— 6.9
Half difference	+ 0.9
Apparent error of the dot under trial . .	— 8.9
Real error	— 8.0

Example 3.

Point 88°.6, or last point, of the third quadrant.	
Real error of the point 84°.4 of the third quadrant	— 21.0
Real error of the point 2°.8 of the fourth quadrant	— 2.9
Half sum	— 11.9
Apparent error of the dot under trial . .	— 4.0
Real error	— 15.9

Example 4.

Point 88°.6, or last, of the fourth quadrant.	
Real error of the point 84°.4 of the fourth quadrant	— 21.6
Real error of the point 2°.8 of the first quarant	— 10.2
Half sum	— 15.0
Apparent error of the dot under trial . .	+ 9.5
Real error	— 6.4

It is convenient, in the formation of the table of real errors, that they should be inserted in the order of the numbering of the degrees on their respective quadrants; although their computation necessarily took place in the order in which the examination was carried on, or according to the arrangement in the table of apparent errors. The first dot of the first quadrant having been assumed to be in its true place, the first of the third quadrant will err by just half the difference found by the examination; therefore these errors are alike in both tables. The real error of the first dot of the second quadrant comes out in the first example; that of the fourth was found in like manner, and completes the first line. It is convenient to put the error of the division 90° of each quadrant at the bottom of each column, although it is the same as the point 0° on the following quadrant. The line 45° is next filled up; the second example shows this; but there is no occasion to dwell longer upon this explanation; for every one, who is at all fit for such pursuits, will think what has already been said fully sufficient for his purpose. However, I will just mention, that there can be no danger, in the formation of this table, of taking from a wrong line the real errors which are to be the criterion for finding that of the one under trial, because they are in the next line to it, the others, which intervene in the full table, not being yet inserted. The last course of all is, however, an exception; for, as the examining microscopes could not be brought near enough to bisect the angle 2° 48′ 45″, recourse was had to that quantity and its half; on which account the examination is prosecuted by using errors at two lines distance, as is shown in the two last examples.

All the computations should be preserved.

When the table of real errors is constructed, the other table, although it is of no farther use, should not be thrown away; for if any material mistake has been committed, it will be discovered as the operation of dividing is carried on, and in this case the table of apparent errors must be had recourse to; indeed not a figure should be destroyed until the work is done. *

Respecting the angular value of the numbers in these tables, it may be worth mentioning that it is not of the least importance, 100 of them being comprised in one revolution of the micrometer screw; and, in the instance before me, 5.6 of them made no more than a second. It is not pretended that one of these parts was seen beyond a doubt, being scarcely $\frac{1}{10000}$ of an inch, much less the tenths, as exhibited in the tables; but as they were visible upon the micrometer heads, it was judged best to take them into the account.

True divisions to be made from the erroneous dots.

Having now completed the two first sections of my method of dividing; namely, the first, which consists of making 256 small round dots; and the second, in finding the errors of these dots, and forming them into a table; I come now to the third and last part, which consists in using the erroneous dots in comparison with the tabulated errors, so as ultimately to make from them the true divisions.

Subdividing sector described.

It will here be necessary to complete the description of the remaining part of the apparatus. And, first, a little instrument which I denominate a subdividing sector presents itself to notice. From all that has hitherto been said, it must have been supposed, that the roller itself will point out, upon the limb of the instrument to be divided, spaces corresponding to others previously divided upon itself, as was done in setting off the 256 points: but, to obviate the difficulty of dividing the roller with sufficient exactness, recourse was had to this sector; which also serves the equally important purpose of reducing the bisectional points to the usual division of the circle. This sector is represented of half its dimensions by Fig. 5, Plate CCLXXXIII. It is formed of thin brass, and centered upon the axis at A, in contact with the upper surface of the roller: it is capable of being moved round by hand; but, by its friction upon the axis, and its pressure upon the roller, it is sufficiently prevented from being disturbed by accident. An internal frame BB, to which the arc CC is attached, moves freely in the outer one, and by a spring D is pushed outwards, while the screw E, the point of which touches the frame B, confines the arc to its proper radius. The arc of this sector is of about four times greater radius than the roller, and upon it are divided the spaces which must be transferred to the instrument as represented on a magnified scale by Fig. 4. Now, the angle of one of the spaces of the circle will be measured by sixteen times its angular value upon the sectorial arc, or 22° 30′; but this does not represent any number of equal parts upon the instrument, the subdivisions of which are to be 5′ each; for $\frac{1° 24' 22''.5}{5}$ is exactly $16\frac{7}{8}$, therefore so many divisions are exactly equal to a mean

Plate CCLXXXIII. Fig. 5.

* This is a very useful hint, applicable on many occasions.

Original Graduation.

Plate CCLXXXIII. Fig. 4.

space between the dots, the errors of which have been tabulated. Let, therefore, the arc of the sector be divided into 16 spaces of 1° 20′ each, and let a similar space at each end be subdivided into eight parts of 10′ each, as in Fig. 4; we shall then have a scale which furnishes the means for making the true divisions, and an immediate examination at every bisectional point.

Dividing by the engine.

I have aways divided the sector from the engine, because that is the readiest method, and inferior to none in point of accuracy, where the radius is very short; but, as it is more liable than any other to centrical error, the adjustment of the arc by the screw E becomes necessary: by that adjustment, also, any undue run in the action of the roller may be reduced to an insensible quantity.

Division by lines preferable to dots.

When the utmost degree of accuracy is required, I give the preference to dividing by lines, because they are made with a less forcible effort than dots are; and also because, if any small defect in the contexture of the metal causes the cutter to deviate, it will, after passing the defective part, proceed again in its proper course, and a partial crookedness in the line will be the only consequence; whereas a dot, under similar circumstances, would be altogether displaced. But, on the other hand, where accuracy has been out of the question, and only neatness required, I have used dots; and I have done so, because I know that when a dot and the wire which is to bisect it are in due proportion to each other, (the wire covering about two-thirds of the dot,) the nicest comparison possible may be obtained. It may be farther observed, that division by lines is complete in itself; whereas that by dots requires lines to distinguish their value.

Apparatus for cutting the divisions.

On the upper side of Fig. 1. is represented the apparatus for cutting the divisions. It consists of three pieces JKL, jointed together so as to give to the cutter an easy motion, for drawing lines directly radiating from the centre, but inflexible with respect to lateral pressure; *dd* are its handles. The cutting point is hidden below the microscope H; it is of a conical form, and were it used as a dotting point, it would make a puncture of an elliptical shape, the longer diameter of which would point towards the centre. This beautiful contrivance, now well known, we owe to the ingenuity of the late Mr Hindley of York; it was borrowed by Mr Ramsden, * and applied with the best effect to his dividing engine.

Invented by Mr Hindley.

It might have been mentioned sooner, that in the instance which I have selected as an example of my dividing, the operation took place when the season of the year, and the smoke of London, had reduced the day to scarcely six hours of effective light; and rather than confine my labours within such narrow limits, I determined to shut out the day-light altogether. Fig. 7. shows the construction of the lanterns which I used. A very small wick gave sufficient light, when kept from diverging by a convex lens; while the inclining nossel was directed down exactly upon the part looked at, and the light, having also passed through a thin slice of ivory, was divested of all glare. I enter into this description, because, I think, I never saw my work better, nor entirely to so much advantage as in this instance; owing, perhaps, to the surrounding darkness allowing the pupil of the eye to keep itself more expanded, than when indirect rays are suffered to enter it. The heat from a pair of these lanterns was very inconsiderable, and chiefly conducted along with the smoke up the reclining chimney.

Lanterns employed. Fig. 7.

Previous to cutting the divisions, the parts now described must be adjusted. The cutting apparatus must be placed with the dividing point exactly at the place where the first line is intended to be drawn, and clamped, so that the adjusting screw may be able to run it through a whole interval. The microscope H must be firmly fixed by its two pillars *b*, *b* to the main frame, with its micrometer head at *zero*; and with its only wire in the line of the radius, bisecting the first of the 256 dots. And it should be observed, that the cutting frame and this must not vary respecting each other, during the time that the divisions are cut; for any motion that took place in either would go undiminished to the account of error. The microscope I is also fastened to the main frame; but it is only required to keep its position unvaried, while the divisions of the sector pass once under its notice; for it must have its wires adjusted afresh to these divisions at every distinct course. The microscope I has two wires, crossing each other at an angle of about 40°; and these are to be placed so as to make equal angles with the divisions of the sector, which are not dots but lines. The sectorial arc must also be adjusted to its proper radius by the screw E, Fig. 5; *i. e.* while the main frame has been carried along the circle through a mean interval shewn by H, the sector must have moved though exactly $16\frac{7}{8}$ths of its divisions, as indicated by I. †

Things being in this position; after having given the parts time to settle, and having also sufficiently proved the permanence of the micrometer H and the cutting frame with respect to each other, the first division may be made; then, by means of the screw for slow motion, carry the apparatus forward, until the next line upon the sector comes to the cross wires of I; you then cut another divison, and thus proceed until the 16th division is cut, $= 1° 20'$: Now, the apparatus wants to be carried further, to the amount of $\frac{7}{8}$ths of a division, before an interval is complete; but at this last point no division is to be made; we are here only to compare the division on the sector with the corresponding dot upon the instrument. This interval, however, upon the circle, will not be exactly measured by the corresponding line of the sector, which has been adjusted to the mean interval, for the situation of the dot 1°.4 is too far back, as appears by the table of real errors, by — 4.8 divisions of the micrometer head. The range of the screw for slow motion must now be restored, the cross wires of H set back to — 4.8 divisions, and the sector moved back by hand, but not to the division 0 where it began before; for, as it left off in the first interval at $\frac{7}{8}$ths of a division, it has to go forwards $\frac{1}{8}$th more before it will arrive at the spot where the 17th division of the instrument 1° 25′ is to made, so that in this second course it must begin at $\frac{1}{8}$th short of 0. Go through this interval as before, making a division upon the circle at every one of the 16 great

* This I learned from that most accurate artist Mr John Stancliffe, who was himself apprentice to Hindley.

† For the sake of simplicity, the account of the process is carried on as if the roller measured the mean interval without error. But it was said (Page 371), that the roller, in a continued motion quite round the circle, would, in some part of its course, err by 30″, or more; therefore, when this is the case, an extreme run of the roller cannot agree with a mean interval of the circle nearer than $\frac{30''}{12} = 0.23''$; and most probably this kind of error will, on some intervals, amount to double that quantity. It, therefore, becomes matter of prudent precaution, to examine every interval previous to making the divisions; and, where necessary, to adjust the sector, so that its arc may exactly measure the corresponding interval as corrected by the tabulated errors.

divisions of the sector; and H should now reach the third dot, allowing for a tabular error of — 10.2 when the division $\frac{4}{5}$ths of the sector reaches the cross wires of I. It would be tedious to lead the reader through all the variety of the sector, which consists of eight courses; and it may be sufficient to observe, that at the commencement of every course, it must be put back to the same fraction of a division which terminated its former one; and that the wire of the micrometer H must always be set to the tabular error belonging to every dot, when we end one interval and begin another. The eight courses of the sector will have carried us through $\frac{1}{32}$d part of the circle, 11° 15′, and during this time the roller will have proceeded through half a revolution; for its close contact with the limb of the circle does not allow it to return with the sector when the latter is set back at every course. Having in this manner proceeded, from one interval to another, through the whole circle, the micrometer at last will be found with its wire at *zero*, on the dot from which it set out; and the sector, with its 16th division, coinciding with the wires of its microscope.

Advantages of this method.

Having now given a faithful detail of every part of the process of dividing this circle, I wish to remind the reader, that, by verification and correction at every interval, any erroneous action of the roller is prevented from extending its influence to any distant interval. It will be farther observed, that the subdividing sector magnifies the work; that by means of its adjustable arc, it makes the run of the roller measure its corresponding intervals upon the circle; and, without foreign aid, furnishes the means of reducing the bisectional intervals to the usual division of the circle. Farthermore, the motion of the wire of the micrometer H, according to the division of its head and corresponding table of errors, furnishes the means of prosecuting the work with nearly the same certainty of success, as could have happened, had the 256 points been (which in practice is quite impossible) in their true places.

Why termed dividing by the eye.

Now, the whole of my method of dividing being performed by taking short measures with instruments which cannot themselves err in any sensible degree, and, inasmuch as those measures are taken, not by the hand, but by vision, and the whole performed by only looking at the work, the eye must be charged with all the errors that are committed until we come to cut the divisions; and, as in this last operation the hand has no more to do than to guide an apparatus so perfect in itself, that it cannot be easily made to deviate from its proper course, I would wish to distinguish it from the other methods, by denominating it, *dividing by the eye*. *

Few persons capable of dividing originally.

The number of persons at all capable of dividing originally have hitherto been very few: the practice of it being so limited, that in less than twice seven years, a man could hardly hope to become a workman in this most difficult art. How far I shall be considered as having surmounted these difficulties, I know not; but if, by the method here revealed, I have not rendered original dividing almost equally easy with what copying was before, I have spent much labour, time, and thought in vain. I have no doubt, indeed, that any careful workman who can divide in common, and has the ability to construct an astronomical instrument, will, by following the steps here marked out, be able to divide it, the first time he tries, better than the most experienced workman, by any former method.

Subdivision with the screw instead of the roller.

If, instead of subdividing with the roller, the same thing be performed with the screw, it will not give to dividing by the eye any very distinctive character: I have practised this on arcs of circles with success, the edge being slightly racked, the screw carrying forward an index with the requisite apparatus, and having a divided micrometer head; the latter answers to the subdividing sector, and, being used with a corresponding table of errors, forms the means of correcting the primitive points; but the roller furnishes a more delicate action, and is by far more satisfactory and expeditious.

Six feet circle for the Royal Observatory, dividing on its edge.

It is known to many, that the six feet circle, which I am now at work upon for our Royal Observatory, is to be divided upon a broad edge, or upon a surface at right angles to the usual plane of division: the only alterations which will on this account be required, are, that the roller must act upon that plane which is usually divided upon; which roller, being elevated or depressed, may be adjusted to the commensurate radius without being made conical, as was necessary in the other case. The apparatus, similar to the other, must here be fixed immoveably to the frame which supports the circle: its position must be at the vertex, where also I must have my station; and the instrument itself must be turned around its axis, in its proper vertical position, as the work proceeds. The above may suffice, for the present, to gratify those who feel themselves interested upon a subject which will be better understood, if I should hereafter have the honour of laying before the Royal Society a particular description of the instrument here alluded to; a task which I mean to undertake, when, after being fixed in the place designed for it, which I hope will be effected at no very distant period, it shall be found completely to answer the purposes intended. See Circle, Vol. VI. p. 485.

A circle may readily be divided centesimally, and in the common way.

Should it be required to divide a circle according to the centesimal division of the quadrant, as now recommended and used in France, we shall have no difficulty. The 100° of the quadrant may be conveniently subdivided into 10 each, making 4000 divisions in the whole round. The 256 bisectional intervals, the two tables of errors, and the manner of proceeding and acting upon them, will be exactly the same as before,

* I must here remark, that Smeaton has represented the greatest degree of accuracy that can be derived from vision, in judging of the coincidence of two lines, at $\frac{1}{4000}$th part of an inch. From this it may fairly be inferred, that he had not cultivated the power of the sight, as he had done that of the touch; the latter of which, with that ability which appeared in all his works, he rendered sensible to the $\frac{1}{60000}$th part of an inch. Were materials infinitely hard, no bounds could be set to the precision of contact; but taking things as they are, the different degrees of hardness in matter, may be considered as a kind of magnifying power to the touch, which may not unaptly be compared with the assistance which the eye receives from glasses. It is now quite common to divide the seaman's sextant to 10″, and a good eye will estimate the half of it; which, on an eight-inch radius, is scarcely $\frac{1}{10000}$th of an inch. This quantity, small as it is, is rendered visible by a glass of one inch focal length; and such is the certainty with which these quantities are seen, that a seaman will sometimes complain that two pair of these lines will coincide at the same time; and this may happen, and yet no division of his instrument err, by more than $\frac{1}{4000}$th part of an inch. All this is applicable to judging of the coincidence of lines with each other, and furnishes not the most favourable display of the accuracy of vision. But with the microscopes here described, where the wire bisects the image of a dot, or a cross wire is made to intersect the image of a line, by an eye practised in such matters, a coincidence may undoubtedly be ascertained to $\frac{1}{30000}$th part of an inch. I am of opinion, that as small a quantity may be rendered visible to the eye, as can by contact be made sensible to the touch; but whether Mr Smeaton's $\frac{1}{60000}$ and my $\frac{1}{30000}$ be not the same thing, I will not determine; the difference between them, however, is what he would no more have pretended to feel, than I dare pretend to see.

Original Graduation.

until we come to cut the divisions; and for this purpose we must have another line divided upon the sector. For $\frac{1}{4000}$th part of the circle being equal to 5′.4 of the usual angular measure $\frac{1^\circ\, 24'\, 22''.5}{5'.4} = 15\frac{5}{8}$ divisions; and just so many will be equivalent to one of the intervals of the circle. The value of one of the great divisions of the sector will be 1° 26′ 24″, and that of the $\frac{1}{8}$th parts, which are to be annexed to the right and left as before, will be 10′.48″, therefore divisible by the engine. Should any astronomer choose to have both graduations upon his instrument, the additional cost will be a mere trifle, provided both were done at the same time.

Dividing by the eye applicable to straight lines as well as circles.

It must already have been anticipated, that dividing by the eye is equally applicable to straight lines as it is to circles. An apparatus for this purpose should consist of a bar of brass, three quarters of an inch thick, and not less than three inches broad; six feet may do very well for the length; it may be laid upon a deal plank strengthened by another plank screwed edgewise on its lower surface. The bar should be planed on both its edges and on its surface, with the greatest exactness; and it will be better if it has a narrow slip of silver, inlaid through its whole length, for receiving the dots. An apparatus nearly similar to the other should slide along its surface, carrying a roller, the circumference of which is 12.8 inches, and turned a little conical for the sake of adjustment. The roller may be divided into 32 parts, each of which, when transferred to the bar, will give intervals of 0.4 of an inch each: the angle of the subdividing sector should of course be 11° 15′, and subdivided into four parts, which will divide the inch into tenths: the surface may also receive other lines, with subdivisions suited to the different purposes for which it may be wanted. The revolutions of the roller and its $\frac{1}{32}$ parts must be dotted upon the bar; taking care, by sizing the roller, to come as near the true standard measure as possible: when this is done, compare the extent of the greater bisectional number that is contained in the length, *i. e.* 128 intervals or 51.2 inches, with the standard measure; noting the difference as indicated by the micrometer heads: the examination and construction of the table of errors may then be conducted just as was done for the circle.

Apparatus for the purpose.

Method of using it.

Being now ready for the performance of its work, the scale to be divided must be laid alongside of the bar, and the true divisions must be cut upon it by an appeal, as before, to the erroneous dots on the bar, corrected by a corresponding table of errors. The apparatus, remaining entire in the possession of the workman, with its primitive dots, the table of errors, &c. is ready for dividing another standard, which will be precisely similar to others that have been, or may be, divided from it. It may be considered, indeed, as a kind of engine; and, as it is not vitiated by the coarse operation of racking with a screw, but performed by only looking at the work, the method will command about three times the accuracy that can be derived from the usual straight-line dividing engine. Should it be asked, if an engine thus appointed would succeed for dividing circles? I answer, Yes; but I would not recommend it; because, beyond a certain extent of radius, it is not necessary; for the errors, which would be introduced into the work by the violence of racking a large wheel, are sufficiently reduced by the comparative shortness of the radius of such instruments as we divide by that method: and, what is still more to the purpose, the dividing engine is four times more expeditious, and bears rough usage better. I cannot quit the subject of dividing straight lines without observing, that I never had my apparatus complete. The standard which I made for Sir George Shuckburgh Evelyn in 1796, was done by a mere make-shift contrivance, upon the principle of dividing by the eye; how I succeeded, may be seen in Sir George's papers on Weights and Measures, in the *Phil. Trans.* for 1798. I made a second, some years after, for Professor Pictet of Geneva, which became the subject of comparison with the new measure of France, before the National Institute; and their report, drawn up by Mr Pictet, has been ably re-stated and corrected by Dr Young, as published in the Journals of the Royal Institution. I made a third for the magistrates of Aberdeen. I notice the two latter, principally to give myself an opportunity of saying, that, if those three scales were to be compared together, notwithstanding they were divided at distant periods of time, and at different seasons of the year, they would be found to agree with each other as nearly as the different parts of the same scale agree.

It might be used for dividing circles, but not to be recommended.

Constr[uc]tion o[f] standa[rd] measu[re].

Inad[ver]tency [of] G. Sh[uck]burgh [E]lyn.

I hope I may here be allowed to allude to an inadvertency which has been committed in the paper mentioned above; and which Sir George intended to have corrected, had he lived to conclude his useful endeavours to harmonise the discordant weights and measures of this country. The instruments which he has brought into comparison are, his own five feet standard measure and equatorial; General Roy's forty-two inch scale; the standard of Mr Aubert; and that of the Royal Society. The inadvertency is this: in his equatorial, and the standard of the Royal Society, he has charged the error of the most erroneous extent, when compared with the mean extent, alike to both divisions; *i. e.* he has supposed one of the divisions, which bound the erroneous extent, to be too much to the right, and the other too much to the left, and that by equal quantities. This is certainly a good-natured way of stating the errors of work; and perhaps not unjustly so, where the worst part has been selected; but in the other three instances, namely, in General Roy's, Mr Aubert's, and his own standard, he has charged the whole error of the most erroneous extent to one of the bounding lines.

Gen[eral ac]cura[cy of] Bird['s di]vidin[g]. The [Green]wich [qua]drant.

I was well confirmed in my high opinion of the general accuracy of Bird's dividing, when, last winter,* I measured the chords of many arcs of the Greenwich quadrant. That instrument has indeed suffered, both from a change in its figure, and from the wearing of its centre; but the graduation, considering the time when it was done, I found to be very good. Sir George, in his paper upon the equatorial, (*Phil. Trans.* for 1793,) after some compliments paid to the divider of his instrument, says, "the late Mr John Bird seems to have admitted a probable discrepancy in the divisions of his eight feet quadrant, amounting to 3″;" and he refers to Bird on the construction of the Greenwich quadrant. This quantity being three times as great as any errors that I met with, I was lately induced to inquire how the matter stood. Bird, in the paper referred to, says, "in dividing this instrument, I never met with an inequality that exceeded one second. I will suppose, that in the 90 arch this error lay toward the left hand, and in the 96 arch that it lay towards the right, it will cause a difference between the two arches of two seconds; and, if an error of one second be allowed to the observer in reading off his observation, the whole amount is no more than three seconds, which is

* This paper was written in June 1808.

Original Graduation.

Compared with Sir G. Shuckburgh's equatorial.

agreeable to what I have heard, &c." Sir George's examination of his own equatorial furnishes me with the means of a direct comparison: in his account of the declination circle, we find an error $+2''.35$, and another $-1''.5$; to these add an error of half a second in each, for reading off, which Sir George also admits, we shall then have a discrepancy of $4''.85$; but, as the errors of reading off are not errors of division, let them be discharged from both, and the errors will then stand for the quadrant $2''$, and for the circle $3''.85$. As the radius of the former, however, is four times greater than that of the latter, it will appear, by this mode of trial, that the equatorial is rather more than twice as accurately divided as the quadrant. In doing justice to Bird in this instance, I have only done as I would be done by: for, should any future writer set me back a century on the chronological scale of progressive improvement, I hope some one will be found to restore me to my proper niche. I now subjoin a restatement of the greatest error of each of the instruments that are brought into comparison by Sir George, after having reduced them all by one rule, viz. allowing each of the two points which bound the most erroneous extent, to divide the apparent error equally between them. They are expressed in parts of an inch, and follow each other in the order of their accuracy.

Errors of different standards.

Sir George Shuckburgh's 5 feet standard	.000165
General Roy's scale of 42 inches	.000240
Sir George's equatorial, 2 feet radius	.000273
The Greenwich quadrant, 8 feet radius	.000465
Mr Aubert's standard, 5 feet long	.000700
*The Royal Society's standard, 92 inches long	.000795

For the justness of the above statement, I consider my name as pledged; requesting the permission to say, that if, on the result of each respective examination, as here presented, there could have been more than one opinion, it would not have appeared here. I am farther prompted to add, that the above comparative view presents one circumstance to our notice, which cannot do less than gratify every individual, who is at all conversant in these matters; I mean, the high rank which General Roy's scale takes in the list; that scale having been made the agent in measuring the base line of our national trigonometrical survey.

Care must be taken, to have the circle of a uniform temperature while turning the outer edge,

To return, finally, to the dividing of circles; I must state, as matter of precaution, that great care should be taken during the turning of the outer edge, to have the circle of the same temperature; for one part may be expanded by heat, or contracted by cold, so much more than another, as to cause the numbers in the tables of errors to be inconveniently large. A night is not more than sufficient for allowing the whole to take the same temperature, after having been handled by the workmen; and the finishing touch should be given within a short space of time. But, if the effects of temperature are to be regarded in turning a circle, it is of tenfold more importance to attend to this circumstance, while the examination of the larger arcs of the instrument is carried on; for it is absolutely necessary, that, during this time, the whole circle should be of the same heat exactly. Few workmen are sufficiently aware of this. They generally suppose the expansion of metals to be a trifle, which need not be regarded in practice; and wonder how the parts of a circle can be differently heated, without taking pains to make it so. One degree of Fahrenheit's thermometer indicates so small a portion of heat, that, in such places as workmen are usually obliged to do their business in, it is not very easy to have three thermometers attached to different parts of a large instrument, showing an equality of temperature within that quantity: Yet so necessary is correctness in this respect, that if a circle has the vertex one degree warmer than its opposite, and if this difference of temperature be regularly distributed from top to bottom, the upper semicircle will actually exceed the lower by $2''$: And, if such should happen to be the case while the examination of the first dot of the third quadrant is made, the regularity of the whole operation would thereby be destroyed.

and while examining the larger arcs.

Effects of temperature much more important than generally supposed.

The apparatus not expensive.

It may not be improper to remark, that dividing by the eye does not require a more expensive apparatus than the operation of dividing by hand; and, indeed, less so when the scale of inches is deemed necessary. The method by adjustment is still more expensive, requiring whatever tools Bird's method requires, and, in addition to these, a frame and microscopes, somewhat similar to those for dividing by the eye.

Much time saved by it.

It is somewhat more difficult to give a comparative estimate of the time, which the different methods of dividing require. I know, that 13 days of eight hours each, are well employed in dividing such a circle by my method; about 52 days would be consumed in doing the same thing by Bird's method; and I think I cannot err much, when I state the method by adjustment, supposing every dot to be tried, and that two thirds of them want adjusting, to require about 150 of such days.

The economy of time, (setting aside the decided means of accuracy,) which the above estimate of its application offers to view, will, I think, be considered of no little moment. By the rising artist, who may aspire to excellence, it will at least, and I should hope with gratitude, be felt in the abbreviation of his labours. To me, indeed, the means of effecting this became indispensible; and it has not been without a sufficient sense of its necessity, that I have been urged to the progressive improvement and completion of these means, as now described. It is but little that a man can perform with his own hands alone; nor is it on all occasions, even in frames of firmer texture than my own, that he can decisively command their adequate, unerring use. And I must confess, that I never could reconcile it to what I hold as due to myself, as well as to a solicitous regard for the most accurate cultivation of the science of astronomy, to commit to others an operation requiring such various and delicate attentions, as the division of my instruments.

That my attentions on this head have not failed to procure for me the notice and patronage of men, whose approbation makes, with me, no inconsiderable part of my reward, I have to reflect on with gratitude and pleasure: and as I look with confidence to the continuance of that patronage, so long as the powers of execution shall give me the inclination to solicit it, I cannot entertain a motive, which might go to extinguish the more liberal wish of pointing out to future ingenuity a shorter road to eminence; sufficiently gratified by the idea of having, in the present communication, contributed to facilitate the operations, and to aid the progress of art, (as far as the limited powers of vision will admit,) toward the point of perfection."

* This is the same which Mr Bird used in dividing his eight feet mural quadrants, and was presented to the Royal Society by Bird's executors.

Remarks on Mr Troughton's method of dividing.

It can hardly have escaped notice, on perusing the above account, how strictly Troughton has adhered to the *maxim* of Graham. Beginning with bisecting the circle, he has, by his mode of examination, without a change, followed the principle through eight successive courses. The action of the roller is stepping, notwithstanding that it consists of the exactest species of contact, and closes without a remainder; and so fully is he aware of this, that 256 checks are employed. As far as the examination and computation is carried, Troughton's method, for aught we know, may be as tedious as any other; but, by the contrivance of combining his subdividing-sector with the roller, he throws the quinquisections and trisections altogether into a species of engine dividing, and thereby reduces the remaining part of the work to a labour little surpassing that of cutting the divisions.

Mr Thomas Jones succeeds in dividing a circle by Mr Troughton's method.

After the above paper was published, several gentlemen were of opinion, that the celebrity of Troughton's graduation was owing more to the hand and eye of the artist, than to the method by which it was effected. Troughton, it will be remembered, in one part at least of the paper, expresses himself of a contrary opinion; and, to shew that he was not mistaken, we insert the following letter, which was addressed to him by a rising artist, who is not too conceited to profit by the skill and experience of a veteran in the art:

Letter from Mr Jones to Mr Troughton.

Dear Sir, "Charing-Cross, 15th July, 1813.

Having now performed the graduation of a circle by your method, I take the liberty of addressing to you the following lines upon the subject. The method which was used at Mr Ramsden's was, before your's appeared, considered as the best. I learned it in the course of instruction, and practised it with patience and perseverance, for it requires much of both. I may, therefore, be allowed to consider myself a competent judge of the two methods; and, without presuming more than becomes me, give an opinion concerning them. From various motives, I feel great pleasure in saying, that *dividing by the eye* is greatly preferable to the other method; the saving in time is very great, and accuracy in the result certain. With these properties, which it possesses in the first degree, were I debarred from using it in future, I should return to the old method with the greatest reluctance. I do not hesitate to say, that I feel myself equal to the dividing of a circle with a degree of accuracy equal to any one except yourself, (nor do I think I should be very far behind you); and I shall solicit that practice, which alone can make me quite your equal in the art. With many thanks for your liberal communications upon this as well as other subjects, I am, Dear Sir, your most sincere and obliged

To Mr Edward Troughton. THOS. JONES.

Mr Cavendish's proposed method of graduating instruments.

A paper by the late Henry Cavendish, Esq. called "An improvement in the manner of dividing Astronomical Instruments," was published in the second part of the *Phil. Trans.* for 1809. Mr Cavendish introduces his improvement in the following words:

"The great inconvenience and difficulty in the common method of dividing, arises from the danger of bruising of the divisions, by putting the point of the compass into them, and from the difficulty of placing that point mid-way between two scratches very near together, without its slipping towards one of them; and it is this imperfection in the common process, which appears to have deterred Mr Troughton from using it, and thereby gave rise to the ingenious method of dividing described in the preceding part of this volume. This induced me to consider, whether the above-mentioned inconvenience could not be removed, by using a beam compass with only one point, and a microscope instead of the other; and I find that in the following manner of proceeding, we have no need of ever setting the point of the compass into a division, and consequently that the great objection to the old method of dividing is entirely done away."

Mr Cavendish's proposed method of graduating instruments.

To this end, Mr Cavendish proposes to have a frame for supporting his beam compass, that shall rest upon the circle to be divided, and which, by bearing against the edge of the latter, may be turned round without altering its distance from the centre. The figure of this frame is triangular, and nearly as large as the circle itself. One of the angles is placed outwards, and the opposite side forms a chord of about 150° to the circle. One end of the beam compass is attached to the outer angle of the frame by a vertical joint, round which it may be turned from one side to the other at pleasure; and the joint must be moveable in the direction of the radius, in order that the beam may be adjusted, so as to form the chords of different arcs. At the opposite end of the beam is a fixed point, wherewith faint arcs are to be cut across the line of division, and with which the divisions themselves are finally to be made. There should be a groove or slit cut out all along the beam, in which a double microscope with cross wires is to slide, and which may be fixed at any required distance from the point. Two props, one to the right and the other to the left, are to support the end of the beam opposite to the joint in the two positions.

With this apparatus, Mr Cavendish shews how to perform the different operations required in graduating an instrument, namely, to bisect, trisect, and quinquisect; but does not follow the subdivision through their repeated courses.

In the bisection of an arc, the distance between the point and the axis of the microscope, is to be taken as nearly as may be to the chord of half the arc, and the joint adjusted, so that the cross wires and point may both at the same time coincide with the line of division. With the beam to the right, by moving the frame upon the circle, the wires of the microscope must be brought to coincide with the point that marks the left boundary of the arc, and then a faint mark across the line of division must be cut with the point. The beam is next turned to the left, and the point which bounds the arc on the right, is by turning the frame to be set to the microscope, and another mark across the line made as before. It is evident, that if the opening between the microscope and point was exactly equal to the chord of half the arc, the two marks would coincide upon the line of division; but if that opening was too great or too little, the marks would cut each other without or within the circle. But in neither of these cases would Mr Cavendish put in a dot. Instead of which, when in subsequent division these marks are to be used, as well as when the final strokes are cut, he would place the wire of the microscope by estimation in the middle between them, where they cut the line of division.

In quinquisecting an arc, the opening being taken as near as possible, equal to the chord of a fifth part of it, bring the microscope to one extremity of the arc, and with the point make a mark across the line; bring the microscope to the mark just made, and with the point make another mark, &c. until four are put in; change the position of the beam, and from the other extremity of the arc set off four marks as before. If the chord in the above operation was not correctly taken, it is evident that there will now be four double marks, and the spaces between them equal to each other, and five times greater than the error of the opening. The real point of quinquisection, reckoning from one end of the arc or

Original Graduation.

the other as the opening, was + or —, will be $\frac{1}{5}$, $\frac{2}{5}$, $\frac{3}{5}$, and $\frac{4}{5}$ of the space between them; and these Mr Cavendish would also use by estimation in the subsequent progress of the work. Mistakes in making a wrong estimation of the spaces are to be prevented, by making proper marks upon the circle opposite to them. Mr Cavendish has given three different ways of proceeding; but that which we have described, is the one which he himself thinks the best.

To give a general idea of Mr Cavendish's method was all that we intended. To follow him through his whole paper would be useless; for, notwithstanding that much ingenuity is displayed in pointing out such errors as he foresaw it would be liable to, and in contriving means to obviate them, we consider it as altogether inconsistent with practice, and inelegant in design.

Mr Lax's proposed method of examining the divisions of astronomical instruments.

Immediately after Mr Cavendish's paper, we find one by Professor Lax of Cambridge in the form of a letter to Dr Maskelyne. It is entitled, *On a Method of examining the Divisions of Astronomical Instruments.*

The learned professor sees no reason why astronomers should trust to the ability and integrity of artists, when, by means of a proper apparatus, they have it in their own power to examine and note the error of every division of an instrument. Mr Lax is in possession of an altitude and azimuth circle, of one foot radius, made by Mr Cary, and it is to this instrument that his examining apparatus is adapted; but the computation of error is expressed in general terms.

His apparatus consists of an arc fixed to the frame of the instrument, exterior to, and concentric with, the circle, and which stands still while the circle is turned round. The arc contains about 90°, and a microscope, which slides upon it from end to end, may be clamped to any part of it. The microscope regards the divisions of the circle, and is used in combination with one of the reading micrometers: the former has an inclination of about 30° to the latter, in order that both of them may be made to coincide with one and the same division of the circle; by means of which contrivance, any opening between them from 0 to 90° may be taken. Professor Lax finds the error of the division 180° by help of the two reading micrometers, exactly as Troughton did, but in every other step the examination is carried on in a way quite different from that pursued by the artist.

The second step is performed when zero of the circle is brought to one of the micrometers, and the microscope fixed to the exterior arc at the division 90°, by bringing in succession to the microscope the divisions 180°, 270°, and 360°, and comparing the first arc of 90° with the other three arcs of 90°, the difference of which having been measured with the micrometer, and distinguished by + or — affords data for computing their respective errors. In like manner, the first arc of 60° is to be measured against all the other five arcs of 60° precisely as the first arc of 90° was measured against all the other arcs of 90°. And again, the first arc of 45° is to be measured against all the other seven arcs of 45°. So far the Professor proceeds before sunrise, in order to avoid the effect of expansion; the rest, on account of the small arcs that are used, may be done at any time. The arc of 30° may now be measured against every succeeding arc of 30° in the first, third, fourth, and sixth arcs of 60°; and let the length be determined from a separate comparison with the arc of 60° in which it is comprehended, and not from a general comparison with all the four. The arc of 15° must then be measured against every succeeding arc of 15° in all the arcs of 30° except the second, fifth, eighth, and eleventh, and the value of each deduced from a comparison with the arc of 30° in which it is contained.

We will follow Professor Lax no farther in his ingenious and laborious examination; suffice it to say, that, by pursuing the same principle of comparing short arcs with their multiples, he obtains the errors of every individual division of his circle, down to the ten-minute spaces into which it is graduated.

Mr Lax says, that with his microscopes and his circle of one foot radius, he cannot commit an error greater than three quarters of a second in reading off, and with this datum and that of the number of times that some divisions have been dependent upon previous examinations, he reckons upon a possibility of error in extreme cases amounting to 9″.63. This is a very large quantity: the truth however is, that the examiner not only under-rates the ability and integrity of artists, but also the powers of his own method. To make out the above quantity, Mr Lax is obliged to suppose, that at every step he commits the greatest possible error, and that, in every course, the error lies in that direction which produces the greatest accumulation. After the examinations have been completed, and the calculations made, the Professor says:

"The time and labour required for this examination are no doubt very considerable; but it ought to be recollected, that it will render any great degree of precision, in dividing the instrument, totally unnecessary. Whoever, indeed, employs this method of examination, will be virtually the divider of his own instrument; and all he will ask of the artist, is to make him a point about the end of every five or ten minutes, whose distance from zero he will determine for himself, and enter in his book, to be referred to when wanted. We may likewise observe, that, by this examination, we shall not only be secured against the errors of division, but against those that arise from bad centring, and from the imperfect figure of the circle, and which, in general, are of too great a magnitude to be neglected."

Remarks on Mr Lax's method.

Now, the greatest part of all this is certainly very true; yet we doubt if astronomers in general will not save themselves the expence of the apparatus, and the trouble of performing the work; and we think that they will continue, as heretofore, to demand of the artist the utmost exertion of his talents.

Professor Lax has shewn the analogy between his method of examination and that of observing by repetition, as much practised abroad, which is but another way of reducing the errors of dividing. As, however, things do not easily get out of their usual course, we are of opinion, that the paper under consideration will have no tendency to relax the efforts of the artists of this island to approach the point of truth, any more than the improvement of the art of graduation will, upon the continent, supersede the use of the repeating circle.

We are not satisfied with the inclining microscope. In order that this should occasion no error, the plane which bears the graduation should be almost a miracle of truth. Were the microscope so fixed as to be capable of being inclined as much the contrary way, the effect of parallax would be contrary too; and if a succession of the same angle were repeated in both positions of the microscope, an identity of results would prove our doubts to be groundless, or a disagreement between them shew the thing we are afraid of.

Captain Kater's proposed method of dividing astronomical circles.

In the second part of the *Phil. Trans.* for the year 1814, we meet with a paper by Captain Kater: it is called, "An Improved Method of dividing Astronomical Circles, and other Instruments."

Original Graduation.

To give a general idea of this method, which is itself ideal, is all that we think necessary; and with it, and a general remark or two, we shall close our article.

Captain Kater's proposed method of dividing astronomical circles.

This method is extremely like that of the Duc de Chaulnes: the chief difference between them is, that, instead of the waxed pieces, Captain Kater proposes to perform the work by means of two pieces which are to be clamped upon the circle to be graduated, and adjusted to their places each by two appropriate screws. He would use three double microscopes, one plain with cross wires, the other two with micrometers: they are to be applied to an exterior arc exactly like that which Professor Lax used in the examination of his circle. Captain Kater leaves the manner of fixing the arc to the frame of the instrument, to the ingenuity of the artist, who may practise the method; a task by no means easy, considering the stability that would be required. The cutting-frame of Hindley is to be used, which, being properly placed at one extremity of the exterior arc for tracing the divisions, the plain microscope should be fixed over the tracer, and adjusted to a line drawn with it exterior to the circles which are to bound the length of the divisions: this is called the line of verification. The fixed microscope not only regards this line and a dot upon the cutting apparatus, but also assists the eye in tracing the divisions. This is altogether a good contrivance; for by it the stability of the several parts may be examined at pleasure, and, if necessary, rectified. The two micrometer microscopes are also applied to the exterior arc, and have a range upon it from contact to a distance of one-fifth part of the circle. After being clamped, they have each a screw-adjustment in the line of the radius, and the adjustment for the correct angular opening is found in the micrometer wire.

Remarks on Captain Kater's method.

Captain Kater would first divide the circle into five equal parts, then trisect each of these, and then would perform another trisection. This is not the course that an artist would take: his instruments are to be read off at opposite divisions, and he would not toil through the most difficult part of the work without a trial. De Chaulnes, in the first instance, bisected the circle, and whatever course he afterwards followed, every division would have its opposite; but Captain Kater's scheme admits of no opposites until his arcs of 8° are bisected. The Duke, in every subdivision, left waxed pieces at every step of an interval, which he could examine again and again, before he cut the divisions. But Captain Kater, by using but two adjustable pieces, deprives his method of that advantage; for, in order to obtain a proper opening between the microscopes, the two pieces are set alternately in advance of each other, and a blank space is left behind.

In all operations of this kind, there is a certain space that one may either see or not see, and which Mr Lax, in his circle of one foot radius, which is the same that Captain Kater proposes to divide, states to be three quarters of a second. Now if, at the time that the opening of 72° for quinquisecting the circle was adjusted, a succession of five + errors to that amount were committed, the circle would appear to be equally quinquisected, by an opening of ″.75 — its proper measure. And with this error of opening in the similar operation for cutting the divisions, let it be supposed, that at each step of shifting the adjustable pieces, a — error to the same amount were committed, then it is evident, that the division 288° would err by a quantity $8 \times {}''.75 = 6''$. This is Professor Lax's way of reckoning the amount of error, which is indeed too severe; but, in the case which we have exemplified, there is nothing improbable in the supposition, that the error might amount to more than half that quantity, and yet neither the apparatus nor artist be at all to blame. Captain Kater observes, that errors, if any, would be seen: True; but divisions have been cut, and what is to be done with them? They are of course to be rubbed out, and a trial again made, in hopes of better luck.

Original Graduation. Remarks on Captain Kater's method.

Besides this, the method before us is still farther very objectionable. A division, when cut, whatever its error may be, communicates that error to others made from it, through every course of subdivision; and thus the sins of the fathers are visited upon the children down to the seventh generation.

There is another thing that is not adverted to by Captain Kater: no division can be viewed by the microscopes, to any useful degree of accuracy, until the *bur* is polished off; and the frequent recourse that must be made to this operation, which could not be done without carrying the circle round, to get it out of the way of the apparatus, would prove a source, not indeed of inaccuracy, but of very much embarrassment and delay. It may be observed, that the method of coaxing is fully as much liable to this objection, and that Troughton's is the only one that is perfectly free from it.

Captain Kater's apparatus is the most complex, and, if made, would be the most expensive, that has been either used or proposed for graduating; and we should remark, that the method would turn out to be extremely tedious. The Captain expresses himself upon both these matters as being of quite a different opinion: we are not surprised at this, considering, as we do, how much faster the nimble ideas of a speculator get on, than the fumbling fingers of an artist.

Observations on theoretical methods of graduating.

The gentlemen graduators have one and all rejected the *maxim* of Graham: they know that it is not geometrically true, and to what extent it is practically so are perhaps incapable of judging. The bisection of an arc, as Graham meant it to be understood, consisted in setting off the chord of half that arc from left to right, and then from right to left. It was a condition, that the points of the beam-compass should be so sharp, short, and strong, that they would not be deflected towards the arc struck in the first position, when that in the second was made, even were the distance between the points somewhat erroneous; for, in this case, the line of division would only be intersected by a broader stroke, which would still occupy the mean distance. Graham would have said, that this kind of bisection continually halved the error; while that of the gentlemen, which he would have denominated stepping with the chord of half the arc, was continually extending it. As division by three, five, &c. cannot be performed without stepping, Graham pronounced them to be practically impossible.

It is our opinion, that the art of graduation is now in a state not to be improved by any one who is not a practitioner. Those who excel in the highest branch, are men capable of thinking for themselves, and of course, for improvement, will naturally look inwards. On the other hand, the effusions of gentlemen can do no harm, for their schemes will ever be inconsistent with practice. Should they, which is possible, suggest an useful hint to the practical man, it ought to be accepted with gratitude; and, at any rate, their well-meant endeavours should be kindly received. With this view before us, we think, that when the real graduators of instruments shall be incorporated into a society, Professor Lax should be chosen an efficient member; that Captain Kater ought to be admitted an honorary one; and that we ourselves, after all this, may look up to the latter distinction.

GRAFTING. See HORTICULTURE.

GRAIN. See AGRICULTURE and CORN LAWS.

GRAHAM, JAMES, *Marquis of Montrose*, an eminent soldier in the reigns of Charles I. and Charles II. and distinguished by his enterprises against the Covenanters in Scotland.

Having been treated with some disrespect by the King, Charles I. he was at first attached to the cause of the Presbyterians, and supported them in their endeavours to secure the civil and religious liberties of the nation. It has been questioned, indeed, whether he was sincere in this attachment; and it must be owned, that, in the early part of his life, his conduct had every mark of duplicity and perfidy. Even his panegyrists have allowed, that his intercourse with the Presbyterians was that of convenience, not of inclination; that he enrolled himself in their armies, and held conferences with their divines, in order to be admitted into their secret counsels; and that having obtained the intelligence which he required, he made use of this intelligence against the very party whose confidence he had enjoyed. The facts are certainly strong. At one time he was entrusted with a high military command among the Covenanters, and actually passed the Tweed at the head of their troops; and the historian of England assures us, that, at this very time, he had entered into a close correspondence with the partizans of the king. At length, after a course of perfidiousness, unworthy of his illustrious birth, and, it must be acknowledged, altogether at variance with his general character, which appears to have been that of manliness and heroism, he disclosed all he knew of the purposes of the Presbyterians, and openly declared his attachment to the royal cause. Such, however, was his vacillation, to give it no other name, that Charles himself was for some time unwilling to trust him; but having succeeded in detaching the Hamiltons, who were his political antagonists, from the confidence of the monarch, he rose in the royal estimation, and was at length appointed lieutenant-general of the king's forces in Scotland.

Yet he who deserted the cause of liberty and of true religion, and betrayed his countrymen, proved faithful to his king. He had taken upon him, however, as Burnet expresses it, the post of a hero too much. With very inadequate means, and relying chiefly on his personal prowess, he undertook to subdue the Presbyterians by force of arms. And, at this time, the Presbyterians were not, in strict language, a party in Scotland; they constituted the strength and the talent, the energy, physical and intellectual, of nearly the whole nation; they were united in the cause of religion and of liberty, bound by a public and solemn engagement to adhere to it with their fortunes and their lives, supported by the English parliament, confident in the purity of their intentions, and not without encouragement from previous success. Yet while all this must be allowed, the progress of Montrose, temporary and partial as it was, may serve to shew how much may be atchieved by the enterprise of one man's mind, and the effort of a single arm.

His first concern was to draw around him those of the Scottish nobility, who were either more attached to the king, or less intimately connected with the Presbyterians. Among the persons of distinction who joined him on this occasion, historians have not failed to mention the Lord Napier of Merchieston, son of the celebrated inventor of the logarithms; the Earl of Antrim, a nobleman of Scotch extraction, and who brought into the field a body of the Macdonalds who had served in Ireland, and the two sons of the Marquis of Huntly. To these we might have added the Marquis himself, the chieftain of the powerful clan of the Gordons; but the Marquis had studied astrology, and had learned from the stars, that neither the king, nor the Hamiltons, nor Montrose, should prosper. According to Burnet, he was naturally a gallant man, but the stars had so subdued him, that he made a poor figure during the whole course of these wars. Discouraging as the prospect appeared, Montrose, or as he was usually called, "the Graham," was in haste to take the field. Joining himself to the Macdonalds, and about eight hundred of the men of Athol, who had flocked to his standard, he prepared, with incredible activity and expedition, to attack the Lord Elcho, who lay with a considerable body of troops in the neighbourhood of Perth. No general, either of ancient or of modern times, was ever more rapid in his marches, or more fierce in his onset, than the Marquis of Montrose. Though inferior in numbers, destitute of cavalry and of artillery, and so ill furnished with ammunition that he was obliged to answer the discharges of the enemy by a volley of stones, he assailed the Covenanters with such unexpected fury, that he threw them into disorder, pushed his advantage, and gained the victory; he himself combating with his broad-sword among the foremost of his troops, and animating them by his example. The slaughter of the Presbyterians was great, amounting, by some accounts, to two thousand men; and the town of Perth opened its gates to Montrose, in consequence of the battle. On this occasion, he had an opportunity of proving his clemency, a quality which entered largely into the formation of his character, and to which he made a consoling allusion when about to prepare for the scaffold; for he took possession of the town without injuring its inhabitants, and restrained even the Highlanders from their well known propensity to plunder.

But if the town of Perth experienced his clemency, he let loose all the rage of predatory warfare upon the country of the Duke of Argyle and the estates of the Hamiltons; the former, a leading man among the Presbyterians, and the personal enemy of Montrose, and the latter his rivals in the favour of the king. At the head of the Macdonalds and the Irish, he attacked Argyleshire with the ferocity of a Tartar, carrying off the cattle, in which the wealth of the inhabitants consisted, burning the houses, and wherever he met with opposition, putting men, women, and children to the sword. His panegyrist Wishart informs us, and informs us without apology or remorse, that he sent out his troops "to kill and to destroy." In these expeditions, the life of "the Graham" was frequently in danger. He was constrained to make very long and fatiguing marches, often in the night and in the depth of winter, through a mountainous and pathless district; and he was opposed by the Campbells, the hereditary enemies of his name, warm from the effects of recent aggression, and equally active and revengeful with the other clans of the north. These, however, were antagonists that might be encountered, or sufferings that might be endured; but the age was barbarous, and he seems not to have perceived that he had tarnished the lustre of his achievements by the rapacity of a free-booter. And what was still more to be regretted by the royalists, he had suffered his numbers to be diminished without rendering any essential or lasting service to the cause of the king.

We must refer our readers to the author of the *Memoirs of the Marquis of Montrose*, for a particular account of his expeditions and battles. Early in the spring of 1645, he carried the town of Dundee by assault, and gave it up to be plundered by his soldiers. In the same year he defeated Urrey at Auldcorne, and Baillie at Alford. But it was at Kilsyth that he performed one of his greatest atchievements, and raised his character as a soldier. The battle of Kilsyth was fought on the 15th of August 1645. The forces on both sides were nearly equal, but the character of the troops was not exactly the same; those of the Covenanters being, for the most part, newly raised, while the followers of "the Graham" had been disciplined under his immediate inspection, and accustomed to the field. The Presbyterians were commanded by General Baillie, the same officer who, in the month of July preceding, had been constrained to yield at Alford; and he was assisted, on this occasion, by the Earls of Crawford and Airly, Sir William Murray of Blabo, Colonels Dyce and Wallace, and other adherents of the popular party. It is said that Baillie was displeased with the quality or the condition of his troops, and engaged with reluctance. The action commenced by an attempt of the Covenanters to dislodge a small party, which Montrose had stationed near some cottages in the vicinity of Kilsyth; but the assailants were very warmly received, and at length driven back with considerable loss. At this moment, a body of Highlanders, amounting to 1000 men, without waiting for orders, rushed furiously upon the Presbyterians; these were supported by the Earl of Airly, at the head of 2000 of the infantry, and three troops of horse. The rest of the army imitated the example of Airly and the Ogilvies; the ranks of the Covenanters were broken; no effort of their generals could restore them to order, and a complete rout ensued. Six thousand of the Presbyterians fell in this memorable action; and, in one disastrous day, the cause of religion and of independence was left without the aid of any regular army in Scotland.

After the victory at Kilsyth, Montrose appears to have been elated beyond what we should have expected in so great a commander, and certainly beyond the amount of the essential and profitable service which he had performed. Though he was not in possession of any of the strong holds, or important passes, he wrote to the king as if the whole country had submitted. In those days, both parties made an indiscreet use of the language of scripture; and with improprieties of this nature Montrose is justly chargeable, as well as the chieftains of the covenant; though, if we were to consult the most popular history of the period, we should be led to believe that the practice was peculiar to the Presbyterians. He assured his Majesty that he had over-run the country, "from Dan even to Beersheba;" and prayed the king to come down, in the words of Joab, the Hebrew leader, originally addressed to king David, "now therefore gather the rest of the people together, and encamp against the city, and take it, lest I take the city, and it be called after my name."

The fortunes of Montrose now began to decline. Having advanced, upon some insufficient encouragement, towards the English border, he attempted in vain to rouse the Earls of Hume, Traquair, and Roxburgh, and to animate them in the royal cause. He was deserted likewise by his own troops; for the Highlanders, unaccustomed to a protracted course of military service, had retired to the hills, in order to secure the plunder which they had obtained. He was, moreover, extremely deficient in cavalry. In these circumstances, "the Graham" was met by Lesly, the general of the Covenanters, who had been detached from the army in England; and at Philiphaugh, in Ettrick Forest, the royalists were defeated in so tremendous and so fatal an overthrow, that they were never afterwards able to make head against their antagonists. Montrose, though worsted in the issue, did every thing which experience could suggest, or bravery could fulfil, but the assault of Lesly's cavalry was not to be withstood. Some say that "the Graham" had become careless, in consequence of his success, and that he had allowed himself to be taken by surprise; and, perhaps, he had dreamt of vanquishing the Covenanters by what his followers were wont to call *the terror of his name.* But whatever truth there may be in these surmises, it is certain that he was compelled to fly with his broken forces into the mountains, and to prepare with more leisure than suited his character for new battles and enterprises. His life was now little else than a series of misfortunes. During the progress of the English parliament, he quitted the kingdom; and some time previous to the arrival of Charles II. in Scotland, he made one other unsuccessful attempt to restore the monarchy by force of arms.

Some prophet of the Royalists had assured him, (for the Royalists had their prophets as well as the Covenanters,) that to him, and to him alone, it was reserved to restore the king's autherity in all his dominions; and he eagerly listened to an intimation which agreed so well with his enterprising genius. But, notwithstanding this augury, he was defeated by Strachan, one of Lesly's captains, and taken prisoner after the battle, in the disguise of a peasant, "having thrown away his cloak and the star upon it."

The Covenanters made a rigorous use of the victory, and treated their illustrious captive with a degree of insolence which can find no other apology than the barbarism of the period in which they lived, and the treacherous manner in which he had deserted them. He was brought to Edinburgh under every circumstance of elaborate indignity; and after a trial before the Scottish parliament, during which he conducted himself with the utmost presence of mind, and with a magnanimity which his enemies were constrained to admire, he was sentenced to lose his life by the hands of the public executioner; and with a lofty composure, and using some pious ejaculations, he submitted to his fate. Thus was closed, at the age of thirty-five, the career of James Graham, Marquis of Montrose, a man unquestionably of a most noble and heroic character, bold, active, and for a time successful. All history unites in recording his atchievements, and in celebrating his valour: but he was brave in the hour and in the tempest of the battle, rather than skilful in forming the plan of a campaign. He took up arms against the Presbyterians, without a prudent estimate of his means. And it may be doubted whether, with all his courage and all his activity, his exploits were of any service to the cause of the king. It has been said that he was no stranger to elegant literature; but while every one allows that the verses which he composed on the evening before his death may be regarded as proofs of the serenity of his mind, there are few who will be ready to acknowledge them as a very favourable specimen of his attainments in the poetical art. One foul spot remains upon his character; he be-

Graham of Claverhouse.

trayed the cause of liberty, and the friends of his early life; if, indeed, it be not a fouler and more indelible stain, that he continued through a series of heroic endeavours, the champion of a cause which had for its object to establish an unlimited power in the nation, and to force, by a military apostleship, an abhorred religion, upon the acceptance of the Scottish people. See Wishart's *Memoirs of Montrose;* Hume's *History of England,* vol. x. xi.; Principal Baillie's *Letters and Journals,* vol. ii.; Burnet's *Own Time,* vol. i.; and Fox's *History of the early part of the Reign of James II.* (*h*)

GRAHAM, JOHN, of CLAVERHOUSE, *Viscount Dundee,* a celebrated military character who flourished in the latter part of the 17th century, was descended from the noble family of Montrose in Scotland. Being of an ardent mind, and animated from his earliest years by the study of the poets and orators of antiquity, as well as by the traditionary songs of the Highland bards, he entered early on a military life, and served in the Low Countries, against the French, in the war of 1672. At the sanguinary battle of Senex, he was instrumental in saving the Prince of Orange's life, and he afterwards made application for the command of one of the Scotch regiments in the Dutch service. The request was premature, and was consequently declined by the Prince of Orange, on which Dundee withdrew from the Dutch service in disdain. Returning to Scotland, he obtained a regiment from Charles II. and distinguished himself by his services against the Covenanters. From James II. he obtained a title, and high command in the army. Having been accused of cruelty in his operations against the Covenanters, he pleaded in excuse, that "terror was true mercy, if it put an end to or prevented war." It was after the flight of James II. and the consequent proceedings in Scotland, on the subject of his abdication, that Dundee became chiefly conspicuous. From his cruelties against the Presbyterians or Covenanters, in Scotland, "a poor people, made desperate by the violence of their persecutors;" he is still spoken of in the western counties under the designation of the Bloody Claverhouse. In the year 1679, he marched with a party of dragoons, in order to disperse a meeting of the Covenanters, at Loudon-hill, in Ayrshire. It was a day of peculiar solemnity, when the sacrament of the Lord's supper was to be administered; a great multitude, amounting, as Defoe assures us, to many thousands, had assembled from different parts of the country; and the people sat upon the ground, on the side of a steep hill, while one of their ministers preached to them from a little *tent* placed at the bottom. As was usual and necessary in those troublous times, a considerable proportion of the audience were provided with arms. When Claverhouse approached, these last withdrew to a short distance from the body of the congregation, and waited in good order for the assault of the king's troops. A close and furious engagement took place at Drumclog; the dragoons, advancing hastily, and without the requisite precautions, were surprised when they found an enemy well prepared to receive them; and the Covenanters, after maintaining their position for a while, pressed forward against the royal forces, and compelled them to retreat. Claverhouse himself had his horse shot under him, and escaped with difficulty. But the victory, which was far from being decisive, was dearly bought on the part of the Presbyterians. For soon after, being collected in greater numbers, and joined by Hamilton of Preston, and other gentlemen of the west, they ventured to oppose the king's troops under the Duke of Monmouth, in the well-known action at Bothwellbridge. Previous to this action, however, dissensions had crept in among them; they were deficient likewise in the subordination and discipline, without which it is impossible to resist the attack of a trained and constituted soldiery; and in addition to all their other wants, they were ill provided with arms, and especially with artillery. The consequence was, that the royalists made themselves masters of the bridge at the very first onset, and drove the Presbyterians before them with a great and indiscriminate slaughter. It is true the Duke attempted to restrain the fury of his troops; but the inferior commanders, Linlithgow, Mar, Hume, and Claverhouse, disregarded the orders of their General, and shewed no symptom, either of pity or of remorse, in the pursuit of the discomfited Presbyterians.

But the cruelties of Claverhouse did not terminate with the battle of Bothwellbridge. What Burnet says of Dalziel may be affirmed of this commander, with equal, or perhaps with greater, truth; that he acted the Muscovite too grossly, threatening to spit men and to roast them alive. A whole year after the battle was spent in attempting to discover those who had been present at Bothwell, and in putting them to death, or otherwise punishing them. Many were slaughtered in cold blood; many were shot because they would not acknowledge the *rising,* (as the Covenanters called it), to be rebellion against the king; not a few were put to death upon their knees, declaring that "they were no way concerned in the Bothwell affair," and recommending their souls to the mercy of heaven. Trials, and juries, and regular proof, were rejected as impediments to the king's service. The prisoners were simply asked whether they owned the rising at Bothwell to be rebellion; and if they hesitated, or answered ambiguously, they were instantly shot. Even the private soldiers were authorised to ask such questions, and to inflict the punishment. Children were tortured in order to force them to discover where their parents were concealed; wives were constrained to lead the soldiers to the retreats where their husbands or near relatives had taken refuge; and young and tender women were stript naked, and thrust out into the cold. There being a great majority in the Scotch Convention on the side of William, Dundee took the determination of withdrawing, and of exerting himself to serve the cause of James in the field. He left Edinburgh with a troop of 50 horsemen, after in vain urging the Duke of Gordon to accompany him to the Highlands, and raise his numerous vassals in the cause of the Stuarts.

In the beginning of May 1689, Dundee openly took up arms in the neighbourhood of Inverness, and exerted himself with so much activity, that his force increased to 6000 men. As a descendant of the Marquis of Montrose, he was the object of much attachment on the part of the Highlanders, some of whom even forsook their family leaders to fight under his orders. King William dispatched General Mackay against him, at the head of a regular force, and two months were passed in great impatience by Dundee, in consequence of orders from King James not to fight until the arrival of a large force from Ireland. During this interval, Dundee was obliged, from deficiency of provisions, to shift his quarters continually, and he performed very extraordinary marches. His men were exposed to frequent privations, but disdained to complain, when they saw their commander living on the same coarse fare with themselves.* When he acted offensively, his approach was so rapid, as generally to outrun the notice of his movements; and in retreating, he was commonly out of reach before the enemy was apprized of his intention. His followers were chiefly Highlanders from the interior, and were extremely impatient of delay in fighting. It proved on all accounts matter of regret, as the reinforcement from Ireland, on arriving at last in the end of June, was found to consist of only five hundred raw and spiritless recruits. General Mackay had now determined to march through Athol, and attack the Castle of Blair, which had been taken by Dundee, and by him put into the hands of one of James's adherents. Dundee, aware that the loss of this place would interrupt the communication between the two divisions of the Highlands, determined to bring on the long delayed conflict, and marched southwards with a force considerably diminished, many of the Highlanders having returned home to get in their fuel for the winter. In marching northwards, General Mackay had to go through the pass of Killicrankie, a pass consisting of a road, where for two miles not more than six or eight men could, at that time, go abreast. On the one hand are steep and rugged mountains; on the other, a precipice hanging over a deep river. Dundee declined to occupy this pass, or to obstruct the advance of the enemy, but determined to fight after Mackay had reached the northern side, in the hope that he might defeat him, and cut off his retreat by obstructing the pass. Mackay's army marched from Dunkeld in the morning of the 16th of July; and after resting at the mouth of the pass, marched through it about noon. Arriving at the open ground on the farther side, they saw Dundee's soldiers resting at a distance on the side of a hill. Mackay drew up his men in order, and wished to bring on the engagement without delay; but Dundee knowing that night would be of advantage to the Highlanders, whether successful or defeated, delayed the attack till half an hour before sunset. At that time he made his men rush down from their station, and begin the attack in a series of small columns on the wings of the enemy, on the calculation that this mode of onset was most likely to bring on an action hand to hand, in which he was certain of the superiority of the Highlanders. Such had been the disposition of the Marquis of Montrose at the battle of Alderne. Dundee's plan was completely successful; his columns piercing, though not without considerable loss, through the opposing line in many places, and taking the soldiers in the flank and rear, in a manner wholly unexpected by regular troops. Of all Mackay's men, in number 5000, the centre only, consisting of a regiment and a half, retreated in good order. The rest fled in confusion; and Dundee having mounted on horseback, pushed forward to point out to his men the manner of cutting off the retreat of the enemy at the mouth of the pass. Perceiving in a little time that he had got a head of his followers, he stopped and waved his arm in the air to make them hasten their pace, pointing with his hand to the pass as the object of their exertion. Being thus rendered conspicuous, he became an object of aim to some of the enemy's soldiers, and a musket ball found entrance beneath his arm pit, in an opening of his armour, occasioned by the elevation of his arm. He rode off the field, after desiring his misfortune to be concealed; but no precautionary orders could make up for his absence, as the Highlanders, on falling in with the enemy's baggage, gave over the pursuit, and betook themselves to plundering. The remains of Mackay's army consequently effected their escape, though with a loss of 2500 men. The loss of the Highlanders was nearly 900. Many of the fugitives were killed or taken by the Athol men, whom Dundee had the day before ordered to be in readiness at the south end of the pass. Mackay not daring to venture through it, took his course through the hills to the westward, whence looking back, and seeing no regular pursuit, he said to those around him, that he was sure the enemy had lost their general. A similar observation was made by King William, who hearing that the express sent to Edinburgh with the account of the defeat had been detained a day on the road, exclaimed, "then Dundee must have fallen, for otherwise he would have been at Edinburgh before the express." Some days after, when William was urged to send a strong detachment of troops to Scotland, he replied, "It is unnecessary; the war has ended with Dundee's life." After riding off the field, Dundee had still strength sufficient to write an account of the action to King James. In this dispatch, he anticipated a general insurrection in the country in favour of the absent sovereign; an attempt in which Dundee might have obtained a degree of success similar to the Marquis of Montrose, had he been spared to follow up his victory. His wounds, however, were mortal, and he expired the next morning.

Though the Highland army was kept together, and even descended during the next two years into the low country, nothing of importance was accomplished, and as William had predicted, there was little difficulty in concluding a peace.

The estate of Lord Dundee was made over, after his death, to the house of Douglas; and his widow marrying again, and retiring to Holland, became, along with her children, the victim of a dreadful misfortune; the house in which she resided at Utrecht falling suddenly in, and overwhelming the whole family in a few moments. The title of Dundee has not been revived since the death of this distinguished commander.

See Wodrow's *History of the Church of Scotland*, vol. ii. p. 1; Defoe's *Memoirs*, p. 197; Swift's *Life of Captain Creichton*, p. 298.

GRAHAME, James, best known as the author of *the Sabbath*, was the son of Mr Thomas Grahame, a highly respected writer, or attorney, in Glasgow. He was born on the 22d day of April 1765. The peculiar mildness, and the religious cast of his character, and of his pursuits in the latter part of his life, may be traced back to his training in infancy and youth, by a father and mother who were distinguished for their warm and enlightened attachment to Christianity, and for their chastened cheerfulness of temper and manners. Grahame's minute and delicate discernment of the beauties of nature, and his delight in observing all those nicer shades, which are unnoticed save by the contemplative eye and the feeling heart, probably had their source in his holiday enjoyments on the picturesque banks of the Cart. He and his elder brother were accustomed to pass, at his father's summer residence, in this sweet retirement, those hours which are distinguished from all the other hours of life, by admitting not only of cessation from study, but of carelessness of the past and future, mingled with the gay and ever-varying illusions of juvenile fancy. His education was begun at the

* He was accustomed to march on foot with his men, at one time by the side of one clan, and afterwards by that of another, displaying his knowledge of their genealogies, and reciting the deeds of their ancestors.

Grahame, James.

grammar school of his native city, where he was distinguished more for playfulness, than for brilliancy of talents; and where he evinced a disposition to frolicsome sprightliness, which gave little promise of the thoughtful and retired character of his manhood. From the school, he passed to the university of Glasgow, which he attended for five consecutive sessions, during the two last of which he studied the theory of law and government under the celebrated Professor Millar, from whom he imbibed that enthusiastic love of freedom, and that warm attachment to the constitution of his country, especially the popular part, which formed a distinguishing feature in his character through life. This attachment to the cause of freedom, induced him at first to take a warm interest in the success of the French revolution, and led him at a later period of his life, with honourable consistency, to express his detestation of that spirit of aggrandisement, which marked the conduct of too many of its abettors; and especially of the military despot, who availed himself of the misfortunes of the country that cherished him as her adopted son, to destroy her liberties, and desolate the fairest portion of Europe.

When the anxious period arrived, at which it was necessary for him to fix on a profession, Grahame would have preferred the simple and unostentatious duties and the humble emoluments of the Scottish church; but he suffered his own choice to be overruled by the persuasions of his friends, who fancied that they could foresee or secure more certain success for him in the law. After receiving some professional instruction from his father at Glasgow, he was indentured, in his twentieth year, as an apprentice to his cousin Mr Lawrence Hill, writer to the signet in Edinburgh, in 1784. It was about the time of his passing writer to the signet in 1791, that he had the misfortune to lose his father; a misfortune which sunk the more deeply into his feeling heart, from the circumstance of his absence on that occasion. The consolations of religion were at this time peculiarly salutary to his wounded spirit, and his desire for the clerical office returned; but he again yielded to the arguments of his friends, who urged the obstacles that his age now presented against his entering the Scottish church, in consequence of the length of previous study required, a circumstance which also appeared to them a barrier to his preferment in the church of England. He acted for some years as a writer to the signet, and passed advocate in 1795. Though his professional knowledge was extensive, and his law papers were ably written, there were various circumstances, which combined to prevent him from attaining a conspicuous station at the bar. Want of relish for the minute and tedious details of the practice of the law, and a bad state of health, were the principal obstacles; and probably these were the chief causes of his seeking relief in poetical composition.

He was most happily married in 1802, to Miss Graham, the eldest daughter of Mr Graham, writer in Annan, and town-clerk of that burgh; and in the endearments of domestic life, which no man could enjoy with a truer relish, he found a never-failing solace amid the cares of business, and the growing infirmities of his delicate constitution. In 1808, his declining health made him resolve to retire from the bar, and at last to adopt the profession, to which his mind had adhered with constancy from his earliest years. After some abortive attempts to obtain ordination in the English church, he was admitted to holy orders by the Bishop of Norwich in May 1809, and soon entered on the curacy of Shipton, in Gloucestershire. He found his new duties easy and pleasant; but family reasons compelled him in a short time to abandon them, and return to Scotland. After various changes, which are too unimportant to be recorded in a work of this nature, he was finally settled in 1811, as curate of the parish of Sedgefield, in the neighbourhood of the city of Durham. His figure was tall, and his features striking, and his sermons, if not animated, were interesting and earnestly impressive. His benevolent and ardent concern for the poor and afflicted of his flock, secured for him an interest in their hearts, which, however, he was not to be permitted long to retain. Severe headach, to which he had been occasionally subject from his early years, and which materially injured his memory and other mental faculties, increased considerably about this time; and the disease had now made an alarming progress, which was soon to rob his flock of their pastor, his family of their best friend, and the world of a poet, who combined the sublime chords of David's harp, with the simplest melody of the sylvan pipe. In August 1811, he returned on a visit to Scotland; and on the 14th of September, he expired in the house of his elder brother at Whitehill, near Glasgow, in his 47th year. His ashes rest in the sepulchre of his fathers. His afflicted widow, who was absent at the time of his death, and occupied with the duties of her family, was little prepared for this severe trial. She soon after fell into bad health, and died in the year 1815, leaving a son and two daughters to bewail the early loss of both their parents.

Grahame, James.

Kindness and sympathy for every thing that could feel, were among the strongest characteristics of Grahame's mind; aud those local attachments, perhaps we may call them local prejudices, which find a place in every mind of sensibility, were deeply rooted in his. We do not think it will be necessary to apologize for mentioning, in a memoir of this amiable man, a little trait which strongly marks this feeling. When he was journeying on horseback towards his native Scotland, he asked of a peasant the name of a stream, which he associated with many tender recollections of times gone by, merely that he might have the delight to hear that name repeated in the native accent, from which he had been lately estranged. One of the tenderest passages in his Georgics, refers to this circumstance:

> " How pleasant came thy rushing silver Tweed
> Upon my ear, when, after roaming long
> In southern plains, I've reached thy lovely bank!
> How bright, renowned Sark! thy little stream,
> Like ray of columned light chasing a shower,
> Would cross my homeward path; how sweet the sound,
> When I to hear the Doric tongue's reply,
> Would ask thy well-known name!" Page 180.

Grahame was early addicted to versification; but his first acknowledged production from the press, was the oft attempted theme of "Mary Queen of Scots," in the form of a tragedy. This is a long and desultory drama, little careful of Aristotle's unities, and is sprinkled with rather too much of the Scottish phraseology; yet it shews so deep and genuine a sympathy, and so high an admiration for the sufferings and virtues of the ill-fated queen, and contains some such tender images, as to give it a claim on the public attention, independently of its dramatic merit. It has amused us to observe also, how his chivalrous enthusiasm and warm nationality seem to have gained such an ascendency over his mind, as to have made him forget the political maxims which he had learned at Glasgow in the school of Millar, as well as those anti-catholic feelings which he had imbibed in his early years. This was a favourite production with the author, but not with the public; and he republished it with very considerable alterations in a 12mo edition of his poems, in two volumes, which appeared in 1807. His next considerable publication in the order of time, and indeed the poem by which his fame is most likely to be established, is "The Sabbath." The day of solemn universal rest, presented peculiar attractions to a soul feelingly alive to the beauties of nature, to the impulses of benevolence, and to the sublime emotions of piety. In Scotland especially, where the duties of that day are still perhaps more decently and religiously observed than in any other part of the Christian world; where the pause from painful toil and frivolous pleasure is more striking; and where even those who do not feel its purest joys, partake by sympathy and association in its reflected influence, the theme could scarcely fail to be a popular one. In short, we are inclined to think, that the subject admits of the highest poetical embellishments which language can furnish, with the additional interest which truth must always claim over fiction. The antiquity of the Sabbath; the authority by which it was appointed; the cause of its institution, first as a memorial of the creation of the world, or rather of that part of the system of the universe with which we are connected, as proceeding from the hand of the Almighty, and as leading us to acts of adoration and praise; the manner in which it was solemnly enacted, amid the stupendous displays of divine power on Mount Sinai; the jubilee, or year of deliverance, as connected with this wonderful institution; then the change from the seventh to the first day of the week, on account of the completion of man's redemption, by the resurrection of Christ; and lastly, its direct and indirect moral influence, its actual and progressive benefits conferred on society, and the prospect of the Sabbath of rest and joy in the realms of endless blessedness;—all these present a combination of grand and affecting topics and images, which are worthy of the highest powers of the noblest poet, and which indeed render it less difficult to find materials, than to select from the abundance that presses on his attention. If Grahame has not attempted to give that kind of unity to his subject of which it would have admitted; if he contents himself with a less ambitious flight, he has, at least, felt the inspiration of his sacred theme, and, by a series of tender and affecting pictures, simply and naturally combined, and derived chiefly from the customs and history of his native land, and from scriptural allusions and associations, has produced a work which renders his name conspicuous, not only among the poets, but among the benefactors of his country.

The "Sabbath Walks" and "Biblical Pictures" which are added in the later editions of this poem, are quite in unison with the spirit of the work; and some of the latter are so strikingly delineated, that a skilful painter might easily give them life and figure, by translating with his pencil the vivid and glowing descriptions of the poet's pen.

The next of Grahame's poems to be slightly noticed, is his "British Georgics," a name which is too boldly chosen, as it leads the mind to the most finished production of the Mantuan Bard; and as it is in itself perhaps the least perfect of the author's writings. When on a visit to a friend on Tweedside in 1797, he inserted a poetic sketch of the month of April, under the signature of *Matilda*, in the Kelso Mail. It was much admired, and was followed by the other months. These sketches are preserved in his works, and there can be little doubt that they gave him the idea of the Georgics, which are only in fact the filling up of the outline, and which afford theoretical and practical instruction to the British husbandman, connected with the different months of the year. An attentive reader will accordingly find in this larger poem, which is also divided into twelve parts, a frequent recurrence of the same thoughts and expressions which occur in the minor pieces. The Georgics, among many prosaic passages, contain also a number of the finest touches of fancy and of feeling, and some affecting allusions to the state of the author's declining health. We are not fond of didactic poetry, especially in blank verse; metre gives at least more entertainment to the ear, when the tameness of the subject precludes the flights of imagination. And we apprehend, that the beauties which are scattered through this poem will hardly preserve it from oblivion.

The "Birds of Scotland," his next large poem, is a production of very superior merit, in which the author describes, with admirable skill and truth, the manners and characters of the winged tenants of our woods and wilds. With his exquisite descriptions are interspersed delineations of the scenes which they frequent, and fine allusions to national character, and historical traditions. He has indeed succeeded in accomplishing the design which he proposed, of "pleasing the imagination, and warming the heart." And he has done more; for he has conveyed much instruction in a most agreeable manner, and furnished us with new sources of delight, in the enjoyment of the cheap and innocent pleasures of nature.

Mr Grahame, whose soul always abhorred the traffic in slaves, and who rejoiced with all good men in its abolition, had the honour of contributing one of the three poems, intended as a grand literary monument, to this noblest triumph of justice and humanity of which our age can boast. The other two were furnished by Eliza Benger and Montgomery, and the whole was published by Bowyer of Pall-Mall in 1809 with most splendid decorations. Mr Grahame also wrote the "Siege of Copenhagen," and published it with the sanction of his name, soon after the details of that expedition were received. It is a spirited little poem, and contains some passages remarkable for beauty and tenderness. It is written in metrical couplets.

Cowper is the poet whom Grahame most resembles, and whom we believe he adopted as his model. Yet there are striking differences between them, independently of the preponderance of talent in favour of the former. Grahame has more flat passages,—Cowper more rugged lines. Grahame is minute in describing all that, in the range of nature, strikes his fancy;—Cowper, with an eye as poetical, was more limited in his sphere of observation, and less ambitious in the choice of his subjects. Cowper's religious views were inwrought and profound;—Grahame's consoling and abiding, but by no means so deep. Grahame feels and admires the simple and varied charms of creation, and expatiates upon them with ever new delight; his forte is accurate description of nature in its simplest forms;—Cowper hunts through the intricacies of the human heart; his chief excellence consists in the faithful delineation of the feelings and moral sympathies of the

Grahame, James.

Grahame, James.

soul. Grahame has more ornament;—Cowper much greater extent and variety of thought. In language they are both careless, and in their measures often incorrect. But there is a grace even in their negligence. To both the praise "above all Roman fame" belongs, of rendering the powers of their cultivated minds subservient to the promotion of the best interests of morality and religion.

Those who only knew Grahame by his works, will form their own estimate of his genius and worth. But his memory will long be embalmed in the minds of those who had the good fortune to enjoy his personal acquaintance, or his friendship. Never, perhaps, did a kinder and gentler heart animate a human frame; never did a man exist more unwilling to give pain to any sentient being, or more desirous of promoting the peace and happiness of all within the sphere of his influence. His country will long cherish the remembrance of the author for the sake of his works; while his friends will, with fond and melancholy pleasure, cherish the effusions of his genius for the sake of the amiable author. (*l*)

GRAMMAR.

Grammar.

GRAMMAR is that knowledge of words which qualifies the possessor for speaking and writing with propriety. PARTICULAR GRAMMAR comprehends the rules of particular languages, as founded on the practice of those who have that sort of conspicuousness in society which is considered as entitling them to fix the standard in each. Every language has thus a grammatical system of its own. All languages, however, possess some circumstances in common. Prevalent analogies are developed in their origin and history, and certain leading principles are found to obtain in the application of them to the purposes of speech. The general doctrines discovered by the comparison of different languages form the important science of PHILOSOPHICAL, or UNIVERSAL GRAMMAR.

UNIVERSAL GRAMMAR.

Universal Grammar.

THIS science unfolds the principles by which man is directed in the contrivance of the varieties of words. Its utility is extended by the opportunities which it gives of tracing the connection which the phenomena of language considered as a production of the human mind have with the other principles of our nature.

[...]ent of [...] subject.

As the term Grammar has been currently applied to a much inferior department of knowledge, some have thought proper to give Universal Grammar the apparently more elegant designation of the THEORY OF LANGUAGE. This latter designation, however, comprehends all the general branches of inquiry connected with language, which are treated under various articles of this work, such as ALPHABET, ETYMOLOGY, PHILOLOGY, and LANGUAGE. Its most interesting branch consists of those inquiries which, under the name of UNIVERSAL GRAMMAR, we here propose to lay before our readers.

Language being the leading instrument by which men communicate their thoughts to one another, it is to it that we undoubtedly owe the most important improvements of which our intellectual character is susceptible. It might therefore have been expected that an inquiry into its nature would necessarily imply an elucidation of all the laws of thought. But its province does not extend altogether so far; and, by keeping it within its due bounds, we shall do greater justice both to this science and to those with which it is connected. We shall find that the points of view in which man appears in thinking and in speaking are not so perfectly identical as has been imagined. It is not true that Universal Grammar implies the whole theory of human thought; yet it implies a great and important part of it: and the habit which the study of it gives us of investigating the subject, and the analogies which it furnishes for the prosecution of the rest, may, under judicious management, contribute materials towards a perfect knowledge of the general philosophy of mind.

Facts by which its doctrines are suggested.

We have intimated that this science originates in the comparison of different languages. It is not indeed very flattering to the pride of human intellect, and it will appear to many inaccurate, as well as undignified, to ascribe the discovery of the principles of Universal Grammar to a circumstance which might be regarded as accidental, viz. the multiplicity of languages existing among mankind. Its principles must operate in the formation of each individual language; and the science might therefore appear to admit of being investigated with sufficient certainty by a direct inquiry into the operations of the human mind, or by the obvious analysis of any single language. This might be thought sufficient to distinguish all that is requisite to the purposes of speech from every thing whimsical or peculiar, that is, from those turns of words and of phraseology which ought to be reckoned idiomatic. It might, at least, seem reasonable to expect that the principles would be discovered by paying attention to the variations and analogies existing among those words of any language which are not immediately and evidently borrowed from a foreign source. It might even be thought possible to collect them by recording the early operations of a child in learning the use of his native language. That the principles of this science *could* have been so discovered, it would be rash to deny. But the well known obstructions opposed to science by the delicacy and proneness to error which mark the human faculties, and the various external biases which the mind receives, operate in all ages to prevent scientific inquiry from being made, and in corrupting the accuracy of the results obtained. Hence we are sometimes indebted to fortunate accidents for an introduction to the right path of inquiry, and for the discovery of truths which had otherwise a chance of remaining

Universal Grammar.

for ever unknown. One of these fortunate accidents, as relating to the subject of our present article, is the existence of various languages in the world, and the access which individuals have to compare them together. The success which philosophers have met with in these inquiries has arisen from the study of languages the most diversified from each other in their structure. Those of ancient Greece and Rome have, for example, been compared with those of modern Europe, and both these with the languages of the East, and the great differences apparent in their origin and structure have afforded a valuable opportunity of tracing, with a scientific hand, the general operations of man in this conspicuous department of his active efforts. An extensive erudition in literature confers emancipation from that enthralling influence which any single language exercises over those whose knowledge is confined to it. The errors which the habits of one would produce receive correction from the attention exacted by the varying genius of another. These inquiries might even lead us a step higher. They might enable us to discover whether or not there are any circumstances in which the habits common to all languages mark a prevailing erroneous bias in our nature, and might lead us to improve and purify in this department the perspicacity of our intellect.

The difficulty of the subject renders it at least prudent to avail ourselves of all the aids which can be afforded by diversities in the structure of languages. These, indeed, are of themselves elegant subjects of study. No person who cultivates them can be indifferent about Universal Grammar, or insensible to the intimate connection which exists between the two pursuits. A very limited fact in philology not unfrequently suggests an important doctrine in the philosophy of grammar, which is afterwards confirmed by multiplied evidences, and, though formerly overlooked, exhibits, when known, a character of internal truth, and throws a broad light over the whole extent of the subject.

Present state of the science.

In no circumstance does the difficulty of this subject appear more conspicuous than in the diversity of sentiment which prevails on it. This diversity is indeed capable of being represented as chiefly, if not entirely, verbal. But, where verbal differences are pertinaciously adhered to, some misconceptions with regard to the subject itself are undoubtedly more or less prevalent. It cannot be said to be clearly understood among all who cultivate it, unless they either agree in the choice of the words by which their theories are expressed, or concur in acknowledging their differences of phraseology to be immaterial.

This is not at present the case. The cultivators of the science are divided into parties, which seem so distant from one another that the philosophical analysis of language may be considered as still in its infancy. The account which we shall now give of it will not arrogate to itself the rank of a system matured for indiscriminate adoption. It will only be offered for deliberate consideration, as an attempt to advance the progress of this interesting branch of study, by exhibiting explanations which will show to partial systems several of their leading defects, and reconcile a variety of disputes without compromising the spirit of investigation.

CHAP. I.

On the Object or Universal Office of Language.

In order to investigate the characteristic differences by which words are distinguished, it is essential that we entertain correct ideas of the OBJECT or PURPOSE of language. Grammarians have hitherto satisfied themselves, with describing it as consisting in the COMMUNICATION OF OUR THOUGHTS. Yet it does not appear certain that they have always entertained the same views of what is meant by this communication. Vague notions of the office of language have in consequence been entertained, and a confusion arising from this cause has impeded the inquiries which were made into the origin and distinctions of the various parts of speech. Mr Harris describes it as consisting in "an exhibition of the energies or motions of the soul." These he divides into perception and volition; and he considers every sentence as either "a sentence of assertion," or "a sentence of volition." Some consider the object of language as simply consisting in the exhibition of a connection betwixt one idea and another, and therefore make the act of AFFIRMATION its universal office. These opinions, though slightly varying, agree in stating the communication of our thoughts to be the object of language.

Universal Grammar. The general opinion.

That we may divest the subject of ambiguity, we shall enquire in what respects thought is ever communicated by language; what are the circumstances that lead to such communication; and whether or not the importance of this object entitles it to be regarded as the sole and definite purpose for which it is formed and employed.

How do languages communicate thought.

Men may evince, by various signs, that particular thoughts occupy their minds. This is not only done by pantomimical language, but by oral sounds constituting the materials of verbal discourse. We sometimes shew by involuntary exclamations that we are affected by certain impressions called passions, which, though they originate from outward causes, do not necessarily point to such causes in our mode of expressing them. At other times, words are employed as the signs of external objects which are known to the person addressed. The effect of the employment of these is to recal to his recollection ideas formerly possessed by him. We show, at the same time, that they occupy our own minds. The meaning of the words being formerly known, they exhibit nothing new except their connection with some present occasion. Old ideas thus recalled, however, do not constitute exactly the same state of thought which accompanied the former employment of the words. The mental exercises excited by the same word at different times are not strictly the same. They cannot be identical, because they are separate instances of mental exercise. But they are not even perfectly similar. Amidst the varying movements of the human mind, in which one thought impels another, and in which external and internal causes modify the state of the percipient being, the appropriate affection produced by any particular word can never be separately obtained. It is always modified either by humour, by degrees of activity in the mind, or by the kinds of exercise in which it has been previously engaged.

The most important modifications of the mental effects of words arise from their connection with one another. By changes in this connection, new conjunctions of ideas are presented to the mind of the person addressed. The signs of thoughts formerly known to him are so exhibited as to excite impressions possessing the most striking novelty, and imparting the most important character both to the immediate thoughts of the individual, and to those which are liable to occur on numerous future occasions. This is the case when, by means of words well understood, and therefore conveying in their separate state no idea that is new, we communicate information to one another, and exercise an influence on human opinions. On this office of language depends the whole benefit which mankind derive from the records of literature and science.

Engrossed by this most dignified application of language, authors have been induced to consider it as consisting entirely in assertion; that is, in expressing the connection of one idea with another, and conveying by these means new information. But, it may be called in question how far this account is strictly applicable to all language, or may be trusted for our guidance in tracing the steps of its earliest history.

...nkind ... always ...lined to ...part their ...ughts.

It has been hastily assumed, that language arises from an original and universal inclination to impart our thoughts gratuitously to one another. From this cause it has sometimes been erroneously concluded that it is nothing else than a faithful transcript of the successions of human thought. This, however, is not its character. A man does not speak simply because he thinks. It is not a necessary result of the possession of a thinking faculty, nor does the inclination to speak regularly accompany its operations. It is the effect of a range of thoughts which must be considered as limited when compared to the whole phenomena of mind. Speech, like every other voluntary act of man, is founded on the presence of particular motives. It originates in his social nature taking advantage of his social state; and it depends on the knowledge which each has of various links of connection existing betwixt himself and other thinking beings.

...gin of ...ught and ...guage ...erent.

It is not natural to man to communicate all his thoughts. Supposing, therefore, that a complete analysis of the origin of thought were in our possession, this would not necessarily bring along with it a perfect theory of the origin and character of language; nor would the most perfect history of the formation of language lead us in the opposite direction to a perfect analysis of the nature of thought.

...anguage ...lied to ...erent ...poses?

But, allowing that we do not by means of language communicate *all* our thoughts, that we make a selection among them suited to our several occasions, it might still be contended that we do *nothing else* by means of language than communicate our thoughts; that this is its universal office; and that this position might be assumed as fundamental in entering on the subject of universal Grammar.

Some considerations will, we conceive, warrant us in hesitating before we concede even this point. We shall not stop to enquire if there is any acceptation in which this theory is true; but it is certainly susceptible of a meaning which is erroneous, and which has tended in some cases to distort philological enquiry. On the supposition now mentioned, language would still be considered as properly an exhibition of human thought. *

...se sen...ces.

The first observation which we have to make on this account of the subject is, that, if it were correct, language ought always to have a definite reference to our sentiments, and ought in fact to express them with fidelity. But we find that, when we desire a person to perform any act, our motives for it are kept out of view, and are not intended to be contemplated by the individual spoken to. The motives which are expected to operate on him are ideas of a different sort which we endeavour to excite. Even in the use of the plainest affirmations, we do not necessarily exhibit our own thoughts. We may excite thoughts completely the reverse of them. This is always the case when we procure reception to a false proposition. The thought conveyed by our words has indeed been revolved in the mind as a contrivance for operating on another. In that other, however, we mean to produce a particular belief. This is certainly a thought; yet it is not the belief, consequently not the thought, which, in so far as truth is concerned, we ourselves entertain.

It might indeed be replied, that this employment of language is unnatural; that it is as much a deviation from its original purpose, in the right use of our faculties, as any act of drivelling folly committed by means of language, which ought not to be regarded as entering into its original character. But it is to be remembered that this use of language, though disingenuous, is still characteristic of intellect and address.

The pretext for language different from its object.

It might also be said that in this use of language we closely *imitate* the sentences in which our own ideas are *bona fide* communicated, and that our success in falsehood depends on the closeness of this imitation. This fact only shows that dissimulation does not affect language in its structure. But its *object* must imply the real motives of the speaker. This account of it, therefore, must be deficient. If we can form a general theory on the subject which will embrace these as well as all other occasions on which it is used, a material advantage will undoubtedly be obtained.

The existence of false sentences is not our only reason for declining to regard the communication of thought, at least that communication which consists in assertion, as the universal office of language. We shall find that *Imperative sentences* cannot, without great awkwardness, be reduced to affirmations or communications of our knowledge. But, reserving that argument for the next Chapter, we shall now endeavour to unfold, in a more detailed manner, some of the intricacies in which this part of the subject is involved.

A more particular statement of the question.

Different circumstances concur to impress the philosophical inquirer with an idea that the communication of our thoughts is the object of language. One, at which we have already hinted, is, that this communication is the object of a *great part* of language, perhaps by far the greatest. This is most especially the case in polished and literary communities. It is the object of the greater part of the language of men of philosophical habits, the only persons who concern themselves with analytical inquiries on the subject; and it recommends itself as exhibiting the most important species of influence which language has exerted on society.

There are also some particulars in which all human speech agrees with the office of communicating thought, and which have led to an acquiescence in that account of its general object. One is, that the use of it always proceeds from some thoughts existing in the mind. Another is, that language consists of the signs of thought. A third, that the thoughts corresponding to these signs are contemplated by the individual using them. And the last is, that language terminates in exciting thoughts in the person addressed. But, though these points of coincidence are real, a closer attention will, we think, convince our readers that they do not of themselves constitute a communication of our thoughts.

The mere circumstance that the employment of language is in every instance the effect of previous thought is by no means peculiar to this department of human

* For a more varied illustration of this and some other views nearly coinciding with those which are here expressed, we refer to a paper on "the theory of language" contained in the 6th volume of the Transactions of the Royal Society of Edinburgh.

Universal Grammar.

exertion. All our voluntary actions are as much the effect of our mental operations as the uttering or the writing of sentences. In the use of language, as in other exertions, we indeed execute our own designs; but the enquiry is still equally open as before, what is our specific design in using language?

The second circumstance essential to language, which has perhaps tended to confirm the notion that its specific object is to communicate our thoughts, is, that the signs of human thought form the materials of which language consists. Such signs are always the media employed when we communicate our thoughts to one another. Yet it may be inquired, whether they admit of being also applied to other uses, and whether the object of language is, on that account, still more general?

The third circumstance of which we took notice, that the thoughts of which our words are the signs are entertained by the individual using them, is little more than a condensation of the two former, and requires no separate observation.

The true object of language, the PRODUCTION OF THOUGHT.

The truth will evolve itself in the clearest light when we discuss the last particular in which language has one common character with the communication of thought, that it produces appropriate thoughts in the mind of the person addressed. This is always the intention of the speaker, and if it is used by him in a skilful manner, the production of such thoughts is the consequence. This object is much more general than the communication of our own thoughts; but it is not too general to be stated as the real object of language. The conveyance of our sentiments, volitions, and opinions, is only an important part of it. The definite object of language consists in THE PRODUCTION OF THOUGHT BY MEANS OF ORAL SIGNS.

By adopting this more comprehensive view of the subject, we avoid all difficulty about the nature of such sentences as are the reverse of the belief of the speaker. We avoid the necessity of any inquiry into the propriety of considering them as in some sense exhibitions of the thoughts which he entertains for the moment, or as partial representations of his habitual thoughts. We consider them, in common with all sentences, in a point of view in which they maintain the same unquestionable ground, that is, as instruments fabricated to execute our designs; and our universal design in language is, to produce in one another such mental impressions as we please. Its ulterior purposes, being considerably diversified, admit of subdivision.

CHAP. II.

The General Nature of Sentences.

ACCORDING to the author of the Diversions of Purley, two parts of speech are necessary to language, the noun and the verb, and every sentence must contain both.

Opinions of Mr Tooke and his followers.

The reason assigned for this is, that one part of speech is required as the sign of the idea, and another as the instrument of communication. The views which this author entertained of the characteristic nature of the verb, and the act of communication as distinct from the exhibition of the signs of ideas, are not fully developed in his writings. We have not, therefore, sufficient data for appreciating their merits. The opinion maintained by some of his most acute followers is, that affirmation is the proper character of all sentences. This is considered as closely connected with the doctrine which makes the object of language to consist in the communication of our thoughts; and by this communication seems to be understood, the act of conveying to our neighbours the same connections betwixt ideas, (formerly known to both,) which they possess in our own minds. This conveyance, and the act of affirmation, are reckoned equivalent. Affirmation, from *ad firmare*, means the establishing of a connection betwixt one idea and another. The doctrine which resolves language into assertion does not depend on the truth of the theory, that its object is the communication of our thoughts. Our readers will perhaps agree with us in denying that sentences intended to deceive are communications of the thoughts of the speaker. It must, however, be allowed by all, that these sentences are assertions, and the inquiry still remains open, whether or not assertion is the proper character of sentences? To this inquiry the present Chapter is devoted.

Analysis of assertions.

A sentence of assertion includes two ideas expressed by two signs, and another sign to indicate the affirmation, or the establishment of their mutual connection. In the sentence, "man is rational," "man" expresses one idea, the first two syllables of the word "rational" another, and the last syllable of "rational" along with the word "is" constitutes a sign expressing the connection betwixt the two. These different signs are not always expressed in separate words. Sometimes two of them are contained in one, as in the last word of the sentence, "John walks." Sometimes all the three are contained in a single one, as in the Latin word *loquitur*, for "he speaks;" or *rubet*, for "he is red."

On a full consideration, however, of the variety of arrangement which words assume in the use of language, and the various kinds of words employed, assertion does not appear essential to it. We may produce thought without making any assertion. We may, for instance, merely call the attention of another person to an object formerly known to him. A very extensive department in the uses to which it is applied is that of exciting the person addressed to the performance of voluntary acts.

Language may be used without assertion.

Imperatives.

This is done by *Imperatives*, which certainly differ from assertions. Attempts have indeed been made to reduce them under this head, and to regard them in the same light with those affirmations in which an abbreviation is produced by condensing a plurality of signs into one. This attempt succeeds in so far as it appears to establish a fact, that, according to the habits of speaking and understanding one another which we now possess, the same meaning may be conveyed by an affirmation and by an imperative sentence. The sentence, *I nunc et versus tecum meditare canoros*, is of the same import with the affirmative sentence, JUBEO TE *nunc ire et tecum meditari versus canoros*. But the question recurs, which of these modes of expression is likely to have been the original one in the contrivance of words?

Language founded in our social relations.

We formerly observed that the contrivances of language are founded on the known relations existing, on different occasions, betwixt the speaker and the person addressed, and are so adapted as to enable the former to avail himself of these relations for accomplishing some definite purpose. An answer to the inquiry, what forms of sentences are likely to be the earliest and the simplest, is not obtained by determining what connections of thoughts are simplest in relation to the mind of the solitary individual, but by finding what those purposes are which he is likely soonest to have in view in employing the influence which language gives him over others.

Inference from this.

The first objects that strike the attention of man in becoming acquainted with his fellows are their motions. In other respects, one man is not more interesting to another than any piece of dead unchangeable matter. He first observes voluntary motions of the most palpable kind, and then gradually becomes acquainted with more delicate phenomena, such as the motions and changes of the human countenance, from which he infers the existence of thoughts in other persons, and judges of their nature. In acquiring this knowledge, he is guided by experience, and by a comparison betwixt the motions of others and those of which he is conscious as the natural accompaniments of his own thoughts.

rly date of impera- es.

The helplessness of man as an individual, and the support which he is capable of deriving from the services of his fellows, create perpetual occasions on which he wishes for their assistance; and one of the earliest as well as the most frequent objects of his wishes is to influence them to perform those motions for which he finds occasion. These necessities are prior to the mere luxury of a mutual communication of knowledge and opinion. This fact seems to point out imperative sentences as the earliest forms of language.

'ey are r contract- asser- tis;

On this account, it is not historically correct to consider the imperatives *I, veni, fac*, and *dic*, as brief modes invented in the progress of language for expressing thoughts originally conveyed by means of such affirmative sentences as *jubeo* or *precor te ire, venire, facere*, and *dicere*. The act of commanding, or requesting, does not require to be mentioned. It is actually exhibited. *Jubeo te ire* is something more than *I*. It is a pleonasm in the form of an affirmative sentence; and has the same relation to this imperative which the sentence "I affirm that man is mortal," has to the shorter one, "Man is mortal." When we speak, there is no meaning in affirming that we speak; and in like manner, when we give a command, or make a request, there is no meaning in telling that we do so, unless we intend to enforce a compliance with our wishes by an additional idea contained in the verb prefixed, as by addressing ourselves particularly to the fears of another in the verb *jubeo*, or to his kindness in the verb *precor*. A command ought, in strict propriety, to be given, before it can become the subject of an affirmation.

n asser- s of ies.

As the imperative is an immediate consequence of our wishes, advantage might be taken of that circumstance to represent it as an "assertion that such wishes exist." But the circumstance of being the consequence of our wishes is common to it with all our actions, as well as all our words. It is rather, however, to be considered as an execution of our wishes, than an assertion of their existence. It is a call of attention; a mode of influencing the volitions of other persons, and thus producing, on their part, certain trains of action.

l impera- the test e of ch.

In corroboration of this view of the subject, we find that words signifying voluntary motion exist in the shortest form in the imperative of the verb. This is the case in all the languages, ancient and modern, which we have had access to examine. Exemplifications of this in the Latin language are afforded in the words already named, *I, veni, fac, dic*, and *duc*; or the common examples of the conjugations in elementary grammars, *ama, doce, lege, audi*. The same comparative brevity takes place in the English language, as in the words, "go," "come," "do," "say," "bring," "love," "teach," "read," and "hear," which never stand by themselves except in the imperative mood. Even when the idea expressed by any verb, in either language, is introduced as an object regarding which an assertion is to be made, the word employed is longer than the imperative. In Latin, the syllable *re* is in this case added to those which constitute the imperative. From *ama* we have *ama*-RE, and from the other imperatives, *doce*-RE, *lege*-RE, and *audi*-RE; also, *i*-RE, *veni*-RE, *dice*-RE, *fac*-ERE, *duc*-ERE. In English, we prefix the word TO, or add the syllable ING; as, "*To* read or read-*ing* is an improving occupation." "Men of intellectual refinement delight in read-*ing*, or delight *to* read." In some instances, the word is equally short in its application to other uses as in the imperative. Of this the noun "love" is an example, being equally short, and indeed the same word, with the imperative of the corresponding verb. Such instances, however, are rare. Brevity, therefore, appears to be an original character of imperatives; a circumstance conformable with the theory, that they ought to be considered as original modes of speech, and not as abbreviations of affirmative sentences. The affirmative form, instead of illustrating the imperative mood, renders it cumbersome, and destroys its characteristic animation.

Apparent exceptions.

To those who have not previously considered this subject, the brevity of imperatives may appear, in point of fact, liable to some exceptions. The Chinese language is said to have no imperatives. That language, however, in so far as we can judge from our scanty knowledge of its structure, seems to owe this apparent defect to affectation and refinement, which have induced men in speaking to prepare the hearer by means of distant and respectful circumlocutions, instead of using direct imperatives, in order to avoid the apprehended indelicacy of dictating an abrupt change of direction to his thoughts. This modification probably took place after men had learned to keep their own objects and their own influence out of view, and to appear solely attentive to the convenience and pleasure of others. In a light nearly similar we are to consider those forms in the languages of modern Europe, originating in ceremony, by which single persons are addressed in the plural number.

Another question may here be asked, Why does this alleged brevity of the imperative not extend to the third person, and the plural number? Why are the words, *amato, amate, amatote*, and *amanto*, comparatively long? Would not this fact seem to intimate that the circumstance of being imperative does not of itself determine this brevity of form? To this we answer, that the word called the third person of the imperative, is not properly an imperative as directed to the person addressed; it expresses either a simple wish, or specifies some *consequence* of an action which the speaker wishes him to perform. The command is then learned by inference, and not conveyed in the word. The imperative in the second person of the plural number is, indeed, a real imperative; but it is to be observed, that it is not of so early natural origin as the imperative singular. It requires a particular arrangement to render it applicable. It implies not merely a wish that a certain action should be performed, but a knowledge that it is capable of being performed by a plurality of people, and that their concurrence in it will promote the same object, or fulfil a variety of objects that are alike desirable. Hence it probably deserves to be considered as equally remote from the original imperative with the other uses of the signs of locomotion.

The relation which imperatives bear to assertions.

Since, then, imperatives are not to be considered as contracted affirmations, it remains to inquire in what relation they stand to sentences of the latter kind? Whether these are originally two distinct species of sentences, merely agreeing in the general character which is common to all language, that of being intended to produce appropriate thoughts in the person addressed?

All language IMPERATIVE.

In tracing the nature and origin of human language, it appears to us, on the whole, most strictly agreeable to the natural history of our species, to consider all lan-

Universal Grammar.

guage as IMPERATIVE, that is, as always implying the imperative of a verb.

This applicable to nouns.

Even when we merely mention an object by making use of a noun, an imperative is implied, desiring the person addressed to think of it. Some more particular intentions on the part of the speaker may be left to be inferred from the occasion on which it is uttered, or may be expressed by some circumstances of manner, or conveyed by means of some further verbal sign; but the noun itself, in the moment of utterance, always implies the general act of demonstration, that is, the imperative of the verb "look," or "think."

Assertions reducible to imperatives.

Assertions may be advantageously reduced to the imperative form, and may be considered as originally and essentially partaking of that character. Imperatives, we have remarked, are deprived of their characteristic animation when reduced to assertions. Assertions, on the contrary, preserve more completely that interest which originally belongs to them, when viewed as imperative directions for regulating the volitions and active thoughts of others. Our opinions proceed from impelling causes which bear a resemblance in their nature to the motives which prompt us to action, and assertions resemble the exhibition of such motives to other persons.

Is the copula reducible to an imperative?

But if each single word possesses an imperative power, it may be asked, in what respects that power can be ascribed to the copula "is?"—When the intention of assertions is considered, this copula will be found equivalent to the imperative of the verb "believe." An opinion asserted by means of it does not retain the simple character of one which remains quiescent. Hence it is always expected to be of a nature fitted to interest the person addressed, and possessing a just claim on his attention. Without this, the declaration is regarded as unmeaning. Keeping this circumstance in view, we shall find nothing forced or exaggerated in representing the "is," in English as equivalent to "believe," and the *est* in Latin to *crede*.

When sentences constructed by means of this copula are not intended for conveying information, but for exhibiting pleasing objects already known, or objects of imagination, as in poetic description or fictitious narrative, the copula has the power of the imperative "contemplate."

Objections answered.

One objection might be made to this theory, that *est* being placed betwixt two nominatives, cannot be equivalent to a word which governs nouns in the accusative. If such an objection should occur, it is sufficient to observe that the cases of nouns are refinements of language, intended for marking in a convenient manner certain uses of the words and certain analogous connections which are formed among them in the composition of sentences, but that our present inquiries relate to a period of language much earlier than such contrivances; and, where the meaning can be shown to be the same, diversities arising from these causes does not fall under our consideration.

It might, however, be objected to the whole reasoning here employed, that, if all sentences appear to be imperatives, there is no meaning in supposing those words which are usually called imperatives of verbs to be the earliest parts of speech, and in deriving from that consideration the brevity of their form. These particularities should at least imply that they differ from other imperatives. The nature and consequences of this difference require therefore to be pointed out. When we use the imperative of a verb of action, the name of the act expresses our ultimate wish, viz. the wish that the person addressed should perform it. Its name is originally contrived for this particular purpose. When we use it for other purposes, these require to be stated; and even the mere absence of the imperative use is denoted by the additional signs which we have already mentioned as distinguishing the infinitive of the verb. When we direct a person to think of objects of other kinds, each object may admit of being expressed by a very brief sign. But, for the most part, various circumstances require to be specified. Our intentions respecting any object admit of considerable latitude, and are to be particularized on each occasion by the indication of a connection betwixt that object and some others, or betwixt it and some voluntary effort which we dictate to the individual addressed. These relations, being various, require signs to distinguish them; and these signs, being generally in the form of terminations, give rise to the greater length of the words. But even in those instances in which the word used for an imperative suffers no change in its form when converted into a noun or any different part of speech, it cannot, like an imperative, stand alone to form a sentence. Though not lengthened by the addition of a syllable, it requires to be accompanied by some other word.

Universal Grammar.

Objection answered.

We have maintained that every noun implies an imperative act of demonstration, or a call for attention; but it may be objected, that, as this is necessary to all language, and does not serve to distinguish one word from another, it cannot be said to be contained in the word, though implied in the act of speaking. Speech may have an imperative character, and yet it may not follow that its materials consist of imperatives alone. The names of surrounding objects may not be necessarily considered as expressive of different imperative acts, like the imperatives of different verbs. When we resolved the copula "is" into an imperative, this, perhaps, appeared an excessive refinement, and a strained attempt to give exclusive support to a particular system. It may appear sufficient for the maintenance of our fundamental theory to keep in mind that a note of attention is implied in the act of speaking. If these views seem to our scientific readers more just than those which have been here suggested, we shall not, on so abstruse and so nice a point, urge any farther argument, but leave the preceding observations to their deliberate reflections. We have endeavoured to make as near an approach as possible to the formation of a general theory on the nature of sentences. But the views which we have given are not all essential to those that are to follow. The latter will, we hope, exhibit evidences of their own, independently of the consent of our readers to give to those contained in the present Chapter, a strict application in every particular to the parts of speech.

Varieti[es] the obj[ect] o[f] langua[ge]

Language must be regarded by all as an instrument by which we direct the thoughts of one another. It has thus an undoubted imperative character, and this character receives subordinate variations depending on the mutual relations of the speaker and the person addressed, with reference to the subject upon which it is employed. It includes four forms of influence, which have been already alluded to, and shall now be enumerated. 1st, We influence one another to exert the powers of voluntary motion. This gives rise to *Imperatives* in their acknowledged form. 2d, We direct the attention of one another to all the varieties of objects already mutually known. This gives occasion to the contrivance of *Names* to represent them. 3d, We influence one another's opinions and state of knowledge. This gives rise to the words which are particularly subservient to *Assertion*. 4th, We influence one

and in e[ach] general forms o[f] sentenc[es]

Universal Grammar.

another to communicate specific information. This gives rise to *Interrogatives*.

Though we have already given some account of the differences of words as subservient to these different uses, there are many varieties, as well as many analogies of form and use among them, which have not come under our consideration. The analysis of these will throw light on the general faculty of speech, and will furnish some rules for preserving us from mistakes in language, and from mistakes of greater importance regarding the diversified subjects to which language is applied. The remaining Chapters of this article will be occupied in investigating the differences which are commonly considered as constituting the different parts of speech.

CHAP. III.

Of the Parts of Speech.

Parts of speech different in different languages.

These have been variously enumerated. Grammarians have not only differed in their arrangements, but in the number of parts of speech which they have allowed. The character of a particular language may, in some instances, determine the propriety of an arrangement in so far as concerns itself alone. The Latin language has no word exactly corresponding to the article ὁ, ἡ, το, in the Greek, and *the* in English. Those therefore who consider these words as the only definite articles in these two languages will consider the Latin language as possessing no such word; the circumstance denoted by it in other languages being left to be inferred from the connection.

Differences of opinion as applied to all languages.

But, independently of any difference originating in causes of this kind, some have called in question the propriety of certain distinctions maintained by others, whether as existing in the same language, or as common to all. Some parts of speech reckoned by the generality to be distinct have been ranked together by a few individuals under a more comprehensive head.

Mr Tooke and Mr Harris.

This generalization has been carried the greatest length in Tooke's *Diversions of Purley*. This author reckons the *Noun* and the *Verb* the only essential parts of speech. He does not, however, acquiesce in the views of Mr Harris, who sets out with a binary division of the subject which has the appearance of being similar. Mr Harris considers the adverb, the preposition, and the conjunction as merely subsidiary and inferior materials which connect the other parts of speech, and give ornament and fulness of expression to the whole; while Mr Tooke considers them, in every instance in which they are used, as equally essential with nouns and verbs, and refuses them a separate rank only because they are possessed of the same character with one or other of these parts of speech. He considers their only peculiarity as consisting in an abbreviated form, which has originated in the efforts of mankind to express their thoughts with celerity.

We have already observed that Mr Tooke founds his doctrine of the distinction of all words into nouns and verbs on this principle, that language implies "the signs of ideas," and also a "separate instrument for the purpose of communication." This separate instrument he calls the verb. He considers every verb as implying a noun, and also as implying something more, though he leaves the problem unsolved, what is that definite circumstance which, when added to the noun, makes it a verb?

Theory here advanced.

We coincide with this author in so far as he maintains that language consists of the signs of ideas, together with certain contrivances for connecting these so as to answer the purposes of language. We adopt from him the valuable suggestion, that the verb contains the name of an idea, and, in this respect, comprehends the character of a noun, together with some additional circumstance; but we are obliged to give this suggestion a much wider extension, and to consider all the parts of speech, the noun itself included, as consisting of two parts, one of which is the sign of an idea, and the other a sign of a definite place which that idea is to occupy in the order of discourse. Instead of saying with this author that the verb is *quod loquimur*, and the noun *de quo*, we would say that both the one and the other contain the name of an idea, and also a mark of some specific application, arising from the present occasions of the speaker. Both express certain objects *de quibus loquimur*, while the *quod loquimur* is the result of the collocation of the words thus mutually adapted.

Division of this subject in some measure optional.

Such differences of mutual adaptation furnish the only good foundation for a distribution of the parts of speech. Great nicety in our subdivision is not essential to the explanation of their nature. We may, independently of this, point out the circumstances in which any part of speech to which we happen to give a separate name approaches to various others, or differs from them in its character. We shall therefore, without condemning the plans of others, adopt the division and arrangement which appear to us, in the mean time, most convenient. Even where a dispute may arise about the propriety of a particular distinction, in consequence of a slight difference in the obvious form of some words, which may have led into an erroneous conception of their nature, this is worthy of being noticed, for the purpose of assigning to it its due share of importance. Useful information may be derived from the detection of deceitful resemblances and deceitful differences, as well as from processes of analytical science apparently more profound. To content ourselves with showing that other persons were misled by them, and reprobating the errors which they embraced, is a plan of conduct neither fitted to promote scientific inquiry nor liberality of feeling.

CHAP. IV.

Of Nouns.

Sect. I. *The Nature of the Noun.*

Differences in the extent of meaning given to the term Noun.

The word *Noun* in our language, as well as the corresponding words used by grammarians in other languages, signifies "a name." Nouns are, for the most part, defined to be "words which denote *objects* or *substances*." Some consider them as including substantives and adjectives; substantives denoting substances, and adjectives denoting qualities. Others regard these two sorts of words as deserving a separate rank in language, and therefore restrict the meaning of the term "noun" to substantives. The words to which these different appellations are assigned agree in some respects, and differ in others; and the propriety of ranking them together or separately will depend on the definition given to the noun. Mr Tooke considers both substantives and adjectives as nouns, and as in fact the same sort of words, only that the adjective contains, besides the name of the object, a sign that it is to be coupled in language with some other. We shall, on the present occasion, restrict the term noun to the substantive, and shall use these terms indiscriminately, sometimes preferring the latter as better fitted to prevent any ambiguity on the part of the reader, created by the general usages of grammarians.

Erroneous distinctions.

We may trace in the prevalent method of describing the nature of the noun, as distinguished from other

Universal Grammar.

founded on erroneous views of language.

parts of speech, some of the hurtful effects of the opinion entertained by grammarians, that the history of language implies a history of human knowledge and thought. Condillac maintains that languages are analytic methods, and are necessary both for giving an account of our thoughts to our own minds, and conducting us to ideas which otherwise we could not have possessed. He thinks that the investigation of them furnishes us with convenient means for the analysis of thought, and he conceives it a radical mistake to regard them merely as the instruments of communication. Conformably with this notion, that author, like many others, considers the different parts of speech as expressions for different kinds of thoughts. We hope gradually to exhibit, in the sequel of this article, an ample collection of facts in refutation of these opinions. We shall, in the mean time, illustrate their fallacy, by pointing out the fallacious character of the metaphysical speculations with which, as applied to the noun, they have been associated.

Are nouns, or substantives, the names of substances?

Substantive nouns have been considered as the names of substances. The word "substance," is derived from *sub* and *stare*, because they are considered as beings existing under the qualities perceived by the senses, and giving these qualities support. It is granted by every person who endeavours to go a step farther back in this speculation, that the nature of a substance, as separate from its qualities, and which metaphysicians, for the sake of distinction, denominate a *substratum*, is unknown. Notwithstanding this, such words as "stone," "earth," "wood," and "iron," are regarded not as the names of particular instances and forms of hardness, weight, visibility, colour, and other qualities which are perceived, but of substrata which possess these qualities.

Doctrine of the French grammarians.

Some grammarians, following a similar theory, have represented the distinction betwixt substantives and adjectives as having for its foundation a difference existing in nature betwixt *things* and their *manner of existence*. Things are said to be substances which exist by themselves, but the manner of existence of things is said to form accidents which only exist in consequence of the existence of substances. This is the opinion advanced by the authors of the *Grammaire Generale et Raisonnée*. Words which signify the objects of thought are, in that work, distinguished into those which signify substances, and which are substantives, and those which signify accidents, and contain at the same time a notification that there is some substance to which these accidents belong. These last words are adjective nouns, or, to express each by a single word, the former are called nouns and the latter adjectives.

Nouns sometimes the names of qualities.

It is, however, an obvious fact with regard to nouns, that many of them are the names of qualities. Such are the nouns, "hardness," "blackness," and "whiteness," which have as much the character of substantives in their use in language as the words, "iron," "wood," and "stone."

Explanations of this fact.

In order to surmount this difficulty, these have been regarded as a secondary or improper kind of substantives, and the ideas expressed by them as not originally entitled to be expressed in that form. They have been considered as originating in a figure of speech by which qualities are treated as if they were substances. The authors of the last mentioned Grammar ingeniously attempt to solve the difficulty, by describing the qualities thus designated as *subsisting by themselves in language*, being so used as to have no need of another noun, although they are, in their own nature, mere accidents. A very little more inquiry would have led these writers to the true doctrine on the subject, that the mode of treating the sign of an idea, and the idea itself by means of it, in language, is the sole foundation of the peculiarities of the substantive noun.

Universal Grammar.

Discussion of the doctrine of a substratum.

The difference betwixt a substance and its qualities, and the whole doctrine of a substratum, seem to be mere assumptions of an excessively inquisitive species of philosophy. The only real objects of our knowledge are qualities. It is vain to tell us that the qualities are merely the media by which we obtain a knowledge of the substance. Our ideas of the qualities themselves are clear and precise; but we never find that our knowledge of them conducts us one step towards the knowledge of the substratum. The doctrine of the existence of the latter ought therefore to be rejected as an unfounded assumption, and the objects which we call substances ought to be considered as consisting entirely of definite assemblages of sensible qualities. We cannot, indeed, disprove the existence of a substratum, nor can we prove that this substratum is not the cause of the qualities, and the bond of their union. Nature contains riches to which the human understanding has no access. But we must have some intelligible description before we can entertain any idea of it, and we must have some proof of its existence before we can reasonably believe in it. If any person should assert that every particle of earth contains a miniature of the planetary system, we should understand his meaning, and it would not be in our power to disprove his assertion. But we should undoubtedly reject it as unsupported by evidence, and ascribe the belief of it on his part to extreme credulity, a passion for singularity, or some other of the sources of self-deception by which men are so often misled. But the doctrine of a material substratum is not merely destitute of proof; it is unintelligible. The word is pronounced without any appropriate meaning. It is not probable that a notion of this sort obtains among mankind at large. It is probable that the vulgar never think of any substratum containing the sensible qualities which they perceive, and that their ideas of matter are restricted to qualities which are the solid and real objects of their knowledge. The doctrine of a substratum has been invented by men in quest of subtleties; and it seems to have been supported by the other error already mentioned, that the structure of language exhibits an analytical view of our thoughts, and that different kinds of thoughts must be expressed where different kinds of words are used. Man is liable, in such inquiries, to give way to a precipitate curiosity, which leads him to frame hypotheses on subjects beyond his reach. He does not repose in his actual discoveries, but labours to account for what he knows; and, rather than leave this unattempted, he explains what he really knows by something which he does not know, and thus infallibly renders it more obscure. He imagines that he obtains solutions of his difficulties, while he only indulges a confused and mystic feeling associated with the use of particular words.

This doctrine not proved, and even unintelligible.

Qualities the only objects of knowledge.

When several qualities are observed to be constantly united in nature, a strong association is formed among our ideas of such qualities; but if we make a careful analysis of mental phenomena, we shall find that, in pronouncing the name of any material being, certain sensible qualities, more or less vaguely conceived, are the only objects of our thoughts.

This dissertation on our ideas of substances may appear a deviation from the subject of Universal Grammar. But, since grammarians have supposed these ideas to be closely connected with the theory of nouns, it

Universal Grammar.

seemed necessary, in order to do justice to our subject, that we should shew the fallacy of the common doctrines from the nature of our thoughts, as well as from the structure of language. The views which we have stated lead us to no vague or perplexing conclusions. The fact of the uniformity of the definite combinations of certain material qualities, is in no degree deprived of its solidity or interest, though we decline to admit the hypothesis of a substratum. The rejection of this hypothesis will assist our physical, as well as our grammatical studies. It will relieve us from the embarrassment of the understanding which sometimes takes place when particular qualities are found in a detached state. Those who are unpractised in the accurate exercise of thought, and have been led astray by words, have, in the outset of their physical inquiries, found it difficult to conceive that a body which is felt yet not seen, as the air, has an existence equally substantial with other matter. They have also considered light, which implies an object of sight unaccompanied by any object of touch, as on this account more difficult to be understood than earth, stones, and other substances which are both tangible and visible. The most rational proceeding is to satisfy ourselves with such qualities of tangibility and visibility as we can ascertain in any of their peculiarities and relations, whether they are observed in a state of conjunction or of separation.

(No disadvantage arises from the rejection of a substratum, but the reverse.)

Thus, when we attempt to trace the supposed differences betwixt substances and qualities, we find no foundation for a distinction into two kinds of objects, and much less for a distinction in the kind of terms by which such objects should be expressed. This is the same conclusion to which we are led in tracing the history of nouns. We find that the same kinds of ideas are designated by them as by adjectives.

(The general origin of the peculiarities of the noun.)

If the distinction betwixt nouns and other parts of speech cannot be founded on the place which the objects expressed by them occupy in nature, it must rest entirely on the manner in which they are introduced with relation to the other words with which they are conjoined. It depends on the rank which the word occupies in a sentence, and which the thought excited by it is intended to occupy in that mental series which we wish to produce.

(Inquiry wherein this consists.)

How, then, are we to define the noun so as to distinguish it from the other parts of speech? Shall we, with Mr Tooke, consider it as the "mere name of an idea?" Shall we consider the verb as a part of speech more complicated in its nature, by containing "some circumstance in addition to the name of an idea?" And shall we be induced to extend a similar character of complication, in a smaller degree, to the adjective? This mode of proceeding might at first appear plausible. But, on closer reflection, we shall find that no word, not even a substantive noun, exists as the mere name of an idea, that there is always a demonstration of some further definite use to which it is to be applied. This we know to be the purpose of the variations called cases. Even the nominative case has a peculiarity which does not consist in the want of any such demonstration. The syllable *us* in *dominus*, denoting the nominative case, informs us that the noun is to be connected with a verb of assertion. The genitive case, and all the others in like manner point out some definite use of the noun. If we separate these terminations, and consider them as distinct signs, and regard the radical syllables as containing the essence of the noun, (as in this example the syllables *domin*,) we shall still retain the name of the idea, but we shall have nothing to distinguish the noun from the other parts of speech. If a verb is deprived of all the parts which are intended to connect the idea which it represents with the other ideas expressed in a sentence, we shall, in like manner, retain the mere name of an object. In *domin* we have the radical syllables of the verb *dominor*, as well as of the noun *dominus*.

(An attempt to describe the nature of the noun.)

Taking the noun with all the terminations incident to it, we might still be supposed desirous of giving it a definition. In its different forms we have a variety of uses to which it is applied. With these in our view, we may now ask, what circumstance is common to them all, which does not belong to the same etymon in the form of a verb. It will not be easy to give a formal definition of this. It appears to us to consist in the degree of conspicuousness which the word has in a sentence, and the ascendant interest which the idea expressed by it is intended to have in the mind of the person addressed. The noun is a name for the central object of interest. When we come to consider the different cases, it will be made to appear that they refer us to degrees of importance different from one another; but they all agree in expressing ideas nearer to the central object than those expressed by the other parts of speech; or, at least, this will be shewn to be their original destination. This may seem a very imperfect definition of a particular part of speech: it expresses, however, nothing but what is true; and the same truth will be more fully developed in other instances, as we proceed with the discussion of the various kinds of words. Although no formal definition has now been given of the noun, the purpose of a definition is ultimately answered when it is described by means of a comparison with other words, the only objects from which it requires to be distinguished.

When no termination is affixed to the radical sign, the distinction betwixt its application as a noun and as a verb is designated by its mode of connection with other words in the sentence. When the general idea expressed by the word "love" is exhibited as the chief object of interest, "love" is a noun, and the purposes of speech require it in that use to be connected with some sort of verb, as "love is a pleasing emotion." It is thus fully distinguished from the *verb* "love," which is known to be a verb from having a noun connected with it as introductory. In such sentences as, "I love," "you love," "they love," the subject of discourse is always denoted by a substantive noun. Other substantive nouns may indeed be introduced as subordinate to that which signifies the subject chiefly spoken of. The differences of these relations will be afterwards attended to. In the mean time we shall regard this general purpose as giving origin to that part of speech. In the noun the name of the idea has also greater latitude in the uses to which it is applied. It is a sign by means of which the same idea may, in the progress of discourse, be represented repeatedly, and in a great variety of aspects.

Sect. II. *Concrete and Abstract Nouns.*

Nouns are either concrete or abstract. A concrete noun signifies a congeries of qualities habitually presented together in nature. An abstract noun signifies a quality separately conceived.

(Nature of concrete nouns.)

The words "man," "woman," "wood," "stone," "house," "city," are examples of *concrete nouns.* They are the same that have been considered by grammarians and metaphysicians as the names of substances, that is, of substrata possessing definite qualities. The qualities and the substances have been supposed to

Universal Grammar.

Concrete nouns.

be firmly conjoined; hence the name concrete, by which their nature is expressed, is derived from the Latin words *con* and *cretus*, signifying "grown together." Though the hypothesis of a substratum is rejected, the term *concrete* is perfectly well adapted to represent a congeries of qualities which have become associated in the mind in consequence of certain specimens of them in nature being habitually found in conjunction. The name of a person well known to us suggests some or all of the qualities by which he is distinguished, such as his appearance, the sound of his voice, and the particulars of his personal character. The name of any well-known river, hamlet, field, or other inanimate object, suggests, in like manner, the distinguishing characters of each. The same thing is even done, though in a different way, by concrete terms of more general application, such as the words "river," "mountain," and "city." Sometimes one quality of the object, and sometimes several, occur to the mind as associated with the word; sometimes merely a vague impression of a scene in which we expect to find certain qualities which are the objects of our remembrance. The limits within which the expectations connected with words of this sort are confined constitute their precise meaning, or mental definition.

Names of habitual groups of qualities.

The scene by which we are continually surrounded consists of groups of sensible qualities, which are various in extent, and variously combined. This diversity gives origin to a diversity of terms. Terms are rendered necessary on account of the subserviency of many surrounding objects to our first wants, and their importance as instruments of mutual assistance among men. When they are present, we may, by merely looking or pointing at them, direct to them the attention of one another, and, when they are absent, we may think of them independently of any names. But, when one man wishes to execute any purpose regarding them in their absence by exciting the ideas of them in the mind of another, he requires signs to represent them; and from the familiarity of the mind with these objects the contrivance of names becomes a very early operation of the social individual.

Abstract nouns.

Abstract nouns are those which signify qualities separately conceived, such as "whiteness," "roundness," "softness," "form," "magnitude," "beauty." The nature of these nouns, and of the objects which they designate, has given rise to controversy. Some have denied that they express definite or separate ideas, because qualities never exist by themselves, but are always attached to some substance; and because it is impossible even to think of the qualities without thinking of the substance. It has, for example, been declared impossible to think of whiteness, blackness, redness, straightness, or hardness, without thinking of a *thing* or substance which is white, black, red, straight or hard. In so far as this doctrine implies the impossibility of thinking of qualities without the substrata, it has been already discussed, and must be laid aside by every person who recollects that the substratum is regarded, even by those who believe most firmly in its existence, as the most difficult to be apprehended of all material objects. Those who imagine that they think about substances to which such qualities as have now been mentioned belong, merely think more or less obscurely of other qualities with which they have a strong inclination to connect those which happen to be named. Each quality is an independent object of knowledge; but the ideas of different qualities are strongly associated in the mind, and the activity and versatility of its operations produce a proneness to conjoin each one that comes into view with others conceived to be collateral. During the first evolution of our senses, our knowledge is acquired by attending to single qualities. Persons who are born blind or deaf, and consequently have none of the ideas imparted by that sense which is deficient to mingle with their other ideas, retain through life a separate conception of certain material qualities which, by the greater part of mankind, are constantly associated with others. When a person, under these circumstances, happens to recover the deficient faculty, the ideas which it conveys are at first separate, and it is only by experience that the habit of associating them with others is gradually produced. This process has been illustrated in the history of persons born blind from an opacity in the crystalline lens of the eye, and cured by surgical operation, at a period of life when their mental faculties were so far unfolded as to enable them to describe their sensations. In mankind at large, the combinations of sensible ideas are formed long before language is attended to; and on this account the structure of language affords no analytical view of the process. If it did, the names of single qualities would be the simplest words, and the names of the assemblages which we denominate matter or substance would be comparatively compound. The reverse of this is the case. The names of habitual assemblages of objects are less compound, because the utility of assigning names to them is of prior suggestion. Single qualities are later in becoming leading subjects of discourse, and hence their names are later in assuming the form of substantive nouns. "Whiteness," "blackness," "redness," "hardness," "straightness," "roundness," are not so short as many names of objects, which comprehend one of these qualities in combination with several others. "Egg" is a shorter word than "whiteness," "soot" than "blackness." Even the names of single qualities, comprehend in their original formation a general mark of reference to some congeries of which they are supposed to form a part, and the name is subordinate in discourse to the name of some such congeries. "White" is the name of a quality, and contains a reference to some congeries to which it is described as belonging. The separate consideration of the quality is a subsequent object of interest; therefore the term for it is of subsequent creation, and an additional sign to denote this separate consideration is attached to it. This sign is the termination "ness." From "white," we have "whiteness;" from "red," "redness;" from "round," "roundness;" from "great," "greatness." Different languages have different terminations adapted to the same purpose. From the Latin *magnus*, we have *magnitudo* in Latin, and "magnitude" in English.

Controversy on the subject.

Can qualities be separated in thought?

Some have denied that we can have any ideas of separate qualities. It must be granted, as has been already observed, that the human mind has a strong propensity to conjoin different qualities mutually as objects of thought, and thus form conceptions of compound individuals. We mentioned, however, that it ought to be recollected that a person whose sensibilities are only as yet beginning to be unfolded has separate perceptions of the different qualities. It is now further to be observed that any person, even one whose habits of association are most inveterate, may direct his *chief* attention to one particular quality. Others may indeed involuntarily intrude in combination with it, or he may have occasion to think of the relations in which it stands to others; but this one in particular is distinguished as the chief object of his attention, and is also thought of with constancy, while the others with which it is accidentally associated are both less attended to and in themselves varying. We therefore see no impropriety in saying that this is a separate ob-

Universal Grammar.

ject of thought. We are certainly entitled to regard it as a separate subject of discourse. It is this alone that gives origin to such terms, and confers on them all their meaning and utility. If the present were a proper occasion for entering on such disquisitions, we might show that even the names of concrete objects do not always excite in the mind the same constant and definite ideas which are, on mature consideration, attached to them. When a concrete noun implies many ideas, we do not think of the whole of them. When it implies very few, we think of something else with which we suppose them to be in contact. It is seldom that the mind is occupied with the full meaning of any word to the total exclusion of other ideas. Very little difference, therefore, exists betwixt our mode of conceiving the objects signified by concrete and those signified by abstract nouns. The comparatively complicated form of the latter arises from the comparative recency of the period at which a distinction becomes requisite for denoting single qualities as the principal subjects of discourse.

Sect. III. *Particular and General Nouns.*

Nouns are either particular or general. Particular nouns, or proper names, are those which are applicable only to individuals. General nouns (commonly called general terms) are those which are applied to a plurality of objects possessing a mutual resemblance.

Origin of general terms.

When human knowledge becomes somewhat extended, it is impossible to conduct language by means of proper names alone. Individual objects are too numerous to receive distinct names; and, if these were imposed, it would be impossible for the most tenacious memory to retain the nouns of any language. A sense of this inconvenience has been supposed by some grammarians to have given origin to the expedient of arranging objects in genera, each genus including all the individuals which resemble one another in certain particulars, and which on that account receive one common name. Such are the words "tree," "field," "house," "bird," "horse," "elephant," "man," "woman." This history of general terms, however, is not agreeable to fact. Mankind have a *native bias* to give the same name to objects which are nearly alike. They delight to show, in this manner, that they recognise in a new object a character similar to that of something previously known. They prefer the use of words habitually significant to the coining of terms entirely new. This tendency is observed very early in children. They apply the same words even in cases in which the resemblances of objects are not sufficiently strong to render the general application of a term satisfactory. A child introduced for the first time to the sight of an uncommon animal, such as a camel, gives it an appellation borrowed from some familiar object. First, observing its majestic size, he calls it a horse; next, the form of its head, he calls it a sheep; and, by passing from one designation to another, he shows a powerful inclination to apply to it some general term. The application of common names is always most constant where the mutual resemblances of individuals are greatest. When they are perfectly alike, it is as natural to give the same name constantly to them all as to give the same name at all times to an individual.

Are they always originally proper names?

It has been said that all terms are at first proper names. But the name which we first apply to an object is proper only when we are acquainted with no other object resembling it, or when an individual so frequently claims our separate interest, that a name to distinguish it from all others is absolutely necessary. This last circumstance is the foundation of the application of proper names from the very beginning to all our familiar friends, notwithstanding the obvious mutual resemblances of human beings. Under other circumstances, we no sooner perceive resemblances than we form general terms, or, which is the same thing, give a general application to such terms as we possess. With regard to the greater part of nouns, it is probably nearer the truth to say that general terms are first in order, and that men, finding it convenient to designate individuals by single terms, subsequently create proper names, than to maintain that a sense of the inconvenience arising from the mere multiplicity of proper names gives rise to the abridged method of forming general terms. By a tenacious disputant, it might be contended that we become acquainted with objects one by one, and that therefore, if a name is given to the first object of our knowledge as soon as known, it must be a proper name; but this speculation supposes man to form words much sooner than it is possible for him to do, that is, before he possesses any variety of knowledge; a state of things which precludes all occasion for language as well as the possibility of articulation.

The creation of proper names.

General ideas.

Do they exist independently of general terms?

Here it will be requisite to describe the nature of general ideas, a subject which has given rise to much controversy. Some have maintained that no such ideas exist; others, that they owe their existence to the previous formation of general terms. The chief argument against the existence of general ideas is deduced from the fact that, when we endeavour to think separately of the circumstance which is common to all the individuals of a genus, we can obtain no distinct image. To think of "man in general" is said to be impossible. The man of whom we think must be tall or short, naked or clothed, fair or dark, lively or dull. In like manner, if we endeavour to form a general idea of "a tree" by contemplating nothing but what is common to all trees, the image no longer resembles any tree.

Difference betwixt external objects and ideas.

The denial of the existence of general ideas has sometimes been accompanied with a misconception arising from the confounding of two things which are in themselves distinct; the existence of ideas in the mind, and the existence of external objects. It seems to have been tacitly taken for granted that the same laws which regulate external objects should apply to the ideas which the mind entertains concerning them. All external objects are individuals, and therefore it has been supposed that all our ideas of them ought to be particular. External objects retain during the lapse of time their individual identity. The names assigned to them have therefore been supposed to retain one constant meaning in our minds, and this constancy has been regarded as the foundation of our ideas of particularity. Hence proper names have been supposed to be peculiarly exact in their meaning. But the fact is, that, even when we think of the same individuals in nature, our ideas at one time are different from what they are at another. They depend on the state of the mind and on the point of view which we take of the object, independently of any change to which its real qualities are liable. If particularity implies invariableness, our ideas, as existing at a specified instant of time, are the only ones that can be regarded as particular. Ideas of the same external object existing at different times, though resembling each other, may also in some respects differ; and however nearly they may coincide, they are always distinct facts in the mind. When two ideas of the same external object entertained at different times are placed together and called one idea, this idea is general in its nature. Thus proper names have not such a steadiness in the ideas which they excite as has been ascribed to them. We shall further find that the ideas attached at any particular moment to a general term, are not so vague as has been supposed. They have a distinct character; they form a definite affection or state of mind, and that state of mind is a particular or individual fact. Individuality, however, as relating to the idea in the mind, does not form the foundation of any sort of words, because words are understood from time to time, and are considered as retaining the same meaning independently of the fluctuations of human thought. The foundation of this supposed constancy is, that the ideas attached to them have always a mutual similarity. They differ from one another, but this difference has its bounds both in proper names and general terms. The ideas attached at different times to proper names differ according to the situations and aspects in which objects are viewed, and according as the mind takes in the whole, or only a part of any object represented. It is evident that the ideas attached to general terms are subjected to the very same variations. They are also liable to variations peculiar to themselves, arising from the dissimilarities subsisting among individuals of the same genus. This cause of diversity seems to have been exclusively attended to in the inquiries instituted into the subject of general terms. Yet it is not always greater than the other. In some instances it has no effect. This takes place wherever these diversities are so slight or so void of interest as to escape observation. Such are the differences betwixt one *fly*, one *swallow*, or one *mouse* and another. The general terms applied to these objects excite no greater variety of ideas than is liable to be excited by the proper names of individuals belonging to the respective species. It is of importance now to remark, that even general words significant of classes of beings among which prominent distinctions exist, along with the similarities which form the foundation of the general application of the words, are to be considered as retaining from time to time the same meaning, because the ideas which they excite are variable only within certain bounds. Some definite idea is therefore strictly attached to each term. This may be considered as a detached thought, in so far as it may be made the only, or at least the leading, object of attention. We may think of the objects signified by any term as one genus, and investigate their common properties. The versatile nature of the human mind makes it prone to mingle its ideas of these properties with various others, and these others are for the most part such as are combined with the character of the genus to form particular individuals. But the general property may be principally thought of, as well as solely designated.

All ideas of objects, in one sense, particular.

In another sense general.

The ideas attached to both kinds of nouns subject to variations which have their limits.

General ideas do not arise from words.

With regard to the opinion of those who allow the existence of general ideas, yet maintain that they owe their existence to the formation of general terms, it seems to us completely incongruous. A term is invented for the purpose of expressing an idea. The recognizance of a resemblance among a plurality of individuals is the foundation of a general idea, and this always exists before any general term is invented, and before any term which was formerly a proper name receives a generic application.

Degrees of generality.

The resemblances among objects have various degrees of extent. Some genera are much more comprehensive than others. Some include subordinate divisions into more limited genera. The word *genus* as technically used in the arrangements of natural history, represents one stage of subdivision: those immediately subordinate to it are called *species*. If it is found convenient to subdivide these, the subdivisions are called *sub-species* or *varieties*. Those which are more comprehensive than genera are called *orders*. Others still more comprehensive are called *classes*. The most general division of all is into *kingdoms*, called the animal, the vegetable, and the mineral kingdom.

The multiplication of general circumstances contributes to particularity of description.

In the greater part of objects, however, the resemblances pass gradually into one another. One object resembles many others, each in different respects and in different degrees. Every point of resemblance and of difference has a generic name, because many exemplifications of all of them occur. In consequence of the endless variety of existing combinations, we may designate a particular object by enumerating the general properties which meet in it to form its character. It is thus that we describe either a limited species or a single individual. This may be done without giving it an appropriate name. We never pursue a system of classification to its utmost extent, so as to give characters to all the subdivisions that might be formed. However near we have brought any two objects together by the limitations of our specific characters, it is still possible to find out some circumstance in which they differ, either in their intrinsic nature or their external relations; and, if upon this, in union with their other characters, we were to establish a term in our subdivisions, the gradations would be so much extended as to become equally numerous with individuals. Thus classification would produce no compendiousness of plan. It would give rise to as many names as there are individuals, besides encumbering us with the names of all the subdivisions. But we have no motives for proceeding in this manner. In most instances, the peculiarities of individuals, or of very limited species, do not sufficiently interest us. When they excite occasional interest, they are designated as possessing certain specific assemblages of qualities expressed by general terms, and our descriptions are aided by the employment of clear references. To designate the properties of interesting genera, species, and individuals, is a great part of the object of written language. It often happens that not only sentences but books are made subservient to the description of one object. Many others are indeed introduced for illustrating the relations sustained by the leading one; relations which undoubtedly constitute part of the character of these others, and more or less promote the elucidation of all.

Names of single qualities always general.

The terms which designate single qualities are always general. The cause of this feature in language is worthy of investigation. The fact itself has given rise to an idea, that single qualities are not individuals; that they are mere modes applicable to different individual substances; or that, if each quality is an universal individual, it is moveable in its relations with other qualities. But single qualities, wherever they come under our knowledge, are in reality different individuals. The whiteness of snow, and the whiteness of bleached linen, are different objects. The whiteness of one piece of linen is a separate object from the whiteness of another. It is the similarity, more or less perfect, of the objects in all instances of whiteness, that gives rise to the general name of the colour; and it is for no other reason that one common name is given to concrete assemblages of objects possessing a mutual resemblance whether in arrangement or in kind. It is for the same reason that a plurality of objects receives the name of "stone," "mountain," or "field." Yet, however exactly coincident the colour of one object may be with that of another, and however hopeless a task it may be to attempt to distinguish them, except by the differences of their association with other qualities, the colour is in each case a separate individual. It has no proper name; because, while our attention is attracted by it, we are at the same time presented with other qualities (that is, other objects) closely conjoined with it, and it is the combined scene that fixes our attention. It is to the combined scene that we apply a name, in consequence of the joint interest which we and others take in it. The only interest that we have in marking a separate quality of this scene is to point it out as a circumstance in which it resembles others. Hence it is only when we perceive similar objects, that we give this single quality a name. Thus the word in its very creation is general. The exactness of the resemblance which different exemplifications of single qualities have to each other is another reason why generic terms alone are applied to them. Although different objects, they are not intrinsically distinguishable, and the idea which we apply to a plurality of instances of them resembles, in its constancy, the idea attached to the same individual.

[margin: Cause of this fact.]

Even when any congeries of objects has a quality (or, in other words, comprehends an object) altogether peculiar, we give it no distinct name. If it is known to other persons, we refer to it by means of the concrete name by which the group of which it forms a part is known. If it is a peculiar sensation, as some of those which arise from disease, the only description that we give of it to one who has not experienced it, consists in a statement of its total dissimilarity to every other. Even when a kind of qualities belongs to a limited range of assemblages, (or, in other words, a limited species of substances,) we borrow the name of the quality from the name of the concrete assemblage of which it forms a part. The taste peculiar to an apple, an orange, a pear, or a cucumber, although forming each a peculiar class of tastes, has for its only designation a reference to the species of fruit with which it is connected.

Sect. IV. *Etymological History of Nouns.*

[margin: Uncertainty of etymology.]

The transmissions of words from one language to another are so much varied that it is not easy to trace the derivation of all. The simple sounds of which they are composed are but few; for, though the modifications of pronunciation may be infinitely multiplied, these variations do not exhibit distinctions of origin and of meaning. On the contrary, we find sounds which are very dissimilar mutually exchanged in the transmission of a word from one dialect to another. The sounds, therefore, that are inconvertible into others, or the collections of sounds which, though mutually convertible, are never exchanged for any that are different from them, are reduced within a small compass. In reviewing the history of languages, we might at times suppose that almost all sounds are mutually convertible, and, in despair of finding satisfaction from etymological researches, acquiesce in this account of them, *Les voyelles sont pour rien, et les consonnes pour peu de chose.* Such researches are most secure from fallacy when we trace the mutual concordance of languages which are historically known to be akin. When we grasp at the resemblances among the languages of nations which can scarcely be supposed to have ever been connected by mutual intercourse, we are in danger of mistaking for actual derivations instances in which a coincidence has accidentally taken place amidst the sparing number of short combinations which can be produced among a few elementary sounds.

We must therefore in many cases abandon the investigation of the origin of oral signs, as concealed by the total want of documents, or other means of tracing them. In some cases, however, the natural relations of objects to certain sounds discover the origin of words; in others, an evident leading analogy enables us to trace the same radical signs through different languages. In both of these fields of research, we have an opportunity of discerning some important mental operations concerned in the formation and application of languages. We shall therefore take notice of a few general varieties in the derivation of nouns.

[margin: Natural origin of some words.]

Some nouns shew an evident adaptation of sounds naturally connected with the objects which they denote. Whether these sounds have been received into one language from another, or owe their origin to the immediate suggestion of nature, is a matter of little moment. The principle which produces an adherence to the use of them is in both cases the same. Among these we may reckon the nouns *cuculus* in Latin, and *cuckoo* in English, evidently intended to imitate the note of the bird which they signify. The Latin *perdrix* for a partridge is a near imitation of the sound made by that bird when disturbed in the field. Of the same kind are some nouns descriptive of particular sounds. We may take for examples, the words *corn-craik* for the land rail, *peesweep* for the lapwing; *hubble-bubble* for a noisy smoking instrument; also such words as *hiss, splash,* and *splutter.* Though some of them are provincial, and others are reckoned extremely vulgar, they exhibit one feature of the tendencies of mankind in the creation of signs.

[margin: Nouns frequently derived from verbs of motion.]

Many nouns are derived from verbs of motion. This is the case not merely with such as signify certain motions in the abstract. Many concrete nouns are also formed from such verbs, in consequence of the selection of qualities or objects to be concreted being originally suggested by some relation to the voluntary motions of mankind. Of these we have an ample list in Tooke's *Diversions of Purley.* That author seems to consider the circumstance of so many names of objects being derived from verbs as leading to important general conclusions, although these are not specified. This feature of etymology evidently arises from the interesting nature of the voluntary motions of our species. From this cause, as we have already remarked, the earliest and simplest form of words of motion is that of the imperative; a wish to receive assistance from the activity of others being the earliest motive for speech. The interesting character of these motions also appears in the prevalent etymology of names for external objects. Though the objects themselves are previously known, our first motives for contriving signs to represent them arise from their known subserviency to the directions which we mean to give to the actions of others. Their connection with these actions affords a principle by which the surrounding scene of things is divided into groups. "Fruit" is derived from the Latin word *fruor,* to enjoy, the participle of which is *fruitus* or *fructus.* It signifies "aliquid *fruit*-um," or something enjoyed.

[margin: Causes of this. Examples from the Latin language.]

Universal Grammar.

A "debt" is aliquid *debit*-um.
"Rent" aliquid *rendit*-um.
"Tribute" aliquid *tribut*-um.
An "act" aliquid *act*-um.
"Expence" aliquid *expens*-um.
"Merit" aliquid *merit*-um.
"Accent" aliquid *accent*-um.
"Fate" aliquid *fat*-um.

Examples from the French.

"Alley" is formed from the French verb *aller*, to go, meaning a sort of passage. "View" is from *vû*, the past participle of the verb *voir*, to see, and signifies something seen. "Destiny," *une chose destinée*. The derivation of all these words is sufficiently obvious.

From English and Saxon roots.

Mr Tooke has with great ability traced to a similar origin many English nouns in which it was not formerly suspected. "Spot" he derives from the verb *spit*, of which he considers it as the past participle. The noun "gate," from the verb *go*, or *gae*; "road," from the verb *ride*, signifying a place that has been *rode* upon. "Head," according to him, is from *heav ed*, and means a part elevated. "Heaven" is from the same verb, and similar in its original meaning, though different in its application. A "flood" is something which has *flowed*. "Bread" is grain which, in one step of its preparation for food, has been *brayed*. "Weft" is the past participle of the verb *weave*. The "haft" of a tool is the part *hav'd*. A "hilt" is a part *held*. "Brood, breed, and brat," are from the Saxon verb *bredan*, to cherish. "Hand" from *hentan*, to lay hold of. "Fang" and "finger," from *fingan*, to take. "Truth" comes from the verb to *true*, and signifies that which a man *tru-eth*, or believeth. "Birth" is that which *bear-eth*: "Growth" that which *grow-eth*: "Wealth" that which *weal-eth*: "Earth," that which a man *ear-eth* or plougheth.

Some of Mr Tooke's etymologies, tending to the illustration of the same general remark, have been disputed; but the etymologies substituted on these occasions generally turn out to be of a similar nature, deriving the names of substances from verbs of motion.

Nouns in *ment* and *tion* both concrete,

When a concrete noun is intended to convey the impression of a connection betwixt an object and any voluntary human act, the etymology is for the most part intentionally obvious. Thus from the verb command we have the noun "commandment," for a sentence employed in commanding. From accompany we have "accompaniment;" from judge "judgment," or opinion; from invest "investment." A great number of nouns of this description derived from Latin verbs, terminate in *tion*; as "fraction, sanction, conflagration, collision." Some terminate in *ance* or *ence*; as "resistance, inheritance, science, prudence." We have others from the same language with different terminations; as "lecture," from *legere* to read. From the English verb know, we have the noun "knowledge." Sometimes nouns are formed, by adding to a verb the termination *ing*, as "landing" from land, and "fighting" from fight. Sometimes the use of the word as a noun is not indicated by any particular sign, but merely by the scope of the sentence. The words "love," "fight," "stand," "fold," "tie," "fly," "escape," are used both as nouns and as verbs.

and abstract.

Nouns of a similar structure, and sometimes the very same nouns, are used to express the abstract ideas comprehended in verbs. "Government" expresses either the abstract idea of the act of governing, or the concrete ideas of a particular instance in which this act is exercised, as "the British, the American, and the Turkish governments." Even the more general expression "a government," is concrete, while "government" is abstract. A similar two-fold application may be made of the nouns "reflection," "understanding," "judgment," "pleasure," "love," "decision," "repetition." We may speak of "love" in general as an affection of the mind; or, a swain, in speaking of his mistress, may call her "his love." We may speak of "judgment" and "reflection" as faculties of mind, or we may call the sentiments resulting from their employment, "judgments" and "reflections." It was, at one time, common in our language to employ different forms of the word on these two occasions. We had, for example, "excellence" and "dependence" in the abstract; and "excellency" and "dependency" in the concrete.

Derivation from adjectives.

Many nouns, both concrete and abstract, are derived from adjectives. Instances of concrete nouns of this origin, we have in the word "white," for the white of an egg, and in the appellation "black, or negro," for a man of a black complexion. On the same principle, articles of merchandise are called "goods." Regiments are distinguished by the designations of "the blues," "the buffs," or "the greys;" and showy persons are denominated "beaux and belles." These words denote collections of ideas, or qualities, each under a designation borrowed from one of the most conspicuous. Hence they are described by Mr Tooke as specimens of subaudition, one quality being mentioned, and the rest which form the individual understood.

Many of them approach in their nature and etymology to nouns which are derived from verbs by passing through the medium of the participle, a part of speech resembling in some respects the adjective, and often considered by grammarians as in no respect different from it.

Abstract nouns also, or the names of single qualities, are derived from adjectives. This is done in our language by the addition of the termination *ness* as in "goodness," "whiteness," "brightness," "redness." Whether or not this termination is originally the same with the French word *nez*, signifying nose, and with the termination "ness," as applied to projecting points of land in such proper names as "Inverness" and "Sheerness," we shall not stop to inquire. Whatever is its derivation, it has the same meaning with the word "quality." Whether it was, at any former period, a separate word under a different extent of application, is a question of inferior importance. A termination regularly used as a sign has all the distinctness of a separate word, though written more close to another connected sign, and sometimes involving a greater rapidity of pronunciation.

Abstract nouns derived from adjectives belonging to other languages are various; some terminating in *tude*, as "gratitude," "magnitude;" others in *ty*, as "purity," "propriety;" or in *ence*, as "prudence," "science," and "patience."

Some abstract nouns are derived from compound adjectives owing their origin to previously existing nouns. "Loveliness" is derived from the adjective "lovely," which comes from the noun "love." We have, in like manner, "faith, faithful, faithfulness;" "boy, boyish, boyishness," and many other exemplifications.

Abstract derived from concrete nouns.

Sometimes an abstract is derived from a concrete noun, by means of a termination, as "boyhood" from "boy," and "neighbourhood" from "neighbour."

Abstract nouns applied as concretes.

Nouns originally abstract are often applied as concretes. A female possessed of the qualification of beauty, is called "a beauty;" a person of a strange character, "an oddity;" and a curious object, "a curiosity."

Mr Tooke endeavoured to prove by the etymology of nouns that abstraction was not an act of the mind, but only an operation in language, and that the whole operation consisted in subaudition. We have found his account of the subject applicable to nouns derived from words signifying single qualities and used as designations of compound objects, while the other qualities are understood. But all these nouns are concrete. Mr Tooke does not acknowledge any difference betwixt these and the nouns which grammarians distinguish by the appellation *abstract*, such as "beauty," "elegance," and "prudence." Without even remarking that they had ever been considered as of a different nature, he includes them in the list of those which imply the operation of subaudition. He considers *providentia*, "providence," as the neuter plural of the participle *providens*, and meaning "provident things," *i. e.* expressing one quality with the subaudition of others. This subaudition is indeed more general than it would have been in the word *providens*, if such a word had been used for "a provident person." He probably considered it as a mode of contriving a word capable of being adapted to every example in which the property denoted is found. But the opinion of this author is not stated with the explicitness due to its singularity and its importance. We must confess that it seems to us totally unfounded.

We have already observed that it is in our power to make single qualities the principal objects of thought, and that no greater difficulty exists in thinking of them exclusively than in making the idea represented by a proper name, at any time, the full and only object of thought. The etymology here advanced by Mr Tooke appears in itself fanciful. Nouns in *antia* and *entia* are the only ones which give it any shadow of countenance. The genius of the Latin language does not incline to the use of other neuter plurals as names for separate qualities. In English, indeed, we say, "the agreeable," "the picturesque," "the sublime," "the beautiful," instead of "agreeableness," "picturesqueness," "sublimity," and "beauty." We also adopt the Latin expression from Horace, "the *utile*" and "the *dulce*." But whatever the etymology of the nouns called abstract may be, the manner of their signification is that which we have already stated.

SECT. V. *The choice of Designations, and the nature of the Pronoun.*

WHEN a compound object is designated by a noun which expresses one of its qualities with a subaudition of the rest, there is evidently no reason why the same quality should always be selected for a designation. Every such object resembles in some one quality a number of others, and admits of being placed in the same class with them. In a different quality it resembles a different set of objects. Hence it may receive various general designations. The choice which we at any time make of a designation for it depends on the design which we have in view in distinguishing it from others. The same human being may be called "a man," "an African," "a slave," "a negro," or "a fool;" or he may be designated by some occasional temporary circumstance; he may be called "a debtor," "a creditor," "a patient," "a culprit," or "a witness." In using any one of these terms, we wish to call into view the very same individual, with all the parts and qualities essential to him, but designated by one of these as the most appropriate to the point of view in which the tenor of our discourse leads us to represent him. Those who regard his proper name as his chief designation will consider the others as occasional substitutes for it. But even that name may be common to him with some other men. If he has two names, (which is the case with Europeans,) a personal and a family name, he will have one of these in common with several other persons, and the other in common with a different number; and it is by the combination of the two that he is distinguished. But this very combination may happen, in some instances, to be applicable to another person equally well known to us. We must then add a third mark of distinction, such as one depending on differences of age, country, or profession. Any designation becomes completely distinctive or not according to the occasion on which it is employed. It is probably most accurate not to consider one as substituted for another, but to consider each as rendered proper on particular occasions, when a complete and interesting distinction is thus formed.

These considerations will lead us, by a direct road, to a proper estimate of the *personal pronoun*, which many grammarians have reckoned a separate part of speech, and have defined to be "a word that is used instead of a noun." Its whole office is to point out an individual by an occasional mark which distinguishes him completely from all others. It is often shorter than the name of the individual, and this seems to have led some to conceive that it is contrived for the purpose of abbreviating discourse. But it does more than this; it points out the person referred to in the most interesting temporary relation.

The *first* personal pronoun *I*, denotes "the immediate speaker" as distinguished from others by this circumstance in preference to any other character that he may bear. The *second* denotes "the party addressed" as characterised by the present circumstance of his being addressed. This character is preferred to any other that he may bear, as distinguishing him from other persons. The *third* personal pronoun has been erroneously defined to be a mere negation of the other two. This is not implied in it. When Cæsar, describing his own actions in his Commentaries, uses the third person, sometimes employing his own name, at other times *ille*, he shews that these designations are applicable to the person who speaks or writes, as well as to others, although it is most natural for all men to use peculiar words for themselves as speakers. Among some nations it is considered as treating the person addressed more delicately, and tending less to look him out of countenance, to call him *he* than *thou*. The Italians say, *Come sta*, literally, "How does he do," instead of, *Come state*, "How do you do;" and the French, in like manner, say, *Monsieur comment se porte-t-il.* A rustic girl in this country meeting a familiar friend, says, with a kind of mirthful respect, "Where is she going?" for "Where are you going?" It is also to be remarked, that a mere negation of the circumstance of being either the speaker or the person addressed would never afford a sufficiently distinctive character, and therefore could be of no use as a designation. The real office of the third personal pronoun is to designate an individual by the circumstance of "having been lately mentioned," or "much nearer to the thoughts both of the speaker and the hearer than any other who could, on that occasion, be referred to by a similar circumstance." It is thus sufficiently distinctive at the moment to prevent ambiguity.

To have a closer illustration of the nature of the pronoun, we may observe that some designations are much

Universal Grammar.

Singular opinion of Mr Tooke.

Designation of the same object various.

The pronoun is a noun, not a substitute for one.

Meaning of the first and second personal pronouns.

Erroneous description of the third.

Its real office.

Universal Grammar.

Designations different in degrees of permanence.

more durable than others. The designations "man," "king," "Dane," "Indian," "sailor," "soldier," are of a permanent nature. Some are founded on more limited external relations, and are seldom used with propriety except in particular connections, as "father," "brother," "friend," "enemy." These generally require mention to be made of the object to which the individual bears this particular relation. Others are merely temporary and occasional, as "plaintiff," "defendant," "speaker," "hearer," "buyer," "seller," "assistant," "opponent." All these words are used on particular occasions with as great propriety as the names, or any other designations of the persons spoken of. Of this last occasional kind are the words called personal pronouns. They distinguish individuals by the temporary characteristics now enumerated.

Personal pronouns the least permanent.

Origin of the prevailing doctrine.

What then has led grammarians to assign to these words a separate place in language under the name of pronouns, and to describe them as possessing the peculiar character of being the substitutes of nouns?—The only circumstances in which they differ from other appellations are, that they are shorter and more familiar. Their shortness has probably made them appear unique, and their familiar recurrence has made them appear of peculiar importance. The frequency of their use, though worthy of attention, is a quality attached to words in various gradations. In this instance we have perhaps the acmé of frequency, because the pronouns are founded on the very circumstance of the use of language. Language always implies a speaker, who to himself appears important, and a person addressed, who, in order to be operated on with advantage, has a prominent interest assigned to him in our discourse.

Their brevity.

Their frequent use.

Etymology of pronouns.

It is probable that pronouns are of very early origin. Attempts have been made to trace the etymology of the first and second in some languages to a word signifying the hand, or some other object near and inseparable. It is sufficiently natural to suppose that persons who have words to represent such objects, and no personal pronouns, might resort to such expedients. But it is equally supposable that certain sounds might, in the very first instance, be applied to this use, on the same arbitrary principles which must have regulated the pristine application of the greater part of articulate sounds.

If no pronouns were in use, a speaker would probably point to his own body in speaking of himself, and to that of the person addressed in speaking of him. On this account some philosophers have considered it as the peculiar nature of the pronouns to be "substitutes for that pantomimical act." But the act of pointing is also used in designating other objects that are presented, especially if the speaker and hearer have no language in common.

General characteristics of the personal pronouns.

The personal pronouns combine a great degree of generality in their use with a well-marked particularity in the instances of their application. The word *I* may be applied to any person, but only by one speaker, viz. that person himself. The quarter from which the sound proceeds determines its exact application. In the same manner *you* may be applied to any one individual, but only when the words are particularly addressed to him, and this circumstance gives us on every occasion an unerring indication of its use. *He* may be applied to any *man*, *she* to any *woman*, *it* to any *thing*, and by any individual. But they imply no reference to the present use of language. They imply some previous mention of the object referred to, and this must be well understood in order that their particular application may become intelligible. They have exactly the same meaning with the word "foresaid." Some assistance is given towards the ready understanding of their application by distinctions founded on personality and sex. The pronoun *it* is distinguished from *he* and *she* by the absence of personality; *he* from *she* by the circumstance of sex.

Vague use of the term pronoun.

The term pronoun, as used by grammarians, is on the whole productive of confusion and ambiguity. It is extended to some adjectives, which are called pronominal adjectives, or adjective pronouns. Such are *ille*, *hic*, *alius* in Latin, and *this*, *other*, in English. The word "other" has evidently the same meaning with "different," although neither the English word "different" nor the Latin word *diversus* is ever included in the list of pronouns.

Sect. VI. *Genders.*

In the following Sections of this Chapter we shall consider some prevailing marks which accompany the application of the noun, and which adapt it to particular purposes.

Distinction of sex influences language.

As our own species comprehends the most interesting subjects of discourse, any common distinctions found among them appear worthy of being pointed out. The situation of the two sexes in society, and their general habit and appearance, afford the most remarkable distinction, and the implication of this naturally accompanies the mention of individuals. Even when it would not be sufficiently interesting to be mentioned, provided a separate word were required for the purpose, it is sufficiently important to determine some part of the names by which persons are designated. The Greeks and Romans effected this by differences of termination. The English language has current proper names exclusively applicable to a particular sex. Similar differences are implied in the names given to domestic animals, and sometimes to animals of other kinds.

Some languages injured by excess in the application of the...

But language has not always stopped at this reasonable point. The active imaginations of those by whom it has been modified have, from vague analogies, ascribed sex to objects destitute of it. In Greek, Latin, and French, this is done in very numerous instances. In French, the genders of nouns are not easily distinguished by their terminations, yet a particular gender is uniformly attached to each, and regulates the termination given to every adjective agreeing with the noun. The details of the genders must therefore be studied by every person who wishes to speak the language with sufficient accuracy to preserve him from ridicule. These circumstances render that language of difficult acquisition.

In the Hebrew, Italian, Spanish, and French languages, there is no neuter form, so that every object must, in the syntax of words, be either masculine or feminine.

Speculations on the cause not important.

Attempts have been made to account for this prevalent arrangement, which appears in itself so absurd. But no explanation has been given that is sufficiently steady in its application to afford material assistance in facilitating the acquisition of any language. Names of objects which are masculine in one language are feminine in a second, and neuter in a third. Names of objects of the same kind, and even nouns that are synonymous, differ in their gender in the same language. Those who take pleasure in tracing these whimsical proceedings in the formation of language, will find some ingenious remarks on the subject in Harris's *Hermes*, and Tooke's *Diversions of Purley*.

Universal Grammar.

The English, the Persian, and the Bengalese languages are free from the embarrassments of arbitrary genders. In English, indeed, a few objects destitute of sex have a phraseology applied to them borrowed from sexual distinctions. But this is on rare occasions; and, as no marks of gender are attached to our adjectives, the inconvenience now stated does not occur. The whole difference in the adaptation of other words consists in the use of the personal pronouns *he* and *she*. This application of words denoting sex only partakes of the nature of poetical personification. It does not consist in such an adherence to gender as affords a basis for grammatical rules. The sun is called *he* on the same principle on which we might compare that luminary to a king, for the splendour which surrounds him; to the cherishing father of a family; or to a presiding mind, by which extensive systems are regulated. The moon is called *she*, on the same principle on which it might be compared to an eminent female who does not overawe by an oppressive effulgence, but diffuses a mild radiance, productive of a gentle pleasure.

Sect. VII. *Number.*

That accident of nouns which we call *number* is a sign for representing the exemplification of a general idea in more than one individual. It does not apply to proper names. A proper name is in its nature descriptive of only one object, and therefore essentially singular. As soon as it becomes susceptible of plurality, as when we speak of the twelve Cæsars, or the seven Jameses, it ceases to be a proper name. Spain is the proper name of a country, and Spaniard has by some grammarians been called the proper name of a people; but the latter is a generic word characterizing any one of a great number of persons by their connection with Spain. When a name is applicable to two individuals, these are to be considered as constituting a limited genus. This circumstance may not depend on any inherent character, but may be an accident occurring in the transference of proper names. The name is originally intended, in both instances of its application, to be completely adequate to distinguish an individual from all those with whom he might have been confounded. But, when the two individuals chance to meet in the same place, or to be mentioned near to one another in discourse, they must be distinguished. If the name of both is Scipio, they are to be considered as a genus coinciding in this trivial circumstance of their history, that they have received the same name.

Some nouns which are general in their acceptation do not admit of a plural, because the objects which they signify are not permanently portioned into individuals. This is the case with nouns which express such plastic materials as are capable of being easily arranged in pieces of any form or size. We have examples of it in the names of the different metals, as "gold," "silver," "iron," and "brass," words which are never used in the plural. The plural word "irons" is not applied to pieces of the metal, but to instruments formed of it. The noun "stone" is also the name of a material of which variously shaped objects may be formed; yet it has a plural in frequent use, because nature divides it into masses which are not easily reunited so as to become homogeneous. These objects have therefore more of the character of permanent individuals. Such words as "gold," "silver," "clay," "dough," may be said to have neither singular nor plural, and to be entirely independent of number. We cannot prefix to them the word *a*, which is the sign of the singular, with any greater propriety than we can invest them with the plural form.

Etymologies of the plural number.

In most languages, nouns receive alterations in their spelling for the expression of plurality. These sometimes consist in the addition of a letter or a syllable, sometimes in the substitution of one for another. Such alterations, however, are not absolutely necessary. Number might be pointed out by separate words, or might be inferred from the connection. Many English words have no distinction betwixt their use in the singular and in the plural, such as "sheep," "grouse," and "deer." Some Latin words are the same in singular as in the plural in one or more of their cases. *Fructus* signifies "fruit" or "fruits." *Res*, "thing" or "things."

In Bengalese.

It is not easy to discover by what circumstances a community, during the formation of its language, has been influenced in choosing its mode of expressing plurality. Some grammarians have thought that much satisfaction would be obtained if we could always trace the plural termination to some separate word signifying a *collection*. The addition of a term of this sort is the mode of expressing plurality in the Bengalese language. *Projaa* signifies a peasant, *lok* people: and *projaa-lok* signifies peasants.

Hypothetical origin of the plural in Hebrew and its dialects.

The authors of Rees's *Cyclopædia* derive the plural sign in Greek, Latin, and the modern languages of Europe, from a word in the Hebrew language המון, which signifies multitude. They suppose that this word was at first subjoined to the singular word, and that afterwards, for the sake of brevity, the Hebrews designated plurality by retaining only one of the letters, *m*; the Chaldeans, Syrians, and others, by retaining the *n*. Thus the plural was in Hebrew *-im*, in Chaldean *-in*, in Arabic *-oon*, and in Persian *-aan*. This theory further supposes the letters *n* and *s* to have had the same origin.

In Greek, Latin, and more modern languages.

The Chaldean *-in*, therefore, is supposed to have become *-es* in the formation of many Greek and Latin plurals. From the same source they even wish to derive the *s* which forms the plural terminations in English and French; while the Italian language is considered as following in all nouns the analogy of the second declension of the Latin by adopting the terminating vowel *i*. The same authors might have added, that this *i* of the Latin and Italian is the vowel letter of the Hebrew plural *im*, (ים.). This vowel does not, indeed, happen to belong to the independent word המון, which they consider as giving origin to the plural sign; but we find it used in Hebrew not only along with the letter *m* for a familiar sign of plurality, but also by itself (י.) And it was sufficiently natural that a language derived from the Hebrew should adopt this plural sign.

Estimate of such hypotheses.

This whole style of etymology, however, is questionable. It has indeed the authority of Horne Tooke's approbation. One great principle of that author was, that terminations were originally separate words; and another principle was, that the alterations which take place in the progress of language have an abbreviating tendency. But terminations ought to be considered as equally independent signs in this form as if they were separate words; and when any idea is of perpetual occurrence in language, as that of plurality is, it is natural to expect that the sign used for expressing it should be originally brief. Signs, however, are often changed. With some people, the mere circumstance of being long familiar renders both words and terminations of words apparently stale, and they apply themselves to the contrivance of others in their stead. These others are generally derived from sounds previously used for ideas somewhat akin.

Probable origin of the English plural in *s*.

The English plural termination may, we think, be traced with greater probability, as well as greater beauty, to a later origin than that now mentioned. Our terminating *s* seems to have arisen from a syllable which was once applied to signify a more extensive modification of the uses of the noun, and was gradually varied, in the improvement of our language, for the purposes of more precise distinction. It was anciently the syllable *is*. "Towns," the plural of town, was *toun-is*. The same syllable was also used for what we call a genitive. "Father's" was *father-is*, or *fader-is*. It is only among those who are inordinately attached to the present habitudes of our language that the termination *is*, in these two applications, will be considered as necessarily of different origin. The sign for the genitive and that for the plural are only different exemplifications of one sign which in its meaning includes both. It was simply a term of relation synonymous with the English preposition "of," i. e. "with respect to." "Bees," for example, signifies relating to the bee; "bees wax," wax connected with the bee; "two bees," a repetition or doubling with respect to the bee. "Scot," is a designation for a native of a particular country. "Scotis," or "Scots," means relating to such a native. Two individuals are "two Scots;" a "Scotswoman," a woman relating to Scot; and, in the same manner, the word might be used in such phrases as, "the Scots court," "Scots customs," "a Scots dress." The meaning of the letter *s* in these different instances is not different: it is only general; and, therefore, susceptible of different specific applications. Any particularity in the application intended was, in the first instance, left to be inferred from the connection; and, afterwards, some slight differences in its orthography, pronunciation, or both, were adopted, and appropriated to the different applications. We have "Scot's" for the genitive; "Scottish," or "Scotch," for the descriptive adjective; while "Scots," if used at all, is restricted to the plural.

Our plural form receives other applications.

This derivation of the English plural from a more general modification of the noun will acquire confirmation when we reflect that, in spite of the strictness of formal grammatical rules respecting the plural number, we often use the same form of the noun which denotes plurality, on different other occasions. We speak, for example, of introducing a knife "lengthways," though the way is only one. "Edgeways" is used in the same manner. The word "otherways," now changed to "otherwise," is a similar example. "Sides foremost" is a common provincial phrase in some parts of England. We speak of going "up stairs" or "down stairs" where there is only one stair, meaning up or down with respect to stair. Some of the English even speak of going "up streets" and "down streets." A boy in tossing a halfpenny calls "heads or tails," though it has only one head and one tail. If to the question, "Have you any pens?" a person should reply, "yes I have one;" the answer would be condemned by some as ungrammatical, because one pen is not plural, and a person who has only one cannot be said to have "pens." Yet we have a constant tendency to this mode of speaking. Common sense, adhering to the powerful analogies of language, bears down the authority of formalizing systems, even in cases in which she does not possess sufficient dialectic knowledge to vindicate her proceedings. The word "pens" in this instance is merely general. It is independent of all ideas of number. It is no more restricted to plurality, so as to exclude the singular, than it is restricted to two, four, or any particular number. Had the word "pen" been used in the question now alluded to, it would have been considered as exclusively singular. But it was necessary to use one of these forms of the noun, in order to represent the genus independently of number. To prohibit the employment of any form of the noun in a manner thus general, would imply an extreme obstinacy of artificial regulation in no degree conducive to accuracy. The want of a *separate* form for this general application of the noun, independently of number, sometimes gives rise to the following awkward circumlocutions in proclamations and legal writings: "If any *person or persons* shall transgress in the manner underwritten, *he or they* shall be subjected to the following punishments."

Plural in *en*.

Another English plural is formed by means of the termination *en* as in oxen. Such plurals were much more common at a remote period of the English language. *Housen*, for example, was used for "houses." They abound in the modern German, which owes them to the same source. This syllable, like the one already mentioned, was originally of a more general application, signifying "of or relating to." The application of it which is most abundantly retained in English is for the descriptive adjective, as "wood*en*, earth*en*, gold*en*," words the same in meaning with the phrases "*of* wood, *of* earth, *of* gold." The old English language was little varied in its modifications. The syllables *is* and *en* both expressed the general circumstance of relation betwixt the idea expressed by any noun to which they were attached and some other. They were applied indiscriminately to relations of every kind, and the occasions of discourse were trusted to for the suggestion of particular ideas. A desire of improving the language amidst the multiplicity of relative ideas which arose from intellectual improvement, led our ancestors to appropriate one termination to one subdivision of that general meaning, as well as to produce a still greater particularity, by varying the modes of writing the termination. The English thus made a nearer approach to the copious and refined languages of classical antiquity. The final *s* and the termination *en* came to signify important distinctions, *en* being used to form the descriptive adjective, and *s* for expressing various relations, including that of plurality. Wood*en* is the adjective: wood*s* is the plural. The word ox is an instance in which the *en* is retained as the plural sign, and the *is* (in ox*is* written ox's) is the genitive. We say a "drove of ox*en*" for the plural: "an ox's gall" for the genitive. Here we have a specimen of the simple but effectual expedients to which mankind so readily recur in order to express the varieties of their thoughts.

Sect. VIII. *Cases.*

General account of cases.

Cases are changes of form to which nouns are subjected for the purpose of denoting annexation. Some of them are more general than others. The marks of annexation are external to the name of the object, and might therefore be expressed by separate words. But they are often attached to the name in the form of terminations. This circumstance, though not affecting their meaning, occasions a particularity of aspect in certain languages in a written state, by abridging the number of words, and also a particularity of sound when a language is spoken, because a termination is placed after the name of the object, but a preposition before it. The cases often express circumstances so general and so evanescent, that no separate word to represent them has ever been used. On this account, it

Universal Grammar.

is convenient, even in a philosophical treatise, to consider them in conjunction with the noun.

The Nominative not mere name.

The *Nominative* has been represented by some as implying nothing more than the name of the idea expressed by any noun, and therefore the least complex of the cases. But it always has a reference to a verb, and this verb for the most part follows it in the same sentence. It often happens that, compared to the other cases, it is short, and that the others are distinguished by the addition of one or more syllables. Of this we have instances in the Latin nouns *vir* and *sermo*. But it more frequently happens that the nominative has a peculiar termination, and that in the formation of the other cases this is left out, and its place supplied by different terminations affixed to the radical letters. The radical letters of *dominus* are *domin-*, and the *-us* is as much a separate sign as the *-i*, *-o*, *-um*, *-e*, *-orum*, *-os*, and *-is*, which form the other cases. *Dominus* is therefore something more than the name of an object. It would be contrary to the analogy of language, and of all the operations of the human mind, even the least correct, to suppose that the syllable *-us* has no original meaning. We may pronounce it a superfluity, if the definite application of the noun which it expresses can be understood without it. Yet we have no right, on this account, to pronounce it destitute of meaning. It is in fact a sign of connection with another word of definite character and use, the verb.

It a sign of connection with the verb.

We have farther to observe, that the nominative gives the noun a higher rank in a sentence than the other cases. It differs from them in a manner nearly resembling that in which the noun differs from the other parts of speech. It expresses the central or focal idea, to the description of which the other words in a sentence, including the other parts of speech and nouns in the other cases, are subordinate.

Sign of the ascendant importance of the object in discourse.

Apparent exceptions accounted for.

The sentences which may appear exceptions to this doctrine are very numerous. This is occasioned by the general pursuit of that variety which gives elegance to language, and by the presence of other circumstances which preserve the importance due to the leading subject of discourse. By some writers the hero of a biographical narrative is mentioned in the nominative case more uniformly than by others; but by none is such a rule invariably followed. Suetonius probably follows it as often as any writer, and thus gives his biographical delineations a more concentrated force. Yet this author, in relating the death of Julius Cæsar, introduces the persons by whom he was killed in the nominative case in preference to Cæsar himself, thus making them apparently the most important subjects for a time. ASSIDENTEM CONSPIRATI *specie officii circumsteterunt: illicoque* CIMBER TULLIUS, *qui primas partes susceperat, quasi aliquid rogaturus, propius accessit: renuentique et gestu in aliud tempus differenti ab utroque humero togam apprehendit, deinde clamantem, "Ista quidem vis est"* ALTER CASSIUS *adversum vulnerat paulum infra jugulum.* 'The conspirators, under pretence of shewing 'Cæsar respect, stood up around him as he sat. Then 'Cimber Tullius, who had undertaken to commence the 'deed, approached nearer to him, with the apparent design of making some request. As soon as he observed 'that Cæsar, by a wave of his hand, declined conversation, 'and put him off till a future time, he laid hold of him by 'the toga on both shoulders an act which made Cæsar exclaim, "This is downright force." At that instant one 'of the Cassii wounds Cæsar in the neck.' In the relation of these circumstances Cæsar might have been mentioned in the nominative case, thus: 'Cæsar was surrounded by 'the conspirators affecting to pay him respect, was approached by their chief Cimber Tullius, who pretended to 'make some request, and, on waving his advances, was 'seized by the toga on both shoulders; but as he exclaimed, "This is downright force," he received a direct thrust 'of a mortal weapon from the hand of one of the Cassii.' This mode of writing would keep the mind of the reader more constantly fixed on the person who is the chief subject of the narrative as a whole; but it would often render language insupportably monotonous. The author, therefore, relieves the attention of his readers, by assigning in some of his details a subordinate place to the principal personage. His importance is always maintained by the ultimate tendency of the narrative, as well as by the advantage of being more frequently than any other subject mentioned in the nominative. After the historian has, in the manner now described, varied the current of his language, he is enabled, with gracefulness as well as force, to introduce the chief subject in that mode of diction in which he will hold, by means of the nominative case, the most dignified rank in the sentence. After these details of the conduct of the conspirators, Suetonius thus proceeds: CÆSAR *Cassii brachium arreptum graphio trajecit: conatusque prosilire alio vulnere tardatus est. Utque animadvertit undique se strictis pugionibus peti, toga caput obvolvit: simul sinistra manu sinum ad una crura deduxit, quo honestius caderet. Atque ita tribus et viginti plagis confossus est; uno modo ad primum ictum gemuit, sine voce edito.* 'Cæsar seized the arm of Cassius, pierced it with his writing style, then endeavoured to rush 'forward, but was prevented by another wound. Finding himself assailed in every direction with drawn 'swords, he covered his head with his toga, and in order that he might fall with the greater decency, drew 'the lap of it with his left hand over his limbs. Thus 'he fell, stabbed with twenty-three wounds. He emitted a single groan when he received the first; but met 'his fate without uttering a word.' The peculiar propriety and force of these latter sentences, and a slight character of inversion of which we are sensible in reading those which precede them, are proofs of the superior rank of the nominative case.

The Vocative. Its early use.

The *Vocative* case, or that which is used in naming the person addressed, comes next in order, not merely from its frequent coincidence in form with the nominative, but from its being probably of earlier origin in the proper names of persons than any other form of the noun. It is peculiar to nouns which designate persons, because it applies only to beings capable of hearing what is said. In these, however, it seems to be prior in the order of nature to the nominative. The Latin vocative, wherever it differs from the nominative, inclines to greater brevity. *Virgilius* was addressed *Virgili*, *Minutius*, *Minuti*, *Dominus*, *Domine*, and *Filius*, *Fili*. In this characteristic the vocative case of the noun resembles the imperative of the verb. Being the earliest use of the word, it is its shortest form.

The other cases.

When we enter on the consideration of the *Genitive*, *Accusative*, and *Dative* cases, especially the two last, it is found difficult to assign to each an invariable meaning, however general. In particular phrases their uses are steady; but no principle strictly universal seems to regulate their application. The most comprehensive that we can adopt is found liable to exceptions. The most likely way to discover their original meaning is to observe the prevailing application of each, and also to enquire if there is any circumstance of application, however limited, which is peculiar to one. It is thus also

Universal Grammar.

that we shall be most likely to trace the species of idiom which has given origin to such exceptions as occur. Some have proceeded in a contrary direction. They have first attached to the particular case a plausible general meaning, and then exerted their ingenuity to show that this meaning would be found applicable to instances which at first appeared most distant from it. But these modes of explanation might easily be applied to account for any possible substitution of one case for another, and therefore are erroneously considered as illustrations of a principle, while they are exceptions to a rule.

General remarks on the oblique cases.

It has been common to consider the different cases as intended to express different sorts of ideas, or different relations existing betwixt the objects named. On mature reflection, we find it more conformable to the general aspect of the facts, to consider them as referring rather to the different parts of speech with which the noun is connected, and the different degrees of importance which are assigned to the idea in the present use of language. These circumstances may sometimes arise out of permanent relations; but this does not uniformly take place, and therefore the cases do not depend on them. This opinion derives presumptive evidence from the illustrations already given of the nominative and the vocative.

Our attention will be chiefly directed to cases as exemplified in the Latin and English languages. The Greek cases follow different rules, a comparison of which with those of the Latin language might suggest some interesting conjectures respecting their original uses; but they would lead us into details too extensive for the limits of this article. The Latin language, when it borrowed its cases from the Greek, deviated from the parent language in the extent which it assigned to each. A different conception seems to have been attached to the use of them. This appears in a particular manner from the addition which they have given of an ablative case, which does not depend on a subdivision of one of the others, but is in some of its uses substituted for the genitive, in others for the dative of the Greeks.

The variations and exceptions to general rules which are so often practised in the use of the cases diminish their importance in the doctrines of universal grammar. Such distinctions as they imply might have been in most instances dispensed with. The discussion of them partakes more of the character of an inquiry into the conjectural history of particular dialects than of an investigation of the radical principles of language; and the length to which that discussion sometimes extends is due rather to the difficulty than to the importance of the subject.

The Genitive

The *Genitive* case, though sometimes governed by a verb, as by the verbs *potiri, fungi, meminisse*, and *angi*, sometimes by an adjective, such as *similis*, appears to have been originally applied in the Latin language to signify a relation betwixt the idea expressed by a noun and that contained in *some other noun* in the same sentence. The English preposition *of* corresponds so exactly to it, that any observations made on the one are equally applicable to the other. Attempts have been made, both by means of etymological derivations and explanations of existing phrases, to represent the word

not expressive of specific relations.

of as signifying some specific relation, as, for example, possession or origin. These attempts, however, have failed. We find it expressing every sort of relation that can exist betwixt the ideas contained in two nouns. This circumstance implies no ambiguity. It arises from the mere generality of the sign. When it is too general for expressing our meaning, we add some more specific ideas. In the article GRAMMAR of the *Encyclopædia Britannica*, it is justly observed that *injuria regis* may mean either "an injury inflicted by the king," or "an injury received by the king." The specific idea intended to be conveyed, must either be inferred from the connection, or pointed out by some additional sign.

How distinguished in its use from the other cases.

The genitive case though thus general, and supposed by some to have in the Greek language derived from this circumstance its technical name πτωσις γενικη, ought not perhaps to be considered as more general than the others. It is distinguished from them by the circumstance of being employed to show that the word put in this case is subordinate to a noun. Nothing more than a general relation betwixt the two ideas is expressed; but the connection thus established has something particular in its adaptation to the purposes of discourse. The ideas thus connected could not exchange places, nor are they of equal importance in the sentence, as they would be if conjoined by means of the word "and." "The man of virtue" and "the virtue of the man" do not mean the same thing. The ideas expressed by the words man and virtue are indeed *connected* in *both* of these phrases; but when we say "a man of virtue," it is intimated that something further is said of "the man." When we say "the virtue of the man," it is intimated that the subject on which we enlarge is "the virtue." Both of these are different from a connection formed betwixt two nouns by the word "and;" which intimates that they are on equal terms in the assertions which are made.

It indicates the subordination of an idea in discourse.

Exceptions and anomalies.

Such instances as we mentioned of the genitive being put after verbs and adjectives are so rare that they may be considered as exceptions in which a stretch is made to give these governing words the power of nouns in the use of language. Every word resembles a noun in containing the name of an object or idea. It is only in relative importance in the syntax of sentences that nouns differ from other parts of speech.

Exceptions of a different kind are also found. Nouns are in some instances annexed to other nouns by marks different from those which form the genitive; e. g. *homo a secretis*, a Latin phrase for a "secretary;" and in English we have the phrases "father-IN-law," "cousin BY the mother's side." This last phrase is seldom employed without the use of the verb IS preceding it, which gives a different turn to the whole phraseology, and has the power of introducing a greater variety of words than can be annexed solely to the noun. Such exceptions as we have now mentioned are equally rare with the former; a circumstance which shews the nature of the genitive case to be almost peculiar.

Genitive in the Hebrew language.

In the Hebrew language, the placing of one noun after another is often the only sign of the genitive. *Jein* signifies wine, *Helbon* is the proper name of a mountain, and *Jein Helbon* is the expression for "wine of Helbon." Sometimes it is expressed in a manner which must appear remarkable to those who are not acquainted with any analogous language. The change indicating this mode of annexation is made on the governing noun, which is then technically said to be in its *constructed state*, while the noun in the genitive case undergoes no change. *Dábar* signifies word, and *Elohim* God; but there is no separate word for *of*, nor is any change made on *Elohim*, to make it equivalent to "*of* God." *Dábar* is put in its constructed state by being changed into *debár*, which signifies *word of*. *Debár*

Universal Grammar.

Elohim is "word of God." In like manner, *gedolim* signifies "great men," *haghir* "the city." Great men of the city is not *gedólim haghir*, but *gedolei haghir*.

In English.

In English, as has been already observed, the genitive case is sometimes expressed by the termination *s* with an apostrophe, as in the first line of Paradise Lost, "Of *man's* first disobedience, and the fruit." It is thought by some grammarians an improvement in nomenclature to call this form of the noun an adjective of possession derived from the noun. This distinction makes no difference of doctrine. That mode of describing it seems to have been inconsciously suggested by the circumstance of its being, like the adjective in English, placed before the noun to which it is subordinate. But nothing more than the meaning of any genitive is signified by the adjective noun itself, as will appear when we come to treat of it. The English *s* has, with regard to its etymology, been considered by some as an abbreviation for *his*. But this (or the equivalent syllable *is*) is evidently an original sign in our language, at least independent of such words as *his;* and the latter is evidently derived from the pronoun *he* by having this sign attached to it.

The genitive case is sometimes expressed in English, as it is in Hebrew, by the mere juxtaposition of the nouns, with this difference, that the governed is placed before the governing noun; as in "cart wheel," "corn field," "garden wall." Some of these phrases are of more frequent recurrence than others. Sometimes the two words thus conjoined have, both in spelling and pronunciation, been run together into one, as in "timepiece," "statesman," "footman." Others of them are frequently connected in writing by a hyphen, to denote that they are scarcely to be considered as one word, yet not so much separated as two words generally are. In other instances, they are kept as distinct in a sentence as any other words. The meaning is not affected by this variety, and is so clearly expressed by simple juxtaposition in this order as never to admit of ambiguity. Here we have one fact by the consideration of which any inordinate predilection for the individuality of words may be reduced within just bounds.

The ultimate effect of the genitive.

The chief ultimate purpose for which the genitive case is employed is, to add a particular circumstance for completing the description of an individual, or of a species of objects, already characterised by a term which is in itself too general for the purpose. "Man" is a general word. "A man of genius," "a country man," are instances in which the genitive is used to point out a relationship for designating a limited species contained in the genus "Man." This may be done when an individual, or a species, is introduced as the subject of discourse; as, for example, "A man of genius differs from other persons in his feelings and habits;" or it may be introduced into the predicate of a sentence, and form a part of some new assertion, as, "Bacon was a man of genius."

The other cases are distinguished from the genitive, by denoting an annexation to some part of speech different from the noun.

The Accusative and Dative.

The *Accusative* and *Dative* have by some been considered as very nearly alike. By others some differences have been stated betwixt them depending on differences in the objects, motions, or relations represented by the governing word. Attempts of this last sort have proceeded on principles which served to explain a limited set of phrases, while they were totally inadequate to explain others.

The Accusative.

The most obvious circumstance which distinguishes the *Accusative* case in Latin from the genitive is, that it is governed not by nouns, but by active verbs and certain prepositions. It is by attending to the different occasions on which it is employed, and tracing the properties which uniformly adhere to it, that we shall make the most convenient approaches to an explanation of its use.

Does not always signify the reception of energy.

Sometimes it represents an object to which some action or motion passes, or in which it terminates, as *Hæc studia adolescentiam alunt, senectutem oblectant.* This character, however, has been ascribed to the accusative in phrases in which it will not apply. When the verb "to love" governs the noun signifying the object of that affection in the accusative, it expresses no transition of an act. The person who is loved may be ignorant of this passion, and totally unaffected by it. When we speak of "loving all mankind," we do not speak of any action which terminates in that extensive range of objects. This remark applies to all transitive verbs expressing emotions of mind that have a reference to external objects, as "to hate," "to dread," "to respect," "to esteem." These affections may be productive of acts by which the objects of them are affected; but such acts are not implied in the affections themselves. They are excited by the objects named in the accusative, but they terminate in the individual mentioned in the nominative. To represent them as terminating in the beings called their objects, is a mere fiction: it applies only to the range of ideas of the individual mentioned, not to the actual relative energies of the different objects. Some other verbs governing the accusative are expressive of quiescent qualities, which do not affect any object different from that to which they belong. Yet these qualities imply a reference to other objects, and the mention of this reference is absolutely necessary. These other objects are put in the accusative case. Such are the verbs "resemble" in English, and *similare*, or *simulare*, and *referre*, when used in that sense in Latin. Here, as no transition of any act or motion from one object to another takes place, the accusative cannot be considered in any respect as expressing such a transition. It will give but little satisfaction to say in reply, that, though nothing of this kind exists, yet it is figured in the speaker's mind, and that even in such a proposition as this, "a benevolent man loves the whole human race," we imagine a benignant emanation proceeding from the benevolent man to influence the whole species. This is an evasion of the argument. It is in like manner an evasion, rather than an explanation, to say that a person who asserts that one man "resembles" another, seems to consider such a man as influencing the state and relations of the other. This is an unconscious acknowledgment that the conceptions of the speaker, or the transitions of his thoughts, and the transitions which he studies to produce in those of the hearer, are the foundation of the use of the accusative case. This is the view which we consider as on all occasions the true one. Such mental transitions have a certain degree of rapidity which corresponds more closely with the idea of an action terminating in an object named, than with the greater part of our associated ideas. On this account the regimen of the accusative case is more frequently applied to signify these than any other trains of thought.

The use of this case does not depend on the kind of idea expressed by the governing word.

When the accusative is governed by prepositions, these prepositions prepare us for a transition equally rapid with that of the active transitive verb. In order to shew that this regimen does not depend on the *idea expressed* by the governing word, we shall take this op-

Universal Grammar.

portunity of stating a circumstance which might otherwise appear an anticipation of our observations on the verb: to wit, that some verbs which are completely synonymous in the ideas which they express, are totally different in the transitions of ideas which they are intended to create in the mind of the hearer. The verbs "to speak," and "to say," signify precisely the same act. Their difference consists in this, that the verb "to speak" does not intimate an intention to state what was spoken, but the verb "say" always does. When we say "Cicero spoke," we may probably rest satisfied with mentioning the act in connection with the agent. Our hearer may, if prompted by curiosity, ask what Cicero said when he spoke? But, if we use the phrase "Cicero said," we pledge ourselves to give some account of what he said, or to subjoin the accusative of some noun, such as the word "nothing." If we do not proceed further than the words "Cicero said," the person who hears us asks the question now mentioned in a different tone: he reminds us that we have stopped short in our discourse, and have not fulfilled the promise implied in the use of the verb "to say."

The Dative.

The *Dative* case might easily receive a plausible explanation in a large proportion of the phrases in which it is employed. But a difficulty has arisen, in consequence of the approximation which some of its uses seem to make to that of the accusative. Some verbs which govern the accusative are synonymous with others which govern the dative. An example of this exists in the verbs *lædere* and *nocere*. *Antonius nocuit Ciceroni* is equivalent to *Antonius læsit Ciceronem*. But though these phrases are synonymous, it is possible that the words of which they respectively consist are not equivalent. It is possible that in one of the phrases a greater share of the meaning may be contained in the verb, and less of it in the governed noun. This is rendered probable from one circumstance, that there are no verbs which admit of either case indiscriminately, so as to form with them two synonymous phrases.

Words governing the accusative with the dative.

We ought first to attend to those phrases in which a verb governs one noun in the accusative, and another in the dative. This may be a verb of *giving*, as in *Dedit mihi dextram*, or a verb of *declaring*, as in *Narras fabulam surdo*. One difference seems here to take place, that there is a more ready and rapid transition to the idea expressed in the accusative, than to that expressed in the dative; and the idea which is expressed in the accusative is more necessary to the completion of a significant phrase than the other. *Dedit dextram* and *narras fabulam*, though both evidently incomplete sentences, are not quite so deficient as *dedit mihi*, or *narras surdo*. The verb is so contrived in the arbitrary application of words, as to lead the hearer to expect with greater rapidity and impatience the idea which is subjoined in the accusative, than that which is in the dative. When the dative is placed first in order, as in the phrase *dedit mihi dextram*, we are sensible of a degree of inversion, or a short suspension of the governed word most nearly connected with the verb. This mode of speech is contrived for the sake of variety and elegance, or for the convenience of dwelling on the idea expressed in the accusative, by attaching to the noun some additional parts of speech; as, *Narras mihi fabulas gigantum incredibiles*.

In the use of verbs of giving and declaring, a difference in the *actual relations* of the *object* mentioned in the accusative and that in the dative case is evident; but in verbs of *comparing* no difference of this sort is necessarily implied. The sentences, *Comparo Virgilium Homero*, and *Comparo Homerum Virgilio*, may be used for conveying the same meaning in exactly the same manner as to thought. The interest taken in one of the objects compared may not be greater than that taken in the other, and the transition made to the two may be equal in its degree of rapidity and deliberateness. At the same time, if there is any such difference of interest, it seems natural to put that object to the description of which the comparison is principally subordinate in the accusative, and the other in the dative.

Words governing the dative alone.

These facts may furnish some illustration of those phrases in which a verb governs the dative case alone, for example, the verbs *nocere*, *favere*, *placere*, and *resistere*. The English verbs into which these are translated are equally transitive, and govern the same form of the noun, with those which correspond to Latin verbs governing the accusative. But in the Latin language it is probable that they are not so completely transitive, and resemble in their genius those English verbs to which nouns are subjoined through the medium of the preposition *to*, as the verbs "yield," and "submit." Thus the translation of *obedire* by the verb "submit" would be more accurate than by "obey" in so far as regimen is concerned, although the former of these English verbs, as applied to the expression of ideas, may be less nearly co-extensive with the Latin word. It is conceivable, that a verb which is originally not used transitively, may be more easily made to govern the dative than the accusative, whether it is employed in its simple state, or in composition. The verb *resistere*, for example, is derived from *sistere*, which signifies to stop or remain fixed, and does not prepare the hearer to expect the mention of any other object affected. This state, however, admits of being also mentioned as an impediment to the progress of another. The name of this other may be subjoined with a slight degree of ceremony; and a semi-transitive verb may be formed signifying that fixed state, together with an intention of mentioning the object impeded. The machinery of prepositions or other intervening words, for the introduction of the latter object, are dispensed with; yet the verb is made to govern a case which implies some slight degree of ceremony in the mental transition intended.

Analysis of the dative and its governing verbs.

We have heard it suggested that a verb which governs a single noun in the dative implies in itself the force of a noun governed in the accusative; that *resistere*, for example, has the force of the phrase *obstaculum opponere*. Whether this suggestion has any truth in an etymological point of view, or is in any degree to be considered as a probable account of the sentiments originally attached to such verbs, we shall not stop to inquire. But a translation of some phrases, on this principle, into the English language, will afford us a clear analysis of these two cases, as well as of the verbs which respectively govern them, and yet are otherwise synonymous. The English language expresses the dative by means of the preposition *to* prefixed to the same form of the word which constitutes the accusative; just as if, in Latin, the dative case were wanting, and the meaning of it always expressed by the preposition *ad* with the accusative. This would certainly shew a more leisurely and ceremonious transition than the accusative without a preposition. Both these sentences, *Nocuit Ciceroni*, and *Læsit Ciceronem*, may be translated, "He did harm to Cicero;" but, in the first, the force of the preposition "to" is contained in the dative *Ciceroni*, and, in the last, it is contained in the verb *læsit*.

Antonius	*nocuit*	*Ciceroni.*
"Antony	did harm	to Cicero."
Antonius	*læsit*	*Ciceronem.*
"Antony	did harm to	Cicero."

Thus the verb which governs the accusative is more completely prepared for the intended transition than that which governs the dative. This view of the cases is not, we confess, in the present instance, supported by the comparative brevity of the Latin dative and accusative, which is in favour of the dative. It depends for its proof on the use of them in language. Their comparative brevity, however, in the English language, contributes to the illustration of our views, especially as it consists in a difference of the entire word *to*, and therefore is less liable to be ascribed to accident.

…rmedi- …a betwixt …t. accusa- …ti and …t or any …oer case …n a go- …ning …position.

The Latin dative appears, on the whole, to be appropriately employed where the verb has a degree of transitiveness intermediate betwixt those which govern the accusative and those which do not govern any case. The latter may express actions in themselves transitive, though they have not been formed for the purpose of transition, but merely for attaching the accident implied in the verb to the subject mentioned in the nominative. After such verbs the object affected may be introduced, but it requires, even in the Latin language, an intervening preposition; we say, *Lutetiam* VERSUS *contendit*, and, AD *prælium progressus est*.

The intermediate character of the dative case betwixt the accusative and the use of a governing preposition is confirmed by this circumstance, (especially as it is apparently accidental,) that, in the English language, which has no termination or peculiar form of the noun for expressing the dative case, it is sometimes expressed by the preposition *to*, and at other times by the noun in the same form which constitutes the accusative. We say, "I sent a letter *to him*," or, "I sent *him* a letter." "Give *him* the money," or, "Give the money *to him*."

…e Abla- …e.

The *Ablative* case of the Latin language has been often considered as possessing a variety of powers. Sometimes one of these, sometimes another, has been selected as its original characteristic. Those who first assigned this case its present name, have considered its original or at least its most conspicuous application, as equivalent to the English preposition *from*, representing the object expressed by the noun as the point of commencement of motion. The author of Grammar in Rees's *Cyclopædia*, describes it as denoting the instrument or medium by which an action is effected, and, of course, considers its meaning as most clearly expressed in such sentences as *scribo calamo*, "I write with a pen." This account of that case, however, will not apply to every sentence in which it occurs. We suspect that any detailed attempt to make instrumentality the universal characteristic of the ablative would involve the subject in inextricable confusion. The writer in the *Encyclopædia Britannica*, impressed with the hopelessness of all attempts to reduce the meaning of the ablative to any one species of relation, describes it as implying nothing more than the simple mention of concomitance. The noun which is put in the ablative may either represent a cause, an instrument, some circumstance of manner, a portion of time, or some other relation; but any one of these is inferred from the nouns employed, and from the evident mutual relations of the words composing the sentence, and not simply from the ablative case. These aids to the meaning are also rather to be regarded as limiting the generality of the case than as correcting any ambiguity. The objection to which this theory is open is, that it is too general to indicate a distinction betwixt this and the other cases of the noun. All the circumstances brought together by words in a sentence may be represented as concomitant. Something further seems necessary for the purposes of precision. The peculiarity of the ablative seems to be, that it is the only case which expresses a concomitant circumstance *by a noun alone*. It is an abbreviating contrivance for dispensing with the introduction of another verb. *Scribo calamo* is used instead of *scribo et habeo calamum, calamus est mihi*, or *moveo calamum*. The pen is merely mentioned in the ablative to supply the place of these circumlocutions.

…rieties … opinion.

It expresses concomitance by the noun alone.

The manner.

In an example quoted by the last mentioned author, *templum clamore petebant*, clamour is represented only as concomitant with the action of going to the temple. These mere concomitances are called by grammarians the manner.

The cause.

When we say *palleo metu*, fear is merely mentioned as a concomitant circumstance with the paleness. Yet it is intended to signify, from the natural connection betwixt paleness and fear, that the latter is the cause, and the inference is instantly made. It is because such inferences are drawn with the utmost readiness, and without any sensible interval of time, that grammarians have been deceived into the belief that the meaning inferred is fully expressed by the ablative case.

The ablative absolute.

The expression of this variety of concomitant circumstances by the ablative without the intervention of an intermediate word, for the sake of connecting the noun with the preceding words, has obtained for some of its uses the designation of *the ablative absolute*; as in the phrases *Illo mortuo; Caio et Cassio consulibus.* It might be considered as absolute in its other uses, as in the annexation of cause, manner, instrument, or time. When an historian says *hoc anno floruit*, it is from the word *annus*, and not simply from the ablative case, that the idea of time is inferred by the hearer.

Attempts are sometimes made in the English language to follow the Latin idiom of using nouns in a form thus absolute; and the nominative or simple form of the noun, is employed instead of the ablative; but when we express the cause, the manner, or the instrument, we always introduce definite prepositions; hence it is translated in our language sometimes *in*, sometimes *by*, *with*, or *from*, and its meaning is rendered more special than in the original Latin. It is scarcely necessary to mention, however, that even in Latin it may also be preceded by prepositions, though it does not necessarily require them. We may say either *se gessit summa cum prudentia*, or *summâ prudentiâ*.

Governed by verbs.

Some verbs govern the ablative as a single case, that is, with the apparent meaning of the accusative. These are chiefly neuter or deponent verbs. They seem to have originally been of the intransitive kind, and afterwards made to govern a noun in this slightly connected and least dependent of the cases. As *gaudere* "to rejoice," *gaudere felicitate alicujus* "to rejoice, the happiness of another being a concomitant event," which evidently would not be mentioned in this connection except as the cause of the joy. The verb *fruor* in all probability, was originally passive in meaning as well as in form, and is capable of being translated "I am privileged," or "I am rendered happy;" *fruor vita*, "I am rendered happy in life," or "I enjoy life." *Potiri viribus*, "to be made rich by, or to possess, power."

By adjectives.

The ablative is sometimes subordinate to an adjective, as *inops ratione*, "needy with respect to reason," translated "void of reason."

Universal Grammar.

By prepositions.

It is also governed by certain prepositions. Among these there are some that are also used in such a manner as to terminate the meaning without being followed by any noun; for example, *clam* "privately," and *palam* "openly." *Clam Cæsare* is "privately as to Cæsar," afterwards translated "without the knowledge of Cæsar." It is indeed true that even such prepositions as govern the accusative are sometimes used in the same manner as adverbs, that is, without any subjoined noun. This is the case with *juxta* and *contra*. But some difference may here be perceived; *juxta* and *contra* always refer to some specific object previously mentioned; *clam* and *palam* may be wholly general.

The syntax of the ablative compared with that of the accusative.

Some illustration of the ablative as compared with the accusative case may be derived from this consideration, that all the prepositions which denote that an action or motion terminates in the object signified by the governed noun, govern the accusative, as *ad* "to," *contra* "against," *in* "into;" they have thus a general analogy to active transitive verbs; while all those which denote that the object signified by the governed noun is the point at which motion commences, govern the ablative, as *a* and *ab*, "from," *e* and *ex*, "out of;" and, finally, those which denote fixed posture or condition are in their regimen distributed betwixt these two cases. *Ante* "before," *apud* "at," *secus* "along," *citra* "on this side of," and some others, govern the accusative; while *cum* "with," *pro* "for," *præ* "before," govern the ablative. But, though no uniform circumstance of syntax marks these last mentioned prepositions, some motive must have directed the persons by whom the language was modified to prefer in each instance one of the cases to the other. If we should suppose that they were derived from pre-existing verbs, the regimen would depend on the genius of each original verb. Prepositions governing the accusative are those which are most completely prepared for a transition of thought to the noun, and thus possess the most complete active energy. *Juxta*, for example, may be held equivalent in force to *jungentia* "joining," *apud* to the word "accompanying," *contra* to the word "opposing." Those which govern the ablative must have been considered as more passive, leading by a more leisurely transition to the subsequent noun. *Cum* might be considered as equivalent to "accompanied." The meanings of these prepositions may be expressed either in an active or a passive form. *Circum* may be analysed into "surrounding," and thus it governs the accusative. If it had originated from some such passive participle as "penetrated," it would have governed the ablative. This variety of syntax might sometimes be founded in etymology, and sometimes the result of arbitrary fancy.

The ablative wanting in the Greek.

The Greek language has no case corresponding to the ablative. The use of the genitive is in that language extended in such a manner as to include it. The Greek genitive seems to have a greater similarity to the Latin ablative than to the Latin genitive, as the ablative is the least dependent of the two, and possesses the most general application. In Latin it is in some instances governed by a noun; a circumstance which we have not before mentioned, as it takes place only in particular phrases, as *vir egregiâ sapientiâ*, or *vir egregiæ sapientiæ*. The Greek genitive is governed by prepositions like the Latin ablative; and the noun in the absolute state, which in Latin is put in the ablative, is in Greek in the genitive. In this latter language therefore we are left to infer from the connection whether the meaning of the genitive case or one of those applications which in Latin are assigned to the ablative is attached to it in each particular instance. The only meaning proper to it is the general one of concomitance; and it may be either a concomitance with an object expressed by a noun, or, like the ablative, it may be concomitance with an idea expressed by an adjective, a preposition, or a verb.

The cases in the French and English languages.

In the French and English languages, the noun is subjected to very few variations corresponding to cases. We have the genitive in *s* with an apostrophe, which is sometimes called the possessive case. In the pronouns "I," "thou," "he," and their plurals, we have one variation, consisting in a case equivalent to the Latin accusative, and technically called the objective case; as "me," "thee," and "him." It is by means of this form, preceded by the prepositions "of" and "to," that the genitive and dative in Latin are translated; and by different other prepositions suited to each occasion, we express a variety of relations which in Latin are indiscriminately, and with less particular meaning, expressed by the ablative. In the French language, the nouns *je* and *tu* have in like manner *moi* and *toi* for their objective cases. *Moi* in that language is even used where the nominative would be used in English, as *c'est moi* for "it is I." Hence some have described *moi* as a complete noun, being a nominative as well as an objective form. In the use of the English language, persons who have not been taught to adhere rigorously to grammatical rules, sometimes say "it is me," instead of "it is I." It is probable that this was originally a legitimate use of the word, and that the establishment of a contrary rule has proceeded from a forced application of a Latin idiom. Even *moi* in French is not used as a nominative to a verb. The French do not say *moi parle* or *moi fais*. It is only that sort of nominative which follows the substantive verb. (We do not here speak of that subsequence in mere arrangement which indicates interrogation, and depends on inversion, in which the nominative always follows the verb, as in *suis je*; and we do not think that any attentive reader would have taken such an exception against our views, though we had not stated this circumstance. Those who would have been so disposed may object to several others which the limits of this article do not allow us to defend against every slight exception. We here speak of that form of the noun which follows a substantive verb, after that verb has been introduced by its proper nominative.)

On the noun following the substantive verb.

This application of the noun after the substantive verb is peculiar, and might with as great propriety have a peculiar form assigned to it as those which are expressed by cases. It has not an appropriate form, because it is of less frequent recurrence. In Latin, it is put in the nominative. In French it is put in the objective case, being treated as a state of the noun introduced (or governed) by the substantive verb. In English we now adopt the Latin idiom. But, while our language was unfixed, it certainly would have been equally natural to have followed a similar usage to that of the French.

CHAP. V.

Of Adjectives.

Sect. I. *The Nature of the Adjective.*

Adjectives do not differ from substantives in the ideas expressed.

The impropriety of considering adjectives as intended to express our ideas of qualities, in contradistinction to our ideas of substances, has been already pointed out. The only objects known to us are qualities, and therefore this distinction has no foundation in nature. Qualities habitually conjoined, and forming definite assemblages, comprehend the whole of our concrete ideas, called ideas of substances. We have words to represent these assemblages, and words to represent single qualities. But this does not constitute the distinction betwixt substantives and adjectives. Both kinds of ideas are indiscriminately expressed by these two parts of speech. The adjective, like the substantive or noun, is the name of an object. The circumstance which constitutes its peculiarity is, that it also contains an intimation of the subordination of the idea expressed by it to the idea expressed by a noun in the same sentence. It has in fact the same application with the genitive case of the noun. Sometimes these two parts of speech may be shown to be synonymous. The words "Peter's," "Solomon's," "Cicero's," are by some called genitive cases, by others adjectives of possession. The words "Aristotelian" and "Ciceronian" are reckoned adjectives by all, and also such words as "Roman" and "Grecian." All of these equally contain the name of a person or country, with an intimation that it is to be connected with some other idea expressed by a noun in the sentence. We shall soon see the similarity of use betwixt these adjectives and such as discover less composition in their structure. We shall also see the cause of their apparent difference.

...es the ...ective ...e a full ...resenta- ...n of any ...ect?

Some have asserted that the adjective by itself expresses no idea. This opinion has arisen from the circumstance that it supposes some other idea expressed by a different word. But this is in reality an addition to its meaning. Every idea expressed by a substantive may also be expressed by an adjective, and *vice versa.* The idea expressed by "man" is also expressed by "manly;" and the idea expressed by the adjective "good" is also expressed by the substantive "goodness."

Perhaps it will be alleged that, when we use the adjective, we do not give a full representation of an object, but merely refer to it by mentioning a quality founded on some connection with it; that the words "Roman," "English," "Ciceronian," do not imply the full meaning of "Rome," "England," and "Cicero." In answer to this we must observe that the greater part of words in a sentence are merely introduced for reference. Sometimes, where many words are used, and many objects of thought mentioned, those which are mentioned on their own account are comparatively few, the greater part of the words, including the nouns employed, being merely introduced for the sake of reference. "A Roman senator," and "a senator of Rome," mean exactly the same thing; therefore the ideas contained in the word "Rome" are also contained in the word "Roman."

...w an ...ective ...ned ...n a pro- ...p name ...mes ...eral.

Those whose reflections are in the habit of suggesting more subtile arguments, may object that the word "Rome" is a proper name, while "Roman" expresses a general quality. This, however, is the same objection in a different form. A part of the word "Roman" is a proper name. The generality of such adjectives arises from the variety of occasions on which proper names may be used. Their application in connection with other words thus becomes general, and the same thing may be said of any form of a noun that implies definite connection with other words. The adjectives "Roman," "Grecian," "French," "English," "Alexandrian," "Ciceronian," "Foxite," "Pittite," contain the names of individuals, but they become general from being applicable to many objects. A relationship to an individual becomes a generic quality.

The least complex adjectives.

There are, however, adjectives which express the possession of general qualities founded on no reference to a particular individual. These adjectives have less appearance of composition than those now mentioned, and are always shorter than the substantive nouns used to represent the qualities as separate objects. "Good," "bad," "hard," "soft," "light," heavy," are shorter words than "goodness," "badness," "hardness," "softness," "lightness," and "heaviness." It is from the aspect of words of this sort that grammarians have concluded that the adjective does not express a complete idea. They are never derived from the general name of the quality. It has been imagined that the ideas which such adjectives express are *essentially* general, that they have no corresponding objects possessed of an individual existence, and that, when substantive nouns, such as "goodness" and "badness," are derived from them, a forced effort is made to treat qualities in language as if they were substances. The just conclusion was not drawn, that substantives and adjectives, as mutually distinguished, are forms fitted for certain purposes in language, and not signs founded in any differences in the nature of the external objects signified.

Reason of the simple structure of some adjectives compared to the corresponding substantives.

The reason of the comparative brevity of words signifying general qualities, when in the form of adjectives, has been already hinted at. Individual instances of these qualities have no separate interest attached to them, and therefore the words expressing them contain an intimation of their annexation to some group. The names of groups, even though generic, are in the first instance so contrived as to be fitted to become the names of leading subjects of discourse; and ever after merely require a proper introduction to render them distinctive signs for individuals. It is at a more advanced period of human thought that single qualities become separate objects of attention, and then it is natural to create names for them by the composition of words previously in use.

The adjective, like the genitive case of the noun, is a word subordinate to a noun by which it is introduced. Sometimes it is employed to remind us of one of the ideas contained in the noun, as when a poet speaks of "fleecy clouds," "the azure sky" and "verdant foliage;" or when a historian, under impressions of indignation at any series of outrageous conduct, uses such expressions as "the infamous Robespierre."

Ultimate effect of adjectives.

The most usual effect of adjectives is, to reduce within a more limited range the application of a general term, by the addition of a circumstance which belongs only to a limited part of the genus which that term expresses. "A man" means one individual belonging to a certain class of beings. The words, "a good man," represent one belonging to a limited part of that class. An additional circumstance, attached by means of another adjective, would limit the meaning still more: and an accumulation of adjectives of this sort is capable of affording a combination of sufficiently limited occurrence for any purpose of distinctive description.

Varieties in the degree of subordination of the idea expressed by the adjective.

The subordination of the idea contained in the adjective to the noun with which it is coupled is in some instances less strict than in others. On some occasions the ideas expressed by these two parts of speech might exchange places without any material alteration in the meaning of the compound designation thus formed. "A written libel" is equivalent to "a libellous writing;" "a false assertion," to "an asserted falsehood." Although the purposes of connection in discourse require one of the ideas thus nearly equal in importance to be expressed by a substantive noun, the choice is left to the option of taste and convenience. In other instances in which they may be made to shift places, when the

Universal Grammar.

ideas which they express are the subject of a sentence, a corresponding change is required in the predicate, in order that the identity of the meaning may be preserved. The sentence, "a good man is a happy man," may be converted into "human goodness is conducive to human happiness."

An anomaly.

It sometimes happens that the adjective expresses the idea which is intended to be the principal, and to which that expressed by the substantive noun is subordinate; as in the Latin phrase *ab urbe condita ad (urbem) liberatam*. In the translation of such phrases, the idea that is primary is expressed by a substantive noun, and the subordinate one by an adjective. The primary ideas introduced in this phrase, by the prepositions *ab* and *ad*, are the "building" and the "deliverance;" hence it is translated, "from the building to the deliverance of the city." Such idioms are to be considered as arbitrary inversions of the parts of speech, and do not invalidate the original subserviency of the adjective to the substantive noun, as well as of the genitive case to the noun by which it is introduced.

The adjective is very often employed as the predicate of a sentence. It then conveys, by the help of the substantive verb or copula, information of a connection betwixt the idea conveyed by it and the leading subject expressed by the nominative prefixed to this verb. As in the sentences "Cicero was eloquent," and "Solon was wise."

Sect. II. *The Etymology of Adjectives.*

A great proportion of adjectives derived from verbs of motion.

Amidst the obscurity in which etymology is involved, it would be difficult to trace all adjectives to other parts of speech, and thus prove that none of them are original. But many of them which might be supposed from their appearance to be simple have been shown to be derived from verbs, and these verbs are expressive of motion.

Sometimes the adjectives thus derived signify qualities *produced* by particular motions The adjective "left," in contradistinction to right, is from the verb *to leave*. The left hand is that which we leave or decline to use. "Tight" is *tied*; "full" is *filled*; "loud" is from *low'd*.

Sometimes the adjectives thus formed merely contain an *allusion* to the motions from which they are derived, as "odd" from *ow d*; "straight" and "strict" from *stringere* to pull; "blind" from the old verb to "*blin*," or stop; "bold" from the verb to *build* or establish. "Brown" is from the verb to *bren* or burn. "Lewd" is the participle of the verb to *lew* or allure. "Profligate," an adjective used to depict a character destitute of all rectitude of principle, is derived from *profligare* to defeat.

Some derived from concrete nouns.

Adjectives expressive of single qualities are sometimes derived from the names of habitual assemblages in which such qualities are conspicuous. The colour "yellow" is in Latin *flammeus* or *luteus*, because it is the colour of flame or of clay. The English word "yellow" is derived from the Saxon verb *geæigen* to burn or flame. *Viridis* in Latin, is from *virere*, to vegetate; and "*green*" in English from *grenian* to grow.

From the analogies in etymology disclosed by the researches of Mr Tooke, it would appear that verbs expressive of human motion have been the roots from which almost all adjectives, as well as substantives, have been derived This fact tends to illustrate the views given at the beginning of this article, on the principles which regulate the progress of the human mind in the formation of language.

Some adjectives contain an intentional allusion to the nouns and verbs from which they are derived, and something more is recognized in them than the current signs for annexed qualities. Such are the adjectives, "*man*ly, *gentleman*like, *prince*ly, *nation*al, *provinc*ial, *world*ly, *earth*ly;" also "*earthy*, *hilly*, *stony*." The substantives are here fully expressed, and the terminating syllable denoting annexation is capable of being separated.

Some adjectives evidently compounds.

Sometimes this last is merely a general sign of connection; at other times it signifies something more specific, and then the adjective is to be considered as formed by the combination of another adjective with a noun. Thus, "faithful" does not mean simply "connected with faith," but "full of faith," and, if analyzed into the genitive case, it would not be represented by the phrase "of faith," but "of fulness of faith." A "gentleman-like youth" is not "a youth of, or connected with, gentleman," but "of the resemblance, or likeness, of a gentleman." Where several synonymous adjective terminations exist, though all general in original meaning, different specific applications may be afterwards appropriated to them Thus "earth-*en*" means made of earth, "earth-*y*." abounding with earth, "earth-*ly*" connected with the earth In some examples we find both parts of the compound word restricted in their meaning. If *ly* means "like," the etymological meaning of the word "earthly" must be "similar to earth;" yet the word is employed solely to signify "connected with the system of our earth" in contradistinction to the invisible world.

There seems to be a constant tendency amidst the fluctuations of language to coin new adjectives, by derivation from substantive nouns, for the sake of producing greater liveliness of expression. When such a word as "manly" is first used for describing an individual, the hearer more readily imagines to himself a "man" with all his suitable qualifications for the illustration of the quality named, than when such epithets as "bold" or "firm" are employed.

Participial adjectives.

Some adjectives derived from *verbs* contain an equally palpable allusion to the parent words as those do which are derived from nouns, and thus bring more fully into view the motions or actions which they denote. The most remarkable adjectives of this sort are also called participles. They resemble other adjectives in every feature which has yet been mentioned; but many of them imply an additional characteristic, which will come into view when we treat of the verb. The participle expresses the meaning of the verb, together with its subordination to the idea expressed by a substantive noun. The words, "pining," "thriving," "dazzling," are as completely adjectives in meaning and use, as "weak," "strong," and "bright." Sometimes it contains the addition of a particular modification of connection. There is generally a difference betwixt the participle in *ans* or *ens* and that in *us* in Latin, and betwixt the participle in *ing* and that in *ed* in English.

Inflection of adjectives.

The adjectives of some languages are subjected to variations corresponding with the cases, numbers, and genders of the substantive nouns to which they are attached. These are terminations. They are extraneous with regard to the meaning of the adjective, and are merely convenient marks for designating, in complicated sentences, the noun with which each adjective corresponds. They served, in the Greek and Latin languages, to obviate that ambiguity which must have been the consequence of the inversions of the order of words which the writers of these languages, especially the poets, perpetually practised. This circumstance, though merely accidental, has probably formed the ground on which grammarians have proceeded in calling the adjective a sort of noun. The declensions have given it a similarity of aspect to the substantive noun. The metaphysical reason for adhering to this nomenclature assigned by Mr Tooke, that both equally contain the name of an object, seems not to have occurred, and labours under the disadvantage of applying also to other parts of speech.

Sect. III. *Degrees of Comparison.*

grees of parison n common to all ctives.

Many adjectives are subjected to variations which indicate a comparison of the degree in which a quality is to be attached to different objects. There are adjectives which do not admit of this variation, because there are qualities which do not admit of degrees. Such are some of those which denote figure; as, "circular," "quadrangular," and "triangular." Adjectives subjected to degrees of comparison are those which express qualities which admit of being more or less intense. No language is without separate words to signify comparison. But an expression of that act is so frequently required, that it has been found convenient to combine the sign of it with the adjective, in the form of a termination.

T com- m divi- n.

Three degrees have been enumerated; the positive, the comparative, and the superlative. But the positive form is the simple state of the adjective, and should not be called a degree of comparison.

The comparative degree is formed, in Latin, by adding the syllables *ior* to the radical letters of the simple adjective; the superlative by adding the syllables *issimus*; as *mitis, mitior, mitissimus;* in English, by adding the syllables "er" and "est," as, "meek, meeker, meekest." When the euphony of our language does not admit of this mode of formation, the same thing is expressed by prefixing to the simple adjective the adverbs "more" and "most." Several grammarians have described the meaning of these degrees of comparison as consisting in this, that the comparative expresses a comparison betwixt two objects, i. e. a comparison of one with another one; while the superlative expresses a comparison with many, i. e. with the whole of a class. But we find that the comparative degree may be employed for comparing an object with many others as well as with one; as when we say, "He was *wiser* than all his teachers;" "Charity is *better* than a thousand sacrifices." The superlative degree, in its turn, may be used when only two objects are compared, as, "James is the *wisest* of the two." The difference betwixt these two sorts of expression, which should rather be called *forms* than *degrees* of comparison, is, that the comparative considers the subjects compared as belonging to different classes, while the superlative, compares them as included in one. When we compare two men, if we oppose the one to the other, we use the comparative, and say "that he is *taller* than that other;" but when we place the two together to form a group, and point out the superior rank which one of them holds in this group, we say, "He is the *tallest* of the two."

T diffe- n e be- n the c parative a super- L e.

In like manner a comparison in which more than two are concerned may be expressed either by the comparative or the superlative. The comparative is thus used when we say, "Greece was more polished than any other nation of antiquity." Here Greece is considered as not belonging to the class mentioned after the words "more polished." For this purpose these nations are designated by the term *other*. "Greece was none of those *other nations;* it was more polished than they." The same idea is expressed by the superlative when the word *other* is left out; "Greece was the most polished nation of antiquity." We here assign it the highest place in the class of objects among which we number it,—the nations of antiquity. A similar option is left in conveying such sentiments as the following: "Mr Fox spoke more forcibly than any other member of the House;" which may also be thus expressed, "Mr Fox spoke the most forcibly of all the members of the House."

Universal Grammar.

The comparative is indeed sometimes used instead of the superlative where there are only two in a group; as when we say in Latin, *senior fratrum,* and in English, "the elder of the brothers;" "the wiser or the taller of the two." The frequency with which the comparative form of the adjective is employed in comparing only two, has misled some technical grammarians to state it as a principle, that this is the only proper form where no more than two objects are concerned, even although they should be represented as belonging to the same collection or class. But, though habit has admitted some instances of this phraseology, it is an error to form such a rule, and it is injudicious to check any tendency to use the superlative in its original application.

Sect. IV. *Numerals.*

The numerals are adjectives in meaning as well as in form.

Numerals have the same relation to the substantive noun as adjectives, and therefore belong to this class of words. They express a modification or limitation of the idea conveyed by some substantive. Their peculiar object is to denote the degree of frequency with which any sort of thought contained in a noun is repeated; that is, the frequency of the exemplification of a general idea.

Sign of the singular.

In English, the singular number is sometimes merely distinguished from the plural by the want of the terminating *s*, as "the house" for the singular, and "the houses" for the plural. At other times the word "one," or the word "an," or "a," is prefixed. "An" and "a" have been called by grammarians indefinite articles, but in this there is no propriety. They merely signify unity, and this is expressed by them in the most definite manner. In the French language, they are always translated by *un*. They ought, therefore, to be called numeral adjectives. They cannot be prefixed to plural nouns, being peculiar to the singular, or the exhibition of an idea without repetition.

The words "some" and "several" are used as general plural adjectives. There are others implying the result of a general comparison with respect to number; as, "few" and "many." But these words do not describe the frequency of the repetition with precision, and for this purpose language is furnished with corresponding numeral adjectives. One added to one, forms a number which has the separate name "two:" one and one and one, or two and one, have the name "three:" one repeated once more, or a repetition of two, forms the number called "four." Our idea of number, as a separate subject of thought and of language, has no existence previous to our experience in numbering individuals. This gives rise to the observation of a general feature in the acts of the mind called numbering; and hence the generalization of numbers. Words signifying a particular degree of repetition become applicable to all acts of

Universal Grammar.

the mind in which an idea is repeated with the same frequency.

Etymology of numerals.

The general words expressive of numbers are derived from the names of particular objects; though, perhaps, we can seldom succeed in tracing them. As the two sides of the body exhibit pairs of organs, two eyes, for example, and two hands, the word for "two" might arise from the most interesting of these pairs. Perhaps the numeral *tres*, "three," has been borrowed from the idea of vibration, and owes its etymology to the verb *tremo*, or some older verb of the same meaning. The two words are at least evidently akin. The words first used to express the succeeding numbers might be suggested by the first two or three, with the help of a sign intimating *reduplication*, as in "two," "four," and "eight," or *addition*, as in "five," "six," "seven," and "nine."

Decimal numeration.

Numeration by *tens* has, with very few exceptions, taken place in every part of the world. This has been suggested by the numbering of the fingers, which form an assemblage familiar to us from our childhood. The word for "ten" would therefore be borrowed from the word signifying "hand," or "fingers." Δεκα in Greek, and *decem* in Latin, evidently spring from the same root with δακτυλος and *digitus*, a finger. The combinations of tens with one another, and the addition of the words for the different units, are prominent processes in the words employed among the ancients as well as the moderns for the higher numbers, and in the marks invented to express them compendiously in writing.

Sect. V. *The Article.*

The article in all respects an adjective.

There is one adjective which, from some peculiarity, has been generally reckoned a separate part of speech, under the title of "the definite article." The English words *an* and *a* have been called indefinite articles, but their nature has been shown to be that of numeral adjectives. The words ὁ, ἡ, το, in Greek, *the* in English, *le* and *la* in French, and the corresponding words in other languages, have been called the definite articles; but they have every characteristic of the adjective. They have even corresponding inflexions in those languages in which adjectives are inflected. Their general meaning, and the purpose of the speaker in using them, are the same with those of the adjective. They represent an idea or quality subordinate to an object expressed by a substantive noun. This quality consists in a reference to some previous mention, or to some knowledge previously possessed of an object. A historian, after having named and described a variety of objects, speaks familiarly of them by using their general names preceded by the adjective *the*, as, "the army," "the town," "the battle," "the siege," and "the truce."

One of its uses.

Another use.

Another use of it is, for attaching a speciality by means of a genitive case, or another adjective, or some of those phrases which we shall afterwards show to be equivalent; as, "*the* King of Prussia," "*the* governor of Malta," and also, "*the* French nation," "*the* Italian territory," "*the* Christian religion." Where no speciality is attached, it means, "known by former mention," or, "mutually understood betwixt the speaker and the hearer." Where it is followed by the genitive or another adjective, it means, "to be known or distinguished by this mark."

Some classes of objects are never mentioned without the use of this adjective, as, "*the* French," "*the* English," This phraseology has arisen from the habit of prefixing the words French and English to more general nouns, as, "the French or English people." We say, "the French are gay;" "the English love the pleasures of the table." We have, indeed, equivalent expressions without the article in the words, "Frenchmen," and "Englishmen."

It does of itself make the meaning of a noun finite.

The only circumstances which have led to the idea that the article was a distinct part of speech, seem to be the same which we have mentioned of the pronoun, viz. its brevity, and its frequency. It is a mistaken notion to consider it as possessing the power of distinguishing the application of a generic name to an individual from the use of that name in a less definite acceptation. It has not this power in a greater degree than other adjectives. If we speak of "the man," we no more distinguish any individual than when we say "a man," and not so much as when we say, "a wise man." It is only after an individual has already been distinguished that the adjective "the" characterises him, by referring to that description. It is of very general and familiar application; because any object may be mentioned as already known, or may be introduced with a view of being characterised by some special mark. Like every other adjective, it becomes fitted to particularise the intended object in proportion as it is used with skill and propriety.

Etymology of *the*.

Mr Tooke (vol. ii. p. 60.) derives "the" from the Saxon verb *the-an*, "to take," of which he supposes it to be the imperative. "The man," accordingly, means "take man;" and implies a direction to the hearer to select an individual from the rest of the class. This is its meaning when the object is first introduced for the purpose of being described. When afterwards used for reference, it must mean "taken" or "selected."

Analogous adjectives.

Very nearly allied to the adjective "the" are the words "this" and "that," which have been denominated by grammarians adjective pronouns. "That" is considered by Mr Tooke as also derived from *the-an*, "to take;" and as, in fact, its past participle. In actual application "this" means "near," and "that" "at a distance." Another adjective "yonder," signifies, "at a considerable distance," or on the other side of something referred to. "This" and "that" are either prefixed to nouns, as "this man," "that thing," or are used by themselves, as "this is good," "that is indifferent." In the last form of speech there is a subaudition of the noun; or the adjective may be considered as converted into a substantive noun, in the same manner as we have shown that many substantives are created. Like them, it expresses one quality, with a subaudition of the rest. An adjective used with the subaudition of a substantive, is very nearly akin to a substantive formed from an adjective by subaudition.

CHAP. VI.

Of Verbs.

Sect. I. *The Nature of the Verb.*

Complicated appearance of the verb.

The verb, as exhibited in elementary grammars, especially those of the Greek and Latin, is much more varied than any of the other parts of speech. Some ingenious attempts have been made to trace its complications, and to analyse its different forms. We find the offices performed by words called verbs to be various, and it would be satisfactory to discover the cause of the application of one common term to words so diversified.

Universal Grammar.

Queries on improper nature.

The following are the queries which this subject suggests. Does the verb perform any office which is peculiar to itself, and is this common to every word which, in the present practice of grammarians, receives the appellation of verb? Are there more points of coincidence than one in the application of the various forms of the verb? Is this coincidence in office strictly universal? Or are these different offices sometimes united in one verbal sign, while only one of them is performed by others? Are the offices performed by the respective words called verbs thus different among themselves? Are there any functions common to the verb with some other parts of speech, though more advantageously and more frequently performed by verbs than by these others? Does this circumstance render it advisable in any instance to retain the name of verb, even while the office performed by it is not peculiar? Or ought scientific accuracy to concur with convenience in leading us to alter in this instance the nomenclature of the parts of speech? These questions can only be answered by investigating the nature and use of every sort of word which, in the habitual language of grammarians, is denominated a verb, and making a comprehensive survey of their applications, in order to assign to all of them respectively their just rank in universal grammar. We must therefore suspend the discussion of the leading problem implied in the title of the present Section, and leave the reply to be gradually unfolded in the sequel of this Chapter.

One important form of the verb, the imperative, created by the earliest occasions for the invention of language, has already come under our notice. We have found imperatives to be the shortest of all words, and to consist of the roots from which the greater part of other words derive their origin. But, since we have considered all language as imperative, that subject does not form an appropriate commencement to our inquiries into the peculiar nature of the verb; and in fact it scarcely requires any additional observations to those already made on it. Many verbs from their meaning do not admit of direct imperatives, (to wit, those which do not signify the voluntary acts of mankind,) yet possess many forms in common with active verbs.

We shall first consider those forms of the verb which are subservient to affirmation, or, as it has been sometimes termed, *predication*, for the sake of including negations.

Sect. II. *Verbs as subservient to Assertion.*

Assertion a frequent, and peculiar to the verb.

Assertion or affirmation is the act peculiar to the verb, being never performed by any word which grammarians have referred to a different part of speech. That part of the verb by which it is most evidently and most frequently performed is called the *Indicative*. By means of it we convey information. This, though not the original object of language, is by far the most frequent application of it, especially in an improved state of society. It proceeds from that great characteristic of our species, the love of knowledge, implying an inclination to convey it to each other. It is by means of affirmation that language becomes the instrument of the most important improvements in human thought and in the character of society. An inquiry into its nature must therefore throw considerable light both on thought and on language.

Nature of assertion.

In affirming, we connect different ideas together, and thus dictate an arrangement which we wish such ideas to assume in the mind of the person addressed. To this object a particular part of spee c is devoted; but that part of speech often consists of a word which contains a sign of various other ideas. When we say "the man walks," the word "walks" contains the name of a particular motion, at the same time that it expresses a connection betwixt that motion and the object denoted by "the man." Mr Tooke considers the verb as containing a noun and something more; and he proposes it as a question worthy of the attention of philosophers, what is that circumstance which, when added to a noun or the name of an idea, makes it a verb? The answer to this, in so far as the indicative is concerned, is, that it contains a sign of asserted connection betwixt the object expressed by that noun or name and some other object which is also mentioned in the sentence. But we have other signs of connection which are never considered as giving a word the nature of a verb. The genitive case implies a sign of connection betwixt the object expressed in that case and some other; the adjective performs a similar office; but there is a difference betwixt these signs of connection and that implied in the indicative of the verb.

Analysis of sentences of assertion.

The nature of these two sorts of signs, and the difference betwixt them, will be most clearly perceived by attending to the structure of those languages which enable us to resolve the indicative of every verb into its constituent parts by affording distinct signs for each. In English "the man walks" may be resolved into this sentence "the man is walking." The termination *ing* implies a connection similar to that expressed by the genitive case or by the adjective, while the word *is* gives the sentence the character of assertion, and fits it or conveying new information.

For the sake of possessing appropriate terms on this part of the subject, it will be convenient to borrow the technical language of logicians, who call a sentence a *proposition*, consisting of three parts, a *subject*, a *predicate*, and a *copula*. In such a sentence as we have now mentioned, each of these parts is expressed by a separate sign. "The man" is the subject, "walking" the predicate, and "is" the copula. The author of Grammar in Dr Rees's *Cyclopædia* maintains that "is" does not express assertion but connection. Connection, however, is often expressed by words of very different import: therefore that term is less appropriate to the copula than assertion.

Sect. III. *The Substantive Verb.*

The copula has been denominated the *Substantive Verb*, and it undergoes a variety of changes, called inflections, corresponding to the changes incident to other verbs.

Mr Harris's account of the substantive verb.

The radical nature and common use of this verb is not, as Mr Harris supposes, to express existence, but to assert a connection betwixt one object and another. The author now mentioned has been unfortunate in his mode of describing the use of this verb. He pronounces it an undoubted axiom, that "an object must first be, before it can be any thing else;" an opinion in all points of view untenable. In the first place, it is not necessary that the subject spoken of should have an actual existence. We can speak of supposed as well as of existing objects. In the next place, an assertion that any object which has existence is something else, implies an absurdity.—What then is an assertion? Do we by means of it assert an object to be the same that is implied in the term used for an introductory designation? This is not the case; it would form an

Universal Grammar.

unmeaning truism; and the predicate is generally a different word from the subject. In this act we neither assert the subject to be the same, nor to be something else. The office of assertion consists in pointing out a relation betwixt the subject and some other idea. The word "gold" has one meaning, and the word "metal" has a different one. When we say "gold is a metal," we do not intend to say that the words "gold" and "metal" have the same meaning, but that the qualities expressed by the word "metal," are connected with the object called "gold." When we say "sugar is sweet," "wormwood is bitter," our intention is to produce in the mind of the person addressed a connection betwixt the ideas which have been previously attached to the word "sugar," and the further idea of "sweetness," and betwixt the ideas attached to "wormwood," and the idea of "bitterness." Sometimes nothing may be previously known concerning the subject of the proposition. We may speak of sugar and of wormwood to a person who has never heard of either. In that case the terms are only introduced as signs requiring the person addressed to attach to the one of them the idea of sweetness, and to the other that of bitterness, as contributing to those compound ideas of which he may afterwards consider the words as significant. The idea expressed in the subject must always be different from that expressed in the predicate. This is the case even though the expressions used would on a different occasion be synonymous. When the sentence "London is the capital of Britain" is uttered, if the hearer had any ideas about London, he is desired to connect with these the further circumstance of its being the capital of Britain: if he had no idea on the subject, except that London was a name written or pronounced in a certain manner, he is desired to connect this word as a name with those which form the predicate of the sentence. Sometimes, by a figure of speech, the same word is used for the subject and the predicate: for example, "Home is home." In the employment of this figure, however, it will be found that such a word as "home" in these two situations has a different set of ideas attached to it. The meaning of this sentence is, "Home, though often thought and spoken of with indifference, is, when made the subject of reflection, connected with feelings which interest and attach us."

The ultimate effect of assertion.

The substantive verb radically indicative.

The substantive verb differs from verbs of motion in being radically indicative in its character. Assertion is the cause of the contrivance of it. It does not originate in the imperative mode, any further than an imperative effort to command attention is implied in all language. The use of the substantive verb is, to direct the thought of a person to the connection of one idea, or one assemblage of ideas, with another, and thus to indicate congruities, incongruities, and relations of all kinds. The substantive verb is employed in the imperative conformably with the usages of other verbs. We say, "be wise;" "be ready to do your duty;" but this imperative has always an awkwardness and a want of emphasis, compared to that of the active verb. An active imperative may be considered in such phrases as understood. It seems an absurdity to desire any person or thing *to be*, or even simply to be connected with another object, or to be endowed with a particular character. The imperative radically implied in such sentences is a command or solicitation to use such *exertions* as tend to the production of a certain state. *Sis probus* means *fac ut sis probus*, cause yourself to be good; act in such a manner as to support a worthy character.

All the other forms of this verb coincide in meaning and emphasis with the corresponding parts of other verbs.

The peculiar character of the indicative of the substantive verb is, to express in a separate word that general act of the mind which is common to all verbs in the indicative mood.

The pr[edi]cate in[tro]duced [by] this ver[b].

The *predicate* of a proposition may either be an adjective noun, as "Cicero was *eloquent*;" "Solomon was *wise*;" or a participle, as, "the man is *walking*;" "the boy is *riding*." A substantive is applied with equal frequency to the same use as "Isaac is *a philosopher*;" "George is *a king*;" "Alexander is *an emperor*." A connection betwixt the ideas expressed by these substantive nouns and those attached to the *subjects* of the propositions, is then asserted by means of this simple verb. The verb still merely serves the purpose of a copula. The noun becomes an adjective by its situation.

Origin [of] this ver[b].

Dr Smith infers from the generality of the character of this verb that it must have been the result of much thought, and could have been formed only after refinement in metaphysical science had made considerable advancement. For this inference, however, there is not sufficient foundation. The acts exerted in all assertions have a character mutually similar, and are therefore called the same act; and nothing is more natural than to express the same act or similar acts by the same sign.

Suppose[d] no dept[h of] reflectio[n].

The early attempts of a child to speak are often made without the use of the substantive verb. He says, "That bread good," instead of ' that bread *is* good." He possesses the ideas of bread and of goodness, and, by pronouncing the one in immediate succession to the other, he attempts to convey the impression which he has received of their mutual connection. The same mode of speaking may be supposed to take place among a people whose mutual communications are few and crudely executed. But, as the juxta-position of nouns may also be applied to other uses, a separate sign is afterwards introduced for indicating assertion; and no depth of metaphysical knowledge is required to induce men to use the same sign on every similar occasion. Although some risk of error attends the intellectual exercise of retracing and analysing the progress of our mental operations, and hence metaphysical mistakes and difficulties have been handed down from age to age, no hesitation or impediment occurs in the employment of the faculties for the common purposes of speech. The human mind has always proceeded without embarrassment in contriving signs for its communications. The formation of a general word is equally easy with that of a significant general termination for shewing that words are applied to similar uses. A termination expresses some point of mutual resemblance in the application of words. The same thing is done by a separate word, and a separate word may be uttered with equal facility. The forms, in fact, which are common to all other verbs are exactly synonymous with the pure substantive verb. All other verbs consist of the signs of ideas, coupled, as we have observed, with the sign of adjection, and the sign of assertion; that is, the meaning of the participle with that of the copula.

Sect. IV. *The Neuter Verb.*

Natur[e of] the ne[uter] verb.

Some languages have verbs which contain the meaning of an adjective and the copula condensed in one word, and which have no further characteristic in the construction of sentences than these parts of speech when separately expressed. Perhaps this is not the

Universal Grammar.

case with every language, and there are probably none in which such verbs abound. In the Latin language, *rubere, virere, calere, frigere*, are instances. In English we have the verbs "to glow," "to blush;" but we for the most part express such ideas by using adjectives with the substantive verb in a separate state. The verbs now mentioned are called *neuter* verbs, in consequence of the absence of certain qualities which we shall find other verbs to possess.

Sect. V. *Assertions made by Verbs of Motion or of Action.*

Origin of ...s of ...ion.

It has been already observed that the first object which a man has in view, in using speech, is to excite to action. Were mankind destitute of vocal language, they would imitate the particular actions which they intend the person to whom they speak to perform. This is always done by persons who wish to converse while they are not acquainted with any common language. The case is necessarily the same with dumb persons. In tracing the origin of the words by which particular actions are represented, and the establishment of them as conventional signs, we find no general principle to guide us. The motive for using a particular sound is of so casual a nature that its history is lost before it receives an established application. The want of written documents, and the total inattention to retrospective analysis, which exist in a state of society so rude, involve the origins of words in obscurity. Etymology can only trace a word from one application to another, and follow its variations through the different languages into which it has been adopted. Even this exercise is liable to deceptions which it is difficult to avoid. Yet it must be allowed that, when conducted with caution, it may prove extremely useful, by discovering analogical principles of transition, which elucidate this department of human art.

After men have learned to employ words for exciting one another to those actions by which reciprocal services are performed, the extent of the uses to which language may be applied must be soon more fully perceived. Men contrive to describe to each other various surrounding phenomena. Some of the most interesting of these consist of the actions of their fellow creatures.

...root ...l in the ...erative ...ives ...r applications.

The same sign by which we desire a person to perform a particular action, is naturally retained as a symbol of that action in describing any series of events of which it forms a part. After we have used the words "come," "go," "stand," "sit," "run," as imperatives, we spontaneously apply the same words, either in the same form or with some slight addition or alteration, in affirmative sentences, such as "John stands," "John sits," or "John runs."

It has been already remarked that these indicative forms may be resolved into the copula with a participle, and are equivalent to "John is standing," "John is sitting," and "John is running." The connexions expressed by the participle are observed in the operations of the solitary mind before we are capable of using language, and form an extensive series of relations among the objects of our knowledge. But the earliest use that arises for connecting the significant words is the conveyance of information. On this account the copula and the participial sign are not originally separate, but condensed into one word with the name of the action specified. This early date of the condensed phrase is the cause of a comparative simplicity in the indicative form. It is prior in formation to the participle. We have occasion to say that a man "walks," sooner than we have occasion to use the compound designation "the man walking" as the subject of a different proposition. It follows *a fortiori* that the simple indicative is prior to that indicative which is formed by the participle and the copula. The division of it into these two parts might make the indicative appear more complicated in metaphysical analysis, and some might be disposed, on this view of the subject, to consider the usual indicative as a species of contraction. But this is not its character. The act which consists in the union of the meaning of these two signs is spontaneous, and of an early origin. On this account the indicative has even less complexity of form than the participle.

...ertion ...arlier ...than ...ple adion.

Sect. VI. *The Active, Passive, and Middle Voices.*

It most frequently happens that, in describing an event, whether consisting of a voluntary human action or not, we have occasion to bring into view, by means of a noun, some object which has a conspicuous concern in it. The occasions on which no inclination to do this exists are but few, and the events which are described in a manner so simple are not of the most interesting kind. They occur in Latin in the use of such verbs as *ningit* and *pluit*, "it snows," "it rains." Each of these verbs, without any nominative, contains a full account of an event.

Some verbs of no voice.

When we describe an action which has an intimate connection with some other objects, we generally have occasion to extend our description by the mention of the object or objects so situated. We may either mention one or more of the agents who perform the action, or an object affected by it. If the noun expressing this object is put in the nominative case, it becomes the leading subject of the sentence.

Origin of voices.

When the nominative is the name of an agent, the verb is said to be *active*. When it is the name of an object affected, it is said to be *passive*. (This mode of expression is somewhat illogical. It is the noun that becomes active in the one instance, and passive in the other. The difference of these two uses of the verb is, that they give these differences of character to the noun. We shall, however, adhere to the established nomenclature as established by common usage, and possessing the advantage of a convenient briefness.) There are not in every language two separate forms of the verb for these two applications of it. In modern English, some verbs are used in the same form in an active and in a passive application. We can use the verb "cut" in any one of the three following ways: "They *cut* the tree;" "These tools *cut* smoothly;" "Fir *cuts* more easily than oak." We say, "Look at that person's face;" also "He *looks* well;" "Drink some wine;" and "This wine *drinks* pleasantly."

Distinct forms not always required.

Some grammarians, impressed with the prominent distinction existing in the Latin language betwixt the verb in the active and the passive voice, would insist that "to drink" and "to cut" are essentially active, and therefore that the phrases "fir cuts easily" and "this wine drinks pleasantly" are ungrammatical. But we shall probably entertain a more enlarged as well as a more correct idea of the verb, by conceiving that those which we call active verbs are in their earliest application of no particular voice, though, from the agent generally appearing in the mind of the speaker more important than any object acted on, the active application of them is the most frequent. The original indicative of

Universal Grammar.

the verb thus points out a connection betwixt an object and an event without specifying the nature of this connection. The circumstance of agency or any other may be safely left to the inferences formed by the understanding of the hearer.

Different contrivances for a passive form.

In other instances, it is found convenient to contrive a mode of expressing by some slight alteration in the form of the verb the circumstance of being the object acted on. An expression of this sort, if found to harmonize with the genius of a language, may be afterwards universally adopted; and the original form of the verb will then be limited to the active application. In such languages the distinction betwixt the active and passive voices will be most constant. This happens in the Latin language, and in the active and passive voices of the Greek. But, where the contrivances adopted for this purpose are in point of convenience less fortunate, they will be more varied and less strictly adhered to. Much will be left to urgent occasion or individual taste. Of this we have instances in the middle voice of the Greek verb, and in several phrases in the modern languages of Europe.

In French.

The French apply the verb in a passive acceptation, by introducing the same object as the nominative and the accusative to it, as *Le vin de Bourgoigne* SE BOIT *partout*, literally "the wine of Burgundy *drinks itself* every where." A verb thus used has been called a reciprocal verb, and it appears particularly appropriate when the same object is the agent and the object affected, as in the phrase "he prepares himself." Yet it is not necessarily limited to such occasions. *Le vin boit* does not mean "the wine performs the act of drinking," but "the wine has some connection with the act of drinking." The nature of that connection is here indicated by the accusative *se*. The phrase *le vin se boit* may be thus analysed, "The wine is concerned in drinking, by being the liquor which some one drinks." But we find that in English, when we say "the wine drinks pleasantly," the kind of connection betwixt the wine and the act of drinking is left to be inferred from the nature of the subject. This is of itself sufficiently prominent to prevent ambiguity, notwithstanding the incomparably greater frequency of the active application of that verb.

In Icelandic and Latin.

In other instances, a slight addition or a mere alteration is used for denoting the passive. In the Icelandic language, *æg elska* signifies "I love," *æg elskast* "I am loved." In Latin, we have *amo* for "I love," and *amor* for "I am loved." The expedients adopted in different languages will depend on the previous state of each. When a language already possesses a word expressive of suffering or being acted on, it will be natural to employ this, or some part of it, in union with the verb to denote the passive. It is not improbable that the letter *r*, which distinguishes the passive voice in Latin, is derived from *res* "a thing," or some previously existing word of similar import. The radical letters *am* signify "love;" *am-o* "I love," i. e. "I have some general connection with loving." *Am-o-r* "I am connected with loving as the *thing* or object loved." The letter *r* runs through all those forms of the passive voice which are produced by inflexion, with the exception of the second person plural.

The preterite tense of the passive verb in Latin is made up of a compound phrase, consisting of the participle with the substantive verb. The participle employed is derived from the past tense. *Amatus* is most probably a contraction for *amavit-us*, and derived from *amavit*. The past tense is thus converted into a part of speech resembling the adjective; and the effect of the past is exhibited as a quality which is to be connected or adjectived to some other idea expressed in the form of a substantive noun. The introduction of the copula forms an indicative or asserting sentence. This shows that assertion was not early appropriated to that particular sort of connection betwixt actions and other objects.

In English.

The best passive form of the verb which the English language possesses is in the preterite tense, and yet it is of an equally compound nature with this part of the Latin passive. We adopt the sign of past action in the form of an adjectived quality, and complete our assertion by inserting the copula. "Destroyed" is the past tense of the verb "destroy." "The enemy's troops *destroyed* the city" expresses the active voice: "The city is *destroyed*" expresses the passive.

We have no good contrivance for a passive voice in the present indicative. *Domus œdificatur* cannot be literally translated into our language. When we say "The house is built," we assert the completion of an action. The nearest approach which we make to it in respect to tense is by the phrase "the house is building;" but here we confound the voices, at least we employ a word which in respect of voice is general, as the participle in *ing* is most commonly used in the active voice. Some of our southern neighbours choose to express their meaning by the phrase "the house is being built," which is no farther appropriate to the present tense than as the same combination never happens to be used for the past. It labours under the disadvantage of an awkward verbosity, which prevents it from being generally adopted, or sanctioned by the authority of persons of taste. Another effort has sometimes been made to supply this want by prefixing the letter *a* to the present participle, and thus converting it into a passive present, as "the house is *a*-building," but this has not succeeded in meeting with a permanent adoption. A strictly appropriate phrase has not been found absolutely necessary, because a slight alteration in the form of our sentence enables us to dispense entirely with the passive form of the verb. We can say "the building of the house goes forward," or "the work people are engaged in the building of the house." No inconvenience is experienced in expressing our meaning; it is confined to our attempts to translate Latin sentences literally into English.

Substitutes for the passive voice.

In the French language the passive voice is much less frequently used than in English. That language has a resource which few others possess for introducing the object acted on after the active verb without the mention of any particular agent, as it has a nominative of a very general application, *on* or *l'on*, signifying merely "some being or beings real or imaginable." This is prefixed to the active form of the verb, and the object acted on is conveniently made to follow in the accusative (or objective) case. *On le dit*, "some being or beings say so," is translated with propriety "it is said."

Our language is equally defective in a passive voice for the future as for the present. If the sentence *domus œdificabitur* is translated by the phrases "the house will be built," or "the house will be building," or "a-building," or "will be being built," we shall find these forms to labour under the same disadvantages with the attempts already mentioned to give a translation of the words "*domus œdificatur*." Yet we experience equally little inconvenience in this as in the former instance,

Universal Grammar.

because a moderate skill in varying the turn of our sentence enables us to convey our meaning clearly without the use of a passive voice.

Impersonal verbs.

A neuter voice might be formed consisting of a separate word to signify that an action takes place, in a manner similar to the words *ningit* and *pluit*. We might have a single word for "there is," or "there was a walking;" in French, *l'on se promene*. In Latin, the passive voice is sometimes used in this neutral or impersonal manner. *Ambulatur* is not passive in any thing else than in form. It means "the act of walking goes on;" *ambulatur ab illo*, "the act of walking is performen by him," for "he walks."

Sect. VII. *Regimen of the Active Verb.*

Origin of the regimen of verbs.

Some actions are of such a nature that the object affected by them is always interesting, and, in the earliest use of language, such actions are never related without immediate mention of an object thus affected. It also happens on such occasions, that the manner in which the object is affected is evident from the nature of the action. Of this nature are the actions expressed by the verbs "to make," "to build," "to cut," "to strike," "to kill." Such verbs in the Latin language generally govern the accusative case, intimating the most rapid transition from the idea conveyed in the governing verb to that conveyed in the noun. The noun governed may, in consequence of its own regimen, be rendered introductory to further additions both to the form and meaning of a sentence. The verb thus becomes a hinge on which the greater part of the meaning of a sentence turns. The large proportion of verbs which govern nouns in this manner has conferred a conspicuous rank on this part of speech. It is in this respect more powerful than the adjective. Even when adjectives are used as predicates in affirmation, the meaning which they introduce generally terminates in themselves, or leads to subordinate ideas only through the medium of prepositions. We say "this man is good," "that man is just;" also, "this man is good at heart," "that man is just in all his conduct." It is seldom that adjectives in Latin can be admitted to govern the accusative; and even the phrases in which this might appear to take place, such as *Os humerosque similis*, are commonly explained by the subaudition of the preposition *quoad*. These differences betwixt the active verb and the other parts of speech have had a secret influence in leading grammarians to attach great importance to the verb. Its full power seems to reside in this form of it. Verbs of other kinds have appeared to be exceptions, or words to which convenience has assigned a verbal form, though they are not originally entitled to it.

Consequences of its extension.

The governing powers of the active verb are retained by the active participle and the infinitive mood. This fact seems to have led grammarians to consider these forms of words as parts of the verb properly so called. The participle is distinguished from the adjective by regimen alone. Hence those grammarians who call participles real adjectives have always been most fully satisfied with the appellation when applied to the participles of verbs destitute of regimen, such as "thriving," "charming," "surprising," words which are in all respects used as adjectives, though participles in etymology and in form.

The infinitive mood has the same similarity to the substantive noun as the participle has to the adjective. It may become a nominative to a verb, as "to enjoy is to obey;" or an accusative, as "men generally wish *to live* long," but, when introductory to other words, it has a more powerful and ready regimen than the noun. In Latin, it like the verb governs the accusative, and not exclusively the genitive, like the noun. We shall afterwards consider more particularly the participle and the infinitive mood. At present we have merely accounted for the fact that grammarians have reckoned them real parts of the verb.

General reflections on the verb.

It must always have been obvious that this office of the active verb is not common to all verbs, and therefore is not characteristic of this part of speech; and, if the participle and the infinitive mood are to be reckoned parts of the verb, the problem still remains unsolved, what is the true characteristic of the verb? Mr Tooke intimated that he was prepared with some doctrine which appeared to himself satisfactory as a description of the verb, including its infinitive mood. Every philologist must regret that this acute writer did not communicate his views more fully to the world. On this part of the subject, it is possible that they may have been both well founded and original. We are certain that they would have been at least worthy of attention. They appear to have been valuable in his own eyes; they would have been exhibited in a forcible manner if he had chosen to publish them, and might have led the way to a more satisfactory account of the subject. But, as no explanation of this sort occurs on our own most matured reflections, we naturally suspect (however presumptuous the declaration may appear,) that his theory would have either turned out eventually inconsistent with some of the opinions which he has published, or would have been in itself unsatisfactory.

A precise answer to the question in the form now proposed is not of great importance. We have pointed out assertion as one office which is performed by verbs alone. We have pointed out the quality of an active regimen, as belonging to an extensive department of verbs, and have shown that this quality is possessed by parts of speech closely allied to the verb in etymology, and generally numbered among its parts, though not possessing an asserting power. We have shown in what words assertion and a transitive regimen are separate, and in what they are combined. Assertion is separate in the indicative mood of substantive and neuter verbs; the transitive regimen, in the infinitive mood and active participle of active verbs. We have endeavoured to investigate the connection betwixt these parts of speech and the indicative of the verb. In so far as their character is inconstant or complicated, we have stated the causes of these characteristics, and the shades of variation by which they are distinguished. We have shown in what respects the intermediate kinds of words partake of the nature of one part of speech, and in what respects they partake of the nature of another. If the particulars on these subjects are impressed on our minds, our theories will be exempt from ambiguity or confusion.

Sect. VIII. *Intransitive Active Verbs.*

Neuter verbs have no such regimen as has been now described. Hence some have assumed this as a mark of distinction betwixt them and active verbs. It did not however escape observation that some verbs which do not govern any noun signify action, and that therefore the term *neuter* as implying the absence of active

Universal Grammar.

power, did not apply to them. For this reason these have been retained in the list of active verbs, but distinguished from verbs of regimen by the additional epithet *intransitive*. Their peculiar character has been generally represented as arising from this peculiarity in the nature of the actions signified, that they do not affect any ulterior object. But this is not true in point of fact. The transitive or intransitive nature of verbs of action depends solely on the occasions of mankind in making use of language. Transitive verbs are those which express actions when we have occasion instantly to mention an object acted on. Intransitive verbs describe actions when we are satisfied with stating the connection betwixt the action and the agent. Verbs which admit of no direct regimen, and therefore are termed intransitive, may introduce other ideas, expressed by nouns, through the medium of prepositions. The verb "to strike" is *transitive*, while the verb "to walk" is called *intransitive*; and yet it is evident that in the act of walking one or more objects are acted on as much as in the act of striking. Only it happens that when we speak of striking, it is generally of importance to point out the object that is struck; but, when we speak of walking, our attention is chiefly directed to the act as connected with the agent. In walking, however, a man walks *upon* some object, which supports him; he walks *from* some place, and *to* some other. Each of the phrases "I strike my horse," and "I walk upon the ground," expresses, in a manner equally explicit, a particular act, together with an object affected. The intervention of a preposition in the one case, and the absence of one in the other, imply no difference in the energy of the act related, but only the different degrees of interest excited in the connection of it with the object affected. It might naturally be expected, from the numerous and varied occasions which we have for the relation of events, that, even in describing the same sort of action, we should sometimes have a motive for mentioning an object affected, and sometimes not. For this reason some verbs differ from each other only in their transitive or intransitive application, of which we have already given an instance in the difference betwixt the verbs "to speak" and "to say." In other instances the same verb is used either transitively or intransitively. We may say at one time, "a miller grinds corn;" in this sentence, corn is the object affected by the act; at another time we may speak of the same act as characteristic of the situation and employment of an individual; as in the sentence, "two women were grinding at the mill, the one was taken and the other left." Here no occasion arises for mentioning any object on which the act of grinding is exerted. These however are not two different meanings given to the verb. In both cases it is used in its full meaning, that of describing a species of action. Whether we choose to introduce or omit the name of the thing acted on, depends on the design which we have in forming our discourse. It may or may not be of use to add this circumstance to the description. It makes no more difference in the original meaning of the word than the introduction of a second sentence in elucidation of the subject would affect the meaning of the words in the sentence first employed.

Verbs often intransitive though they signify transitive acts.

Some verbs both transitive and intransitive.

Sometimes verbs which are originally intransitive, and evidently not intended to have nouns subjoined to them, except through the medium of prepositions, are afterwards applied as active verbs governing the accusative, in consequence of the familiarity which the expression of particular kinds of connection acquires from habit. The verb "escape" originally required the preposition "from" to express a certain sort of connection betwixt the act and other objects. Yet we not only say "a prisoner escaped from prison," but, speaking of our own memory, we may say that "names and dates escape us." *Fugire* in Latin, is a verb of the same kind, and the corresponding phrase *me fugit* is used in that language. *Me latet* is of a similar nature. *Ardere* is intransitive, or perhaps ought rather to be called neuter, yet it is made to govern the accusative: *Formosum pastor Corydon* ARDEBAT *Alexin*.

Univer[sal] Gramm[ar.]

In some instances an active verb, which we are in the habit of connecting with nouns by means of prepositions, is used to form a transitive verb by being compounded with a preposition governing the accusative, and evidently derives its transitive power from the preposition. Such a verb, like others which govern the same case, may be used in the passive voice. In Latin we have such words as *initur*, "it is entered on." In English the same thing takes place, though the two words continue separate. The phrase thus formed is treated like a compound word, and made to pass through variations similar to those to which entire words are subjected. Such are the phrases "to laugh at," and "to trifle with:" the preposition and the verb coalesce to form a sort of compound verb, which is used passively in the phrases "to be laughed at," and "to be trifled with." This species of coalescence of words into phrases, subjected to a peculiar inflection, even takes place in instances in which an active verb governs a noun in the accusative, and then leads to another by means of a preposition; as in the phrase "to make a fool of;" for we do not say in the passive "a fool was made of him," but "he was made a fool of." We have many analogous examples; as, "to be made game of," "to be evil spoken of," "to be taken notice of," "to be taken care of." Some even say, "to be paid attention to." This last expression is inelegant, because it shews an unsuccessful grasping at a variety of accommodation.

Intransi[tive] verbs be[come] tra[n]sitive by composi[tion.]

On the *diversity* of regimen of verbs, see our account of the cases of the noun. The subjects are inseparably connected, and under that head such observations as appeared necessary have been delivered.

SECT. IX. *Persons and Numbers.*

VERY little remark is required on the meaning attached to the *Persons* and *Numbers* of the verb. But the nature of their connection with this part of speech may be illustrated by their etymology.

In those languages in which verbs receive separate terminations for distinguishing the first, second, and third persons, such terminations are pronouns, and are equally complete as if they were separate words. The termination *o* in *amo* was probably derived from *ego*, the *s* in *amas* from συ, the *t* in *amat* from αυτος, the *amus* in *amamus* from ἡμεις. These terminations shew traces of being the same pronouns slightly modified. Some philologists who find themselves at one time dazzled by Mr Tooke's plausible etymologies, are at another startled on finding instances to which his principles cannot be applied, and on this ground rashly become disposed to condemn the whole as fanciful. A person under these impressions might perhaps stop us short in the inflections of *amo* with asking the etymology of the terminations *-atis* and *-ant* in the second and third person plural. *Atis* affords no vestige of the Greek ὑμεις, nor *-ant* of αυτοι. It would be too bold to maintain that they are derived from words so dissimilar to

The te[rmi]nation[s] pronou[ns.]

themselves, unless we were able historically to point out the intermediate steps of their transmutation. But difficulties of etymology do not in the least invalidate the general position, that such terminations are real pronouns. *Atis* and *ant* have exactly the same meaning with ὑμεις and αὐτοι. Whether they were derived from words subsequently forgotten, or were applied in the first instance as terminations, they are to be considered as complete signs equally significant with separate words, and differing from the latter only in being placed not before but after the radical letters of the particular verb, and written in closer connection with them. The resemblance of some of the terminations to the separate pronouns is a fact happily adapted to corroborate the identity of their signification; but though no such resemblance existed, just reflection would lead to the same conclusion.

Pronominal terminations attached to other parts of speech.

In speaking of the personal pronouns, we observed that they have all the characters of nouns, and that their whole peculiarity consisted in their frequent use, which has occasioned a convenient brevity in their form. It is to the same cause that they owe the further distinction of being attached to many important words in the shape of terminations. In Greek and Latin we find them attached to the verb. In the Hebrew and Arabic they are attached in the same manner to nouns. *Ism*, the Arabic word for "a name," receives the terminations *-i*, *-ek*, and *-ou* for signifying "my name," "thy name," and "his name."

Inflections of the English verb.

The inflections of the English verb possess a character somewhat different from those used in the Latin language. They do not supply the place of nominatives, but are used along with them. We say "I love," "thou lovest," "he loveth" or "loves." We never say "love" for "I love," "lovest" for "thou lovest," nor "loveth" and "loves" for "he loveth" and "he loves." The terminations in English therefore are not complete pronouns as in Latin; they are only accompanying signs, denoting that a particular sort of word is the nominative to the verb. They might be represented as redundancies, but they are not destitute of meaning and utility. Though not absolutely necessary to guard us against mistake, they contribute to precision. They enable us to expatiate on a variety of circumstances in connection with the object exhibited in the nominative case, before we introduce the verb; and then the form of the verb shows its connection with the person mentioned in the nominative. But as the terminations in English are not so essential as in Latin, they are fewer and less varied. The first person singular, and all the three persons plural, consist of the simple verb with the pronoun prefixed. "I love, we love, ye love, they love." For this, among other reasons, our language admits of less inversion in the order of the words.

Numbers.

The same observations apply to the *Numbers* as to the persons of the verb. The use of them in the imperative mood is conducted in the same manner as in the indicative. In the passive voice they follow similar analogies as in the active.

Sect. X. *Tenses.*

Origin and general division of tenses.

A reference to time is inseparably connected with the narration of events, and therefore many parts of the verb are so contrived as to indicate in their structure a connection with some portion of time in contradistinction to another. The point of reference naturally first assumed is the instant in which the sentence itself is uttered. Hence the first general division of tenses is into present, past, and future. Points of reference may also be selected from the past and the future, and expeditious methods, suited to our various occasions, adopted for expressing relative precedence or subsequence.

References to the division of time into definite portions, as hours, days, weeks, months, and years, are always made by means of nouns contrived for the purpose.

1. *Tense of the Imperative.*

The imperative essentially future.

Before proceeding to the tenses of the indicative, which are the most important and precise, that of the imperative claims some attention. The form most frequently used in Latin and in English has been called the present imperative; but a little attention will shew that imperatives are essentially future. The act to be performed must be subsequent in time to the command. In many instances they may be separated by a considerable interval, without any alteration in the form of the verb employed; as when we say, "come to this place to-morrow." Though sensible of this circumstance, grammarians seem not to have been aware of its importance in demonstrating the tense proper to this form of the verb. Perhaps a vague idea existed that the time of the *giving of the command* ought to fix its tense, but this is obviated by the slightest reflection on the subject, as the act performed by the speaker in every sort of sentence is present. Perhaps the *immediate* nature of the *influence* intended to be produced by the imperative on the mind of the person addressed has, though future, been considered as sufficient to entitle it to the appellation of present. But this influence is in no respect a proper foundation for a distinction of tense. All language is intended to produce an immediate effect on the mind. It is therefore solely with the time of the action or event specified in the verb that philosophical grammar is concerned in tracing the different tenses. The future in English is sometimes used instead of the imperative, as "thou shalt not kill;" "thou shalt not steal." Perhaps grammarians who delight in distinctions would perceive in this phraseology, as compared to the common English imperative, some analogy to the varieties of imperatives in the Greek language, and would denominate the sentences last mentioned future imperatives, in contradistinction to the common form called the present. But in the meaning of the sentences the tense is equally future in both.

Objections answered.

The Greek imperatives.

The Greek language has various imperatives which grammarians arrange along with the different tenses, and distinguish by the names of the present, the aorist, and even the preterite imperatives. But this diversity of form can produce no corresponding diversity of tense, unless this should consist in discriminations in the portions of future time to which the commands refer. We may order a person to begin an action at a particular time; or we may order him to be engaged in some occupation which is supposed to be previously begun; or we may order him to have an action completed. But, with reference to the primary division of tenses into past, present, and future, the imperative must be regarded as essentially future.

2. *The Aorist and Present Indicative.*

The primary indicative implies no tense.

Mr Tooke has remarked that the part of the verb called the present indicative is a simple or general indi-

Universal Grammar.

cative, and that no tense is implied in it. When we say "the sun rises in summer much earlier than in winter," we assert a fact applicable to past, present, and future. Of the same nature are mathematical theorems and all general propositions. This form of the verb might therefore with respect to tense receive the appellation of a universal aorist. This indeed is the form of the verb used for describing present transactions. The idea of present time is on such occasions attached to the sentence, in consequence of an inference drawn from the nature of the subject.

Sometimes applied to the past,

In some languages it is elegantly used to describe a long portion of past time extending to the present: as in French *Je suis ici trois ans*, and in Latin *Tres annos hic adsum.* But it is also used in describing events which have been completed at a time past, as, "Yesterday, when walking along, whom *do* I meet but my old kinsman:" "I am glad, *says* he, to find you looking so well." Grammarians, never doubting that such indications are essentially of the present tense, have supposed that in such sentences the past is, for the sake of vivid representation, described by a figure of speech as present. The facts now stated shew that such explanations are unnecessary; and if they are in any degree just, or adapted to the conceptions which we attach to this form of the verb, the consideration that this indicative is not restricted to any tense will account for the facility with which we reconcile our minds to a figure of speech which would otherwise appear a distortion.

Sometimes to the future.

We sometimes also use this general indicative in describing future events, and their futurity is pointed out by some other word in the sentence, or by the evident import of the whole. "Next Tuesday *is* the first of April," is a sentence equally proper with "next Tuesday will be the first of April." And we say without any dread of being accused of vicious diction, "To-morrow he *begins* his journey."

Tenses not indispensible.

It would be possible for men to convey their meaning on all occasions by indicatives, without any distinction of tenses. The mention of other circumstances might serve to prevent the hearer from confounding the past, the present, and the future. But a sign of general application, consisting either of a separate word, a termination, or a systematic variation of the verb, is an important convenience.

The true present tense.

We are not altogether destitute of resources for marking with precision the present tense. Every language possesses separate words for the purpose, such as *now* in English, and the corresponding words in other languages. It happens that, in our language, without the use of such additions, we indicate present time by employing the substantive verb with the participle instead of the usual indicative. "He writes" is the indicative without tense. "He is writing" is the present indicative. When we say "He writes a good hand," or "He writes to his relations every month," we restrict our meaning to no particular time. But, when we say "he is writing," we describe a present transaction. This distinction is entirely conventional. The original meaning of this combination of words implies nothing to distinguish it from the simple indicative, as the verb "is," and the termination "ing," are, with respect to tense, equally general.

3. *The Preterite Imperfect and Perfect.*

Importance of the preterite.

The preterite tenses are of great importance in language; and all tenses by which knowledge is communicated imply a reference to past time. To the past we owe our information. Our efficient communications of knowledge consist in references to the past. Though the present exhibits nature as immediately perceived by the senses, which are the inlets of knowledge, it is by means of the past that we are enabled to form a judgment concerning the objects perceived. On our past experience depend all our judgments and expectations regarding the future. If language consisted essentially in assertion, the past tense would be the original form of the verb. Grammarians state this to be the fact in the ancient Hebrew. In that language the preterite is in all verbs simple and uniform, consisting of two syllables, which are formed of three consonants, with two interposed vowel sounds. The differences of the consonants distinguish the verbs from one another, while the vowel sounds are the same in all. Such are the verbs פקד (*pakad*) *visitavit* נתן (*nathan*) *dedit.* The verb in this form is considered as furnishing roots from which all other words are derived. But those who have concluded, from the concurrence of all the facts in other languages, that the imperative is the original form of the verb, will find no necessity for adopting a different opinion of the formation of that ancient language. The imperative is in it equally simple with the preterite, generally consisting of the same consonants, varied most probably by a variation of the vowels. It has, therefore, on this principle, an equal claim to be considered as the root. In some instances it is shorter: in the verb נתן (*nathan*) it is תן (*then.*) Verbs thus formed are on that account denominated irregular. But the fact, in such instances of the greater brevity of the imperative, shews that the Hebrew in this respect does not differ from other languages. The simplicity and regularity of the preterite, however, in Hebrew may be considered as a consequence of the important rank which that tense holds in the most prevalent application of language.

Its simplicity and uniformity in Hebrew.

The English preterite imperfect.

In English, the past tense is formed by a variation on the root of the verb as used for the imperative. This most commonly consists of the addition of the termination "ed." Others are formed by variations of the vowels; as "struck" for the preterite of "strike," "wore" of "wear," "bore" of "bear, "drove" of "drive." "I walk," and "I drive," are assertions in the aoristic or present indicative; "I walked," and "I drove," are in the past. This tense implies that an action was begun, and was continued at some past period. It is called the *imperfect*, because no definite relation to the present state of the event is implied in it, and room is left for supposing that the action may be still continued.

The perfect.

When we mean to assert that an action is accomplished, we introduce before the expression of past tense the auxiliary verb "to have" in the present or general indicative. "I have walked," signifies, "I am in possession of the complete act." "I have (by my own exertions) assured myself of its completion."

Some English verbs have two variations of the radical word for expressing past time, "strive," has "strove," and "striven;" "weave," "wove," and "woven;" "break," "broke," and broken;" "do," "did," and "done." The completed act is expressed by the last of these forms, the words "striven," "woven," "broken," and "done." Mr Tooke considers this contrivance as a redundancy, because one word for past time is sufficient for every purpose. In verbs which have the preterite in "ed," the same word is used for the simple description of an event in a train of progress at some past period, and for being conjoined with the verb "have," to signify that the act is completed. The insertion of that verb is sufficient for marking the distinction. "He walked," and "he has walked," are equally distinct from one another, as "he did," and "he has done." In some verbs in which the preterite is formed by a change of the vowel, the same simplicity is observed: "struck" is used for both these varieties in the expression of past events.

Erroneously analysed.

That form of the past tense which is conjoined with the verb "to have," some grammarians consider as originally and properly the passive participle. In this sentence, "I have driven a nail into the wall," they consider the verb "have" as governing the noun "nail" in the accusative, and "driven" as the passive participle agreeing with the noun. In this form of the past tense the same word is always used as for the passive participle. Therefore the sentence is considered as signifying in etymological analysis, "I have a nail (which is) driven into the wall," transferred by use and common consent to signify that the action is performed by the individual mentioned in the nominative. This theory receives apparent support from the structure of some phrases in the Italian language, which show that the passive participle is really the word employed, as its inflections are varied and made to agree with the noun in gender and number. Such is the phrase *Ho aperte le vostre lettere.* "I have opened your letter." This analysis of such phrases would have great probability, if the facts uniformly corresponded with it. But it is not a constant rule. It is often left even in the Italian to the option of the speaker. We may say *Ho aperto* or *aperte le vostre lettere, e veduto* or *veduta ivi la vostra cortesia.* The French say *J'ai donné,* not *donnée occasion. Il a tué,* not *tués, ses ennemis. Donnè* and *tué* therefore merely signify a past action, and, like any other part of the verb, introduce or govern the subsequent noun. They cannot be considered as agreeing with it like a passive participle. If it is convenient to have a separate name for that part of the verb, it may with sufficient propriety be called a *Preterite Gerund.* The peculiarity of its nature will appear in the most convincing light, when we turn our attention to neuter and intransitive verbs, which, having no passive voice, cannot be said to have a passive participle. When we say "he has gone," "I have come," the words "gone" and "come" cannot be past participles agreeing with nouns, as no nouns are introduced after them. There is no sufficient reason why the introduction of a noun should alter the nature of the word. In the phrase "I have struck," the word "struck" signifies action, and, as a part of the active verb, it may govern the accusative case with as much propriety as any other part of it. When we say "I struck my enemy," and "I have struck my enemy," the word "struck" is in both instances equally active in its meaning. There are certain occasions in which the past participle in the French language is used to agree with the governed noun; but these are altogether peculiar, and cannot give any room for supposing that this is the original construction of this form of the preterite, afterwards transferred to an active meaning; for it only takes place when the substantive noun has been previously introduced, and then referred to by means of the relative *que.* The French say *Il a* TUE' *plusieurs hommes*; but, *Les hommes qu' il a* TUE's. This was a subsequent arrangement, admitted after a long discussion of the French academy. There is some affinity betwixt this gerund and the past participle, though their syntax is not identical. Both signify an event completed. The participle is only the past tense, transferred to the adjective or participial application, by which a past action is treated as a quality introduced for describing an object. Its active application is of prior date, and is in constant use.

The preterite gerund.

The French idiom.

It is not necessary to treat particularly of the other forms of past tenses, as they are regulated by the same principles, whether they are formed of combinations of words, as in the modern languages of Europe, or combinations of syllables, as in the ancient languages. Some observations connected with the general subject of their varieties will be suggested by certain forms of the subjunctive mood.

4. *The Future.*

The future indirectly expressed.

The signification of the future tense requires no illustration. The remarks which we have to make on this subject will therefore be confined to its etymology. Our conceptions of future events are mere deductions from known arrangements in the past or present, tending to modify their character. Hence all the contrivances for expressing futurity, that can be traced to their origin, are founded on the connection in which the future stands to the past and the present as an effect to a cause. They are derived from verbs signifying resolution, obligation, or other preparatory circumstances, and, with respect to etymology, are equivalent to the words employed in such English expressions as "I intend to go," "I must go," "I am likely to go," "I prepare to go."

Its etymology in Latin.

Mr Tooke ingeniously derives the Latin future in *bo* from βȣλειν "to will" or "to be resolved." In *ibo*, for example, *i* signifies "go," *b* (from βȣλ) "will," and o (from εγω) "I." *Amabo* and *docebo* are formed by annexing the same letters to *ama* "love," and *doce* "teach." The future in *am* he considers as an adaptation of the radical letters of *amare*, "to love." *Legam* is thus equivalent to *legere amo, audiam* to *audire amo.* By those who indulge a general scepticism in etymology, or who have other systems to support, these derivations may be thought improbable, and abundant opportunities are afforded of taking refuge in the obscurity of old derivations. It may be said, if *b* means βȣλω in *amabo*, what is meant by the *b* in *amabam*? Such objections can have no further effect than to throw discredit on instances of etymology that are somewhat obscure. Let us therefore attend to some which are of recent formation, and which, as the successive steps of their change are easily traced, are superior to all objection. If general principles of analogy are there disclosed, by which the abbreviating contrivances of language have been conducted, the uncertainty of some antique instances is not to be much regretted. The former will also assist us to judge of the degree of probability to be attached to some etymologies otherwise uncertain.

In Italian.

In Italian, the future tense has undoubted marks of a derivation from the verb *avere* "to have." *Partiro* "I shall depart," is evidently derived from *partire-ho* "I have to depart." This is evinced by the identity of the terminations of the future with those of that verb in the present in all its persons and both numbers. *Ho, hai, ha; havemo, avete, hanno: Partir-o, partir-ai, partir-a; partir-emo, partir-ete, partir-anno.*

In French.

The French future is as evidently derived from the

Universal Grammar.

present of the verb *avoir*. In the verb *parler* it is *Je parler-ai*, "I shall speak," *tu parler-as, il parler-a, nous parler-ons, vous parler-ez, ils parler-ont*. These are the terminations of the present of the verb now mentioned, *J'ai, tu as, il a, nous avons, vous avez, ils ont*.

In English.

The French language has various modes of expressing futurity by combinations of entire words into set phrases. The verb *devoir*, which signifies to be obliged from duty, is employed for this purpose, as, *Je dois faire cela*, "I am to do that." The same verb continues in other instances to retain its full original meaning. The verb *aller* is used for a similar purpose; as, *Je vais lui rendre mes respects*.

In the English language combinations of this sort are the only futures, and they are often used in such a manner as to express something more than futurity. We have thus a beautiful intermixture of their original meaning with their modern application. The verbs "will" and "shall" are most commonly used, but they are not indiscriminately applied to signify futurity. Each of these verbs is employed to signify the resolution of the speaker, or simple futurity, according to certain habits of collocation with certain nominatives. "Will" in the first person, and "shall" in the second and third, signify resolution. Simple futurity is expressed by "shall" in the first, and "will" in the two others. The simple future is as follows:

"I shall," "thou wilt," he will."
"We shall," "ye will," "they will."

The future of determination is,

"I will," thou shalt," "he shall."
"We will," "ye shall," they shall."

Rule on the use of *shall* and *will*.

The perplexities occurring in the use of these auxiliaries, in consequence of the tendencies of the Irish and Scotch being different from those of the English dialect, which is the acknowledged standard, may be avoided, if we always recollect that it is not the resolution of the *person spoken of* that they are at any time employed particularly to express, but of *the speaker*. "Will," therefore, is employed for simple futurity in the second and third persons, and is even appropriate where an event is mentioned that is opposite to the inclination of the person who is the subject of the assertion. We say, "If you become obnoxious to the criminal law, you *will* be punished." The word "will" does not here imply intention or even consent, yet it is appropriate, because "shall" would imply constraint or authority on the part of the speaker. It is also to be remembered that, in mentioning any thing future with respect to ourselves, although it should be the effect of our intention, this does not render it proper to use the auxiliary verb "will." "Will" in the first person always expresses emphatic resolution, implying the apprehension of difficulty or resistance from others. If another has said, "you shall not," a man replies, "I will;" but in expressing the common acts which are to fill up our future time, we say simply, "I shall go home," "I shall tell you the whole matter when we next meet."

Occasional uses of these auxiliaries.

But there are occasions, independently of provincial solecisms, in which "will" may be employed in the second and third person to express the resolution of the person spoken of, and "shall" in the first, the resolution of some other. Observing another person obstinate, we may say, "It seems you *will* do it, and cannot be prevented." If another person has said to us, "You do not admire my friend, but you *shall* treat him civilly," we may reply, "perhaps I may, but you are mistaken in telling me that *I shall*." These last modes of speaking, however, are awkward, and require an uncommon emphasis to be laid on the respective auxiliaries, in order to express the full meaning of the speaker. It is therefore more elegant to employ more explicit phrases, as, "it seems you *are resolved* and cannot be prevented." "Perhaps I may, but you are wrong in supposing that I *am to be forced*."

Other English expressions of futurity.

Our language, like every other, has various words and phrases which express futurity along with something more, as "I intend," "I am obliged," "I am likely." We have also a phrase for expressing simple futurity in the use of the substantive verb followed by an infinitive, as "I *am to* go," "he *is to* come in my stead." We have the phrase, "to be about," which literally means to be somewhere in the neighbourhood of an action, and is by conventional application appropriated to the expression of *near futurity*.

5. *The other Tenses.*

General character of the other tenses.

It is unnecessary to consider particularly the other modifications of tense, such as the *plu-perfect*, and the *paulo-post futurum*, or to enter on an analysis of the phrases formed by the combinations of the auxiliaries "have," "do," "shall," "will," "had," "did," "should," "would," "shall have," "will have," "should have," "would have," to which grammarians add "can" and "could," with their combinations. All these are conducted on the same principles with the combinations already explained.

Combinations of meaning which are expressed in our language by the junction of several words, are expressed in Greek and Latin by means of syllables added to the radical letters of each verb, and forming with them entire words; as *amarem*, "I should love," *amaverim*, "I could love," or "I would love," (translated in our grammars "I may have loved,") *amavissem*, "I should have loved."

Dr Smith's observations on the ancient and modern structure of the verb.

Dr Adam Smith, in the comparison which he makes betwixt the ancient and modern languages, considers the former as deriving, from the use of syllabic variations, a great simplicity compared with those which fulfil the same purpose by means of auxiliary verbs. He thinks it more natural, after men possess a word for representing an event, to express the modifications of that event, in respect to person, number, and time, by altering the word, or giving various terminations, than by inventing separate words for the modifications intended. He considers the formation of a separate word of this kind in the same light with the formation of the substantive verb, that is, as a great effort of abstraction, which could only be the result of refined metaphysical speculation. His observation, however, loses all force when we recollect that a termination is as really a sign as a word is; and that the general employment of a termination or any other modification, on a number of analogous occasions, is the same kind of mental exertion as the prefixing of a sign of this variation in the form of a distinct word. It is not necessary to suppose that a general word in the form of an auxiliary verb is first contrived and perfected in all its parts, and then applied to use. It may first be used in a single form suggested in a moment of need, while we are using the verb descriptive of the event. It may be afterwards readily transferred to an association with a different verb; and this facility of association is the same, whether it is a subjoined syllable or a separate word. The distinction betwixt syllables and separate words is probably not fully acknowledged till mankind commit language to writing. The fact however is, that verbs which previously existed as expressions for separate assertions, are afterwards adopted as auxiliaries; a circumstance which removes still farther the necessity of ascribing the invention of them to refined metaphysical speculation.

Dr Smith further considers this mode of expressing the modifications of the verb in the ancient languages as conferring on them a great advantage over the modern languages in respect of brevity and force. But this brevity is often a deception arising from the prejudices attached to the appearance of written language. That author adduces as an exemplification of his remark the Latin word *amavissem*, which expresses a modification of thought, which in English requires no fewer than four, being translated by the phrase, "I should have loved." The English phrase, however, is pronounced with equal facility and dispatch as the single word *amavissem*; it consists of the same number of syllables, and these have no greater character of perplexity or tardiness in the one case than in the other. The Latin syllables, in this instance, nearly correspond to the separate English words; *am*, signifies "love;" *av*, "have" with "ed;" *iss*, "should;" and *em*, "I."

G eral remark on assertion and indicative mood.

Hitherto we have been occupied with those parts of the verb which serve as the copula in the composition of a sentence, and which, in technical language, are called *indicatives*. This appellation, however, if it is not a name for a mere form, if it has any scientific meaning, must be extended to some forms which have usually been considered as belonging to the subjunctive mood, as they are not confined to the purpose of subjunction, but sometimes form the only verb in a sentence: as *Illi potius quam alteri* CREDEREM. MALUERIM *te quam ullum alium imitari. Si cum hoste dimicâsset* PERIISSET. The words here marked in capitals have the full force of the indicative; that is, they convey affirmations; they indicate new connections of ideas, intended to be impressed on the mind of the person spoken to. They are therefore improperly distinguished by the title of *subjunctives*, if this implies that they are fitted only to maintain a subordinate rank in the composition of a sentence. Some further observations will be made on them in the sequel.

Sect. IX. *The Subjunction of Sentences.*

Sentences be various degrees of importance.

Every improved language possesses various contrivances for the subjunction of certain sentences to others. In every continued discourse, some are distinguished as of greater importance, and holding a more eminent rank than the rest. These others may be equally necessary to the full elucidation of the subject; but their utility arises from their subserviency to the developement of the former. Some sentences are preparatory, and contain propositions which are said to be premised. Others are inserted as constituent parts of more prominent sentences. This last operation may be denominated *subjunction*.

Sentence may be used as noun.

A whole sentence is capable of being used as a noun, and applied to every species of syntax competent to the noun. Sometimes the sentence retains the same form as when it stands unconnected. It may, for example, be made the nominative to a verb. This use of sentences is of frequent recurrence in treating of the subject of language, as in treatises on universal grammar, in which sentences as such, are the subjects of discussion. We can make a sentence by conjoining the three words "this is right," and we can then make it a nominative to the verb "is" by saying, "*This is right* is a short sentence." We can also make it an accusative to the verb "think," or the verb "say:" "He thinks or he says *this is right*."

Expedients for including one sentence within another.

Sentences may also be rendered parts of other sentences, by means of slight changes on some of the words composing them, or by the interposition of other parts of speech, contrived either for simple annexation, or for pointing out at the same time the particular relation in which the subjoined sentence stands to the whole.

Subjunction is of two kinds; subjunction to nouns, and subjunction to sentences.

I. *Subjunction to Nouns.*

Nature of subjunction to the noun.

A sentence is subjoined to a noun when it is employed for the same purposes of amplification or qualification as the genitive case or the adjective. This is done by using, instead of the nominatives "he," "she," "it" or "they," the relatives "who," "which," or "that;" as in the sentences, "Men who speak little are esteemed prudent:" "A man who commits murder deserves death:" "Men who speak ill of their neighbours are dangerous:" "Men who are capable of hypocrisy are not to be trusted." Here each of the sentences introduced by the relative "who," limits the assertion to a definite part of the general class of beings represented by the nouns "men," or "man."

It may be objected that the words, "who speak little," do not of themselves form a significant sentence. If this is the case, however, it depends entirely on the nature of the nominative "who;" and it may be remarked, that this nominative has the full meaning of the pronoun "he;" "he speaks little" is a complete sentence, though, in order to be made intelligible, it requires some previous knowledge of the person referred to by the word "he;" but the case is the same with innumerable entire sentences in language. "Who" implies the meaning of "he," and something more; it implies a mark that the sentence of which it is the subject is subjoined to a noun, and is thus an entire sentence with something additional.

Analysis of the relative.

The author of the article Grammar in the *Encyclopædia Britannica*, ingeniously analyses the relative into the preposition "of" preceding the pronouns "he," "she," "it," or their plurals, or oblique cases. When thus analysed, this word "of" must govern not the pronouns separately, which in fact are sometimes nominatives, but the subjoined sentences to which they belong. He shews that Mr Harris was deceived in supposing that the relative might be resolved into the third personal pronoun preceded by the conjunction "and." The phrase "Men who speak little," may be resolved into "Men *of they* speak little." Readers who are not accustomed to such analyses, and who regard the present habitudes of language as exclusively significant, may imagine that this analysis renders the sentence u. meaning. But, if we could suppose that the preposition "of" were one of those which govern nouns and sentences indiscriminately, we should find that the uncouthness of this paraphrase does not render it unintelligible. To these the words "before and after" belong. We can either say "before his dinner," or "before he had dined." It is sufficiently supposable that our language might have been so constructed as to put it in our power to say, not only "the time of dinner" but "the time of he dines;" and to say not only "men of few words," but "men *of* *they* speak little." In this paraphrase we shall have an intelligent analysis of the relative.

Varieties in the application of the relative.

In sentences thus subjoined, the relative may sometimes be the nominative, as in the examples which we have given; or it may be the accusative; or it may be subjected to any other regimen competent to the noun. We may say, "A man *whom* the world admires. "A man *whose* veracity is unimpeached," or "A man *of whom* all are forced to speak well."

It is also to be remarked, that the noun to which such sentences or clauses are subjoined, may occupy any place in the larger sentence that is competent to a noun; it may form either part of the subject, or of the predicate. We may either say, "The man *who* loves his country deserves honour," or "the world respects Cato as a man *who* loved his country."

Query on the nature of assertions.

When we attempt to reduce sentences to a precise and uniform theory, the following question will arise. Is the verb when thus subjoined by means of the relative, actually used for assertion? or is it deprived of this power by the relative? and ought the indicative of the verb to be on that account considered as applicable to other purposes besides assertion? It seems unscientific to maintain that the verb, separately considered, performs in this instance a different office, since the whole change of application is produced by the power of the relative. It would be most advantageous to consider the office performed by it in real assertions and in subjunctions of this kind as possessing some character in common, and to consider the modifications to which it is liable as consisting in the differences of the nominatives. If to any of our readers there should seem to be a gap in this part of our theory, we should be happy to have the means of supplying it pointed out. But to us there appears to be no impropriety in calling this general character by the name of *assertion*. An assertion may be first made, and may afterwards be mentioned for the sake of reference. An assertion may be used as the definition of an object. Of this object we may speak either by a single name, or by using the terms of the definition introduced by the relative "which." It seems rather incongruous to maintain that the definition in that case loses its character of assertion. The most that can be said is, that its office has been previously performed, and that it is now in this respect dormant. Its adaptation to that original application, even in the present connection, is certainly still apparent.

All uses of the indicative may be denominated assertion.

Substitutes for a sentence as introduced by the relative.

It is worthy of remark, that the place of a sentence thus subjoined to a noun often admits of being supplied by a noun in the genitive, or by an adjective. The meaning expressed by the phrase, "A man who is capable of hypocrisy," may be expressed by the phrase, "A hypocritical man;" therefore a new theoretic question arises, does the adjective "hypocritical" imply the copula used in assertion? Nay, the whole meaning may be condensed into a single noun. Instead of either of the preceding phrases, we may say, "A *hypocrite* is not to be trusted." Does the noun "hypocrite" imply an assertion? Then it will follow, that the office of assertion is not peculiar to the verb, but is included in the noun itself. This is so far true, that every noun is susceptible of a definition containing the indicative or asserting form of the verb. A noun signifying a compound idea may be defined by an enumeration of the parts of which that idea consists. A noun signifying a simple idea may be defined by pointing out the relation of that idea to various others, whether by resemblance, connection, or contrast.

Cause some v ties in structu senten

In the progress of human knowledge, combinations and distinctions of ideas are created, which are at first expressed in propositions and afterwards by single words; and these words are not understood till the processes of thought which gave origin to them, and which were first expressed by asserting propositions, are comprehended. Condensed signs, however, are not attached to all the results of these mental processes. This is only done when they are to be frequently referred to or treated as the chief subjects of discourse. When only occasionally mentioned, they are expressed in a more circuitous manner. Instead of a single word, we on some occasions use a noun with an adjective, as "an honest man," "a faithful servant;" or a noun governing another in the genitive, as "a man of consequence," "a man of probity," "a member of parliament." Sometimes these modes of annexation are accumulated, as, "a wealthy citizen of London," "a man of the highest reputation." On other occasions, when the combination of ideas is less familiar, we describe an object by attaching to a noun a regular sentence by means of the relative, thus; "a man *who* has, in a certain circle, the highest character for understanding."

Freedo used w the rela

Sometimes the relative is employed to introduce a sentence which is not intended to form a descriptive definition of any object, but part of a narrative conveying new information; as, "Peter, *who* had all the time *listened* to my words, now presented himself before me." This has the same meaning with two sentences connected by the conjunction "and," viz. "Peter had all the time listened to my words, and now presented himself before me." The obliquity which this use of the relative produces is but slight, and promotes an elegant variety of diction.

2. The Participle.

The pa ciple u for sub tion.

In the use of the participle we have a method of subjoining a descriptive sentence to the noun, which, with respect to briefness and extent of regimen, is intermediate betwixt the use of the adjective, or of the genitive case, and that of the relative. It resembles the adjective in the manner in which it is introduced, but always follows the particular verb to which it belongs in the regimen which it possesses as introductory to other words. Hence it is capable of annexing a train of ideas to the noun. We say "a case *bearing* an analogy to the preceding;" "a man possessed of fine sensibility;" and, in a mathematical theorem, "the square of the side of a right angled triangle *subtending* the right angle is equal to the sum of the squares of the other two."

Analy a the pa ciple.

After the remarks which we have made on the possibility of resolving the meaning of any noun into a a definition, we can have little difficulty with the participle. It is obviously resolvable into an indicative sentence introduced by the relative: "A man walking" is resolvable into "a man who walks."

A designation formed by the annexation of the participle to a noun, differs from the use of a noun which contains the whole meaning, by approaching nearer to the form of assertion. It prominently exhibits the analysis of that meaning which in the corresponding noun is more condensed, and, like the relative with the indicative mood, it enables us to extend considerably our specifications.

Freens used th the pa ciple

The participle may, like the relative and the indicative of the verb, be used for immediate assertion, as

Universal Grammar.

well as for definition. Thus Hume says of Charles V. "At last the emperor, *dreading* a general combination against him, was willing to abate somewhat of his rigour."

We formerly observed that the indicative mood of a verb might be resolved into the participle with the copula: that "he walks" might be resolved into "he is walking." And we have now remarked that the participle may be resolved into the indicative mood introduced by the relative; that "a man walking" might be resolved into "a man who walks." The indicative is of earlier origin, and therefore less complex than the participle. The participle is an ulterior accommodation in language, though, when once contrived, it has in some respects no greater complexity than an adjective, or the genitive case of a noun.

Tenses and voices in participles.

Participles are varied in their form and meaning, as they often express something more than the subjunction of the general meaning of a verb to that of a noun. They are employed to express time, and also to give either an active or passive character to the object expressed by the noun.

There are in most languages two participles, one of which has been called the present participle active, and the other the perfect participle passive. The former is distinguished in English by the termination "ing:" the latter, sometimes by a change in the vowel of the verb, but most frequently by the termination "ed."

English participles in ing not always present,

The participle in "ing," however, is often used without any implication of tense, and therefore may be applied to the past or the future, as well as the present. When we say "Yesterday, the public attention was excited by an aeronaut ascending;" if the word "ascending" were necessarily present, it would contradict the expression of past time contained in the verb "was." Grammarians avoid that absurdity by observing that the act was present at the time expressed by the verb, and therefore may be mentioned in the present tense, as the principal verb of the sentence gives its own tense to all the subordinate words. But this statement will not apply, otherwise we might as well use the expression, "The public attention was excited by an aeronaut who *ascends*," or "who *is ascending*." And we might say, "I thought that he *ascends* in a beautiful style." These phrases would be condemned as not only chargeable with bad grammar, but with incongruity and absurdity. It is therefore necessary to allow that the participle in "ing" is not restricted to any tense.

nor always active.

This participle, though generally active, is not confined to that voice. It is passive in such phrases as the following. "The house is *building*." "I saw a man *carrying* to prison." "I heard of a plan *forming* for his rescue." "A large sum of money is *owing*." The French sometimes use the passive participle *du* on the same occasions on which the English use the word "owing."

Participle in ed always preterite and not always passive.

The participle in "ed," and others called perfect participles, belong essentially to the preterite tense. But with respect to voice they are not exclusively passive. The words "gone," "landed," "departed," "strayed," "decayed," "well behaved," "drunk," "mistaken," are active participles. The participle in *us* corresponding to it in Latin, is also sometimes active; as in *tacitus* "silent." Although these words may appear to express quiescent qualities, they are such qualities as the action produces in the agent and not in an object acted on.

3. *Subjunction to Verbs or to Sentences.*

Subjunction to verbs by conjunction.

An assertion is sometimes employed for the purpose of being subjoined to a verb. This is for the most part effected by the interposition of the parts of speech commonly called conjunctions, and which are to be considered in the sequel under the name of sentential prepositions.

Meaning of the general conjunction "that."

Some assertions introduced in this manner are subjoined to the verb by a regimen bearing an exact resemblance to that of a noun governed in the accusative. The conjunction "that" is indeed interposed; a word not expressive of any particular relation, but merely a general sign of subjunction. Its sole office in this application is to shew that the sentence which it introduces is subjoined. It is ingeniously and justly considered by Mr Tooke as the same word with the *pronoun* or *adjective* "that." Their identity of form is not the effect of accident, which sometimes produces an ambiguous coincidence in signs which are of different origin and intended to perform totally different offices. This is merely an instance of a word single in its origin and meaning, and applied on different occasions. It is in fact an adjective, agreeing with the sentence as a whole. In the sentence "I believe that he is come," we take the subjoined part "he is come" as an object, and say with respect to it "I believe that." Hence it is in Latin *quod*, which is also the relative; or *uti*, or *ut*, which Mr Tooke with great probability derives from the Greek word ὅτι. This last is closely connected in its etymology with the article ὁ, ἡ, το, and the relative ὅς, ἥ, ὅ, and is in reality the neuter gender of ὅτις. The circumstance of being made introductory to a sentence is a variety of application. Hence it is on some occasions of this sort subjected to a variation in its form. When placed before a sentence, it is commonly called a *conjunction*, and thus is ranked along with some other words which have a similar destination. This form of subjunction is extremely familiar in all sorts of language, colloquial, historical, and poetical. "I hope *that* you are well." "The general saw *that* the enemy was too powerful for an attack in the open field, and concluded *that* it would be more prudent to harass him by the well-timed operations of partisans." In our language the conjunction is sometimes dispensed with: as, "I hope you are well." All these instances, whether introduced by the word "that" or not, as well as the corresponding ones in Latin and Greek, are placed in the same situation with a noun in the accusative. Thus in the following Latin phrases, the verbs *dicit*, *vult*, and *timet*, have the same regimen. *Quid dicit? Dicitne nihil? Dicit quod sapis. Quid vult? Vult ut huc venias.—Quid timet? Timet ne discedas.*

Subjunction by the infinitive.

This mode of subjunction is sometimes performed by the infinitive of the verb. "I suppose him to be sincere" is equally good English with "I suppose that he is sincere." In Latin it is far more common. *Dicit te sapere* is more agreeable to common use than *Dicit quod tu sapis*. This interchange of phraseology will be more particularly illustrated under the head of the infinitive mood, which will be delayed till we have finished the consideration of some other parts of speech subservient to the same end.

Sentences are also subjoined to verbs by the medium of conjunctions signifying particular relations. Some of them express hypothetical representation, as "if," "suppose," "provided;" others causation, as "be-

Universal Grammar.

By particular conjunctions.

cause," since;" others concession, as "though," "granting;" others time, as "while," "when," "after," "before;" others alternation, as "whether," and "or," (not the same application of the word "or" which is made of *vel* in Latin, but one corresponding to the Latin *an.*) These words, like the preposition, are interposed betwixt the verb and the words standing for the governed object, and they express a specific relation of the one idea to the other. They bring along with them various modifications of the form of the verb which they introduce. These will come into view under the next head, the Subjunctive Mood, which has received its name from the frequency with which it is thus applied. We shall naturally be led to inquire into its various forms and uses as compared with those of the indicative, and thus trace the comparative adaptation of both to the purposes of subjunction.

4. *The Subjunctive Mood, and other Forms of the Verb allied to it.*

The subjunctive mood varied in its meaning.

The moods of the verb are different in different languages. Sometimes a mood in one language comprehends two or more of those in another. One of the most frequent is the subjunctive, such as it exists in the Greek, Latin, and French languages. In the English it is sometimes expressed as the indicative, sometimes by means of auxiliaries. The various applications of it, and the variety of translations which its parts receive into English, as adapted to the occasions on which it is used, render it a matter of some interest to discover what properties are common to it on all occasions. It so happens that we have exactly that number of varieties of it in Latin which corresponds to the number of the tenses in the indicative, and hence they have been distributed into tenses under the same names; the present, the preter imperfect, the preter perfect, the pluperfect, and the future.

The indicative may be used subjunctively.

This mood has been called subjunctive from the circumstance of its being used in assertions which are subjoined by the relative and by various conjunctions. But this office is not peculiar to this mood. It is sometimes performed by the indicative preceded by the relative or by some of the conjunctions, such as "before," "after," "when," "where," "while," "if," and the words by which these are translated into other languages. On some occasions of subjunction the two moods are used indiscriminately; *Si hic adest*, and *Si hic adsit*, are equivalent. We also say, *Qui vinum amant*, or, *Qui vinum ament.*

And the subjunctive indicatively.

It is equally true that the subjunctive mood is not restricted to this office, but may with equal propriety be on certain occasions used indicatively, that is, for expressing the leading assertion in a sentence; as, *Si cum hoste dimicasset*, PERIISSET In this instance, the subjunctive mood in Latin when used subjunctively is translated into the English indicative, "if he *had* fought with the enemy," whereas that which conveys the assertion which is the ultimate object of the sentence, receives a peculiar translation by means of the auxiliaries "would have:" *periisset* "he would have perished." This is remarkable in most instances, though not in all, of the translations of Latin subjunctives into English. When used subjunctively, they are translated by the English indicative; when used indicatively, they are translated by a peculiar phraseology.

Peculiarity in the English language.

Real subjunctives translated indicatively.

They are translated indicatively, when introduced by the words, *qui, quoniam, cum, quanquam, si, etsi, quasi.* This takes place in all the tenses: *si venias* "if you come;" *si venires* "if you came;" *si veneris* "if you have come;" *si venisses*, "if you had come;" *si veneris* "if you shall come."

Sometimes by auxiliaries.

On some occasions they are translated into English by peculiar auxiliaries. *Uti* or *ut*, and *ne*, are the words which chiefly give rise to a translation different from the indicative in the subjunctive mood which they introduce, and this takes place only in the present and preter imperfect: *ut eas* "that you may go;" *ut ires* "that you might go." Yet *uti* appears to have originally been equally extensive in its meaning with the word "that," by which it is translated. It is not merely applied to denote the *purpose* of an asserted event, but to intimate other forms of subjunction: as *odisti ut amas*, "you hate as you love;" *ut veniebat* "as he came," or "when he came." *Ut* with the present and preter imperfect subjunctive, (as *ut amet* and *ut amaret,*) may be supposed to have been originally fitted for any general subjunction, and afterwards applied to express the subjunction of a purpose; or, *ut* may have been adopted for variety as a synonymous word with *quod*, in order to introduce a more special phraseology by performing a certain department of the same office. *Ut venias* may originally signify "that you come," and may be used as a noun in the ablative. *Quâ causâ hoc mihi dixisti? Hâc causâ, ut iterum venias.* In English, the same word "that" by which *quod* is translated is on such occasions used for translating *ut*, but the verbal expression is then varied by the introduction of the auxiliary "may." The production of the effect is expressed by the production of the *power*. This is sufficiently natural, as the effect implies the power. It is an accidental pleonastic idiom, probably adopted for the sake of distinguishing this form of subjunction from the form of it expressed by the particle "that" with the simple indicative.

The same observations apply to the introduction of the imperfect subjunctive in Latin, by means of the word *ut*. It gives the verb the same relation to the past which the former gives it to the present. It expresses the purpose, and it is to be remarked that in both instances it renders the verb in the subjoined phrase significant of something subsequent in order and in time. The tense called the present subjunctive when introduced by *ut* is future, and the imperfect expresses something subsequent to a past event.

Latin subjunctives used imperatively.

The present and the future subjunctive are sometimes used imperatively: as, *audiant meum sermonem*, "let them hear my discourse;" *doceas filios sapientiam*, "teach your sons wisdom." These have every appearance of being instances of ellipsis, in which *obsecro* or *precor te ut* is understood. The Italians often use the *infinitive* imperatively; as *non stringere la mia mano cosi*, "not to grasp (that is, "do not grasp") my hand so tight." This part of the verb expresses the simple act, or a connection which may be subjoined to another part of speech; and custom assigns to it the additional circumstances conveyed, as suited to the different occasions on which it is introduced.

The future subjunctive is applied imperatively, most probably on the same principles as the future indicative, and it is often translated by that part of the English verb; as *ne occideris*, "thou shalt not kill." The Latin phrase has however the additional advantage of being originally subjunctive, and thus possessing the same fitness to be used imperatively by ellipsis as the present tense of the same mood.

Indicative use of the subjunctive.

All these tenses are also occasionally used indicatively, and the application of them is so contrived that they express some modification of the simple assertion.

This more rarely happens with the present than with the others. Yet we have instances of such an application. Thus, in the ninth book of the Æneid, Nisus says to Euryalus,

Si quis in adversum rapiat casusve Deusve
Te superess VELIM.

"If chance or Providence should render the enterprise unfortunate, I wish (or I should wish) you to survive."

In like manner, in the 7th book, Juno dismissing Alecto from the superior regions, says,

Te super æthereas errare licentius auras
Haud pater ipse VELIT *summi regnator Olympi.*

This part of the subjunctive, when thus employed, is translated by the auxiliaries, "can," "may," "should," and "would," and generally refers to future events.

The preter-imperfect subjunctive, when used indicatively, is translated by "should" or "would." *Illam si amaret, in matrimonium* DUCERET, "If he loved her, he would marry her." The preterperfect is used on similar occasions, and translated in the same manner. *MALUERIM illum quam ullum alium imitari,* "I would rather imitate him than any other man." It is a remarkable circumstance, that these three subjunctive forms, called the present, the preter-imperfect, and the preter-perfect, when used indicatively, are often applied to the future. This cannot be considered as accidental; for, when translated into the English language, which adheres to no form of expression as an appropriate version of the Latin word, but varies it as occasion seems to require, they retain the form of the past tense "would" and "should," even when the event spoken of can apply only to the future. It might therefore seem interesting to inquire what peculiarity the meanings of these expressions have which should render them analogous to the past tense. We clearly see that there is a foundation for such an inquiry, when we advert to the import of some English phrases. "I may go," and "I might go," are radically future in their application. "I should go," is equally future with "I shall go," though not otherwise synonymous. "I can go," and "I could go," are also future as applied to the verb "go." The analysis of these phrases is comparatively easy, as they consist of auxiliaries. We at once recollect that the future of a verb may be expressed by the present of a verb preceding it signifying preparation for futurity; and, as the present is only one instant, and therefore has been said by some metaphysicians to have no existence, we consider it as including some adjoining portion of time, (most generally a part of the past,) at least as great a range as gives us scope for that short exercise of memory which we confound with consciousness, and which is necessary for reviewing any event and enabling us to describe it. There seems to be no impropriety in describing by a past tense a present action at least that is to be discontinued. If the present may be thus delineated, it follows that the verb preparatory for the future may also be used in the preterite tense. "I might go," is future as applied to the verb "go," though the preterite of the verb "may." For the purpose of tracing the source of this phraseology, it is of importance to observe that "may" and "might," which are different in their own tense, impress different characters on the future event which they are employed to introduce. Both of them express an uncertain or conditional futurity. But "may" signifies a state of greater preparation, and expresses a belief in the probability of the condition being obtained, and the consequent contingency taking place. "I may if you will," expresses greater readiness than "I might if you would." The latter phrase is either a hesitating way of intimating that we are partially prepared, on which account it would on some occasions be reckoned less polite; or, signifies a hesitation originating in our modified hopes respecting the condition, and then it is a more diffident manner of making a proposal. But the question recurs, why should the past tense be preferred for this uncertain mode of speaking of futurity? We should be happy to present a satisfactory solution of that problem. Although we had none to offer, we should have thought it unfair to decline stating the query. Perhaps this form of expression is used, because these uncertain expectations consist of images which possess the same sort of dimness with any object which retires to a distance in time or place, and consequently with an event which fades from the view by taking its place among ideas of distant recollection. Or, if this explanation is objected to as a refinement too subtile to have given origin to expressions so common, perhaps the choice of the past tense of the auxiliary on such occasions has proceeded from its signifying that the state of things preparatory for the future is discontinued: this want of extension to the present may conventionally be held equivalent to a less confident mode of representing a contingent futurity. But, though this explanation of the English phraseology now under review should be thought in some degree plausible, it might still be asked, How are such principles to be applied to the Latin subjunctive tenses? Do these tenses imply in their etymological structure all the force of the English auxiliaries? Did they possess that force in the intentions of the persons by whom they were first employed? Or are they mere general modes of stating a connection of ideas applicable to conditions and other subjunctions, as well as to conditional assertions? The difference betwixt these two methods of explaining them is perhaps merely verbal. If the subjunctive is an instrument intended to be applied indiscriminately to all connections of ideas whether actual or hypothetical, the purpose fulfilled by it is the same, whether it consists in the want of some character belonging to the indicative, or in the possession of a superadded character, including the meaning of an additional sign. Even if it were acknowledged to be of subsequent invention, and on the whole more complicated in its form than the indicative; this is to be accounted for, not by its expressing more ideas, but by its later use as applied to the purposes of human language. The English auxiliaries express something indefinite with regard to the events described; and the same thing is done by the subjunctive form of the Latin verb. But the variety of the English auxiliaries, as applied to translate the same Latin word, leads us to regard the Latin subjunctives as of less special meaning, and therefore partaking more of the character of general marks of annexation, which admit of being applied to a variety of purposes, the particulars of which are left to be inferred from the tenor of the discourse. If we knew the etymology of the ancient subjunctive forms, some light would be thrown on their history, but very little on their intrinsic nature. Words derived from the names of particular kinds of objects often become much more general; and, though they receive subsequent limited applications which render them again particular, they do not denote the same kinds of objects by which they were

Universal Grammar.

first suggested. The expedients adopted for varying general signs, and fitting them for expressing different particular meanings with precision, are entirely arbitrary, and often consist in an advantage taken of accidental original synonymes. This last stage of variation is that which has given the Latin language the form in which it is found in the writings of the classics. The varieties of phrase are not in general founded on corresponding differences in the direct etymological origin of the words. The indicative uses of the subjunctive mood therefore may on the whole be considered as elliptical.

Indicative use of the pluperfect.

The pluperfect subjunctive, when used indicatively, expresses a conditional assertion concerning the past. This is the meaning of it in the example already mentioned, *periisset*, "he would have perished." Sometimes it may be translated by "ought to have." Thus in the fourth book of the Æneid, after Dido's voluntary death, her sister says, *eadem me ad fata* VOCASSES, "You *ought to have* invited me to share your fate." This is a conditional preterite, and may be considered as implying, "If this had been the character of past events, all would have been well." The past is subjoined to an implied regret, and resembles such an ellipsis as the following English phrase. "If I had but seen him before he died!"

The future.

The future subjunctive is justly considered as differing slightly in tense from the future indicative, by expressing the "future completion of an event." But it is not on that account deprived of the peculiar character of the subjunctive mood; nor can we think, with some, that it differs from the future indicative in tense alone. It is not used, in general, for the simple and unconditional assertion of this species of futurity. It is not probable, for instance, that it would be used for expressing the assertion in the following sentence: "As soon as you have finished your letter, I *shall have* finished mine." That the tense in this sentence may be literally expressed in Latin, the passive voice is preferred, as it supplies an indicative tense of this sort by the combination of the future indicative of the substantive verb with the past participle. *Quum literas tuas scripseris, meæ etiam* FINITÆ ERUNT. This combination is denominated in our grammars a future *subjunctive* of the passive voice. The cause of this denomination is, that it is similar in tense. It unquestionably belongs to the indicative mood, while the others coupled with it in our grammars are subjunctive. The future of the subjunctive is indeed like its other tenses used indicatively; but like these others it is limited to uncertain and hypothetical assertions.

The subjunctive mood of the verb is on the whole a generic form applied chiefly to two less general uses, viz. subjunction, and the assertion of uncertain or conditional connections betwixt different objects. The property which these two uses of the verb have in common is uncertainty. There is one use of this mood which we have not hitherto mentioned, as it did not require to be separately illustrated, to wit, interrogation; as in this phrase, *An sit quies scelerato?* This will be considered as an instance of subjunction by those who allow, what we shall afterwards more fully state, that an interrogative sentence implies the imperative of the verb "to tell." *Quis est* signifies *Dic mihi quis est*. From this it follows, as well as from the obvious nature of a question, that uncertainty is also involved in that application of the subjunctive. Its imperative application has been already stated to be an instance of subjunction by ellipsis.

Use of the subjunctive in interrogation.

Theory of Dr Gregory.

In Dr Gregory's memoir *On the Theory of the Moods of Verbs*, contained in the 2d vol. of the Edinburgh Philosophical Transactions, there are some apposite observations on the application of the subjunctive mood to a great variety of phrases mutually analogous, which had occasioned some difficulty. That author considers the moods of the verb as formed for giving a direct representation of the feelings, intentions, or present actions of the speaker, and resolves them into a variety of affirmations in the first person singular. *Oro* or *jubeo* is, according to this theory, implied in the imperative; *dico*, in the indicative; *opto*, in the expression of wishes, and a variety of others on different occasions as suited to the various applications of the subjunctive. From the great diversity of feelings and purposes which may actuate a speaker, he infers that the real moods are too numerous to be expressed by separate modifications of the verb without rendering language cumbersome and complicated; but that those which are most common are expressed in this manner, for the sake of giving a condensed force to the utterance of human thought.

General observations on argument.

The view which we have given of the moods of verbs, and of language in general, differs from the principles now mentioned. We have considered language as not originally directed to the object of expressing spontaneously and naturally our own thoughts. It executes our purposes, by arranging the signs of thought in that order which is in our opinion best fitted to influence another person; an object which may be sometimes most successfully accomplished by concealing our own sentiments. To express our mode of thinking is indeed a very frequent object of language, and naturally has certain contrivances adapted to it; but to tell that we are speaking or asserting, seems to constitute no part of its object in addition to the use of the signs fitted for performing that office. The author, therefore, acknowledges that his principles have not so full an application to the indicative as to the other moods.

With whatever degree of vehemence or of delicacy men wish to express their feelings, they are provided with means adapted to their object. Significant gestures and tones independent of language may be employed. When it is thought proper to exhibit the same animation in the form of written language, syllabic imitations of involuntary exclamations are committed to writing, and are afterwards employed by rule. We sometimes execute the same purpose by placing our communicable ideas in such a point of view as tends to produce in others the feelings which occupy our own minds, sometimes by describing in more deliberate and explicit language the manner in which we are affected. Language is on other occasions fitted for expressing the feelings of the speaker by elliptical turns of phrase, in which more is at first meant than is verbally stated. These phrases are afterwards appropriated to the expression of specific feelings. Moods of the verb which were originally of a more general meaning may, by transpositions of words, or by an abruptness in the manner of their introduction, be subjected to such diversities as to become characteristic of the most vehement, the most rapid, or the most subtile modifications of sentiment. For example, instead of telling that we wish for the occurrence of a particular event, we may express the ardour of our wishes by the exclamation "oh." "Oh that he would return!" Or, without such an exclamation, we may say, "That he would return!" or, "That he would but return!" The Romans may be supposed to have at one time been in the habit of using the word *uti* in this manner, *Uti rediret!* But, as this might have been ambiguous from being too general, and might be supposed by the hearer to signify some purpose entertained in the performance of another act, as, *uti rediret, veniam ei polliciti sunt*, another particle *nam* is introduced to indicate that this kind of

Universal Grammar.

event is abruptly mentioned as an object of the wishes of the speaker. It may not be easy to shew why a particle equivalent to the English word "for" was preferred to any other; but, when habitually used in this connection, it becomes appropriate. It is thus that *utinam* becomes equivalent to "oh that," or "I wish that."

The optative mood.

The Greeks have an optative mood adapted to the expression of wishes, though it appears not to be applied exclusively to that object.

Various expedients for giving brevity and force to language.

The brevity and force thus created by means of the moods of verbs are effects of the contrivances of language which abound in all the different parts of speech. When a combination of ideas or an assemblage of thoughts or feelings becomes habitual, it receives an appropriate condensed expression. We complain of tediousness when an idea which might have been expressed by a single word or a short phrase is slowly brought out by means of a long series of words or of sentences. But when we have an unusual assemblage of ideas to express, no circumlocution is to be spared which may be necessary to give our language perspicuity, and the beauty of felicitous contrivance is often conspicuous in the invention of means for exhibiting thoughts which servile imitators would either not have conceived, or not have attempted to express. Language is happily used, where those phrases and words which are rendered intelligible and appropriate by established usage are employed judiciously for expressing complicated ideas. They may be placed in a connection with each other fitted to create combinations which are still more complicated, and possess a character of novelty which is rendered necessary by the purpose of our discourse. In fine, the skill of a writer may occasionally be discovered by the use of simple signs, in such a fortunate succession as to express, apparently by accident, some novel but well defined state of feeling and of thought. The expedients suited to these purposes are therefore not confined to the use of particular moods of the verb, and the act is not characteristic of their nature.

5. *The Infinitive Mood.*

We had occasion, in describing other parts of speech, to mention the *Infinitive* of the verb. We observed, that it is not an original word, nor the earliest form of the verb, but consists of the imperative in composition with a sign derived from some different source. In explaining the uses of the subjunctive mood, we observed that in the Latin language that mood with the introductory particle *ut* may have its place supplied by the infinitive. *Volebat ire* is equivalent to *volebat ut iret*. We shall now inquire more particularly into its nature and uses.

General character of the infinitive mood.

Both its etymology and application shew that it expresses merely the specific idea conveyed by the particular verb to which it belongs, in such a way that it can be used as a noun by becoming the subject or predicate of a sentence, or part of either. It does not, like the indicative, appear to contain the copula, except when substituted for that mood by ellipsis, as it frequently is by Sallust and other authors in depicting scenes of bustling activity or striking interest. Hence it has by some been denied the properties of the verb, and considered as in all respects nothing more than an abstract noun. It is formed in Latin by adding to the radical letters of the verb, as existing in the imperative, the termination *re*. From *ama* we have *ama-re*; and from *doce*, *doce-re*.

Its etymology.

This termination, being identical with the radical letters of *res* "a thing," seems to be exactly the same original sign, and in this application it retains the same meaning. *Ama* signifies "love;" *ama-re*, "love-thing," i. e. "love" considered as "a thing," or object of thought. In English the infinitive consists of the radical letters of the verb preceded by the word "to;" as "*to* love" and "*to* teach." Mr Tooke considers the infinitive as possessing the character proper to the verb, though he does not tell us in what this consists. He describes the word "to" as having the power to confer the verbal character on a noun. At the same time he considers it as originally the same with the verb "do," and as meaning "act," "effect," or "consummation." These suggestions are extremely obscure. It is not easy to conceive what influence the additional idea of "effect" or "consummation" could have to impress the character of a verb on a word which is otherwise a noun. We must therefore leave the opinions of that author in the same ambiguous state in which we find them. On some occasions in the English language this prefixed word is dispensed with. As "we saw him *go* away," and "we bid him *write* to us when he arrived at the end of his journey." In whatever light the infinitive mood of the verb may be considered, we find that this form of it, as existing in the English language, has the same meaning and uses with the words formed by such terminations as the Latin *re*, and receiving the same appellation in other languages.

Is it a noun or a verb?

The following is the question which claims our present attention. Is the infinitive mood of the verb properly and in all respects a noun? Is *amare* "to love," for example, a word of the same signification and uses with *amor amoris* "love?"

We shall obtain the most advantageous view of the nature of this part of speech, by taking in detail a survey of the circumstances in which it resembles the noun, and those in which it deviates from it.

It coincides with the noun in some uses;

It resembles the noun in being used as a nominative to a verb; as in the following Latin sentence from Cicero, as well as in the translation of it into English: *Loquor de docto homine et erudito cui* VIVERE *est* COGITARE. "I speak of a man of learning and erudition for whom *to live* is *to think*." It is also, like the noun, capable of being governed by an active verb; as *Oblitus est* SCRIBERE, "He has forgot *to write*." On some rare occasions in the Latin language, an adjective is employed to agree with it as with a noun. Thus Cicero says, *Cum* VIVERE *ipsum turpe sit nobis*; also, *Totum hoc displicet* PHILOSOPHARI. Persius says, VELLE *suum cuique est*. Petronius, *Meum* INTELLIGERE *nullâ pecuniâ vendo*. In these instances *vivere* is used in the same manner as *vita*; *velle* as *voluntas*; *philosophari* as *philosophatio*, if such a noun existed; and *intelligere* is used as *intellectum*, the accusative of the noun *intellectus*. Sometimes it is employed as the genitive of a noun; thus Cicero says, *Tempus est* ABIRE, à phrase equivalent to *tempus est abeundi*. Sometimes as an ablative. Thus in Plautus, *Ego sum defessus* REPERIRE, *vos defessi* QUÆRERE.

But differs from it in others.

In other respects, however, it differs from the noun. The concordance of an adjective with it in the manner now mentioned is a rare occurrence even in the Latin language, and does not take place in the English and others. The additional idea which the adjective would express is connected with the infinitive by a different sort of syntax. In Latin, *meum intellectum*, or *meam intelligentiam* is more consonant to general usage than *meum intelligere*. We should not in that language say *bonum intelligere*. If *bonus* were employed, it would be along with *intellectus* or some other noun; and, if the infinitive *intelligere* were employed, the additional idea would be conjoined by means of a part of speech which we have not yet considered, the adverb; in this instance, *benè intelligere*. In English we should not say, "my to understand," but "my understanding;"

nor "a good to understand," but "a good understanding," or "to understand well."

Peculiarities of the infinitive.

When an agent is mentioned along with an action in the infinitive, it is not in the form of a noun in the genitive, as it would be if the act were expressed by a noun. We do not say *illius amare* as we should say *illius amor*. Nor is it put in the nominative. Though we say *ille amat* we do not say *ille amare*. The syntax of the infinitive is in this instance peculiar; the agent is put in the accusative: *Illum amare*. This arrangement does not arise from the regimen of a preceding word expressed or understood governing the noun in the accusative. The combination of the noun in this form with the infinitive sometimes constitutes a phrase which is used as a nominative to a verb. In the Greek language this combination is sometimes even used as a noun in different oblique cases in which it has an adjective agreeing with it. Thus Anacreon says,

Σὺν ΤΩ, δὲ ΠΙΝΕΙΝ ἩΜΑΣ,
Εὕδουσιν αἱ μέριμναι.

The accusative here only intimates that the noun and the infinitive occupy the place of a subjoined sentence. In English, when the phrase is to be employed as a nominative to a verb, we use the noun preceded by the particle "for," which may be reckoned equivalent to an oblique case in Latin. We say, "*for a man to tell a lie* is a sign of cowardice." We sometimes find this differently expressed in low and provincial dialects. "To," for example, is employed instead of "for;" as, "*To you* to deceive me was unbecoming." At other times the noun in the objective case is used without any preposition, as, "But *him* to think that he was entitled to any credit was ridiculous."

Its coincidence with the verb.

When an *object acted on* is mentioned in connection with an act expressed by the infinitive, or when the name of an object referred to, and usually governed by a verb in some oblique case, is introduced, it is not put in the genitive as when it follows a noun signifying the same action. In this respect the infinitive retains the regimen of the verb to which it belongs. We say *amor uxoris*, for "the love of one's wife," or, if the person entertaining this affection is already mentioned in the genitive, the object of it is introduced by a preposition in such a phrase as *amor illius erga uxorem*. But when the infinitive *amare* is used, it governs *uxorem* in the accusative. We say, *Illum amare uxorem*, "for him to love his wife." Sometimes an ambiguity might thus be created, because both the agent and the object are mentioned in the same case, and, on account of the common practice of inversion in the Latin language, the order in which the words are placed does not strictly follow that of their syntax. Hence the ambiguity of the famous response of the Pythian oracle to Pyrrhus, *Aio te Romanos vincere posse*, which admits of being translated, "I say that you can overcome the Romans," or "I say that the Romans can overcome you." In general, however, the connection renders the meaning of such sentences evident, and their perspicuity is assisted by the name of the agent being placed before the infinitive, or nearest to it, while the accusative signifying the object acted on either comes after, or is at a greater distance before it. The same thing takes place in the English language, although in it the infinitive differs a little in its mode of formation, as it consists of the prefixing of a separate word. When we use the noun "desire," we say, "the desire *of food*," "*of money*," or "*of fame*." But "*to* desire *food, money*, or *fame*." The production of this mode of transition seems to us to be the great power conferred on a noun by the word "to" prefixed as the sign of the infinitive. In this therefore, according to Mr Tooke, the nature of a verb should consist. It might appear, however, that this is not common to all verbs, and therefore is not the characteristic circumstance which, when added to a noun, makes it a verb. In neuter and intransitive verbs it scarcely appears. Yet it is not always lost even in these. Every verb admits of a transition of discourse to some other ideas expressed by nouns, if not by direct regimen, yet through the medium of prepositions, and this is generally more or less altered when a word from being a noun receives either the form of assertion so as to become a verb, or is transformed into that part of speech called the infinitive of the verb. Let us take, for example, the word "struggle," which is used both as a noun and as a verb. We say, "his struggles were strenuous and incessant." When we use it as a verb, we say, "he struggled with a powerful antagonist." We often also use such expressions as, "His struggles with his antagonist were obstinate." But in this last phrase we are conscious of a slight defect; and, although the brevity and manifest meaning of it may in general enable it to pass without censure, an accurate writer will prefer the introduction of a verb for the purpose of completing the series of words demanded by the syntax. It will be felt more strictly agreeable to the import of the different materials of language to say, "the struggles *which he maintained* with his antagonist were obstinate." It is also to be remembered, that even the least transitive verbs differ from nouns by having all qualifying ideas conjoined with them not by adjectives but by adverbs, and that in this particular the infinitive mood follows the law of the verb; we say, "a *violent* struggle," but "to struggle *violently*." It is only in these peculiarities of transition, and in receiving adverbs instead of adjectives, that we can perceive any difference betwixt the infinitive of a verb and the corresponding noun. The former of these differences depends, in a great measure, on the character of particular verbs, and both of them seem too slight to confer on the infinitive the same rank with the asserting verb, and to divest it of the character of a noun. This is more especially the case when we consider that it is often used without an adverb, and without any such transition as has now been described, but is never independent of some character of syntax which is common to it with the noun. With this statement of the facts, we leave the argument to the consideration of our readers. We deprecate, in the mean time, any premature attempt to improve, in this or any other instance, the nomenclature of grammar.

Use of … infinit… subjun… tion.

The infinitive mood, in consequence of resembling in some particulars the noun, and in others the verb, is rendered fit for performing, in a manner peculiar to itself, the office of the subjunction of sentences to verbs. It may be made a question whether connections of words formed by means of it ought to be called sentences; but they certainly contain the meaning of sentences. We have already remarked that every noun may be resolved into a sentence, by means of a definition. But by the use of the infinitive, we have the parts of the sentence in a more distinct state than if they were all implied in a noun, though not so explicitly as in a definition, or even in a sentence formed by the subjunctive mood. It has thus a character intermediate betwixt the noun, with its regimen of genitives or the accompaniment of adjectives, and such subjoined sentences as have been already described. The same connection of ideas may be expressed by any one of the three following modes of diction:

Subju… tion t… tence… three … feren… mode… compared.

Universal Grammar.

1. By nouns alone, as in this sentence, "he wishes his son's *departure*."

2. By the infinitive mood, as when we say, "he wishes his son *to depart*."

3. Or by a sentence subjoined in the subjunctive, thus, "he wishes *that* his son *would depart*."

Here the verb "to wish" is that to which the other ideas are subjoined; and the verb "to depart" is that which is variously implied in the subjoined series of words.

The preference of one of these to another will sometimes be dictated by convenience, according as the intention of a writer is to study brevity, or to indulge in minuteness of detail; and sometimes there will be so little foundation for any particular preference, that the choice will be left to fancy, to habit, or to the love of variety. Sometimes a sentiment expressed in one of these modes in one language requires a different one when translated into another. *Credo te sapere* may be translated "I believe you to be wise;" but *dixi te sapere* cannot be translated "I said you to be wise;" the infinitive is here to be laid aside, and instead of it, a sentence must be subjoined by means of the word "that." "I said that you were wise."

We generally find it more eligible to use an infinitive than a noun, when we have occasion to connect with the meaning of the word any considerable variety of circumstances. We say "murder is a heinous crime;" but when we mention the agent and the object, we prefer using the infinitive mood, we say, "for a son *to murder* a parent is a heinous crime." This is a more complete expression than "the murder of a parent by a son." Indeed this last phrase evidently requires a verb or a participle to make it complete; thus, "the murder of a parent *committed* by a son, is a heinous crime;" and, as this makes the phrase verbose and tedious, it is better to say, "for a son to murder a parent is a heinous crime." In the Latin language, this idea would be most conveniently expressed by the subjunctive mood preceded by the particle *ut*. *Ut filius parentem interficiat nefas est.* It is but seldom that the mention of the agent is combined with the use of the infinitive, when the combined phrase is to be made the nominative to a verb. Such expressions as *filium interficere parentem nefas est*, are sometimes used, but they are inconvenient and ungraceful, and therefore not common.

Tenses of the infinitive.

The infinitive mood is varied in respect of tense. That form which is called the present infinitive is in reality of no tense. It is pure, absolute, and aoristic. It may be employed without the implication of time, and it admits of being applied equally to past, present, and future transactions. The remarks which we have made on that part of the *indicative* mood called its present tense, will suggest sufficient proofs of this fact; and the subjects are so nearly analogous, that it is unnecessary to bring forward particular illustrations of this point.

The general infinitive.

The preterite.

The infinitive in the past tense is, in the Latin language, fully expressed by the termination *isse*, which is nearly allied to the pluperfect subjunctive, a circumstance probably arising from the coincidence of their use as consisting in a subserviency to subjunction.

The future.

The future infinitive, both in Latin and in English, is formed by circumlocution. In Latin the general infinitive of the substantive verb is, for this purpose, conjoined with the future participle. *Iturum*, or *iturus esse*. In English it is constructed on similar principles. We say "to be about to go." We sometimes merely use the general aoristic infinitive after a verb which implies a reference to futurity, as "I expect him to go." In expressing such ideas, however, we frequently reject the infinitive as not well fitted for our purpose, and in its stead employ a sentence in the future indicative, subjoined by the word "that;" as "I expect that he will go."

Similar principles are discovered in the formation of the tenses of the infinitive in the passive voice.

6. *The Gerund and Supine.*

The gerund nearer to the noun than the infinitive mood.

The *Gerund* is a part of speech nearly resembling the infinitive, but tending more strongly to the noun, both in form and syntax. Like the noun, it is governed by prepositions, which the infinitive, at least in the Latin and English languages, is not. We say, "much harm is done to the constitution *by drinking*." In Latin this idea is expressed by the ablative of the gerund (*potando*.) The infinitive is sometimes thus used without a preposition, as in a passage already quoted from Plautus, *Ego sum defessus reperire, vos defessi quærere*; but the gerund is, in almost every instance, better adapted to such purposes. Such passages contribute to show to what extent the infinitive may be used as a noun; but the infrequency of that mode of employing it, and the frequent use of the gerund, prove to us that differences in the forms of words, or parts of speech, often consist in a different extent of adaptation to particular purposes, and that the characters of some pass almost insensibly into those of others.

The gerund differs from the infinitive in not admitting the mention of the agent in equally close syntax. It does not even, like the noun, admit of the annexation of this or any other idea by a genitive or an adjective, nor has it any power analogous to that which the infinitive has of taking an accusative before it, to signify the agent. The gerund therefore is employed only when no mention of the agent is required, or when this is done by connecting it with some other word in the sentence, as when we say "*men* hurt themselves *by drinking*."

Yet differs from the noun.

The gerund takes the regimen of the verb with respect to the nouns which it introduces. In Latin we say *potando vinum*; and in English, "by drinking wine." The same word may however be also used as a noun, and then it may take an adjective and govern the genitive; as "by *the* drinking *of* wine." The difference betwixt the word in "ing," in these two modes of employing it, is analogous to the difference betwixt the Latin gerund in *dum*, and the noun in *tas*, or in *atio* or *itio*, formed from the verb. Instead of the preceding phrase, we may employ *potu*, or *potatione vini*. The Latin word called the gerund also admits of being used as a noun; we can say *potando vini*, as well as *potando vinum*.

The preterite gerund.

The gerunds now mentioned have no accident of tense conjoined with them. We formerly observed, however, that the preterite form of the English verb, as used after the auxiliary "to have," has the nature of a preterite gerund. "Gone" is the name of an act completed. In the phrase "I have gone," it occupies the place of a noun governed in the accusative. In verbs of the transitive kind, while it is thus governed, it governs in its turn another noun, in the same manner as the other parts of the verb to which it belongs. We say "I have *given* them my promise." This is the nature of the word separately considered; but it is never used as a gerund in any other connection, and therefore grammarians have neglected to ascertain its proper character.

The supine.

The word called a *supine* in the Latin language is, in structure and use, similar to the gerund, though not possessing all its inflections, and more limited in its application.

Sect. XII. *Interrogation.*

Interrogation is a part of the object of language, performed by means of the verb, which remains to be considered. We have mentioned it (at p. 397.) in enumerating the forms of imperative influence which mankind, by means of language, exert on one another. Its peculiar object is, to obtain information from the person addressed. Mr Harris considers it as a modification of the use of the verb, and constituting a distinct mood, although the verb when thus applied should not possess a distinct form. It is a direct request, and therefore implies the imperative in a very prominent degree. "What is your name?" is another mode of saying "tell me your name." Interrogative words and interrogative arrangements of words are abbreviations implying the subaudition of the imperative of the verb "to tell." "Who is there?" means "tell me the person who is there."

The interrogative mood of Mr Harris.

Analysis of interrogative forms.

Selective questions.

Interrogative words implying a request for the particular mention of one circumstance that must be *selected* as true, from many others that are imaginable, have a close etymological connection with the relative, and sometimes consist of it unaltered. *Quis* in Latin is different from *qui*, but is evidently derived from it, and the variation which it receives is intended to intimate that the imperative of the verb "to tell" is understood; or rather it is so altered as to express this imperative distinctly and fully. In the Italian language, we have an instance of the employment of a different sort of word; "what do you want?" is expressed by *cosa volete*? which literally translated is, "thing you want." But on most other occasions, in every language the interrogative words are more or less allied to the relative. From *qui* in Latin, we have *quis? qualis? quando? quo? quorsum?* and from "who," and "which," in English, the words "when?" "where?" and "whence?" are evidently derived.

Alternative questions.

There are other questions which may be denominated *alternative* in their nature, because the speaker supposes two opposite statements, one of which must be true and the other false. A subject and a predicate are connected in a question, and the only reply that it admits of is, either an assertion of a connection betwixt the subject and this predicate, or betwixt it and a predicate which is completely the reverse. This may be also done by single words of affirmation or negation, rendered completely significant by their reference to the question. Interrogations of all kinds, however, imply the meaning of the imperative of the verb "to tell." The words of which they consist are a sort of subjoined sentences to this imperative, and are in some degree elliptical in their first creation, though generally rendered precise by receiving a peculiar form.

CHAP. VII.

Of Adverbs.

Want of precision in the description of the adverb.

The term *Adverb* is considered by Mr Tooke as expressive of no character by which a part of speech can be distinguished. He considers the adoption of it as an artifice by means of which, under the colour of scientific order, grammarians have brought together a variety of words, originating in abbreviations and corruptions, and possessing in no other respect any common property. In this opinion we cannot acquiesce, although we are sensible that some confusion has arisen from the unskilfulness of grammarians in ranking among adverbs some words which ought to have been included under a different head.

Its gene characte

Adverbs are words expressly formed for the purpose of subjoining an idea to that which is contained in an adjective or a verb. They are all capable of being annexed to verbs, and some of them to no other part of speech. From this circumstance the whole class has derived its designation. They never express an idea in so close subjunction as a noun governed by a verb in the accusative; they rather resemble nouns which are governed in the ablative, or phrases consisting of a noun with a governing preposition. They sometimes are employed to qualify the character of an idea expressed by an adjective or a verb. At other times they superadd some circumstance of relationship to objects which are capable of being separately conceived.

It does owe its gin to c ruption

We cannot concur with those recent grammarians, who consider as instances of corruption the formation of adverbs by means of alterations made in the forms of words belonging to different parts of speech. They are words skilfully devised for fulfilling a definite object. They do not, as has been supposed, always arise from abbreviation. Although they are capable of being expressed by a plurality of words, this property is common to them with all parts of speech. Some of them are evidently abbreviations, while others have marks of being used as single words previously to any phrases into which they can be resolved. We have not even any demonstrative evidence that all of them are derivatives, and that none are original words.

Distrib tion of verbs.

Adverbs are divided into different species. Some express intensity, remission, or other modifications of attributes expressed by adjectives and verbs. Such are the adverbs "very" and "much;" as "very good" "much better," "much obliged;" also their comparative and superlative forms, as "more" and "most." The words "slightly," "little," "less," and "least," are of a similar nature. Some have considered the comparative and superlative degrees of nouns as condensed combinations of adjectives in their positive state with the adverbs "more" and "most," because they can be resolved into phrases thus constructed. "Richer" and "richest," are "more rich" and "most rich." But these adverbs may in their turn be resolved into other phrases containing adjectives. "More" is "in a greater degree," and "most" "in the greatest degree;" and, from the first consonant being common to them with the positive adjectives *magnus*, *multus*, "many" and "much," and their terminations being characterised by the consonants *r* and *st*, it appears evident that "more" and "most" are derivatives. The Latin word *maximè* is evidently derived from *maximus*, in the same manner as a great variety of adverbs is derived from adjectives.

Advert intensit

Adverl of manne

Adverbs expressing modifications of qualities are generally derived from adjectives. Such are adverbs in *è* and *ĭter* in Latin, as *longè, ingenuè, breviter, feliciter*. In English they are formed by the addition of the termination "ly," as in "shortly," "considerably," "wonderfully." This termination seems, as Mr Tooke remarks, to owe its origin to the word "like," of which it is an alteration, or, as he terms it, a corruption. It is sometimes used as an adjective termination in composition with a substantive, as in "princely," "kingly," which mean "prince-like" and "king-like." The adoption of it for distinguishing the adverb is entirely conventional, and the most profound investigation of its meaning will not lead us to a satisfactory conclusion on the nature of this part of speech. Yet the use made of this termination, and the

Universal Grammar.

nature of the adverb, are sufficiently apparent. They imply a notification that the idea expressed by the compound word is to be annexed in syntax, not to a substantive noun, but to an adjective or a verb. They are also capable of being attached to other adverbs; as "very nobly," "surprisingly well," "too uniformly."

The adverbs just mentioned are called *adverbs of manner*. Some of them merely express a general reference, and have the same relation to the words called demonstrative pronouns which others have to different adjectives. Such are the adverbs "thus," "so," and "as." In Lancashire, instead of "thus" and "so," it is common to say "i' this'n," and "i' that'n."

Numeral adverbs.

There are numeral adverbs as well as adjectives. Such are "once," "twice," and "thrice." These belong to the cardinal numbers, as expressing repetition. There are also adverbs which signify a mere reference to repetition, such as "first," "secondly," and "thirdly," and belong to the ordinal.

Adverbs of place.

There are adverbs of local situation, as "here," "there;" and of local aspect, as "hence," "thence," "hither," "thither," "upward," "forward."

Of time.

Adverbs of time, as "now," "formerly," "soon," "afterwards," "immediately."

It is unnecessary to enlarge on the nature of these words, or to point out the phrases into which they are resolvable, and of which they often are abbreviations.

Of affirmation and negation.

The adverbs of *Affirmation* and *Negation* have been reckoned different in their nature from all the others. When the subject, the predicate, and the copula are arranged in the order of assertion, no separate word is necessary to affirmation; but sometimes an adverb is conjoined to call the attention of the mind with greater emphasis to the truth of the assertion. Such are the adverbs "indeed," "truly," and "certainly." If a question is asked which admits of an answer by the simple affirmation or negation, the answers in the affirmative may be given in English by such adverbs as "certainly," "even so;" or in Latin by *etiam*, *imo* or *utique*. Sometimes a peculiar word, and one which is never used as an adverb in a sentence, is applied to this object. The English word "yes," is of this kind. "Yes," is considered by Mr Tooke as derived from *ay-es* "have" or "enjoy," and meaning "have or entertain that belief." The English "yea," the German *ja*, and the corresponding words in the northern languages, are derived from a similar source. It is therefore to be considered not as an adverb, but as an abbreviation for a sentence. The adverb "certainly," and others equivalent to it, become by ellipsis contractions for the same sentence. If we keep out of view the etymological origin of the words used on such occasions, and consider them all as containing an equally full expression of the meaning of the speaker, we must reckon them abbreviations for sentences; but wherever they are introduced into the body of a sentence, they are adverbs possessing the same properties as other words of that class. They signify that the assertions to which they are applied are not hypothetical, but in conformity to the nature of things.

The negative adverb expresses the absence of this conformity. The same word is in some languages either used singly as an answer to a question, or annexed to a verb in the formation of a sentence. The Latin words *minimè*, *nequaquam*, and *non* are used in both of these ways. But in English the word is on these occasions subjected to a slight change. The adverb is "not." The negative answer is "no." This last is said to be of prior date, and derived from a verb signifying "I deny," or "I am averse;" but, whatever its etymological origin may be, it is, like the word "yes," a contraction for a sentence, with this difference, that the sentence for which it stands implies the force of the adverb "not," and thus reverses the meaning. "Not" has the same general character with the other adverbs: it modifies the verb, and thus forms part of the predicate.

Remarks on negative sentences.

A negative sentence is the reverse of the corresponding affirmation. Yet there is no general difference of character betwixt affirmations and negations. Affirmations are often as directly opposite to each other as to negations. "He is without," and "he is within," are directly contrary. Many assertions can be made equally well in the negative and in the affirmative form. "He is at home" is an affirmative sentence, and the same idea is expressed by these negations, "He is not from home," and "He is no where but at home."

CHAP. VIII.

Of Prepositions.

Difficulties in defining prepositions.

Differences of opinion have been entertained on the nature of *Prepositions*. It is easy to give a character which will apply to them all; but it has been found difficult to give one which will apply to them exclusively. Mr Tooke has been considered by some as solving every difficulty, by pronouncing them abbreviations of nouns or verbs. This author shews that many of them are of the same nature with some of those words which are called conjunctions, and considers that circumstance as proving the inaccuracy of this instance of grammatical distinction. In so far as *the idea expressed* has been represented as a ground of distinction, this author is correct. But when we abandon that system, and take the circumstances of syntax as the foundation of our classifications of words, we shall find that some distinctions which were formerly improperly accounted for are referable to satisfactory data.

Extension of the term.

The classification of the short words called particles appears to us defective, and we shall in the present instance introduce a slight variation from the common usages of grammarians. We shall apply the term preposition to a more extensive genus than our predecessors have done, by including under it some words hitherto called conjunctions. Those words which are usually called prepositions, we distinguish by the appellation of *Nominal prepositions*, because they are introductory to nouns; and the others by that of *Sentential prepositions*, because they are introductory to sentences.

Distribution of them into two species.

Sect. I. *Nominal Prepositions.*

Character of the nominal preposition.

Nominal prepositions have been described by many grammarians as "words which signify the mutual relations of objects." But these relations are equally expressed by every part of speech. Mr Ruddiman with greater propriety describes the preposition as "An indeclinable part of speech signifying the relation of one *substantive* to another." We prefer saying that it signifies "a relation subsisting betwixt the idea expressed by one substantive noun and that expressed by another." It is to be observed that, with the exception of the preposition "of" in English, and some rare expressions already alluded to under the head of the genitive case, a verb, adjective, or participle is interposed between the first of the nouns and the preposition. The preposition "of" is as frequently employed immediately after a noun in English as the genitive case is in Latin; but such phrases as "Newcastle-*on*-Tyne," and "Ashton-*under*-line," are in very small number. The prepositions "on," "under," and all the others except "of," subjoin a noun to an adjective, a participle, or a verb; as "fit *for* use," "good *at* singing," "depending *on* his fidelity," "connected *with* the government." "He has gone *from* home, *along* the road, *to* a distant place."

Mr Tooke's etymologies.

Mr Tooke has shewn great learning and ingenuity in proving that the prepositions, both in ancient and modern languages, are derived from nouns or verbs. *Chez* he derives from *casa*, "a house." *Avec* from *avez que*, "you have that:" *Sens* in French, and *senza* in Italian, from *assenza* "absence:" The Latin *sine* from *sit ne*, i. e. *ne sit* "let it not be:" The Italian *fuori*, the Spanish *afuera*, the French *hors*, (formerly *fors*,) from the Latin *foris*; and this from the Greek word θυρα, in the Doric dialect φορα, "a door or gate." "Through" is derived from a Teutonic word *thuruh*, signifying "a door or passage." *Ad* he derives from the past participle of the verb *agere*, by these steps of transmutation, *agitum, agtum, agd, ad*. He considers the English "to" as the same word with the verb "do;" and "till" as derived from "to while." "For" comes from a Gothic word signifying "a cause;" "of" from *afora*, "progeny;" "by" from *be-on*, "to be;" "with" from *withan*, "to join;" "betwixt" from the imperative "be," and *twos*, the Gothic word for "two." "Before," "behind," "besides," are from the same imperative conjoined with nouns which are either still separately used, or have left familiar traces in different forms. "Beneath" is from an old word *neath*, signifying "bottom; "under" from *on* and *neder*; "beyond" from *geond*, which has the same meaning with "gone" or "past." The termination "ward," which is used both in forming adverbs and prepositions, is from the Saxon verb *weardian*, "to look at," which also gives origin to the word "regard." "Athwart" comes from *thweorian*, "to wrest or twist;" "among" is from *gemengan*, "to mix;" "along" means "on long," i. e. "on length;" "round" and "around" come from a word signifying "a circle;" "near" from *neahg*, "neighbouring;" "instead" is "in station," or "in place;" "down" is from *dufen*, "to dive or dip;" "up," "upon," "over," "above," he derives from *ufa*, "high." The same sort of investigation has been with considerable success applied to the Greek prepositions by Mr Bonar, in the 5th volume of the Transactions of the Royal Society of Edinburgh, and by Professor Dunbar in a separate work on the subject.

The grammatical system founded on these etymologies is in a great measure the contrivance of Mr Tooke. Some of his etymologies have been called in question by Mr Bonar and others. The author of the article Grammar in Dr Rees's *Cyclopædia* attempts to controvert the greater part of them in support of a different system in which he traces the modern languages of Europe to an Oriental origin. Some of Mr Tooke's etymologies however are unquestionable; and it is of great importance to observe, that the author has shewn that all prepositions are resolvable, *with regard to their meaning*, into nouns or verbs. The same ideas may be expressed by all these parts of speech. This property is independent of any opinion that may be formed regarding their particular etymology. "From," for example, may have its place supplied by the noun "beginning." "The figs came from Turkey," means "The figs came *beginning* Turkey." "The lamp fell from the ceiling," "The lamp fell *beginning* the ceiling." "The lamp hangs from the ceiling," "The lamp hangs *beginning* the ceiling."

Prepositions resolvable into nouns.

Do they represent real objc?

Mr Tooke's opinion was, that prepositions represent objects in the same manner as nouns. This is denied by other authors, who proceed on the presumption that nouns are the names of *things*, but prepositions the names of the *relations* of things. And some have derided the absurdity of pronouncing things and their relations to be the same. It might however be maintained that, as variety is essential to the existence of human knowledge, its objects wholly consist in relations. If there should be any difficulty in conceding that point, it ought to be remembered, even in a grammatical view, that the relations of things may be expressed by nouns as well as by prepositions, and that therefore no distinction betwixt these two parts of speech can be founded on such data. Mr Tooke, however, is not content with observing this coincidence betwixt nouns and prepositions. He considers prepositions as invariably derived from *concrete* nouns, or verbs containing these, and insists that they are the names of substantial material objects. The preposition "through," for example, being according to him derived from a word signifying "a door," carries along with it the full meaning of that concrete noun. This statement has been supposed to favour the system of materialism, and perhaps it was so intended; but it is in itself too inaccurate, or at least imperfect, to lead to any general conclusion. If the whole meaning of the concrete noun is retained in the prepositions thus derived, it is only in the form of allusion. A language is not pure and perfect till the allusion itself disappears, and till the word is employed to express an appropriate and well-defined degree of generality, independently of the concomitant ideas contained in the subject from the name of which it has been borrowed. "Through" expresses only one property of a door, and a property in which it resembles many other objects which have different names. This preposition is indeed equivalent to a noun, but it is to a more general one than that which suggested the term. The noun to which it is nearly equivalent is "passage" or "medium."

Proper[ty] of the [pre]position [in] syntax

It is from its properties in syntax that the preposition must take its rank among the parts of speech. In this respect it deviates from the noun. When, instead of the preposition, we employ simply a substantive noun, as in the examples formerly mentioned, in which the noun "beginning" was substituted for the preposition "from," the sentence labours under an awkward chasm. The meaning may be fully understood, but it appears to be imperfectly expressed. There seems to be as great a deficiency as if in an affirmative sentence we should omit the copula, saying, like a lisping child, or an unpractised foreigner, "That man good," instead of "that man is good." In order to complete the syntax, we must either use an additional word along with the noun thus substituted, or supply its place by a different part of speech. The force of those Latin prepositions which govern the accusative, is on the whole more completely expressed by a word which has the regimen of an active verb. This character will apply to all the prepositions of the English language, as they all govern the noun in the same form. Those Latin prepositions which govern the ablative must be considered as less transitive in their regimen. (See our observations on the Ablative Case, at p. 414.)

It ha[s the] regim[en] of a ver[b].

Some[times] resem[bl]es the a[...] geru[nd]

The part of speech to which the preposition is most nearly allied in the mode in which it is introduced, will differ according to the sort of words to which it is immediately subjoined. When it is subjoined to a verb, the verb will govern it nearly in the same manner as it governs the gerund of another verb in the ablative. *Trans* will be represented by *transeundo*; *per* by *perforando*, or *permeando*. The English preposition "from" might be represented by the Latin gerund *linquendo*; the Latin *a*, *ab*, or *abs*, by *abeundo*. The prepositions imply no such specification as is signified by any of the verbs with which, for the sake of pointing out the properties of their syntax, we have here combined them. It was necessary to make gerunds by combining them with verbs, and thus appearing to add to the ideas which they express rather than to explain them, because we have no verb exactly corresponding to the simple preposition. The preposition itself is the gerund, though indeclinable.

Sometimes a participle.

If the preposition is introduced by the substantive verb alone as the first word of the predicate, it will possess the syntax of a participle agreeing with the nominative which precedes. *Sub* will have the regimen of *subjacens* or *subjunctus*. *In* will approach to the participle *habitans* or *inclusus*, though more general in the idea which it conveys. "Out of," when used in such a sentence as "He is out of town," will also have the power of a participle, though we cannot name any word in that form to which, with respect to generality, it makes any approach. This cannot always be expected. If the office of a preposition were to be performed with equal advantage by the gerund or participle of a verb in present use, there would be in some respects no occasion for the prepositions themselves.

The peculiarities of the preposition.

Here we trace the peculiarities of this part of speech. It is usually more general than any other to which it is allied. It is marked by a peculiar brevity, and by the absence of inflexion. Without the formality of significant terminations, prepositions possess all their force. They thus correspond to the rapidity of human thought, and to the subordinate rank of the ideas which they convey. They have been called the pegs and nails of language. This account of them is severely censured by Mr Tooke, and is inaccurate when intended to intimate that they differ from other words in not expressing ideas. Yet it is certainly true that the ideas which they express might often be left to be inferred from the other words of the sentence. They are not the central ideas in discourse. The preposition *secundum*, "according to," implies all the ideas expressed by the noun "harmony" or "agreement;" the word "from" those expressed by the noun "beginning;" "above" those of the noun "top;" "below" those of the noun "bottom." But such ideas are never interesting on account of any general properties of their own. We never have occasion to write dissertations on "tops," "mediums," "beginnings," "endings," "outsides," or "insides." Yet the frequent recurrence and consequent familiarity of these ideas, together with their subordinate character, render it desirable for us to express them with rapidity, by endowing them with all possible brevity of form. Words possessing this character render language copious and minute without incumbrance. They are the Επεα πτεροεντα, the winged words, of discourse. Whether we consider them as always derived from other parts of speech of greater length, which a large proportion of them undoubtedly is, or suppose it possible that they have occasionally consisted of syllables thrown in at random, and afterwards adhered to as significant, in the same manner as almost all original words must have been produced, we see, in their general form and application, their excellent adaptation to the completion of language.

Sect. II. *Sentential Prepositions.*

Nature of the sentential preposition.

The *Sentential Preposition* is a sort of words generally numbered among conjunctions, and forming in elementary grammars more than one half of that list. But the conjunctions, as thus classified, are not susceptible of any common definition; and this proceeds not merely from their coincidence in use with words of a different kind, but from their dissimilarity to one another. That this disadvantage may be diminished, if not entirely remedied, we here give a separate consideration to those words which have the power of introducing subjoined sentences in the same manner as the words called prepositions have with respect to nouns. We denominate them *sentential prepositions*, in contradistinction to the others, to which we have given the designation of *nominal*. In some instances the same word serves for a preposition of both kinds. "After" is a nominal preposition in the phrase "after dinner," and a sentential preposition in the phrase "after we have dined." In other instances the word employed as a nominal preposition undergoes some slight alteration, or receives some addition, to distinguish its application as a sentential preposition. The Latin *cum*, ("with,") sometimes retains the same form when used for subjoining a sentence, and sometimes is transformed into *quum*. *Ante* and *post* are converted into *antequam* and *postquam*.

The general kinds of it.

The nature of the general sentential preposition "that" in English, and *quod* and *ut* in Latin, has been already discussed. *Quam* is another, like these, of very general meaning. It is sometimes translated "as," sometimes "than." It then performs the part of a relative, and has the same relation to an antecedent adverb which the relative noun has to the noun antecedent. *Quam* has the same relation to *tam* as *qui* has to *ille*. *Tanquam*, from *tam* and *quam*, may be called a sentential preposition, but it differs from *quam* in being more particular, as including the antecedent adverb. Of this last kind are also the sentential prepositions *antequam* and *postquam*. *Ante* and *post* are used adverbially, and the Roman authors often disjoin them from the subsequent *quam*: as, *Ante autem huc venerat* QUAM *sperâssem*. It might appear that *quam* should be considered as giving the subjoined sentence the character of a noun, and the word *ante* or *post* as a preposition governing or introducing it in that state. It is however more agreeable to the analogy of language to consider *ante* and *post* as adverbs, and the compound words *antequam* and *postquam* as synonymous with *anteaquam* and *posteaquam*, formed from the adverbs *antea* and *postea*. Adverbs in general might be resolved into nouns in the ablative case; and a special sentential preposition, or one which implies the meaning of an antecedent adverb, would, on this principle, be resolved into the ablative of an antecedent noun and that of the relative. *Antequam* is equivalent to *tempore* ANTERIORE *illi tempori* QUO. *Ut* is also used as a relative; *sic* is often its antecedent when it introduces the indicative mood, and *ita* when it introduces the subjunctive. *Ut* has sometimes in itself the force of *sicut* or of *ita ut*, and, when no antecedent adverb is expressed, may always be considered as implying by ellipsis the meaning of one. The sentential prepositions *dum* and *quum* have the same relation to *tum*; "when," "while," and "where," to the adverbs "then" and "there." The resemblance and near relation subsisting betwixt "when," and the adverb "then," have led many grammarians to give to both the common designation of adverbs. *Postquam*, *antequam*, and other ana-

Their affinity to the relative.

Special words of this class have a compound form.

Or a compound signification by ellipsis.

Universal Grammar.

logous words, have also been denominated adverbs; and thus the whole of this part of grammar has been involved in confusion: but we shall see the difference clearly if we recollect that the words now mentioned are not attached to verbs to modify their meaning, or exhibit in themselves any concomitant circumstance, but to introduce a subjoined sentence. The word "as" is used both for an antecedent adverb, and a sentential preposition. It is an adverb in the phrases "*as* good," "*as* soon," and a sentential preposition after the adverb "so," "He did not come so soon *as* I expected." All special sentential prepositions might be resolved by an analysis similar to that which we have given of *ut* and *antequam*. We have not antecedents in the form of adverbs for them all, but we may express them by ablatives of nouns or of gerunds. *Si*, "if," implies the meaning of *ea conditione, eo casu*, or *supponendo. Quanquam, etiamsi, etsi*, "though," "although," (words of nearly the same meaning with *si*, and differing slightly in the occasions of their application,) imply the force of *concesso* or *concedendo*.

Always distinguishable from adverbs.

Mode of analysing them.

Station of the sentences subjoined by special sentential prepositions.

It is in fine to be observed, that the special sentential preposition and the sentence subjoined by it, taken as a whole, occupy the place of an adverb, or of a noun in the ablative case. In some instances we find single words in this form equivalent to such sentences. *Citò* is equivalent to *priusquam multum temporis preterierit*. In the following sentence, "He was appointed to the office *till the propriety of the continuance of that measure should be ascertained*;" the whole subjoined ideas marked in italics may be fully expressed by the single adverb "provisionally." When *ita* is used without any subjoined regimen, it is an adverb implying a reference to some assertion previously made, or some connection of ideas exhibited at the instant of speaking: When it is employed as the antecedent to *ut* with a subjoined sentence, the whole sentence along with the *ita* and *ut* occupy the place of an adverb or the ablative of a noun.

Mr Tooke's etymologies.

The following is Mr Tooke's account of the etymology of some English words belonging to this part of speech. "If" is from *Gif* the imperative of *Gifan* "to give." The old synonyme "an," from *Anan* "to grant." "Unless," from *Onlesan* "to dismiss." "Though," from *Thafigan* or *thafian*, to "allow." "Without," from *Wyrthanutan*, to "be out." "Lest," from *Lesan*, "to dismiss." "Since," from the participle *Seon*, "to see." "As" is *es*, a German word for "it," "that," or "which."

Some words are used as sentential prepositions which still retain the form of gerunds or participles; as "supposing," "provided," "providing that," "granting that." "Seeing," was formerly used in the same manner.

CHAP. IX.

Of Conjunctions and Miscellaneous Particles.

Conjunctions connect words or sentences on equal terms, without regimen or subjunction. They continue the syntax of the introducing word to that which they introduce. General words of this description are not numerous, as the purposes to which they are applied do not admit of great variety. One kind of them may be termed *Conjunctions of union*, as they unite the meanings of the words which they connect. Such are the English word "and" and the Latin *et, ac, atque*. Another kind may be termed *Conjunctions of alternation*, as *aut* and *vel* in Latin, and "or" in English. The negative "nor" is a conjunction combined with a negation. It might appear in its etymology the reverse of "or," but in meaning it is the reverse of "and." It is equivalent to "and not." In Latin this is also its etymology. It is not *non vel* or *ne vel*, but *nec* from *ne ac*, and *neque* from *ne* and *que*.

General conjunctions.

Conjunctions of union.

Of alternation.

Words announcing conjunctions.

Sometimes the first of the nouns or verbs connected by conjunctions is preceded by a peculiar word. "Both" is used to precede words connected by "and;" "either" those connected by "or;" and "neither" those connected by "nor." It is natural to ask to what head "both," "either," and "neither" are to be referred. In the English language, their etymology might strongly lead a grammarian to refer them to the class of adjectives when they precede nouns, and thus make them equivalent to *ambo, uter*, and *neuter*. When they precede verbs, they might be reckoned adverbs, and in English would be equivalent to adverbs formed by adding the termination "ly" to the adjective, as if we said "bothly," "eitherly," "neitherly." They perform the office of an adverb referring to concomitance. In Latin the same word is used both as the preceding and the conjoining word. *Et ille et alter; Et venit et vidit.* It will be found, on the whole, that conjunctions are near akin to adjectives and adverbs. They are necessarily frequent in the use of language, and therefore have received an abbreviated form.

Conjunctions resemble adjectives, and adverbs.

Special conjunctions.

Some miscellaneous particles may be called *special conjunctions*, as including a more particular character of mutual relation betwixt the ideas contained in the words or sentences which they connect. Such are the words "also," "farther," "moreover," "but," "likewise," "yet," "notwithstanding," "however."

CHAP. X.

Of Interjections.

Nature of interjections.

The term *Interjection* is applied to those words which express by short exclamation certain overpowering emotions of mind. Such as 'Αι αι! *Heu! Atat! Proh!* "Ah!" "Oh!" "Alas!"

This part of speech is treated by Mr Tooke with great contempt, as a brutish inarticulate sound which has as little to do with speech as the neighing of a horse, the barking of a dog, coughing, groaning, shrieking, or any other involuntary convulsion with oral sound. These words, however, though at first involuntary, are afterwards uttered from design. A man desirous of impressing another with a particular passion, first contrives to excite it in his own mind, and then utters the sound by which it is expressed. Hence corresponding syllables are committed to writing in works which depict human passions and manners. They belong to language, as language must include every sound addressed by one man to another, from the highest to the lowest state of mental cultivation. Interjections may be considered as a mixture of involuntary expression with social discourse. In the use of this part of speech, man is seen to rise from the character of an animal impelled by passion to that of a reflecting being, who displays intelligence and address in influencing his fellow creatures.

Either voluntary or voluntary sounds.

Not to refuse place in language.

Special interjections.

Sometimes words belonging to other parts of speech, and expressing definite ideas, are introduced abruptly to express emotion, and numbered among interjections; as "Amazing!" "Wonderful!" "Prodigious!" "Shocking!" "Horrible!" "Mercy!" "Pitiful!" "Woe's me!" Whether we call such exclamations as these interjections, or abbreviations by ellipsis, is of little importance. Their meaning is never ambiguous.

In the introductory part of this article we described language as essentially imperative; and the slightest reflection will shew that interjections, in so far as they partake of the nature of social discourse, possess an imperative character.

Books of merit on universal grammar are but few. But numerous observations on the subject are to be found in all good and complete grammars of particular languages, and in the larger Dictionaries. Some parts of it are also occasionally discussed in books of metaphysics. The principal English and French works on this subject are the following: Monboddo's *Treatise on the Origin and Progress of Language;* Harris's *Hermes;* Beauzée's *Grammaire Générale; Grammaire Générale et Raisonnée,* par M. M. de Port Royal; Condillac's *Grammaire* in his *Cours d'etudes;* Tooke's *Diversions of Purley;* Beddoes *on the Nature of Demonstrative Evidence;* Pickbourne's *Dissertation on the English Verb;* Mr Dunbar's *Analysis of the Greek Verb;* Dr Gregory *on the Theory of the Moods of Verbs in the* 2d vol. of the *Transactions of the Royal Society of Edinburgh;* Mr Bonar's *Essay on the Greek Prepositions,* in the 5th Vol. of the same work; Dr Jamieson's *Hermes Scythicus;* Beattie's *Essay on the Theory of Language;* Hutton's *Dissertation on the Theory of Language;* Dr Adam Smith's *Essay on Language,* (published with his *Theory of Moral Sentiments*); Mr Stewart's *Philosophical Essays,* Part I. Essay 5th; and the article *Grammar* in the *Encyclopædia Britannica,* and that of Dr Rees. *

GRANADA, a celebrated city in Spain, and capital of the province of that name, is pleasantly situated on two small hills, at the extremity of a beautiful and extensive plain. It was built by the Moors in the tenth century, and was finally reduced by the Spanish armies in 1492, after a siege of more than twelve months. At that period it is said to have covered a space three leagues in circumference, and to have contained 400,000 inhabitants, a statement unquestionably far above the truth. Its walls were defended by more than a thousand towers; and it was farther protected by two fortresses, on the summits of the two adjoining hills, each of which was capable of containing 40,000 men. These fortresses still remain, but the walls and gates of the city are demolished, and many of its finest structures in a state of decay. It nevertheless exhibits evident proofs of its former magnificence; and its appearance from a distance is described as peculiarly majestic. The plain before it is above 30 leagues in circumference, and about 1200 miles above the level of the sea, but so completely inclosed by mountains of stupendous height, as to have all the appearance of a delicious valley. It is watered by five rivers, and intersected by numerous rivulets and canals; covered with the richest meadows, forests of oak, plantations of orange trees, and sugar cane, fields of corn and flax, orchards of fruit-trees, and all kinds of vegetables; bounded on the north by the lofty Sierra Nevada, with the mountains of Elvira, and on the other sides by successive amphitheatres of hills; agreeably planted with vines, olive, mulberry, lemon, and orange trees. It contains within its circuit not less than 52 towns; and in its centre appears the Soto de Roma, which is a beautiful wood of elms, white poplars, and ash trees, full of game, especially pheasants, more than a league in length, and half a league in breadth, and formerly the retreat of the Moorish kings. At the termination of this fertile plain, the city of Granada is perceived from a considerable distance, extending in the form of a half moon from the river, along the gradual ascent of a hill, its streets rising above each other, exhibiting a profusion of turrets and gilded cupolas; the summit of the whole crowned by the palace of the Alhambra, and the back ground composed of the majestic Sierra Nevada, covered with snow. But the splendid illusions, created by this distant view, are sadly dissipated by a nearer inspection of its fallen grandeur. It was formerly divided into four quarters, which may still be considered as distinctly marked, namely, the quarter of Alhambra, which principally contains that immense citadel on the mountain of the sun, and where the splendid palace of the Moorish kings is still in existence, and in a state of sufficient repair to impress the spectator with the most lively idea of its original beauties; the quarter of Albayzin, a kind of suburb on the rising ground, separated from the town by a rampart, and containing about 4000 houses; the quarter of Antiquerula, which has the appearance of another suburb built upon the plain, was peopled by settlers from Antequera, and is principally occupied by dyers and silk-weavers; and the quarter of Granada which covers the commencement of the plain, and a part of the valley between the two mountains, and is the best built and best inhabited part of the town. The river Darro runs through the middle of the city, and empties itself into the Xenil, which passes near the walls. The extent of the whole town is much the same as it was in the time of the Moors, but it is thinly inhabited in proportion to its buildings; and the present population is only about 60,000. The streets are generally narrow, and the houses very inferior in their appearance to those of many other cities in Spain. Even those which surround the market-place are very despicable, few of the upper apartments having glass in the windows, and the shops below being very indifferently supplied with goods. But there are many fine buildings, handsome squares, extensive gardens, and beautiful fountains in different parts of the city. The El Campo is a large square at the entrance of the town, on the road from Antequera, and is partly occupied by an hospital, which is a large and handsome building. The Plaza Mayor in the middle of the town is very spacious; and is used for public shows, particularly the bull-fights. The Biva Rambla, a handsome area, 400 feet by 200, is embellished by an elegant jasper fountain, and has on one side the Alcaxeria, and on the other the Chancery; the latter of which has a very handsome front, ornamented with alabaster columns, and a range of windows with gilt balconies; and the former, an immense edifice without ornament, formerly the bazar of the Moors, still contains about 200 shops: these shops are so very small, that the owner, sitting in the centre, is able to reach whatever his customers may require, without rising from his seat. The cathedral is a very splendid but irregular building. It has a handsome dome resting on twelve arches, supported by twelve pilasters; and against these columns are placed the statues of the twelve apostles in gilt bronze, as large as life. The vault is full of paintings, and two rows of

* The Editor is indebted for this valuable article on GRAMMAR to Henry Dewar, M.D. F.R.S.E.

Granada, Province.

gilded balconies run round it above the arcades. In this church are some of the best pictures and statues by the celebrated Spanish artist Alonzo Cano, and his pupil Pedro de Mena. The palace of the archbishop stands close to the cathedral, and is a very extensive mansion, and of a handsome appearance. But the most interesting and splendid object in Granada is the Alhambra, the ancient fortress or palace of the Moorish kings, described in a former article: (See ALHAMBRA.) Though this noble structure is fast hastening to decay, and likely to become in a few years a heap of ruins, it is still viewed by travellers with the strongest sensations of wonder and delight. In a higher situation on an opposite hill, is another palace, called the Generaliffe, which was used as a retreat in the intense heats of summer. The rooms are floored with marble, and have streams of the clearest water rushing through them. It is surrounded by gardens, groves, and orchards, planted with orange, lemon, and cypress trees, and provided with a multiplicity of transparent pools and crystal fountains. Most of the houses have fountains and baths in their courts, which, besides supplying water for domestic uses, moderate by their coolness the extreme heat of the climate in the summer season. In imitation of the Moors, the present inhabitants spread an awning over these courts to keep off the sun, and live there all the summer, eating their meals and receiving their visitors amidst its refreshing coolness. The environs of the city are delightful, and the shady walks on the banks of the Xenil, with others more wild and romantic on the Darro, afford the most refreshing and pleasing retreats. The sides of the hills around the city abound with caves resembling the troglodyte habitations in Abyssinia. They were originally employed as granaries for corn, but are now inhabited by gipsies, who are very numerous in the south of Spain, and are said to bear a great resemblance to the same class of people in England. Granada contains an university, and an academy for mathematics, but they have no library, few masters, and scarcely any students. There is a royal manufactory for saltpetre and gun-powder; and several for woollen cloths and serges, which are said to employ about 7000 persons, and to consume 460,000 pounds of wool annually. Silk stuffs, such as velvets, sattins, and taffetas of a very durable quality, are made in the city, and a considerable quantity of ribbons, in the manufacture of which the spring shuttle used at Coventry is generally adopted, the only kind of machinery observed in the manufactories of the place. See Jacob's *Travels in Spain;* Townsend's *Travels in Spain;* Laborde's *View of Spain;* and Murphy's splendid work, entitled, the *Arabian Antiquities of Spain*, Lond. 1815. (*q*)

GRANADA, a province of Spain, sometimes called Upper Andalusia, is bounded on the east and south by Murcia and the Mediterranean, and on the west and north by Andalusia. It is situated between 36° 20′ and 38° North Latitude, and between 5° 5′ and 1° 30′ West Longitude from Greenwich. It is of a very irregular figure, approaching to the shape of a pyramid, with its base to the east on the kingdom of Murcia, and its apex to the south-west, towards the straits of Gibraltar. It is 58 leagues in length from the east to the south-east; and in breadth, in some places 8, in others 18, and at its base 28. The principal towns are Granada, the capital, already described, Malaga, Almeria, and Amunecar, three sea-ports on the Mediterranean; Guadix, Motrel, Morbella, Velez-Malaga, Baza, Vera, Ronda, Loxa, Santa-Fé, Huesca, Antequera, and Alhama. Its rivers are the Verde, Xenil, Las Feguas, Guadalentia, Guadavar, Guadalmeja, Rio de Almeria, Rio Frio, Guadalmerina, Darro, Guadix, Bravata, Marchan, &c.

Extent and boundaries.

History.

The Moors having acquired possession of Spain after the bloody battle of Xeres in 711, in which Roderigo, the last of the Gothic princes, was slain, Granada became a part of their empire in the south of the peninsula; and, in 1013, was chosen by Almanzor as the royal residence, instead of Cordova. In 1051, the family of Almanzor were deprived of the sovereignty by Joseph ben Taschphen, King of Morocco, who filled the throne with dignity and splendour. After his death, the kingdom was divided among a number of pretenders; but, in 1146, was again united under a prince of the family of the Almohades. Mahomed the First, one of the greatest of the Moorish princes, laid the foundation of a new dynasty in 1232, and raised the kingdom of Granada to its greatest degree of prosperity. While he kept on foot a powerful army for the defence of his dominions, he was equally attentive to promote the welfare of his subjects by the arts of peace. He regulated the revenues, administered justice, cultivated science, endowed hospitals, and laid the foundation of the Alhambra, the glory of Mahommedan Spain. Mahomed the Second succeeded his father, and was distinguished, above all the monarchs of his race, as the protector of science, and the patron of arts and commerce. His court was the resort of astronomers, physicians, philosophers, orators, and poets; and his own compositions in verse are celebrated by Arabian writers for their epigrammatic humour. He was succeeded in 1302, by his son of the same name, who resembled him in his love of literature, and his patronage of the fine arts; but, while he was engaged in war with the King of Arragon, an insurrection in his capital transferred the crown to his brother Almasser, a young prince of 25 years of age, celebrated for his progress in mathematical and astronomical learning; but who, yielding to the turbulent dispositions of his subjects, was in his turn supplanted, in 1314, by Ismael, Prince of Malaga.

State of the Moors in Granada.

The kingdom of Granada, hard pressed by the Christian states in the north of Spain, and thus torn by a succession of intestine commotions, was fast approaching to its fall. Its sovereign Albohassen, availing himself of the discontents created in Castile by the accession of Ferdinand and Isabella, marched a hostile army into their dominions in 1482. Ferdinand, having procured a truce of three years, and quieted his rebellious subjects, became the aggressor in his turn; and, aided by the dissensions among the Moorish chiefs, pushed his conquests with such rapid success, that in the course of two years, he had reduced the power of Abo Abdeli, the eldest son of Albohassen, within the city and plain of Granada. Having occupied the surrounding country with his troops, and built the city of Santa-Fé, he was preparing to invest the Moorish capital, when the besieged prince, more afraid of his subjects than of the enemy, proposed to capitulate, and submitted to the power of Ferdinand. In defiance of the terms expressly stipulated for the protection and toleration of the vanquished, the Moors were finally banished to the sterile regions of their ancestors; and their empire in Spain completely terminated in the year 1492. But for a considerable period after the conquest of Granada, a few scattered bands, who had taken refuge in the mountains, maintained an unavailing struggle with their conquerors, displaying the most heroic spirit in their sufferings, and unshaken constancy to their chiefs. Under the sway of the Mahommedan princes, which comprehends a period of nearly eight centuries, the kingdom of Granada was the seat of opulence, arts, and

Granada, Province.

learning, while the other states of Europe, under the spiritual domination of Rome, were sunk in the deepest mental barbarism. The Omniades in Spain, following the example of Almamon, the seventh caliph of the Abassides, exerted themselves so sedulously in the advancement of knowledge, that they are said to have collected 600,000 volumes, and to have established 70 public libraries in the cities under their dominion. The Arabian writers enumerate, in 1126, 150 authors natives of Cordova, 52 of Almeria, 76 of Murcia, and 53 of Malaga, besides those of Seville, Valencia, and Granada, where the spirit of literature was preserved in full vigour nearly four centuries. In this last mentioned city, where it principally flourished, there were at that time two universities, two royal colleges, and a public library, stored with the productions of the best Greek and Arabic writers. The love of learning was so general in Granada, that, in spite of the prohibitions of Mahomed, it extended to the female sex; and we find recorded the names of the poetess Naschina, the historian Mosada, and the mathematician Leila. Their physicians, though imperfectly acquainted with anatomy, as their religion prohibited all dissections of the human frame, acquired great celebrity. Botany was one of their favourite studies; and they made some progress in the operations of chemistry. They chiefly excelled in the various branches of mathematics, namely astronomy, arithmetic, geometry, trigonometry, and optics; but they were little acquainted with physics, and, though they were instrumental in preserving many Greek authors, they were as little acquainted as the nations of Christendom at that period, with the classical authors of Greece and Rome. Among the Arabians, in short, in the south of Spain, human genius is said to have produced more prodigies in a few centuries, than it has done in the history of ages in all the rest of the world. All the great modern discoveries, paper, printing, the mariner's compass, glass, gunpowder, &c. are affirmed to have been there anticipated and again forgotten; and in the exercise of fancy and invention, they are considered as having far surpassed all former and succeeding ages. Agriculture formed the principal occupation of the Saracens in Granada; and, while it was stimulated by the demands of an extensive population, it was improved by the aids of science. They were particularly attentive to the application of manure, which they preserved in pits, that none of the salts might be lost; and they carried the practice of irrigation to a very great extent. But, as their bigotry forbade the sale of their superfluous grain to the neighbouring nations, they pursued its cultivation no farther than was requisite for their own subsistence; and directed much of their attention to the culture of fruits, which generally formed their principal aliment. To them Spain is indebted for the introduction of an infinite variety of fruits, and of its best horticultural productions, for the sugar-cane also, and the cotton-tree. Their commerce was not less extensive, and the luxuries of India were brought from Alexandria to Malaga at an early period. The silks of India, and the porcelains of China, were soon imitated, and even excelled by the Moors. They were skilled in the manufacture of woollen, cotton, and flax, but, above all, in the art of dyeing of leather. They made some progress in working mines, especially of lead and iron; and their articles of steel, particularly the swords of Granada, were preferred to all others in Spain. In their architectural plans and ornaments, they were deficient in taste; but their joiners and inlayers of wood worked with the utmost nicety; and they painted and gilded their stucco work with singular skill. Upon the banishment of this ingenious people, the arts and sciences departed with them; the magnificence, commerce, and manufactures of Granada rapidly decayed; and the indolence, poverty, and barbarism, which succeeded in their place, continue, in no small degree, to overspread the face of the most highly gifted region in the world.

Mountains.

Granada is beautifully diversified with majestic mountains, extensive plains, and delightful vallies. A chain of mountains, named the Alpuxarras, extends through the province from west to east. The loftiest points of the whole range are those of the Sierra Nevada, near the city of Granada, one of which, called Mulhacen, is 12,762 feet above the level of the sea; and all above 9915 feet are covered with perpetual snow. The mountains towards the south gradually decline in height, till at the Sierra de Gador, near Almeria, where they rise to the elevation of 7800 feet. At this extremity near Macael is the celebrated rock called Filabres, which is four miles in circumference, two thousand feet in height, and which consists of one entire and solid piece of white marble. The secondary mountains are of various kinds; but many are composed of marble of different colours, black, white, red, and flesh colour. About two leagues from Granada, on the banks of the Xenil, is a quarry of green serpentine beautifully veined, and capable of receiving a fine polish. There are many sorts of alabaster in the mountains which environ the city, some of which are as brilliant and transparent as oriental cornelians. There are also quarries of jasper, and a variety of precious stones. In the mountains of this province are several mines of silver, copper, and lead, some of which were formerly worked by the Moors. Gold is found in the sands of the river Darro; but of late the quantity has been small. Mineral waters, both cold and hot springs, are very abundant in the province; but few of them have been analysed: They are chiefly chalybeates, and sulphureous. But one of the most remarkable circumstances in the mountains of Granada is the quantity of bones, of men and other animals, found on their summits, especially at Concud, where there is a hill entirely composed of them, lying under a stratum of limestone.

Climate.

The climate of Granada is cold in the mountainous districts; extremely hot and sultry in the vallies; but it is tempered in the plains by the coolness of the waters, which are conveyed in all directions. The country is exposed to a number of winds, particularly on the coast; one of which especially, called Solano, is attended with the most pernicious effects. It is a hot wind, which blows from Africa, dries up the plants as soon as it touches them, affects the body with the feelings of strong fever, and throws the mind into a state little better than madness. Murders and assassinations are observed to be most frequent during its prevalence.

Soil and produce.

In this province agriculture is in a more flourishing state than in any other district in the south of Spain; and the Vega of Granada, already described, is the finest and richest plain in the kingdom. The principal mode employed for aiding the crops is the irrigation of the soil. Streams are conveyed along the upper side of every field by means of embankments, in which sluices are cut, which convey the water into small gutters; and these are allowed to run at short intervals, so as to flood the whole field with ease in the hot season. Great attention is paid to the preservation of manure, which, according to the old Moorish practice,

Granada, Province.

is collected in large pits, well rammed, to prevent leaking; and, when once well rotted, is distributed over the land, in a state almost liquid. It is not applied, however, to the production of corn, but is used in the gardens, the melon grounds, and the mulberry plantations. Yet, without any manure, and by the mere assistance of irrigation, the most abundant crops of grain are raised, especially of wheat, barley, and maize. On land capable of being properly watered, the annual produce of wheat is said to be fifty bushels per acre. Great quantities of rice are cultivated in the lower grounds near the rivers, and subject to floods; and frequently a crop of hemp, or flax, is taken from the land before the rice is sown. But the Spanish farmers pay more attention to the breeding and fattening of cattle, than to the cultivation of grain or fruits. They make no hay; but the grass grows most abundantly in winter, when the cattle are fed in the uplands; and after harvest, which is generally in June, the stubble fields furnish subsistence to the flocks and herds. The flax and hemp are very cheap; and the latter, having a remarkably strong fibre, is thought to make the best sail cloth. There are very extensive plantations of mulberry trees, which are cultivated solely for the sake of the leaves, as the food of the silk worm. The white mulberry, grafted on the wild stock, is considered as the best for that purpose, and as making the worms yield a finer silk than the red or black species: The tops are cut off to increase the quantity of leaves. As much silk is annually raised in the plain of Granada as furnishes employment to 1500 persons. The manufactures in the city alone are calculated to require a supply of 100,000lbs. It is estimated, that 1500 worms produce about one pound of silk; and it is found, that a mulberry tree, of ten years of age, will scarcely supply food for as many of these insects as yield seven pounds. The mountains round the city of Granada are well calculated for vines, but so little attention is paid to their cultivation, that the wine produced from them is of a very inferior kind, and generally acquires a disagreeable taste from the sheep skins with tarred seams in which it is brought from the vineyards; but, in other parts of the province, excellent wines are made, especially the Tierno, Moscatel, and Malaga. The grapes often grow in bunches of eight, ten, and even fourteen pounds weight, and great quantities are dried in the sun for exportation. Olive trees are numerous; but oil is not produced in sufficient quantity for the consumption of the inhabitants. Sugar canes are cultivated in many parts, but especially around Malaga; and are as large and juicy as those of the West Indies.

Commerce.

The commerce of Granada with the other provinces, consists chiefly in exchanging corn, wine, and dried fruits, for oil and silk. Its trade with foreign countries is carried on from the ports of Almeria and Malaga, (see Almeria and Malaga,) and consists in exports of wine, dried fruits, oil, anchovies, lemons, almonds, lead, kali, sumach; and in imports of cloths, ironware, mercery, lace, &c.

Inhabitants.

The inhabitants of this province, like the Andalusians in general, are considered as the Gascons of Spain, vain, talkative, boastful and licentious. The women are represented as sufficiently seducing, handsome in their figure, and peculiarly attractive as dancers. The language is mixed with so many Arabic words, and the pronunciation so guttural and vitiated, that a Castilian often finds it difficult to understand the speech of an Andalusian. See the works referred to under the preceding article. (*q*)

Granada, New.

GRANADA, New, a division of Spanish America, lying between 2° and 8° of North Latitude; is bounded on the north and east by Caraccas and Cumana, on the west by Popayan, and on the south by Peru. It extends in length about 300 miles, and nearly as much in breadth. It is so far elevated above the level of the sea, that, though approaching almost to the equator, its climate is remarkably temperate. Its vales and level districts are not inferior in fertility to the richest spots of America. Its mountainous tracts abound in mines of gold, silver, lead, copper, and in precious stones of various kinds. Its forests afford a variety of excellent timber, adapted particularly for ship-building. Its principal towns are Bogota, or Santa Fé de Bogota, the seat of government, and the see of an archbishop, situated nearly in 4° North Latitude, and containing 40,000 inhabitants; Flonda, a pleasant little town on the river Magdalena, about 60 miles north-west of the capital, the principal port for the commerce of the interior provinces, and containing about 10,000 inhabitants; Merida, a considerable manufacturing town in 8° 11′ North Latitude, situated in a well-watered valley, about 20 leagues south of Lake Maracaiba, and containing 11,000 inhabitants; Neyva, 107 miles south-west of the capital; Maraquita, 59 miles north-west; St Miguel, 94 miles north-east; Caguan, south of Neyva and Tunia in 5½° North Latitude; all small settlements, rather in a declining state. There are likewise several missionary stations, especially towards the south of the province, called Los Llanos, and several villages of the Indians. Antioquia, perhaps rather a separate province, is also generally comprehended in that of New Granada. It is situated towards the west, bounded by Carthagena on the north, by Popayan on the south, and on the west by Choca. It is mountainous, and abounding in mines; temperate, well watered, and rich in pastures. Its capital, of the same name, in the valley of Nori, is situated in 7° 14′ North Latitude.

A few manufactures of cotton cloths, carpets, counterpanes, and woollens, chiefly for the purposes of internal consumption, are carried on in the province. Several of its native productions, especially chocolate, tobacco, and cotton, all of excellent quality, might be collected in great abundance for exportation; and the river Magdalena, which runs through the province into the Atlantic, and is navigable as far as Florida, 160 leagues from its mouth, affords a commodious outlet to the European markets. But agriculture and trade are said to have greatly declined of late years in the province; and its present unsettled state, struggling for independence of the mother country, though likely to issue at length in its prosperity, must obviously be extremely unfavourable to every kind of cultivation or commerce. Its chief support is derived from the produce of its gold mines. These indeed can scarcely be called mines, as the metal is not generally procured by digging into the earth, but is mingled with the soil near the surface, from which it is separated by repeated washings. This work is commonly performed by Negro slaves, who cannot bear the chill air of the mines, but are more able than the Indians to support the labours of the field. In some districts, the metal is found in large grains; and on some spots, particularly near Pamplona, single labourers have collected in one day a quantity equivalent to 1000 pesos. One of the governors of Santa Fé procured a mass of pure gold estimated to be worth £740, which was deposited in the royal cabinet of Madrid as the finest and largest specimen ever found in the New World.

Granada, or Santa Fé as it is sometimes called, gives name to an extensive viceroyalty, which is sometimes confounded with the province, properly so denominated. This kingdom of New Granada was originally established in 1547, and was governed by a royal audience, with a captain-general as president. In 1718, it was formed into a viceroyalty, which was suppressed in 1724, and finally restored in 1740. It comprises the provinces of Carthagena, Panama, Santa Martha, Maracaibo, Porto Bello, Antiognia, Choca, Granada Proper, Veragua, Mariquita, Rio de la Hacha, Giron, Neyva, and the Llanos, which form the northern division, under the jurisdiction of the royal audience at Santa Fé; and the southern districts, Jaen de Bracamoros, Loja, Cuenza, Macas, Riobamba, Popayan, Quito, Guaynquil, &c. which are under the jurisdiction of a governor and royal audience at Quito, who are subordinate to the viceroy of New Granada. This extensive territory, when first subjected to Spain in 1536, was more populous, and its inhabitants more civilized, than any other portion of America; but the amount of its whole population is now calculated by M. Humboldt only at 1,800,000. Nothing is wanting for its prosperity, but the revival of industry and commerce; and nothing prevents it from enjoying these benefits, but the impolitic restrictions and oppressive system of its European rulers. See Robertson's *History of America*, vol. iii.; Playfair's *Geography*, vol. vi.; Pinkerton's *Geography*, vol. iii.; and Humboldt's *Account of New Spain*. (*q*)

GRANGE, Joseph-Louis la,* a celebrated mathematician and natural philosopher, was born at Turin, on the 25th of November, 1736. He was the son of Joseph-Louis la Grange, treasurer of war, and of Marie-Therese Gros, only daughter of a rich physician of Cambiano.

His father was rich, and had made an advantageous marriage; but was ruined by hazardous undertakings. Let us not, however, lament the situation of M. la Grange. He himself viewed it as the first cause of all the good fortune that afterwards befel him. "Had I been in possession of a fortune," said he, "I should not probably have studied mathematics." In what other situation would he have found advantages that could enter into comparison with those of a tranquil and studious life, with that splendid series of discoveries in a branch of science considered as the most difficult, and with that personal respectability which was continually increasing to the very last period of his life?

His taste for mathematics did not appear at first. He was passionately devoted to Cicero and Virgil, before he could read Archimedes and Newton. He then became an enthusiastic admirer of the geometry of the ancients, which he preferred to the modern analysis. A memoir which the celebrated Halley had composed long before, to demonstrate the superiority of the analytic method, had the glory of converting him, and of teaching him his true destiny. He devoted himself to this new study with the same success that he had in the synthesis, and which was so decided, that at the age of 16 he was professor of mathematics in the Royal Military School. The extreme youth of a professor is a great advantage to him when he has shown extraordinary abilities, and when his pupils are no longer children. All the pupils of M. la Grange were older than himself, and were not the less attentive to his lectures on that account. He distinguished some of them, whom he made his friends.

From this association sprung the academy of Turin, which in 1759 published a first volume entitled Acts of a private Society. We see there the young La Grange directing the philosophical researches of the physician Cigna, and the labours of the Chevalier de Saluces. He furnished to Foncenex the analytical part of his memoirs, leaving to him the task of developing the reasoning upon which the formulæ depended. In these memoirs, which do not bear his name, we observe that purely analytical method, which afterwards characterised his great productions. He had discovered a new theory of the lever. It constitutes the third part of a memoir, which was very successful. Foncenex, in recompense, was placed at the head of the Marine, which the king of Sardinia formed at that time. The two first parts have the same style, and seem written by the same person. Do they likewise belong to La Grange? He never expressly laid claim to them; but what may throw some light on the real author is, that Foncenex soon ceased to enrich the volumes of the new academy, and that Montucla, ignorant of what La Grange revealed to us during the latter part of his life, is astonished that Foncenex interrupted those researches which might have given him a great reputation.

M. la Grange, while he abandoned to his friend insulated theorems, published at the same time, under his own name, theories which he promised to develope further. Thus after having given new formulæ of the *maximum* and *minimum* in all cases, after having shown the insufficiency of the known methods, he announces that he will treat this subject, which he considered as important, in a work which he was preparing, in which, would be deduced from the same principles all the mechanical properties of bodies, whether solid or fluid. Thus at the age of 23 he had laid the foundation of the great works, which have commanded the admiration of philosophers.

In the same volume he reduces under the differential calculus the theory of recurrent series and the doctrine of chances; which before that time had only been treated by indirect methods. He established them upon more natural and general principles.

Newton had undertaken to submit the motions of fluids to calculation. He had made researches on the propagation of sound; but his principles were insufficient, and his suppositions inconsistent with each other. La Grange demonstrates this. He founds his new researches on the known laws of dynamics, and, by considering only in the air the particles which are in a straight line, he reduces the problem to that of vibrating cords, respecting which the greatest mathematicians differed in opinion. He shows that their calculations are insufficient to decide the question. He undertakes a general solution by an analysis equally new and interesting, which enables him to resolve at once an indefinite number of equations, and which embraces even discontinued functions. He establishes on more solid grounds the theory of the mixture of simple and regular vibrations of Daniel Bernoulli. He shows the limits within which this theory is exact, and beyond which it becomes faulty. Then he comes to the

* This excellent life of La Grange is taken, with a few slight abridgments, from the eloge of the Chevalier Delambre, with whose kind permission it is here published. As we have not been able to get a copy of the original eloge, we have been obliged to make use of the translation in Dr Thomson's *Annals of Philosophy*, vol. iii. Ed.

construction given by Euler, a construction true in itself, although its first author had arrived at it by calculations which were not quite rigorous. He answers the objections of D'Alembert. He demonstrates that whatever figure is given to the cord, the duration of the oscillations is always the same: a truth derived from experiment, which D'Alembert considered as very difficult, if not impossible, to demonstrate. He passes to the propagation of sound, treats of simple and compound echos, of the mixture of sounds, of the possibility of their spreading in the same space without interfering with each other. He demonstrates rigorously the generation of harmonious sounds. Finally, he announces that his intention is to destroy the prejudices of those who still doubt whether the mathematics can ever throw a real light upon physics.

We have given this long account of that memoir, because it is the first by which M. la Grange became known. If the analytical reasoning in it be of the most transcendent kind, the object at least has something sensible. He recals names and facts which are well known to most people. What is surprising is, that such a first essay should be the production of a young man, who took possession of a subject treated by Newton, Taylor, Bernoulli, D'Alembert, and Euler. He appears all at once in the midst of these great mathematicians as their equal, as a judge, who, in order to put an end to a difficult dispute, points out how far each of them is in the right, and how far they have deceived themselves; determines the dispute between them, corrects their errors, and gives them the true solution, which they had perceived without knowing it to be so.

Euler saw the merit of the new method, and took it for the object of his profoundest meditations. D'Alembert did not yield the point in dispute. In his private letters, as well as in his printed memoirs, he proposed numerous objections, to which La Grange afterwards answered. But these objections may give rise to this question: How comes it that, in a science in which every one admits the merit of exactness, geniuses of the first order take different sides, and continue to dispute for a long time? The reason is, that in problems of this kind, the solutions of which cannot be subjected to the proof of experiment, besides the part of the calculation which is subjected to rigorous laws, and respecting which it is not possible to entertain two opinions, there is always a metaphysical part which leaves doubt and obscurity. It is because in the calculations themselves, mathematicians are often content with pointing out the way in which the demonstration may be made; they suppress the developements, which are not always so superfluous as they think. The care of filling up these blanks would require a labour which the author alone would have the courage to accomplish. Even he himself, drawn on by his subject and by the habits which he has acquired, allows himself to leap over the intermediate ideas. He defines his definitive equation, instead of arriving at it step by step with an attention that would prevent every mistake. Hence it happens that more timid calculators sometimes point out mistakes in the calculations of an Euler, a D'Alembert, a La Grange. Hence it happens that men of very great genius do not at first agree, from not having studied each other with sufficient attention to understand each other's meaning.

The first answer of Euler was to make La Grange an associate of the Berlin academy. When he announced to him this nomination on the 20th of October, 1759, he said, "Your solution of the problem of isoperimeters leaves nothing to desire; and I am happy that this subject, with which I was almost alone occupied since the first attempts, has been carried by you to the highest degree of perfection. The importance of the matter has induced me to draw up, with your assistance, an analytical solution of it. But I shall not publish it till you yourself have published the sequel of your researches, that I may not deprive you of any part of the glory which is your due."

If these delicate proceedings, and the testimonies of the highest esteem, were very flattering to a young man of 24 years of age, they do no less honour to the great man, who at that time swayed the sceptre of mathematics, and who thus accurately estimated the merit of a work that announced to him a successor.

But these praises are to be found in a letter. It may be supposed that the great and good Euler has indulged in some of those exaggerations which the epistolary style permits. Let us see then how he has expressed himself in the dissertation which his letter announced. It begins as follows:

"After having fatigued myself for a long time and to no purpose, in endeavouring to find this integral, what was my astonishment when I learnt that in the Turin Memoirs the problem was resolved with as much facility as felicity! This fine discovery produced in me so much the more admiration, as it is very different from the methods which I had given, and far surpasses them all in simplicity."

It is thus that Euler begins the memoir, in which he explains with his usual clearness the foundation of the method of his young rival, and the theory of the new calculus, which he called the *calculus of variations*.

To make the motives of this admiration which Euler bestowed with so much frankness better understood, it will not be useless to go back to the origin of the researches of La Grange, such as he stated them himself two days before his death.

The first attempts to determine the *maximum* and *minimum* in all indefinite integral formulæ, were made upon the occasion of the curve of swiftest descent, and the isoperimeters of Bernoulli. Euler had brought them to a general method, in an original work, in which the profoundest knowledge of the calculus is conspicuous. But however ingenious his method was, it had not all the simplicity which one would wish to see in a work of pure analysis. The author admitted this himself. He allowed the necessity of a demonstration independent of geometry. He appeared to doubt the resources of analysis, and terminated his work by saying, "If my principle be not sufficiently demonstrated, yet as it is conformable to truth, I have no doubt that, by means of a rigid metaphysical explanation, it may be put in the clearest light, and I leave that task to the metaphysicians."

This appeal, to which the metaphysicians paid no attention, was listened to by La Grange, and excited his emulation. In a short time the young man found the solution of which Euler had despaired. *He found it by analysis.* And in giving an account of the way in which he had been led to that discovery, he said expressly, and as it were in answer to Euler's doubt, that he regarded it not as a metaphysical principle, but as a necessary result of the laws of mechanics, as a simple corollary from a more general law, which he afterwards made the foundation of his *Mechanique Analytique.* (See that work, page 189 of the first edition.)

This noble emulation, which excited him to triumph over difficulties considered as insurmountable, and to rectify or complete theories remaining imperfect, appears to have always directed M. la Grange in the choice of his subjects.

D'Alembert had considered it as impossible to subject to calculation the motions of a fluid inclosed in a vessel, unless this vessel had a certain figure. La Grange demonstrates the contrary; except in the case when the fluid divides itself into different masses. But even then we may determine the places where the fluid divides itself into different portions, and ascertain the motion of each as if it were alone.

D'Alembert had thought that in a fluid mass, such as the earth may have been at its origin, it was not necessary for the different beds to be on a level. La Grange shows that the equations of D'Alembert are themselves equations of beds on a level.

In combating D'Alembert with all the delicacy due to a mathematician of his rank, he often employs very beautiful theorems, for which he was indebted to his adversary. D'Alembert on his side added to the researches of La Grange. " Your problem appeared to me so beautiful," says he in a letter to La Grange, " that I have sought for another solution of it. I have found a simpler method of arriving at your elegant formula." These examples, which it would be easy to multiply, prove with what politeness these celebrated rivals corresponded, who, opposing each other without intermission, whether conquerors or conquered, constantly found in their discussion reasons for esteeming each other more, and furnished to their antagonist occasions which might lead them to new triumphs.

The academy of sciences of Paris had proposed, as the subject of a prize, the theory of the libration of the moon. That is to say, they demanded the cause why the moon, in revolving round the earth, always turns the same face to it, some variations excepted, observed by astronomers, and of which Cassini had first explained the phenomena. The point was to calculate all the phenomena, and to deduce them from the principle of universal gravitation. Such a subject was an appeal to the genius of La Grange, an opportunity furnished to apply his analytical principles and discoveries. The attempt of D'Alembert was not disappointed. The memoir of La Grange is one of his finest pieces. We see in it the first developement of his ideas, and the germ of his *Mecanique Analytique*. D'Alembert wrote to him: " I have read with as much pleasure as advantage your excellent paper on the Libration, so worthy of the prize which it obtained."

This success encouraged the academy to propose, as a prize, the theory of the satellites of Jupiter. Euler, Clairaut, and D'Alembert had employed themselves about the problem of three bodies, as connected with the lunar motions. Bailly then applied the theory of Clairaut to the problem of the satellites, and it had led him to very interesting results. But this theory was insufficient. The earth has only one moon while Jupiter has four, which ought continually to act upon each other, and alter their positions in their revolutions. The problem was that of six bodies. La Grange attacked the difficulty and overcame it, demonstrated the cause of the inequalities observed by astronomers, and pointed out some others too feeble to be ascertained by observations. The shortness of the time allowed, and the immensity of the calculations, both analytical and numerical, did not permit him to exhaust the subject entirely in a first memoir. He was sensible of this himself, and promised further results, which his other labours always prevented him from giving. Twenty-four years after, M. La Place took up that difficult theory, and made important discoveries in it, which completed it, and put it in the power of astronomers to banish empiricism from their tables.

About the same time a problem of quite a different kind attracted the attention of M. la Grange. Fermat, one of the greatest mathematicians of his time, had left very remarkable theorems respecting the properties of numbers, which he probably discovered by induction. He had promised the demonstrations of them; but at his death no trace of them could be found. Whether he had suppressed them as insufficient, or from some other cause, cannot now be ascertained. These theorems perhaps may appear more curious than useful. But it is well known that difficulty constitutes a strong attraction for all men, especially for mathematicians. Without such a motive would they have attached so much importance to the problems of the brachystrochonon, of the isoperimeters, and of the orthogonal trajectories? Certainly not. They wished to create the science of calculation, and to perfect methods which could not fail some day of finding useful applications. With this view, they attached themselves to the first question which required new resources. The system of the world discovered by Newton was a most fortunate event for them. Never could the transcendant calculus find a subject more worthy or more rich. Whatever progress is made in it, the first discoverer will always retain his rank. Accordingly, M. la Grange, who cites him often as the greatest genius that ever existed, adds also, " and the most fortunate. We do not find every day a system of the world to establish." It has required 100 years of labours and discoveries to raise the edifice of which Newton laid the foundation. But every thing is ascribed to him, and we suppose him to have traversed the whole country upon which he merely entered.

Many mathematicians doubtless employed themselves on the theorems of Fermat; but none had been successful. Euler alone had penetrated into that difficult road in which M. Legendre and M. Gauss afterwards signalized themselves. M. la Grange, in demonstrating or rectifying some opinions of Euler, resolved a problem which appears to be the key of all the others; and from which he deduced a useful result; namely, the complete resolution of equations of the second degree, with two indeterminates, which must be whole numbers.

This memoir, printed like the preceding, among those of the Turin Academy, is notwithstanding dated Berlin, the 20th September 1768. This date points out to us one of the few events which render the life of La Grange, not entirely a detail of his writings.

His stay at Turin was not agreeable to him. He saw no person there who cultivated the mathematics with success. He was impatient to see the philosophers of Paris, with whom he corresponded. M. de Caraccioli, with whom he lived in the greatest intimacy, was appointed ambassador to London, and was to pass through Paris on his way, where he intended to spend some time. He proposed this journey to M. la Grange, who consented to it with joy, and who was received as he had a right to expect by D'Alembert, Clairaut, Condorcet, Fontaine, Nollet, Marie, and the other philosophers. Falling dangerously ill after a dinner in the Italian style given him by Nollet, he was not able to accompany his friend to London, who had received sudden orders to repair to his post, and who was obliged to leave him in a furnished lodging, under the care of a confidential person charged to provide every thing.

This incident changed his projects. He thought only of returning to Turin. He devoted himself to the mathematics with new ardour, when he understood that the Academy of Berlin was threatened with the loss of Euler, who thought of returning to Petersburgh. D'Alembert speaks of this project of Euler, in a letter to Voltaire, dated the 3d March 1766: "I shall be sorry for it," says he; "he is a man by no means amusing, but a very great mathematician." It was of little consequence to D'Alembert, whether this man, *by no means amusing*, went seven degrees nearer the pole. He could read the works of the great mathematician as well in the Petersburgh Memoirs as in those of Berlin. What troubled D'Alembert was the fear of seeing himself called upon to fill his place, and the difficulty of giving an answer to offers which he was determined not to accept. Frederick in fact offered him again the place of president of his Academy, which he had kept in reserve for him ever since the death of Maupertuis. D'Alembert suggested the idea of putting La Grange in the place of Euler; and, if we believe the author of the *Secret History of the Court of Berlin*, (vol. ii. p. 414,) Euler had already pointed out La Grange as the only man capable of filling his place. In fact, it was natural that Euler, who wished to obtain permission to leave Berlin, and D'Alembert, who wanted a pretext not to go there, should both of them, without any communication, have cast their eyes on the man who was best fitted to maintain the eclat which the labours of Euler had thrown round the Berlin Academy.

La Grange was pitched upon. He received a pension of 1500 Prussian crowns, about £250, with the title of Director of the Academy for the Physico-mathematical Sciences. We may be surprised that Euler and La Grange, put successively in the place of Maupertuis, received only the half of his salary, which the king offered entire to D'Alembert. The reason is, that this prince, who at his leisure hours cultivated poetry and the arts, had no idea of the sciences, though he considered himself obliged to protect them as a king. He had very little respect for the mathematics, against which he wrote three pages in verse, and sent them to D'Alembert himself, who deferred writing an answer till the termination of the siege of Schweidnitz; because he thought it would be too much to have both Austria and the mathematics on his hands at once. Notwithstanding the prodigious reputation of Euler, we see, from the king's correspondence with Voltaire, that he gave him no other appellation than his *narrow-minded geometer, whose ears were not capable of feeling the delicacy of poetry.* To which Voltaire replies: *We are a small number of adepts who know one another: the rest are profane.* We see that Voltaire, who had written so well in praise of Newton, endeavours in this place to flatter Frederick. He enters out of complaisance into the ideas of this prince, who wished to put at the head of his academy a man who had at least some pretensions to literature. Fearing that a mathematician would not take sufficient interest in the direction of literary labours, and that a man of literature would have been still worse placed at the head of a society composed in part of philosophers, of whose language he was ignorant; on that account he divided the situation, and put two persons in it, that it might be completely filled.

M. la Grange took possession of his situation on the 6th of November 1766. He was well received by the king; but soon perceived that the Germans do not like to see foreigners occupy situations in their country. He applied to the study of their language. He devoted himself entirely to mathematics, and did not find himself in the way of any person, because he demanded nothing; and he soon obliged the Germans to give him their esteem. "The king," said he himself, "treated me well; I thought that he preferred me to Euler, who was something of a devotee, while I took no part in the disputes about worship, and did not contradict the opinion of any one." This prudent reserve, if it deprived him of the advantages of an honourable familiarity, which would have been attended with some inconveniences, left him the whole of his time for mathematical labours, which hitherto had brought him nothing but compliments the most flattering and the most unanimous. This concert of praises was only once interrupted during the whole of his life.

A French mathematician, who to much sagacity united a still greater degree of selfishness, and scarcely gave himself the trouble to study the works of others, accused M. la Grange of *having gone astray in the new route that he had traced, from not having well understood the theory of it.* He reproached him with *having deceived himself in his assertions and calculations.* La Grange in reply expresses some astonishment at these harsh expressions, to which he was so little accustomed. He expected at least to have seen them founded on some reasons either good or bad; but he discovered nothing of the kind. He shews that the solution proposed by Fontaine was incomplete and illusory in certain respects. Fontaine had boasted that he had taught mathematicians the conditions which render possible the integration of differential equations with three variables. La Grange showed him, by several citations, that these conditions were known to mathematicians long before Fontaine was capable of teaching them. He does not deny that Fontaine discovered these theorems himself; "at least I am persuaded," says he, "that he was as capable of finding them as any person whatever."

It was with this delicacy and moderation that he answered the aggressor. Condorcet, in his *eloge* of Fontaine, is obliged to avow that, on this occasion, his friend deviated from that politeness which ought never to be dispensed with, but which perhaps he thought less necessary with illustrious adversaries, whose glory did not stand in need of these little delicacies. Every one can estimate the value of that apology, especially when applied to a man who, by his own acknowledgment, studied the vanity of others, that he might have an opportunity of wounding it. We must at least acknowledge, that he, who saw himself attacked in that manner when he was in the right, and who knew how to maintain politeness with an adversary who had himself dispensed with it, acquired a double advantage over him, besides victoriously repelling his imprudent attack.

It will not be expected that we should follow M. la Grange in the important researches with which he filled the Berlin Memoirs; and even some volumes of the Memoirs of the Turin Academy, which was indebted to him for its existence. All the space that can be devoted to this biographical account would not be sufficient even to convey an imperfect idea of the immense series of his labours, which have given so much value to the Memoirs of the Berlin Academy, while it had the inestimable advantage of being directed by M. la Grange. Some of these Memoirs are of such extent and importance, that they might pass for a great separate work, yet they constitute a part only of what these twenty years enabled him to produce. He had composed his *Mecanique Analytique*, but he wanted to have it printed at Paris, where he expected that his formulæ would be given with more care and fidelity. On the other hand, it was running too great a risk to intrust the manuscript into the hands of a traveller, who might not be aware of the whole of its value. M. la Grange made a copy of it, which M. Duchatelet undertook to deliver to the Abbé Marie, with whom he was intimately connected. Marie fulfilled with honour the confidence placed in him. His first care was to find a bookseller who would undertake to publish it; and, what it will be difficult to believe at this time, he could not find one. The newer the methods in it were, and the more sublime the theory, the fewer readers would be found capable of appreciating it; hence, without entertaining any doubts of the merit of the work, the booksellers were excusable in hesitating to print a book, the sale of which would probably be confined to a small number of mathematicians, disseminated through Europe. Desain, who was the most enterprising of all those to whom application was made, would not undertake to publish it, till Marie entered into a formal engagement to take all the copies of the edition which were not sold by a given time. To this first service, Marie added another, of which M. la Grange was not less sensible; he procured him an editor worthy of superintending the publication of such a work. M. Legendre devoted the whole of his time to the troublesome task of correcting the press, and was repaid by the sentiment of veneration for the author with which he was penetrated; and by the thanks which he received from him in a letter which I have had in my possession, and which M. la Grange had filled with expressions of his esteem and his gratitude.

The book was not yet published when the author came to settle in Paris. Several causes determined him to take this step; but we must not give credit to all that have been stated. The death of Frederick had occasioned great changes in Prussia, and still greater were to be apprehended. Philosophers were no longer so much respected as formerly. It was natural for M. la Grange again to feel that desire which had formerly conducted him to Paris. These causes, together with the publication of the *Mecanique Analytique*, were sufficient. It is not necessary to add other causes, which several publications that made their appearance in Germany, and particularly the anonymous historian of the court of Berlin, have noticed. We never, during a residence of 25 years in France, heard M. la Grange prefer the slightest complaint against the minister, who is accused in that publication of having disgusted him by a treatment full of haughtiness and contempt, which, out of respect for himself, it was impossible for M. la Grange to overlook. We might suspect that M. la Grange had sufficient generosity to forget or pardon bad treatment, which he punished in the only way worthy of himself, by leaving the country where his merit was overlooked; but when he was directly questioned on that subject by a member of the Institute, (M. Burckhardt,) he only gave negative answers, and assigned no other motives than the misfortunes which it was thought were about to fall upon Prussia. M. de Hertzberg was dead, and M. de la Grange, a senator and count of the French empire, could have no interest in concealing the truth. Hence we must consider his own statement as affording the only true reasons.

The historian, therefore, whom we have quoted, has been ill informed. But the spirit of calumny and satire, which has so justly rendered his work suspected, ought not to prevent us from extracting from it the lines in which he explains, with that energy which is peculiarly his own, his opinion, which is that of all Europe, when he does justice to M. la Grange.

"I think," says he, (*Hist. Sec. de la Cour de Berlin*, 1789, tom. ii. page 173,) "that there is at this moment an acquisition worthy of the king of France, the illustrious La Grange, the greatest mathematician who has appeared since Newton, and who in every point of view is the man that has the most astonished me;—La Grange, the wisest, and perhaps the only practical philosopher that ever existed, meritorious by his undisturbable wisdom, his manners, his conduct; the object of the most tender respect of the small number of men with whom he associates:—La Grange is misunderstood; every thing leads him to leave a country where nothing can excuse the crime of being a foreigner, and where in fact he is merely tolerated. Prince Cardito de Laffredo, Neapolitan minister at Copenhagen, offered him the most flattering conditions on the part of his sovereign. The Grand Duke, the king of Sardinia, invited him eagerly; but all their proposals would be easily obliterated by ours. I am very eager to see this proposal made, because I consider it as noble, and because I tenderly love the man who is the object of it. I have induced M. la Grange not to accept immediately the proposals made to him, and to wait till he receives ours."

The author whom we quote appears to fear the opposition of M. Breteuil; but, according to M. la Grange himself, it was the Abbé Marie who proposed it to M. Breteuil, who on all occasions anticipated the desires of the Academy of Sciences, presented the demand to Louis XVI. and induced him to agree to it.

The successor of Frederick, although he did not much interest himself in the sciences, made some difficulty in allowing a philosopher to depart whom his predecessor had invited, and whom he honoured with his particular esteem. After some delay, M. la Grange obtained liberty to depart. It was stipulated that he should still give some memoirs to the Berlin Academy. The volumes of 1792, 1793, and 1803, show that he faithfully kept his promise.

It was in 1787, that M. la Grange came to Paris to take his seat in the Academy of Sciences, of which he had been a foreign member for fifteen years. To give him the right of voting in all their deliberations, this title was changed into that of *veteran pensionary*. His new associates shewed themselves happy and proud in possessing him. The queen treated him with regard, and considered him as a German. He had been recommended to her from Vienna. He obtained a lodging in the Louvre, where he lived happy till the Revolution.

The satisfaction which he enjoyed did not show itself outwardly. Always affable and kind when interrogated, he himself spoke but little, and appeared absent and melancholy. Often in companies which must have been suitable to his taste, among the most distinguished men of all countries who met at the house of the illustrious Lavoisier, I have seen him dreaming, as it were, with his head against a window, where however nothing attracted his attention. He remained a stranger to what was passing around him. He acknowledged himself that his enthusiasm was gone, that he had lost his taste for mathematics. When informed that a mathematician was employed at such a task, "so much the better," he would say; "I had begun it, now it will be unnecessary for me to finish it." But he merely chan-

La Grange, Joseph Louis.

ged the object of his studies. Metaphysics, the history of human nature, that of different religions, the general theory of languages, medicine, botany, divided his leisure hours. When the conversation turned upon subjects with which it was supposed he was unacquainted, we were struck by an unexpected observation, a fine thought, a profound view, which excited long reflections. Surrounded by chemists who were reforming the theory and even the language of the science, he made himself acquainted with their discoveries, which gave to facts formerly isolated that connection which distinguishes the different parts of mathematics. He undertook to make himself acquainted with this branch of knowledge, which formerly appeared to him so obscure, but which he found on trial *as easy as algebra.* People have been surprised at this comparison, and have thought that it could come from no one else than La Grange. It appears to us as simple as just; but it must be taken in its true sense. Algebra, which presents so many insoluble problems, so many difficulties against which La Grange himself struggled in vain, could not in that sense appear to him an easy study. But he compares the new elements of chemistry with those of algebra. They constituted a body, they were intelligible, they offered more certainty; they resembled algebra, which in the part of it that is complete presents nothing difficult to conceive, no truth to which we may not arrive by the most palpable reasoning. The commencement of the science of chemistry appeared to him to offer the same advantages, perhaps with somewhat less stability and certainty; but, like algebra, it has no doubt also its difficulties, its paradoxes, which will require to explain them, much sagacity, reflection, and time. It has likewise its problems which never will be resolved.

In this philosophic repose he continued till the Revolution, without adding any thing to his mathematical discoveries, or even opening his *Mecanique Analytique,* which had been published for two years.

The Revolution gave philosophers an opportunity of making a great and difficult innovation; the establishment of a system of weights and measures founded on nature, and perfectly analogous to our scale of numbers. La Grange was one of the commissioners whom the Academy charged with that task. He was one of its keenest promoters. He wished to see the decimal system in all its purity. He was provoked at the complaisance of Borda, who got quarters of the *metre* made. He thought the objection of little importance which was drawn against the system from the small number of divisors that its base afforded. He regretted that it was not a prime number, as 11, which would have given the same denominator to all the fractions. This idea perhaps will be regarded as one of those exaggerations, which are hazarded by men of the best understandings, in the heat of dispute. But he mentioned the number 11 merely to get rid of the number 12, which more intrepid innovators would have wished to substitute in place of the number 10, that constitutes the base of the whole of our numeration.

When the Academy was suppressed, the commission charged with the establishment of the new system was retained for a time. Three months had scarcely elapsed when, in order to purify that commission, the names of Lavoisier, Borda, La Place, Coulomb, Brisson, and Delambre, were struck out. La Grange was retained. In quality of president, he informed me, in a long letter full of kindness, that I should receive official information of my removal. As soon as he saw me on my return to Paris, he expressed to me his regret at the dismissal of so many associates. "I do not know," said he, "why they have retained me." But unless the suppression had been total, it could scarcely have extended to him. The more losses the commission had sustained, of the more importance was it not to deprive it of the consideration attached to the name of La Grange. Besides, he was known to be wholly devoted to the sciences; he had no place either in the civil department or the administration. The moderation of his character had prevented him from expressing what he could not but think in secret; but I shall never forget the conversation which I had with him at that period. It was the day after the atrocious and absurd sentence, contrary to every thing like justice, had thrown all lovers of the sciences into mourning, by cutting off the most illustrious philosopher in Europe. "It has cost them but a moment," said he, "to cut off that head, and a hundred years perhaps will not be sufficient to produce another like it." Some months before we had had a similar conversation in the cabinet of Lavoisier, on account of the death of the unfortunate Bailly. We lamented together the dreadful consequences of the dangerous experiment which the French had attempted. All these chimerical projects of amelioration appeared to him very equivocal proofs of the greatness of the human mind. "If you wish to see it truly great," added he, "enter into the cabinet of Newton employed in decomposing light, or in explaining the system of the world."

Already for some time he had regretted not having listened to the advice of his friends, who at the commencement of our troubles had recommended him to seek an asylum, which it would have been so easy for him to find. As long as the revolution seemed only to threaten the pension which he enjoyed in France, he had neglected that consideration, out of curiosity to be upon the spot of one of those great convulsions which it is always more prudent to observe at a distance. "It was your own choice," said he several times to himself when he entrusted me with his regret. It was to no purpose that a special decree of the Constituent Assembly had ensured the payment of his pension. The decree was of no value, because the depreciation of the paper currency was sufficient to render it illusory. He had been named member of the *Board of Consultation,* appointed to examine and reward useful inventions. He had been appointed one of the administrators of the Mint. This commission offered him few objects to fix his attention, and could in no degree remove his apprehensions. It was again proposed to draw him to Berlin, and to restore him to his former situation. He had agreed to the proposal. Herault de Sechelles, to whom he had applied for a passport, offered him, for the greater security, a mission to Prussia. Madame La Grange would not consent to quit her country. This repugnance, which at that time he considered as a misfortune, was to him a source of fortune and of new glory.

The Normal School, of which he was named professor, but which had only an ephemeral existence, scarcely gave him time to explain his ideas respecting the foundation of arithmetic and algebra, and their application to geometry.

The Polytechnic School, the result of a happier idea, had likewise a more durable success: and among the best effects which it produced, we may place that of having restored La Grange to Analysis. It was there that he had an opportunity of developing those ideas, the germ of which was to be found in two memoirs that he had published in 1772, and the object of which was to explain the true metaphysics of the differential and integral calculus. To render these happy developements more easily understood, the professor associated himself with his pupils. It was then that he composed his Analytical Functions, and his Lectures on that Calculus, of which he published several editions.

It was then likewise that he published his treatise on the numerical solution of equations, with notes on several points of the theory of algebraic equations.

It is said that Archimedes, whose great reputation, at least with the historians, is founded upon the machines of all kinds, by means of which he retarded the taking of Syracuse, despised these mechanical inventions, on which he wrote nothing, and placed importance only in his works of pure theory. We may sometimes conceive, that the great mathematicians of our age entertained the same sentiments with Archimedes. They consider a problem as solved when it presents no analytical difficulty, when nothing remains to be done but differentiations, substitutions, and reductions, operations which require merely patience, and a certain dexterity derived from practice. Satisfied with having removed all the real difficulties, they concern themselves perhaps too little with the embarrassments which they leave to the calculator, and with the long labour necessary in order to make use of their formula, even after it has been suitably reduced. M. la Grange had more than once attempted to abridge the usual calculations.

The general resolution of algebraic equations is subject to difficulties which are considered as insurmountable; but in practice every determinate problem brings us to an equation, all the co-efficients of which are given in numbers. It would be sufficient, therefore, to have a sure method of finding all the roots of such an equation, which is called *numerical*. This was the object which M. la Grange proposed to himself. He analyses all the known methods, and shews their uncertainty and insufficiency. He reduces the problem to the determination of a quantity smaller than the smallest difference between the roots. This is something. We cannot too much admire the analytical skill displayed throughout the whole work. But notwithstanding all the resources of the genius of M. la Grange, we cannot conceal that the labour of his method is exceedingly great, and calculators will doubtless continue to prefer methods less direct indeed, but more expeditious. The author resumed this subject no less than four times. It is to be feared, that a commodious and general solution will never be discovered, or at least it must be sought for by other means. The author seems to have acknowledged this himself, as he recommends the method of M. Budan as the most convenient and elegant for resolving equations whose roots are all real.

The desire of multiplying useful applications induced him to undertake a new edition of the *Mecanique Analytique.* His project was to develope the most useful parts of it. He laboured at it with all the ardour and intellectual power which he could have applied at any period of his life. But this application occasioned a degree of fatigue, which threw him into a fainting fit. He was found in that state by Madame La Grange. His head in falling had struck against the corner of a table, and this shock had not restored him to his senses. This was a warning to take more care of himself. He thought so at first; but he was too anxious to finish his work. The first volume had appeared some time before his death. It had been followed by a new edition of his *Fonctions Analytiques.* So much labour exhausted him. Towards the end of March a fever came on, he lost his appetite, his sleep was uneasy, and his waking was accompanied by alarming swoonings. He perceived his danger; but, preserving his undisturbable serenity, he studied what passed within him, and, as if he were assisting at a great and uncommon experiment, he bestowed all his attention on it. His remarks have not been lost. Friendship conducted to his house on the 8th of April, in the morning, MM. Lacepede, Monge, and Chaptal, who took care to write down the principal points of a conversation which was his last. (We have scrupulously followed these notes, and the passages under inverted commas are faithfully copied from the manuscript of M. Chaptal.)

"He received them with tenderness and cordiality. I was very ill, my friends, (said he,) the day before yesterday; I perceived myself dying, my body became weaker, my moral and physical powers were gradually declining; I observed with pleasure the gradual diminution of my strength, and I arrived at the point without pain, without regret, and by a very gentle declivity. Death is not to be feared, and when it comes without violence, it is a last function, which is neither painful nor disagreeable." Then he explained to them his ideas respecting life, the seat of which he considered as spread over the whole body, in every organ and all parts of the machine, which in his case became equally feebler in every part by the same degrees. "A little longer, and there would have been no functions, death would have overspread the whole body, for death is merely the absolute repose of the body; I wished to die," added he with greater force, "I found a pleasure in it; but my wife did not wish it. I should have preferred at that time a wife less kind, less eager to restore my strength, and who would have allowed me gently to have finished my career. I have performed my task, I have acquired some celebrity in the mathematics, I have hated nobody, I have done no ill; it is now proper to finish."

As he was very animated, especially at these last words, his friends, notwithstanding the interest with which they listened to him, proposed to retire. He retained them, began to relate to them the history of his life, of his labours, of his success, of his residence at Berlin, where he had often told us what he had seen near a king; of his arrival at Paris, the tranquillity he had enjoyed at first, the anxiety occasioned to him by the Revolution, and how he had been finally rewarded by a powerful monarch, capable of appreciating his worth.

He had neither been ambitious of riches nor honour; but he had received both with respectful gratitude, and rejoiced at the acquisition for the advantage of the sciences.

La Grange had not lost all hope of cure; he believed only that his convalescence would be tedious. He offered, when he recovered his strength, to go and dine at M. Lacepede's country house with MM. Monge and Chaptal, and proposed to give them details respecting his life, which could be found nowhere else. These details are irretrievably lost. We do not even know to what he alluded, nor what he could have added to the second volume of the *Mecanique Analytique*, which was then in the press. We have just learned that the Countess la Grange has put into the hands of M. Prony the complete manuscript of the second volume, in which will be found important additions, and sections entirely written anew. By the care of an editor so skilful, and so devoted to the memory of the author, the philosophical world is sure of obtaining with the greatest ac-

La Grange, Joseph Louis.

curacy and dispatch what is wanting to complete the work, and perhaps even memoirs entirely new.

"During this conversation, which lasted more than two hours, his memory often failed him; he made vain efforts to recover names and dates, but his discourse was always connected, full of strong thoughts and bold expressions." This exercise of his faculties wasted the whole remains of his strength. Scarcely had his friends left him, when he fell into a fainting fit, and he died two days after, on the 10th of April, 1813, at three quarters past nine o'clock in the morning.*

M. la Grange was of a delicate but good complexion. His tranquillity, his moderation, an austere and frugal regimen from which he rarely deviated, prolonged his life to the age of 77 years, two months, and ten days. He was twice married: first at Berlin, in order to be on a footing with the rest of the academicians, none of whom were bachelors. He brought from Turin one of his relations. He married her, and lost her after a long illness, during which he had bestowed on her the most tender and unremitted care. When he afterwards married, in France, Mademoiselle Lemonnier, daughter of the celebrated astronomer of that name, he said to us, "I had no children by my first marriage; I do not know if I shall have them by my second; but I scarcely desire them." What he principally wished was an amiable companion, whose society might afford him some amusement during the intervals of his studies, and in this respect he was very successful. Madame la Grange, daughter, grandaughter, and niece, of members of the Academy of Sciences, was deserving of the name which he gave her. This advantage in her eyes making up for the difference of their ages, she soon felt for him the tenderest regard. He was so grateful that he could scarcely bear to be separated from her, and it was on her account alone that he felt any regret at relinquishing this life; and he was often heard to say, that of all his good fortune, that which he prized the most was having obtained a companion so tender and attached to him. During the ten days that his illness lasted, she never quitted him for a moment, and was constantly employed in recruiting his strength and prolonging his existence.

He loved retirement; but did not insist upon his young wife following his example. On her account he went out more frequently, and indeed his high situations obliged him to show himself in the world. It was often apparent that he continued the meditations in public which he had begun in his cabinet. It has been said that he was not insensible to the charms of music. In fact, in a numerous company he was not displeased at a concert. On one of those occasions I asked him what he thought of the music: "I love it," says he, "because it leaves me to myself. I listen to it during the first three measures, but I hear no more of it; I give myself up to reflection, nothing interrupts me, and in this way I have solved many a difficult problem." Hence the finest music must have been that during which he was inspired with the finest of his thoughts.

Though he had a venerable figure, he would never allow his portrait to be drawn. More than once, by a very excusable piece of address, persons have been introduced during the meeting of the Institute, to take a sketch of him without his knowledge. An artist sent by the Academy of Turin drew in this manner the outline from which was constructed the bust that was exhibited for some months in the hall of the Institute, and is at present in the library. A cast was taken of him after his death; and some time before, while he slept, a picture of him was taken, which is said to resemble him very much.

Gentle and even timid in conversation, he took a pleasure in asking questions, either to draw out others, or to add their reflections to his own vast knowledge. When he spoke, it was always in a tone of doubt, and his first words usually were, *I do not know.* He respected the opinions of others, and was very far from laying down his own as a rule. Yet it was not easy to make him change them. Sometimes he even defended them with a degree of heat, which continued to increase till he was sensible of some alteration in himself; then he immediately resumed his usual tranquillity. One day, after a discussion of this kind, M. la Grange having left the room, Borda remaining alone with me, allowed these words to escape him: "I am sorry to say it of a man like M. la Grange, but I do not know a more obstinate person." If Borda had gone away first, La Grange might have said to me as much of our associate, who was a man of excellent sense and considerable wit; but who, like La Grange, did not easily abandon those opinions which he had adopted after a mature examination.

A gentle and good-natured irony was often remarkable in the tone of his voice; but I never saw any person hurt at it; because it was necessary to have well understood every thing that went before to perceive the true intention of it.

Among all the master-pieces which we owe to his genius, his *Mecanique* is certainly the most remarkable and the most important. The *Fonctions Analytiques* hold only the second place, notwithstanding the fruitfulness of the principal idea, and the beauty of the developements. A notation less commodious, and calculations more embarrassing, though more luminous, will prevent mathematicians from employing, except in certain difficult and doubtful cases, his symbols and names. It is sufficient that he has proved the legitimacy of the more expeditious processes of the differential and integral calculus. He has himself followed the ordinary notation in the second edition of his *Mecanique.*

This great work is entirely founded on the calculus of variations, of which he was the inventor. The whole flows from a single formula, and from a principle known before his time; but the whole utility of which was far from suspected. This sublime composition includes all his other preceding labours which could be connected with it. It is distinguished likewise by the philosophical spirit which reigns from one end of it to the other. It is likewise the best history of that part

* The body of La Grange was deposited in the Pantheon, beside those of a number of unknown senators. We copied the following inscription from his stone tomb.

Joseph Louis La Grange
Senateur, Comté de L'Empire
Grand Officier de la Legion d'Honneur,
Grand Croix de L'Ordre Imperial de la Reunion.
Membre de L'Institut, et de Bureau des Longitudes
Né à Turin Departement du Po, le xxv Janvier 1736,
Decedé a Paris le x Avril 1813. ED.

of the science,—a history which could only have been written by a man perfectly master of his subject, and superior to all his predecessors, whose works he analyses. It forms a most interesting piece of reading, even to him who is not capable of appreciating all the details. Such a reader will at least find the intimate connection of all the principles on which the greatest mathematicians have founded their researches into mechanics. He will there see the geometrical law of the celestial motions deduced from simple mechanical and analytical considerations. From these problems, which serve to calculate the true system of the world, the author passes to questions more difficult, more complicated, and which belong to another order of things. These researches are only objects of pure curiosity, as the author announces, but they show the extent of his resources. Finally, we see there his new theory of the variations of arbitrary constant quantities of the motion of the planets, which had appeared with so much eclat in the *Memoirs of the Institute*, where it had shown that the author, at the age of 75, had not sunk from the rank which he had filled for so long a time in the opinion of all mathematicians."

GRANITE. See Mineralogy.

GRANSON, or Grandson, is the name of a small town in the canton of the Pays de Vaud. It is situated on the western bank of the lake of Neufchatel, about a mile from the foot of Mount Jura, which here bears the name of Thevenon. In approaching this town from Yverdun, it appears finely situated above the lake, and is particularly distinguished by its lofty chateau crowned with five or six towers. At the entrance to the town there is an old church, which does not appear to be used. The road passes through an arch surmounted with a tower and spire. The number of houses in 1814, when we passed through it, was 100. The opposite bank of the lake of Neufchatel is a lofty ridge finely wooded, with the grand range of the eastern Alps towering above it.

Granson is celebrated in the history of Switzerland, for the great battle which the Swiss gained over Charles the Bold, Duke of Burgundy, on the 3d of March 1476. The Duke's army, which was 6000 strong, occupied Granson, and the villages of Poissine, Corsalette, Giez, Vallieres, and Tuileries, and was defended on the right by the lake, and on the left by Mount Arnou, and on the east by the Thevenon, and by entrenchments on every other point. The battle began near Concise and the Chartreuse of Lalance, and terminated in the complete defeat of the Duke of Burgundy, who lost all his baggage and jewels. One of his diamonds, which was the largest then known, was found by a Swiss soldier, and sold for a florin to the curate of Montagny. This diamond was afterwards sold to Pope Julius II. for 20,000 ducats. Other two diamonds were found by the Swiss, one of which now forms part of the imperial treasury of Vienna, and the other belongs to the crown of France.

GRANTHAM, a town of England in Lincolnshire, is situated on the river Witham, near the ancient Roman road, called Ermine Street. The town, which is neat and clean, and contains many excellent houses, consists of four principal streets, called Westgate, Watergate, Castlegate, and Swinegate. The church, which is elegantly built of stone, consists of a nave, with spacious north and south aisles. It is lighted with handsome painted windows, and has been celebrated for the elegance of its spire, which consists of a quadrangular tower, containing three stories. At each angle of the parapet is an hexangular crocketted pinnacle, over which rises an octagonal spire, ornamented with crockets in the angles, and at these several distances encircled with windows having triangular heads. The height of the tower to the battlements is 135 feet, and from that to the top of the vane 138, making a total height of 273 feet. The nave, including the chancel and side aisles, is 116 feet long inside, and 80 feet broad. The church contains several handsome marble monuments. The front, which is octangular, is deemed a handsome specimen of ancient sculpture. The crypt under the aisle is used as a charnel-house, which contains great numbers of bleached sculls and bones. The vestry has been fitted up to receive the library of the Rev. Dr Newcome, a native of Grantham, who bequeathed it for the use of the town and neighbourhood.

The guildhall was rebuilt in 1787, and contains a large apartment for an assembly-room. The free-school was founded by Richard Fox, Bishop of Winchester, and in the present school-house Sir Isaac Newton studied the classics for several years. Without the Spittlegate is the Grantham Spa, a mild chalybeate, containing a small portion of aërated iron.

A canal has some time ago been cut from Grantham to the river Trent, a distance of 30 miles, with a fall of 148 feet to the river Trent. In 1798, £114,734 had been expended on the undertaking, and the tonnage then amounted to £4381. Corn and coals are the principal articles which it conveys. There is a race-course in the neighbourhood of Grantham, where races are held annually.

The following is the population of the borough and parish, according to the census of 1811.

Number of inhabited houses	673
Do. of families	776
Do. employed in agriculture	61
Do. in trade and manufactures	430
Males	1677
Females	1969
Total population	3646

See *Beauties of England aad Wales*, vol. ix. p. 766.

GRANTOWN. See Morayshire.

GRAPHOMETER, is a name sometimes given to instruments similar to goniometers, or to particular modifications of the theodolite. See Goniometer.

GRATZ, or Graz, is the name of an ancient town in the duchy of Styria, situated on the river Muehre. The town of Gratz is well built, the streets spacious and well laid out, and the houses, which are almost all of stone, are neat and commodious. The town, properly so called, is very small, and is surrounded with walls, ditches, and fortifications; but the suburbs are very large, and have lately increased with rapidity. The suburbs lie round the town like distinct villages, and are intermingled with gardens and vineyards. The citadel is situated within the town, on a very steep hill, about 600 or 700 feet above the level of the river, and has a well communicating with the Muehre. It was once a place of considerable strength; but it has been so much neglected, that in the year 1797, it offered no resistance upon the approach of the French. One of the principal objects of interest at Gratz is the imperial mausoleum of Ferdinand II. who was born in this town in 1578. The architecture is not in the best style; but its interior is richly ornamented with sculpture. The life of the Emperor Leopold is represented on the roof, in several emblematic paintings. On the top of the mausoleum is an observatory, which was once well furnished with astronomical instruments. The emperor's second son John Charles, and Mary Anne, Duchess of Bavaria, his consort, are buried along with Ferdinand in the circular chapel in the lower part of the mausoleum.

The assembly-room and the theatre, which are both under one roof, form a very extensive building. The arsenal, the house of the states, and the private residences of the Count Sauran, Loibel, and Wermbrand, are the other buildings deserving of notice. The castle, which was formerly the residence of the Dukes of Styria, is now the dwelling of the governors, and the seat of the regency. The house in which Bonaparte resided is very spacious, and is now shown as one of the curiosities of the town. Gratz is the see of a bishop, who generally resides at it about eight months in the year.

At no great distance from the town are several handsome villages, and the intermediate space between them and the suburbs is covered by country houses, large and small, farm houses, and detached cottages, so that the whole of this tract, when seen from the citadel, forms a rich and pleasing picture, and not only occupies a plain of above 18 square miles, but encroaches even upon the neighbouring hills. These hills are of a moderate height, and are partly covered with wood, and partly occupied with fields, vineyards, and meadows, up to their very summits. The population of Gratz has been stated in some statistical tables at 40,000; but it probably does not exceed 33,000. The population of the circle of Gratz, one of the five circles of Styria, is 296,424. East Longitude, according to accurate observations, 15° 27′ 15″, North Latitude 47° 4′ 9″. See STYRIA.

GRASSES. See AGRICULTURE *Index*.

GRAVE-HARMONICS, in Music. See HARMONICS, *Grave* and *Acute*.

GRAVE *Intervals*, according to Maxwell and Liston, are such as are lessened by the major comma; they are marked with the grave accent (\`), and are usually called by us, *Comma-deficient* intervals.

The GRAVE *Diesis* of Liston, $\mathcal{E}' = \mathcal{E} - c = 10\,\Sigma + m$, is the *Minor* COMMA, which see.

The GRAVE *Limma* of Liston, $\mathcal{S}' = \mathcal{S} - c, = 36\,\Sigma + f + 3\,m$, is the SEMITONE *Minor*, which see.

The GRAVE *Tone* of Liston, (p. 14.) $T' = T - c, = 93\,\Sigma + 2\,f + 8\,m$, is the TONE *Minor*, which see.

GRAVE *Fourth* of Holden, or bearing fourth, has the ratio $\frac{16}{21}$, $= 240.06077\,\Sigma + 5\,f + 20\,m$; and is the *Lesser false* FOURTH of the trumpet, which see.

GRAVE *Semitone* of Holden, or deficient semitone of the same author, (p. 341.) has the ratio $\frac{20}{21}$, $= 43.052904\Sigma + f + 4m$; its common log. $= .9788107,0093$; it is $+ 43.234017 \times \Sigma, = 3.92754 \times c, = .070389 \times$ VIII. M. Feyton mentions it as his *Semitone* E E※, and it is the *Semitone* of Ptolemy's Diatonicum molle.

GRAVEL. See MEDICINE.

GRAVER. See ENGRAVING.

GRAVESEND, is a town of England, in the county of Kent, built on a gentle declivity, on the banks of the Thames. It consists of several narrow streets, the best of which are the one on the great London road, and another at right angles to it, leading to the river. The church, which is dedicated to St George, was erected near the river between 1731 and 1733. It is built of brick, with stone quoins and cornices, and consists of a spacious nave and chancel, &c. The town-hall was erected in 1764, and has a poultry market below it. It is supported by six columns in front, and three arches behind. A neat little theatre, with a brick front and wooden sides, and a small projecting wooden portico, surmounted by a bust of Shakespeare, was built in 1808; and a handsome chapel in 1812, on the north side of the London road. A new wharf and crane were erected in 1767, and two batteries of 16 guns each have more recently been built, for the defence of the town. There is here a small manufactory for cables and ropes, and a yard for ship-building. Most of the outward bound ships are supplied with live and dead stock at Gravesend, and also with vegetables, for the cultivation of which about 80 acres of ground are appropriated. The town is often crowded with seamen and strangers, from the great quantity of shipping that usually lie at anchor in the channel near the town; and in summer many visitors are attracted by the accommodations of a new bathing-house, which was built by subscription in 1796. About 18 or 20 Gravesend smacks are employed in the cod and haddock fishing.

According to the population return for 1811, Gravesend parish contains

Number of inhabited houses . . .	525
Number of families	698

GRAY, THOMAS, an eminent English poet, was born at Cornhill in London, on the 20th of December 1716. His father, Philip Gray, was a money scrivener of the city. His mother, whose maiden name was Dorothy Antrobus, was, owing to the bad usage of her husband, obliged to apply to an eminent civilian for his advice as to a separation from him. Our poet, their fifth child, owed his life to the affectionate courage of his mother, who, by opening a vein with her own hand, removed a paroxysm which attacked him in his childhood. To this parent's exertions he was also indebted for his education; so that, considering the unhappiness of her life, and the gratitude which her son owed her, we can easily conceive the truth of what Mason tells us, that Gray always mentioned his mother's name with a sigh. Gray was educated at Eton, under the protection of Mr Antrobus, his maternal uncle, who was a fellow of Peterhouse, Cambridge. At that university, Gray was admitted a pensioner in his 19th year. During his first four year's residence there, he seems to have withdrawn himself from the severity of mathematical studies, while his enquiries centered in classical and modern literature.*

In 1738, he removed to the Inner Temple; but laid aside his legal studies to accompany Horace Walpole on a tour through France and Italy. An unhappy difference, however, with the blame of which Walpole has

* His productions during that period, were some Latin verses, entitled *Luna Habitabilis*, inserted in the *Musæ Etonenses*; a poem on the marriage of the Prince of Wales; and a Sapphic Ode to his friend West, both in Latin. A Latin version of a passage the *Pastor Fido*, and Fragments of Translations from Italius and Tasso.

candidly charged himself, parted the travellers at Reggio, and their broken friendship, in spite of a formal reconciliation, seems never to have been entirely cemented. Gray returned to London in 1741, in the same year in which his father died. His mother, with a very small fortune, had retired to live with her sister at Stoke, near Windsor. Mr Gray, therefore, found his patrimony too small to enable him to prosecute the study of the law; and though his mother and aunt would undoubtedly have contributed all in their power to assist him, he could not brook the idea of becoming a burthen to them. Yet such was his delicacy, that he could not peremptorily declare to his relations his resolution of abandoning his profession: he therefore pretended only to change the line of it, and accordingly he went to Cambridge, where he took a bachelor's degree in civil law. In the same year in which he graduated, (1742,) he lost his friend West, with whom his friendship had commenced at Eton, and had continued with unabated warmth after they had gone to different universities. The sorrow which the death of this amiable young man left upon our poet's mind, and the tenderness with which he honoured his memory, form one of the most interesting traits of his character. *

On his second return to Cambridge, he applied himself for about six years with the most intense assiduity to the perusal of Greek authors, and made himself a consummate scholar and critic in that language. In 1747, he appeared for the first time as an author, by the publication of his Ode on the prospect of Eton College, of which it would seem that at first little notice was taken. His Ode to Spring had been already written at Cambridge; and soon after the publication just mentioned, he sent to Dr Wharton of Durham, his poem on the Alliance of Education and Government, which he never pursued much farther. In 1749, he finished his Elegy, which he had begun seven years before, and which when published obtained immediate popularity.

In 1754 and 1755, he appears to have written his beautiful lines on the Pleasures arising from Vicissitude, his Ode on the Progress of Poetry, the Bard, and probably some of those fragments with which he seems to have amused himself, without much design of completion. About this period, he complains of listlessness and depression of spirits, which prevented his application to poetry; and from this time we may trace the course of that hereditary disease in his constitution, which the temperance and regularity of a whole life could not subdue. Next year, he left Peterhouse at Cambridge, where he had resided above twenty years, on account of some incivilities which he met with, and which Mason thus mentions. Two or three young men of fortune, who lived on the same staircase, had for some time intentionally disturbed him with their riots, and carried their ill behaviour so far as to awaken him at midnight. After having borne a considerable time with their insults, Gray complained to the governing part of the Society, and not thinking that his remonstrance was sufficiently attended to, quitted the College. He now removed to Pembroke Hall, which he describes "as an era in a life so barren in events as his."

In the July of 1757, he took his Odes to London to be published. "I found Gray (says H. Walpole) in town last week. He brought his two Odes to be printed. I snatched them out of Dodsley's hands, and they are to be the first fruits of my press." Although the genius of Gray was now in its firm and mature age, and though his poetical reputation was deservedly high, it is plain that these Odes were not favourably received. "His friends (he says) write to him that they do not succeed." Yet there were some better judges who admired them. Garrick wrote lines in their praise; and Warburton, while he bestowed his honest applause on them, shewed his indignation at those who condemned without being able to understand them. In this year Cibber died, and the laureatship was offered by the Duke of Devonshire, then Lord Chamberlain, to Gray, with a remarkable and honourable privilege to hold it as a mere sinecure. This offer he respectfully declined; and in a letter to Mr Mason, he gives some of his reasons for declining it. "The office itself (he says) has always humbled the possessor hitherto:—if he were a poor writer, by making him more conspicuous; and if he were a good one, by setting him at war with the little fry of his own profession: for there are poets little enough even to envy a poet laureat." In 1758, Gray describes himself "as composing for his own amusement the little book, which he calls a Catalogue of the Antiquities, Houses, &c. in England and Wales." † About this time, the study of architecture seems to have employed much of his time, in which his proficiency (as in every branch of study which he pursued) was accurate and deep. Early in the next year the British Museum was opened to the public, and he went to London to read and transcribe the MSS. which were there collected from the Cottonian and Harleian libraries. A folio volume of his transcripts was left among his papers. No other remarkable date occurs in the peaceful tenor of our poet's days, till in 1762, the professorship of modern history being vacant, by the advice of his friends, he applied to Lord Bute for the place through the medium of Sir Henry Erskine. He was refused, and the professorship was given to another; and "so (says Gray) I have made my fortune like Sir Francis Wronghead."

In the summer of 1765, he took a journey into Scotland to improve his health, which was then weak, and to gratify his curiosity with the romantic scenery of the north. He went through Edinburgh and Perth to Glammis castle, the residence of Lord Strathmore, where he stayed some time. Thence he took a short excursion into the Highlands, crossing Perthshire by Loch Tay, and pursuing the road from Dunkeld to Inverness, as far as the pass of Killikrankie. Then returning to Dunkeld, he travelled on the Stirling road to Edinburgh. In Scotland, his general shyness to men of letters was felt and complained of; but he formed an acquaintance with Dr Beattie, which was kept up by subsequent correspondence. The university of Aberdeen was disposed to confer on him the degree of Doctor of Laws; but he refused it, lest it should seem a slight to his own university. At Dr Beattie's desire, a new edition of his poems was published by Foulis at Glasgow, whilst Dodsley at the same time was printing them in London. In both these editions the long story was omitted, and some Welch and Norwegian fragments inserted in their place. To his Odes, Gray now found it necessary to add some notes; "partly," he says, "from justice to acknowledge a debt when I had borrowed any thing; partly from ill temper, just to tell the gentle reader, that Edward I. was not Oliver Cromwell, nor Queen Elizabeth the witch of Endor."

* Richard West was the son of the Lord Chancellor of Ireland, and grandson by the mother's side of the famous Bishop Burnet.

† It was printed and distributed among his friends by Mr Mason after his death.

Gray.

In 1768, the professorship of modern history became again vacant, and the Duke of Grafton, then in power, at the request of Mr Stonehewer, bestowed it on Gray. Soon after the Duke of Grafton was elected to the chancellorship of the university, and Gray wrote the Ode, that was set to music, on the occasion of his installation. "He thought it better that gratitude should sing than expectation." When this ceremony was past, he went on a tour to the lakes of Westmorland and Cumberland, from which his letters are written in a style of the most picturesque description. "He that reads his epistolary narrative," says Dr Johnson, "wishes that to travel, and to tell his travels, had been more of his employment."

In the April of 1770, he complains much of a depression of spirits, and talks of an intended tour into Wales, which took place in autumn; but not a single letter is preserved in Mr Mason's book on this journey.

In May 1771, he wrote to his friend Dr Wharton, just sketching the outline of his tour in Wales, and some of the adjacent country. This is the last letter that remains in Mr Mason's collection. He there complains of an incurable cough, of spirits habitually low, and of the uneasiness which the thought of the duties of his profession gave him, which, Mr Mason says, he had now a determined resolution to resign.* He mentions also different plans of amusement and travel which he had projected, but which unfortunately were not to be accomplished. Within a few days after the date of this letter he removed to London, where his health more and more declined. His physician Dr Gisborne advised free air, and he went to Kensington. There he in some degree revived, and returned to Cambridge, intending to go from that place to Old Park, near Durham, the residence of his friend Dr Wharton. On the 24th of July, however, while at dinner in the college hall, he was seized with an attack of the gout in his stomach. The violence of the disease resisted all the powers of medicine. On the 29th he was seized with convulsions, which returned more violently on the 30th, and he expired on the evening of that day in the 55th year of his age, sensible almost to the last, aware of his danger, and expressing no visible concern at the thought of his approaching death. His friend Mr Mason was at that time absent; and the care of his funeral devolved on the other executor Dr Brown, the president of Pembroke Hall, who saw him buried as he desired, by the side of his mother, in the church-yard of Stoke.

Gray, independently of his poetical character, sustained that of a first-rate scholar. He was perhaps (says the Rev. Mr Temple in the summary of his character) the most learned man in Europe. He knew every branch of history, natural and civil; had read all the original historians of England, France, and Italy; and was a great antiquarian. His skill in zoology was accurate; and in an interleaved copy of Linnæus which he had left behind, he had not only concentrated what other writers had written, but had altered the style of the Swedish naturalist into classical Latin.† Botany, which he had studied in early life, was also an amusement of his later years. In architecture he was eminently skilled; and in heraldry a complete master. To these accomplishments must be added his exquisite and scientific taste in painting and music. Walpole, in his History of Painters; Bentham, in his History of Ely; Pennant, in his Antiquities of London; and Ross, in his edition of Cicero's Familiar Epistles, were all respectively indebted to the learning of Gray.

Grazing || Great Scale.

As a man, the only blemish in his fine character seems to have been an excessive and half-affected delicacy. His genius as a poet is not of the most extensive, but of the highest cast. He is the only English poet who has divested elegiac poetry of its tædium; placed its sombrous images in a light of picturesque fancy; and given a tone of stedfast though subdued romantic feeling to the plain reflections of truth. Respecting his lyric poetry, the suffrages of criticism are certainly more divided. While by some his Odes have been extolled as the model of lyric poetry, they are esteemed by another school of taste to abound in over-wrought refinements, and obscurity of language. Our limits preclude dissertation; yet whatever justice there may be in the charge of obscurity which attaches to his Odes, the grandeur of thought, and the harmony of versification which pervade them, will for ever support their general merit, and their rank in the first rate productions of our language, and the muse of England will be for ever acknowledged to have expressed

A Pindar's raptures in the lyre of Gray.

See Mason's *Life and Letters of Gray*; and Mitford's *Life*. (*n*)

GRAZING. See AGRICULTURE.

GREAT INTERVALS, in music, are the same with *major* or *greater* intervals, and are marked with the large Roman numerals; as I. II. III. IV. &c. See MAJOR *Intervals*. But Mr Holden has used this term in a different way. See his *Great* SIXTH, and *Great* THIRD. (ϱ)

GREAT OCTAVE of the German theoretical writers on music, is that octave (or septave rather) which begins with C on the second leger line below the bass stave, and ends with B on the second line of that stave, or the *mi* of Guido. To this septave they exclusively apply the capital letters C, D, E, F, G, A, B, in their tablature or literal notation; and in the next octave above, the letters c, d, e, f, g, a, b are used. See SMALL OCTAVE, ONCE-MARKED, TWICE-MARKED, &c. *Octaves*; and Dr Callcott's *Musical Grammar*, Art. 34. (ϱ)

GREAT SCALE of M. Overend, approved by Dr Boyce, is a musical curiosity preserved in the library of the Royal Institution in London, in the Overend Manuscripts, vol. ii. pp. 113—133, 143—149, &c. It contains 86 notes within the octave, and was thought by the indefatigable musicians above named, to be capable of unravelling all the mysteries of the various ancient Greek scales of music, as Dr Pepusch had explained them diatonically, or by the use of the prime integers 1, 2, 3, and 5 only, in their ratios; but to the various systems of those, who, according to Dr Wallis, used the higher primes 7, 11, 13, 17, 19, &c. in the ratios, and in consequence have *decimals* of schismas, or Σ's in our notation; or of those, who divided the major *tone*, or the minor *fourth*, into *aliquot parts*, for obtaining their intervals or degrees, this great scale has no near relation. See CHROMATICUM, DIATONICUM, GENERA, and GREEK *Music*. (ϱ)

* He had held his professorship of history nearly three years without having begun to execute the duties of it, which consist of two parts; one, the teaching of modern languages; the other, the reading of lectures on modern history. The former he was allowed to execute by deputies; but the latter he was to commence in person, by reading a public lecture in the schools once at least in every term. He was at liberty to chuse his language, and chose the Latin, which Mr Mason thought somewhat injudicious; and although we do not find that he proceeded farther than to draw up a part of his introductory lecture, he projected a plan of very great extent, which, from his indolence and ill health, he would not in all probability have been able to execute. His death, however, prevented the trial.

† It is a circumstance not generally known, that he translated the Linnæan genera, or characters of insects, into elegant Latin hexameters.

GREECE,

Greece. Extent and situation.

THE most celebrated country of antiquity, was of very inconsiderable extent, and scarcely equalled in size the half of England. It is comprehended between 36° and 41° of North Latitude; and is bounded on all sides by the sea, except on the north, where it borders upon Epirus and Macedonia. Thessaly, its most northern province, is an extensive and fertile vale completely surrounded by lofty mountains; by Olympus on the north; by Ossa on the east; by Pindus on the west; and on the south by Oeta, at the foot of which lies the famous pass of Thermopylæ. The tract extending from the borders of Thessaly and Epirus to the Corinthian isthmus, contains the provinces of Acarnania, on the east frontier of which runs the river Achelous; Ætolia, bounded on the south by the sea, but defended on every other side by mountains almost impassable; Doris, wholly a mountainous country; Locris and Phocis, both of small extent, but full of fertile plains; Bœotia, a well-watered vale, bounded, except on the north-east, by the mountains Parnassus, Helicon, Cithæron, and Parnes; and Attica, a rocky and barren country, producing little grain or pasture, but yielding a variety of fruits, particularly figs and olives. The isthmus of Corinth, a mountainous ridge, at one place only five miles in breadth, leads farther south to the peninsula of Peloponnesus, which contains Achaia, a narrow strip of country on the northern coast, bounded on its inland frontier by a ridge of mountains, running along its whole extent from Corinth to Dyme; Argolis, a remarkably fruitful valley, included between two mountainous branches, stretching from Cyllene, the most northern of the Arcadian summits, and terminating, the one in the gulf of Argos, and the other at the promontory of Scylla; Elis, or Eleia, watered by the rivers Peneus and Alpheus, and less mountainous than the other provinces in Peloponnesus; Arcadia, the central state, consisting of a cluster of lofty mountains, the principal of which are Taygetus and Zarex; Messenia, the most level district in the peninsula, the best adapted for tillage, and most fruitful in general produce; and Laconia, traversed by two branches of the Taygetus and Zarex, between which runs the river Eurotas, watering several very fertile but not extensive vales.

Aspect, climate, and ...

The general aspect of Greece is rugged, but its climate is highly propitious; and both the summer heat and winter cold are preserved by the surrounding seas in an equable state of temperature. Some of its mountains contain valuable metals; others are composed of the finest marble; and many are covered to a great extent with a variety of useful timber. Its central plains produce corn, oil, and wine; its valleys afford the richest pasturage; and its long winding coast abounds with excellent harbours. The great variety in its surface gives occasion to considerable diversity both of produce and of climate in every season of the year. It has been remarked, as a peculiar feature in the topography of the most ancient cities of Greece, that every metropolis possessed its citadel and its plain; the former as a place of refuge in war, and the latter as a source of agriculture in peace. The most remarkable of its towns were,—in THESSALY, Gomphi, Metropolis, and Scotussa, north of the river Peneus; Atrax, Larissa, the city of Achilles; Magnesia, and Aphetæ the port of the Argonauts; Heraclea, named from Hercules, who is said to have thrown himself into the pile on the summit of Oeta, in its vicinity; Lamea and Hypata, on the banks of the Spercheus; Thaumaci, Halos, and Pthia, the country of the Myrmidones, Demetrias, Pheræ, Pharsalia, on the banks of the river Enipeus.—In ACARNANIA, Amphilochicum, Stratus, and Actium, at the bottom of the Ambracian Gulf.—In ÆTOLIA, Chalydon, Chalcis, on the river Evenus; Thermæ, Lysmachia, Canope, Naupactus, Erythræ, and Antirrhium.—In DORIS, Cytinium, and three smaller towns of little note.—In LOCRIS, Amphissa, Opus, Cnemis, Narix, the native country of Ajax, Thronium, Nicæa.—In PHOCIS, Delphi, accounted the centre of Greece; Elatea, on the river Cephissus; Crissa, and Anticyra.—In BŒOTIA, Thebes, near the river Asopus; Platæa, Leuctra, Orchomenos, Haliartus, Coronea, Cheronea, Lebadia, Thespiæ; Ascra, the birth-place of Hesiod; Aulis, Delium, and Tanagra.—In ATTICA, Athens, with its harbour Piræus; Phalereus and Munichia, Marathon, Phylæ, and Decelia.—In MEGARIS, Megara, Eleusis, and Nycæa.—In ACHAIA, Corinth, Sicyon, Patræ, Ægium, Dyme, and Pallene.—In ARGOLIS, Argos, on the river Inachus; Mycenæ, the city of Agamemnon; Epidaurus, Nemea, and Tiryns.—In ELIS, Elis, on the river Peneus; Olympia, and Pisa.—In ARCADIA, Megolopolis, Tegea, Mantinea, and Pallantium.—In MESSENIA, Messene, Stenyclarus, and Pylos, the city of Nestor.—In LACONIA, Sparta, on the river Eurotas; Gythium, Selasia, Helos, Amyclæ.

Periods of Grecian history.

It has been customary with most writers on the subject of Greece, to distribute its history into distinct periods or epochs; but few authors happen to agree in fixing upon the same points of division. If we proceed upon the principle of marking the degree of credibility in its records, there will then be only two portions to be contrasted; the one the period of uncertain, and the other that of authentic history.

The *first*, " the period of uncertain history," extends from the earliest accounts of the country, to the commencement of the first war with Persia, in the year B. C. 490; a period very variously computed, but, according to the lowest estimate,* comprising a space of nearly 700 years. Of this large portion of time, there are no documents really deserving the name of history; and the accounts which have been given of its events, were drawn up by writers who lived long posterior to the transactions of which they treat, and were compiled from scattered records and fragments, of which there are no sufficient data to ascertain the authenticity. Of this period, however, there may be specified four distinct subdivisions, which are marked by some peculiar historical features. The first, reaching from the earliest accounts of Greece to the commencement of the Trojan war, B. C. 900; a period of 200 or 300 years, and which, without scruple, may be termed " the fabulous age." The second, reaching from the expedition against Troy to the death of Homer, B. C. about 800; a period of at least 100 years, generally called " the heroic age,"

* The Chronology of Sir Isaac Newton.

of which the only history is contained in the poems of the Iliad and Odyssey. The third, reaching from the death of Homer to the death of Lycurgus, B. C. about 700; a period of another 100 years, which may be denominated "the era of revolutions," and of which scarcely any species of history exists. The fourth, reaching from the time of Lycurgus to the first invasion of Greece by Persia, B. C. 490; a period of 210 years, which may be termed "the era of traditionary history," possessing a considerable degree of credibility.

The *second*, "the period of authentic history," extends from the first invasion of Greece by the Persians, B. C. 490, to its final subjugation by the Romans, B. C. 146; a period of 341 years, the history of which, luminous and connected beyond that of any other portion of Pagan antiquity, has been recorded by writers of the greatest ability, who were contemporary with the events which they relate, and in which many of them bore a distinguished part. These writers were all Greeks, and some degree of national partiality may be suspected to have guided their narrations; but their number, and their connection with different states, renders them in some measure checks upon one another. This period, also, may be subdivided into four portions, distinguished rather by political than historical characteristics. The first, reaching from the Persian invasion, B. C. 490, to the commencement of the Peloponnesian war, B. C. 430; a period of 60 years, the era of Grecian unanimity and triumphs. The second, reaching from the beginning of the Peloponnesian war, to the accession of Philip of Macedon, B. C. 360; a period of 70 years, the era of civil wars and intestine commotions among the states of Greece. The third, reaching from the accession of Philip to the death of Alexander the Great, B. C. 323; a period of 37 years, distinguished by the entire ascendancy of Greece over Persia, and its own partial subjection to the foreign dominion of Macedonia. The fourth reaching from the death of Alexander, to the final subjugation of the Grecian states by the Romans, B. C. 146; a period of 177 years, during the greater part of which the destinies of Greece were directed by foreign influence, and were placed successively under the protection of Macedonia, Egypt, and Rome.

First inhabitants of Greece.

The early history of Greece, like that of most other countries, is involved in obscurity and fable. Its original inhabitants, generally considered as the descendants of Javan, son of Japhet, appear to have led a migratory and savage life, sheltering themselves in caves and huts, feeding upon acorns, clothing themselves with skins, and gradually associating in small bodies for their mutual support against the wild beasts of the woods and mountains, by which they were everywhere surrounded. Many different wandering hordes, of whom the Greek writers give no satisfactory account, seem to have successively overrun the country; sometimes mixing with the ancient inhabitants, and sometimes driving them from their possessions. These, in their turn, expelled and plundered others; and a state of petty piratical warfare characterised the first ages of every Grecian settlement. These plundering excursions became so general, that all the shores, both of the continent and the islands, are said to have been deserted, and the lands cultivated only at a considerable distance from the sea. From this state of barbarism, the inhabitants

Visited and civilized by foreigners.

of Greece began to emerge at an earlier period than those of any other country in Europe; and this advantage they seem to have owed entirely to their communication with the civilized nations of the East. Its islands were visited by the Phenician navigators, who introduced the knowledge of the precious metals. A people, named Pelasgi, apparently from Asia, extended their dominion over all the northern parts of the country; and various contemporary colonies from Egypt, (of whose migration the cause is not known, but for which the supposition of some political revolution may easily account,) appear to have founded the principal Grecian states.

Crete.

The island of Crete, which seems to have been occupied, and its inhabitants enslaved by some of these adventurers, first attained a considerable degree of civilization under Minos, above 1000 years before the Christian era;* and became the general fountain of legislation and jurisprudence to the other settlements. Of these, Sicyon and Argos are considered as the most ancient, and as having been founded nearly at the same time, about 80 years before the reign of Minos, and 1080 before the Christian era.

Sicyon.

Sicyon, till a very late period, had little influence in the affairs of Greece; and its early history is as uninteresting as it is uncertain. Ægialeus is mentioned as its first king; but the list of his successors rests on no authority, and is not worthy of being transcribed. It seems to have been soon eclipsed by the neighbouring

Corinth.

state of Corinth, which was noted, even in the days of Homer, for its commercial wealth. Among its early princes are numbered Sisyphus, Glaucus, and Bellerophon, whose exploits present a subject for poetry rather than materials for history.

Argos.

But the city of Argos, if not actually the oldest in Greece, was the first that acquired political eminence; and was founded by Inachus, or by his son Phoroneus, who is considered as having been the contemporary and brother of Ægialeus, the first king of Sicyon. Io, the daughter of one of the Argive princes, having been carried away to Egypt, her descendant Danaus, afterwards arriving at Argos, claimed the sovereignty, and extending his power over the whole of Peloponnesus, the inhabitants (called Pelasgi before his arrival) received from him the name of Danai. Perseus, one of his descendants, and the first Grecian who is celebrated as a warrior, founded the city of Mycenæ, which became for some time the capital of Argolis; but soon afterwards lost its pre-eminence.

Mycenæ.

Contemporary with Perseus was Pelops, son of Tantalus, King of Phrygia, who, being driven from his native land by unsuccessful war, came with immense treasures into Greece; and, being accompanied by a band of Achaians from Thessaly, established himself in Laconia. Marrying Hippodameia, daughter of the chief of Pisa, he succeeded to the sovereignty of that territory; and, by his numerous family connections, as well as able conduct, acquired so much influence throughout the peninsula, that it derived from him the name of Peloponnesus. His daughter Astydameia was united in marriage with Sthenelus, the son of Perseus; and their son Eurystheus was the prince so often mentioned in Grecian fable as the rival and persecutor of his kinsman Hercules. Pursuing the children and adherents of that deceased hero into Attica, he was slain in battle, and succeeded in the sovereignty of Argos by his uncle Atreus, who, uniting in his person the claims of both the houses of Perseus and Pelops, extended his authority over all Peloponnesus, and transmitted the Argian sceptre in its greatest glory to his son or grandson Agamemnon.

Lacedemon.

Lacedemon, or Sparta, concerning the origin of which there is no certain memorial, had

* The chronology of Sir Isaac Newton is here followed.

Greece.

now become distinguished under its sovereign Tyndareus, whose sons Castor and Pollux died in the prime of life, and whose daughters, Clytemnestra and Helen, were given in marriage to Agamemnon and his brother Menelaus. Through these princesses, the domains of Tyndareus fell to the two sons of Atreus; and Menelaus was invested with the immediate command of the Lacedemonian territory.

Thessaly.

Of the provinces without the peninsula, Thessaly (next to Crete, the most ancient scene of Grecian story,) first became celebrated for the wisdom of its princes, who extended their sway at an early period as far as the Corinthian Isthmus. In that country, always famous for its horses, the Centaurs were first known, who are supposed to have been a band of foreign adventurers of superior attainments to the more southern Greeks of their time. From a port in Thessaly, sailed the expedition of the Argonauts under Jason, who may be considered as merely the leader of one of the most considerable piratical expeditions, which had hitherto been undertaken. Bœotia, though a country originally subject to earthquakes and inundations, yet, from its great fertility, attracted at an early period the attention of adventurers; and a Phenician colony under Cadmus is understood to have founded its principal city of Thebes. The numerous fabulous stories relating to its history, comprehending the adventures of Bacchus, Amphion, Amphitryon, Hercules, Laius, Œdipus, Eteocles, and Polynices, serve at least to prove that it must soon have become a flourishing and powerful state; and the war, which it sustained against seven united potentates, the subject of the *Thebaid* by Statius, presents the first instance of a political league, and a regular warfare, recorded in the annals of Greece. Ætolia, though not inferior to the adjoining countries in early civilization, and though sufficiently celebrated in the histories of its heroes Tydeus, Meleager, and others; yet, from the dangers of its seas, being much excluded from the intercourse of more civilized nations, made little comparative progress in political improvement, and, for several centuries even after the Trojan war, had little communication with the rest of Greece. Phocis, Doris, and Locris, also afford no materials for history at this early period; and the only remaining state, whose origin is worthy of being narrated from tradition, is that of Attica. The first king of this country is said by some to have been Ogyges, whose name, however, is not mentioned by the older Greek historians, and who is conjectured at the utmost to have been only the leader of a band of Bœotians; who, having been driven from their own country by an inundation, had taken refuge in the adjoining districts of Attica. The first, at least, who introduced regular government and the arts of civilization among the Athenians, was Cecrops, the leader of a colony from Egypt, who introduced the worship of the goddess Athena, or Minerva; and thus gave a name, if not also a beginning, to the city of Athens. He is considered as the founder of the celebrated court of Areopagus; and, in consequence of his wise institutions, aided by the natural security of the country from invasion, strangers were attracted, population increased, and civilization made more rapid progress than in any other province of Greece. Of his successors, little is recorded even by tradition, till the time of Ægeus, contemporary with Minos, King of Crete, and the father of the renowned Theseus, whose romantic history bears no inconsiderable resemblance to that of the Gothic knight-errants, and whose wise measures as king of Athens laid the foundation of its future greatness. By the united influence of persuasion and authority, he consolidated, in one well-regulated government, the independent districts in Attica, and endeavoured to secure the stability of his improvements, by procuring the approbation of the Delphic oracle. Though well entitled, by his political regulations, to be ranked among the most illustrious patriots of ancient times, he is nevertheless represented, in his future history, as having forfeited the esteem of his subjects, and having at last died in exile. After him, the sovereignty of Attica was held by Menestheus, a descendant of the royal family, and the leader of the Athenian troops in the Trojan war.

Council of the Amphictyons.

These petty states, each of which was governed by its respective sovereign, and all of them independent of one another, were continually at war among themselves, and exposed to the incursions of foreign barbarians. To obviate these evils, and to secure, as far as possible, the general tranquillity, an assembly was formed of deputies from the different countries of Greece, whose business it was to decide all disputes between the states of which the association was composed, and to concert measures of defence against their common enemies. This was called the council of the Amphictyons, from its supposed founder Amphictyon, one of the sons of Deucalion, and king of Attica; but its original constitution, and the period of its commencement, cannot be satisfactorily ascertained. It is supposed by Sir Isaac Newton to have commenced about a century before the Trojan war. Besides its primary object of establishing a kind of national law among the Greeks, its attention was principally occupied in managing the concerns of the Delphian oracle. But, though its decrees were respected, its power was not very efficacious. It contributed to restrain the violence of wars, but was not able to prevent their frequent occurrence. It derived its greatest consequence from the increasing fame of the oracle at Delphi; and the superintendence of the religious institutions of Greece became ultimately its principal office. It is not mentioned by Homer; but its existence seems to be implied in the ready union of the Grecian states against Troy. See Amphictyons, Cadmus, &c.

Origin of the Trojan war.

Frequent piratical excursions appear to have been carried on between the inhabitants of the eastern and western coasts of the Ægean Sea; and the rape of Helen by Paris the son of Priam may be considered, according to Herodotus, as an act of retaliation for some similar injury received from the Greeks by the Trojan people. An outrage, however, so nearly affecting one of the greatest princes of Greece, and aggravated by a breach of the rights of hospitality, was considered as demanding the united vengeance of the Grecian chiefs; and the hope of returning home enriched with the spoils of Asia, presented no small incentive to the expedition. The extensive influence also of Agamemnon king of Argos, and brother of the injured Menelaus, urged on the general confederacy; and, under his supreme command, the chosen warriors of every Grecian state, from the southern extremity of Peloponnesus to the northern regions of Thessaly, assembled at the port of Aulis in Bœotia. The fleet, consisting of 1200 open vessels, conveyed to the Trojan coast, an army of 100,000 men, who speedily compelled the enemy to take refuge within the walls of their city; but, unable to surmount its strong and well defended fortifications, they attempted its reduction by excluding every kind of succour and supplies. Obliged, however, to detach large bodies from their army to procure subsistence for themselves, they were unable to prevent the Trojans from again taking the field, and receiving every requisite relief to their wants. In this way, the siege was prolonged for the space of ten years: and even at the last, the house of Priam was not overthrown without the aid of stratagem and treachery.

Its disastrous effect

But, while the allied Greeks triumphed over Troy, it was to each of them a victory dearly purchased. Few of the princes, who witnessed the successful termination of their expedition, were permitted to enjoy in their native country the renown and repose, which their exertions had earned; but, having made no provision for the administration of their affairs during their absence, were either murdered at their return by some usurper of their power, or compelled to reimbark with their adherents, in quest of distant settlements.

Flourishing state of Athens.

The Athenian state, which seems to have made the nearest approach to a settled government, suffered least by the absence of the commander of their army; and regular magistrates supplied the place of their chief. In this city, Orestes, the son of Agamemnon, obtained an asylum; and, after remaining seven years in exile, found means to avenge his father's death, and to recover the throne of Argos, which he held with great power and reputation till his death. See ACHILLES, AGAMEMNON, AJAX, HOMER, TROY, &c.

Here terminates the history contained in the writings of Homer, who seems to indicate, that the concluding events which he records were within the reach of his own memory; and whose works, in fact, contain almost the only materials for an account of the heroic age. He affords at least the best and most authentic view of the political and domestic state of the Greek people, during the period which preceded his death; and to his poems we may refer for a description of the religion, government, arts, and manners of the early Greeks.

Customs and manners of the early Greeks.

The ancient Pelasgian inhabitants of Greece are said by Herodotus to have prayed and sacrificed to gods, to whom they gave no name or distinguishing appellation; and the works of Hesiod still more clearly prove that they drew their first notions on the subject of religion from Oriental traditions.

Religion.

Their future system of polytheism seems to have been imported by the Egyptian colonists; but to the principal divinities thus introduced, their own lively fancy soon added a multitude of other imaginary beings, presiding over every mountain and river, every season and production; and these were arranged by Hesiod and Homer into a kind of system of the most extravagant and inexplicable description. There is neither omnipotence nor omnipresence among the attributes which the last mentioned poet ascribes even to the father of the gods; neither perfect goodness nor perfect happiness in the heaven, which he assigns as their residence. An incomprehensible power, denominated Fate, is represented as directing all events; and it seems to have been the principal office of Jupiter to superintend the execution of its decrees. Idolatry, as denoting the worship of visible objects, was at this period unknown; and even temples appear to have been rare. Prayers were addressed as to invisible deities; and sacrifices, the only duty which they seem to have been considered as expecting from their worshippers, were offered upon altars erected in the open air. A few crimes are sometimes denounced as exposing to the vengeance of the gods, but morality in general finds very little support in the religion of this period. Soothsayers, who professed to foresee future events, were sufficiently numerous; but fixed oracles had not yet attained any extensive celebrity. The salutary doctrine of the immortality of the soul, and a future state of rewards and punishments, was taught in those days; but the ridiculous absurdities, with which it was clothed, tended, when men had learned to despise the fables, to throw contempt also upon the momentous truth which they had veiled.

Government.

The form of government was monarchical, and in some degree hereditary; but the authority of the kings was extremely limited, and always controuled by established customs. It was the universal prerogative of the prince to exercise the judicial power, to superintend the institutions of religion, to command the armies, and to direct the ordinary business of the community; but, in any extraordinary or very important measure, he was required to consult, not only a council of the principal men, but also an assembly of the people; and a high degree of personal strength and accomplishments seems to have been always necessary to maintain his authority.

Letters & writing

It is generally admitted that letters were introduced into Greece from Phœnicia by Cadmus the founder of Thebes, at the lowest calculation 1045 years before Christ; but it is equally ascertained, that the use of writing had not become common till more than 400 years after his time; and nothing, in the whole history of the ancient Greeks, is more difficult to be explained than the high state of excellence, which the language had attained in the days of Hesiod and Homer, while so little of it could have been reduced to writing.

Poetry

In the absence of letters, poetry seems to have been invented, or at least to have been originally employed for the assistance of memory. Laws, among the early Greeks, were always promulgated in verse, and frequently sung in public. Morality was taught, and history related in the same manner. All, who wished either to instruct or amuse their fellow-citizens, were thus necessarily poets; and they who possessed so important a talent, were considered as sacred characters, favoured and inspired by the gods.

Music

The first poetry of the Greeks was uniformly accompanied with music, and both stringed and wind instruments are mentioned by Homer. But, there are no means of ascertaining its peculiar features; and, however powerful may have been its effects, it appears to have been extremely simple and inartificial in its composition.

Agriculture

Their agriculture appears to have been carried on with considerable regularity; and the practice of manuring, as well as ploughing and sowing, is expressly mentioned by Homer. Wine was made from the vine, and oil from the olive; but the principal source of wealth was found in pasturage; and cattle were made, in place of coin, the usual measure of the value of commodities.

Commerce.

Commerce was chiefly carried on by an exchange of articles; and the foreign trade of the Grecian cities was principally in the hands of the Phenicians. There were Greeks, indeed, in the days of Homer, who pursued a kind of coasting traffic among themselves; but the profession of a merchant for gain was not held in much estimation, and was less respected than even that of pirate.

Navigation.

Their navigation was very imperfect; and they used oars more frequently than sails. Their ships had no decks; and the largest that went to Troy, contained only 120 men. Anchors were unknown; and the vessels, when in port, were either moored to large stones on the shore, or were actually drawn out of the water upon the beach. The early Greeks, in short, were rather boatmen than seamen; and, indeed, to this day, the skill of the navigator is of little avail in their narrow and tempestuous seas.

Science

They had little knowledge of astronomy; and marked the length of the year by 12 revolutions of the moon, reckoning the months to consist of 29 and 30 days alternately. But, in progress of time, they learned to fix the seasons more correctly by the rising and setting of the stars; and had arranged them in constellations, much in the same manner, and with the same names as at the present day. They considered internal diseases as inflicted by the immediate hand of the Deity, and as therefore beyond the reach of human skill. Their medical art was thus restricted to the practice of surgery, which was held in high esteem; but which seems to have extended no farther than the extraction of a weapon, or any other extraneous body from a wound, and the application of a few simples to stop a hæmorrhage, or to assuage inflammation. Their architecture was more improved than most other arts; and Homer speaks of houses built of polished stone, with large and numerous apartments. Other mechanic arts were not exercised as distinct trades; and even princes were frequently their own carpenters. Ornamental works, however, in metals, wood, &c. were not uncommon in those days; but the greater part of the trinkets and more luxurious utensils in use among the early Greeks appear to have been procured from the Phenician merchants. Their principal study, and most constant practice, was the art of war; and they seem to have improved considerably upon that tumultuary warfare, which is generally practised among barbarous nations. Their infantry were commonly heavily armed with helmet, breastplates, greaves, and shield; and were regularly drawn up in close ranks or phalanges, marching in steady silence under their respective leaders. Cavalry were not yet employed in their battles; but chariots were generally used by the chiefs, as the means of conveying them more rapidly along the line, and of annoying more effectually a flying army. The skirmishing of the commanders, however, in front of the troops, and their mixing with the soldiers in the heat of the fight, left little room for the exercise of generalship; and their fashion of stopping in the midst of the action to strip the slain, sufficiently marks their want of military discipline and skill. They encamped with much regularity, sleeping under their cloaks, or sheltering themselves with huts; and generally fortified their post, when exposed to the attack of a powerful enemy; but, though a small guard might be placed at an out-post, they were unacquainted with the important precaution of stationing and relieving a line of sentinels. In the frequency of war, courage was regarded as the highest virtue; and the manners of the early Greeks were decidedly barbarous. Quarter was rarely granted to a fallen enemy; and the capture of a city was succeeded by the massacre of all the men who were able to bear arms, and by the captivity of the women and children. The spirit of hospitality, however, was generally diffused, and tended often to alleviate the miseries of military devastation. Women appear, as well as men, to have united the highest rank with the humblest occupations, but evidently enjoyed a greater degree of influence and freedom, than has been usual in subsequent ages among oriental nations. There has been supposed to exist, a striking resemblance between the manners and sentiments of the Greeks in the heroic age, and those of the Gothic nations of Europe, except that the latter displayed more generosity in war, and gentleness towards the female sex, than their ancient prototypes.

The period immediately succeeding the Trojan war, affords few lights to history, and is even involved in deeper obscurity than the heroic age. Supposing Homer to have lived within a century, or rather half a century of the Trojan war, his works may be allowed to supply a tolerable record of the previous events best authenticated by tradition, and of the most important occurrences which took place during his own life. His history terminates with the accession of Orestes to the throne of Argos; and total darkness thenceforth rests upon the historian's path, relieved only by a few uncertain glimmerings, till the first Persian invasion of Greece. About 80 years after the destruction of Troy, a great revolution took place, which dissipated ancient traditions, stopped the progress of civilization, and changed the governments, and even the population, of most of the Grecian states. The descendants and partizans of the celebrated Hercules had found a refuge in Doris from the persecutions of Eurystheus; but had never ceased to prefer their claims to the kingdom of Argos, and even to the dominion of all Peloponnesus. Twice had they attempted, without success, to make their way through the isthmus. But, at length, the great grand-son of Hyllus, the oldest son of Hercules, crossed the Corinthian gulf with a powerful armament, and speedily overran the whole peninsula, with the exception of Arcadia and Achaia, where Tisamenus, son of Orestes, made a resolute and successful stand. All the rest of the conquered country was divided among the princes of the Heraclides, and their allies from Doris and Ætolia; and the greater part of the old inhabitants either emigrated from the oppressions to which they were subjected, or were reduced by the invaders to a state of servitude. A new distinction of the Grecian people was the consequence of this revolution. The Pelasgian name, which had prevailed on the continent, and the Lelegian in the islands, had, at an early period, but for reasons not clearly ascertained, given place to the Æolian and Ionian; the latter designation being applied principally to Attica with its colonies, and the former to all the rest of Greece, both within and without the peninsula. Out of these two, four distinctions of the Grecian people arose, after the irruption of the Heraclides. In all the immediate establishments and distant colonies of these invaders, the Doric name and dialect prevailed. The Athenians rose to such pre-eminence, as to give rise to a new designation, namely, the Attic. Excepting them and the Megarians, who retained the Doric name, all the other Greeks, without the isthmus, claimed Æolic origin; and the Ionian name and dialect was retained only by those Ionians who had migrated to Asia and the islands. Except in the rugged province of Arcadia, nothing remained unaltered; and the Dorian invaders brought every thing back to that ruder state, in which they had lived among their native mountains. Disputes soon arose among these allied princes, respecting the partition of the conquered countries. Internal dissensions, occasioned by their turbulent subjects, were continually raging in their respective governments. The enterprising Arcadians seldom suffered them to rest from external hostilities. And, by all these concurring causes, Peloponnesus was rapidly falling back into that state of anarchy and barbarism, in which it had been before the time of Pelops and Hercules. Nothing tended so effectually to resist this tendency to disunion and turbulence, as the revival and regular establishment of the public games, by Iphitus, sovereign of Elis. These athletic games, as is evident from the writings of Homer, had been occasionally celebrated under the superintendence of different princes; and at the funerals of eminent men, many traditions prevailed,

that Eleia in Peloponnesus had frequently been the chosen scene of these contests, and the resort of princes from various parts of Greece. Iphitus, therefore, having procured a favourable response from the oracle at Delphi, established a regular festival for that purpose, to be held every four years at Olympia, in the territory of Elis. Solemn sacrifices were to be offered to Jupiter and Hercules, and games celebrated in honour of these divinities. In these games, all Greeks were free to partake; and, for a certain period, before their commencement, as well as after their conclusion, a general armistice was ordained to take place. The territory of Eleia particularly, was to be at all times counted sacred, and secured from every hostile encroachment. This Olympian meeting, instituted about half a century after the return of the Heraclides, served as a common capital to the Grecian people, and contributed more effectually than could possibly have been anticipated, to the advancement of arts, science, and civilization, in all the different states.

General abolition of monarchy.

A general revolution in the government of every state, began about the same period to take place, from causes very imperfectly known. The republican spirit, which seems to have existed in all of them, even under their early monarchical constitutions, acquired so much strength, that, in a few ages, monarchy was every where abolished, and the name of tyrant applied to all who attempted its support, even under the mildest form. For a sketch of the peculiar political institutions, and separate history of the several states of Greece, we must refer to their respective names, which form distinct articles in this work, especially to ATHENS and LACEDEMON; and shall, at present, restrict our attention to those more extensive events which affected the Grecian people in general. The first important occurrence of this description which communicated a new and powerful spring to the genius of the Greeks, and greatly influenced their future progress in every path of art and science, was the unparalleled struggle which they so long and successfully maintained with the whole power of the Persian empire. See OLYMPIC GAMES.

Power of Persia.

In the reign of Darius, the son of Hystaspes, the power of the Persian arms was extended on every side of that vast empire. All was subdued to the west, as far as Macedonia. Amyntas, the king of that country, acknowledged subjection to the Persian monach; and the Grecian islands soon began to feel his ambitious and overwhelming influence. Cyprus, Samos, Lesbios, Chios, and most other islands on the Asiatic coast, were either persuaded or compelled to admit his supremacy. Most of them, according to the uniform policy of the Persians, were nevertheless allowed to retain their own magistrates and laws. One of their own nation was appointed to preside as governor; and this person, whatever was his personal character, was always, from his official situation, denominated Tyrant by the Greeks. Athens itself, hard pressed by the powerful alliance, which the Lacedemonians had formed against them, had begun to solicit the protecting aid of Persia; but Artaphernes, satrap at Sardis, having patronised the pretensions of the tyrant Hippias, whom they had driven from his power, they were filled with detestation of the Persian name, and the more readily consented to assist the Ionians in Asia, who had revolted against the authority of Darius.

Origin of the war with Greece.

These, however, were speedily reduced; and the Persian monarch, in order to punish Athens and Eretria, who had given aid to the insurgent states of Asia, or rather in prosecution of his ambitious views for the enlargement of his dominions, sent a powerful army into Greece under the command of his son-in-law Mardonius. Darius had previously dispatched heralds to each of the Grecian states, demanding earth and water as an acknowledgment of his supremacy; and, if wholly independent of each other, the greater part would probably have soon submitted to the Asiatic yoke.

United ... of Greec...

But, happily for Greece, its little commonwealths were at that period so united together by reciprocal treaties and obligations, and especially by a formal confederacy under the Lacedemonians, that a kind of general tribunal existed for the punishment of treachery or cowardice, which enabled them, in a great measure, to act as one nation. Macedonia, which had formerly paid homage, was more effectually subdued, and compelled to pay tribute to the Persian king. Thebes, by the influence of a faction, and a few other cities, particularly Ægina, made submission to his demands; but the Lacedemonians and Athenians were so indignant at the requisition of Persia, that, forgetting the law of nations and of humanity, they put the heralds to death with the utmost ignominy and barbarity. The Athenians, who had been at war with the Æginetæ, and were thus the more excited to adopt opposite measures to their hostile neighbours, accused them at Sparta of desertion from the common cause of Greece; and the chief persons of that state were instantly ordered to be seized as traitors to their country.

Progress of the Pe... army.

Little progress was made by the invading army. The Persian fleet lost nearly three hundred vessels by a storm in doubling the promontory of Athos; and the land forces suffered so severely from the Brygians, a people of Thrace, that the season for military operations was lost, and the whole armament was led back to winter in Asia. A second army, under the command of Artaphernes, son of the late Satrap of that name, and of Datis, a Median nobleman, avoiding the circuitous march by Thrace and Macedonia, sailed from Cilicia in a numerous fleet, reduced every island and appurtenance of Greece in their way, and approached the frontiers of Attica, with the exiled tyrant Hippias as their guide, before any measures had been concerted by the Greeks for the general security. A messenger was now dispatched from the Athenians to Sparta with the intelligence of the capture of Eretria, and, at the same time, with a request for assistance to themselves.

Dilat... condu... of Lace...

The Lacedemonians readily promised their utmost aid; but, in conformity to a superstitious law, unworthy of their boasted political wisdom, declared, that they could not take the field before the full moon, of which it then wanted five days. Immediate assistance from Sparta being thus denied, it became a question with the ten generals, whom the Athenians had chosen to command their army, whether they should venture to meet the enemy in the field, or apply their whole exertions to prepare for a seige. Opinions were equally divided, and the decision was, by ancient custom, referred to the polemarch Archon, who was persuaded by Miltiades to recommend an immediate engagement; a measure obviously contrary to all principles of defensive war, but rendered necessary by the dread of internal factions in the city.

Battl... of Mar...

The Persian army, amounting, according to the lowest calculation, (though even that is probably overrated) to 100,000 infantry, and 10,000 cavalry, accustomed to conquer, and having frequently engaged the Greeks of Asia and Cyprus, advanced with confidence as to certain victory. The amount of the Athenian force has been stated as low as 9,000 heavy-armed infantry, and 1,000 Platæans, who had bravely hastened to share the desperate struggle for the freedom of their

Greece. country. Various considerations,* however, make it probable, that the regular Grecian troops, now opposed to the Persians, were not much less than 20,000, with about an equal number of armed slaves. With this army, still fearfully inferior to the invading host, the genius of Miltiades, who was well acquainted with the nature of the Persian troops, seconded by the determined bravery of his soldiers, gained, on the plain of Marathon, a most decisive victory, and drove the routed Persians to their ships with great slaughter. But this distinguished commander, having failed in a subsequent expedition against the Ægean islands, which had submitted to the Persians, was, by the base machinations of party spirit, condemned to pay a fine of 50 talents, and died in prison of the wounds which he had received.

Second Persian invasion. B.C. 480.

The death of Darius, the revolt of Egypt, and the disputes which arose about the right of succession to the throne of Persia, procured to the Greeks a respite of several years from any farther attempts against their independence. But Xerxes, the young Persian monarch, was sufficiently ardent to revenge the disgrace, which the arms of his nation had sustained, and to prosecute those schemes of conquest, which his predecessors had planned. Four years are said to have been employed in preparations for the punishment of Athens, and the reduction of Greece; and an army was collected, more numerous than had ever before, or than has ever since been known in the annals of the world. To prevent the disasters, which might attend the conveyance of the armament by sea, as well as to provide for the future security of the intended conquest, a canal, navigable for the largest galleys, was, (according to the united testimony of all the Greek historians and geographers,) actually formed across the isthmus, which joins mount Athos to the continent of Thrace. Two bridges of boats also, the one to withstand the winds and the other the current, were extended across the Hellespont nearly between Abydos and Sestos, where the street is about seven furlongs in breadth. Early in the spring, the army moved from Sardis, the principal place of rendezvous; and seven days and nights are said to have been occupied in passing the bridges of the Hellespont. The land and sea forces met at Doriscus near the mouth of the Hebrus, where, according to Herodotus, the Persian monarch reviewed his enormous army, which is said to have been composed of twenty-nine different nations. This historian (whose testimony, as he lived so near the time of the expedition, ought to be most worthy of credit, but whose detail of many incredible concomitant circumstances casts a doubt over his whole narration) estimates the effective strength of the infantry at 1,700,000 fighting men, and the cavalry at 80,000, exclusive of attendants and followers, whose number defied calculation. The fleet consisted of 1207 galleys of war, carrying about 277,600 men; besides transports, store-ships, and a variety of smaller vessels, amounting, at a gross calculation, to 3000, and their crews to 240,000. The land forces marched from Doriscus in three columns, every where adding to their numbers, by compelling the youth of the countries through which they passed, to follow their standards. They met again at Acanthus, where they were joined by the fleet, which then proceeded through the canal of Athos, into the bay of Therme, where the whole army coming up, formed an encampment, extending from Therme and the borders of Mygdonia to the river Haliacmon, near the confines of Thessaly. The Greeks, in the mean time, were slow in concerting any measures for their common defence; and many of the smaller republics readily made the required submission to the Persian monarch, whose sway had been experienced by many Grecian states to be much less oppressive than that of the domineering rule of the Spartan oligarchy, to which the greater part of them had long been subjected. The determined resistance of the Athenian people first arrested the progress of the Asiatic host; and to them chiefly belongs the honour of having preserved Greece from a foreign yoke. To this daring resolution they were prompted, not entirely by the love of freedom, but by the dread of certain punishment. The whole armament was ostensively prepared for their destruction, and their courage therefore was nearly that of despair. Their success at Marathon may have thrown a ray of hope through the gloomy prospect before them; and, at this critical moment, they happily possessed in Themistocles a leader of extraordinary talents, peculiarly fitted for conducting the arduous contest. Deputies from the confederated states at length assembled at Corinth, to consult respecting the conduct of the war; and an attempt was at first made to defend the passes into Thessaly. An army of 10,000 men from the different states, joined by all the Thessalian cavalry, was actually sent to occupy the vale of Tempe; and was competent to have defended the pass against any number of assailants. But the Grecian leaders, alarmed by the accounts which they received of the multitude of their invaders, and understanding that there was another opening into Thessaly, which they did not think themselves strong enough to occupy, were struck with a sudden panic, and, embarking their troops, returned to the Corinthian isthmus; while the Thessalians, now left to their fate, made an immediate submission to the demands of Xerxes. It was next resolved to make a stand at the pass of Thermopylæ, which afforded every possible advantage to an inferior force; but their mutual jealousies and selfish anxiety to reserve their strength for their proper defence, prevented the assembling of a sufficient body of troops; and not more than 4000 men, most of them Arcadian mountaineers, were collected to dispute the passage with the whole Persian army.

Amount of invading army.

Tardy measures of the Greeks.

Resolute resistance of Athens.

Battle of Thermopylæ, B. C. 480.

Xerxes having halted several days at Therme, to procure proper intelligence and guides, resolved to proceed by Upper Macedonia into Thessaly, and reached the neighbourhood of Thermopylæ without opposition. His fleet, after suffering immense loss by a storm in the bay of Casthanæa, entered the Pelasgian gulf; and the Grecian fleet, which was stationed off Artemisium to support the army at Thermopylæ, succeeded in capturing fifteen galleys, which had been dispersed by the tempest. This favourable event at once revived their spirits, and added greatly to the strength of their little navy. Xerxes, in the mean time, having fixed his head quarters at the town of Traches, in the Malian plain, waited four days, in expectation that the Greeks would yield to his numbers, and leave him an uninterrupted passage. A herald also was dispatched to Leonidas, who commanded at Thermopylæ, requiring him to deliver up his arms; to whom the Spartan replied, with laconic brevity, "Come and take them." The Persian monarch, therefore, on the fifth day, ordered the Medes and Cissians of his army to bring Leonidas and his Greeks into his presence. These being quickly repulsed, the Persian guards, called "the immortal

* See a very satisfactory statement in support of this opinion in Mitford's History of Greece.

Greece.

band," were marched to the attack. Their numbers were unavailing on so narrow a field; their short spears were very inferior in close fight to the longer weapons of the Greeks; and their repeated and courageous efforts, to which Herodotus bears ample testimony, made no impression. The assault was renewed on the following day, in hopes that wounds and fatigue might exhaust the little army of the Greeks; but still without the smallest prospect of success. A Persian detachment, however, having penetrated during the night by another pass, and surprised the Phocians, who had been intrusted with its defence, shewed themselves, on the morning of the third day, far in the rear of the Grecian army. Information of this fatal advantage being conveyed to Leonidas, it was immediately resolved that they should all retreat to their respective cities, and preserve their lives for the future wants of their country. Leonidas, however, in obedience to a law of Sparta, which forbade its soldiers, under whatever disadvantage, to flee from an enemy, resolved to devote his life to the honour and service of his country. Animated by his example, every Lacedemonian and Thespian under his command, determined with him to abide the event. The Thebans also, on account of the disaffection of their city to the Grecian cause, were detained, rather indeed as hostages than as auxiliaries.* Leonidas stationed his little band at the wall of Thermopylæ, where the pass was scarcely 50 feet wide; and all of them resolved to sell their lives to the enemy at the dearest rate. With the fury of men resolved to die, they rushed against the advance of the Persian army, and made a dreadful slaughter of the crowded and ill-disciplined multitude. Numbers of them were forced into the sea, and many of them expired under the pressure of their own people. Leonidas fell early in the fight, at the head of his troops; but the engagement was continued, with advantage on the side of the Greeks, till the Persian detachment came in sight in their rear. They then retreated to the narrowest part of the pass, where the Thebans began to sue for mercy, and were most of them taken prisoners. The surviving Lacedemonians and Thespians gained a little rising ground, where they fought in the midst of a surrounding host, till they were utterly cut to pieces. In the conduct of the Spartan prince, there was wisdom as well as magnanimity. His example checked the disposition which prevailed among the Greeks to shrink from the Persian power; and gave a convincing proof to the invaders, at how vast a price of blood they would purchase their conquest. During the transactions at Thermopylæ, the Grecian fleet gained several advantages over that of the Persians; and about two hundred galleys of the latter, attempting to take the Greeks in the rear by sailing round Eubœa, were totally lost in a storm. Having received intelligence of the fall of Leonidas, and the retreat of the rest of the army, the Grecian fleet retreated from Artemisium, and sought the interior seas of Greece. The Persian army experienced no opposition in their march through Doris and Bœotia, which, excepting the cities of Thespiæ and Platæa, had always been adverse to the confederacy of the Greeks. Phocis alone, of all the provinces between Thessaly and the isthmus, remained faithful to the cause of Grecian independence. Its territories, therefore, were ravaged without mercy by detachments of the enemy; while the main body advanced in a direct course to the devoted city of Athens. The Peloponnesian troops having resolved to confine their operations to the defence of the peninsula, Attica was completely abandoned to the whole weight of the invading host. Athens was filled with alarm, and all were convinced that their destruction was inevitable. The oracle at Delphi, however, having recently pronounced, that "the wooden wall" alone would afford an impregnable refuge to themselves and their children, Themistocles, who had probably himself suggested the response, persuaded his countrymen that they were thus directed to embark on board their fleet. Their families and effects were, in conformity to his advice, immediately transported to Salamis, Ægina, and Træzene; and all the males who were able to bear arms repaired to the ships. A few of the poorer citizens, who were unable to bear the expence of a removal, and some others, who conceived the answer of the oracle to point out their citadel, which was built of wood, as the place of safety, refused to abandon the city. The Persian army, advancing from Thebes, burned the forsaken cities of Thespiæ and Platæa; and experienced no resistance till they reached the citadel of Athens, which was immediately invested; and, being taken by assault, all within its gates were put to the sword. The commanders of the Grecian fleet, which was now assembled in the bay of Salamis, alarmed by the intelligence of the fall of Athens, had resolved in a council of war to retreat without delay, when Themistocles, addressing Eurybiades the Lacedemonian, who had the chief command, threatened, if such a resolution were adopted, to withdraw the whole of the Athenian ships, which composed nearly one-half of the allied fleet, and either to make peace with the enemy, or seek some distant settlement for his deserted people. His advice prevailed; and it was determined to await the approach of the enemy in the straits of Salamis. This Athenian chief, however, still fearful lest some of the squadrons should depart, is said to have accelerated the approach of the Persians, by causing their monarch to be privately informed, that the Greeks were planning a retreat, and that he would thus lose the most favourable opportunity of destroying their whole navy at one blow. His stratagem was attended with entire success. The Persian fleet hastened to make a general attack; while their army lined the adjacent shores, and their monarch himself was seated upon an eminence to view the approaching battle. His fleet amounted to 1200 galleys, and that of the confederated Greeks to 300; but the narrow strait prevented the numerous ships of the Persians from being regularly brought into action, and the crowded situation rendered it impossible for the Phenician squadron to avail themselves of the superior swiftness of their galleys, and skill of their seamen. The very zeal of the Persian commanders to distinguish themselves in the presence of their monarch, tended to increase the confusion. The resolute and persevering attacks of the Greeks, aided by the united talents of Themistocles and Aristides, allowed not a moment's respite to the enemy to restore order, or recover from alarm. The confusion soon became so general, that even flight was impracticable, and the sea itself (according to the description of the scene by the poet Æschylus, who fought on board the Athenian fleet) became scarcely visible from the quantity of wreck and corpses floating on its surface. Forty Grecian galleys are said to have been sunk or destroyed; but most of the crews saved themselves on board of the other ships, or on the neighbouring shore of Salamis.

Advance of the Persians to Athens.

Battle of Salamis.

* In the army at Thermopylæ there were originally 300 Lacedemonians, 700 Thespians, and 400 Thebans.

Greece.

But the Persians had no refuge; and their defeat was attended with immense loss. Still the remains of their fleet were so large, that the principal port of Attica could not admit half its numbers; and the Greeks were expecting a renewal of the action on the following day. But the Persian commanders appear to have concerted no measures on the supposition of a retreat; and a hasty order during the night, directed the whole fleet to steer immediately for the Hellespont. The army, thus destitute of the supplies derived from the ships, and unprovided with sufficient magazines on land, fell back upon the friendly province of Bœotia, and speedily retreated into Thessaly. Three hundred thousand men were chosen to remain, under the command of Mardonius, to complete the conquest of Greece in the following summer. Of this number, 60,000 of the best troops were selected as a royal guard, to accompany their monarch as far as the Hellespont on his return to Persia.

Sufferings of the Persian army in its retreat.

The rest of the immense multitude which he had led into Greece, left to their own resources, suffered beyond description, from the haste of their march, and the want of magazines. They subsisted by rapine from friends as well as foes; and were reduced at last to eat the very grass from the ground, and the bark from the trees. Disease destroyed whom famine had spared; and the towns of Thessaly, Macedonia, and Thrace, were crowded with the sick and the dying. Upon reaching the Hellespont, the bridges were found to have been destroyed by the violence of the current and the storms; but the fleet had arrived to transport the wretched remains of the Persian host; and its discomfited monarch proceeded to Sardis, not indeed entirely unattended, as some of the Greek historians relate, but with such a diminished retinue as might almost be called nothing, when compared with the incalculable numbers who formerly surrounded his person, and obeyed his command.

Renewal of hostilities by Mardonius.

Early in the following spring, the Persian fleet assembled at Samos; and Mardonius, having attempted without success to detach the Athenians from the Grecian confederacy, compelled them again hastily to abandon their country; and, without opposition, regained possession of Athens. The Athenian people, under the protection of their fleet, withdrew to Saliams; and there, though deprived of their country, and disappointed of the timely assistance which they ought to have received from the Peloponnesian states, still rejected, with the most enthusiastic magnanimity, all the conciliatory proposals of Persia. The Lacedemonians, who were at the head of the allies, at length ashamed of their ungenerous and dastardly delays, dispatched an army of 5000 Spartans and 35,000 Helots, under the command of Pausanias. These were joined at the isthmus by the other Peloponnesian troops, and by the Athenian army under Aristides. Mardonius, secretly apprized of their march, gave up the city of Athens and its surrounding territories to be pillaged by his troops, and fell back upon his magazines in Bœotia, where he extended his camp along the course of the Asopus to the frontiers of Platæa.

Battle of Platæa. B.C. 479.

The confederated Greeks, animated by the propitious omens which had been indicated at their solemn sacrifices, advanced with confidence to meet the Persians, and pitched their camp at the foot of Mount Cithæron, on the opposite side of the river Asopus, composing a force of 110,000 men. Mardonius, who appears from the account given by Herodotus (the most impartial historian of the Persian invasion) to have been deficient neither in courage or policy, anxious to draw the Greeks from their advantageous position, harassed them greatly with incessant charges by his cavalry; and more than ten days were spent in various evolutions on both sides to gain the superiority of the ground, and to induce each other to commence the attack. In one of these movements, the greater part of the Grecian troops, excepting only the Tegeans, Lacedemonians, and Athenians, actually fled to the walls of Platæa; and the Persian commander, imagining the retreat to be general, hastily advanced with his infantry as to certain victory. A fierce engagement ensued, in which the Persian soldiers, though insufficiently armed for close fight, and unequal to the Greeks in the practice of war, discovered no inferiority in point of courage and enterprise; and were often seen, in their vigorous assaults, seizing and breaking with their hands the long spears of their opponents. Multitudes perished in these vain attempts to penetrate the Spartan phalanx. Their efforts, after repeated failures, began to relax. The Greeks advanced in their turn; and confusion soon became general among the Persian infantry. Their commander Mardonius, while leading on a chosen body of cavalry to support his broken troops, received a mortal wound; and his fall was the signal for flight to the whole Persian army. Artabazus, next in command, who is said to have dissented from his general in the conduct of the battle, as soon as he was assured of the rout of the main body, retreated with 40,000 men towards Phocis; but the Persian and Bœotian cavalry still kept the field, and afforded considerable protection to the flying infantry. The Lacedemonians and Athenians, however, having succeeded in carrying the Persian camp by assault, a dreadful slaughter ensued; and, excepting the detachment which had escaped under Artabazus, only 3,000 finally survived of 260,000 Asiatics, who composed the rest of the army of Mardonius. In the mean time, the Grecian fleet, which had remained during the summer inactive at Delos, was encouraged, by a private assurance of the favourable disposition of the Ionians, to attack the Persian fleet at Samos. The Persian admiral, having suffered the Phenician squadron to depart, in the idea that the season was too far advanced for naval operations, as soon as he received intelligence of the approach of the Greeks, hastily sailed from Samos; and, passing to the opposite promontory of Mycale, drew his galleys upon the beach, and prepared to defend them on shore.

Battle of Mycale.

The Greeks, resolving to attack the fortified camp, disembarked their forces in two divisions, one under the command of Xanthippus the Athenian, and the other led by Leotychides the Lacedemonian. The former arriving first at the Persian entrenchments, immediately commenced the assault; and, aided by the Greeks in the Persian service, had entered the rampart, before the Lacedemonians came up. The other Asiatics instantly fled from the Athenian assailants; but the native Persians resisted with the utmost bravery, till the arrival of the Lacedemonians, when they were completely overpowered, and almost entirely cut to pieces. The victorious Greeks, after carrying off the most valuable part of the spoil, set fire to the camp, and consumed the whole of the Persian fleet on the very same day that their army was annihilated at Platæa. This successful resistance of Greece to the Persian invasion, holds out an encouraging example to all free states, to maintain their independency against any power, however formidable; and clearly shews, that an obstinate determination never to submit, accompanied with wise counsels and steady discipline, will

Greece.

Farther successes of the Greeks.

rarely fail of ultimate success. The Persian war, indeed, was not yet terminated. The Greeks, in their turn, became the assailants and invaders. They prepared to protect the Ionians, who had thrown off the Persian yoke, and particularly to restore freedom to those Grecian cities in which the Persians had left garrisons. Under the Spartan general Pausanias, but especially under Cimon the Athenian, they carried their victorious arms to Byzantium, to the island of Cyprus, and even into Egypt. By a double victory gained on the river Eurymedon, under the last mentioned commander, both over the fleet and army of Persia on the same day, its naval strength was so broken, and its land forces so disheartened, that offensive operations against Greece were totally intermitted; and it became the boast of the Grecian states, that no armed ship of Persia was to be seen westward of the Chelidonian islands, or the entrance of the Euxine, and that no Persian troops dared to shew themselves within a day's journey of the Grecian seas. But the ambitious views, and political jealousies, which arose among the confederated states of Greece during the prosecution of these successful operations, prepared greater evils for their country than all that they had endured, while struggling under the pressure of the Persian hosts. The Athenians, though apparently the greatest sufferers by the invasion, derived the greatest benefits from its effects. They found their country laid waste, and their city in ruins; but, in consequence chiefly of their naval superiority, and a succession of great commanders, they rapidly attained that supremacy in Greece, which the Lacedemonians had hitherto enjoyed; and by the able conduct of Cimon, the most distinguished of all their leaders, soon reached the summit of their political influence and military power. The Lacedemonians had not been inattentive observers or inactive opponents of the growing consequence of the rival state; but, usually slow in their counsels, (and weakened by an earthquake which laid their capital in ruins, and by a consequent insurrection of the Helots, which reduced them to the necessity of requiring aid from their neighbours,) had long evaded an open rupture with the Athenian republic. The latter people, however, accustomed to war, elated with success, swayed by a turbulent democracy, and unable longer to disguise their ambitious designs upon the liberties of Greece, not satisfied with repeated interferences and aggressions against the ancient allies of Lacedemon, proceeded at length to make a direct and unjustifiable attack upon its armies, while returning from the protection of Doris, against the inroads of the Phocians. Aided by the Argians and Thessalians, they met the Lacedemonians and their Peloponnesian allies at Tanagra in Bœotia. After a severe action of two days, and great slaughter on both sides, the Athenians were compelled to retreat, and the Spartans pursued their march without farther obstruction.

Divisions among themselves.

In the view, however, of raising a state without the peninsula, to balance the power and curb the ambition of Athens, they formed a close alliance with the Thebans, and willingly seconded their attempt to recover that supremacy in Bœotia, which they had been accustomed to claim before the event of the Persian war. But the Athenians under Myronides speedily regained the influence which they had lost by their defeat at Tanagra; and all Bœotia, with the exception of Thebes, was brought either into their alliance, or under their dominion. Burdened at length by the variety of their military operations, and even by the extent of their conquests, they were disposed to enter into negotiations with their Peloponnesian adversaries; and by the good offices of Cimon, whom they recalled from exile, and who had always been greatly esteemed at Lacedemon, a truce for five years was concluded between the rival powers. But, after the death of that distinguished commander, who had uniformly exerted himself to divert the military spirit of the Greeks from internal wars, hostilities were again renewed. The Athenians, however, being hard pressed, and even invaded by the Peloponnesian confederates, as well as encumbered by the numerous islands and colonies subject to their empire, a second time sought an accommodation; and a truce was concluded for the space of thirty years, upon terms by no means advantageous to their influence. But the constitution of Greece, composed of so many small and independent states, was unfavourable to a long continuance of general tranquillity. Its governments were so distinct, that no common authority could prevent the occurrence of partial wars; and yet so connected, that war in any part always endangered the peace of the whole. This was more especially the consequence of a practice, which had become universal among the weaker states, to provide for their protection by courting the alliance, or rather acknowledging the dominion of one of the two leading republics of Lacedemon or Athens. These two rival powers also differed considerably in the political principles which they respectively favoured, the former being generally the patroness of aristocracy, and the latter of democracy. Hence their influence was extended according as one or other of these opposite factions prevailed in the different states; or rather, according as their arms were severally crowned with success, the party to which they were friendly gained the ascendency, and succeeded in bringing the state which it ruled to the side of Sparta or of Athens. This constant rivalship, never wholly dormant, and kept in continual excitement by the frequent quarrels of the minor commonwealths, at length gave rise to the long and bloody contest of the Peloponnesian war. The Athenians, having assisted the Corcyræans against the Corinthians, were formally accused by the latter people, joined by many other complainants, of having broken the truce, and insulted the Peloponnesian confederacy. An assembly of deputies from the different states, of which that confederacy was composed, having met at Sparta, a great majority decided for an immediate recourse to arms; and even the historian Thucydides admits, in the most explicit terms, that a general sentiment of indignation had been excited among a large portion of the Grecian people, by the arbitrary and oppressive sway of the Athenian republic. See Aristides, &c.

Greece.

B. C. 44[illegible]

Circumstances unfavourable to tranquillity in Greece.

Origin of the Peloponnesian war.

The two hostile confederacies, though very differently composed, divided between them very equally the force of the Greek nation. All the Peloponnesian states, except the Argians, who remained neutral, joined the Lacedemonians. In Northern Greece, the Megarians, Bœotians, Locrians, Phocians, &c. formed a part of the same alliance; and external assistance was expected from the king of Persia, and the Grecian colonies of Italy and Sicily. The Athenians had few allies, and some of them not very zealously inclined to their cause. The principal were the Thessalians, and Acarnanians, and the islands of Corcyra, Zacinthus, Chios, and Lesbos. But all the other islands of the Ægean Sea, except Melos and Thera, and all the wealthy Grecian cities of Thrace, of the Hellespont, and of Asia Minor, were tributary subjects of Athens, and entirely subject to its controul. The Spartan king Archidamus,

State of the contending parties, B. C. 4[illegible]

Greece.

who had the chief command of the Peloponnesian forces, amounting to 60,000 men, advanced slowly to the invasion of Attica; but, before actually commencing hostilities, he once more proposed the terms of accommodation, which the Athenians had formerly rejected. The celebrated Pericles, who had long directed the councils of Athens, and who is supposed to have plunged his country into war, for the purpose of prolonging his personal influence in the state, easily induced his fellow citizens to refuse all farther negociation; but all his extraordinary talents were necessary to persuade the Athenian people to adopt the measures of defence, to which they were reduced by the power of their enemies. Abandoning their country to the ravages of the hostile army, they were compelled to secure themselves and their effects within the walls of the metropolis, filling the temples, the turrets of the ramparts, the tombs, even, and the lowest hovels, with their wives and children. Pericles, reproached and threatened as the principal author of their calamities, and vehemently urged to meet the invaders in the field, directed all his attention to the defence of the city, and the preservation of good order. The Lacedemonians and their allies, having exhausted the means of subsistence, and loaded themselves with plunder, returned to Peloponnesus, and dispersed to their respective cities. The Athenian fleet, in the mean time, ravaged the coasts of Peloponnesus, taking, in its return, the island of Ægina; and, towards the end of autumn, Pericles, with the whole of the land forces, laid waste the neighbouring territory of Megara. At the commencement of the second summer, the confederates under Archidamus again entered and ravaged the country of Attica; while a more dreadful scourge, a pestilential fever resembling the modern disease of the plague, raged in the crowded streets of the city. The war, however, was not arrested by this awful calamity; and, for several years was regularly conducted in the same manner. The Peloponnesian states were so superior in land forces, that they annually invaded the territories of the Athenians, who could not risk a general action, without exposing themselves to certain ruin; yet the confederates were, on the other hand, so ignorant of the art of attacking fortified places, that they could make no impression upon a city like Athens, defended by 30,000 men, and supplied by a powerful fleet. The war thus continued to rage, for many years, with nearly the same success, and equal losses on both sides. It consisted in a succession of partial engagements, hasty excursions, and distant sieges, which never affected the main object in view, or brought the contest one step nearer to a conclusion. Partaking also in a great degree of the nature of a civil war, it was carried on with a spirit of ferocity rarely exemplified among civilized nations; and, though the time of its continuance, the very age of Socrates himself, was an era, at least in the history of Athens, characterised by the high perfection to which arts and sciences, philosophy and refinement, had been brought; yet, in no period of Grecian history, were more atrocious barbarities committed. Every transaction has been minutely recorded by the Athenian historians, Thucydides, and Xenophon, who were contemporary with most of the events, which they describe; and our account must be greatly compressed, not from the scarcity, but from the abundance of materials. The league, headed by the Athenians, was almost entirely under their command; while that of Peloponnesus, being composed of independent states, was continually changing in its component parts, and liable every instant to be utterly dissolved. Had the Athenian people therefore steadily adhered to the plan of Pericles, and, renouncing every idea of conquest, confined themselves to a defensive war by land, and offensive operations by sea, they might ultimately have triumphed over their numerous opponents; and, at least, have inflicted more serious injuries than they could have received. From the excessive diversity and disproportion of the forces engaged in the contest, the one over-running the land, and the other scouring the seas and coasts, the war was inevitably spun out to an indefinite length; and often were both parties, wearied of their accumulated sufferings, desirous of peace; but proposals for negociation were as often prevented by the vain ambition of Cleon, who had succeeded, at the death of Pericles, to the direction of the Athenian counsels, and by the warlike spirit of Brasidas, the bravest of the Spartan leaders. After their death, a truce was concluded for the space of fifty years; and every thing was restored to the same situation in which it had stood at the commencement of hostilities: but mutual hatred, and boundless ambition, had acquired such hold of the minds of the principal men on all sides, that the appearance of concord was of short duration. New leagues and dissensions arose, which led to reciprocal recriminations and partial hostilities; but it was not till the expiration of nearly seven years, that they again came to an open rupture. Athens was the aggressor, and the ambition of Alcibiades was the sole cause of the renewal of hostilities. This celebrated character, with all his accomplishments and talents, was guided by principles so inveterately vicious, that he alone may be charged with having accelerated the ruin of the Athenian state, and completed the corruption of its citizens. He persuaded the people, without any other reason, except that the city Egesta in Sicily had solicited the assistance of the Athenians, to undertake the conquest of that island; but, scarcely had the expedition, in which he was appointed a commander, commenced its operations, when he was recalled to stand his trial, upon a charge of impiety. Aware of the caprices of his countrymen, he took refuge in Peloponnesus; and, enraged by the sentences pronounced against him in his absence, he instigated the Lacedemonians to assist the Syracusans, and to attack the Athenians, while their army was engaged in the remote and romantic enterprize which himself had planned. The Sicilian expedition terminated in the most disastrous manner; and almost the whole of the Athenian army was destroyed or taken captive. The Lacedemonians, supported by a powerful confederacy, and assisted even by the Persian viceroys, invaded Attica, blockaded the city of Athens, and would speedily have terminated the war by its reduction. But Alcibiades, having been expelled from Sparta on account of his licentious practices, exerted himself to detach their Persian allies, and to retrieve the falling hopes of his country. Recalled by the army, and raised to the chief command by the unanimous acclamations of the people, he recovered many of the lost colonies, defeated the fleet of the confederates, and so alarmed the Lacedemonians, that they were ready to have treated for peace. But the Athenians, intoxicated with success, prolonged the war; and, insensible to their interest, again threw away the instrument of their victories. Their fleet having sustained a trifling loss while Alcibiades was absent, and employed in levying contributions in Ionia, for the support of the forces, he was instantly disgraced by the fickle voice of the populace;

Truce concluded B. C. 422.

War renewed.

4

Greece.

and the power of Peloponnesus again acquired the ascendency. The confederates, taught by experience, had exerted themselves to increase the number of their ships, and had at length succeeded in attaining also a portion of that maritime skill, which had hitherto given to the Athenians so decided a superiority by sea. The Athenian navy, however, trusting to their long acknowledged eminence, and elated by a victory which they had gained over the Spartan fleet at Arginusa, near Lesbos, despised their enemies, and neglected all ordinary precautions, with unexampled imprudence. Lysander, the ablest of the Lacedemonian generals, having succeeded to the command of the allied fleet, and taken the city of Lampsacus upon the coast of the Hellespont, resolved to avail himself of that self-confidence which guided the counsels of the Athenian captains. In order to increase their insolent security, he repeatedly declined battle, which they daily offered him, but kept his own crew prepared for action at a moment's warning. Having learned that they regularly drew their fleet ashore on the open beach at Aigospotami, on the opposite coast, not more than two miles from his own station, and then suffered the soldiers and crews to disperse over the adjoining country in quest of lodgings and provisions; he easily found means to surprise them in this unguarded condition, made himself master of their whole fleet except nine galleys, and took prisoners the greater part of their forces, by which it had been manned. A striking instance now occurred of that savage barbarity, with which the different powers in the Peloponnesian war were generally chargeable. The Athenians had resolved, in their assurance of victory, to cut off the right hand of every prisoner whom they should capture; and this intended cruelty, with many similar acts which they had perpetrated, was immediately requited by a general massacre of the captives at Aigospotami. Lysander, with his own hand, cut down their general Philocles, after reproaching him with having first set the example among the Greeks of such violations of the laws of war; and, upon this signal, about 3000 Athenian citizens were butchered in cold blood, by the allied troops. The Lacedemonian commander, now completely master of the seas, speedily reduced the principal colonies and dependencies of Athens; and then hastened, with a fleet of 200 galleys, to blockade the port of that devoted city, while the land forces of the confederates, at the same time, surrounded its walls. No assault was attempted, and its reduction was left entirely to the sure operation of famine. The haughty and turbulent citizens discovered not even the courage of despair in their defence; but were solely anxious to avert the sentence of utter extermination, with which they were threatened by some of the allied states. The Lacedemonians, however, probably as much from policy as generosity, secured for them more favourable terms, and saved their persons from servitude and slaughter. But it was determined, as a measure absolutely necessary to the safety and repose of Greece, that their tyrannical spirit should be effectually humbled, and their power as a state entirely broken. They were spared upon the following conditions; that all their ships of war should be surrendered, except 12; that the long walls and the fortifications of Peiræus should be destroyed; that all exiles and fugitives should be restored to the rights of the city; that the Athenians should hold always as friends or enemies those states, who were the allies or the adversaries of Lacedemon; and should be ready to attend the Spartan power, by sea or land, as they might receive orders. These terms being accepted, the Spartan fleet entered the Peiræus, and the army took possession of the walls. The fortifications, which had been condemned, were instantly thrown down, to the sound of military music, and their demolition celebrated with triumph as an æra of recovered freedom to Greece. The popular assembly was abolished; the government changed from democracy to oligarchy; and thirty magistrates were appointed to form the new administration of the commonwealth. Such was the termination of the Peloponnesian war, in its twenty-seventh year; and Lacedemon, now in alliance with Persia, having again become the leading power in Greece, the aristocratical interest reigned paramount in almost every Grecian state. See Alcibiades, &c.

Decisive defeat of the Athenian fleet at Aigospotami, B. B. 404.

Athens reduced to the last extremity.

Sparta having recovered her influence in Greece, acted not less tyrannically than on former occasions; and, under the ambitious projects of Lysander, became daily more corrupted in her principles of policy. The thirty magistrates, who had been placed at the head of the Athenian state, were supported by assistance from Lacedemon in the most atrocious acts of cruelty and injustice; and the other Grecian cities were prohibited even to afford a refuge to the unhappy Athenians, who fled from their oppressors. Not contented with cutting off their political adversaries, the thirty tyrants, under the direction of Critias, proceeded to murder, upon frivolous pretences, all persons whose riches they wished to seize; and the slightest murmur against their oppressions was punished with imprisonment, exile, or death. In the space of eight months, fifteen hundred citizens were sacrificed to their avarice or vengeance; and Xenophon goes so far as to affirm, that their short reign was more destructive to Athens, than the preceding war of thirty years. At length, however, Thrasybulus, at the head of his exiled countrymen, drove the tyrants from their seat of abused power, and restored the ancient democratical form of government at Athens. By his wise moderation, the spirit of retaliation was restrained, a general amnesty proclaimed, and tranquillity restored to the Athenian state. But whatever was the form, tyranny was too generally the spirit of the Grecian governments, and especially of the pure democracy at Athens. Equally unjust and cruel as the most lawless despots, they were often much more inconsistent with themselves, and fickle in their proceedings. While they allowed their poets, for their amusement, to ridicule the gods upon the stage, they punished their sages, who endeavoured, for their instruction, to introduce worthier sentiments of religion. By their sentence, the celebrated Socrates, (whom even the thirty tyrants had spared, though he often opposed their measures,) was iniquitously put to death.

The Greeks were again involved in a contest with Persia, by the attempt of Cyrus the younger to dethrone his brother Artaxerxes. That ambitious prince being governor of Asia Minor, and friendly to the Spartans, persuaded them to join his standard with 13,000 Grecian troops; but, excepting their leader Clearchus, they are said to have been entirely ignorant of his views upon the Persian crown. The celebrated retreat of the remains of this army, after the death of Cyrus, generally called the retreat of the ten thousand, is considered as one of the most extraordinary exploits recorded in the annals of the military art; and, by proving the weakness of Persia, is supposed to have had considerable influence in promoting the Macedo-

ece.

nian invasion, and conquest of that extensive but feeble empire. It had the more immediate effect of encouraging an expedition, under Agesilaus king of Sparta, to recover the liberty of the Grecian colonies in Asia. Assisted by 30 captains, with Lysander at their head, he filled all Asia with a dread of his arms; and was preparing to carry the war into the heart of the empire, when he was suddenly recalled for the protection of his own country. The Persian monarchs had discovered a more easy and effectual defence against Grecian valour, than their most numerous armies had been able to provide; and, by a seasonable distribution of bribes among the leading men of the different states, succeeded in turning the arms of these warlike republics against one another. The Thebans were first gained to their interests, who easily succeeded in persuading the Athenians. Even Argos and Corinth, two Peloponnesian states, joined the confederacy, to which were added Acarnania, Ambracia, Leucadia, Eubœa, part of Thessaly, and Chalcidice in Thrace. The haughty tyranny of Lacedemon furnished sufficiently ostensible reasons for the union; and Persian gold readily supplied the arguments which were wanting. The confederates sustained a severe check in the vicinity of Corinth, and were afterwards defeated by Agesilaus at Coroneia with great loss on both sides; but Pharnabazus, assisted by the Athenian commander Conon, having defeated the Lacedemonian fleet, completely destroyed their influence in Asiatic Greece. They proceeded even to ravage the coasts of Laconia; and, assisting the Athenians to rebuild their long walls, which connected the Peiræus with the city, again laid the foundation of their naval power. After various vicissitudes and intrigues, all parties became tired of war, and disposed to peace. The Lacedemonians, though still superior in the field, yet destitute of the aid which they had formerly derived from the Persian treasury, were straitened in their pecuniary resources; and Pharnabazus, the friend of Athens, having been succeeded in Lydia by Teribazus, the new Satrap became favourable to the interests of Sparta. By the able negociations of Antalcidas the Lacedemonian, the Persian monarch was brought in as mediator, or rather dictator, for a general pacification among the states of Greece, of which the conditions were simply these; "that all cities on the continent of Asia, together with the islands of Clazomene and Cyprus, should belong to the Persian empire; and that all other Grecian cities, small and great, should be completely independent, except that the islands of Lemnos, Imbros, and Sciros, should remain as formerly under the dominion of Athens." Against all who should refuse these terms, the court of Persia declared itself ready to unite with those who accepted them, and to render every assistance, by land and sea, to reduce the refractory. The weaker states were well pleased to be secured in their independence. The Athenians were gratified, by the exception in their favour. The Thebans, anxious to preserve their authority over the smaller towns of Bœotia, wished to stipulate for that superiority; but were compelled to concur in the terms. And the Lacedemonians, while they lost nothing by abandoning the Asiatic Greeks, whom they had already been obliged to desert, gained the great object of the war,—the separation of the states which had combined against them, and the emancipation, especially, of the Bœotians from the growing power of Thebes. They soon shewed that they accounted themselves to have established their supremacy; and were the first to disturb the general tranquillity. They demolished the fortifications of Mantinæa, as a punishment for the disaffection of its citizens to the Lacedemonian interests, during the preceding wars. They marched against Olynthus, a Grecian city of Thrace, because, by associating the smaller towns in its vicinity under one government, it was considered as infringing the conditions of the late treaty; though its only offence was the increase of its strength by a wise and liberal policy, which ought to have been emulated, rather than opposed by the other Greeks. They interfered also, in the most unjustifiable manner, in the political contests which agitated the Theban state; and, by this rash measure, gave rise to a long and complicated struggle, which ended only with the general overthrow of Grecian independence. Their general Phœbidas, returning from an expedition against the Olynthians, was persuaded to join the leader of the aristocratical party in Thebes, and to occupy the citadel with a Lacedemonian garrison. This unauthorised step, though at first disapproved by the government of Sparta, was finally sanctioned by their retaining possession of the fortress thus treacherously seized, and by their bringing to trial and punishment the chief of the adverse faction, as if they had been the constituted judges of Thebes. For the space of four years, they succeeded in holding the Thebans under the most humiliating subjection; but suddenly the Theban exiles, with the assistance of the Athenians, by one of the boldest and best conducted exploits recorded in history, recovered possession of their power in the city, and compelled the Lacedemonians to evacuate the citadel. With difficulty the Thebans at first withstood the armies of Sparta, by acting on the defensive; but gradually improving in military skill, they learned to face in the field, and to combat, even with inferior numbers, the experienced troops of their powerful adversary. Under the able direction of Epaminondas and Pelopidas, they ventured, though then without an ally, to persevere in the unequal contest; and, in the famous battle of Leuctra, the bloodiest action hitherto known in Greece, these distinguished commanders, by their skilful dispositions, and the enthusiastic courage which they inspired their troops, defeated an army nearly four times the number of their own. Never had the Lacedemonians, before that day, retreated from an inferior force, or lost in any one engagement so many of their citizens. Another of their boasts, "that never had the women of Sparta beheld the smoke of an enemy's camp," was now also done away.

Their occupation of Thebes. B. C. 382.

Defeated at Leuctra. B. C. 370.

City of Sparta threatened.

The victorious Thebans, headed by Epaminondas, and joined by many of the Grecian states, ravaged the Lacedemonian territories to the very suburbs of the capital; and on their return reinstated the Messenians, whom the Spartans had driven from their country. The Lacedemonians, alarmed not merely for their supremacy but their safety, secured assistance from Athens, from Syracuse, and even from Persia, while the Thebans were hard pressed by a war in Thessaly, against Alexander, tyrant of Pheræ. Pelopidas, however, having been dispatched to the Persian court, succeeded in recommending himself to the esteem of the monarch, and in turning his friendship to a state which had never been at war with Persia. Thebes, intoxicated with her rising power, which she owed chiefly to the abilities of her leaders, obstinate in maintaining her authority over the cities of Bœotia, which was perhaps necessary for her resistance to Lacedemon, and aiming to become the arbitress of Greece, which her sudden elevation provoked many of the states to regard as unpardonable presumption, may be considered as at this period the cause of the continuation of hostilities among the Greeks.

Greece.

Sparta, however, was equally obstinate in refusing to acknowledge the independence of the Messenians, and war was prolonged for some time with little effect, chiefly between the confederates of the two principal powers. The Thebans, having at length terminated the war with Thessaly, with the loss of their able general Pelopidas, were at liberty to take part more effectually in the transactions of Peloponnesus. A civil war having broken out in Arcadia between the cities of Mantinæa and Tegea, the Thebans supported the cause of the latter, while the Athenians and Lacedemonians declared for the former. The very existence of Sparta was threatened by the bold and enterprising measures of Epaminondas, who had nearly taken the city by surprise; but, frustrated in his plan by the activity of Agesilaus, he returned and gave battle to the Lacedemonians and their allies at Mantinæa, where he was mortally wounded in the moment of victory, and where with him the power of the Theban state expired. A general pacification succeeded, upon the basis of the former treaties prescribed by Persia, that every city should be independent; but the Lacedemonians still persisting in their wish to reduce the emancipated Messenians, were excluded from the treaty, and remained nominally at war with the confederates of Thebes. Exasperated by the friendly dispositions which the Persian court had manifested to the Thebans, and perhaps expecting to acquire some pecuniary resources for the recovery of their power in Greece, they sent an army to aid the insurgents in Egypt. After the death of Agesilaus, on his return from Africa, little occurs in the history of Greece deserving of notice, till the appearance of Philip of Macedon. A great change had taken place in Grecian politics. There was now no leading state, either of the aristocratical or democratical interests; and, though every city exercised a jealous watchfulness to prevent any overbearing superiority in another, there were no extensive confederacies or hostilities; but lassitude, indecision, and divisions, pervaded the nation, and paved the way for the universal subjugation of their liberties by the Macedonian monarchy. See Agesilaus, Epaminondas, &c.

Battle of Mantinæa. B. C. 363.

Spartan army sent to Egypt.

Irregular and ineffective administration at Athens.

In consequence of the blow given to the Spartan power in the battle of Mantinæa, and the decline of Thebes after the loss of Epaminondas, Athens remained the most prominent and respected of the Grecian republics. In want, however, of any salutary check from a powerful rival, its government became extravagant and irregular in the most extraordinary degree; the inconsiderate voice of the multitude deciding every measure, frequently ratifying at night what they had rejected in the morning, and ready to follow every varying scheme of every flattering orator. The citizens also, sinking into unbounded luxury, declined all military service, and resorting to the aid of mercenaries, engaged in hostilities chiefly for the purpose of collecting plunder, or of extorting tribute. Every marauding expedition was approved, provided the leaders brought home a sufficiency of treasure to provide amusements for the people, and to bribe the orators to silence. The official men, in short, inadequately rewarded by their regular salaries, learned, as is almost uniformly the case, to recompense themselves; and the people, either become necessitous by their idle attendance on political matters, or injudiciously supported by the public funds as an encouragement to population, actually depended for their subsistence upon the sacrifices, feasts, and spoils connected with their military expeditions. While Athens was in this situation, strangely feeble in the whole constitution of its government and population, yet by means of its naval force still the principal republic in Greece, a rival to its power arose in a quarter, which had hitherto attracted little attention, and had even been regarded by the Grecian states as undeserving of their notice. Though the kings of Macedonia pretended to be the descendants of Hercules, the Greeks considered them as no part of their nation, but always treated them as barbarians. This kingdom had existed more than four hundred years, but had generally stood in need of protection from Athens or from Sparta; and had never risen to a capacity of partaking in the eminence of these republics. But it now furnished an example, similar to that of Thebes, of the power of one distinguished individual to accomplish, in favourable circumstances, the most important revolutions. It was in Thebes, indeed, that the new leader of the Macedonians had received his best instructions in the arts of policy and war. Philip had been taken to that city as a hostage when he was only ten years of age, and had been carefully educated under the eye of Epaminondas, assisted by the celebrated Pythagorean philosopher Lysis. At twenty-four years of age he ascended the throne of Macedon, and gave early indication of his talents for government. At the period of his accession, he found himself at war with the Athenians, who supported one of his competitors for the kingdom. Having defeated his adversary, who was slain in the action, he instantly liberated, and loaded with favours, all the soldiers of Athens whom he had taken prisoners. Having discovered, that the Athenians were intent upon the recovery of Amphipolis, which they claimed as one of their colonies, but which he had seized as the key of his dominions on that frontier, he was equally reluctant to put it in their power, or to come to a rupture for which he was not prepared. With his usual consummate policy, therefore, he declared it in the mean time a free city, and left the inhabitants to maintain their own independence. A peace and alliance were ratified between the Macedonian prince and the city of Athens; but their agreement was of short duration. A contest speedily commenced, which led to the subversion of Grecian freedom by the arts and arms of Philip; but which owed its origin as much to the unprincipled aggressions of the Athenian democracy, as to the ambitious views of the Macedonian monarch. While in full alliance and co-operation with Philip against the Olynthians, they suddenly indicated their hostility to his interests, by detaching the town of Pydna from his kingdom, and making a direct attempt to possess themselves of Amphipolis. Failing in their design, it was soon after occupied by Philip, and rendered a strong barrier between his dominions and those of the Grecian states. Before this time had commenced "the Sacred War," undertaken by the Bœotians, Locrians, Thessalians, &c. in order to punish the Phocians, who had ploughed a field sacred to Apollo at Delphos, and had refused to discharge the fine which the council of the Amphictyons had sentenced them to pay, as an atonement for the sacrilegious deed. They were supported by the Lacedemonians, Athenians, &c. and Philip, well pleased to leave the Grecian states to exhaust their strength against each other, had employed himself in the meantime in extending his power in Thrace, and in attaching Thessaly to his interests, by delivering its cities from the oppressive sway of the tyrants of Pheræ. Irritated, however, by the defection of Olynthus from the Macedonian to the Athenian alliance, he laid siege to that city; and, having gained possession of the place

Greece. by bribing a party of its inhabitants, he razed its walls to the ground, and sold the people for slaves. The Sacred War, which was still carried on by both parties with the most sanguinary retaliations, next afforded him a fair opportunity of bringing his power into full contact with the Grecian states. Professing to adjust, as arbitrator, the matter in dispute, promising to the Phocians his protection against the fury of their enemies, and soothing the Athenians by the reports of his friends, that he was secretly intending to humble Thebes rather than Phocis, he marched an army into Greece; gained quiet possession of the Phocian cities; secured to that people, as he had promised, their personal safety; but procured, or at least sanctioned, a decree of the Amphictyonic Assembly, annihilating their political existence as a nation, and expelling them from the number of the Grecian states represented in the council. He was himself elected in their place as a member of the Assembly; invested with the double vote which they had enjoyed; and usually denominated in their future operations the Amphictyonic general. The Athenians refused to acknowledge his election; and manifested, in all their measures, an ambition even more unprincipled and indefensible than that of the Macedonian monarch. Guided rather by the inflammatory eloquence of Demosthenes, than by the pacific counsels of Phocion, they plunged at length into a destructive contest with their powerful rival and neighbour.

Termina... by Phi... B. C. 347.

A second sacred war again drew Philip into the midst of Greece. The Locrians of Amphissa having encroached upon the consecrated ground of Delphos, and having refused to obey the decrees of the Amphictyonic council, the Macedonian monarch was invited, as their general, to vindicate their authority by force of arms. Many of the Grecian states were now alarmed, and not without reason, by the forwardness of Philip to interfere in their politics, and by the reluctance which he shewed to withdraw his army, after the punishment of the Amphissians. Demosthenes hastened to Thebes, where he succeeded in rouzing the utmost enthusiasm for the liberties of Greece, and persuaded the Thebans to adopt the immediate resolution of uniting with the Athenians, to resist the dangerous progress of the Macedonian influence. In vain did Phocion recommend, and Philip request, the Athenians to lay aside their measures for instant hostilities. They excluded the former from the command of their army, and marched without delay to join their Theban allies against the enemy. The two armies, consisting of about 30,000 on each side, came to a general engagement at Cheronea. The battle was long doubtful. Alexander, who was only seventeen years of age, at the head of a chosen body of noble Macedonians, cut down the Sacred Band of Thebes; and the Athenians, for a time successful, but urging their advantage with imprudent impetuosity, were overwhelmed by the Macedonian phalanx under Philip. The vanquished were treated with a degree of clemency and generosity, of which there had been few examples in Grecian warfare. Philip hastened to stop the slaughter of the flying Greeks, and dismissed the Athenian prisoners without ransom, and voluntarily renewed his former treaty with that republic. To the Thebans he readily granted peace; but stationed a Macedonian garrison in their citadel. By this decisive victory, he secured the most entire ascendancy in Greece; and, on that side, there was little farther left for his ambition to desire.

...w reli... war.

...e of ...onea. ... 338.

Either, however, with a view to extend his conquests, or in order to unite the Greeks more firmly under his power, he planned the invasion of the Persian empire, and procured himself to be appointed generalissimo in the expedition. No measure could have been conceived more popular in Greece. A general council of the states was summoned, and the quota determined which each of them was to furnish. Philip exerted himself with extraordinary activity to complete his formidable preparations; and his whole army, in the most perfect state of military discipline and equipment, was in readiness to cross the Hellespont. But, in the midst of his greatest splendour, while solemnizing, before his departure, the nuptials of his daughter Cleopatra, surrounded by his guards and principal officers, and receiving, among the assembled states of Greece, little less than divine honours, he was stabbed to the heart by a desperate assassin. See DEMOSTHENES, and PHILIP.

Philip meditates the invasion of Persia; but is cut off by an assassin. B. C. 336.

Upon the accession of Alexander to the throne of Macedonia, when only twenty years of age, the different nations whom his father had brought under his dominion made an attempt to regain their independence; and Demosthenes exerted all his powers of persuasion to engage the Greeks to unite against the youthful successor of the formidable Philip. But Alexander, having punished the Thracians, Illyrians, and other barbarians, for their indiscretion, turned, with the utmost expedition, the whole weight of his arms upon Greece. The Thebans, who had massacred the Macedonian garrison, which Philip had placed in their citadel, having refused the offer of a free pardon made to them by Alexander, upon condition of their surrendering the principal leaders of the insurrection, were defeated with great slaughter, their city given up to be pillaged, and the inhabitants sold as slaves. These dreadful acts of severity filled the Athenians with alarm, and an embassy was instantly dispatched to implore the clemency of the Macedonian prince. Alexander at first insisted that ten of their principal orators should be delivered into his hands; but was at length satisfied with the banishment of Charidemus, and expressed the highest regard for the republic of Athens. The other states hastened, in like manner, to make their submission; and, in one campaign, the whole nation of the Greeks acknowledged his supremacy. Having assembled their deputies at Corinth, and renewed the proposal of invading the Persian empire, he was appointed, as his father had been, to the chief command. His rapid conquest of Persia, which would form too extensive an episode in this brief sketch of Grecian history, and which must therefore be passed over without detail, produced one of the most extraordinary and important revolutions in the political aspect of the world. No national contest recorded in history was ever more interesting in its progress, or involved consequences of greater magnitude, than the struggle which had so long been maintained between Persia and Greece. Its object was to decide the great question, whether Europe or Asia should have the ascendancy; and at length, under the auspices of the Macedonian prince, the former gained a superiority, which it has preserved to the present day. During the progress of Alexander's conquests, various attempts were made by the Grecian states to shake off the yoke of Macedonia. The Spartans especially, under the direction of their king Agis, excited a powerful insurrection in Peloponnesus; but Antipater, who had been left to govern in Macedonia, marching a powerful army into the peninsula, completely broke their spirit by a decisive defeat of their

Accession of Alexander, who destroys Thebes, and conquers Persia. Insurrections in Greece.

forces, and the death of Agis, who fell in the pursuit. Harpalus, one of the officers of Alexander, who had incurred the displeasure of that prince by his extortions, when governor of Babylon, took refuge in Athens; and, by means of his treasures, succeeded in attaching them to his cause; but, upon the report of a powerful army being dispatched by Alexander to punish their treachery, they expelled Harpalus from their city, and banished Demosthenes, who had been convicted of accepting his bribes. A new commotion also had been excited throughout all the states of Greece, by a proclamation of Alexander to restore the exiles to their respective countries and possessions; and, upon the event of his death being known, the revolt which had already commenced instantly became general. Demosthenes was recalled, and a powerful army of confederated Greeks, under the Athenian commander Leosthenes, marched against Antipater. Elated by the success which attended their first operations, they despised, as usual, the prudent warnings of Phocion, and began to calculate upon the return of their ancient greatness. But Antipater having been joined by Craterus with a part of the victorious army of Alexander, speedily reduced the insurgent states in succession; and, advancing towards Attica, as the great object of his vengeance, though in some measure softened by the intercession of the virtuous Phocion, he abolished the democracy of the Athenians, and established the aristocratical government, as it had existed in the days of Solon; obliged them to pay the expences of the war; and placed a Macedonian garrison in the port of Munychia. Similar changes were made in most of the other states; and, though the people loudly complained, in the first instance, of these infringements upon their liberties, they began at length to feel, that their freedom was in reality greater than it had hitherto been, and acknowledged their obligations to Antipater, by entitling him the Father and Protector of Greece. After the death of Antipater, the Grecian states largely shared in the revolutions and dissensions which agitated, for so many years, the empire of Alexander. Polysperchon, who had been associated with Cassander, the son of Antipater, in the regency of Macedonia, being engaged in a contest with his ambitious colleague, sought to attach the Greeks to his interests, by displacing the governors whom Antipater had placed over them, and by restoring the power of democracy. Several of the cities, particularly Megolopolis, resisted his decree, and drew upon their heads a bloody revenge. Athens, on the contrary, gladly hailed its recovered liberty; and proceeded, in its moments of renewed turbulence, to put to death the friends of Antipater. Among these perished the greatest ornament of their city, the incorruptible Phocion, who had served in the armies and councils of his country till he was above eighty years of age; and whose distinguished merit his fellow citizens soon after acknowledged, with their accustomed inconsistency, by erecting a statue to his memory, and inflicting punishment upon his accusers. But Cassander, by the aid of Antigonus, having recovered his influence in Greece, restored the aristocracy, replaced the Macedonian garrison, and appointed Demetrius Phalerius governor of the city, who conducted himself in his office with so much wisdom and moderation for ten years, that more than three hundred statues are said to have been erected in testimony of his benefits. The power of Cassander prevailed also in Peloponnesus; and, excepting a very few cities, Greece was again entirely subjected to the Macedonian dominion. See ALEXANDER.

Antipater settles the affairs of Greece.

New changes by Polysperchon.

Athenians put Phocion to death.

Prosperity of Athens under Demetrius Phalerus, B. C. 317.

During the revolutions which agitated Macedonia, after the death of Cassander, it was invaded and overrun by an immense body of Gauls, who pursued their course like a torrent, and poured upon the enfeebled states of Greece with the utmost fury. They were successfully resisted in the defiles of Thermopylæ, by the Grecian army under Calippus the Athenian; but, forcing their way by the path over mount Oeta, by which the Persians had penetrated under Xerxes, they directed their march to Delphos, with the design of plundering the temple of its accumulated treasures. But, meeting with a brave resistance from those who were assembled to protect the sacred spot, and, being thrown into confusion by a violent storm and earthquake, they fled in the utmost terror, and turned their arms upon one another, in the darkness of the night. They were keenly assailed by the Greeks in their flight, and the greater part of them cut to pieces. Scarcely recovering from the inroad of those barbarians, the states of Peloponnesus were involved in new calamities, by the ambitious arms of Pyrrhus king of Epire, who had reduced the greater part of Macedonia, and having been invited by Cleonymus, an exiled Spartan prince, to redress his grievances, led a powerful army to the gates of Sparta, while their king and the best of their troops were absent in Crete. But the inhabitants of the city, even the women, assisting in its defence, made so heroic a resistance, that time was allowed for the arrival of reinforcements; and Pyrrhus, being compelled to retreat, was slain in an attempt to enter the city of Argos. Antigonus, the son of Demetrius Poliorcetes, being again replaced on the throne of Macedonia, began to meditate the complete subjugation of Greece, and commenced his operations with the siege of Athens, which he speedily reduced, and garrisoned with Macedonian troops. Pursuing his schemes of conquest, he gained possession of Corinth by artifice, but was arrested in his ambitious career by the hand of death. His son Demetrius maintained a commanding influence in the different states of Greece, not by attempting to hold the sovereignty himself, but by supporting those who found means to usurp the supreme authority. His successor Antigonus Doson, a prince distinguished by his justice and moderation, avoided all interference in the affairs of foreign states; and the cities of Greece, imitating the example of the Achæan league, made one last attempt to recover their long lost independence.

Invasion Greece ... the Ga... B. C. 2...

Appear... of Pyrr... in Gre...

During the distracted times of Macedonia, under Lysimachus and Ptolemy Ceraunus, the cities of Achaia gradually recovered their liberties, and renewed their ancient confederacy: (See ACHÆANS.) Aratus of Sicyon, having freed his native city from the government of Nicocles, joined the Achæan league, and was chosen prætor of the associated states. Intent upon delivering Peloponnesus from foreign dominion, and hoping to render the Achæan confederation a barrier against future invasion, he surprised the Macedonian garrison in Corinth, and attached the liberated city to the Achæans. He persuaded the governor of Megalopolis to abdicate his power, and follow the example of the Corinthians. Protected by the king of Egypt against the Macedonians, the Achæan confederacy was thus extending on all sides, and might soon have united all the peninsula as one nation, under one government, when its progress was interrupted by the hostility of Sparta. The ancient institutions of that distinguished city had fallen into

Acha... league revived B. C. 30...

total disuse, and the manners of its inhabitants had become entirely changed. Many of its kings had incurred deposition, exile, and death, by their attempts to resist the torrent of corruption; and Agis particularly, a young and virtuous prince, had fallen a sacrifice to his well-intended, but ill-executed scheme for restoring the laws of Lycurgus. Cleomenes, one of his successors, revived the prosecution of the plan, but pushed its accomplishment with the spirit of a tyrant, rather than of a reformer. Having massacred the Ephori, and banished the citizens who were unfriendly to his views, and rendered himself despotic at home; he turned his arms against the Achæans, either for the purpose of gratifying his ambition, by acquiring the direction of the confederacy, or, perhaps, only with a view of securing his usurped authority in Sparta, by having an army at his disposal. So strong was the antipathy of the Achæan republics to the prospect of Spartan domination, and so great at the same time their dread of its powerful tyrant, that Aratus was urged to the ruinous resource of calling in the aid of Antigonus Doson, king of Macedonia. * Cleomenes defeated by Antigonus in the famous battle of Selasia, abandoned his ambitious projects, advised his subjects to submit to the conqueror, and sought a refuge for himself in Egypt. The Spartans were treated by Antigonus with the greatest moderation; but, from that period of its subjection to a foreign power, it sunk into insignificance, and the race of the Heraclidæ became extinct with the successor of Cleomenes. The Achæan league was still preserved entire and powerful, by the able conduct and prudent measures of Aratus; but having sought assistance from Philip of Macedonia, the son of Antigonus, against the Etolians, the inveterate enemies of Achaia, that ambitious ally, conceiving a design to subjugate the cities of Greece, and regarding the integrity of Aratus as an insurmountable obstacle in his way, caused the virtuous patriot to be secretly taken off by poison. The Romans, however, having formed an alliance with the Etolians, in order to occupy the arms of Philip, who had become the active ally of their formidable opponent Hannibal of Carthage, thus acquired a footing in Greece, which gradually led to its final subjugation, as a part of their empire. Philopœmen, the successor of Aratus, supported the cause of Philip as the professed protector of the liberties of Greece, and inspired the confederated states with an ardent love of independence, which long withstood the encroachments of the policy and power of Rome. The struggle maintained in Greece between the Macedonian and Roman interests, was languid and indecisive, while the latter were intent upon reducing the power of Carthage. But, after the conclusion of the second Punic war, more active measures were pursued against Philip. Titus Quintus Flaminius, the consul, partly by the vigour of his arms, but still more by his political dexterity, detached the Etolians, Achæans, and the most considerable of the other states, from all connection with Macedon; compelled the discomfited Philip to accept the most humiliating terms of peace; made a pompous proclamation, at the public games, of the freedom of Greece; withdrew, according to his promise, every Roman garrison from the different states; and left them in full possession of all that political independence which was compatible with the alliance of Rome. Antiochus, king of Syria, instigated by Hannibal, and aided by the Etolians attempting an invasion of Greece, recalled to that devoted country the armies of Rome, and afforded them an opportunity which they did not fail to embrace, of subjecting all that part of Europe to their growing dominion. After reducing and dismembering the kingdom of Macedonia, they were invited to assist the Spartans in a contest with the Achæan states: they soon succeeded in breaking the power of the confederacy, by seducing a part of the cities of which it was composed; and Philopœmen, generally designated the last of the Greeks, having fallen in an expedition against the revolted Messenians, it became no difficult task to accomplish the total overthrow of the confederacy, of which he had been so long the principal ornament and support. Above a thousand of the Achæan chiefs, accused of having acted in concert with Macedonia, were transported to Rome to answer for their conduct, at the tribunal of the senate. The Achæan constitution was, soon after, entirely dissolved; the whole of Greece reduced to the state of a Roman province, under the name of Achaia; and, from that period, its history comes properly to be included under that of Rome. See ACHÆANS, MACEDONIA, and ROME.

Death of Philopœmen, and subjection of Greece to Rome. B. C. 146.

But Greece, though subject to the Roman arms, soon acquired, by her arts of peace, a silent superiority over her conquerors. The victors became the disciples of the vanquished; and the most distinguished Romans learned, in the Grecian schools of philosophy, to regard the country which they held in subjection, with the gratitude and respect due to a benefactor. These considerations probably contributed to secure to the inhabitants of Greece a milder exercise of authority, and more distinguished marks of favour, than were enjoyed by any other province under the yoke of Rome. Of these arts and attainments, to which this singular people were thus indebted for higher honours and advantages than all their military prowess had been able to command, we now proceed to offer an abridged view, as a suitable conclusion to the preceding sketch of their eventful history.

The arts, literature, and science, of the Greeks.

Of the state of society and knowledge among the earlier Greeks, particularly in what has been called the heroic age, as described in the writings of Homer, some account has already been given, when narrating the events of that period: and the remarks which follow apply chiefly to those times which were posterior to the first Persian war.

Agriculture.

To agriculture, as an object of study, the Greeks paid little attention; and the care of its operations was almost entirely left to slaves. The Athenians considered themselves as having first received the common principles of the art from Egypt, and as having communicated the knowledge of it to the other countries of Greece. Attica itself, however, was adapted rather to the cultivation of fruits than of grain. Olives and barley formed its principal produce, and the citizens of Athens received their great supplies of wheat from the neighbouring states of Bœotia, or from their own colony of Byzantium. Their writers on the subject, among whom was Xenophon, have done little more than merely detail the common practices of their own times.

* The cities of Greece being so much decayed in strength, and unable to assume the attitude of independence, Aratus may be regarded as having adopted, if not the wisest, at least the only measure of security in his power. His object was to render the kings of Macedonia the allies and protectors, in place of the masters and tyrants of the united commonwealths; and, by yielding so far to an influence which could not be withstood, to procure a free regulation of their internal concerns, and particularly an exemption from the odious and oppressive presence of foreign garrisons.

Greece. **Navigation.** The inhabitants of Greece, though possessing a maritime country, surrounded with islands, and provided with excellent harbours, were extremely slow in availing themselves of these advantages; and made little progress in navigation and commerce, till after the expedition of Xerxes into Peloponnesus. After the example of Athens, especially in the course of the Peloponnesian war, the other states at length directed their attention to the maintenance of a navy; but chiefly for the purposes of warfare. The voyage of Alexander's fleet from Patala to Susa, after sailing down the Indus, was the first instance of Greeks navigating the ocean; and, previous to that expedition, they were entirely confined to the waters of the Mediterranean.

Commerce. Excepting Corinth and Athens, it was principally in the smaller states, such as Megara, Sicyon, Cos, and Cnidus, (which possessed not sufficient political influence to interfere in the general affairs of Greece,) that the arts of commerce were most sedulously prosecuted. Athens, however, was the great seat of commercial views, where every circumstance favoured the acquisition, and encouraged the expenditure of wealth. Its port, Piræus, was then the centre of the traffic of those times, and there every commodity was to be found in abundance.

Fine arts. The fine arts appear to have attracted earlier attention in Greece, than the more useful occupations; and some of the ancient medals, long prior in date to the oldest historians, exhibit a chasteness and grandeur of design, both in architecture and sculpture, for which it is difficult to account.

Architecture. The customs and circumstances of the Grecian states tended directly to encourage the progress of these arts. Three public buildings were indispensible in every city; a temple, a theatre, and a gymnasium, to which were afterwards added the baths, and portico or place of shelter for walking and conversing. In larger towns these edifices were soon multiplied, especially those for the service of religion; and every city almost forming a distinct community or nation, each required to possess these different buildings within its own walls, and strove to surpass its neighbours in the solidity and beauty of its public structures. The exertions of the Greek artists in this at once useful and ornamental study, are not therefore very wonderful; but, when it is considered, that its first architects derived their skill from those of Egypt and Persia, and that the Doric order, the foundation of all the rest, and the source of pure taste to all the architecture of Greece, was actually the most ancient, it is not easy to conceive by what accidental or intended principle of the art, a beautiful simplicity, so opposite to the enormous masses of the Egyptians, and cumbrous ornaments of the Asiatics, should have been so happily introduced; unless we ascribe it to the mere circumstance of necessity (the origin of so many human improvements) which obliged the early architects of that country to work with wooden materials: (See Civil Architecture, vol. vi. p. 529.) But in whatever way we may account for the rise of Grecian architecture, its principles have received the approbation of every enlightened people in modern times; and its three orders, the Doric, Ionic, and Corinthian, still continue to form the invariable standard of good taste in the art. *

Sculpture. The same causes which rendered the skill of the architect so much in request, equally tended to encourage the labours of the painter and sculptor; and it is a remarkable circumstance, that, in the most turbulent periods of Grecian history, the fine arts received the most distinguished patronage, and made the most rapid progress. At Athens, particularly, the genius of Greece was nourished by Pisistratus, and brought to perfection by Pericles. The most eminent sculptors of those times were Phidias, Alcamenes, and Myron, of Athens; Polycletes and Lysippus, of Sicyon; Praxiteles and Scopas of Paros; and many of the ancient statues which have escaped the ravages of time, furnish ample testimony of the progress which had been made in the art. See Drawing and Sculpture.

Painting. Of the state of painting among the Greeks, many exaggerated and incredible accounts have been given by ancient authors. They used only four colours, black, white, red, and yellow; and knew nothing of painting in oil. They are considered also as having been very imperfectly acquainted with the effects of light and shade; and many pieces of ancient Mosaic, still preserved, are not much admired as performances in painting. Both in painting and statuary, the Greek artists produced representations of the human form, which could scarcely be called natural. By taking collective views of the species, and studying accurately the physical constitution of the body of man, they combined its various and scattered excellencies in one figure, and thus exhibited, what nature never does, a model of abstract and ideal perfection. Among the celebrated painters may be mentioned Polygnotus, who received the thanks of the Amphictyonic assembly for his painting of the Trojan war, placed in one of the porticos of Athens; Apollodorus, who is supposed to have invented the art of painting in clear-obscure; Zeuxis, who displayed himself at the Olympic games, dressed in purple and gold, and, having become wealthy, gave his works as presents, because he said they were above all price; Parrhasius, who insolently presented himself to public view with a crown of gold upon his head; Pamphilus, the first who applied the principles of science to his art; Timanthes, who produced the celebrated painting of the sacrifice of Iphigenia; Apelles, who exposed his works to public view, that he might derive improvement from the remarks of passengers; and Protogenes, the rival of Apelles, who censured the extreme minuteness of his contemporary, by saying, that "he knew not when to lay down his pencil."

Music. Few things are more remarkable in the manners of the ancient Greeks, than the great importance which they attached to the musical art, which, in many of the states, was even regulated and recommended by the laws. It was considered as one of the most powerful means of influencing the sentiments of the people, and formed an essential part in the education of the youth. The ancient musicians are supposed to have been wholly ignorant of the art of performing pieces of music in different parts at the same time; and their compositions, especially the pathetic and warlike, are generally understood to have derived much of their effect from the poetry and sentiments with which they were combined.

The honours and rewards lavished upon those who excelled in the fine arts, were doubtless one principal cause of the improvement which they reached; but often were they carried to a hurtful excess, exhausting the wealth which was wanted for the support of the state, and engrossing the rewards which were due to more essential services.

* See an examination into the grounds of this preference in the Rev. Mr Alison's *Essay on Taste*, vol. ii. p. 156.

of war.

But the great occupation of the Greeks as a people, were war and politics. Leaving the ordinary labours of agriculture and the mechanical trades to the slaves, the citizens of the different states considered it as their peculiar privilege to share in the government of their country, and to fight in defence of its rights, or for the advancement of its power. Every citizen, therefore, being bound to serve in arms, was enrolled as a soldier at a certain age; and one of their regular employments was the exercise of the gymnasium, as a preparative for the toils of war. The armies were composed principally of heavy-armed infantry, attended by a number of slaves to carry the baggage, and serve in the camps, and sometimes to act as light armed troops. The arms of the infantry were a helmet, corselet, large brazen shield, leathern greaves or boots, long pike, and short sword. They were long accustomed to advance, in a compact body, to close fight; but Iphicrates, an Athenian general, introduced the employment of a greater proportion of light infantry, diminishing the weight and size of the buckler, exchanging the metal corselet for one of canvas, lengthening considerably the lance and sword, and accustoming the troops thus accoutred to the most active evolutions. That celebrated commander, describing an army as a human body, compared the general to the head, the heavy-armed infantry to the breast, the cavalry to the feet, and the light troops to the hands. Chariots were little used after the heroic age; and, for want of horses, cavalry were never numerous, generally consisting of the wealthier citizens, or of soldiers fitted out at their expence. Till the time of Philip of Macedon, the Greeks were little acquainted with the art of conducting sieges, but commonly limited their operations to a general assault, or inactive blockade. In long or distant wars, especially in the later ages of Greece, the citizens received pay, while serving in the field; but the constant object of every Grecian state was to support their troops at the expence of the enemy. Even in the most civilized periods, Grecian warfare was conducted with a spirit of rapine and barbarity, which seemed to increase, instead of diminishing, as knowledge and refinement spread among the people. Retaliation was considered as justifying the most atrocious measures, of which, in the course of the Peloponnesian war particularly, many instances occurred, in the proceedings of all parties. The Lacedemonians regularly massacred the crews of the Athenian merchant vessels, and even of neutrals, whenever they came in their way; and the Athenians deliberately decreed the extermination of the Æginetans and Scyonians, whom they put to death without distinction.

P. ics.

The Greeks distinguished six simple forms of government, namely, monarchy, hereditary or legally established oligarchy, aristocracy, democracy, tyranny, and assumed oligarchy, of which the two last were considered as illegal and inadmissible. The title of King never implied among them the possession of absolute power, but only a legal and regulated superiority, particularly in directing the observances of religion, and the operations of war, and sometimes also in dispensing justice, but rarely in enacting laws. After the general abolition of monarchy in Greece, whenever a citizen of a commonwealth was raised by any means to monarchical authority, he was denominated Tyrant, not originally as a term of reproach, though in future times it came too justly to be applied in that sense. In Athens especially, as early as the days of Theseus, the nobly-born formed a distinct class of the community, and were invested with great privileges; but hereditary nobility declined every where along with monarchy, and wealth became the principal cause of distinction among the citizens. Those who were able to serve in war on horseback at their own expence, began to be regarded as a superior rank; and to the same circumstance may be traced the order of knighthood in most countries. Aristocracy, however, was less a regularly instituted form of government, than an assumed title adopted by the rich and the noble in those states where they held the chief power; but, as their administration was generally oppressive, oligarchy, or the government of a few, became a more frequent, though less honourable form of polity; and the term aristocracy was at length employed rather to signify those persons who, on account of distinguished merit, were elected by the people to undertake the management of public affairs. This last was commonly the mode adopted in the most democratical states; and pure democracy, in which all the freemen of the republic, in assembly, formed the supreme and absolute administration, was very rarely exemplified, and was usually denominated ochlogracy or mob-rule. Most of the Grecian governments contained a union of two or more of these forms; and, from these various mixtures, new distinctions and designations arose, which it would be tedious and unprofitable to trace. Of political economy the Greeks seem to have been extremely ignorant; and very little is known respecting their mode of managing the public finances. On the subject of population, it does not very clearly appear what was their regular system. They certainly employed many regulations for keeping up at least, if not for increasing, the number of their citizens; yet they shewed a decided aversion to any augmentation of their strength by the admission of foreigners to the privileges, or even to the protection of their state. They studied to preserve their townships completely insulated and distinct from all others; and prohibited intermarriage with the members of a different community, with all the jealousy of feudal clanship.

Literature and science.

Amidst all the turbulence of the Grecian states, and the almost perpetual hostilities in which they were engaged, there were many circumstances favourable to the cultivation of literature and science. Few individuals possessed large properties, but many of them lived in great leisure, following no occupation themselves, and principally maintained by the labour of slaves. Assembled generally in towns, and having free intercourse with one another, polite manners were formed, and various opportunities were presented for the display of taste and genius. A lively imagination, and love of novelty, were general characteristics of the Greeks, and disposed them to welcome every ray of knowledge which beamed upon their limited society. Many, possessed of active and intelligent minds, yet less daring in their dispositions, or more scrupulous in their integrity, shunning the stormy paths of political ambition, sought employment and distinction by attainments in literature or science. Even those who aimed at the offices of statesmen, found a degree of general knowledge, especially in the pursuits of taste, and the arts of eloquence, highly advantageous to enable them to command attention in the public assemblies, and to assist them in swaying the minds of their fellow citizens. As knowledge increased among the members of a community, these qualifications became not merely useful, but essential to every political leader; and many, who were unable, or unwilling, to mingle in the struggle for public situations, found a less splendid, but often more

Greece. Literature and science.

gainful occupation, in communicating to others those literary acquisitions which had become so subservient to the success of public men. At length every city in Greece, but especially Athens, abounded with those persons, who, under the name of Sophists, undertook to teach every branch of science; and, at a time when books were few and expensive, the oral communication of knowledge was obviously a matter of the utmost importance.* These professors of wisdom studied the accomplishments of eloquence, to render their instructions more attractive; and frequenting all the places of public resort, strove to recommend themselves to notice by an ostentatious display of their abilities, especially by public disputations with one another, or with any who chose to converse with them amidst a circle of hearers. Grecian philosophy is generally admitted to have originated with Thales of Miletus, the contemporary of Solon, and the founder of the Ionian school. Soon after him arose Pythagoras, a native of Samos, who was compelled, by political troubles, to take refuge in Italy, and thus became the leader of what has been called the Italian school. Both these sages are understood to have acquired their learning in Egypt and Persia; but so much was it the practice of the Greeks to claim as their own, what they had merely purloined from the literary treasures of other nations, that it is impossible to ascertain what portion of their science was indigenous, and what of foreign growth. Both Thales and Pythagoras inculcated many valuable moral precepts, but they were not teachers of ethics as a system; and their countrymen of the Asiatic Greeks were more delighted with those metaphysical enquiries, respecting the nature of matter and spirit, the formation of the world, and laws of the heavenly bodies, which gratified their imagination, without proposing any restraint to their passions. It was during the administration of Periander at Corinth, and Pisistratus in Athens, that the love of these sciences was first kindled in Greece; but the growth of every liberal art was entirely checked by the violent political contests and revolutions which ensued, and particularly by the general alarm of the Persian invasion, which left no leisure for speculative pursuits. But when the commanding talents of Pericles had quieted the tumults of faction in Attica, the pursuits of science revived at Athens with new vigour; and, together with the fine arts, continued to receive improvement during all the turbulence which attended the progress and effects of the Peloponnesian war. During this period it was, that Anaxagoras of Clazomene introduced the best principles of the Ionian school, that Socrates dispensed his more practical instructions, that Plato wrote and taught his more refined speculations, that Lysias and Isocrates pleaded in the forum, and that Aristotle and Demosthenes studied in the schools of Athens.

Theology.

Anaxagoras first taught in Athens the existence of one eternal and supreme Being, or, as he is said to have expressed himself, "a perfect mind, independent of body," as the cause or creator of all things; and, by enabling his pupils to calculate eclipses of the sun and moon, proved these hitherto reputed divinities to be mere material substances. But his doctrine was so directly repugnant to the whole religious notions of the Grecian people, that he was accused of impiety, and obliged to withdraw from the Athenian territories. Socrates, early impressed by the sublime principles of theology taught by the exiled philosopher, yet, perceiving the inutility, or at least the unpopularity of such discussions respecting the nature of the Deity, applied himself rather to investigate the duty which man ought to render to such a Being, as Anaxagoras had described the great Creator. He seems to have settled it as a first principle, that, if the providence of God interfered in the government of the world, the duty of man to man must form a distinguished branch of the divine will. He therefore applied himself to examine and inculcate the social duties; and, possessing a most discriminating and ready eloquence, he rendered his conversation (the only mode of teaching which he employed) at once amusing and instructive. He was always to be found wherever there was the greatest resort of company, and was ready either to receive or to communicate information; but he would neither undertake the office of private instruction, nor accept a reward for his public labours. While he maintained the perfect wisdom and perfect goodness of the Supreme Being, and the constant superintendence of his providence over the affairs of men; he continued to observe and to recommend the various acts of religious worship, which were practised in his native country. But all his caution and worth were unable to secure his protection against the jealous tyranny of Athenian democracy; and, either from an impression that he disapproved of their popular constitution, or from a dislike of his purer system of morals, he was rendered so obnoxious to his fellow citizens, that a decree was easily procured for his death. After the time of Socrates, the Greek philosophers were divided into two opposite sects, the Theists and Atheists. The latter, among whom were Leucippus, Democritus, Epicurus, &c. supported the opinion of Anaximander, that, without the aid of a supreme intelligence, all things were produced by a necessary action of matter, assuming all kinds of forms; and the former, among whom were Plato, Aristotle, Zeno, &c. adhered to the doctrine of Anaxagoras, respecting the existence of a Deity, while they held different notions as to his nature and attributes. Even those, however, who possessed the more correct ideas of the Supreme Being, almost without exception conceived the world to be governed by a number of inferior divinities, to whom different departments of the universe had been committed; and, as they readily conformed to the existing religious usages of their respective countries, their philosophical system and private example, rather countenanced than counteracted the popular poly-

* If an attempt were made to estimate the literary and scientific attainments of the ancient Greeks, the following would probably be found to be a few of the principal results; namely, that, in *literature*, it was rather in the entertaining than in the instructive branches that they made any extraordinary progress, and, even in history, produced merely exquisite narratives of events, without any exposition of their causes or relations;—that, in *moral science*, they excelled in acute disputations upon practical questions, and elegant manuals of useful precepts, but never ascended to any enquiry deserving the name of philosophy;—that, in *political science*, they described the most striking phenomena of government in the different states of their own country, or of the neighbouring nations, but made no researches into the principles, the ends, the safeguards of national constitutions;—that, in *physical science*, their progress was astonishing in the single branch of geometry, while they never thought of investigating the properties of physical bodies, or the order of physical events;—that, in *the philosophy of mind*, the logic of Aristotle contains an ingenious but unsuccessful analysis of the process of general reasoning, while his metaphysics explains only the various uses which were made of general terms, and vainly attempts to penetrate the essences and causes of things, but nothing is done to arrange the phenomena of thought, or to ascertain the order of their succession; that "not one, in short, of the ancient philosophers had any conception of the real nature of general terms, or of the operation of mind which is called abstraction; and that it was chiefly by this radical defect, that they were perpetually perplexed, and led into all their trifling and absurdity."

theism of antiquity. The origin and progress of the Grecian mythology, it is now impossible to trace with any probable degree of certainty. Whether it arose from the Chaldean hypothesis of the planets and elements being inferior divinities, and established mediators between man and the one supreme God; or from the allegorical mode employed by the Egyptians of describing the attributes of the Deity; or from a poetical personification of the operations of nature; or from a fabulous embellishment of real events, in the first periods of Grecian history; or from mutilated traditions of the lives of the Hebrew patriarchs; or rather, which seems the most likely, from a mixture of all these, and perhaps other unknown sources;—one thing seems evident, that if it ever possessed the symmetry of a philosophical system, its unity was destroyed before it was described by any writer of antiquity whose works are now extant.

The theogony of Hesiod may be considered as the earliest and most entire account of the religious tenets of the Greeks; but it is affirmed by Herodotus, that, along with the divinities of the first inhabitants of Greece, the poet has mingled the gods of Libya and Egypt. The system, in short, admitted in some degree by the philosophers, assumed and altered by legislators, as best suited their purposes, embellished and expanded by the poets, as their imaginations pleased, became at length an inextricable mass of mysterious absurdities, and ideal beings, of which we cannot attempt to furnish any consistent account. Neither can we afford space for enumerating the leading sects, and distinguishing tenets, and scientific attainments of the different philosophers of Greece; but the most important and authentic information on these topics will be found under the articles devoted to their respective names. (See particularly ACADEMICS, ATOMICAL PHILOSOPHY, PERIPATETICS, STOICS, ANAXAGORAS, ARISTOTLE, EPICURUS, PLATO, PYTHAGORAS, SOCRATES, ZENO.) It may be observed, in general, that the great defect of their physical science was, the want of experiment; and thus, having no fixed principles upon which to proceed, they had recourse to mere hypothesis and conjecture, amusing themselves with framing fanciful systems, while they should have been employed in actual observations. Hence a taste for sophistry and subtilty prevailed in every school of Grecian philosophy; and it became the boast of their teachers of wisdom to be able to support either side of a question, and to give plausibility to the most paradoxical opinions. This pernicious practice was soon transferred from the more abstruse speculations, to the more practical, political, and moral obligations. Its prevalence naturally gave rise to the sect of the Pyrrhonists or Sceptics, whose distinguishing principle was universal doubt, which they carried to such a degree of extravagance, as to pronounce every external object a mere illusion, and the life of man a perpetual dream. Neither the speculations of the philosophers, nor the fictions of the poets, were much calculated to favour the obligations of moral duty; and, even where their tendency was most unexceptionable, their influence was feeble.

Morals of the Greeks.

At no period of Grecian history does there appear any thing deserving the name of evidence to prove the existence of that virtuous age, which more modern declaimers have delighted to describe rather in the spirit of poetical romance, than of historic accuracy. In the earlier ages, violence and rapine, except in as far as they were occasionally restrained by the solemn obligation of oaths, form the prevailing feature of the people and their leaders. In the more enlightened periods, in the times even of Plato and his disciples, the clearest principles, we do not say of moral purity, but even of moral integrity, were not better understood, and still less better observed, than in the days of Homer. Philosophy relaxed the hold of superstition upon the conscience, without substituting any efficacious restraint in its place; and "it is evident," to use the words of Mitford, "from the writings of Xenophon and Plato, that, in their age, the boundaries of right and wrong, justice and injustice, honesty and dishonesty, were little determined by any generally received principle." The philosophy of Epicurus had completely gained the ascendency in the age preceding the Christian era; and the greatest characters, and most learned scholars, wavered between the tenets of the theistical and atheistical systems. Corruption of manners, and the subtilties of scepticism, had reached a height of extravagance, which it seemed scarcely possible to exceed. Human reason had lost itself in the labyrinths of philosophical speculation; and human virtue had been abandoned to the wayward direction of the fancy or the passions. The history of the world had demonstrated (and it is the best lesson, which a review of its most interesting portions can teach) the necessity of some surer and more authoritative guide to man than what the wisdom of the world had been able to afford him, either as a member of society, or a being formed for immortality. See *Ancient Universal History*; Millot's *Elements of General History*, vol. i.; Goldsmith's *History of Greece*; Rutherford's *View of Ancient History*; Gillies's *History of Greece*; Gillies's *History of the World*; Potter's *Antiquities of Greece*; Anacharsis's *Travels in Greece*; Leland's *History of Philip of Macedom*; Pausanias' *Description of Greece*; *Religion of the Ancient Greeks illustrated, by* M. Le Clerc; Newton's *Chronology*; Bossuet's *Universal History*; and particularly Mitford's *History of Greece*, a historical work, unequalled in modern times for extensive research, judicious conclusions, and well-arranged narrative. *(q)*

GREECE, MODERN. See TURKEY.

GREEK MUSIC, *Ancient*. It appears from the writings of Aristoxenus, the earliest writer on the music of the Greeks whose works are extant, that before his time, their scale of music had been extended to two octaves, by the raising of a major tone, and then three succeeding minor fourths, upon the lowest of the notes of this double octave, and by the descending of two such succeeding minor fourths, from the upper note of this double octave: each of these fourths, or diatessara, being exactly of the same magnitude, and alike constituted, as to the situations of its two interior notes, throughout each of their several genera, and the colours or species of each.

The *fourth* being thus made the unvarying boundary of every one of the numerous Greek systems, as the *octave* is now with us, and as the major *sixth* was with Guido, in the formation of his scale: In the genus DIATONICUM (which see) each fourth was made up of a semitone and two tones; in the genus CHROMATICUM, of two semitones and a minor third; and in the genus ENHARMONICUM (see GENERA) of two quarter tones or diesis, and a major third; each of which semitones, tones, thirds, and diesis, were varied, or have different values assigned them, by almost every different writer, as references to our articles above mentioned will shew; but so as always to preserve the fourth entire and perfect: and it has been concluded, that every one of these writers intended five of the *fourths* which he has described to be disposed within two octaves, from A to A, as above mentioned; the third of these fourths, tuned from below, overlapping the second of those two tuned from above, by a grave or comma-deficient minor third, as will be best explained by giving an example of the *Dialonicum intensum* of Ptolemy, which can be done, with reference to the notes of Mr Liston's scale, (see Euharmonic *Organ*), using the artificial commas of Farey's *Notation* (which see,) for expressing the magnitudes of the several intervals; viz.

		Σ	Σ		Σ	Σ	
	A		1224	Second Octave.			
	G		1131			93	5th 4th.
	F		1027			104	
	E		970			57	
	D		877			93	4th 4th.
D'		866				104	
C	C	773	773		93		3d 4th.
	B		716		104	57	
B♭		669				104	
A		612	612	First Octave.	57		
G		519			93		2d 4th.
F		415			104		
E		358			57		
D		265			93		1st 4th.
C		161			104		
B		104			57		
A		0			104		
Notes in Liston's Scale		Values of the Notes above A.			Intervals of the several adjacent Notes.		

The first of the above three columns contains the notes of Mr Liston's scale, and opposite to each of these, its value in the artificial comma (Σ) is placed. In column three, intermediary to the lines of the first two columns, the difference of the adjacent numbers in column two are placed, by which it will appear that each of the five tetrachords or fourths, BE, EA, AD'; and BE and EA are exactly alike constituted, that is, rise each by the intervals 57, 104, and 93 artificial commas each, answering to the major semi-tone, the major and the minor tones respectively.

The interval AB, is in each case 104, or the major tone; and thus, exclusive of the notes B♭ and D', the system comprised in these two octaves may be more simply expressed thus, viz. T + 4th + 4th + T + 4th + 4th = 2 VIII, forming thus far two similar octaves. The interval D'B or 866 — 716 = 150, is the comma-deficient minor third, by which interval the two series of fourths over-cap each other.

It would be easy for the musical student to prepare a similar table to the above columns two and three, for each of the many Greek systems, whose fourths are given in ΣS, in our articles on the *Genera* above referred to, and to place Liston's corresponding notes against them, in column one, as far as is practicable, by reference to the values of his notes in the *Philosophical Magazine*, vol. xxxix. p. 419, whence the above numbers were derived, by adding 161 from C to C, and 773 from C to a; that is, by reducing Liston's series to A as a bass or key-note, instead of C. (ϛ)

GREENHOUSE Plants. See Horticulture.

GREENSTONE. See Mineralogy.

GREEN, Matthew. Of this author of a popular poem, *The Spleen*, very few particulars are known. He was nephew to a Mr Tanner, the clerk of Fish-mongers Hall, and belonged to a reputable family among the Dissenters. But though bred among the sectaries, he grew disgusted with their precision, and probably left them without being reconciled to the mother-church, as he is said to have thought freely on points of religion. He had a post at the custom-house, which he discharged with great fidelity, and died at a lodging in Nag's-head Court, Grace-church street, at the age of forty-one, in 1737. Green's character is given by his intimates as that of an exceedingly honest man, witty and original in conversation, though slenderly educated; and agreeable in manners, though subject to the hip. Once when his friend Sylvanus Bevan, a Quaker, was complaining at Batson's coffee-house, that, while bathing in the river, he had been saluted by a waterman with the usual cry of *Quaker Quirt*, and wondered how his profession could be known while he was without his clothes; Green replied, "by your swimming against the stream." A reform took place at the custom-house, while he belonged to it, by which, among other articles, a few pence, weekly allowed for milk to the cats, were taken away. On this occasion, Green wrote a petition from the cats, which prevented the regulation from taking place. The poem of the Spleen was never published in his lifetime, nor any of his fugitive pieces. Glover, his warm friend, presented it to the world after his death; and, it is much to be regretted, did not prefix any account of its interesting author. It was originally a very short copy of verses, and was gradually and piece-meal enlarged. Pope speedily noticed its merit; Mr Melmoth praised its strong originality, in Fitzosborne's Letters; and Gray duly commended it in his correspondence with Lord Oxford, when it appeared in Dodsley's Collection.

It would be as superfluous here to enter upon a serious defence of the poem of the Spleen, as it was absurd in the last editor of the British Poets to attack it upon the grounds of its author professing to offer no religious consolations for the cure of splenetic temperaments. Religion would have been quite as much misplaced amidst those light views of life which the author exhibits, as in a sentimental comedy. The views of life which he takes, are not indeed marked either by strong sensibility, or profound observation; but the *light* in which he arrays familiar scenes and situations, is peculiarly original. The matter of his precepts is common, while their manner of expression is happy, and all his own. The concluding allegory, for instance, in which life is compared to a sea voyage, is extremely hackneyed, yet nowhere has the allegory been renovated by so many, and by so fine picturesque circumstances. Reason at the helm; the Passions forming the crew; Philosophy putting forth the lights; Experience employing the glass and lead; the careening places of Bath and Tunbridge; and the dolphins sporting round, all compose a picture of animated and amusing effect. Many of his scattered thoughts and detached sentences, fairly rival the best in Butler; and, upon the whole, leave it much to be regretted, that so ingenious a mind should have been destined, by a short life, and by the bondage of a confined vocation, to leave such scanty relics of its powers. (η)

GREENLAND.*

Greenland.

Progressive Geography.

Greenland is the most northern country of the western hemisphere of the globe. It reaches as far as the land is discovered, from Cape Farewell, in Latitude 59° 30′ to the 78th degree of North Latitude. Its eastern coast runs north-east towards Spitzbergen, and is bounded by the Atlantic Ocean. Its western coast has a northwest direction, and is bounded by Davis Straits and Baffin's Bay. Its southern coast is very narrow, not occupying one degree. The borders of its northern coast are entirely unknown. The eastern coast is commonly called East Greenland, and Osterbygd by the old Icelanders and Norwegians; the western, West Greenland, and Westerbygd; *bygd* signifying, in the old Icelandic language, settlement. From the date of its discovery, the former is called Old Greenland, the latter New Greenland. The whale fishers, speaking of Greenland, include under this name the islands of Spitzbergen, so called from the many sharp-pointed mountains with which it abounds, and they call the whole west side Davis Strait. The Danes further divide the west coast into South Greenland, a distance from 59° 30′ to the 68th degree, and into North Greenland from the 68th degree to the most northern point. That Greenland joins the continent of America on the end of Baffin's Bay, is nearly ascertained.

The discovery of Greenland between the years 830 and 835, is mentioned in the chronicle of Snorre Sturleson, a learned Icelander, who wrote about the years 1212, or 1215. Another Danish writer, Claudius Christofferson, places the discovery in the year 770. An Icelander, Eric Raude, or Eric the Red, so called from his red hair, having killed another powerful chief of that land, was obliged to quit the country, and determined to make a voyage of discovery, a practice very common at that time. Soon after he set sail, he reached the point of a cape on the continent of Greenland, which cape he called Heriolfsnæs in commemoration of one of his ancestors. Turning from this to the south-west, he entered a very large inlet, which he called Eric's Sound, probably the sound called by the natives Ikareseksoak, which separates Cape Farewell from the continent of Greenland; he then stopped and remained on an island in the vicinity of it. The following summer he explored the continent, and returned in the third year to Iceland, where he boasted very much of the fertility of the new country which he had discovered, to which he gave the name Greenland, hoping thereby to induce a great many people to follow him. Of 25 vessels which set out with him for Greenland, only fourteen arrived safe. These settlers were soon followed by others, both from Iceland and Norway, and their number in a very short time increased so much, that they occupied part of the east and west coast of Greenland. Eric Raude and his sons Leif and Thorstein afterwards made excursions from time to time to the opposite side of Davis Strait, or the North American coast, and founded colonies there, to which they gave the name of Winlandia. In the year 999, Leif made a voyage to Norway, and was persuaded by King Tryggegon to embrace the Christian religion; he took priests with him to Greenland, for the conversion of his countrymen; and his father Eric Raude, with many of the people, went over to the Christian faith, and there was afterwards established a bishopric, and a great number of churches. The old Icelandic and Danish writers tell us, that there existed 12 parishes on the east coast of Greenland, containing 190 villages; and four parishes, containing 100 villages on the western coast. The last Bishop Andrew was sent there in 1408, and after that year Greenland was no more thought of for a very long time.

Antonio and Nicolo Xeno, A. D. 1380.

Amongst the foreign travellers who visited the coast of Greenland very early, about the years 1379 and 1380, were the Venetian noblemen Antonio and Nicolo Xeno, to whom we are indebted for the first map of Greenland, published with a description of their voyage, by Francesco Marcolin, at Venice, in 1558. From the year 1408, all intercourse was cut off, and all knowledge of Greenland has been buried in oblivion. Previous to that time the Esquimaux, now called Greenlanders, began to shew themselves on the western coast. It cannot now be ascertained whether these Esquimaux, harassing incessantly the Icelandic and Norwegian settlers, have at length prevailed against them, and extirpated the whole race. Some suppose that the plague called the black death, which devastated the north of Europe, from the year 1402 to 1404, reached this land, and carried off a great number of the settlers, so that, by their diminution, they were weakened to such a degree, that at last it became an easy matter for the Esquimaux, (called Skrællingers by the settlers) to make war upon them, and to extirpate them. In this forgotten and neglected state Greenland still remained, until the beginning of the 16th century, when a new spirit burst forth in Europe, to explore the unknown regions of the earth.

Frobisher. A. D. 1576.

Martin Forbisher, or Frobisher, was, in the year 1576, the first that navigated this coast, and called it *Meta Incognita*. A sound which, according to him, divided that continent, was called Forbisher Strait. He was sent out again by Queen Elizabeth, in the year 1578; but he lost two of his vessels, and could find neither the sound nor the land. The Forbisher Strait is marked on all charts of Greenland, but it does not exist anywhere on the whole coast.

John Davis, A. D. 1586.

Baffin, A. D. 1616.

John Davis followed the same course, in the year 1585, and discovered that strait which now bears his name, viz. Davis Strait, which reaches to the 70th degree. Some public-spirited gentlemen sent out Robert Bylot as captain, and William Baffin as pilot, with the ship Discovery, in the year 1616: they reached Davis Strait, and advanced as far as the 77° 30′.

The Danish government, animated by these discoveries, began also to think of their lost Greenland, or the Osterbygd, (eastern settlements,) and during the reigns of seven kings, spent considerable sums upon it, but without success; the eastern coast having become inac-

* The Editor has been indebted for the following article on Greenland to the Chevalier Charles Louis Giesecke, Professor of Mineralogy to the Dublin Society, who resided many years in that country, for the express purpose of examining its mineralogy and natural history.

Greenland.

cessible by the floating ice. Finally, in the reign of Frederic the Fourth, Hans Egede, a clergyman from Vogen, in the North of Norway, animated by a religious enthusiasm, offered himself for the conversion of the Greenlanders, and, accompanied by his wife and children, left his office, and his native country. He was furnished by the Danish government with two vessels; and, being provided with the necessary stores, he embarked on the 2d of May, in the year 1721, and, after struggling with many dangers, landed on the 3d of July, at Baal's river, in 64° 5′ of N. Lat. The Greenlanders did not like their new guests; but, by degrees, they were influenced, by friendly treatment and presents, to entertain those who visited them. The trade had a very poor appearance in the beginning, but all succeeded very well in the course of three years. From time to time, the establishments both for the mission and the trade were increased, and Mr Egede built the first European house in Baal's river, calling the settlement, metaphorically, Gotthaab (Good Hope.) The three first missionaries of the German *Unitas Fratrum*, or the Moravian Brethren, were sent out in the year 1733. They established their first settlement in the vicinity of that of Mr Egede, and gave to it the metaphorical name New Herrnhut, their first settlement in Germany being called Herrnhut, that is, protected by our Lord.

Hans Egede.

Moravian Missionaries.

The Danish government were not discouraged by the unpromising appearance of the missions and the colonies, but made ample provision for upholding and extending them, and formed permanent settlements for the best possible cultivation of the land. Horses and soldiers were sent over to Greenland, that the settlers, by their aid, might travel over land to the east coast, or the lost Greenland; but the icy vallies, and glaciers crossing the interior of the country, were found impassable; the horses perished, and all those endeavours proved abortive. The only possible way to come there, would be with Greenlandish leather boats, which are easily transportable over the floating ice, travelling round Cape Farewell, and never losing sight of the coast. But the reports of the Greenlanders, who dwell in the most southern part of the country, give sufficient reason to suppose, that none of the old settlers will be found there; it being probable, that a coast incessantly surrounded by ice fields, which have lain there from time immemorial, and increase every year, as is ascertained by the whale-fishers, who go to Spitzbergen, will be now much colder than it was some centuries ago, when the sea was still open for sailing from Iceland and Norway, and free from floating ice during the whole summer.

Colonies and settlements.

The colonies and settlements existing at this time on the whole coast of West Greenland, in a line from south to north-west, are,

1. *Nennortelik*, or Bear-island, lying on the east of the promontory of Cape Farewell. The Greenlanders, who live on the remotest places in the south, come there, if the floating ice permits it, with their articles of trade, such as the skins of the blue and white fox, and of the white bear. The island is only inhabited by one Greenlandish family.

2. *Lichtenau*, the most southern establishment of the Moravian Brethren, lying in the Firth Agluitsok, in the 60° 34′ of latitude.

3. *Julianeshaab*, established in the Firth Kakortok, in the 60° 43′. In its vicinity are the ruins of an old Icelandic or Norwegian church.

4. *Fredrikshaab*, in the 62° 30′, is one of the oldest colonies, established in 1742.

5. *Fiskerness*, a Danish lodge, in the 63° 20′. Four leagues from this is,

6. *Lichtenfels*, a settlement of the Moravian Brethren, founded in the year 1754, on an island called Kikertarsoeitsiak.

7. *Godthaab*, in the 64° 5′, in Baal's river, the first settlement for the mission and trade, established in the year 1723, by Mr Hans Egede, the first missionary of Greenland. A dwelling-house of stone was built by him in the year 1726, the walls of which are three feet in thickness; it is 27 feet long, and 16 feet broad. Some hills, at the distance of one league, separate Godthaab from New Herrnhut, the first Moravian settlement in this country. The governor of South Greenland resides here.

8. *New Herrnhut*, which has also a very large dwelling-house, built of stone, by the Moravian Brethren.

9. *Zukkertoppen* (*Sugar-loaf*,) so called from a conical mountain in the vicinity of the settlement, established in 1755, in 65° 40′ North Lat.

10. *Holstein-burg*, established in 1770, in 67° 10′ North Lat. the last colony of South Greenland.

11. *Egedesminde* (that is, *Memory of Egede*) is established in honour of the first missionary, Hans Egede. It lies in 68° 40′ North Lat. on the most southern point of Disko Bay, generally called on the charts South East Bay, and Fish Bay, which is one of the most convenient places for the whale fishery.

12. *Christianshaab*; 13. *Clanshavn*; and, 14. *Jakobshavn*, in 68° 50′, are the settlements established round the continent of Disko Bay.

There are two other colonies, called, 15. *Klokkerhuk*, and, 16. *Rittenbenk*, situated in 70° N. Lat. on islands in the Waygat, which is a sound that separates those islands from Disko island.

17. *Omenak*, another settlement, established 1768, in 70° North Lat. is situated on an island of the same name in James's Bay, which, in the English charts, is called Cornelius Bay. The most northern colony which existed, was,

18. *Upernavik*, on one of the Women Islands, 72° 32′ North Lat. although now abandoned by the settlers, for want of intercourse with, and support from, the other settlements. It is still inhabited by some Greenlanders, who have very little intercourse with the Europeans, and never venture farther to the north than to the 73d degree.

There is another settlement, *Godhavn*, on Disko island, where the governor of North Greenland resides, and two others at *Kronprinz island* and *Hund island*, called, on the charts, Whale Island. The English whale-fishers visit frequently those places. On the whole coast are five Protestant Lutheran Danish churches, where the gospel is preached both in Greenlandish and Danish; there are also three meeting-houses of the Moravian Brethren. The Lutheran churches are at Frederikshaab, Godthaab, Holsteinsburg, Jakobshavn, and Claushavn. The Moravian meeting-houses are at Lichtenau, Lichtenfels, and New Herrnhut. The Moravians have no mission farther to the north.

Greenland was always considered to be a property of the King of Denmark, the Danish flag having been hoisted there so early as in the 13th century. The trade with the Greenlanders was several times interrupted, as already mentioned, the inhabitants wishing to avoid all intercourse

Greenland. with foreign countries. The religious zeal of the venerable Lutheran clergyman, Hans Egede, by degrees attached the Greenlanders to the Danes: the uninterrupted communication with the Greenlanders made the Danes acquainted with the language of the country; and as the natives began to feel the want of some European articles, a commercial intercourse was established. The trade was always a monopoly, undertaken at first by a company of merchants, and afterwards conducted on account of the government. Each settlement is managed by a trader and his assistant, both of whom are paid by the government. These officers and their workmen are subjected, besides the Danish law-book, to another regulation of trade, called Instruction. The general inspection of the trade, and the administration of the laws, is placed by the king under the care of two governors, or general inspectors, one of whom resides at Godthaab in South Greenland, the other at Godhavn (Good Harbour) on Disko island. Their power is very extensive, but is restricted to the settlements; the natives being without laws, except such individuals as are in the pay of the Danish government. The trade and the navigation to the colonies is governed by the royal direction of the Greenland trade at Copenhagen. The Danish missionaries, their installations, functions, and residences, are settled by the royal Danish college for converting the heathens. The Moravian Brethren there are under the immediate direction of the *Unitas Fratrum* of Herrnhut in Germany.

Exports. The exports from Greenland are, feathers and eider-down, horns of the sea unicorns (*Monodon monoceros,*) skins of seals, of the blue and white foxes, white bears, white hares, and rein-deers, whale-bone and blubber, or oil of every kind.

Imports. The imports directly from Copenhagen to Greenland are, guns, powder and shot, all kinds of iron-mongery, particularly knives, files, axes, needles, nails, arrow-heads, linen, and hosiery; articles of luxury for the women, such as cottons, ribbons, gloves, looking-glasses, snuff-boxes; tobacco is an article in great demand everywhere. They are also anxious to obtain rye-bread, barley, tea, coffee, beer, and brandy. The latter article, however, is strictly prohibited from being sold, or even given to any Greenlander. Every spring, in the beginning of May, five or six vessels go out from Copenhagen to Greenland with the articles of trade for the natives, and the necessaries and comforts of life for the Europeans. The cargoes of these vessels may be calculated at 65,000 rixdollars (£13,000 sterling.) The value of the productions carried to Copenhagen may amount, on an average, to 85,000 rixdollars (£17,000 sterling.) But the communication between Greenland and Copenhagen was entirely suspended for five years, in consequence of the war between Great Britain and Denmark. The buildings and stores of the Greenland company have suffered very much, from not having been repaired, in consequence of the want of timber and other materials; and it is now supposed that the establishments will be reduced to a smaller scale.

Natives. The natives inhabiting the western coast of Greenland, from the 59th degree to the highest north, belong to the Mongolic race of mankind. They were called Skrællingar by the old Icelanders and Norwegians, on account of their little stature; but they call themselves, in their own language, Innuit, that is, men or human beings, in opposition to other creatures, and this not from presumption. They are called Esquimaux, or Eskimos, by some authors. They speak the same language as the inhabitants of Labrador and part of Hudson's Bay, and their mode of living is very similar. They are probably spread over Bhering's Strait, and part of Nootka and William's Sound, as it appears from the maps of the late Captain Cook, where some islands are marked with names used by the Greenlanders in Davis Strait. They resemble one other in their stature, their complexion, and their customs. Living under a rigorous climate, which presents very few productions, the size of their bodies is reduced by the nature and scarcity of their food, and the extreme cold. Although the stature of the Greenlanders is in general below the common standard, their persons are not proportionally slender, being usually pretty plump, but very seldom muscular. Their face is large and broad, the nose not very flat, but small and short; the nostrils somewhat wide, the cheek bones high, the cheeks round and plump. The face frequently appears fallen in quite across between the temples. The forehead is low, the eyes little and black, dull and drooping, but having the power to distinguish accurately at a very great distance. The eyelids are drawn towards the temple; the mouth is generally little, and round; the teeth very regular, and beautifully white; the lips thick, and turned outwards; the under lip somewhat thicker than the upper. The beards and eyebrows are thin, but they have abundance of hair on their head, which is black, long, coarse, and straight. Their necks are short, their legs thin, but their feet and hands are small and very well formed; their heads are uncommonly large. The shape of the women is very similar to that of the men, and they resemble them so nearly, that one cannot at first distinguish the sexes, their dresses being nearly the same. The appearance of the women is by no means feminine; they have high breasts and broad shoulders, being accustomed, when very young, to labour hard, and carry great burdens. The Greenlanders are of a yellowish grey colour, which approaches somewhat to olive green; but this may be attributed not only to the climate, but to their dirty habits, and to the great quantity of smoke and soot which their houses contain; for their children are born as white as any European child.

The oily nature of their food contributes probably somewhat to deepen their colour; their blood becoming so dark, dense, warm, and oily, that their skin has the smell of oil, and their hands and feet are as clammy as bacon. Their bodies being very fleshy and fat, and coated as it were with a varnish of oil and dirt, they can bear the cold better than an European. They sit commonly naked in their houses; and the effluvia from their bodies is such, that an European who sits by them can scarcely endure it. Their children are in general very healthy; and one rarely sees among them a human being misshapen from its birth. They consider themselves to be very well educated and informed; and when they meet together, nothing is so customary among them, as to ridicule the Europeans and their manners. The women in particular, understand that sort of humour extremely well. They use a mode of very expressive mimicry, consisting of certain grimaces, by means of which they can make themselves understood from one corner of the house to the other; and a European coming to their country will instantly be characterised by a nickname, expressive of his manners, or behaviour, or personal defects. They reckon themselves the most modest people in the world: and seeing a modest foreigner, they say, *innucksisimavok*, or *innungorpok,* that is, "he is as modest as a Greenlander." Although there may be some presumption in this, yet it cannot be denied, that they are modest, friendly, and not litigious; generally compliant; but, when exasperated, they are so desperate, that no danger deters them from their revenge. Although very ignorant, they are by no means stupid. They learn easily to read and to write their language, not only the children, but also men advanced to 20 and 30 years of age. Some of them, besides their maternal tongue, speak Danish very well, and they have a great inclination to mechanics. As their supply of food is but precarious, their patience in hunger is astonishing. Their strength, in proportion to the size of their bodies, is not less wonderful. Pinched with hunger for some days, the man is nevertheless able to row out, and to manage his kajak in the most boisterous sea.

Dress.

Their manner of clothing is quite correspondent to the climate. Men, women, and children, from the time they are three years old, are clothed nearly in the same manner. Their ordinary dress is a sort of close frock, or rather robe, which reaches to the knees. It has at the upper part a round hole, sufficient to put the head through, and not large enough to admit the cold. The sleeves are rather wide on the shoulders, becoming narrower as they reach the wrists. A hood similar in shape to the cowl used by monks, is attached to the back of the frock. This is drawn over the head in winter or bad weather. In warm weather they generally walk bareheaded. Some of them now use the round hats of the Europeans. Their breeches are nearly like those of Europeans. Their stockings are in summer of seal-skin, in winter of dog or rein-deer skin; and those of the women are of fowl-skin. Their boots are made in a very neat and ingenious manner; sometimes of seal-skin, sometimes of rein-deer skin. The frocks are also made of seal or rein-deer skin. At the seams where the different skins are sewed together, they are usually adorned with narrow thongs of different skin, sometimes coloured red; they are worn with the hairy side outwards. In cold weather they use under the frock a shirt made of fowl-skin, of the *Alca pica*, or *Anas mollissima*, or *Pelicanus carbo.*

When at sea in their small canoes (called *kajak*), they use a sort of frock impenetrable to water, with the hair taken away, called *Erysak.* The bottom part is fastened round a ring or hoop made of bone; and this hoop is joined to the hole in which the Greenlander sits, so that no water can penetrate it. They have also another frock made very ingeniously from the intestines of whales, dolphins, or seals, prepared with such skill as to resemble, in a great measure, our goldbeater's leaf. The clothes of the women differ very little from those of the men. The sleeves are very high and wide on the shoulder, and reach only to the elbow. They are cut out downwards from the top of the thigh, and form a long tongue-formed flap both behind and before, the end of which reaches to the knee. It is very carefully sewed, and bordered round the body with narrow thongs of white or coloured leather, sometimes of red cloth. They wear breeches, with very short drawers underneath. Their common boots are made of black or brown seal-skin, their dress boots of white or red coloured seal-skin, reaching over the knees. Shoes are rarely used either by the men or women.

They live in winter in houses, and in summer in tents. When the summer is over, which is generally at the end of August, the women belonging to the family or to the house are very busy in repairing an old or in building a new house. It is done in a very few days; and this labour resembles the liveliness of an ant-hill. Some carry stones, others bring sod; several turf, timber, shrubs, or earth. The walls are made of water-worn stones, put together with turf or sod instead of mortar; and the roof is formed of pieces of floating timber. It is flat, and is covered with shrubs, turf or sod, and earth. The stones are taken from the shores, as they never build a house at a greater distance from the sea than 20 or 30 paces; the timbers are picked up from the sea during the summer. Their houses are sometimes regular, sometimes oblong squares; being from 12 to 18 feet in length, and from 10 to 12 feet in breadth. The height is generally six feet. The walls are at their base two feet, and on the top one foot thick. The entrance is usually under the earth, two feet high, two feet broad, and from 12 to 15 feet long. It is in the centre of the house, and generally faces the south. The house has no door, and one must always creep in on hands and feet. Above the entrance is one, and sometimes two windows, which are made of the intestines of whales, or dolphins, or seals, sewed together. The house consists of only one room, at the back of which there is a kind of stage, raised from one foot to one and a half from the ground, and extending the whole length of the house. It is covered with seal-skin, and is used as bench, chair, table, and bed-stead. Being divided in the front by perpendicular standing timbers, it has the appearance of low cow-sheds or stables, separated by skins. Each family occupies such a division. They sit on this bench the whole day, the men with their legs hanging down, the women generally cross-legged. Each family has at least one burning lamp, made by the Greenlanders themselves of pot-stone. All round the margin of the vessel oiled moss is placed, which serves instead of a wick; and the vessel contains about a quart of oil. The lamp serves them as candle, chimney, and cooking fire; and is attended by the women. On the roof of the house, over the lamps, are racks for the purpose of drying clothes, boots, gloves, &c. The extremities of the large bench on both sides of the house are considered to be the best places, being most removed from the entrance, and therefore given to the first women of the house, or to travellers of distinction. A narrow bench runs along on both sides, and under the windows of the house; and in this place strangers of less consideration sit and sleep. The houses are very well heated, and the heat is increased by the uncommon evaporation of the natives. A European is obliged to go out occasionally, to get fresh air. The interior of their houses looks very well at the beginning of the winter, as long as any degree of order exists in them. But this is over in a very short time; and even this irregularity and confusion is exceeded by their nastiness and stench. They not only keep a number of dead seals, fowls, &c. in their warm houses, but they also gut them there. This, together with the bones, and rotten or half eaten fragments of boiled and raw flesh, occasions several heaps of filth, which are never removed, till, from their bulk, it becomes troublesome to pass over them. Every thing about the house smells of train oil and smoke; and every part of it is as filthy as can be imagined. It is revolting to Europeans to see their dirty hands and face, almost always dripping oil; their meat dressed and eaten in such a disgusting manner; and their nasty clothes, literally alive with vermin. They are also very dirty in cooking their meat; they seldom wash a

Houses.

Greenland.

vessel; the colour and the odour of the last dish must remove that of a former one. They lay their boiled meat in wooden dishes of fir wood, made by themselves, which are never cleaned; and first drink the soup, or eat it with spoons made of bones or wood. Their undressed meat lies on the bare ground, or on an old seal-skin. They have no determined time for dinner or supper; but, when the men of the house return with the game, which generally happens in the evening, part of the day's spoil is immediately boiled, and all the people who live in the neighbourhood are invited.

The men get their meal first, sitting upon the ground, round a large wooden dish, and taking the meat with their fingers. When this is over, the women begin in the same stile, but at the opposite end of the house. If there be a European guest, or any other stranger, the woman of the house takes a piece from the kettle, licks it clean from blood and scum, and presents it to him with her own hands. It would be considered a high degree of impoliteness to decline it.

Tents.

Their time of removing from their houses to their tents is not exactly fixed. It takes place generally at the end of April, or in the middle of May, as the snow melts sooner or later; and it frequently happens that part of the badly supported roof of the house gives way and falls down, an accident which forces them to remove to the summer place. The tents are larger and smaller, in proportion to the size of the family and its fortune, but rarely exceeding the length of 12 feet, and the breadth of 10 feet. A wall one foot high is first made of stones and sods, on which they rest the poles, which form an acute angled triangle with the ground. The poles are then covered with seal-skin; and a curtain is placed before the entrance, made from the intestines of the whale, dolphin, or seal. The bed-places are similar to those in their houses. The tents are, like the houses, near the shore, as the sea supplies them with all their wants, and the seal provides them with all the necessaries of life. The instruments to procure their food are very simple, but they are admirably adapted to their purpose. The principal of them is the harpoon, called *erneinck*, and *unnereek*, which is the largest of them all, being two yards and a half in length. The second is the lance, called *angoviak;* the third, a smaller lance, is called *kapput:* these three are generally used for seal-game, the first to attack, the two others to kill the animal. The first was also formerly used to attack the whale; but now the Greenlanders do it in the European manner, with large harpoons. A fourth instrument, called *akligak*, is a kind of javelin with a head of iron, barbed, to prevent its becoming disengaged from the animal. It is generally used when they pursue their game in company. For catching birds, they use the *nugit*, or fowling-pike, headed with iron like the last, and furnished, towards the middle of the shaft, with three notched forks made of bone, that one of these may reach the bird, if he escapes the apex, which is of iron. For land-game they formerly used the common Indian bow, with its arrows made of fir, and stiffened with sinews of animals, with a string likewise made of sinews; but the use of it was nearly abolished on their being provided with guns by the Europeans; although they were obliged, during the time of the late war, to resort to their old method of shooting, which succeeded very badly, from the want of that dexterity which they formerly possessed. The Greenlanders being a very pacific people, none of the dreadful instruments of war used by other Indians are found among them. They use for fishing the same apparatus as other nations, the lines being generally made of very thinly shaved thongs of whalebone.

Instruments and weapons.

Greenland.

Canoes.

Their canoes are of two different sorts; the one large and open, the other small and covered. The framing of both consists of slender pieces of wood, covered on the outside with skins of seal sewed together. The wooden framing is joined by thongs, cut from seal-skins, or by thinly shaved whalebone. This manner of putting them together, gives to the canoes so great a degree of flexibility, or rather elasticity, that they very seldom can go to pieces, even in the most boisterous sea. The large canoe, called umiak, or the canoe for women, is generally twenty-four or thirty feet long, four or five feet wide, and two or three feet deep, terminating acutely at both ends. The bottom is flat. It is used in summer to transport the whole family, and its utensils and tent, from one place to another; and is in the evening always taken up on land, in order to be dried, repaired, and varnished on the outside with old thick rancid oil, called Minnek, to prevent the water from penetrating the seams.

The other small canoe is called kajak, and is only used by the men; it is sharp at both ends, and its entire shape and appearance is not unlike a weaver's shuttle. It is from four to five yards in length from one extremity to the other, about a foot and a half wide in the middle, and scarcely one foot in depth. In its centre is a round hole, with a prominent ring of bone or wood, in which the man seats himself, and fastens the underpart of his frock round that ring, forming thus one body with his canoe. Upon his kajak he has his instruments, striking the sea alternately on both sides with a paddle called pautik, four fingers broad at each end. He can row in a very boisterous sea, and if overturned by the billows, he is able to raise himself again. All their sea game is procured in these small boats. The boy is employed by his father in his earliest age, that is, in his sixth or seventh year, to prepare himself to perform the business of a man. The first sea-fowl caught by a boy gives occasion to a great festival, and dinner of the family, for the purpose of doing homage to the rising master of the house. Another kind of sea-amusement, or rather ice-amusement, is used in winter, in the north of Greenland, from the 70th degree to the highest northern latitude, by means of sledges drawn by 6 to 12 dogs. The Greenlanders drive them over the frozen sea, a distance of 50 and sometimes more miles from the lands, to the rifts and clifts of the ice, and catch there the dolphins, sea-unicorns, and seals, which come there in great numbers to take air. The spoil is carried home by the assistance of the sledges. The velocity of the dogs is astonishing; they may be driven 100 miles in 9 or 10 hours.

The men take no charge of any of the domestic operations. The women must make clothes, boots, canoes, and tents, dress leather, clean and dry clothes and boots, gut and dismember the spoil, cook the meat, cut the pot-stone-lamps, prepare oil and wicks, and build houses and tents. The girls are employed to this business from the time they are twelve years old. The boys are, from their first childhood, regarded as the future masters of the house. The Greenlanders never strike their children, who are very untractable until their sixth and seventh year; afterwards they follow their parents very willingly, and shew with their increasing age a still more respectful behaviour towards them.

Greenland. Marriages. The men seldom marry before the twentieth year of their age; and the women in their seventeenth or eighteenth year. The bridegroom never concerns himself about marriage-dowry; he is well satisfied if his bride understands housewifery; that is, all the business which we have already mentioned as belonging to the female. The parents never interfere, but they always wish that their son-in-law should be a good hunter; and on the other hand, that the wife should understand housewifery. The girl always makes great difficulties, runs to the mountains, or cries *pro forma*, and the bridegroom generally takes her by force from the house of her parents, and puts her, supported by some old women, in his umiak, which is lying on shore. He brings her to his house, and they are considered as married. They never marry their relations. Polygamy is not very common among the unconverted, and is strongly prohibited among the baptized. It occurs, however, though very rarely, that a heathen has three or four wives. The most respected of them is she who is so fortunate as to have boys. They are not very prolific, the number of children seldom exceeding five or six. If a wife has no children, she herself often requests the man to take a second wife, it being thought ignominious among them not to have a family. The second and third wife is always inferior in rank to the first. Their marriages are not indissoluble; the man sometimes puts his wife away, and the wife also occasionally elopes, and generally retires to her parents, if she is not satisfied with the man, or with his conduct. The women bring forth their children very easily, and perform their usual business in the house to the last moment, and go out again the day after the delivery; they are assisted in the delivery by some old women, as many as there are in the neighbourhood; they rarely bring forth a child before the proper time; the birth of a child is always followed by a dinner. As the people are not very prolific, the coast is very thinly inhabited; the population of which was stated to have been about 20,000 souls, on the arrival of the first missionary, Mr Hans Egede. The small-pox, carried hither from Europe in the year 1733, swept away more than 3000 souls. Other diseases diminished the number of the natives from time to time very much, which, according to the latest accounts given by the governors and missionaries, does not surpass the number of 7000 on the whole coast, from the 60° to the 73° of Latitude. Venereal diseases are unknown. It is a curious circumstance, that the fruitfulness of the native women increases, when they are married to Europeans. This is still perceptible at this day in Greenlandish families, mixed with Europeans at the time of the first mission (1721), the European features being still visible.

Population.

The Greenlanders are very sociable; although they do not live in towns or villages, they like to visit and to be visited. A man or woman never pays a visit to a person residing at a distance, without making some present at the house she visits, either a skin or fowl, or some sinew. They are very fond of making bargains, and often part with their most useful utensils in exchange for trifles, particularly to satisfy the capricious frivolity of their wives. No one desires to usurp any authority over another, to make regulations for him, or to call him to account for his actions; for, as they have no riches, one individual supports another; the helpless finds refuge in the house of the more fortunate, without being related to him, and each Greenlander has his landed property where he resides. They may therefore change their residences as often as they like. Whatever the sea drives on shore, particularly floating timber, is the property of him who has taken it up, and brought it on shore. Notwithstanding, however, their honesty towards each other, they are not scrupulous in stealing from Europeans.

Religion. It is very singular, that the heathens inhabiting this country, have no worship. It was believed by some navigators, who saw the Greenlanders observing the rising sun in the morning, that this people worshipped the sun. They were confirmed in their opinion by the squares of stones, which they saw erected for the purpose of their tents, and supposed that they were places of worship; but they have no religion at all, although they are not without some notion of a Divine Being, and of a future state.

They frequently speak of a Supreme Being, called by them Tornarsuk, a compound of bad and good, probably a remnant of the religion of the old Norwegians. He is the oracle of the Angekut, or Greenlandish philosophers, (if this word may be so improperly used,) who are alone admitted to have intercourse with that great spirit. Besides Tornarsuk, they speak of many inferior beings or spirits residing in every corner of their country. Each Greenlander may become an angekok or sorcerer, if he will submit to certain trials and ceremonies; but the angekok never enjoys any peculiar veneration from the Greenlanders. He profits by the superstitious credulity of his countrymen, pretending to cure the sick with magic art, and presenting amulets of seals, reindeers, &c. as a preservative to those in health. The angekut have their peculiar kind of language, a kirendum or jargon, understood only by themselves.

Language. The Greenland language might with more propriety be called the language of the Esquimaux, as it is spoken by the Esquimaux in Labrador, on the shores of Hudson's Bay, and in various other places of that coast, the Greenlanders being only part of that nation. It probably also extends to Behring's Strait, Nootka Sound, and William's Sound, and has no affinity to any of the other north Indian languages, as far as they are known. There is but little variation in the dialect on the coast of Greenland, but in the south it is spoken in a more singing tone. The letters *b, d, g, h, l, v* are never used in the beginning of a word; the letters *c, f, q, x,* and *z,* are not used in their language. It abounds with double consonants, particularly *k* and *r*, and is very guttural. The language is made extremely difficult, in consequence of the great number of polysyllables, by the use of which a whole sentence is put together in an elliptical manner. They have very few adjectives, and use the participles of the verbs to supply their place. In the language are a great number of *affixa verbalia*, by the use of which an astonishing variety is produced in the signification of their verbs. Thus from the radical verbs, *innuvok,* "he lives is a man," is derived *innugikpòk,* "he is a handsome man;" *innurdlukpòk,* "he is a mis-shapen man;" *innukulukpòk,* "he is an unfortunate man;" *innuksiorpòk,* "he is a good man;" *innukpilukpòk,* "he is a bad man;" *innuksisimavòk,* "he is a man as a Greenlander, (a modest man;") *innungorpòk,* "he begins to be a Greenlander. The third person *singularis præsentis* is its radix. Every verb has its corresponding negative, formed by the addition *ngilak* to the radix, thus: *pekkarpok,* "he has," *pekkangilak,* "he has not." Each

Greenland. Language. flexible word has its dual, ending with the letter *k*, the plural ends with *t*; thus, *nuna*, "land, country;" *nunæk*, "two countries;" *nunæt*, "countries." The articles, pronouns, and prepositions, are formed by suffixes, changing the termination of the noun thus: *nalegak*, "master, lord;" *nalegama*, "my lord;" *arnak*, "mother;" *arnamut*, "to the mother." A great number of augmentatives and diminutives are also formed, by varying and adding to the termination; and this circumstance contributes to make the language agreeable and expressive. Thus, *kikertak*, "island;" *kikertangoak*, "a small island;" *kikertarsoak*, "a large island;" *kikerteitsiak*, "a fine island;" *kikertarsoeitsiak*, "a large fine island." Their numerals are limited to five. They express numbers from six to twenty with the help of addition. Thus; five and one, five and two: twenty is expressed by *innùk*, man; that is, 10 fingers and 10 toes; numbers exceeding 20 are generally called innumerable.

They have no traditions from their ancestors, except an incongruous account of their battles with the old Norwegians; the history of the Greenlanders is therefore buried in impenetrable darkness. They have no chronology, no one can tell his age; but they are well acquainted with the north star. The angekut call the ursa minor *asellut* in the south, and *kuttak* in north Greenland, the ursa major *tukto*, or *reindeer*. They divide the day according to the tide, and reckon their years by winters. The distance of 32 miles, from one place to another, is called one day's voyage, (made with a canoe.) The different seasons are marked by the migration of birds, fishes, and other animals which regularly visit their coast.

Angekut, philosophers. The angekut are somewhat acquainted with physics, particularly meteorology; they observe the weather with great attention, and from the state of the atmosphere they make very accurate conclusions respecting its changes, even at a distance of three or four days; and as the natives procure their food from the sea, this habit is of great importance to them. The angekut are also the physicians of their countrymen, and prescribe generally a certain diet, as most of the diseases result from their very irregular mode of living. If diet is ineffectual, amulets are applied, presented in bones of different animals, particularly of rein-deers and seals. The most common diseases are eruptions of the skin; one is a sort of small pimple, which in a very short time covers the whole body; the best remedy, is to drink a decoction of *ledum groenlandicum*. The other is a kind of leprosy, which infects their whole body with cancerous boils and scurf. Those who are afflicted with it, are abandoned by their relations, and die in the greatest misery. The smallpox and measles were formerly unknown to them, but were conveyed from time to time by European vessels to these poor people, and committed dreadful devastations. These diseases are mortal to the Greenlanders, their skins being so dirty and oily as to prevent the eruption. In the year 1733, the first year of the mission, 3000 people died of the smallpox. But vaccination is now employed by the Danish government with great success. All the other diseases which arise, where the air is condensed by cold, and perspiration is obstructed, are very common in Greenland. A wounded or fractured limb is cured very quickly by themselves, but they have no remedies for internal diseases, such as consumption, blood-spitting, pleurisy and diarrhœa. Scurvy is not very common amongst them, as they do not use salt meat or fish. The want of food, to which they frequently are exposed in winter, produces very serious complaints, which are particularly perceptible in the following spring. It frequently happens in winter, when the frozen sea refuses the necessary supply to the wretched family, when the last thong of leather is swallowed up, and when there is no longer oil to burn in their lamps, that the hunter returns with an animal, and some of these poor creatures devour the raw or half-boiled meat, and falling victims to the indulgence of their appetite, instantly die of indigestion.

Burying the dead. They bury their dead generally on a small hill, in a sitting posture, dressed in their best clothes, and covered with seal-skin. The land being a mass of rocks, the inhabitants are obliged to build graves of stone, which are covered with plates of mica slate, or clay slate, to prevent carnivorous animals from destroying the bodies. Their kajaks (canoes), instruments, and utensils, are placed by the side of the grave. They return from the burial-place to the house of the deceased, to continue the lamentation, which consists of a dreadful monotonous howling, supported by all the attendants, who sit with their faces turned to the ground. When this is over, some refreshment is taken, and each returns to his own house.

Climate. The whole coast of Greenland, receiving the beams of the sun in a very oblique direction, is deprived of that general comfort which other parts of the earth enjoy. The soil being shallow, is frozen during the greater part of the year; and the ice, having taken possession of all the vallies of this barren and rocky land, the winds which blow over these are, even in summer, extremely cold. The prevailing winds are those from the east and north-east, north-west and north. The cold which the north-eastern wind brings in winter is almost insupportable; and the thermometer is very often at —35° or 36° of Reaumur (—48° of Fahrenheit). The winds which blow directly from the sea (Davis' Strait), are moist, and generally attended with rains, in winter with snow and sleet; and are more boisterous in spring and autumn than in other seasons. Winds reflected from the mountains, and striking through the vallies with great violence, are extremely dangerous to vessels sailing near the coast. Strong stormy winds from the west or south-west always break the sea-ice, even in the middle of winter. The cold sets in with the month of January, accompanied with but little snow, which generally falls either before or after that time. More snow falls in the south than in the north. The sea does not freeze before the beginning of January, forming thus on its surface clammy spherical concretions, which increase rapidly, and as they join together, present a crust of the thickness of an inch in a very few hours. This coagulation only takes place when the sea is calm. Previous to that operation of nature, the sea smokes, like burning turf-land; and a fog or mist arises, called *frost-smoke*. This cutting mist frequently raises blisters on the face and hands, and is very pernicious to the health. It appears to consist of small particles of ice, and produces the sensation of needles pricking the skin. The same icy particles carried up by the wind, cause probably another phenomenon which is frequently seen in winter round the moon, a ring of light, or halo, called by the Greenlanders *Illuparosek*; this ring appears at a great distance from the moon, and has a fine pearly lustre. It is seen at a time when the horizon is quite clear, and every star may be distinguished. Mock suns are also very frequently seen in this country, but only in winter. In

Greenland. January 1809, six were observed at the same time, all of a pale yellow colour. The remotest was paler than the others.—See Halo.

Aurora Borealis. Of all the phenomena peculiar to this country, the aurora borealis is the most beautiful. It streams here with peculiar lustre, and with a variety of colours, which, having great brilliancy, sometimes dart their sportive fire, and fill the whole horizon with the most beautiful tints of the rainbow. They are very rarely observed in the north of the horizon, commonly in the east and in the zenith. They appear sometimes to stand very low, and then they are much agitated, and a crashing and crackling sound is heard like that of an electric spark, or of the falling hail. They are more frequent and more powerful from the 60th to the 67th degree than in higher latitudes. The Greenlanders believe, that they are the souls of the deceased fighting together in the air.

Another very curious optical phenomenon presents itself, partly in clear, partly in thin foggy weather. The islands lying at a distance from the continent appear to approach to the spectator, and to increase in size. They form to the eye various and peculiar groups, very different from their proper shape. At other moments they appear to hang in the air. If this phenomenon appears with respect to the islands which lie in the south, southerly winds will follow; if the object be in the west, westerly winds may be expected. The winds decrease generally after sun-set.

Meteors. Fire-balls are rarely seen in this country, although one was observed in the year 1808, taking a direction from north-west to south-east. The comet of 1807 was first observed on the 4th October, in the north-west; and that of 1811 on the 4th September, in the north, and disappeared the 14th January. Thunder is very seldom heard, but sometimes flashes of lightning are seen. The air is extremely pure and light; the rains are not of long continuance; and the heat, particularly in the islets, is astonishing, being caused principally by the reflection of the solar beams from the mountains. The saline particles of the sea-water are frequently found crystallised on the shores. In the month of July, the thermometer of Reaumur rises in the shade to 24 degrees, (86° of Fahrenheit). The moskitos (*culex pipiens*) are at that time as painful and troublesome as in a southern climate.

Ice. The ice, which embarrasses the polar regions, and disturbs the navigation, is of different kinds, some of it being of fresh water, some of salt water. The former is clear, very hard, brittle, having an appearance entirely glassy, and presenting sometimes colours of the finest pale emerald green, or the brightest sky-blue; when cut in pieces, the fragments are as sharp edged as those of rock crystal. The ice of salt water has the appearance of frozen snow, is greyish white, not transparent, and has generally a clammy coherency; when very thin, it is flexible, to a certain degree, under the step of a man. It coagulates in small spheroidal particles; whereas that of fresh water presents rather acicular and prismatic forms. The fresh-water ice forms tremendous masses and mountains of different magnitudes, and wonderful shapes, sometimes rising more than 500 feet over the surface of the water. The salt ice occurs always in flakes, called by the mariners ice fields, sometimes of many thousand fathoms in length and breadth, divided by fissures, but following close to each other. These flakes of driving ice are not found so large in Davis Straits, as between the east coast of Greenland and Spitzbergen. The surface of the salt ice is generally covered with a crystalline crust, deposited by hoar frost or snow; it has a mealy or sandy surface, and becomes brackish by the tides. The salt ice never forms large mountains. On the shores, however, where the sea freezes, the mass becomes enlarged by the effect of the tides, and by stormy weather, which breaks the ice, and heaps it up.

Ice mountains. Ice mountains are formed, during a series of years, in the inlets and bays, in valleys, or on precipitous rocks reaching to the sea. As they melt in summer at the base, where they are in contact with the rock, they get rift; and at last, losing their points of support, they plunge into the sea with a thundering noise; an awful and imposing spectacle, which may be seen in the Ice Bay, near Disko island, particularly at the time of the tides. These mountains very often enclose vegetable substances, earth, and stones; and are sometimes so large as to reach to the bottom of the sea, a depth of more than 300 fathoms, until they lose somewhat of their mass, and roll over. Immense masses of ice are driven out from the Ice Bay in the tides, at the time of high water, covering the sea of Disko Bay, to a distance of many miles.

The driving ice which comes from Spitzbergen, is generally seen at Cape Farewell in the month of May, setting over to the eastern coast of Davis Straits; but it returns again with south-west and west winds, filling all the bays and inlets of the south of Greenland, and is again thrown out from the land by the easterly winds. This ice is always followed by impenetrable fogs; a circumstance, which makes it much more dangerous to navigators. The specific gravity of the ice depends upon its density or porosity.

Floating timber. The floating timber, mostly pine, which comes with the ice round Cape Farewell, affords great relief both to the poor Greenlanders and the European settlers. It furnishes materials to the natives to roof their houses, to support their tents, to strengthen their canoes, to shaft their instruments, and to prepare their utensils. It supplies the Europeans with building materials and fuel. It is very difficult to say from what country these timbers come; undoubtedly from a very remote land, washed away from shores covered with forests. The timber is always much injured, generally without bark or roots, and great part of it is worm-eaten by the *Pholas teredo*, (*Teredo navalis*, Lin.) It is mostly found in the small bays of those islands which are nearest to the open sea.

Islands. The continent of Greenland is surrounded by many thousand islands of different sizes, upon which the Greenlanders generally reside, on account of their good situation for sea-game. The continent of Greenland itself is intersected by innumerable bays, inlets, and firths, many of them 100 miles in length. Their direction is generally from south-west to north-east; and some reach as far as the tremendous glacier which covers uninterruptedly the middle of the continent, and separates the east coast from the west. The connection of these firths with the large continental ice causes the numerous ice-mountains which plunge down in the summer, and are driven by the currents into the open sea. The most remarkable

Firths. of the firths are, 1. *Tunugliarbik*, and 2. *Ikarcseksoak*, both in the 60th degree of latitude; these reach to the glacier, and are generally full of floating ice. 3. *Sermiliarsuk*, the same firth or bay which is marked on the charts with the name Forbisher or Frobisher Strait, but falsely, as this bay extends to the great continental gla-

Greenland. cier, which surrounds it. 4. *Baal's River*, one of the largest firths, is divided into several branches by large islands. 5. *Nerusutok*, remarkable for its violent currents. 6. *Sermilik*, or *Icefiord*, a firth, which presents the largest ice mountains on the whole coast. It is supposed to have been formerly a sound, which divided the continent, but is now shut up by ice. 7. *Omenaks Bay*, called *St James Bay* and *Cornelius Bay* on the English and Dutch charts, which is the most extensive firth on the whole coast, and contains more than twenty islands. It is situated in the 71° of latitude, and in all its different branches is connected with the large glacier. 8. *Kangerdluarsursoak*, in Baffin's Bay, called *Horn's Sound* on the charts, in the 74° of latitude, is likewise a most dreadful firth, on account of its monstrous masses of ice. In the months of May and June, the Greenlanders visit the firths, to provide themselves with a kind of small fish, the *salmo arcticus*, Fabricii, (*clupea villosa*, Mulleri,) which visits the firths in millions at that season. They are dried in the sun on the rocks, and used instead of bread. They are the principal food of the seal in summer, and followed by them in great numbers. Seals are also caught here.

Rivers. The *rivers* are neither numerous nor large. They can have but a small supply in that desolate region, where the valleys are covered with eternal ice, which does not melt frequently, and then only on the surface. In the vallies between precipitous mountains, there are occasionally very large lakes, which have their origin from the melting of the ice and snow on the mountains, and are confined by the rocky bottom of the valley. The springs and rivulets which come from the mountains, rapid as they are in the spring, generally dry up in summer. The inundation of these rivers in the spring, makes the soil marshy, and produces good vegetation on the shores of the firths. The old Norwegians and Icelanders formerly made all their settlements in such situations.

Springs. What are called *springs* by the Greenlanders, frequently consist only of ice-water, forced out of its accustomed channels by the power of the waterfalls running through the ruins of destroyed rocks. There are, however, some spring wells, one of which is very remarkable from its rising and falling with the tide, although it is situated more than 36 feet above the level of the sea. Its water is not brackish, perhaps from the circumstance of its being filtered in passing through a bed of very fine sand. The most interesting is a warm spring on the island Ounartok, which has a temperature of 32° of Reaumur (104° Fahrenheit) at all seasons. It is situated in the south-east of the coast, in the 60°.

Currents. *The streams or currents of the sea* have an easterly direction, and are in some places very rapid and dangerous, particularly during high tides. It is supposed, that these currents are produced partly by the unevenness of the bottom of the sea, and partly by the numerous islands, which increase the rapidity of the currents by diminishing their channels. The obstacles, which rise from the bottom of the sea, may assist in producing back currents and whirlpools. One of the most dangerous whirlpools exists at the mouth of a firth, (called by the natives Puiosortok,) in the south-east of Greenland.

Water. *The water of the sea* near the shores, is less salt than that at some distance from them, the former being always in contact and communication with the ice-water.

Tides. *The rising of the tides* is very unequal, in consequence of the number of islands through which the tide passes. They rise in the south (from 60° to 64° of N. Lat.) to eleven feet, and decrease gradually in the north of Davis Strait, (74°,) where they do not rise more than four and six feet. The highest flood is the third day after new moon, and the third day after full moon. The Icefiord, or Sermilik, in Disko Bay, has flood but no ebb. Greenland, from its most southern point to its most northern extremity, consists of insulated rocky mountains and sharp acuminated cliffs, separated by narrow valleys, which are rendered inaccessible by the glaciers. These places never enjoy the rays of the sun, and are mostly intersected by rapid torrents, which precipitate themselves from the mural cliffs of the mountains. Ice and snow accumulate here in dreadful masses, and fill the spaces with increasing devastation. Even the Greenlanders, so accustomed to the horrors of nature, call some of these spots places of desolation. The water, converted into ice, splits the rocks with mighty force, which are precipitated from the summits with thundering noise in the summer, threatening death to the wanderer. The mountains themselves are covered with a mourning veil of black lichens, variegated here and there with spots of crumbling snow, which, being dissolved by sun and rain, run in small torrents along the precipice. The view of the valleys watered by the inlets and firths is more agreeable, and presents the entire vegetation of that deserted country.

Islands. *The small islands* which surround the continent, are generally of a different character, forming small roundish elevations or hills, the base of which is inhabited by innumerable sea fowls, which breed there at the return of spring. The large islands are similar to the continent, and consist of barren insurmountable rocks, the valleys of which are filled with eternal ice. Amongst the largest, are particularly remarkable: 1st, Cape Farewell, called by the Greenlanders Kangekkyadlek, that is, the cape running towards the west. The entire island, which turns from west to east and south-east, has the name Sermesok, or Iceland, its narrow and dreadful valleys being always covered with ice. It has very little low land, and is therefore very seldom visited in summer by the natives. No family lives there in winter; but the ruins of old houses on the west side, shew that it was formerly inhabited. The most eastern islands nearest to Sermesok, or Cape Farewell, are Omenak and Kangersoak: The latter is called Statenhuk by the navigators, and both are uninhabited. In the east of Kangersoak, or Statenhuk, are more than 100 small islands called Kittiksorsoit. The Greenlanders of the neighbourhood visit these islands in the beginning of spring, to procure seal game, which is there very plentiful. The large islands, which form the promontory of the southern coast, extend $1\frac{1}{2}$° from the west to the south, and are separated from the continent of Greenland by a sound of five English miles in breadth, called Ikareseksoak, through which runs a very rapid current. The sound is generally filled with immense flat masses of floating ice, and innumerable ice mountains, which are driven out from the inlets and firths of that continent. Many vessels have been beset in this floating ice by currents from north-east, and have been lost on the coast. From this, a series of small islands border the continent as far as the 61° 21′, where the eye is terrified by another island, barren, precipitous, and of considerable extent. It presents so dreadful a view, that the older navigators, although accustomed to dangers and terrors, called it the *Cape of Desolation*. This cape, which reaches far to the open sea of Davis Strait, Greenland. Islands.

is always intrenched by floating ice to a great distance. The island is called by the natives *Nunarsoit*, that is, a great land, and is separated from the continent by a narrow sound called *Torsukatek*. It is uninhabited, and even the Greenlanders but seldom visit it. There is no island of importance between this place and the 64°, where Baal's River falls into the ocean. This river, or rather this firth, is one of the largest on the whole coast. It extends 64 English miles to the interior of the continent, and then divides into two arms, one of which runs towards the north-east, the other towards the south-east. Both arms are bounded by the glacier. In this firth are three large islands, *Sermitsiak*, *Kikertarsoak*, and *Karosut*, the first of which consists of one large and high mountain, called Saddle by the Danes, from its saddle-shaped top. It is seen at a distance of 30 leagues from the coast. Another large island (called *Omenak* by the Greenlanders, and *Kin of Saal*, or *Faal*, on the charts) is situated in the 65°, and being easily distinguished by its conical form, which resembles a sugar-loaf, it serves as a landmark to navigators. No large island occurs until the 69° 14′, where the *Island Disko* is situated. It is the largest on the whole coast, its length from the north to the south occupying one degree of latitude. It forms (with the continent) Disko Bay, called Fish Bay on the charts, and is separated from Greenland by a narrow strait called Waygat. It is uninhabited, except by the Danish settlement called Godhavn, which is established in Love Bay, or Lief de Bay, for the purpose of whale fishing. To the north of Disko is an island, which deserves to be noticed, called by some navigators *Haze*, or *Hazen Island*, by others *Waygat Island*; and in the mouth of Cornelius Bay is situated another, called *Unknown Island*. These places are visited by the whale fishers in the month of May. All the islands from the 71° northwards are small, and generally marked on the charts with the name *Vrowen*, or *Women Islands*. The height of the mountains decreases gradually towards the north.

Mineralogy.

Mineralogy.—The accumulation of the ice having rendered the interior of Greenland totally inaccessible, it can only be examined on different parts of the coast; and the promontory Cape Farewell, which is its most southern point, presents to the eye immense groups of precipitous mountain masses, insulated, barren and naked, sharp-pointed at the top, greatly decomposed at the surface, and cleft by the action of the snows and the ice. These rocks are intersected by narrow valleys, where immer . broken and scattered masses are borne along by irresistible currents, and carried immediately to the shores, where there is no low land to intercept their course. The Granite of this island is fine granular, consisting of pearl white felspar, greyish black mica, and very little quartz of an ash grey colour. The whole rock is very much ironshot, and disintegrated. At the foot of the granite rocks occur beds of common quartz of a milk white colour, (not milk quartz,) and flesh red felspar, with small crystals of moroxite, (foliated or common apatite). In another place are found flesh red felspar, with little quartz, common hornblende, magnetic iron-stone, and gadolinite, crystallized in longish four-sided pyramids. A bed on the east side of this promontory, contains garnets in a fine granular greyish white rock, very much resembling the rock of Namiest in Moravia, called by Werner weiss-stein, (white stone); but the crystals of garnet here are larger, and perfect dodecahedrons. The granite extends from Cape Farewell to the east and south-east of the coast, viz. over the islands of Staaten-huck and Kakasoeitsiak, Alluck, and Cape Discord, to a distance of more than 400 miles. Gneiss and mica slate lie upon it at Kippingajak, both rocks containing garnets. Talc slate forms a large bed in it at Akajarosanik, along with actynolite, which occurs in large masses. Near the coast of Akajarosanik, is the small island called Kakasoeitsiak. It consists of one hill, formed of a granitic rock, mixed with some horn-blende, slender crystals of zirkon, and the new mineral called *Allanite*. (See *Edin. Trans.* vol. vi. p. 371.) The rock here assumes the character of the Norwegian zirkon-syenite; but its constituent parts are of a finer grain. All the granitic mountains of the islands of Staaten-huck and Cape Farewell, are surrounded by numerous very small islands, presenting round-backed or flat conical low hills of primitive syenite. To the west of Cape Farewell, at a place called Niakornak, is a very extensive bed of yellowish white felspar, crystallized in large flat six-sided prisms, the crystals being only separated by black mica, which gives to the rock a porphyritic appearance. The place is very difficultly accessible, it being harassed perpetually by the most boisterous sea, and washed by the tide at high water. Not far from this, at an elevation of about 1000 feet, the granite is divided into immense columnar or quadrangular pieces, which, seen from a distance, present an appearance similar to the ruins of a town. The Greenlanders state, that the masses were carried thither by some giants, who inhabited the country in the oldest times, and, having been sorcerers, disappeared from the earth.

1. Granite. Allanite, new mineral.

As granite is the principal rock which constitutes the mountains of this vast coast, to enumerate all the places where it is found would exceed the limits of such an article as the present. Its most common colour is greyish white, flesh-red, and tile-red: the latter colours are characteristic of the coarse granular felspar. Magnetic iron ore is generally found either disseminated or imbedded in the red variety. In some places, molybdena occurs, and in others graphite imbedded in the rock. At Baal's river and at Disko island, iron pyrites is found; but, excepting there, the rock is not very metalliferous. Precious garnet occurs very frequently; also common schorl, tourmaline, common hornblende, jade, rock crystal, moroxite, calcareous spar, fluor spar, and the above mentioned substances. Rock crystal is only found in veins traversing the red coarse granular variety, and appears to be contemporaneous, the vein being intimately mingled with the rock, and presenting no walls. Beds of hornblende slate, mica slate, felspar, and quartz rest upon it; and on the red coarse granular granite at Kogneckpamiedluœk, there is an extensive bed of red ironstone mingled with massive iron-flint (eisenkiesel of Werner.) At the end of the north-eastern arm of Baal's river, in the vicinity of the great continental ice, the traveller, ascending from a narrow cliff, suddenly beholds a dreadful chaos of immense columnar granitic blocks detached from each other, and heaped together in the most fantastic groups, the planes of fracture being so fresh, that the points from which they are broken are distinctly observable. Places of desolation and devastation of this kind are very frequently met with in the mountains of Greenland. Most of the granitic rocks affect the needle.

2. Gneiss.

2. The next rock, which forms numerous mountains in this country, is Gneiss. It occurs very often alternating with granite, sometimes with mica slate. Its character or texture may be ascertained partly in the cliffs and on the shores, partly by the forms of the mountains. The granitic mountains are always more

decomposed, and therefore more precipitous, presenting very sharp-edged summits: the summits of the gneiss are more flat and round-backed. The texture of the gneiss is thick and thin slaty; its felspar generally pearl-grey and pearl-white, seldom flesh-red, fine granular: its mica grey, pinchbeck-brown, and blackish brown: it contains but little ash-grey quartz. The valleys and clefts round the mountains are filled with rhomboidal fragments, many of them of immense size. The smaller fragments were used by the old Norwegians, with mica slate, hornblende slaty, and slaty claystone, to build their houses; the walls of which, although not cemented, after a lapse of several centuries, still brave the power of this destructive climate.

Gneiss constitutes one of the most elevated points of this extensive coast, viz. the mountain *Kingiktorsoak*, situated in the 62d degree of latitude. It is covered with mica slate from the shore to a heighth of about 1000 feet above the level of the sea, where the gneiss again becomes visible, and continues to a heighth of nearly 3000 feet. The top of this mountain is similar in shape to the roof of a house, where the ridge is not much elevated. It is entirely free from snow in summer, except a few small spots, where it rests in the hollows of its summit.

The mica slate resting upon the gneiss presents a variety of beds of hornblende slate, whitestone, (weissstein) with small garnets, talc-slate, with common and indurated talc, potstone, actynolite, and precious splintery serpentine. The gneiss is traversed with numerous veins of greenstone, varying in thickness from one inch to six feet. The greenstone which occurs in the veins resembles basalt; but it is more crystalline in its texture, lighter in its colour, and not quite so hard. Common schorl, tourmaline, and precious garnet, occur imbedded in gneiss. It contains veins of tinstone, accompanied by arsenical pyrites, wolfram, fluor, and quartz, in a firth, called Arksat, situated about thirty leagues from the colony of Juliana-Hope, towards northeast. The same place is remarkable for two thin layers of cryolite resting upon gneiss; and it is the only place where this mineral has hitherto been found. One of these layers contains the snow white and greyish white variety, unmixed with any other mineral. Its thickness varies from one foot to two feet and a half, and it is divided from the underlying gneiss by a thin layer of mica, always in a state of disintegration. The other variety is of a yellowish brown colour passing into tilered. It occurs along with iron pyrites, liver-brown sparry iron ore crystallised in rhombs, earthy cryolite, quartz, compact and foliated fluor, earthy fluor, and galena. It is remarkable, that the galena is sometimes coated with a greyish white sulphureous crust, which burns in the flame of a candle with a bluish colour, emitting a sulphureous smell.

Cryolite.

These layers of cryolite are situated very near each other, only separated by a small ridge of gneiss, of a thickness of 27 feet: both are washed at high water by the tide, and for the most part exposed, the superincumbent gneiss having been removed. The white cryolite, seen at a distance, presents the appearance of a small layer of ice; small detached fragments have acquired, from decomposition, the shape of cubes. This mineral is called by the Greenlanders *orsuksiksæt*, from the word *orksuk*, blubber, to which it bears some resemblance. The same name is also given by the natives to white calcareous spar.

3. Mica Slate.

3. Mica Slate is likewise one of the most common rocks in Greenland, and an inseparable companion of gneiss: There are very few instances where they are not found in the vicinity of each other, and frequently in contact. Mica slate forms in this country a very extensive series of insulated mountains, which never rise to a considerable height, and appear generally to rest upon gneiss. Mica slate is frequently visible on the shores, and the gneiss itself forms also very extensive beds in it at Disko bay, where the white-stone also occurs in beds. The Greenlandish mica slate abounds in mica; it is generally thin-slaty, and only thick-slaty when the quartz prevails. Sometimes it has an undulating aspect; but when this is the case, it passes into primitive clay slate. The mica of this mica slate is mostly greyish-black and pinchbeck-brown, passing into brownish-black, seldom silver-white. Its quartz is pearl-grey. It is sometimes mingled with nodules of pearl-grey felspar, from the size of a pea to that of an orange, and this gives it the appearance of gneiss; but they may be easily and accurately distinguished, as the mica-slate presents a surface perfectly continuous, and easily separable in the direction of the plates of the mica. The strata dip towards north-west. Mica slate also occurs in beds in various parts of this country. One of the most remarkable, most interesting, and most extensive, is that in the firth Kangerdluarsuk, in the 61st degree of latitude, in the district of Juliana-Hope. It extends about five miles in length, and four miles in breadth; its thickness varies from six to twelve feet; and it contains, besides felspar, which is its principal constituent part, hornblende augite, actinolite, sahlite, garnet, and that new mineral which has been analysed by Dr Thomson and Professor Eckeberg, called *Sodalite*. It is of pale apple-green, leek-green, greenish white, and pearl-grey colour, partly massive, partly crystallised. Another mineral, which has not yet been analysed, occurs also with the sodalite: it is of a peach-blossom red and purple-red colour. On the shore, the underlying gneiss is visible in several places. In the superincumbent mica slate, granite is found of very fine texture, partly disseminated, partly imbedded. Calcareous spar and fluor occur in veins, both of which are sometimes coated with a thin crust of chalcedony, also galena in small veins. Blue phosphate of iron in detached pieces is found on the shores. The mica slate is generally decomposed and iron-shot, where the graphite is imbedded. In the firth of Arksat, a bed of very fine granular limestone is found in mica slate, which resembles the Carrara marble. The beds which occur in this rock on the mountain Kergiktorsoak have been already mentioned. Hornblende slate, forming beds in mica slate, is found in many places.

Sodalite, a new mineral.

Another new mineral.

In the 64th degree of latitude, in a firth called Ameraglik, in the south of the Danish colony Godthaab, (Goodhope,) a variety of mica slate is found, which passes into talc slate, forming a very small layer in coarse granular granite. It is very remarkable, on account of the large groups of tourmaline which occur, imbedded or rather involved in talcose mica; and which are the largest crystals of this fine mineral that have been met with. At the end of the same firth, at Auaitsirksarbick, in the neighbourhood of the great continental glacier, the finest garnets are found. They are of a lamellar texture, and surpass the oriental specimens in colour, lustre, and hardness. At the same place, dichroite and hyperstene of a beautiful blue colour occur, along with precious garnet, in decomposed mica slate.

All the lower mountains from the 66th to the 71st degree of north latitude, and particularly all the mountains of the continent forming Disko-bay, with the greatest

Greenland.

part of the adjacent islands, are composed of mica slate. There is scarcely a square mile where the rock is entirely free from garnets. A large mountain in Omenaks firth, called Sedliarusæt, presents on its surface only the powder of mica slate, and fragments of precious garnet. From the appearance of this powder, it is probable that the rock formerly contained great masses of imbedded iron pyrites. No snow rests on the surface of this mountain in the coldest winter. The fragments of precious garnet which are found here, when clear, are the most highly prized of any on the coast. Other minerals which are found in mica-slate in Greenland, are, emery, on the island Kikertarsoeitsiak, in South Greenland; granatite, on the island Manetsok; moroxite, in very large six-sided prisms, at Sungangarsok, in North Greenland; and dichroite, in six-sided prisms, on the island Ujordlersoak, in the 76th degree of N. latitude. Except iron pyrites, copper pyrites, and galena, no metal occurs in this rock.

White-stone.

White-stone, (Weiss-stein,) which has lately been determined by Werner, appears to belong to this rock. It presents a white and greyish-white granular appearance, which was formerly supposed to be compact or granular felspar. It is in this country characterised by very small and minute crystals of garnet disseminated through the whole mass. Here it is found in layers of inconsiderable extent, resting on mica slate, very seldom on gneiss. It is also found in detached pieces.

4. Clay-slate.

4. Clay Slate is very seldom met with on this coast, and consequently the different beds which are characteristic of this rock, viz. flint-slate, lydian-stone, alum-slate, but rarely occur. Nevertheless, at the mouth of the firth Arksut it forms two islands of some importance called Arksut and Ujorbik. The colour of the slate is ash-grey and bluish-grey; its fragments present a double cleavage, and it is traversed in all directions by numerous veins of massive and crystallized quartz, massive hornstone, and sparry iron ore of an isabella yellow colour. An extensive bed of flinty-slate and lydian-stone rests upon it on the east side of the island Ujorbik. In Ameraglikfiord, in the 65° 4′, there is a small island, where the clay-slate forms small layers in fine-grained granite, fine cubes of iron pyrites, with various truncations, occur in this slate, which is greatly decomposed. Some small islands in the south-east of Disko bay consist of clay-slate, with a variety of small beds and layers, viz. very ironshot hornblende-slate with small garnets, whet-slate, granular hornblende and greenstone. This clay-slate may perhaps belong to the class denominated transition rocks.

5. Porphyry.

5. Porphyry is very common in the south of Greenland, from Cape Farewell to the 64th degree of latitude; but it is generally found towards the interior of the continent, forming insulated rocks. In the interior of the firth Igalikko, at Akulliaraseksoak, hornstone-porphyry is found, very distinctly stratified, and resting upon fine-grained granite, containing large crystals of reddish-white, flesh-red, and tile-red felspar, and another mineral of a talcose appearance, crystallised in six-sided prisms, and hitherto unknown. The mass of the porphyry is brownish-red, and passes in some places into clay-stone, forming clay-stone porphyry, the crystals then becoming less distinct. Hornstone porphyry, with a few very small crystals of felspar, occurs also in an adjacent firth called Tunugliarbik. This rock rests upon old red sandstone. The porphyry is very much decomposed. It is of a brown-red colour, and called by the natives *aukpadlrtok*, that is, blood-red rock. It contains small layers of a kind of brown-red iron ochre, which the Greenlanders use as a dyeing material, to embellish their utensils, and the interior of their houses; a species of luxury they have learned from the Europeans.

New mineral.

6. Syenite.

6. Syenite, and all the porphyritic rocks belonging to the primitive and transition trap-formation, are found in great abundance in this country. Hornblende is a mineral which occurs almost every where. A kind of coarse granular syenite, composed of coarse granular Labrador-felspar, and crystallized common hornblende, rests upon fine grained granite at the mountain Illejutit, or Redekammen, in the 61st degree of latitude, in the neighbourhood of that extensive bed of sodalite, sahlite, and hornblende, which has been already mentioned before. This Labrador-syenite occurs also at the mountain Kognek, in the 62d degree, upon granite of a coarser grain. In the vicinity of the mountain Kognek, is a group of more than 50 islands, lying in a western direction, in Davis Strait, and called by the natives Kittiksut, from kitta, *west*. These islands form round-backed low hills, and consist of common felspar, of yellowish-brown and leek-green colours, and common hornblende of raven-black, and sometimes velvet-black colour, accompanied by small four-sided prismatic crystals of zirkon of red-brown, and purple-red colour, with fine-grained common magnetic iron-stone interspersed, and very little black mica. In some parts of the rock allanite occurs, of a pitch black colour. The rocks are somewhat ironshot, and disintegrated on their surface. Titanium iron ore is found in small layers, and fine granular chromate of iron. The rock itself has a striking resemblance to the zirkon-syenite, found at Friedrichswærn and other places in Norway, and described by Von Buch, Esmark, and Hausmann. The neighbouring mountains have no trace of that rock. At Narksak in the vicinity of Baal's river, brown titanite, or brunon, is found disseminated in syenite.

Granular porphyritic syenite is found at Nunarsoit, (Cape of Desolation.) Its stratification is not very distinct. It contains very extensive beds of coarse grained, tile-red felspar, and common magnetic iron-stone.

7. Primitive trap.

7. Primitive Trap. (*Greenstone.*) The islands which lie between the 62° and 63° of latitude, present a very complete series of the rocks that belong to the primitive trap formation. The greenstone first appears at Sakkak and Ujorbik in the mouth of Arksuts-fiord, where clay-slate predominates, and extends from those islands towards the east, that is, to the continent of Greenland, alternating with greenstone of a porphyritic structure, (*porphyrartiger grunstein* of Werner,) and green porphyry or *verde antico*. Another rock of slaty texture, consisting of compact felspar and hornblende, appears to be intermediate between hornblende slate and greenstone slate; it is here the only rock which presents very distinct stratification. The greenstone slate covers uninterruptedly both the greenstone and the green porphyry, and appears to belong to the transition greenstone formation; and perhaps the whole formation should be referred to it. It probably extends farther to the interior of the continent, as the fragments which are thrown out from the continental ice have an appearance exactly similar. Variolite is found there in small roundish rolled pieces. The greenstone, alternating with syenite, is found upon gneiss and mica slate, on the large island Nunarsoit.

8. Primitive limestone.

8. Primitive Limestone, of fine granular texture, is found only in beds and rolled pieces, and occurs very seldom in Greenland. Its beds are confined to gneiss and mica slate, and it is mingled with minute leaves of silver-white mica, seldom with grains of quartz. It is gene-

Greenland.

rally accompanied by tremolite, asbestos, actynolite, sahlite, and seldom with rock-cork. Thus situated, it occurs at the island Akudlek, at the island Manetsok, at Kakarsoit and Kangerluluk, mountains in the vicinity of Jakobs-havn and Christians-haab, in Disko bay. It is very surprising, that no vestige of flœtz-limestone is found on this vast coast, nor does any petrifaction occur there. Very distinct impressions of the *salmo arcticus,* with its bones very little altered, occur in detached pieces on the alluvial land, which are forming daily. In the uppermost sand-stone, which belongs to the brown coal of the flœtz trap formation, fragments of *pecten Islandicus* are found, which have undergone but little alteration.

Flœtz trap formation.

The flœtz trap formation of Greenland, is perhaps the most extensive that has yet been discovered. It begins at the 69° 14′ of latitude, occupies the large island Disko, and the eastern coast of the Waygat, from Niakornak, on the northern cape of Arve-prinz island, round the Cape Noursoak, as far as the end of the southern coast of Cornelius Bay, where it reaches the great continental glacier. Hare island in the north of Disko island, Unknown island in the mouth of Cornelius bay, the islands Kakiliseit in the north of the latter, and many other northern islands, consist entirely of flœtz trap. From thence it extends over a part of the continental coast of Greenland, viz. London-coast, Svartenhuk, Ekalluit, Kangersoeitsiak, Karsorsoak, and disappears in the 76th degree under the most northern continental ice, or glacier, which precludes all further investigation.

The whole flœtz trap formation of Greenland, as far as it has been examined, rests on gneiss or on mica slate, these rocks alternating continually. The underlying primitive rocks, as well as the superincumbent flœtz trap, are always somewhat decomposed, where they come in contact. Trap-tuff generally rests immediately upon the primitive rock; it consists of balls and nodules of basalt and wacke, joined together by a cement of the same substance; the centre of the balls and nodules is very often filled with mesotype, blended with massive or crystallized apophyllite, the crystals of which are sometimes penetrated by acicular mesotype. This trap-tuff scarcely presents another mineral, and the apophyllite, or ichthyophthalmite, does not occur there in any other rock. The underlying primitive rock is very variable in its elevations, sometimes it does not surpass the level of the sea, sometimes, (for instance, at Godhavn,) it reaches a height of from 500 to 600 feet, which can be observed very exactly in the cliffs there. Columnar basalt lies upon trap-tuff; it presents four, five, and seven-sided columnar distinct concretions; the columns very seldom exceed a foot in diameter. This basalt does not include any mineral except sometimes very minute spots of greyish white glassy felspar. Wacke generally rests upon it, forming an amygdaloid with different minerals, viz. chabasite, stilbite, analcime, chalcedony, opal, heliotrope, quartz, zeolite, miemite, and basillar arragonite. At Hare island the chalcedony is found crystallized in cubes. At Kannioak, in Omenaks-fiord, miemite occurs in kidneys, along with chalcedony, opal, wavellite, arragonite, and some quartz in grey decomposed wacke. The wacke of the flœtz trap formation of this country is generally intersected by small veins of iron-clay and bole. Lithomarge and green earth occur in nodules. Olivine and augite are but seldom met with in the flœtz trap of Greenland. Laumonite, in a friable state, is found in very small veins, traversing wacke at Sergvarsoit, on the northern coast of Disko island. Most of the Greenlandish basalt affects the needle very powerfully. There are generally two, and sometimes three strata of columnar basalt, and one of them forms the summit, except at Hare island, where the summit consists of porphyry slate resting upon wacke. The shape of the mountains is very various, some of them present pyramidal, some conical forms, and some are entirely flat: Their stratification is very nearly horizontal, and the valleys between the mountains are generally narrow. There is no doubt that some of the mountains have been separated by very recent eruptions of rapid torrents.

Coal.

On some parts of Disko island beds of brown coal occur in flœtz trap: they rest upon yellowish-white coarse-grained sandstone, which is very friable;—large balls of iron pyrites are imbedded in it. The beds of coal are generally divided from each other by strata of fine-grained sandstone, and are of very unequal thickness. In some places of the east coast of Disko island, in the Waygat, the sandstone becomes harder, and carbonized impressions of leaves are found in it, which are similar to those of sorbus and angelica.

The coal of Disko island is common brown coal, of slaty texture: it burns very easily, but it leaves a great residuum in the form of white ashes, which have a slaty texture, and somewhat resemble the polishing slate from Bilin in Bohemia. A very remarkable variety of brown coal, passing into bituminous wood, occurs in a small bed at Hare island. It is of slaty texture; and honey-yellow amber, in numerous grains of various sizes, is disseminated parallel to the cleavage of the coal. It rests upon ash-grey coarse-grained sandstone, is covered with grey common clay, and belongs undoubtedly to the newest brown coal formation. At Koome, in Omenaks-fiord, native capillary and fibrous sulphate of iron, of a beautiful green colour, is found in the cliffs of the brown coal. All the Greenland coal is subordinate to flœtz trap.

Alluvial land.

Alluvial land has been formed at the end of every bay and firth of the coast, and, in addition to grey and greyish-white sandy clay, it contains fragments of the neighbouring mountains. This formation is daily increasing, and contains no metallic substance, except magnetic iron sand, with which it generally abounds.

Botany.

Botany.—Although Greenland affords a great variety of objects to the mineralogist, yet it offers but few to the botanist, when compared with other countries, the first efforts towards vegetation being repressed by the barrenness of the soil, and the want of the sun's genial influence. Those shrubs and trees, therefore, which in milder climates afford a comfortable shade to the wanderer, creep in this forlorn land under scattered rocks, to find shelter from their destroying enemies,—storm, snow, and ice. This land, however, presents a series of plants, which probably could not subsist in a milder climate; and in the interior of the inlets and firths may be found many species hitherto unknown in other countries. Some of the new species are published in the last number of the *Flora Danica.* There are also other spots which boast the most luxuriant verdure, but they are only places in the neighbourhod of the Greenland houses, which have been improved for many years by the blood and fat of seals and other animals. There are also small hills on the uninhabited islands, where the birds build their nests, and manuring the decomposed rocks, extort vegetation to their abode from the unfertile soil. These places, however, are but of rare occurrence, in proportion to the immense extent of the country. Innumerable cryptogamic plants, growing with great rapidity under snow and ice, supply the want of flourishing vegetation on the rocks and cliffs.

Greenland.

The vegetation commences very late, not till the end of May or June, in proportion to the different latitudes, and is over by the end of August or September. The bottom of the sea in these climates appears to be better suited to vegetation than the surface of the land; there is a great variety of fuci, ulvæ, and confervæ. The plants which have been hitherto found, are,—

Zoology.

ZOOLOGY.—The character of the man who inhabits these latitudes, is given in a former part of the article: it will therefore only be necessary to enumerate the animals which can bear the hardships of this climate.

Mammalia.

Mammalia.—There are only four different land quadrupeds, which are found in every season on the coast of Greenland, viz. the dog, the isatis, the arctic hare, and the reindeer. The arctic, or white bear, is a migrating animal: It comes from the eastern and north-eastern polar regions, in the beginning of the winter, with the floating ice, to the western coast of Greenland, and leaves it again about the end of June.

The dog.

The *dog* is the faithful companion of man in this as in every other country, and would undoubtedly be so in a higher degree, if the Greenlanders treated this poor animal in a more humane manner. The dogs are in general large, and have the size and appearance of wolves. Their colour is very various, generally greyish brown, greyish white, mixed with yellow and black: they bark very seldom, but set up a dreadful howl. They sleep on the roofs of the houses of their masters, or lodge themselves in the snow, lying with only their noses out. They swim very well. The Greenlanders use them in place of horses: they harness them to their sledges, side by side, by means of thongs cut out of the *Phoca barbata*, or great seal: These thongs are ten yards long, the common distance between the dogs and the sledge; and in this manner they visit their friends in winter, or draw home the seals which they have killed over the ice of the frozen sea. They will travél sixty English miles in a day with sledges or sliders of whalebone, loaded with their two masters and five or six seals, Greenland. and 100 miles if they have no load. In the most northern parts they use the dogs also in the chace of the white bear. The Greenlandish dogs are very ferocious, and often fight among themselves till one of them is killed. Canine madness is unknown in Greenland. These dogs are very prolific, having frequently nine and ten whelps twice in a year: some of the bitches eat their whelps. The Greenlanders put their dogs generally on uninhabited islands during the summer, the season in which they are useless, where these poor animals are obliged to provide for themselves, and very often perish by famine. The Greenlanders use the skins for shirts, stockings, and gloves: they make strings of the guts: they are very fond of their flesh as food, and reckon a very fat dog a great delicacy. The dog skins having a very unpleasant smell, do not form an article of trade.

Isatis or Arctic fox. The *isatis* (*canis lagopus*) generally called the arctic fox, or blue and white fox, is only found in the arctic regions, a few degrees within and without the polar circle. It inhabits the whole coast of Greenland, but lives always in the neighbourhood of the sea, in cliffs and cavities, or holes formed accidentally from fragments of rocks, and having many outlets. Their food is small birds and their eggs, eggs of sea fowls, shell-fish, and, when compelled by want, they eat grass, and all that the sea throws up. The arctic fox is of a bluish grey colour: one variety is entirely snow white both in summer and winter. The hair is very thick; thicker in winter than in summer; and very soft and silky. The blue variety changes its colour in summer. and acquires a spotted skin of grey, blue and white, The isatis is undoubtedly the hardiest of quadrupeds. It sets out for prey to the houses of the Greenlanders, during the severity of winter. It couples twice a year, like the dog, and, when with young, the female retires to her kennel. It swims uncommonly well from one island to another, to the distance of four and five miles, in search of prey. It is very harmless, and, when young, is very easily tamed. Its skin is highly prized, and very much thought of in China. It is generally caught by the natives in traps made of stones, like small huts, with a broad flat stone of hornblende slate, or mica slate, hanging perpendicularly by way of a door, which falls down by means of a string baited on the inside with the *salmo arcticus*, a small fish, which the isatis is very fond of. It is also taken by the European settlers in pitfalls, and in springes of iron. The flesh is not eaten by the Greenlanders, unless when they are in the greatest want of food.

White hare. The *white hare, arctic hare*, or *varying hare*, is in Greenland of a snow white colour, both in summer and winter, and lives in great numbers amidst the snowy mountains. It is usually fat, and feeds in summer on grass, and in winter on cryptogamic plants, particularly on lichen islandicus and nivalis (*Cetraria islandica* and *nivalis.*) Its hair is very thick and soft, but very loose. The Greenlanders are not very fond of its flesh, but they like very much to eat the raw contents of the intestines, together with the stomach. They make use of the skins, which are not an article of trade, to clothe their children.

Rein-deer. The *rein-deer*, (*Cervus tarandus*), though very useful to the Laplanders, is only considered as an object of chace by the Greenlanders, and of no utility until deprived of life. They kill every summer more in the interior than they can carry to the shores, and their number is rapidly diminishing every year. Besides this, these thoughtless people neglect the time of their best fish and seal game for this sport. They eat the flesh, which is tender and well-tasted, raw, boiled, and dried. The hunters drink the warm blood, dressed with some berries; the contents of the stomach, called *nerrikak*, is a delicate dish. They are also very fond of the fat of the animal. The skin forms a part of their clothing, particularly of that of the women; and the inhabitant of this dreadful climate is obliged to procure a couple of fine rein-deer skins during the summer, if he wishes to be agreeable to his wife. The sinews, when split, are very good threads, with which the women sew their clothes. The horns are employed for utensils and instruments. The greatest number of rein-deers is found in the vicinity of Baal's river, near to the continental ice, from the 63d to the 66th degree. They occur very seldom in more southern or more northern latitudes.

White bear. The *white bear, polar bear, or arctic bear*, (*Ursus maritimus*, or *Ursus arcticus*), is a migrating animal. It is never seen after the large or black whale (*Balæna mysticetus*) leaves the coast of West Greenland. Their size is stated by some authors to be from 13 to 23 feet, but this is probably too much exaggerated. The largest white bear which was met with on the west coast of Greenland, measured 9 feet and 4 inches from the snout to the tail, the skull of which is now in the museum of the Dublin Society. Another, caught by the celebrated navigator, Captain Phipps, (Lord Mulgrave) at Spitzbergen, measured 7 feet from the snout to the tail. The white bear seems the only animal, that, by being placed in the coldest climate, grows larger than those that live in the temperate zones. Its flesh is not so good as that of the other kinds of bear; it has an oily taste, and a fishy flavour; the liver is very unwholesome, and causes vomiting. The usual food of this animal is fish, seals, and the carcases of whales. On land, which it seldom approaches, it preys on rein-deer, hares, foxes, and birds. It lies in ambush on the flakes of the floating ice, and lurks there after seals and other marine-animals; it also attacks the morse, or walrus, with which it is in constant enmity. The walrus, by reason of its large teeth, has generally the superiority, but frequently both the combatants perish in the conflict. In winter, when hungry, it sometimes attempts to break into the houses of the Greenlanders, allured by the scent of the flesh of seals, but it is very easily driven away with fire-arms and dogs. The female has only one young one, and lodges it in the snow of the floating ice, or on the shores. The affection between the parents and their young is so great, that they will sooner die than desert one another. The Greenlanders kill them with fire-arms, generally assisted by dogs; and both the man and dog, feed on the flesh and fat. The skin is used for boots, and some other domestic purposes; it is also a valuable article of trade, a good skin being generally sold for three or four pounds.

Walrus. The pinnated quadrupeds, or quadrupeds with fin-like feet, are, the *morse*, or *walrus*, (*Trichechus rosmarus*). It is sometimes found of the length of 18 feet, and the circumference in the thickest part is ten or twelve feet. Its weight is from 600 to 1500 pounds. It has very short legs, and five toes on each foot, joined together by webs, with a small roundish blunt nail to each. Its skin is generally an inch thick, thicker on the neck, and very much wrinkled about the joints; it is very thinly beset with grey and reddish grey hair, sometimes mouse-coloured. It has two large teeth or tusks in the upper-jaw, from a foot to two feet long, and four grinders, flat at the top, above and below, the surfaces of them generally being very much worn. It is found of the largest size in the Icy Sea. The animals feed both upon seagrass and small marine animals, Greenland. viz. shells and small fishes. It sleeps upon the floating flat ice, or on the surface of the sea, and when attacked by men, will endeavour to overset the boat, or to make holes in it with their teeth; but it is very clumsy when out of the water upon the ice, where it may be killed with little difficulty. When a walrus or morse is struck with the harpoon, the Greenlanders let it run till it is wearied, and then draw in the line to kill it with the lances. The Greenlanders very seldom kill them in their small canoes; but if they do, they are always in company with three or four men. They are no more seen in large flocks on the coast of West Greenland as formerly, having been diminished by the whale fishers, who killed a great number of them. A flat island on the southern coast of Disko island, called Saitok, situated in the mouth of Disko firth, consists of alluvial land, which is covered with numberless bones and skulls of the walrus. The Greenlanders feed on their flesh, which is of a dark red colour; they use the oil in their houses, cut thongs out of the skin, and employ the tusks for their utensils and instruments.

Walrus.

Trichechus manatus, which is called *auvekœjak* by the Greenlanders, is very seldom seen on the coast, according to their own accounts; and it appears more towards Bhering Straits, and the sea in the vicinity of Kamtschatka.

Seals.

The *seals* may be called the flocks of the Greenlanders. They supply them with flesh, the most desirable food of this nation. The blubber furnishes them with oil for their lamps, and for their chamber and kitchen fire; the fibres of the sinews of the seal furnish thread for their clothes; of the skins of the intestines they make their windows, and their curtains for the tents; the stomach is used as a train oil vessel, and the bladder is employed for the javelins. The blood, mixed with flesh, is eaten as soup. But the most valuable thing is the skin: it covers their boats and their tents; it furnishes clothes, boots, stockings, gloves, and coverings for their bedsteads.

There are different species of seals, partly migrating, partly living on the coast of Greenland. One of the most remarkable is,

Hooded seal.

The *hooded seal*, *Klappmutze* of the Germans, *Klapmyds* of the Danes, *Neitsersoak* of the Greenlanders, *Phoca cristata* of Gmelin. It is so called from a thick folded skin on the forehead of the male, which it can draw over the eyes like a cap, to defend them against its enemies. Its hair is of a double kind, the longest silver white, the shortest black and woolly, which gives it a very beautiful appearance. It grows to the length of ten and twelve feet. The Greenlanders value the skin of the young ones very high. It is uncommonly fierce when wounded, and often attacks the canoe. These seals fight very stoutly among themselves, from jealousy, as the natives suppose. They live in flocks; are found in great numbers round Cape Farewell, and go very seldom to the northern parts of the coast. It is falsely called *Phoca leonina* by some zoologists, this being a very different animal.

Common seal.

The *common seal*, called *Spragled Sael* by the Danes, *Kobbe* by the Norwegians, *Meerkalb* by the Germans, and *Kassigiak* by the Greenlanders, (*Phoca vitulina* of Gmelin) is found sometimes in very large flocks on the coast of Greenland. It is one of the smaller animals of the family, but its skin is the finest of them all, and is of great value among the Greenlanders. It is principally employed for female dresses. The common seal is very cautious, and therefore caught with difficulty.

Harp seal.

The *harp seal*, or *half-moon*, (*Phoca groenlandica*,) called *Svartside* by the Danes, *Robbe* by the Germans, and *Atarsoak* by the natives. It is nine feet long when full grown, and gives the best blubber. Its skin is of a yellowish-white and greyish-white colour, with two large black spots on the opposite sides of its body, in the form of two half-moons, the horns of which are turned in an uniform direction towards one another, and therefore called Half-moon. It becomes like the black spots in its fourth year when full grown. Its skin is the most durable, and therefore used to cover the canoes and the tents. It is incautious, and very easily taken. It never ascends the fixed ice. It is a migrating animal; comes with its young from Spitzbergen to Davis Strait about the end of March, returns in May to Spitzbergen, and comes back again in July. Three or four of them afford a barrel of blubber. It comes in great flocks, and visits the firths of Davis' Strait.

Rough seal.

The *rough seal*, (*Phoca hispida* and *Phoca fœtida*,) called *Neitsek* by the Greenlanders, is the smallest of the generally known species, very seldom exceeding four feet in length. It never frequents the high seas, but keeps always in the vicinity of the fixed ice, generally in high latitudes, and is very seldom seen southward from Disco Bay. Many thousand are killed every winter in Omenak's firth or Cornelius bay, in the 72° of latitude. The male emits an insupportable smell in its coupling time, nevertheless it is eaten with great avidity by the northern Greenlanders.

Great seal.

The *great seal*, (*Phoca barbata*,) called by the Greenlanders *Urksuk*, is of the largest kind, but is very seldom met with on the coast of West Greenland. It measures sometimes ten feet in length, has a thick skin, with very thin brown hairs; and on its upper lip very long white pellucid whiskers, which are curled at their points. Its flesh is white and very good. The Greenlanders cut out of the skin thongs and lines for their seal game, whips, and other domestic articles.

The Greenlanders mention some other species of seals, which very seldom occur, viz.

Siguktok, having a very long snout; in its body it is similar to the *Phoca groenlandica*. Perhaps it is the *Phoca ursina*.

Imab-ukallia, of a snow-white colour, the eye presenting a fire-red iris, probably the *Phoca leporina*.

Atarpiak or *atarpek*, the smallest species of seal, not exceeding the size of the hand, of a whitish colour, with a black spot of the form of a half-moon on each side of the body.

Kongeseteriak has, according to the description given by the natives, some resemblance to the sea-ape, which is described by Mr Heller.

Sea unicorn or narwhal.

The *Sea-unicorn* or *narwhal*, (*Monodon monoceros*,) called *Kernertak* by the Greenlanders, is a migrating animal. It is generally from seventeen to twenty feet long, has a smooth black skin, and a small mouth in proportion to its body. It has no teeth, but a horn, wreathed or twisted on its surface, and from eight to ten feet long, runs from the left point or end of the upper jaw. It is white, has the solidity of the hardest bone, and far surpasses ivory in all its qualities. The animal uses the horn to get at its food the sea-grass, and also as a weapon against its enemies. It has two nostrils in the skull, but they emerge in one aperture through the skin. It swims with wonderful velocity, and can only be killed when there is a great number of them together. They are always seen in flocks, in the severest winter, amidst the fissures of the fixed ice, in the bays from 70° of N. Lat. to the most northern regions. They never occur in more southern latitudes. The Greenlanders drive with their sledges to the fissures of the ice, where the animals generally come up to take air, and kill them there with their harpoons, or with guns. They eat both their flesh and skin, raw, dried, or boiled; use the blubber for their lamps; and the horns, which are highly valued, as an article of trade. Most of them are killed in Disco bay, in the 70°; in Omenak's firth, or Cornelius bay, in the 72°; and at Upernavik, in the 73°.

White fish.

The *white-fish*, *beluga* of the Russians, and *kelleluak* of the Greenlanders, is likewise a migrating animal, and visits the coast of West Greenland regularly every year about the end of November. It is, next to the seal, the most useful animal to the Greenlanders, and it comes at a season when their provisions fall very short. It arrives in flocks, in very stormy weather, when the wind blows from the south-west. It has a short, roundish, very fleshy head, but the skull is longish and flat; the eyes and the mouth are small; in each jaw of each side are nine teeth; the pectoral fins are nearly of an oval form; and beneath their skin may be felt the bones of five fingers, which terminate in five very distinct projections. The body is round, oblong, and well proportioned; and its tail is divided into two lobes, which lie horizontally. Its length is from twelve to seventeen feet. In swimming it makes great use of the lobes of its tail, bending them under the body, and working it with such force as to dart along with the velocity of an arrow. One of the large size yields five barrels of good blubber. Its flesh is somewhat similar to that of beef, though oily; its skin is eaten raw, dried and boiled. Its oil is of the best, whitest, and finest quality. The intestines are used for windows, and the curtains of tents. The sinews, when split, give the best sort of strong thread. The female white-fish has two nipples, and yields a yellowish-white milk, but it produces only a single young one, which is of a fine pearl-grey colour, but it afterwards grows white. The pearl-grey young is called *utak* by the natives. The full grown are the most beautiful animals; they are not shy, and sometimes follow, tumbling themselves round the boats. They are killed with harpoons, and also caught in large strong nets, which are set in narrow sounds between the islands.

The *porpoise*, or *Delphinus delphis;* the *nise*, or *Delphinus phocœna;* and *the sword-fish*, or *Delphinus orca*, are frequently seen on the coast, but very rarely caught.

Whales.

Whales.—There are different species of whales which visit the coast of West Greenland, viz. *Balæna physalus*, or fin-fish, called *tunnolik* by the Greenlanders; *Balæna musculus*, or *northcaper*, (Green. *keporkarnak*); *Balæna rostrata*, (Green. *tigagulik*); *Balæna boops*, (Green. *keporknak*), and *Balæna mysticetus*, or the Greenland whale, called *arbek* by the natives. The *Balæna boops*, or *butskopf*, comes regularly to the coast in the neigbourhood of Fredrikshaab about the end of July, when the Greenlanders, both men and women, go out in their canoes. The men in their small canoes follow the whale, and continue to throw a great number of harpoons and lances into the animal, until it dies from loss of blood. They afterwards join their canoes, fasten their spoil to them, and carry the booty to their houses, where it is divided.

Balæna boops.

The *Balæna boops* is a smaller kind of whale, its length being from twenty to twenty-five feet. It has a fin on its back, and also a protuberance which grows towards the tail. It has long rugged wrinkles under its neck, that are white inside, and greyish-black on their elevation. A great number of the shells called *Lepas balænaris*, or *Lepas diadema*, are found near its fins. Its body is longer, and sharper behind and before, than that of the other whales. Its back is of a black, and its belly of a greyish-white colour; the whalebones of this species rarely exceed the length of one foot. Its blubber is thin, and not very oily. This whale follows always along the coast farther to the north, and it is also caught by the Greenlanders in Disco Bay.

Balæna mysticetus.

Balæna mysticetus, the great or Greenland whale, is the most valuable and lucrative species of this genus, on account of its bigness, and the great quantity of fat, which affords much oil; it is also the most tame, and the easiest to be caught, on account of its unwieldy size. It has no back-fin. The head of it forms one-third part of the whole body. Its eyes are very small in proportion, not much bigger than those of an ox, and black, with a white iris; they lie deep, and are placed above the junction of both lips. Instead of ears, a hole appears on each side of its head, so small that it is scarcely discernible, not admitting any thing thicker than a goose-quill; but within the flesh there is a larger orifice, formed like an ear, which enables it, as has been noticed, to hear very distinctly. The two holes, or pipes, on the top of its head, are crooked, and very similar to the holes in the belly of a violin. They are for receiving air, as well as for discharging the water which it swallows by its mouth. This is forced upwards through these holes in very large quantities, and to a considerable height, (of some fathoms) with such a noise, that it roars like a hollow wind, and may be heard at three miles distance. When wounded, it blows more fiercely than ever, the water frequently being mixed with blood. Its throat is uncommonly narrow, not exceeding the width of one inch and a half. Its tongue is eighteen feet long, when the animal measures fifty-six or sixty feet; it is then ten feet broad, is very fibrous, floats on the water, and affords four to six barrels of oil; its weight is to 600 or 800 pounds. The tongue is inclosed in long pieces of a corneous substance, generally called whalebones; and these are covered on their interior side with a kind of fibre, or straight hair of the same substance, similar to coarse horse hair. On each side of the tongue are commonly found 250 of different lengths; the longest are about the middle, and decrease towards the snout and the throat; they are attached to the upper jaw. The under jaw forms with the jaw bones an oblong triangular deep bason, of a tendinous and cartilaginous substance, which is as deep as to cover the longest whalebones in their perpendicular shape, when the mouth is closed; this receptacle is, of course, deepest towards its middle part. The broad ends of the whalebones, where they are joined to the palate, are generally one foot broad; they terminate very pointed, and have the form of a curved sword; they would wound the tongue, which is very delicate, if they were not covered with hair on their inside. There are no other teeth in the mouth. This whale is very thick from the head to the middle, but thinner and sharper towards the tail; its fins and its tail stand horizontally.

Dimensions of the Greenland whale.

In the spring of 1813, a whale was killed at Godhavn, of the length of 67 feet. The dimensions of a whale, killed in the year 1811 at Godhavn, was, from the centre of the mouth to the point of the tail, 56 feet. From the point of the under lip to the root of the fins 23½ feet. From the fins to the point between the two lobes or wings of the tail 33 feet. The length of the head was 18 feet. From the middle point of the upper lip to the blow-holes 16½ feet. The length of one of the fins 8 feet 4 inches. The thickness of a fin, on its thickest part, 1 foot 9 inches. The breadth of the tail from one extremity of its wings to the other, 22 feet 7 inches. The length of one of the blow-holes 11 inches. There were 13 ribs on each side, and in all 26 ribs. The animal was a female. The fins serve this large animal for rudders, to turn in the water, and to give a direction to the velocity impressed by the tail. The tail serves for an oar, to ad-

Greenland.

vance itself in the water; wherewith it swims with incredible force and celerity. When swimming a little under the surface of the water it leaves a track in the sea like a great ship, and this is called its wake, by which it often is followed. The female makes use also of the fins, when pursued, to bear the young one, placing it on its back, and supporting it by the fins on each side, from falling. They are also seen sometimes having their young upon the tail.

The skin of the whale is of a different nature. The epidermis resting upon the skin is not thicker than parchment; but when this is removed, the real skin appears, which is about an inch thick, of a bluish-black colour, fibrous and spongy; it is called by the Greenlanders *maktak*; it is very much wrinkled in the old whales, and smooth in the young ones. Beneath the skin (*maktak*) lies a yellowish white, very tenacious, reticulated fibrous substance, which affords more fritters than oil; it is called *maksak* by the natives: with this substance the real blubber is immediately connected. The blubber is of very unequal thickness, from 10 inches to one foot thick upon the back, and on the under lips two feet thick; but the latter is very cartilaginous, and intermixed with coarse nerves. The head and the back of the whale is bluish-black, the under jaw is white, and sprinkled or spotted with bluish-black, and the tail is greyish black. The skin of the suckers is greyish blue. The Greenlanders state, that the old animals become more and more of a greyish white colour. The blubber of young whales is reddish white and rose red, that of the old is yellowish white; the flesh of the young is dark blood-red, that of the old is dark red-brown. The bones of the whales are very porous, and afford, when sawed in pieces, the finest oil. The female whale has two breasts, with teats like a cow, and has one young one, very seldom two. When it suckles the young it lies on its side, on the surface of the sea, and the young one attaches itself to the teat. The food of the whales is the *clio arctica*, the *argonauta arctica*, *cancer pedatus*, and *cancer oculatus*, none of them exceeding the size of a common wasp. Sometimes also *oniscus pulex*, and other species of oniscus are found in its stomach. It takes its food under water; these small insects become entangled by the hair of the whalebones, and the water is emitted partly on the sides of the mouth, partly through the blow-holes. The whale cannot remain longer than from 15 to 20 minutes under water. It sleeps on the surface of the sea, and is often caught asleep.

Settlements for the Danish whale fisheries.

The settlements or colonies, which are established and supported by the Danish government on the coast of West Greenland, for the purpose of the whale-fishery, are Holsteinsburg in 67° 10′, Egedesminde and Wester-island on the southern point of Disko bay, Hunde Island, and Crown-prince-island in Disko bay, Christianshaab, Claushavn and Jacobshavn on the continent of Disko bay, Godhavn on Disko island, and Klokkerhuck on Arve-Prince-Island, situated on the entrance of the Waygat. The fishery is carried on in boats, by natives and settlers, on the account of the Danish government. The fishery was not very successful during the last ten years. The English and Scotch whale-fishers visit Disko bay every year about the end of April, and leave it again in June. The Dutch whale-fishers, who formerly also came there every year, were prevented from fishing at all during the late war. It is only the balæna mysticetus, which is caught there at that season. It comes to the coast about the end of December, and leaves it again in June.

The spermaceti whale, or cachalot, (*Physeter macrocephalus*) the enemy of the balæna mysticetus, is seldom seen on the coast of West Greenland.

Birds. Land birds.

Birds.—West Greenland presents very few land birds. The largest of them is the *vultur albicilla*, the cinereous eagle, called *nektoralik* by the natives; it feeds on seals, fishes, and all kind of birds; is of a greyish brown colour, and inhabits Greenland the whole year, sitting on the rocks with flagging wings, and flies slowly. It is eaten by the Greenlanders, and the skin employed for clothing.

The *falco rusticatus*, the *falco islandus*, and the *falco fuscus*, or Greenland falcon, called by the natives *Kirksoviarsuk kernertok*, inhabit the most remote parts of the firths; they feed on birds. The latter is of a very fine appearance. Its colour is marbled of white grey and brown. It is only eaten by the natives when compelled by hunger. All falcons inhabit Greenland the whole year.

The *beautiful snowy owl*, or *stryx nyctea*, called *orpik* by the Greenlanders, is found in the interior of the continent, in the vicinity of the glaciers. It preys on every kind of bird day and night.

The *raven*, (*Corvus corax*,) (Green. *Tulugak*,) occurs in great number, and frequents the huts of the natives, who abhor its flesh.

The *white partridge*, (*Tetrâo lagopus*), called in North Greenland *ageiksek*, and in South Greenland, *kauio*, inhabits in summer the mountains for the sake of crowberries, (*Empetrum nigrum*). In winter it descends to the valleys near the shores. It is brownish in summer, and changes its colour in winter into a snow white. The Greenlanders like very much to eat its intestines raw.

Of small land birds, which all leave this country in the beginning of winter, are only seen the *fringilla lapponica*, (Green. *Narksamiutak*), the *fringilla linaria*, (Green. *Orpingmiutak*), the *motacilla oenanthe*, (Green. *Kusseklak*), and the *emberiza nivalis*, (Green. *Kopanauarsuk*). The arrival of the latter about the end of May announces the approach of spring. In autumn, in the beginning of September, it collects again in great flocks, in order to migrate.

Water birds.

Of water birds, there occur on the coast,—

1. *Anas bernicla*, bernacle. Green. *Nerdlek*.
2. *Anas clangula*, golden-eye. Green. *Kærtlutorpiarsuk*.
3. *Anas histrionica*, harlequin. Green. *Tornaviarsuk*.
4. *Anas boschas*, mallard. Green. *Kertluctok*.
5. *Anas glacialis seu hyemalis*, long tailed duck. Green. *Aglek*.
6. *Anas spectabilis*, king-duck. Green. *Siorakitsok*.
7. *Anas mollissima*, eider-duck. Green. *Mitek*.

Eider duck.

The *Anas mollissima*, or eider-duck, visits the coast as soon as the grass begins to grow, and plucks the finest down from its breast to form its nest. The down taken from the nest, is the finest and most elastic. It is customary to take away the first eggs, which occasions a second laying, and a second deplumation. They lay their eggs on uninhabited islands among the grass growing near the shores. They brave the severest winter of the arctic regions, and their breeding-places are the most northern. They come constantly every spring to the same spot again if not disturbed. The Greenlanders kill them with darts and guns, watching their course (when they dive) by the air-bubbles, and strike them when they ascend. The flesh is valued as food. The skin of this duck is the most valuable of all as a garment placed next to the skin. The down forms a very considerable article of trade. The colony Egedesminde produced in the year 1808, 1000 pounds weight of that article. One pound sterling is paid for one pound weight of the best sort of down.

enland. Of *Merganseres* occur,—1. *Mergus serrator.* Green. *Paik.*

2. *Mergus merganser*, goosander. Green. *Pararsuk*

ks. Of *Auks.*—1. *Alca impennis*, great auk. Green. *Isarokitsok.*

2. *Alca torda*, razor-bill. Green. *Akpardluk.*

3. *Alca pica*, black-billed auk. Green. *Akpa.*

4. *Alca arctica*, puffin. Green. *Killangak.*

5. *Alca alle*, little auk. Green. *Akpalliarsuk.*

The *alca pica* vies with the eider-duck in point of utility to the Greenlanders. The skins are used for clothing, and the flesh is eaten. They only approach the coast when the cold becomes very severe, and breed in summer in the clefts of the remotest rocks. They are killed in canoes with darts, and give food to the Greenlanders in the months of February and March, when they want every other supply from the sea. It appears that the words *alca*, *auk*, and *akpa* are formed from the note or sound which the bird emits when flying or swimming in large flocks.

els. Of *Petrels*, or *Procellariæ*, are seen,—

1. The *Procellaria glacialis*, fulmar. Green. *Kakordluk* ; and,

2. The *Procellaria puffinus*, shear-water. Green. *Kakordlungoak.*

The prey of these birds being the blubber of the whale, they are only found in the vicinity of the whale-fisheries. They are, from the nature of their food, extremely fetid; and so stupid and voracious, as to be killed with rods in their attempt to obtain prey. They are rarely eaten.

lemots. Of *Guillemots.*—1. *Colymbus grylle*, black guillemot. Green. *Sergvak.*

2. *Colymbus glacialis*, northern guillemot. Green. *Tudlik.*

3. *Colymbus septentrionalis*, red-throated guillemot. Green *Karkfak.*

Their skins are very excellent for clothing, in consequence of their durability.

Tns. Of *Terns.*—*Sterna hirundo*, great tern. Green. *Imerkoteilak.*

Their eggs are the most delicate of all water-birds. They come latest in summer, that is, in the beginning of June, and leave the coast earliest, that is, in the beginning of September, under great noise.

Gs. Of *Gulls.*—1. *Larus marinus*, black-backed gull. Green. *Nayardluk.*

2. *Larus tridactylus*, kittiwake. Green. *Tattarak.*

3. *Larus candidus*, ivory gull. Green. *Nayauarsuk.*

4. *Larus arcticus, cataracta parasitica*, arctic gull. Green. *Meriarsairsok.*

5. *Larus glaucus*, glaucous gull. Green. *Naya.*

ans. Of *Pelicans.*—1. *Pelicanus carbo*, corvorant. Green. *Okaitsok.*

2. *Pelicanus cristatus*, crested corvorant. Green. *Tingmik.*

3. *Pelicanus bassanus*, gannet. Green. *Kuksuk.*

All these birds are used as food; the skins for clothing.

pax. Of *Scolopax.*—1. *Scolopax gallinago*, common snipe. Green. *Sigrektok.*

2. *Scolopax jardreka*, jardreka. Green. *Sargvarsursoak.*

Tga. Of *Tringa.*—1. *Tringa striata*, striated sandpiper. Green. *Sirksariarsungoak.*

2. *Tringa interpres*, Hebridal sandpiper. Green. *Telligvak.*

3. *Tringa lobata.* Green. *Nelloumirsortok.*

4. *Tringa fulicaria.* Green. *Kajok.*

5. *Tringa alpina*, dunlin. Green. *Tojuk.*

Plers. Of *Charadrius*, or *plover.*—1. *Charadrius apricarius*, alvargrim. Green. *Najoiroveck*

Greenland. 2. *Charadrius hiaticula*, ringed plover. Green. *Tukagvajok.*

Fishes. Fishes.—Greenland cannot boast of valuable fisheries. The natives attend only to their seal-game, and neglect entirely every other branch of industry. The few Europeans residing there are occupied with trade. There can be no doubt, however, that such an extensive coast would afford numerous and profitable banks. Some have already been discovered at Tunugliarbik, Guannersoak, Fredrikshaab, Fishfiord, Sukkertop, Amertlok, where *different species of cod fish* are caught, for instance, *Gadus æglefinus*, (Green. *Misokarnak*); *gadus callarias*, (Green. *Sarolik*); *gadus morrhua*, (Green. *Saraudlirsoak*); and *gadus barbatus*, (Green. *Ogak*). In the north of Greenland, in the 70, 72, and 73d degrees, were discovered very extensive *flounder banks.* The *pleuronectes hippoglossus*, holibut, (Green. *Netarnak*), sometimes of a weight of more than 100 pounds, is found in abundance in the neighbourhood of the colonies Godthaab and Sukkertop. Extensive banks of the *pleuronectes cynoglossus*, (Green. *Kaleraglik*), were lately discovered at Jacobs-havn in Disko bay, and at Omenak in Cornelius bay. Different species of *salmo*, viz. the *salmo carpio*, (Green. *Ekalluk*), the *salmo alpinus*, (Green. *Iviksarsok*), and the *salmo rivalis*, visit every year the friths and inlets of the continent. But the most remarkable of all the fishes is the *salmo arcticus*, called *Angmarsæt*, the Greenlanders deriving their daily food from them. It forms their bread, and makes also a sort of dessert after their most delicate repasts. The *Angmarsæt* live at sea most part of the year; but, at the end of May, they come in immense numbers into the bays and friths. They are taken in nets, in all kinds of vessels, and even with the hands, in great multitudes. The whole bottom of the sea seems covered with them. They are dried on the rocks, put into sacks, and preserved for the winter under heaps of stones. They are generally eaten dried instead of bread, but many are dressed fresh as soon as they are taken. They seldom exceed seven inches in length. They have a very strong sharp smell when they are dry; and are, on the whole coast of Norway, in bad credit, as a very noxious fish, a calumny which they do not deserve. The impression of this fish occurs frequently in an indurated grey sandy marl on the end of the bays. Next to *angmarsæt*, the Greenlanders eat most of the *ulkes*, a kind of *cottus*, particularly *cottus scorpius*. They eat the fishes dried, or boiled in sea water, but the heads of *pleuronectes* are eaten putrid. Salmo arcticus.

Insects.—The Greenlanders are tormented with very troublesome insects. The *culex pipiens*, a kind of musquitoes, appears in the months of June, July, and August in myriads. But a great number of other insects increase, from the incredible filthiness of the natives. Insects.

The insects, which contribute to the comforts of life, are, *Cancer phalangium*, a species, which has some resemblance to *cancer longimanus*, the cancer *squilla*, and cancer *homaroides*. The minute species of *Cancer pedatus* and *Cancer oculatus* afford food to the whale, and their existence is therefore of great importance to the natives. Numerous species of *oniscus* are found partly in the sea, and partly attached to the bodies of several marine animals.

Vermes.—Numerous species of *gordius* and *lumbricus* are found, and the intestines of the arctic quadrupeds, birds, and fishes, swarm with different species of *ascarides*. Of the interesting family of *Nereis* occur 10 species. Worms.

Shells.—The coast of Greenland cannot boast of numerous varieties of beautiful shells, of which the seas Shells.

Greenland. Shells.

of the warm climates abound. Of *Asterias* occur the *asterias rubens*, with 6 rays; the *spongiosa*, with 5 conical rays; the *papposa*, with 12 and 13 rays; the *minuta*, with 6 rays, and the *ophiura*, with 5 rays. In Discofiord is found the *asterias caput medusæ*. Of *Echinus* exists only the *saxatilis*; 12 species of *Serpula*; 3 species of *Chiton*, one of which is new, and not yet described; its testæ are marbled of a yellow and red colour. Of *Lepas* occurs on the shores, *lepas balanus*, and *balanoides*; and on the skin of the Balæna boops, the *lepas balænaris*, or *diadema*.

Of Bivalvia are found the *mya* arenaria, arctica, truncata and byssifera, the latter a new species; only one *Cardium*, viz. ciliare; three *Veneres*, the islandica, minuta, and fragilis. The *pecten* islandicus. The *mytilus* edulis, discors and faba. The myæ and mytili are eaten by the natives; and the shells used as spoons.

Univalvia are: some *patellæ*, *argonauta arctica*, the favourite food of the balæna mysticetus; the *helix* pellucida, nitida and haliotoides; the *trochus* cinerarius, divaricatus and helycinus; the *tritonium* undatum, despectum, antiquum, glaciale, lapillus, fornicatum, clathratum, craticulatum, and ciliatum; the two latter are new species. Of *Nerita*, the littorea only is found.

In the friths and inlets are found various *tubiporæ madreporæ*, *milleporæ*, and *celleporæ*, but all very minute. *Flustræ* and *sertulariæ* grow on the whole coast in great numbers; *alcyonia* and *spongia* occur very seldom.

Catalogue of books respecting Greenland.

It will no doubt be interesting to our readers to have a catalogue of works concerning Greenland, which have been published at different times.

The oldest accounts of Greenland will be found in *Kongs-speilet*, or *Speculum regale*. More in Whitfeldt's *Chronica*, and in Lychsander's *Chronike*. Copenhagen, 1602. Part of it is translated into English, and published in Purchas' *Pilgrims*.

Jens Munks *Navigatio Septentrionalis*, in Danish, was published at Copenhagen, 1624, 8vo. It contains his voyage for discovering a north-western passage, and some account of Greenland.

Isaac de la Pereyre wrote a *Relation de la Groenlande*. Paris, 1613, 8vo. It was translated into the Danish and German language.

From this time to the year 1721, some curious critical pamphlets were written concerning East and West Greenland, viz.

Rudolph Cappel, *Orbis Arcticus*. Hamburgi, 1675, 4to.

Arngrimi Jonæ, *Groenlandia*, (in Latin.) Hafniæ, 1688, 8vo.

Thormodi Torfæi, *Historia Vinlandiæ Antiquæ*. Havniæ, 1705, 8vo.

Thormodi Torfæi *Groenlandia antiqua*. Havniæ, 1706, 8vo. and 1708, 8vo. *cum tabulis geographicis*.

Pierre de Mesange, *les aventures et les voyages de Groenlandt avec une relation de l'origine, de l'histoire, des mœurs, et du paradis des habitants du pole arctique*, à Amsterdam, 1720, 2 vols. 8vo.

Zorgdrager *oud en nieuwe Groenlandish Walvischery*, 4to. Amst. translated into German, Hamb. 1724, 4to.

Hans Egede, the celebrated Danish missionary, went to Greenland in the year 1721, and published, in the year 1729, at Copenhagen, in 4to. *Den gamle Groenlands nye perlustration*. It was soon translated into English, German, Dutch, and French.

Afterwards he published, in the year 1738, at Copenhagen, in 4to. *Omstændelig og udforlig Relation angoende den Gronlandske Missions Begyndelse og Fortsættelse*, (containing his Journal).

Paul Egede, his son, the second Danish missionary, published soon afterwards, continuation of *Relationerne betreffende den Gronlandske Missions Tilstand* from 1734 to 1740.

Greenland ‖ Greenock. Catalogue of books respecting Greenland.

In the year 1788 he published his last work, *Efterretningerne om Groenland, uddragne af en Journal holden fra Aarene*, 1721 till 1788. Copenhagen, 8vo. with plates.

Nils Egede, his brother, who was a merchant in Greenland, published a continuation of *De Gronlandske Relationer*, from 1739—1743.

In the year 1761 David Crantz, of the German Unitas Fratrum, visited their settlements on the coast of West Greenland, and remained there till August 1762. In the year 1765 he published, *Historie von Gronland*. 2. Bande, 8vo. with plates. Barby; and in the year 1770, Fortsezzung (continuation) *Der Historie von Gronland*. His account was translated into English, Dutch, and Swedish.

The Rev. Otto Fabricius, who was a missionary in Greenland during five years, published his *Fauna Groenlandica* at Copenhagen, in 1780, in 8vo.

The first Greenlandish Grammar was published by Paul Egede in the Danish and Latin language at Copenhagen in 1760, in 8vo.

The first Dictionary in Greenlandish, Danish, and Latin, was published by Paul Egede, in 1750, in 8vo.

Both works were very much improved by Otto Fabricius, the Grammar in 1791, and in a second edition in 1801, and the Dictionary in the year 1804, 8vo.

Paul Egede was also the first who translated the New Testament into the Greenlandish language. It was reprinted in the year 1803, and very much improved by Otto Fabricius.

Besides this, partly by the Danish Society for the furtherance of the missions, partly by the Unitas Fratrum, psalm-books, prayer-books, and other religious books, have been printed, and distributed gratis amongst the Greenlanders.

GREENLAW, is a small town of Scotland in Berwickshire, and is situated on a plain, watered by the Blackadder, nearly in the centre of the county. There are here the remains of two religious houses, which were dependent on the priory of Kelso. Marchmont house, the seat of the family of Marchmont, is about 2 miles from the town. Greenlaw is the county town of Berwickshire. Its population is about 600.

GREENOCK, is a sea-port town in Scotland, situated on the Frith of Clyde, about 22 miles below Glasgow, and 46 above Ayr. It contains many neat and well-built houses, but its streets are irregular and narrow; and its general appearance is far from being elegant. Of late years, it has extended very much to the west, and there, as might have been expected from the opulence and taste of the inhabitants, a great improvement has taken place both in the general plan and in the structure of individual edifices. The principal public buildings of Greenock, consist of the infirmary, which was erected in the year 1808 at an expence of nearly £2400, and contains good accommodation for a considerable number of patients; the theatre, erected the same year, at an expence of £2500; a bridewell, erected in 1809, at an expence of £1340; and a tontine inn, erected in 1802, at an expence of £10,000. There are three established churches, viz. the West Church, which serves the country part of the parish, is very old, and very uncomfortable; the New Church, built in 1762, a large commodious place of worship in the centre of the town, and having a steeple attached to it 146 feet high; and the East Church, originally built in 1774 as a chapel of ease, but erected into a parish church in 1809. There is also a Chapel of Ease for the Gaelic population, built in 1791 at an expence of £ 1700, and containing 1600 people. Besides these, there are various dissenting meetings: the Burgher meeting, erected in 1791 at an expence of £ 1300, and containing 1000 sitters; the Antiburgher, erected in 1803 at an expence of £ 1122; the Relief, erected in 1808 at an expence of £ 2200, and containing 1700 sitters. There is also a Tabernacle, a Methodist meeting, and a Roman Catholic chapel. A Unitarian preaches in the theatre on Sunday evenings. There are public schools for all the various branches of literature and science. A free school, established in 1790, is under excellent management, and gives useful and religious education to hundreds of poor boys and girls, at an expence of 6s. 8d. per annum for each child. In 1812, a society was instituted in Greenock and Port Glasgow for the encouragement of arts and sciences. About 150 subscribers, at 5s. each per annum, were obtained, and the whole funds are distributed in prizes to persons of genius and merit. For some years, there has been connected with this an exhibition of paintings. Since 1793, there has existed an institution, under the title of the Greenock and Innerkip Farmer and Agricultural Society. There are several subscription and circulating libraries, with extensive collections of books. One newspaper, the Greenock Advertiser, is published thrice a week. The poor, who are very numerous, are supported partly by the public collections, partly by voluntary assessments, and partly by the interest of sums, which from time to time have been bequeathed to them by the charitable. There are various societies established by particular trades and professions, whose principal object is to afford relief to their decayed members: Such as the Ship-carpenters Society, instituted in 1732; Master Wrights Society, instituted in 1734; Shoemakers Society, instituted in 1754; Journeymen Coopers Society, instituted in 1792; Widows Society, instituted in 1796, &c. The Merchants House Society was instituted in 1787; five guineas are paid on admission, and 5s. annually for the support of those families or individuals belonging to it, who have grown indigent. There was formerly in Greenock a society, designed the Clyde Marine Society; but in 1786, it was incorporated by act of parliament with the Glasgow Marine Society. This institution is very rich, and very useful. There are several banks and branches of banks established at Greenock, which do a great deal of business.

The old harbour of Greenock, begun to be built in 1707, contains about 10 acres. These are inclosed within two circular quays, in the middle of which is another quay built in 1712, projecting like a tongue. The original cost was 10,000 merks Scots, or £ 5625 sterling, which was to be defrayed by a malt duty, and was liquidated in 1740, leaving a surplus of £ 1500. In 1801 and 1803, acts of parliament were obtained for enlarging and improving the harbour; and when all the plans are executed, the accommodation for shipping, &c. in this port will be of a very complete and superior kind. The new harbour will contain about 8 acres of ground, which were obtained from Sir John Shaw Stuart and Lord Cathcart at 5 guineas per fall, and a shilling per fall of feu duty. During the last ten years, £ 85,000 have been expended in extending the harbours, by building new quays, sheds, &c. and an additional sum of £ 25,000 will be required to finish the work, including the expence of building a new graving dock.

The expence of erecting the present sheds, and keeping them in repair, has cost the trustees of the harbour £ 9868, and those yet to be erected will not cost less than £ 3132, making together £ 13,000.

The revenue received from them for the year ending September 1812, was £ 1201
Do. 1813, 1472
Do. 1814, 2052
Do. 1815, 2053

And the yearly rent on an average for five years ending in April last, is £ 1609.

The anchorage or ring money for the year ending September 1813, was £ 175 13
Do. 1814, 181 17
Do. 1815, 218 12

making the yearly rent on an average for three years £ 192.

Ship-building is not so much followed as might have been expected at such a port as that of Greenock. On an average, there are about 10 or 12 vessels built annually. As to quality and construction, these vessels are equal to any in the united kingdom. There is a graving dock, which was erected by share holders in 1783. The building yard of Messrs John Scott & Co. containing a graving dock, a basin, boat and mast sheds, blacksmith's shop, &c. is, in point of size and convenience, superior to any private establishment of this kind in the kingdom. Mr Steele also has excellent premises for building and repairing ships.

There are four large rope works, and several smaller ones. They employ from 200 to 300 hands, and manufacture annually about 1000 tons of cordage, which is sold for the use of the shipping of the port, and for exportation to the colonies. There is one rope-work for making patent cordage. Sailcloth is also manufactured here to a considerable extent. There are two manufactories for this article. Greenock contains two soap and candle manufactories, which are carried on to a large extent, principally for supplying our North American and West India colonies with these articles. One of them is an old establishment, having existed since the year 1772. There are also two extensive breweries, both of which export large quantities, solid and in bottles. While the French West India islands were in our possession, the supply of this article was very great, particularly light coloured table beer. There are two iron and brass founderies; one large hat manufactory, and several smaller ones; a green glass and a flint glass work; three tan works; a pottery; and a lamp-black manufactory. All these depend greatly on the export trade, and the demand for the shipping.

An account of the number of ships and vessels, with their tonnage, and number of men and boys usually employed, registered and belonging to the port of Greenock for the years ending 30th Sept. 1814 and 1815:

	Ships.	Tons.	Men.
Year ending 30th Sept. 1814,	360	34,159	3325
Do. 30th Sept. 1815,	336	35,210	3220

At present there are 379 ships, brigs, sloops, &c. registered at the custom-house, admeasuring 47,268 tons, and navigated by 3457 men.

An account of the number and tonnage of ships and vessels, which were of, and belonging to, the port of Greenock, with their number of men, that have traded to and from foreign parts, or coastwise, or been employed in fishing, in the years ending 5th January 1815 and 1816, accounting each vessel but once in the year.

The herring fishery has been long an object of importance to the town of Greenock. So far back as the year 1688, it was carried on to a considerable extent. Since that period, it has experienced frequent vicissitudes. The following statement will shew its present situation:

In the year ending the 5th of April 1815, there cleared out for the herring fishery 177 vessels, 6896 tons, manned with 958 men. Carried out 688,171 square yards of netting, 68,205½ bushels of British salt, and 36,861½ barrels.

Entered inwards from do. 174 vessels, 6612½ tons. Carried in 24,503½ bushels salt, 11,394¼ barrels (not filled) with herrings, and 23,603½ barrels of herrings.

Exported to Ireland, 5828 barrels; to the north of Europe 350; to the West Indies 24,203. Total exported 30,381 barrels.

In the year ending the 5th of April 1816, there cleared out for the fishery 149 vessels, 5623 tons, manned with 814 men. Carried out 547,167 square yards of netting, 53,434½ bushels of salt, 30,172 barrels.

Entered inwards from the fishery 157 vessels, 5975 tons. Carried in 15,382 bushels salt, 6941 empty barrels, and 24,275½ barrels of herrings.

Herrings exported to Ireland, 4478 barrels; to the north of Europe 859; and to the West Indies 23,368. Total exported 28,705 barrels.

An account of the amount of duties received at the port of Greenock, for the two years ending 5th January 1815 and 1816.

Year ending 5th January 1815,	£376,713	15 10½
Do. 5th January 1816,	403,176	6 8

Account of the amount of drawbacks and bounties paid for the same period.

	Drawbacks.	Bounties.
Year ending Jan. 5. 1815,	£41,120 5 7¼	£67,978 8 3¾
Do. Jan. 5. 1816,	32,924 2 3¾	81,617 19 1¾

The excise duties and drawbacks are not included in the above.

The total receipt of the duties of customs at the port of Greenock, year ending 5th January 1816, was £403,176, 6s. 8d. principally under the following heads:

Upon general goods imported	£115,717 13 11¾
Upon sugar, rum, coffee, tobacco, wine, &c. for home consumption	275,111 10 2¼
And upon general goods exported	12,347 2 6
	£403,176 6 8

And there was paid during said year for bounties, on linen, sail cloth, silk, sugar, and cordage exported, £81,617, 19s. 2¼d.

Vessels entered and cleared at the custom-house 1815, and paid harbour dues in and out.

	Harbour Dues.
1638 vessels, 177,906 tons, ...	£4811 13 4
150 lighters employed on the river .	214 18 3

1815	2391	1996	15,105	8500	—	285	272 6 3

Making an average per year for three years of £247, 5s. 10d.

In 1757, the population of Greenock was 3900. In 1781, it was 12,000. In 1792, it was 14,299. In 1797, it was 15,000. In 1802, it was 17,458, the number of houses being 1029; of males 8194, and of females 9262. In 1804, it was 20,000. And in 1811, it was, exclusive of those at sea, 19,042, having increased in the preceding 20 years 4743, or 1212 males, and 3531 females. Greenock is a burgh of barony. It was erected in 1757, by Sir John Shaw Stuart the superior, and is governed by a council of 9 feuers, 2 of whom are annually elected to the office of bailies, with corresponding powers. In 1795, the rental of the parish, comprising 5065 Scots acres, was £3500 sterling, its valued rent being £2285 Scots. In 1810, the rental was 10,000 sterling. (τ)

GREENWICH, is a market town of England, in the hundred of Blackheath, and county of Kent. It is delightfully situated on the south bank of the Thames, where the river is from 320 to 360 yards broad at low water, and is principally celebrated for its splendid naval hospital, and for the Royal Observatory. The kings of England had a royal residence at Greenwich since the reign of Edward I. A.D. 1300. After the restoration of Charles I. when the buildings had fallen almost

Greenwich. into ruin, this monarch ordered them to be taken down, and a magnificent palace of freestone to be erected on the spot, from the designs of Webb, the son-in-law of Inigo Jones. Only one wing of this edifice was completed at the expence of £36,000. Charles occasionally resided in it; but it was not till the reign of William III. that any farther progress was made in the building. The government having resolved, on the suggestion of the queen, to provide an asylum for old and disabled seamen, Sir Christopher Wren recommended that the unfinished palace should be devoted to this purpose. A grant of the palace and adjoining lands was made in 1699 to commissioners. The foundation stone was laid on the 3d June 1696, and was gradually enlarged and improved till it reached its present state of splendour and magnificence.

The following account of Greenwich Hospital has been abridged from a very full and excellent description of it in the *Beauties of England and Wales*.

Greenwich Hospital. Greenwich Hospital is principally built with Portland stone, and consists of four distinct quadrangular masses of buildings, distinguished by the names of the respective sovereigns, in whose reigns they were founded or built. The grand front opens on a terrace, skirting the southern bank of the Thames, and extends 865 feet in length, in the centre of which is a descent to the river, by a double flight of steps. The ground plan of the whole edifice forms nearly a square, of which King Charles's building occupies the north-west angle; Queen Anne's, the north-east; King William's, the south-west; and Queen Mary's, the south-east. The interval between the two former buildings forms a square 270 feet wide, in the middle of which is a statue of George II. sculptured by Rysbrach, out of a single block of white marble, which weighed 11 tons, and was taken from the French by Admiral Rooke: this statue was given to the hospital by Sir John Jennings, who was governor from 1720 to 1744. The inscriptions on the pedestal were by Mr Haugan. The space between the two latter buildings which include the hall and chapel, with their elegant domes, and the two colonnades, forms a lesser square. The two squares are intersected by a spacious avenue, leading from the town through the hospital. The buildings which immediately front the Thames have a general correspondence in style and arrangement. The north and south fronts of each exhibit the appearance of a double pavilion, conjoined above by the continuation of an Attic order, with a balustrade, which surmounts the whole, but is separated below by an open portal. The centre of each pavilion displays an elegant pediment, supported by four Corinthian columns, and the sides a double pilaster of the same order. King Charles's building contains the apartments of the governor and lieutenant-governor, the council-room, and anti-chamber; with 14 wards, wherein 300 pensioners may be accommodated. In the council-room are several portraits: in the anti-chamber two large sea-pieces, given to the hospital by Philip Harman, Esq.; and a series of six small pieces, representing the loss of the Luxemburgh galley, in 1727. Queen Anne's building, which was erected between 1698 and 1728, contains several apartments for inferior officers, with 24 wards for 437 pensioners. King William's building stands to the south-west of the great square, and comprises the great hall, vestibule, and dome, designed and erected by Sir Christopher Wren, between the years 1698 and 1703. To the inner side of each range is attached a colonnade 347 feet in length, supported by Doric columns, and pilasters 20 feet in height. The great hall, or saloon, is 106 feet in length, 56 in width, and 50 high: the ceiling and sides are covered with portraits and emblematical figures, executed by Sir James Thornhill, for which he was paid at the rate of L.3 per square yard for the ceiling, and L.1 for the sides, amounting in the whole to L.6685. The west front of King William's building, which is of brick, was finished about 1725 by Sir John Vanbrugh: the building contains 11 wards, wherein are 551 beds. The foundation of the eastern colonnade, which is similar to that on the west side, was laid in 1699; but the chapel, and the other parts of Queen Mary's building which adjoin to it, were not finished till 1752. It corresponds with King William's, and is furnished with 1092 beds, in 13 wards. The chapel which forms part of Queen Mary's building, is one of the most elegant specimens of Grecian architecture in this kingdom, and was erected from the classical designs of the late James Stuart, Esq. It is 111 feet in length, and 52 in width, and is capable of accommodating 1000 pensioners, nurses, and boys, exclusive of the seats for the directors and other officers. The entrance portal consists of an architrave, frieze, and cornice, of statuary marble: the folding-doors are of mahogany, highly enriched by carving. The interior is finished in an elegant style, and is adorned with many appropriate paintings, the most distinguished of which is the altar-piece, executed by West, and representing the preservation of St Paul on the island of Melita. There is a double range of windows on each side of the chapel. Without the walls of the hospital stands the infirmary, erected in 1763, after a design by Stuart: it forms an oblong quadrangle, 198 feet long and 175 broad, consists of two stories, and is divided into two principal parts, appropriated respectively to those whose cases require surgical aid, and to those who need only medical assistance. It contains sixty-four rooms, and each is fitted up for the accommodation of four patients. It also includes a chapel, hall, kitchen, and apartments for the physician, surgeon, and apothecary; with hot and cold baths, and other necessary offices. Near the hospital is the school, where 200 poor children are educated. The school-house was erected in 1783, by Stuart. It is 146 feet long, 42 broad, exclusive of a Tuscan colonnade in front 180 feet long, and 20 broad, for the boys to play in during bad weather. The pensioners, who are the objects of this noble charity, must be seamen disabled by age, or maimed, either in the king's service, or in the merchant service, if the wounds were received in defending or taking any ship, or in fight against a pirate. Foreigners who have served two years in the British navy, become entitled to the benefits of this institution in the same manner as natives. The widows of seamen are provided for, having the exclusive privilege of being nurses in the hospital. The number of pensioners is upwards of 2400, (of whom at an average 203 die annually,) who are furnished with clothes, diet, and lodging, with a small allowance of pocket-money. The nurses are 144, each of whom receives eight pounds per annum as wages, with every necessary of life. The commissioners of the hospital are about 100, and consist of all the great officers of state, the archbishops, the lord chancellor, the judges, the master and five senior brethren of Trinity-house, the lord mayor, and three senior aldermen of London, with some of the principal officers of the hospital. The annual average expence of each pen-

Greenwich.

sioner, according to the report of the commissioners of naval enquiry, was estimated at L.27 : 10 : 9 per man; and of the nurses, L.29, 15s. each, the total annual expence being L. 69,206, 5s. The funds of the establishment are principally derived from a duty of sixpence per month, paid by every mariner, either in the king's or merchant's service; the forfeited estates of the Earl of Derwentwater, containing many valuable lead and other mines; various benefactions from different sovereigns, from parliament, and from private persons, from fines for offences committed on the Thames, from the half-pay of such of its officers as have regular salaries, and from other sources of less importance.

Greenwich park.

Greenwich park, which is vested in the crown, was encircled with a wall by James I. and contains 188 acres. It is planted chiefly with elms and Spanish chesnuts, some of which are of a very large size. In one part of the park are the remains of many ancient barrows, in some of which were found human bones, spear heads, &c. The upper part of the park is considerably elevated above the Thames; and on one of the eminences stands the Royal Observatory, which was built by Charles II. in 1675, on the site of the ancient tower erected by Duke Humphrey in the reign of Henry VI. It is built of brick, and is by no means an elegant structure; but it contains excellent apartments for the Astronomer Royal, and commodious rooms for the admirable instruments, with which it is now furnished. Flamstead, the first Astronomer Royal, died in December 1719, and was succeeded by Dr Halley. Dr Bradley succeeded upon the death of Halley in 1742, and died in 1762. Dr Bliss held the office for two years, and was succeeded in 1764 by Dr Maskelyne. Mr Pond, the present Astronomer Royal, suceeded Dr Maskelyne in 1811, and, by means of the fine mural circle constructed by Troughton, has already made a series of the most valuable observations, decidedly the most accurate that have been made in any of the other observatories of Europe.

Royal observatory.

A farther account of the institution, and of the instruments it contains, will be found in our history of ASTRONOMY, and in the articles CIRCLE and OBSERVATORY.

The church of Greenwich is an elegant stone building, and was erected in 1718. Greenwich contains two hospitals for poor people, and several schools for the education of the poor, and some excellent boarding schools.

The following is the population abstract for 1811, for the town of Greenwich:

Number of houses	2,315
Number of families	3,276
Ditto employed in agriculture	96
Ditto in trade and manufactures	1,002
Males	8,723
Females	8,224
Total population	16,947

Gregorian || Gregory James

GREGORIAN CALENDAR. See CHRONOLOGY.

GREGORIAN TELESCOPE. See OPTICS.

GREGORY, ST VINCENT. See GEOMETRY.

GREGORY, JAMES, an eminent Scotch mathematician and natural philosopher, was born at Aberdeen in the month of November 1638. He was a son of the Rev. Mr John Gregory of Drumoak, in Aberdeenshire,* who was married to the daughter of Mr David Anderson of Finshaugh, the brother of Alexander Anderson, who was professor of mathematics at Paris: (See ANDERSON). Having lost his father in the 13th year of his age, the charge of his education devolved upon his elder brother David Gregory, who put into his hand the Elements of Euclid, and stimulated the ardour which he had begun to show for mathematical learning. After having completed his philosophical studies at the Marischal College of Aberdeen, James Gregory directed his particular attention to the subject of optics, and he published the results of his labours in a work entitled

* The following quotations, relative to the Rev. John Gregory of Drumoak, are taken from Spalding's *History of the Troubles in Scotland*, from 1624 to 1645:

"Upon the second day of June 1640, Mr John Gregory, minister at Drumoak, was brought into Monro by a party of soldiers: He was taken out of his naked bed upon the night, and his house pitifully plundered. He was closely keeped in Skipper Anderson's house, having five musketeers watching him night and day, and sustained upon his own expences. No not his own wife could have private conference with him, so strictly was he there watched. At last he is fined to pay Major-General Monro 1100 merks, for his outstanding against the covenant, and syne got liberty to go; but in the General Assembly holden in July, he was nevertheless simpliciter deprived, because he would not subscribe the covenant; and when all was done, he is forced to come in and yield to subscribe the covenant.

"Next, Mr John Gregory having been summoned to appear before the General Assembly (1640), by and attour his being fined in 1000 merks, as ye have before, was deposed from the ministry of Drumoak. The Laird of Drum deals for him, being his own pastor, and upon swearing and subscribing the covenant, and teaching penitentially, with great difficulty he was again restored (1641) to his own parish kirk.

"Upon Thursday, the 15th of April 1641, being a presbytery day, Mr John Gregory, of whom ye heard before, teached a penitential sermon in New Aberdeen. It was not found satisfactory by Mr James Hervie, Moderator, and the remanent members of the Presbytery, and he was ordained to put the same in write. The brethren advised the same with the next Provincial Assembly, who found it not satisfactory, and therefore they ordained him to preach penitentially at certain kirks, till he gave content to the next ensuing General Assembly; which he obeyed. He was received and reinstated in his kirk (1641).

"Upon Tuesday, the 6th of September 1642, Mr John Gregory, at the visitation of the kirk of New Aberdeen, teached most learnedly upon the fourth verse of the second chapter of the Colossians, and reprehended the order of our kirk, and new brought in points. Mr Andrew Cant, sitting beside the reader, as his use was, offended at this doctrine, quickly closed the reader's book, and laid down the glass before it was run, thinking the minister should the sooner make an end; but he beheld and preached half an hour longer than the time. Sermon being ended, the brethren conveen to their visitation, where Mr Andrew Cant impugned this doctrine, desiring the said Mr John to put the same in write. He answered, he would not only write, but print his preaching, if need so required, and abide by all that he had teached as orthodox doctrine. The brethren heard all, and had their own opinions, but without any more censure they dissolved, somewhat peturbed with Cant's curiosity.

"Upon Thursday he railed out in his sermon against the said Mr John Gregory's doctrine, and on Sunday likewise. At last, by mediation of the town's baillies, at a cup of wine, they two were agreed, and settled, with small credit to Cant's business."

Mr Gregory of Drumoak was one of the first persons in Scotland who understood the use of the barometer as an instrument for predicting the weather. Having one day observed that the mercury was falling rapidly, he advised his parishioners to remove the sheaves of corn from the low grounds on the banks of the river Dee. They immediately followed his advice, and when they found his prediction verified by an unusual rise of the river, they were naturally led to regard him as a being of a superior order. Mr Gregory died about the year 1652.

Optica promota seu abdita radiorum reflexorum et refractorum mysteria, geometrice enucleata, cui subnectitur Appendix subtilissimorum astronomiæ problematum resolutionem exhibens, Lond. 1663. It was dedicated to Charles II. and was completed with the assistance and encouragement of his brother David, after he had been stopped a long time at the twenty-sixth problem.* This work is remarkable, as containing the description of a new reflecting telescope, and the deduction of the true law of refraction. The method in which he has investigated this law, is remarkable for its elegance and originality; and, in his experimental demonstration of it, we are furnished with a striking proof of the accuracy of his observations. In comparing the refractions calculated by the law, with the experiments of Vitellio on the refractions of water and glass, the greatest error amounts to 61′ in water, and 94′ in refractions from glass into water. When compared with the experiments of Athanasius Kircher, the greatest error in water is 89′, in wine 110′, in oil 104′, and in glass 93′; but in comparing them with his own observations, the greatest error is only 15′; and it is remarkable, that he made the index of refraction for water 1.3347, differing only 0.0018 from 1.3358 the most accurate measure, whereas Vitellio made it 1.306. Before the publication of the *Optica Promota*, Gregory was informed, that he was anticipated in the discovery of the law of refraction by Descartes, and he thus alludes to it in his preface:—*Et ex analogiis in prima hujus tractatuli propositione declaratis, inveni primam hujus opticæ partem, de genuina refractionum hypothesi et mensura nescius scilicet (propter inopiam novorum librorum Mathematicorum in alias inclyta Bibliotheca Abredonensi) hæc eadem a Cartesio fuisse inventa.*

The invention of the reflecting telescope formed an epoch in optics and astronomy. Gregory was not acquainted with the errors in dioptric instruments, arising from the unequal refrangibility of the rays of light; and his principal object in proposing this new instrument, was to avoid the error arising from the spherical figure of the lenses. It consisted of a parabolic concave mirror, near whose focus is placed a small concave elliptic speculum, having a common focus with the parabolic one. This instrument gave rise to the Newtonian telescope, in which the small mirror is plane, and reflects the image to the side of the tube where the eye-glass is placed; and also to the Cassegrainian telescope, which differs only from that of Gregory, in having the small speculum convex instead of concave. The Gregorian principle has been almost universally used for telescopes of a moderate size. The Newtonian form has been adopted in the magnificent instruments used by Dr Herschel; but it is extremely probable, that the Cassegrainian telescope, in which the rays never cross each other at a focus, † will hereafter be considered as the most valuable of the reflecting telescopes. The *Optica Promota* is terminated by a collection of astronomical problems. The object of one of these, is to determine the parallaxes of two planets from their conjunction; and, in a scholium to this problem, he points out the great use of the transits of Venus and Mercury, in determining the sun's parallax. ‡ This happy idea, which has since been of such service to astronomy, has always been ascribed to Dr Halley.

Mr Gregory went to London about the year 1664 or 1665, and was introduced to Mr Collins, the secretary to the Royal Society, who introduced him to some of the best practical opticians, for the purpose of having his reflecting telescope executed. A Mr Rives was employed for this purpose, but he could not polish the speculum upon the tool, and was therefore obliged to do it with a cloth and putty. The success of this trial was so little, that Gregory was discouraged from making any farther attempts, and a tube was never even made to hold the mirrors. He afterwards, however, made some trials with a little concave and convex speculum; but, to use his own words, "they wer but rude, seeing I had but transient views of the object; being so possessed with the fancie of the defective figure, that I wold not be at the pains to fix every thing in its due distance."

After these unsuccessful attempts to construct a reflecting telescope, Gregory left England, and fixed his residence at Padua, which was then in high repute as a seat of mathematical learning. Here he published, in 1667, 1668, his work, entitled, *Vera Circuli et Hyperbolæ Quadratura in propria sua proportionis specie inventa, et demonstrata*, which contains his discovery of an infinitely converging series for the areas of the circle, ellipsis, and hyperbola. A copy of this work was laid before the Royal Society by his friend Mr Collins, and was honoured with the approbation of Lord Brouncker and Mr Wallis. In the following year he reprinted it at Venice, and added a new work, entitled, *Geometricæ pars universalis quantitatum curvarum transmutationi et mensuræ, inserviens*, which contains a new method for the transmutation of curves. This work had previously appeared at Padua in 1668; and, upon its arrival in England, was read by Mr Collins to the Royal Society.

In the year 1670, Mr Gregory received, in a letter from Mr Collins, a series for the area of the zone of a circle, and being informed that Newton had invented an universal method by which he could square all curves geometrical and mechanical by infinite series of that kind, Gregory applied himself to the investigation of the subject, and discovered an universal method of series, which he communicated to Newton, and the other English mathematicians, by a letter to Collins, dated February 1671. His brother David urged him to publish this method without delay; but he declined this from the most honourable motives; for Newton having been the first inventor, he thought himself bound to wait till his method should be published.

Upon Mr Gregory's return to London, we believe in-

* "Ubi diu hæsi omni spe progrediendi orbatus; sed continuis hortatibus et auxiliis fratris mei Davidis Gregorii in mathematicis non parum versati (cui siquid in hisce scientiis prestitero, me illud debere non inficias ibo) animatus tandem incidi in seriam imaginis considerationem, &c." *Pref. ad Optic. Promot.*

† The effect of the collision of the rays in the focus was first noticed by Dr Brewster, in the most perfect achromatic telescopes: (See *Treatise on New Philosophical Instruments*, p. 44 and 193.) It was afterwards observed in reflecting telescopes by Mr Kater, who has examined the subject with much attention and success: (See *Phil. Trans.* 1813, 1814.) We have found from experiment, that the heat of a burning lens, as well as the light, is more intense within than without the focus, and that radiant heat is also most intense within the focus. Mr Leslie had long before obtained the same result with regard to radiant heat. It is therefore certain, that this diminution of effect must arise from the collision of the luminous as well as of the calorific rays. We may therefore lay it down as a principle in the construction of optical instruments, that the rays should, if possible, never be brought to a positive focus.

‡ "Hoc Problema pulcherrimum habet usum, sed forsan laboriosum in observationibus Veneris vel Mercurii particulam solis obscurantis: ex talibus enim solis parallaxis investigari poterit." *Optic. Promot.* schol. prop. 87.

1668, he was elected a fellow of the Royal Society, and laid before them an account of a dispute in Italy relative to the Earth's motion, which Riccioli and his followers had denied. About this time also he engaged in a dispute with the celebrated Huygens through the medium of the *Philosophical Transactions.* Huygens published in the *Journal des Sçavans,* July 2d 1668, some animadversions on Gregory's quadrature of the circle, and particularly objected to the proposition which stated, the impossibility of expressing perfectly the area of a circle in any known algebraical form besides that of an infinite converging series. Gregory defended himself in the 37th Number of the *Philosophical Transactions,* and the dispute was carried on with considerable warmth by both parties. The whole of the controversy will be found in Huygens' *Opera Varia,* vol. ii. p. 463.

In 1668, Gregory published in London his *Exercitationes Geometricæ,* a small work of twenty-six pages, which contains the following subjects:

Appendicula ad verum Circuli et Hyperbolæ Quadraturam.

N. Mercatoris Quadratura Hyperbolæ Geometrice demonstrata.

Analogia inter Lineam Meridianam Planispherii Nautici et Tangentes Artificales Geometrice demonstrata; seu quod secantium Naturalium additio efficiat Tangentes Artificiales.

Item, Quod Tangentium Naturalium additio efficit Secantes Artificiales.

Quadratura Conchoidis.

Quadratura Cissoidis.

Methodus Facilis et Accurata componendi Secantes et Tangentes Artificiales.

The preface to this work, and the introduction to the *Appendicula,* &c. are remarkably interesting, in so far as they throw considerable light on the dispositions of our author. He speaks with great severity of the jealousy and injustice of his contemporaries, and alludes to the treatment which he had received from Huygens. In the introduction to the *Appendicula,* he resumes this subject with more keenness. He declares, that Huygens had accused him of ignorance and plagiarism; and after arguing against Huygens' claim to the discovery, he concludes with this remarkable passage: "At parum refert quis sit ejus primus inventor, satis enim constat me primum esse publicatorem; neque mihi esset difficile affirmare (si modo mentiri vellem) me ante 20 annos illam cognovisse: utcunque sit, conabor hic circuli et hyperbolæ quadraturam ad talem perfectionem promovere, ut Hugenius prolem suam vix cognoscat."

Mr Gregory was about this time elected professor of mathematics in the university of St Andrew's. In 1669, he married the daughter of George Jamieson, the celebrated Scottish painter, by whom he had a son, James, the father of Dr John Gregory, (the subject of a succeeding article,) and two daughters. In August 1672, he began a correspondence with his friend Mr Collins, relative to the comparative merits of his own telescope, and that of Sir Isaac Newton. The sentiments of the two philosophers were communicated to each other by their respective friends, and the dispute was thus carried on in the most amicable manner. The correspondence has been published by Dr Desaguliers, at the end of his edition of Dr David Gregory's Catoptrics, and Dioptrics.

In the year 1669, a work was published at Rotterdam, by Mr George Sinclair, professor of philosophy in the university of Glasgow, entitled *Ars nova et Magna Gravitatis et Levitatis*; and another work on hydrostatics, by the same author, appeared at Edinburgh in 1672. Mr Sinclair had been dismissed from his professorship soon after the restoration, on account of his political principles, and had given offence to the Royal Society of London, by charging them with negligence and injustice. He appears also to have acted improperly towards one of Mr Gregory's colleagues, and thus to have incurred the displeasure of that mathematician. In the year 1672, Gregory, under the assumed name of Patrick Mathers, archbedal to the university of St Andrew's, attacked Sinclair in a tract, entitled *The great and new art of weighing Vanity, or a discovery of the Ignorance and Arrogance of the great and new Artist, in his Pseudo-philosophical writings.* To this work is annexed *Tentamina de motu penduli et projectorum.*

In 1674, Gregory was called to the mathematical chair in the university of Edinburgh, a situation which he did not live long to enjoy. In the month of October 1675, when he was walking home from supper, he was struck suddenly blind, and expired a few days afterwards, in the 36th year of his age.

The following is a list of the inventions and discoveries of James Gregory, as given by Dr Hutton. The reflecting telescope; burning mirror;* quadrature of the circle, ellipse, and hyperbola; method for the transmutation of curves; geometrical demonstration of Lord Brouncker's series for squaring the hyperbola; demonstration that the meridian line is analogous to a scale of logarithmic tangents, of the half complements of the latitude; a simple converging series for making logarithms; solution of the famous Keplerian problem, by an infinite series; method of drawing tangents to curves geometrically, without previous calculation; a rule for the direct and inverse method of tangents, depending on the principle of exhaustions; a series for the length of the arc of a circle from the tangent, and *vice versa,* and also for the secant and logarithmic tangent, and secant and *vice versa*; and serieses for the length of the elliptic and hyperbolic curves. See Hutton's *Mathematical Dictionary,* 2d edition, p. 601, &c. and the other works quoted in the article.

GREGORY, David, Dr, a celebrated astronomer and mathematician, was the nephew of the subject of the preceding article, and the eldest son of David Gregory of Kinnairdie. He was born at Aberdeen in the year 1661, and after receiving his education at the grammar school of that town, he went to Edinburgh for the purpose of completing his studies. In 1684, when he was only 23 years of age, he was appointed professor of mathematics in the university of Edinburgh, and in the same year he published his work, entitled, *Exercitatio Geometrica de Dimensione Figurarum sive specimen methodi generalis Dimetiendi quasvis figuras.* Mr Gregory having found among his uncle's papers particular examples of infinite series, without any of the methods, proposes in this treatise to explain a method which may suit the examples given by his uncle; and he does this by applying the principles of indivisibles, and the arithmetic of infinites, to particular cases in hyperbolas, parabolas, ellipses, spirals, cycloids, conchoids, and cissoids. He also explains several methods of reducing compound quantities into infinite series, so that

* See our article Burning Instruments, vol. v. p. 131.

the method of infinites may be conveniently applied to them.

Dr Gregory seems to have been one of the earliest supporters of the Newtonian philosophy in Britain; and while the doctrines of Descartes were in the highest esteem at Cambridge, the true system of the universe was publicly taught in the university of Edinburgh.

In consequence of a report that Dr Bernard proposed to resign the Savilian professorship of astronomy at Oxford, Gregory went to London in 1691, and, in spite of the brilliant talents of his competitor Dr Halley, he was appointed to succeed Dr Bernard, through the friendship and influence of Sir Isaac Newton and Mr Flamstead. Halley, who lost this appointment in consequence of his attachment to infidelity, became afterwards the colleague of Dr Gregory, when, in 1703, he succeeded to Dr Wallis as Savilian professor of geometry. During Mr Gregory's residence in London, he was elected a fellow of the Royal Society, and before his appointment to the mathematical chair, the university of Oxford had conferred upon him the degree of doctor of physic.

In the year 1692, Viviani, one of the disciples of Galileo, had proposed to mathematicians the Florentine problem of the quadrable dome. Leibnitz and Bernoulli had resolved this problem on the very day on which they had received it, and the Marquis L'Hospital had also given a solution. Dr Wallis and Dr Gregory were equally successful, and the latter published his solution in the *Philosophical Transactions* for 1693, under the title of *Solution of the Florentine Problem, concerning the Testudo veliformis Quadrabilis.* In 1694, he published another paper in the *Transactions*, containing a vindication of his uncle from a charge preferred by the Abbot Galloise, * that James Gregory and Dr Barrow had stolen from Roberval their general propositions concerning the transformation of curves. Galloise replied in the *Memoirs of the Academy* for 1703; and Dr Gregory put an end to the controversy by a very sharp answer, which appeared in the *Philosophical Transactions* for 1716, and which was the last of his communications to that learned body.

In 1695, Mr Gregory published at Oxford his *Catoptricæ et Dioptricæ Sphericæ Elementa*, a work which formed the substance of lectures which he delivered in 1684, in the university of Edinburgh, and which require no higher mathematical knowledge than the elements of Euclid. This work was republished and translated by Dr William Browne, with several important additions; and a third edition of it by Dr Desaguliers, appeared in 1735. In this work it is stated, that in the construction of telescopes, "it would perhaps be of service to make the object lens of a different medium, as we see done in the fabric of the eye, where the crystalline humour (whose powers of refracting the rays of light differs very little from that of glass) is by nature, who never does any thing in vain, joined with the aqueous and vitreous humours, (not differing from water as to their power of refraction,) in order that the image may be painted as distinct as possible on the bottom of the eye." We cannot agree with the biographers of Dr Gregory, in considering this suggestion as any thing like an anticipation of the principle of the achromatic telescope; for it was impossible to form an idea of the construction of that instrument, till it was discovered that bodies possess different dispersive powers. This remarkable property of light, even the penetrating mind of Newton failed to discover; and we must not allow ourselves to diminish the well-earned reputation of Dollond, by giving to another any portion of the praise which is so exclusively due to himself. In the year 1747, more than 50 years after this conjecture of Dr David Gregory was published, the celebrated Euler suggested the human eye as the model of an achromatic telescope, and several ignorant foreigners have ventured to claim a share of Dollond's merit for this illustrious mathematician. Whatever credit therefore may be given to Euler, must now be claimed for our countryman David Gregory.

In the year 1697, our author published, in the *Phil. Transactions*, a long paper *On the properties of the catenaria or curve line, formed by a heavy and flexible chain, hanging freely from two points of suspension.* The leading properties contained in this communication, had been previously discovered and published by Huygens, Leibnitz, and Bernoulli, but without demonstrations; and Mr Gregory proposed to himself to demonstrate these properties. An anonymous writer in the Leipsic Acts for February 1691, attacked this paper as destitute of originality. Dr Gregory replied to this attack in the *Phil. Trans.* for 1699, and claimed as his own discovery the property of the catenaria as being the true geometrical figure of an equilibrated arch. This discovery, however, had been previously made by Dr Hooke. †

The greatest of Dr Gregory's works, and that on which his fame must rest, appeared at Oxford in 1702, entitled *Astronomiæ Physicæ et Geometricæ Elementa*, Fol. In this valuable work, all the physical explanations are founded on the principles of the Newtonian philosophy; and the geometrical parts are either proved by reference to the writings of standard authors, or demonstrated by lemmas inserted in their proper places. A very admirable analysis of this work was given, apparently by Dr Halley, in the *Phil. Trans.* for 1703. Newton himself considered these elements as an excellent defence and exposition of his philosophy.

This work was followed, in 1703, with an edition of Euclid, entitled *Euclidis quæ supersunt omnia, Gr. et Lat. ex recensione Davidis Gregorii*, M. D. &c. It was published in prosecution of a plan of Sir Henry Saville to print the works of the ancient mathematicians. It contains the Elements; the Data; two musical tracts; the Optics and Catoptrics; the tract *De Divisionibus*; and a fragment, *De Levi et Ponderoso.*

In the year 1704, Dr Gregory published, in the *Philosophical Transactions*, a paper on *Cassini's Orbit of the Planets*, in which he shewed that the hypothetical curve proposed by that astronomer, is not consistent with the received doctrines of astronomy.

After Dr Halley had been appointed to the Savilian professorship of Geometry in 1703, he embarked with Dr Gregory in the prosecution of Sir Henry Saville's plan, and had begun the publication of the Conics of Apollonius; but after having proceeded a short way in this undertaking, he was seized with an illness of which he died, at Maidenhead in Berkshire, on the 10th of October 1710, in the 49th year of his age.

He left behind him four sons by his wife Elizabeth,

† See Robison's *System of Mechanical Philosophy*, Vol. I.

daughter of Mr Oliphant of Langtown, to whom he was married in 1695. Among his manuscripts were found *A Short Treatise of the Nature and Arithmetic of Logarithms*, which was afterwards published in Dr Keill's translation of Commandine's Euclid; a *Treatise of Practical Geometry*, which was translated and published by Mr Maclaurin in 1745; and a commentary on the *Principia*, which Newton kept by him many years after the author's death. Sir Isaac had entrusted Gregory with a manuscript copy of the *Principia* for this purpose, and he availed himself of the annotations of his friend in the second edition of that immortal work. A complete copy of these observations was presented, by the present Dr James Gregory, to the library of the University of Edinburgh, where it is carefully preserved. There are some paragraphs in this manuscript in the handwriting of Huygens, concerning his theory of light.

His wife, who survived him, erected an elegant monument to his memory in the church of St Mary, Oxford, with the following inscription:—

P. M.
Davidis Gregorii, M. D.
Qui Aberdoniæ natus, Jun. 24, 1661,
In Academia Edinburgensi
Matheseos prælector publicus,
Deinde Oxonii
Astronomiæ Professor Savillianus,
Obiit Oct. 10. A. D. 1710;
Ætatem illi heu brevem Natura concessit,
Sibi ipsi longam prorogavit
Scriptor illustris.
Desideratissimo viro
Elizabetha Uxor.

David Gregory, of Kinnairdie, the brother of the celebrated James Gregory, was born in 1627, and served an apprenticeship to a mercantile house in Holland; but having a great passion for knowledge, he returned to Scotland in 1655, when he was 28 years old, and having succeeded to the estate of Kinnairdie, by the death of an elder brother, he devoted his time to mathematics and philosophy. He appears to have been the first person in the country who had a barometer, and he had the honour of corresponding, upon meteorological subjects, with the celebrated Mariotte. "About the beginning of the last century," says Dr Reid, "he removed with his family to Aberdeen, and, in the time of Queen Anne's war, employed his thoughts upon an improvement in artillery, in order to make the shot of great guns destructive to the enemy, and executed a model of the engine he had conceived. After making some experiments with this model which satisfied him, the old gentleman was so sanguine in the hope of being useful to the allies in the war against France, that he set about preparing a field equipage with a view to make a campaign in Flanders, and in the mean time sent his model to his son, the Savilian Professor, that he might have his and Sir Isaac Newton's opinion of it. His son shewed it to Newton, without letting him know that his own father was the inventor. Sir Isaac was much displeased with it, saying, that if it tended as much to the preservation of mankind as to their destruction, the inventor would have deserved a great reward; but as it was contrived solely for destruction, and would soon be known by the enemy, he rather deserved to be punished, and urged the professor very strongly to destroy it, and if possible to suppress the invention. It is probable the professor followed this advice; for at his death, which happened soon after, the model was not to be found.

When the rebellion broke out in 1715, the old gentleman went over a second time to Holland, and returned when it was over to Aberdeen, where he died, about 1720, in the 93d year of his age. He left behind him a historical manuscript of the transactions of his own time and country."

Mr Gregory had twenty-nine children by two wives, and he had the good fortune to see three of his sons professors of mathematics at the same time, viz. David Gregory at Oxford, James at Edinburgh, and Charles at St Andrews. James was first a professor of philosophy at St Andrews, and succeeded David when he removed to Oxford. Charles was created professor of mathematics at St Andrews in 1707, and in 1739 he resigned that office in favour of his son Professor David Gregory, who died in 1763, and left behind him a good compendium of arithmetic and algebra, with the title, *Arithmeticæ et Algebræ compendium, in usum Juventutis Academicæ*, Edin. 1736. His son David was master of an East India ship. David Gregory, the eldest son of the Savilian professor, was appointed Regius Professor of Modern History, at Oxford, and died in 1767, after having filled, for many years, the situation of dean of Christ's church. The celebrated James Gregory, the inventor of the reflecting telescope, had only one son, James, born in 1674, who was professor of medicine in King's College, Aberdeen. His youngest son was Dr John Gregory (the subject of the next article), and the father of the present Dr James Gregory, professor of the practice of medicine in the university of Edinburgh.

GREGORY, John, Dr, an eminent physician, was born at Aberdeen on the 3d of June 1724, and was the youngest child of Dr James Gregory, professor of medicine in King's College, Aberdeen, by his second wife, Anne Chalmers, the only daughter of the Rev. Principal Chalmers of King's College.

In consequence of the death of his father when he was only seven years old, the charge of his education devolved upon Principal Chalmers, his elder brother Dr James Gregory, who had succeeded his father as professor of medicine, and his cousin the late celebrated Dr Reid. After receiving the first rudiments of his education at the grammar school of Aberdeen, he entered King's College, and made rapid progress in the knowledge of ethics, mathematics, and natural philosophy.

In 1742, he went to Edinburgh, accompanied by his mother; and having resolved to pursue the study of medicine, he attended the different medical lectures, and became a member of the Medical Society, at a time when his friend, the celebrated Dr Akenside, was a member of the same institution. In the year 1745, Mr Gregory went to Leyden, to complete his professional studies, under the care of Albinus, Gaubius, and Van Royen, who were at that time the ornaments of the university. Here he became acquainted with the famous John Wilkes and the Hon. Charles Townshend, two of the greatest wits of the age; and before he left this university, he received from King's College, Aberdeen, an unsolicited degree of doctor of medicine. Upon his return from Holland, he was chosen professor of philosophy in the same college; and during the years 1747, 1748, and 1749, he read lectures in mathematics, experimental philosophy, and moral philosophy.

Having resolved, however, to establish himself as a physician at Aberdeen, he resigned his professorship in the end of 1749, and went for a few months to the continent.

After he returned to Scotland, he married, in 1752, Elizabeth, daughter of William Lord Forbes, who brought him a handsome addition to his fortune. This accomplished and amiable woman, who possessed the rare combination of great beauty and great intelligence, lived only nine years after her marriage, and left her husband and six children to lament their premature loss.

Perceiving little prospect of succeeding in Aberdeen to the full extent of his wishes, Dr Gregory resolved to settle in London, where he arrived in 1754. He was chosen a Fellow of the Royal Society in the same year; and, from the influence and attachment of his friends, as well as from his own professional talents, he had the best prospects of an extensive practice. The death of his elder brother, however, occasioned a vacancy in the professorship of physic in King's College, Aberdeen; and being solicited to accept of this situation, he returned to his native country in 1756, and began to discharge the duties of his new office.

Among the eminent young men who at that time adorned the university, were Reid, Campbell, Beattie, Gerard, John Stewart, professor of mathematics in Marischal College, and David Skene, a correspondent of the celebrated Linnæus. These young men established a literary society or club, which met weekly at a tavern. A short essay was read by each member in rotation, and a literary or philosophical question was proposed every night as a subject of discussion at the following meeting. The proposer of the question was obliged not only to open the discussion, but to digest the opinions of the different members in the form of an essay, which was engrossed in the album of the society. Several of those composed by Dr Gregory on philosophical, moral, and political questions, still exist, and contain some of his favourite opinions. Some of the separate essays which Dr Gregory contributed were afterwards corrected, and published in 1765, under the title of *A Comparative View of the State and Faculties of Man with those of the Animal World*. It was considerably enlarged by the author in a second edition, and has passed through other editions since his death.

About the end of the year 1764, Dr Gregory removed from Aberdeen to Edinburgh. In 1766, he was appointed professor of the practice of physic, on the resignation of Dr Rutherford; and in the same year, he succeeded Dr Whytt as first physician to his Majesty for Scotland. His lectures on the practice of physic were delivered in the years 1767, 1768, and 1769; but, in consequence of an arrangement with Dr Cullen, professor of the theory of physic, these celebrated individuals gave alternate courses of the theory and practice of medicine. The lectures of Dr Gregory were never committed to writing. Having made himself fully master of his subject by previous meditation, he required no other aid than a few notes containing the heads of his lecture. The introductory lectures, however, were carefully composed, and related principally to the duties and qualifications of a physician. Many copies of these lectures having been taken by his pupils, one of them was offered for sale to a bookseller. It therefore became necessary to anticipate this fraudulent design, by the publication of a correct copy, which appeared in 1770, and afterwards in a more enlarged and perfect form, in 1772. In the same year, Dr Gregory published *Elements of the Practice of Physic, for the use of Students*, a work intended as a text-book for the use of his pupils. He proposed to embrace all the diseases of which he treated in his lectures; but he did not live to bring the work farther down than to the end of the class of febrile diseases.

After the death of his wife in 1761, Dr Gregory occupied his solitary hours in the composition of a *Father's Legacy to his Daughters*. This admirable work, which every mother should study, and every daughter read, was written under the impression of an early death. It is marked by a deep knowledge of the world and of human character, and abounds with the finest lessons of piety and virtue.

From the eighteenth year of his age, Dr Gregory had been, at irregular intervals, attacked with the gout; a disease which he inherited from his mother, who died suddenly, in 1770, while sitting at table. Dr Gregory anticipated a similar event for himself, and often mentioned this impression to his friends. In January 1773, when conversing with his son, the present Dr Gregory, the latter remarked, that having had no attack for the three preceding years, he might expect a pretty severe fit of it that season. His father was displeased with the prediction, which was unfortunately too correct; for he was found dead on the morning of the 10th of February, although he had gone to bed in his usual health.

"Dr Gregory," says his friend and biographer Mr Tytler, "was in person considerably above the middle size. His frame of body was constructed with symmetry, but not with elegance. His limbs were not active; he stooped somewhat in his gait; and his countenance, from a fulness of feature, and a heaviness of eye, gave no external indication of superior powers of mind or abilities. It was otherwise when engaged in conversation. His features then became animated, and his eye most expressive. He had a warmth of tone and of gesture, which gave a pleasing interest to every thing which he uttered. But, united with this animation, there was in him a gentleness and simplicity of manner, which, with little attention to the exterior and regulated forms of politeness, was more engaging than the most finished address. His conversation flowed with ease; and when in company with literary men, without affecting a display of knowledge, he was liberal of the stores of his mind.

He possessed a large share of the social and benevolent affections, and which, in the exercise of his profession, manifested themselves in many nameless, but important, attentions to those under his care; attentions which, proceeding in him from an extended principle of humanity, were not squared to the circumstances or rank of the patient, but ever bestowed most liberally where they were most requisite. In the care of his pupils, he was not satisfied with a faithful discharge of his public duties. To many of these, strangers in the country, and far removed from all who had a natural interest in their concerns, it was a matter of no small importance to enjoy the acquaintance and countenance of one so universally respected and esteemed."

Dr Gregory left behind him three sons and two daughters, the eldest of whom is Dr James Gregory, professor of the practice of medicine in the university of Edinburgh, who fully inherits the virtues and talents of his ancestors. The works of Dr John Gregory were published at Edinburgh in 1788, in 4 vols. duodecimo, and were enriched with a well written life of the author, by the late Mr Tytler, Lord Woodhouselee, to which we have been indebted for the preceding facts.

GRENADA, the most southerly of the Caribbee islands, in the West Indies, is situated between 12° 20′ Description.

Grenada.

and 11° 58′ North Lat. and between 61° 20′ and 61° 35′ West Long. It is twenty leagues north-west of Tobago, and the same distance from the nearest point of the American continent. It is about twenty-five miles in length, from north to south, and fifteen at its greatest breadth, contracting gradually towards both extremities. A chain of mountains traverse the whole island from north to south, and give rise to a great number of small rivers; and in the highest ground is a circular lake, called Grand Etang, from which several of these streams derive their source. There is a bay on the north-west coast, (which has been recently fortified at great expence,) so capacious and secure, that sixty men of war may ride in it safely almost without casting anchor. The air is salubrious, and the soil fruitful in the productions of the climate.

History.

Grenada was discovered by Columbus in 1498, and was at that time inhabited by a warlike people called Charaibes or Caribbees. The Spaniards do not appear to have made any attempt to form a settlement on the coast, and the natives remained free and undisturbed till the year 1650. At this period, the French governor of Martinico, Du Parquet, landed on the island with 200 adventurers, who seem to have been resolved upon a wanton destruction of the unoffending inhabitants, and an unwarrantable possession of the country; but, being hospitably received by the unsuspecting objects of his unjustifiable attack, they pretended to make a purchase of the island for a few knives and hatchets, a quantity of glass beads, and a barrel of brandy to the chief. Immediately assuming the sovereignty, and having roused the natives to resistance by their tyrannical proceedings, they took measures to extirpate the whole race as lawless rebels. This they are said to have speedily accomplished by a course of atrocious massacres; and a few wretched survivors of their butcheries having thrown themselves headlong from a steep rock, rather than fall into the hands of such merciless enemies, the French settlers, with characteristic levity, gave to the spot the name of *Le Morne des Sauteur*, the Hill of the Leapers. The perpetrators of these enormities soon began to quarrel among themselves, and to suffer, in their turn, the oppressions of tyrannical governors. By a succession of calamities and revolutions, the narration of which would interest few readers, the prosperity of the settlement was so much impaired, that, in the year 1700, more than twenty years after the sovereignty had been vested in the crown of France, there were found on the whole island only 151 white inhabitants, 53 free negroes or mulattoes, 525 slaves, 64 horses, 569 horned cattle, 3 plantations of sugar, and 52 of indigo. Above fourteen years afterwards, however, an active commercial intercourse was opened with the island of Martinique, cultivation was rapidly extended, and, notwithstanding the interruption which these improvements sustained by the war in 1744, Grenada was found, in 1753, to contain 1262 white inhabitants, 175 free negroes, 11,991 slaves, 2298 horses or mules, 2456 horned cattle, 3278 sheep, 902 goats, 331 hogs, 83 sugar plantations, &c.; and in 1762, when it surrendered to the British arms, it is said to have yielded annually, together with its dependencies the Grenadines, a quantity of clayed and muscovado sugar, equal to 11,000 hogsheads of 15 cwt. each, and 27,000 lbs. of indigo. Having been finally ceded to Great Britain by the treaty of peace in 1763, a duty of 4½ per cent. upon all exported produce was ordered to be levied in place of all customs and duties formerly paid to the French king; a measure which gave rise to a great constitutional question, in which, after a long and elaborate law discussion, judgment was given by Lord Mansfield against the crown, and the duty was abolished in Grenada and the other ceded islands. Great commotions and divisions also were excited in the island, respecting the election of Roman Catholic inhabitants as members of assembly. By these party-contentions, the colony continued to be disturbed till its recapture by the French in 1779; and they were again renewed with additional violence, after its restoration to Great Britain in the general pacification which took place in 1783.

Division and tow[ns]

The island of Grenada is divided into six parishes, viz. St George's, St David's, St Andrew's, St Patrick's, St Mark's, and St John's; and, since its restoration to Great Britain in 1783, a Protestant clergy have been established by law. Four clergymen are allotted to the whole, and each is provided with an annual stipend of £330 currency,* £60 for house rent, and a considerable portion of the valuable glebe lands which had formerly been appropriated to the support of the Romish clergy, for whose benefit a part of the amount is still reserved. The capital of Grenada, formerly named Fort Royal, but now St George, is situated close to the spacious bay on the west coast, already described, and is divided by a ridge into two towns; the Bay-town, in which is a handsome square and market-place; and the Carenage-town, where the principal merchants reside. On the ridge, between the two towns, stands the church; and on the promontory above it is an old fort built of stone, and capable of accommodating an entire regiment. The other towns are only villages or hamlets, which are generally situated at the bays or shipping places.

Government.

The governor of the island is also chancellor ordinary and vice-admiral, and his salary is £3200 currency per annum, which is raised by a poll-tax on all slaves. The council consists of twelve members, and the assembly of twenty-six. A freehold or life estate of fifty acres in the country, and of fifty pounds house rent in the capital, qualifies for a representative. An estate of ten acres in fee, or for life, or a rent of ten pounds in any of the country towns, and a rent of twenty pounds out of any freehold or life estate in the capital, gives a vote in the election of the representatives. The law courts, besides those of chancery and ordinary, in which the governor presides, are the court of grand sessions of the peace, held twice a year, in which the person first named in the commission of peace presides; the court of common pleas, in which a professional judge, with a salary of £600, presides; the court of exchequer, lately fallen into disuse; the court of admiralty, and the court of error, composed of the governor and council, for trying appeals. In all cases the common statute law of England is the rule of justice, unless where particular laws of the island interfere.

Popul[ation].

The white population of Grenada has decreased considerably since it came into the possession of the British. In 1771, their number was above 1600; in 1777, they had diminished to 1300; and in 1791, they were not supposed to exceed 1200. Of these about two-thirds are able to bear arms, and are incorporated into five regiments of militia, with a company of free blacks, or mulattoes, attached to each. There are likewise about 500 regulars from Great Britain, for the defence of the island. The negro slaves, also, which, in 1779, were

* The currency of Grenada, or rate of exchange, is commonly £65 per cent. worse than sterling.

Grenada.

stated at 35,000, including those which were in the smaller islands, were found, in 1785, to have decreased to 23,926. The free people of colour amounted, in 1787, to 1115, whose evidence is received in the courts of law, upon proofs of their freedom being produced; and who are allowed to possess lands or tenements to any amount, provided they are not aliens.

State of cultivation and soil.

There are 80,000 acres of land in the island, but only 50,000 were brought into cultivation in 1791. The face of the country is mountainous, but every where accessible, and well provided with rivulets and springs. On the west side, the soil is a rich black mould, lying on a substratum of yellow clay; on the north and east, it is a brick mould; on the south, and in the interior, it is of a reddish hue, and generally poor. In 1776, the exports from the island and its dependencies were 14,012,157 lbs. of muscovado, and 9,273,607 lbs. of clayed sugar; 818,700 gallons of rum; 1,827,166 lbs. of coffee; 457,719 lbs. of cocoa; 91,943 lbs. of cotton; 27,638 lbs. of indigo, and some smaller articles, the whole of which, at a moderate computation, was worth, at the ports of shipping, £600,000 sterling. The sugar was the produce of 106 plantations, worked by 18,293 negroes, which gives rather more than a hogshead of muscovado sugar of 16 cwt. from the labour of each negro,—a return which Mr Edwards affirms, to be unequalled by any other British island in the West Indies, except St Christopher's. In 1787, the exports were 175,518 cwt. of sugar, 670,390 gallons of rum, 8812 cwt. of coffee, 2,062,427 lbs. of cotton, and 2810 lbs. of indigo. In 1810, the value of the exports amounted to £388,936, and of the imports to £173,366.

The following Table shews the Articles imported into Grenada in the Years 1804, 1805, *and* 1806.

Sugar ant.

The sugar plantations in this colony are subject to great ravages, from the carnivorous or sugar ant, an insect which is thought to be common to all the West India islands, but which has been peculiarly destructive in Grenada. It is the *Formica omnivora* of Linnæus, and is described by Sloane as the *Formica fusca minima antennis nis longissimis*. They are of an ordinary size, a slender shape, a dark red colour, remarkable for the quickness of their motions; but are distinguished from every other species, chiefly by the sharp acid taste which they yield when applied to the tongue, and the strong sulphureous smell which they emit when rubbed together between the palms of the hands. Their numbers have often been so immense, as to cover the roads for the space of several miles; and so crowded in many places, that the prints of the horses feet were distinctly marked among them, till filled up by the surrounding multitudes. They were never seen to consume or carry off any vegetable substance whatever, but always laid hold of any dead insect or animal substance that came in their way. Every kind of cold victuals, all species of vermin, particularly rats, live poultry, and even the sores of the Negroes, were exposed to their attacks. But they were chiefly injurious by constructing their nests among the roots of the lime, lemon, orange trees, and sugar canes, and so obstructing their growth, as to render the plants sickly and unproductive. A premium of £20,000 from the public treasury, was offered to the discoverer of any effectual method of destroying them; and the principal means employed were poison and fire. By mixing arsenic and corrosive sublimate with animal substances, myriads were destroyed; and the slightest tasting of the poison rendered them so outrageous as to devour one another.

Grenoble. Lines of red hot charcoal were laid in their way, to which they crowded in such numbers, as to extinguish it with their bodies; and holes full of fire were dug in the cane grounds, which were soon extinguished by heaps of dead. But, while the nests remained undisturbed, new progenies appeared as numerous as ever; and the only effectual check which they received, was from the destructive hurricane of 1780, which, by tearing up altogether, or so loosening the roots where they nestled, as to admit the rain, almost extirpated the whole race, and pointed out the frequent digging up and consuming by fire of those stools and roots in which they take refuge, as the best preventative of their future increase. See Edward's *History of the West Indies*, vol. i.; Abbé Raynal's *History of the Indies*, vol. v.; and Gray's *Letters from Canada*, p. 379. (*q*)

GRENOBLE, a city of France, the capital of the former province of Dauphiny, and, under the late government, the chief town of the arrondissement or district of Grenoble, and of the department of the Isere. This city stands at the confluence of the rivers Drac and Isere, the latter dividing it into two unequal parts; the former, which is crossed by a bridge with a single lofty arch, is liable to overflow its banks, and commit considerable devastation both in the city and its environs. Grenoble is situated at the foot of the Alps, in an agreeable country, abounding in wood and water, but of a climate so variable, that the thermometer sometimes ranges through nearly 30° in a day: the greatest heat is from the 10th of July to the 15th of August, and the greatest cold from the 20th of December to the 20th of January The city stands 900 feet above the level of the sea, and the medium height of the barometer is 27 inches two lines. Nine-tenths of the city are on the left bank of the Isere, constituting the portion chiefly exposed to inundations, several of which have done much damage, and the water has been known to rise three feet deep in the streets.

Grenoble is surrounded by a wall, and is commanded by a citadel; but, unless its fortifications have been lately augmented, it is not considered a strong place. Within the walls, its area occupies about 64,000 square feet. It consists of 1200 or 1300 houses, and is inhabited by 23,500 souls, according to recent computations, for those of older date increase that population above a fifth. The streets are broad, and tolerably regular; and the houses, in general well built, consist of four or five stories. There are several fine public edifices, particularly the Episcopal palace, and that wherein the parliament formerly held its sittings. Among the charitable institutions which sufficiently illustrate the disposition of the citizens, the general hospital is the chief, and is governed by directors selected from the most distinguished of the inhabitants. The building, which is very spacious, is appropriated for incurables; persons insane; the indigent, who commonly amount to 400; and the foundlings of the city, about 150 in number, are also received here. This institution occupies an inclosure to the south-east of the city, and adjoining to it is the military hospital. In the hospital of Providence there are 60 beds, and in the hospital of the Ladies of Charity, for females, there are 20; besides which institutions, there is a poor's house in the suburbs. Grenoble has also a museum of the arts, and a botanical garden well managed. A garrison, consisting of a small body of troops, is kept here.

The principal manufactures of this city, are woollen cloths, muslins, hats, and particularly gloves, the principal towns of France, Spain, Italy, and Britain being supplied with them. Marble cutting is also carried on to some extent, for which purpose there are mills driven by water from the adjoining rivers.

Grenoble Gretna.

Grenoble is the see of a bishop who formerly arrogated the title of Prince of Grenoble, and enjoyed those peculiar privileges, which, in less enlightened ages, were reserved almost exclusively for ecclesiastics. Besides the parish churches, there are several monastic institutions.

Grenoble is celebrated for the complaisance and polished manners of its inhabitants, many of whom have shewn a distinguished taste for letters. Condillac and Mably, well known among the modern literati of France, were both natives of this place. It has also to boast of having given birth to the Chevalier Bayard, characterised by his sovereign Francis I. as one *sans peur et sans reproche*, and who, if we are to credit history, singly defended the narrow pass of a bridge against 200 horsemen. The Baron Adrets, a sanguinary chief of the Huguenots, during the wars for the reformation of religion, was born here, and distinguished himself by his cruelty on the miserable prisoners who fell into his power.

As the site of this city is elevated only 15 feet above the level of the river Isere, an unusual humidity prevails, which is the source of many serious distempers among the inhabitants. Though standing at the edge of a plain, extending over a square league, and surrounded by fertile fields and gardens, these advantages are counteracted by the miasmata emanating from the depositions of the waters. Certain seasons of the year are extremely unhealthy; slow fevers are seldom eradicated; and it has been remarked, that even the children are, in infancy, of smaller size, and longer of attaining the strength and complexion of those in the neighbouring country. "The river Isere," an intelligent physician observes, "has become a kind of domestic enemy to Grenoble, with which it is necessary to live; the constant humidity and the mud deposited by its tranquil waters in the neighbouring marshes, are inconveniences with which beneficent nature has accustomed the inhabitants; but they excite less attention than the tendency of all the prevalent diseases to terminate in dropsy." It has been proposed to counteract the deleterious effects arising from local circumstances, by digging a canal to drain off the stagnant waters, and which, at the same time would prevent the overflowing of the river; as also to deepen the bed of the Isere, in order to give it a stronger current.

Grenoble has subsisted from a very ancient period, and was known by the name of *Cularo*, under which it is designed in a letter from Plancus to Cicero. It is said to have been called *Gratianopolis* from the Roman emperor Gratian; but since the period when it was possessed by the Allobroges, and when it was denominated a city, it repeatedly changed its masters. After various revolutions, Dauphiny came under the dominion of the kings of France, and Louis XI. instituted a parliament in Grenoble, founded on the model of the parliament of Paris, since which time it has remained an integral part of the kingdom. (*c*)

GRETNA, or GRAITNEY GREEN, is the name of a village and parish in Scotland, in the county of Dumfries. The village of Gretna, which is the first stage in going from Longtown in England, to Annan in Scotland, is built on each side of the road, and has, for more than 70 years, been famous as a place for the celebration of the clandestine marriages of English lovers. This ceremony was generally performed by a blacksmith or tobacconist, and the number of marriages have been calculated at 65, which brought in an annual income of about £1000, at the rate of 15 guineas each. The remains of an oval druidical temple, occupying about half an acre of ground, has been discovered at Gretna Mains. The mansion house of Gretna hall has been fitted up by the proprietor the Earl of Hoptoun as an inn. The population of the parish, in 1811, was 1749.

GREW, Nehemiah, a celebrated botanist, was born at Coventry, about the year 1628, and was the son of Dr Obadiah Grew, vicar of St Michaels. At the restoration of Charles II. being a non-conformist, he went abroad, and prosecuted his studies at a foreign university, where he took the degree of Doctor of Medicine. Upon his return to England he settled at Coventry, and, in the year 1664, his attention was first directed to the anatomy of plants; and he was encouraged to proceed in this branch of natural history by his brother-in-law Dr Henry Samson, who pointed out to him a passage in Glisson's work *De Hepate*, in which this subject is represented as an unexplored, but promising line of study. In the year 1670, Dr Sampson, who had seen the first book of Grew's *Anatomy of Plants*, put it into the hands of Oldenburg, who gave it to Dr Wilkins, bishop of Chester, by whom the manuscript was read to the Royal Society, under the title of a *Philosophical History of Plants*. This work was highly approved of, and was printed by that distinguished body in 1671, under the title of the *Anatomy of Vegetables begun, with a general Account of Vegetation founded thereon*. In consequence of the reputation which this work acquired for its author, Grew was invited to settle in London, where he arrived in 1671.; and, upon the recommendation of Dr Wilkins, he was elected a Fellow of the Royal Society, and admitted on the 30th November 1671. At the suggestion of the same learned divine, Grew was appointed curator to the Royal Society for the anatomy of plants, which led him to draw up the 2d, 3d, and 4th Parts of his work, and the various lectures on the same subject, which form a part of his Anatomy of Plants. All these papers were composed between the years 1670 and 1676, and were read at various meetings of the Royal Society. They were afterwards collected in 1682, with 83 plates, and published in a folio volume, under the title of the *Anatomy of Plants*, a work full of the most important facts in vegetable physiology.

In the year 1673, Dr Grew published in the Transactions, a paper, entitled *Observations on Snow*, in which he supposes, that the snowy particles are formed by the drops of rain containing spirituous particles, and meeting in their descent with others of a saline, partly nitrous, but chiefly urinous or acido-salinous nature. In the year 1677, he was appointed secretary to the Royal Society, in which capacity he published the *Phil. Trans.* from January 1678 to February 1679. In the year 1680, he was made an honorary fellow of the College of Physicians, and attained to considerable practice in the medical profession.

Dr Grew drew up a catalogue of the natural and artificial rarities belonging to the Royal Society, and preserved at Gresham College, which was published in 1681 in folio, with the title of *Museum Regalis Societatis*, containing 22 plates. It was accompanied with another work, entitled the *Comparative Anatomy of Stomachs and Guts begun*, being several lectures read before the Royal Society in 1676. The description of the Museum, though by no means free from mistakes, is a work of merit, and is remarkable for an ingenious scheme or disposition of shells.

The other papers which he printed in the Transactions, were

The Description and Use of the Pores in the Skin of the Hands and Feet. Phil. Trans. 1684.

Some Observations on a diseased Spleen, Id. 1691.

Description of the American Tomineius, or Humming Bird, Id. 1693.

On the Food of the Humming Bird, Id. 1693.

A Demonstration of the Number of Acres in England or South Britain, and the use which may be made of it, Id. 1711.

One of the last works of Dr Grew, was his *Cosmographia Sacra*, or *a Discourse of the Universe, as it is the Creature and Kingdom of God*. The principal object of this work, was to demonstrate the truth and excellence of the sacred writings. The works of Dr Grew were translated into French and Latin. He died after a short illness on the 25th of March 1711, about the 83d year of his age.

GRIDIRON Pendulum. See Horology.

GRIES, is a mountain of Switzerland, situated in the Alpine chain which separates Piedmont from the Upper Vallais. The road over this mountain leads from Oberghestelen, in the Vallais, to Domo d'Ossola, in the Val-Maggia, and to Locarno. This road rises to the height of 7336 feet, and traverses a glacier a quarter of a league wide, and blackened by the dust of the mica slate. The distance from Oberghestelen to Formazza, at the southern foot of the Gries, is 7½ leagues. The descent of the Gries is by four different terraces or vallies. The first is called Bettelmatte, celebrated for its fine cheese, and for the small lake from which the Toccia, or Tosa, issues. The second valley is called Morast, and from this the road descends by a very steep path to a third valley, occupied by the hamlet of the Auf der Frout, where the valley of the Toccia, or the Dolgia, commences. Another steep declivity conducts to the south valley, called Froutval, which is celebrated for the cataract of the Tosa, or Toccia, which, excepting the fall of the Rhine, is reckoned the most magnificent in Switzerland. It is about 300 or 400 feet high, and forms a species of pyramid, whose base is extremely wide, while its summit is only 4 or 5 feet in breadth. The rock is inclined about 140° or 150° to the horizon. This cataract is surrounded on all sides with lofty rocks, crowned with wood. The southern side of the Gries is inhabited by Germans as far as the village of Foppiano. The south side of the mountain is composed of gneiss, of veined granite, and of mica slate. In the valley of Egino, there are beds of potstone, which are wrought about a quarter of a league on the east side of the bridge. Slates occur to the south, and lower down the mica slate appears. The first valley is composed of gneiss and calcareous strata. Below the second valley, rocks of argillaceous schistus stretch to the north-east; and, on the other side, are rocks of a ferrugineous aspect. All the rocks from the north to the south, as far as Pommat, lie in strata almost vertical, in the direction from north-east to south-west. See Ebel's *Manuel, &c.*

GRIMALDI, Francis Maria, a learned Italian Jesuit, was born in the year 1619, and cultivated the sciences along with his friend Riccioli. Grimaldi was the first person that observed the lengthening of the solar image when refracted by a prism; and he is principally known for his discovery of the diffraction of light; a subject which was afterwards examined by Sir

Isaac Newton, under the name of the Inflexion of Light. These discoveries of Grimaldi are contained in his work entitled *Physico-Mathesis de Lumine, Coloribus et Iride*, Bononiæ, 1665. The principal object of this work, is to determine whether light be a substance or a quality; and, after occupying 535 quarto pages in this discussion, he concludes, with the Aristotelians, that it is not a *substantial*, but an *accidental* quality. A full account of this work will be found in the *Phil. Trans.* for 1672, No. 79, p. 3069. Grimaldi died in 1663, in the forty-fourth year of his age. The discovery of the solar spots, and the present nomenclature of the lunar spots, have been erroneously ascribed to him. See *Phil. Trans.* abridged, vol. i. p. 675, Note. See also OPTICS.

GRIMSBY, or GREAT GRIMSBY, is a borough and seaport town of England, in Lincolnshire, situated near the mouth of the Humber. The streets are clean, and the houses in general well built. The church, which is called St James, is spacious and handsome, and is built in the form of a cross, with a tower in the centre. The steeple is a fine specimen of English pointed architecture. A part of the choir fell down in 1600, but the steeple has scarcely suffered from the depredations of time. In the upper part of the steeple is the singular inscription, "Pray for the soul of John Empringham." The church contains many ancient monuments. Grimsby had formerly a monastery of Gray Friars, a convent of Benedictines, and a priory of Augustine canons. Grimsby was once a rich and populous town, with a considerable foreign and inland trade. It was a mayoralty in the reign of King John; and in the reign of Edward III. it furnished 11 ships and 170 mariners to assist at the siege of Calais. The harbour, however, was gradually choked up, and a dangerous sand bank having drifted near its mouth, its trade declined, and was transferred to Hull. Of late, the trade of the place has revived; the harbour has been improved, a dock constructed at great expence, and the town enlarged by additional buildings. A small coasting trade is carried on with sloops. Salt and coals are the chief articles of importation. There was once at Grimsby a castle, but it is entirely decayed. There are some very extraordinary fountains near the town, called Blow Wells, which never overflow, though they rise to a level with the surface of the ground. Grimsby is a port town under that of Hull, and has a deputy collector, comptroller, and coast surveyor. The Grimsby canal is a short canal which leads from the Humber to Grimsby wet docks. Population of the burgh and parish, in 1811, 2747. See the *Beauties of England and Wales*, vol. ix. p. 689, &c.

GRIMSEL is the name of a lofty mountain in Switzerland, over which there is a road from the canton of Berne into the Upper Vallais. The distance from Meyringen on the Aar, to the Hospice of Grimsel, is about seven leagues, and from thence to Oberghestelen on the Rhone, is three leagues. This road is bordered in several places with frightful precipices, and it is often necessary to pass over bridges apparently insecure.

After leaving Meyringen, the traveller passes through the forests of Mount Kirchet, by the agreeable valley of Im Grund. The gneiss here appears below the calcareous strata, lying above the primitive rock. The strata of the gneiss are almost vertical, a little inclined to the south. Beyond the forest which occupies the extremity of Grund, the calcareous rocks cease altogether, and the gneiss and micaceous schistus replace it on the side of Guttaner, the southern dip of these rocks being a little increased. In the valley of D'Urbach, the great glacier of D'Urbach or of Gauli descends into the plain; and after passing the Aar by a bridge, a rough and solitary path cut out of the rock leads between the mountains of Urbach, Ritzli, Gauli, and Gouttan, to the hamlet of Im Boden, and thence to the village of Gouttanen, situated 3198 feet above the level of the sea, where there is a tolerably good inn. This village was burnt in 1803, but, in consequence of the liberality of the Swiss, it has been rebuilt. About a quarter of a league above Gouttanen, the granite appears in mass, and extends to the Grimsel. Its stratification is distinctly seen. At first the strata stretch from north-east to south-west, and afterwards from east-north-east to west-south-west. About half a league from Gouttanen, the Aar forms a cascade at the side of the road; and a fine rainbow may be always seen in clear weather between ten and two o'clock. Beyond Goutanen the road passes Mount Stampf, and, after twice crossing the Aar, the traveller reaches the chalet of Handeck in two hours. The glacier and the lake of Ghelmer are distinctly seen from that mountain to the east, and to the south-west appear the glaciers of Erlen and Ritzli, and the Handeckhorn to the south. At a considerable distance below the chalet, the Aar forms one of the finest waterfalls in Switzerland. It should be visited during sunshine, between half-past nine and eleven o'clock, and from the bed of the river, as near the bottom of the fall as possible. From Handeck to the Hospice is a distance of two leagues, over a terrible road, which is three times crossed by frightful though substantial bridges. About half a league from Handeck appear immense rounded surfaces of granite, in which steps have been cut for the feet of the horses and of travellers. After travelling half an hour longer, we cross the fine Alpine pastures of Roderischboden. At the last bridge, not far from the Hospice, the Aar suffers another remarkable fall.

The Hospice, which was built in 1557, is surrounded with frightful rocks, and is situated at a height of 5628 feet above the level of the sea. The keeper of it is allowed to hunt in any of the cantons of Switzerland, and is bound, in return, to feed and lodge all travellers that cross the Grimsel. He remains at the Hospice from March till the beginning of November. He can furnish seven good beds, though there are sometimes more than a hundred candidates for them. Near the Hospice is a small lake called Kleinsee, from thirty-two to sixty-two feet deep. The Sassbach throws itself into the lake in a fine cascade. After leaving the Hospice, the road continues to ascend for three quarters of a league, and at its most elevated point the height is 6570 feet. The height of the Seidelhorn, which is the highest summit of this mountain, is 8580 feet. From the highest part of the road, there is a fine view of the Furca, of the Galenstock, of the peaks of St Gothard, of the Gries, and of the southern chain of the Vallais, as far as Mont Blanc. The descent to Oberghestelen occupies only about two hours.

On the top of the Grimsel a reddish granite occurs; mica slate appears in the southern face; and argillaceous schistus at the southern foot of the mountain. A singular grotto, filled with crystals, was opened on Mount Jochli, upon the Zinkenstock, in 1720. It was the richest ever found in Switzerland: It was 120 feet deep and 18 wide, and contained crystals of which a small number weighed nearly eight quintals, and several four or five quintals. Several thousands of quintals were obtained, of the estimated value of 30,000 florins. One of the largest of these was $3\frac{1}{2}$ feet diameter, 2½ feet long, and one of its six faces 1¼ feet wide. It is now in the museum of Natural History at Paris.

The glaciers of the Aar are generally visited by the travellers that cross the Grimsel. In the month of August 1799, the French ascended the mountain, and, after a severe conflict, drove the Austrians from their position on its summit. See Ebel's *Manuel, &c.*

GRINDELWALD is the name of a village of Switzerland, in the canton of Bern. It is situated in a rich Alpine valley, at the height of 3150 feet above the level of the sea. The direction of the valley is N. E. and S. W. and it is encircled with lofty mountains. The Faulhorn, to the north of Grindelwald, is 8020 feet high; the Wetterhorn, to the east, is 11,433; the Eiger, to the south, is 12,268. The Schreckhorn, to the south-east, is 12,530 feet; and the Jungfrau, to the S. S. W. is 12,840 feet. The valley is shut up at the north-east by the Scheideck, which is 6045 feet high.

This valley is one of the most frequented in Switzerland, both from its proximity to Bern, and from the facility with which its two glaciers may be visited. These glaciers are parallel to each other, and are each about a league distant from the Inn. The smaller glacier forms an arm of the immense valley of ice which is situated between the Schreckhorn, the Viescherhorn, and the two Eigers. In the middle of this glacier there is a rock, almost vertical, on which the snow cannot rest, and which has, therefore, received the name of the *warm rock*. The surface of the glacier is extremely unequal, and is formed into many splendid pyramids of ice. Near it is a wood of elder trees, where excellent strawberries may be gathered almost close to the ice.

The great or upper glacier, almost entirely separated from the small one by the rocks of the Schreckhorn, lies between the Mettenberg and the Wetterhorn. Its ancient limits were formed by a hill of debris, thirty feet high, and covered with pines of considerable height. In 1720, the glacier extended thus far, but it afterwards retired, and the space which it left was covered with trees. A new augmentation, however, which it experienced in 1780, destroyed this wood. The torrent which flows from it is the Black Lutschinen. In this valley the traveller frequently hears the thunders of the glaciers, and experiences the violence of the winds which issue from their crevices.

The road from Grindelwald to Meyringen, in the valley of Hasli, by the Scheideck, is extremely interesting. It is only a distance of seven leagues, and may be performed on horseback without any danger. See Ebel's *Manuel, &c.*

GRINDING OF DRUGS. See DRUG-MILL.

GRINDING AND POLISHING OF PLATE GLASS. See GLASS, Sect. vi. p. 314.

GRINDING OF LENSES AND MIRRORS for optical instruments. See OPTICS.

GRINSTEAD, EAST, is a borough and market town of England, in Sussex. It is pleasantly situated on a hill, near the northern border of the county. The town is irregularly built, but it contains many neat modern houses. The church, which stands on the east side of the main street, is a spacious and handsome structure. It has a lofty and well-proportioned tower, adorned with pinnacles at the corners. Sackville college, a large quadrangular stone building, stands at the east end of the town. It was built in 1616, as a charitable institution for the support of 24 old persons of both sexes. A suite of rooms is set apart for the Duke of Dorset, who gave the use of them to the judges when the assizes were held here. There is here a neat chapel belonging to the college, and also a free school here for 12 boys. Population, in 1811, 2804. See *Beauties of England and Wales*, vol. xiv. p. 150.

GRINDSTONES, from the Latin *Gyrandus*, are circular stones, a few inches thick, which are mounted on a spindle, and turned with a common winch, for the purpose of grinding edge tools. When a great number of these stones are driven by machinery for the purposes of cutlery, they are called *blade mills* or *grind mills*. Grindstones are formed of a gritstone, in which the grains of silex are firmly cemented to each other by a siliceous or other hard cement, the interstices not being filled up as in other kinds of sand stone. The following is a list of the grindstone quarries in England, with their degrees of fineness, drawn up, we believe, by Mr Farey for Dr Rees's *Cyclopædia:*

Ashover, N. W. (hill quarry) Derbyshire, middling.
Beely Moor, E. of the town, Derbyshire, coarse.
Belper, S. E. (Hungerhill) Derbyshire, middling.
Biddulph-Hall, N. W. of Leek, Staffordshire, coarse.
Bilstone, S. E. of Wolverhampton, Staffordshire, middling.
Bolsover, N. W. (nunnery) Derbyshire, middling.
Bredsal Moor, N. of Derby, middling.
Brinclif-edge, S. E. of Sheffield, Yorkshire, fine.
Buxton, N. (Corbar) Derbyshire, fine.
Darley Moor, E. of the town, Derbyshire, coarse.
Gate-head fell, 2¼ miles south from Chester Ward, Durham.
Glossop, Derbyshire, coarse.
Harthill, S. E. Yorkshire, fine.
Hooton-Roberts, near Rotherham, York, middling.
Horsley, N. of Derby, fine.
Lane-top, N. of Sheffield, Yorkshire, whitening.
Little-Eaton, N. of Derby, coarse.
Milford, S. of Belper, Derbyshire, coarse.
Molecopt-hill, S. of Congleton, Cheshire, coarse.
Morley-moor, N. of Derby, fine.
Norton, W. (Hemp-yard lane) Derbyshire, fine.
Overton (Gregory) in Ashover, Derbyshire, coarse.
Polesworth, S. E. of Tamworth, Warwick.
Purton, W. of Wolverhampton, Staffordshire, fine.
Ridgeway (Lum-delph) in Eckington, Derbyshire, fine.
Stanley, N. E. of Derby, fine.
Stanton by Dale, E. of Derbyshire, fine.
Stanton Moor, N. E. of Winster, Derbyshire, coarse.
Therberg, near Rotherham, Yorkshire, fine.
Treton, ditto, ditto, fine.
Warton E. of Tamworth, Warwickshire.
Wickersley, near Rotherham, Yorkshire, middling.
Wokes, near Barnsley, Yorkshire.

The most extensive grindstone quarries are those near Gateshead. They are sent to all quarters of the globe under the name of Newcastle grindstones, and constitute a great branch of the trade of Newcastle and Gateshead.

The explosion of grindstones when in motion is a phenomenon which has frequently happened, and which has been attributed to the effect of the centrifugal force, and to the expansion of the wooden wedges. On the 8th June 1768, a very singular accident of this kind happened to a cutler at Ivry-sur-Seine, near Paris, who was grinding kitchen utensils. The stone flew into the air apparently on fire, and burst into innumerable fragments, with a dreadful noise. One of the fragments, of about three pounds weight, flew over a building 40 feet high, and alighted 108 feet beyond it in the garden, where it broke the branch of a lime tree. Another

Grisons.

fragment, of nearly the same size, grazed the parasol of a young lady who was standing beside the cutler. A part of the stone was found upon the pavement reduced to powder. A similar accident happened to a cutler at Strasburg, who was killed by the explosion.

Our readers will find some curious facts relative to grindstones, and to their sudden explosions while they are at work, in the *Encyclopedie Methodique*, art. Tourneur; *Collection Academique*, tom. xiii. p. 45, 48, 413. and tom. xii. p. 109; *Mem. Acad. Par.* 1762. *Hist.* p. 37; and *Id.* 1768.

GRISONS, the *Upper Rhetia* of the ancients, is the name of a republic which was formerly independent, but since the year 1798 it has formed one of the nineteen cantons of Switzerland. It is bounded on the north by the canton of Glaris, from which it is separated by a chain of mountains, and by the German districts of Schweiz, and the Voralberg, in Suabia; on the east by the Tyrolese; on the south by the Valteline, and the Ticino; and on the west by the canton of Uri.

Boundaries.

Extent.

This canton is the largest in Switzerland. It contains 140 square geographical miles (15 to a degree), and comprehends no fewer than 60 principal and lateral vallies. From its most eastern part at Finstermunz on the Inn, to the Mountain Badus at the source of the anterior Rhine, is 32 leagues; and from its most northern part at the Mountain Seesa Plana, to its most southern part near the Mountain St George, is 23 leagues.

Natural divisions.

The natural divisions of the Grisons form five great vallies, viz. the valley of the posterior Rhine, the valley of the anterior Rhine, the valley of the Inn or the Engadin, the valley of the Albula, and the valley of the Landquart, or the Prettigau.

1. Posterior Rhine.

1. The valley of the Posterior Rhine includes the vallies of Rhinwald, Schams, Via Mala, and Domlesch. The Rhinwald is about eight leagues long, and is surrounded on all sides by lofty mountains. It is accessible only by one road, which passes through the defile called Rofflen, which leads into the valley of Schams. The surrounding mountains, of which the Avicula and the Piz-val-Rhin are 10,280 feet high, are covered with enormous glaciers, and the valley is exposed to frightful avalanches. The winter continues nine months. The grass does not begin to grow till the end of June, and it is necessary that the hay be got in before the beginning of September. This valley is inhabited by Germans of the Suabian colony, which the Emperor Frederick I. sent, at the end of the 12th century, to ensure a passage into Italy over the Splugen. The two principal roads for crossing the Alps pass through the Rhinwald; one of them over the Splugen, and the other over the Bernardin. In taking the road over the Splugen, eighteen hours are necessary to go from Coire to Chiavenna. From the village of Splugen, the road follows the brook Hausle all the way to the inn on the summit of the hill on the Italian side, which is a distance of three leagues. The height of the road is here 6170 feet; but that of Tombo-horn, the neighbouring summit of the mountain, is 9795. The gorge called the Cardinell is truly horrifying and dangerous. The road then follows the impetuous course of the Lira, and the traveller arrives in two hours at Isola. In two hours more, after passing through the valley of St Jacques, and by Campo Dolcino, where the customhouse officers examine all baggage, he reaches Creston, and then Sta Maria, which is only a league from Chiavenna. General Macdonald crossed this mountain in 1800, between the 27th of November and the 1st of December, and lost many men and horses by the avalanches. The northern side of the Splugen is chiefly composed of gneiss and micaceous schistus. Very fine white marble occurs near the summit of the road. It stretches between the micaceous schistus from south-west to north-east. The inhabitants of the village of Splugen make very fine articles of it. There were once two roads over the Bernardin, but the shortest is passable only in summer. The longest is kept in repair by the commune of Hinter-Rhein. At the highest part is a Hospice, which is three hours distant from the village of Hinter-Rhein on the north, and two hours from the village of Bernardin, in the valley of Misox, on the south. The small lake of Muesa, with several islets, is situated on the summit of this mountain. The water that runs from the southern face of the glacier of the Rhine throws itself into this lake, which again forms the brook of Muesa, and after running through the valley of Misox, joins the Tesino at Bellinzone. This mountain is composed of gneiss. It was crossed in 1797, on the 7th March, by the French army under General Lecourbe.

Road over the Splugen.

Road over the Bernardin.

In entering the Rhinwald from the valley of Schams by Rofflen, the road passes the villages of Suvers, Splugen, Medel, Ebi or Planura, Noveina or Noufenen, and Hinter Rhin. The church of Hinter Rhin is 4770 feet above the level of the sea. From the very bottom of this valley, which extends itself with a singularly wild aspect, among the horrible rocks of Avicula and the Piz-val-Rhin, the glacier of Rhinwald and the source of the posterior Rhine may be distinctly seen, and can be reached in three hours from Hinter-rhin. From a station a little way beyond the chalets of Tessini upon Zaport, may be seen the basin formed by the rocks of the Black Muschelhorn, and by a ridge of mountains about two leagues long, from which 13 torrents descend. At the bottom of this basin lies the glacier of Rhinwald. The torrent of the glacier issues from a magnificent vault of ice, and receiving the 13 brooks already mentioned, it forms the true source of the posterior Rhine. On leaving this deep gorge, it receives 16 torrents before reaching Splugen. After this it escapes through the gorge of Rofflen, receives other six brooks from the valley of Schams, throws itself into the abysses of the Via Mala, and, still farther enlarged in the valley of Domlesch by ten tributary streams, particularly the Albula, it joins itself at Reichenau to the anterior Rhine, which is considerably less in size, though enlarged by nearly 30 torrents. The Via Mala is one of the most frightful defiles in Switzerland. It extends two leagues from Tousis to Zilis. See Via Mala.

Valley of Schams.

The valley of Schams, which is two leagues long, contains eight or nine considerable villages, on both sides of the Rhine. It is lower and more fertile than the Rhinwald, and is one of the richest and most populous in Switzerland. See Schams.

Valley of Domlesch.

The valley of Domlesch, or Tomleasca, is formed by the posterior Rhine, after its junction with the Albula, and before it falls into the anterior Rhine. It is about two leagues long and one wide, and is the most temperate in the Grisons. It derives much of its celebrity from the picturesque and cultivated mountain of Henzenberg, about two leagues long, and stretching along the west side of the valley. The northern entrance to the valley is scarcely 100 paces wide; and on the south it is shut up by the Beverin and the Mouttnerhorn, between which the river forces itself with great fury. Soon after it receives the black stream of the Nolla, and half a league lower that of the Albula. The valley of Domlesch contains no fewer than 22 villages, and 12 ruined and inhabited castles, some of which are re-

Grisons.

markable for their antiquity. Excepting at Tonsis, the Romansh is here the general language. The base of the mountains is composed of argillaceous schistus, covered with calcareous schistus. Gypsum appears in vertical beds in the Via Mala, and in the western part of the valley. See TOMILS and TOUSIS.

Anterior Rhine.

2. The anterior Rhine comprehends the valleys of Tavetsch, Medels, Sumvix, Lugnetz, Petersthal, &c. The valley of Tavetsch forms the upper part of the anterior Rhine. Sadrun is the principal place. Ruaras is the highest Grison village in the south-east. Selva and Camot are the only other places of note. The anterior Rhine is formed by three branches, which unite at Camot. The middle branch comes from the mountain Badus, and is called Rhin-de-Camot. It is formed by the glaciers on the eastern side of that hill, which throw their waters into the small lakes of Lac-de-Toma and Lac-Palidulca, and form the branch already mentioned. The second branch, called the Rhin-Cornara, flows out of the valley of the same name, having risen in the mountains of la Sceina de la Reveca. The third branch comes from Kamerthal, and rises at the foot of the Crispalt. The anterior Rhine formed by these branches, receives ten brooks before it falls into the middle Rhine, which flows through the valley of Medels. Badus is 9085 feet above the bottom of the valley. It is accessible from the north, south. and east, and commands a grand view of the distant Alps. From Camot and Selva, this mountain may be ascended and descended in one day. The valley of Tavetsch is peculiarly exposed to avalanches. In 1749, an avalanche came from Crispalt, a mountain two leagues distant, and overwhelmed 100 persons, of whom 80 were taken out of the snow alive. On the night of the 13th December 1808, another descended from Rouenatsch on the village of Selva, and killed 42 persons, and 237 cattle.

Mountain Badus.

Valley of Medels.

The valley of Medels is very narrow and picturesque. It is watered by the middle Rhine, and extends five or six leagues. Wheat, barley, flax, and hemp, are here cultivated; but the care of the cattle is the principal concern of the inhabitants. Very fine cheese is also produced in this valley. Beyond the junction of the middle and anterior Rhine, the valley is for 1½ miles very narrow and dark, owing to the height of the rocks, and the fir trees which cover them. The middle Rhine runs in a very narrow channel, and forms many fine cascades. In leaving this defile, the smiling valley of Medels appears. The village of Kurajla is seen situated above the river; and on the left the lateral valley of Platas, which contains the hamlets of Soliva and Bisquolm. At the Hospice of St Maria, on the Lucmanier, the Val-Kadelina opens, in which the middle Rhine has its origin. See LUCMANIER.

Valley of Sumvix.

The valley of Sumvix opens into the Rhine opposite the village of Sumvix, and has the village of Surhein at its mouth. It is about five leagues long, and stretches between huge mountains covered with glaciers. It is rich in mountain pastures, meadows, and forests. The mountain of Tenija, situated at the upper extremity of the valley, divides it into two branches, viz. Val-vijlots and Val-greina. The torrent which runs through the valley, has its origin in the vast glacier of Medels. Though the valley is more fertile than that of Medels, it has only two chapels, and 121 inhabited houses. There is a sulphureous spring half a league above Surhein. The view of the cascade of the Greina, and the surrounding glacier, is particularly admired.

Valley of Lugnetz.

The valley of Lugnetz opens into the Rhine near Ilantz (See ILANTZ). It is eleven leagues long, and contains many lateral vallies. From Ilantz to the central point where the valley divides is three leagues. To the south-west of this point stretches the valley of Urin, and to the south-east that of St Petersthal. The greater part of the inhabitants are Catholics. See LUGNETZ.

Banks of the Rhine from Dissentis to Coire.

The road from Dissentis to Coire, along the banks of the Rhine, is extremely interesting. The Benedictine abbey of Dissentis is situated above the town of the same name on the northern face of the mountain Vakaraka, whose great forests protect both it and the town. It enjoys a splendid view of the Rhine as far down as Coire. It was founded in 614, by Sigebert, a Scottish Benedictine, who came to preach Christianity to the Rhetians. Placide Toparcha of Trons gave him the ground for this purpose, and became himself a monk. The convent and a part of the town were burned by the French in May 1799, and the inhabitants were put to the sword, in consequence of the women having massacred a company of soldiers without arms in a general insurrection. A collection of books and precious manuscripts, and the mineralogical collections and journals of R. P. Placide a Specha fell a prey to the flames. The convent has been rebuilt, and the Catholic school of the canton has been established here since 1804. The town is the chief place of the district of Dissentis, which is one of the most ancient and populous of the Grey league. From Dissentis to Trons is a distance of 3 leagues. The best wheat in the Grisons grows about Sumvix. The mountains are all primitive to Trons, but to Ilantz they are composed of beds of calcareous stone and schistus. To the north of Trons (See TRONS) opens the wild valley of Puntajlas, indented with glaciers from which issue the torrent of Ferrara. From Trons to Ilantz by Tavenas and Rauvis, is a distance of four leagues through a very narrow valley. The great road recrosses the Rhine below Tavenas, and passes by Rauvis, Schlowis, Sagens, Lax, Flims, Trins, and Tamins to Reichenau. At Rauvis, a league below Ilantz, is a mine of galæna, containing silver. The galæna is in masses of gneiss. At Obersax, a village on the other side of the Rhine, there is a mine of pale red copper, containing much silver. There is also here abundance of borax. These two mines have been wrought since 1806. The road through Schowis, Sagens, and Lax, traverses thick forests of pines, and a wild country, diversified with grain and pastures. At Flims, which is situated on beautiful hills in a pleasant place, and also at Tamins, the houses stand in separate clusters. Flims is remarkable for the beauty of its inhabitants, and for the excellence of its springs of water. The torrent Blaun sometimes commits dreadful ranges. From Flims to Elm in the canton of Glaris, is 7½ hours by the Hunter's road. Reichenau is the key of the anterior Rhine, and is situated at the confluence of the posterior and anterior Rhine. The former has an ash-grey colour, and the latter is a limpid green. See REICHENAU.

Town of Dissentis.

Trons.

Mines.

Flims.

Reichenau.

The road from Reichenau to Coire or Chur by Ems, is a distance of 2 leagues. Between Reichenau and Ems, are 15 or 20 conical hills, covered with oak, and adorned in the most picturesque manner by chapels and ruins. From Ems to Coire is a fine rich valley, bounded on the right by the mountains of Malix, and on the left by the Galanda. This mountain is 6598 feet high, and rises like an enormous pyramid. It is ascended most easily on the side of Coire. It is composed of calcareous rocks, and of calcareous schistus containing much argil. The strata are inclined to the south. Coire is situated on the left

Mountain of Galanda.

Grisons.

Town of Coire.

bank of the Rhine, in a rich plain between 2 or 3 miles wide. The town lies partly in the plain, and partly on the steep side of a rock. It is encircled with ancient brick walls, strengthened with round towers. The streets are narrow and dirty. The bishop's palace and the cathedral, built in the 8th century, stand in the highest part of the town. The convent of St Lucius, is situated above the palace. The library of the town, an institution for the poor, the cantonal school. are the other principal establishments. In 1806, about 200 copper medals of the Roman emperors were found near the anterior gate. The plain around Coire is diversified with corn and pasture, and the sloping hills are covered with vines, which yield a pleasant but not a strong wine. The population of the town is 3000. Rafts carrying from 20 to 50 quintals, descend the Rhine from the bridge over the Albula to the Lake of Constance.

Country from Coire to Luciensteg.

Below Coire, the road passes through the fine villages of Masans, Trimmis, Zitzen, and Ighis, to the chateau of Marschlen, where the Messrs Salis have a fine library, and a superb cabinet of natural history. The Economical Society of the Grisons was established at

Zitzen.

Zitzen in 1778, and had published nine fasciculi in 1803. The road now crosses the Lanquart by the bridge of Zollbrucks, where there is a pontage, and passes

Malantz.

through Malantz, Jennins, and Mayenfield. Malantz is a small handsome town on the side of a hill. Its red and white wines are reckoned the best in the Grisons. There are beds of gypsum near Jennins,

Jennins.

and much blue marl in the neighbourhood. Jennins is half a league from Mayenfield, and three quarters of a league from the defile of Luciensteg. The

Mayenfield.

fine valley of Mayenfield is a league wide, and is surrounded with lofty calcareous mountains. The defile

Luciensteg.

of Luciensteg is situated near the northern frontier of the Grisons, on the side of Suabia, between the Gouscher Alp 5573 feet high, and the Flesch 3114 feet high. A wall 100 toises long, and a rampart of the same length, defends on that side the entrance to the Grisons. The frontier passes near Balzeres, situated

Gouscha.

on that defile. At the village of Gouscha near Luciensteg, the mothers are accustomed to tie their children to a rope of a certain length, when they are obliged to leave them at home, lest they should fall over the precipices.

3. Valley of the Inn.

3. The valley of the Inn or the Engadin, is one of the finest in Switzerland. It has 28 lateral vallies, several of which have two or three ramifications. It stretches from the south-west to the north-east, and is 18 leagues long from the Maloggia to the bridge of St Martin. It is divided into the higher and the lower Engadin. The former is seven leagues long from the mountain Maloggia to that of Casanna, and the latter is 11 leagues long from Brail to the bridge of St Martin. It is subject to frequent earthquakes. A full account of this interesting district will be found in our article Inn.

4. Valley of the Albula.

4. The valley of the Albula comprehends the vallies of Davos and of Oberhalbstein. The principal valley of Davos is five leagues long, and is watered by the Landwasser, which falls into the Albula near Filisour, the end of the valley, where the river runs through a defile 1200

Valley of Davos.

feet deep. The lateral vallies of Davos are those of Flula, Dischma, and the fine valley of Sertig, which is divided into two, and has a sulphureous spring, and another mineral water of a purgative quality. Each of these three vallies is four leagues long. Opposite the gorge of Zughen is the valley of Montstein, which has two branches, each a league in length. The district of Davos contains six lakes; the greatest of these, which is half a league long and a quarter wide, contains great quantities of fish. This district possesses several mines of galæna, copper, lead, and iron. The river Albula issues from a small lake in a mountain of the same name, over which there is a road to the Engadin. It descends into the valley across a dreadful gorge called the rock of Bergun or Bergunerstein, and meets the Landwasser at Filisour. Though the smallest of the two, the united stream is called the Albula. It receives the Rhin-d'Oberhalbstein at Tiefenkasten, and is then lost in the posterior Rhine at Furstenau.

Valley of Oberhalbstein.

The valley of Oberhalbstein lies on the northern face of the mountains Septimer and Julier. It is 8 leagues long, and its river rises in a small lake on Mount Septimer. Savognin is the chief place in the valley. About Tintzen the valley grows very narrow, and the road ascends at the side of a torrent, bounded by horrible rocks. At the end of three-fourths of an hour it enters the meadows of Rofna. Near Molins, the castle of Splondatsch appears at the bottom of a frightful gorge. On the road to Marmels, the ruins of the castle of the ancient lords of Marmels rises on the right, upon the summit of lofty rocks. There is a mine of silver and of tin near Ziteil; and the remains of a copper mine between Ochsenberg and Tintzen.

5. Valley of the Prettigau.

5. The valley of the Lanquhart, or the Prettigau, is 8 leagues long and 4 wide, and has 9 or 10 lateral vallies. An account of it will be given under Prettigau. For still farther topographical information respecting the Grisons, see Misox, and the other articles already referred to.

Political divisions.

The Grisons are divided into three leagues. 1. The League of God's House; 2. The Grey League; and 3. The League of the Ten Jurisdictions.

The League of God's House is divided into 11 districts, and 21 communes, and sends 22 deputies to the general diet. Coire is the capital. The jurisdictions are,

1. Coire.	7. Obervats.
2. Pregalia.	8. Oberhalbstein.
3. Upper Engadin.	9. Puschiavo.
4. Lower Engadin.	10. Munster.
5. Bivio or Stalla.	11. Villages of Zitzen, Ighis, Trimmis, and Unter Vatz.
6. Ortenstein.	

The Grey League is divided into 8 high jurisdictions and 27 communes, and sends 32 members to the general diet. The following are the jurisdictions:

1. Dissentis.	5. Flims.
2. Valley of Lugnetz.	6. Rhinwald and Schams.
3. Grub.	7. Henzenberg and Tousis.
4. Waltensburg.	8. Misox.

Government.

The League of Ten Jurisdictions is composed of 11 communities, and send 14 members to the diet. It comprehends the rest of the Grisons, viz. the vallies of Davos, Prettigau, Mayenfield, &c.

Annual diet.

These three leagues are connected by an annual diet of the congress and of the three chiefs. The diet consists of 63 deputies, who are chosen in the several communities by every male above a certain age. The diet meets about the beginning of September at Ilantz, Coire, and Davos, in rotation, and sits three weeks or a month. The chief of the league, in whose district the diet is held, is president, and has a casting vote. In all affairs of importance, the deputies act according to the instructions of their constituents. A majority of votes decides every thing; but they vote in the following manner: When the communities send instructions, the secretary reads them aloud, and the votes are taken from these instructions. In all resolutions respecting which instructions are not received, the deputies may vote as they please; but these resolutions are subject to the revisal of the communities. For this purpose, a congress is held in February or March at Coire, consisting of the three chiefs and three deputies from each league, for the purpose of receiving the votes of the different communities relative to the questions referred to them at the preceding diet. The three chiefs, and the other members of congress, receive 54 florins, about £4, to defray their expences. The deputies to the general diet receive a salary, which never exceeds five shillings a day.

The three chiefs meet three times in the year at Coire, and send information to the different communities respecting the subjects of discussion at the general diet.

rts of ice. The Roman law, modified by municipal customs, prevails in the three leagues. It appears from the concurring testimony of several travellers, that the administration of justice, both in the civil and criminal courts, is very imperfect. The judges are capable of being bribed; and confessions are obtained by torture.

The public chamber of justice, called the *Strafgericht*, is a court composed of ten judges out of every league, and 20 advocates. It is assembled, by a demand made by the peasants to the general diet, and is paramount to all law. There is no appeal from the decisions of this inquisitorial tribunal. The worst effects resulted from the meeting of this court, but fortunately it is now gone into disuse.

ion. The Catholic and Protestant religions both prevail in the Grisons. The Protestants form about two-thirds of the population. There are 135 Protestant parishes, viz. 53 in the League of God's House, 46 in the Grey League, and 36 in the League of Ten Jurisdictions. The livings are from £6 to £25 per annum. The clergy are here obliged to increase their income by traffic; and their poverty is rendered more oppressive from their dependence, as they are generally chosen by the people. Several of the ministers are, however, very respectable, and well informed. The Protestants are educated at Zurich and Basle; and the Catholics at Milan, Pavia, or Vienna. A Latin school was established at Coire for the children of the burghers; and another in 1763, for those intended for the church.

nues. The expenditure of the government consists merely in the salaries of the deputies, and in the expences incurred at the sitting of the diet. The revenues are drawn from the duties upon merchandize, which passes through the canton of the dependent states, and was farmed at 17,000 florins, or £1259: from fines upon delinquents; from a tribute of 500 Philips, or £125, from the Valteline; and 100 Philips, or £25, from Chiavenna; and from the interest of a small sum, the principal part of which, viz. £4000, was vested in the British funds.

nerce. rts. The commerce of the Grisons is very limited. Its principal exports are cheese and cattle, and some planks, stones, and coal, to Milan. The care of the cattle is the principal employment of the peasantry. The canton possesses 8000 head of great cattle, about 30,000 cows, from 60,000 to 70,000 goats, and nearly 100,000 sheep, which come annually from Italy to feed upon the fine pastures of the Grisons. The cattle of the Prettigau are the finest breed. Vines are cultivated in the vallies on the northern and southern frontiers.

rts. The imports of the Grisons, are grain, rice, salt, and silk stuffs, from Milan; grain from Suabia and the Tyrol; salt from the Tyrol and Bavaria; fine linens and muslins from Switzerland; and English, French, and Silesian fine cloth through Germany. The only manufactory in the country, is that of cotton at Coire. The trade of the Grisons, and the subject provinces, is carried on with Milan across the Lake of Como, by its branch the lake of Lecco, by the river Adda, and by the canals of the Adda and the Trezzo.

Languages. The Italian, German, and Romansh languages, prevail in the Grison territory. The inhabitants of Pregalia and Puschiavo, and of the vallies of Misox and Calanca, speak the Milanese dialect of the Italian tongue. The inhabitants of the Ten Jurisdictions, with the exception of a few villages; those of the League of God's House, at Avers, Coire, and the four villages; those of the Grey League, at Splugen, Cepina, and other villages of the Rhinwald; at Valts, in the valley of St Pedro; at Tousis, Reichenau, Feldsperg, Tamins, Meyerhof, Versam, and Valendros.

The Romansh, or Rhetian language, is the vernacular tongue throughout the greater portion of the Grison territory. It was formerly spoken at Coire, and the adjacent districts, and as far as Inspruck in the Tyrol. It is divided into two principal dialects; the one called Cialover, spoken in the Grey League; and the other Ladin, in that of God's House. These dialects vary both in pronunciation and orthography, and they have a great affinity to the Latin, and other languages derived from the Latin. Planta seems to have proved, that the Romansh of the Grisons is the same with the ancient Romansh, called *Lingua Romana*, the mother of the French tongue. It was the earliest language derived from the colloquial Latin, and was understood in Italy, in the Morea, and at Constantinople, having been universally diffused throughout the south of Europe in the 11th and 12th centuries.

Antiquities. The antiquities in the Grisons are very numerous. There are no fewer than 180 castles and ruins of the middle ages.

Population. Mr Coxe reckons the population of the Grisons at 98,000.

The Grey League contains	54,000 souls.
League of God's House	29,000
League of Ten Jurisdictions	15,000
	98,000

In the year 1806, the population was 73,862, viz.

Protestants	44,982
Catholics	28,880
	73,862

Or they may be divided into

Germans	28,000
Those who speak the ancient Rhetian language	36,065
Italians	9797
Total population	73,862

This number is exclusive of the provinces formerly subject to the Grisons. See Coxe's *Travels in Switzerland*, vol. iii.; Ebel's *Manuel d'un Voyageur en Suisse*, passim; and Planta's *Account of the Romansh Language*, in the Philosophical Transactions for 1776, vol. lxvi. p. 129.

Grodno, Groins.

GRODNO, is a town of Poland, in Lithuania, and, with the exception of Wilna the capital, is the most important place in that province. It is now a frontier town in the Russian division of Poland. It is built upon an eminence which overlooks the river Niemen, which is here a broad, clear, and shallow stream. Grodno is a large and straggling place, and has the appearance of a town in decay. The few houses that are in good repair, form a singular contrast with the wretched habitations, the falling houses, the ruined palaces, and the magnificent gateways, which are every where to be seen. Some remains of the old palace, in which the kings formerly resided during the diets, are still to be seen upon a hill of sand, rising abruptly from the river, and forming part of the bank. The new palace is opposite to this hill. It was built, but never inhabited, by Augustus III. and became the temporary residence of Stanislaus Augustus after his abdication. It contains the apartments for the meeting of the diets. The late King of Poland established at Grodno a royal academy of physic for Lithuania, in which ten students are instructed in medicine, and twenty in surgery, and are lodged, boarded, and taught at the royal expence. The physic garden contained 1500 exotic plants, when Mr Cox passed through the town in 1778. The principal manufactures here, are cloth and camlets, linens and cottons, silk stuffs, embroidery, silk stockings, hats, lace, fire arms, needles, cards, bleaching wax, and carriages. They were chiefly established by the king in 1776, and in 1778 they were carrying on in wooden sheds, built by Augustus III. for stables, which were converted into temporary working looms, and dwelling houses for the workmen. The establishment was subsequently removed to Lossona, a village near Grodno, where convenient buildings were erected at the public expence. The country furnishes a sufficient supply of wool, flax, hemp, beavers' hair, and wax, for the manufactories that require these articles; but the silk, cotton, iron, colours, gold, and silver, for the embroidery, and the fine thread from Brussels, are all articles of import. Three thousand persons are employed in these manufactories, including those in the neighbouring villages who spin linen and worsted. Seventy foreigners direct the different branches, and the rest are natives. Grodno contains nine Catholic churches, and two Greek churches. The population consists of 3000 Christians, exclusive of those engaged in manufactures, and 1000 Jews. See Cox's *Travels in Poland, &c.* vol. i. p. 220, 223.

GROINS. In our article CARPENTRY, Book iii. p. 522, &c. we have already treated the subject of groins at some length. We proposed, under the present head, to have investigated the subject of *Domes*, from which we have made a reference; but we have found it necessary to include this subject under that of ROOFS, to which the reader is referred.

In the article CARPENTRY, we have mentioned the great improvement in the construction of brick groins, rising from rectangular piers, as made by Mr George Tapper. The following account of this improvement has been drawn up for our work, by Mr John Narien.

If a square or rectangular area be covered with two vaults, penetrating each other at right angles, and forming two ridges which cross the area diagonally, and intersect each other at the common summit of the vaults, the arch thus formed is called a groined vault: the penetrating vaults may be either semicircular, or semi-elliptical, or one of them may be semicircular, and the other semi-elliptical. The intersections of the circular or elliptical vaults, forming the ridges or groin angles, will be ellipses, because every oblique section of a cylinder or elliptical prism produces an elliptic curve, and the case will be the same when one of the vaults is circular and the other elliptical; for if horizontal lines were drawn from points in the diameter or chord of the circular vault perpendicularly to that diameter, and cutting in different points a line drawn diagonally across the area, the ordinates drawn up to the ridge or groin angle from these points, will be respectively equal to the ordinates at the corresponding points under the circular vault, and consequently their ends will be in the periphery of an ellipse.

The four vaults or arches forming the groined vault, spring from the angles of four square abutment piers, and if the intended vault is to be built of stone, the courses in each arch respectively, are laid upon the centering in lines parallel to the axis of the arch they compose, in such a manner that the voussoirs of each arch meet the voussoirs of its adjacent arch at the groin angle, where the faces of the angular voussoir in each course are wrought in such a manner as to form the curve of the groin, which springs from the angle of the pier on which the arches stand. The upper surfaces of these angular voussoirs are also wrought, so that on both faces they may coincide with the other stones of the same course, by which means these surfaces meet in a ridge which is always perpendicular to the curve of the groin angle. When the intended vault is to be built of brick, the internal faces of the brick voussoirs in each course are cut away at the groin angle, to receive the wedge-like end of a brick in the adjacent arch in the same course, in order to bind the arches together more firmly: (See Fig. 1.) But as bricks have not, like wrought stones, the form of a frustum of a wedge by which they may sustain themselves when arranged in the shape of an arch, their stability must depend upon the strength of the cement placed between them, which, uniting them into one mass, renders a structure of this kind a sort of vault hewn out of a rock.

PLATE CCLXI. Fig. 1.

From a consideration of the above mentioned mode of constructing groined vaults, it will be evident that the pressures, both vertical and lateral, of all the arches of which they are composed, are resisted and sustained by the mutual intersections of the courses of masonry at the groin angles; these intersections may be considered as squares upon the corners of the piers from which they spring, the side of the square being equal to the thickness of the course of voussoirs, so that the diagonal ribs of the vault form as it were two arches, which are kept in a state of equilibration, by the weight of the spandrils immediately over them, and serve as bases upon which the side arches with their spandrils, and all the superincumbent loading, ultimately rests; hence it will be evident, that if the weight of the arches, with their loading over them, were in a constant ratio to the weight necessary for keeping the ribs in a state of equilibration, the whole vault would be in equilibrio in all its parts. This, however, cannot be attained in practice, because the distances between the ribs at any part are never in proportion to the height of the spandrils over the ribs at those parts, and therefore the groined vaulting will always in some degree be defective in its equilibration; besides the disadvantage arising from the whole of the weight falling entirely upon the ribs, which receive no support from the voussoirs of the contiguous side arches, whose joints are all oblique to the directions of the ribs.

But as groined vaults are absolutely necessary in warehouses, and many other buildings, for the purpose of giving communication throughout the same in every direction, which cannot be obtained where waggon-head vaults are used; and as there is a great saving of materials, resulting from the arches bearing on piers only instead of parallel walls, it follows, that an improvement in their construction, which tends to bring them nearer to an equality in strength with the waggon-head vaulting, must be a great acquisition. This improvement has been lately made by Mr George Tappen, an architect of London, who, instead of the square piers hitherto used, has adopted octangular ones, (by which a considerable saving of room is made,) and has thrown stout ribs diagonally over the vault whose breadths are equal to the sides of the octagons on which they stand. The side arches, which in brick-work are set four inches back from the face of the ribs, in order to save the trouble and expence of cutting the groin angles, are worked into, and rest upon these ribs. By this improved construction, the ribs form a much stronger support for the weight of the incumbent vault, and the loading above, than by the old method, as the following comparison will shew.

Since the force of the superincumbent weight has been found by experience to act chiefly in the direction of the groins, they require the greatest strength that can be given them; at the same time, the side arches should be made to throw as little weight as possible upon them, particularly about the summit of the vault, that their tendency to fracture towards the crown may be diminished as much as the nature of the case will admit. In the groined vaults hitherto constructed, where the groins spring from the extreme corners of the square piers, their section, taken perpendicular to their length, forms a square, (see *a*, Fig. 2.) having one of its angles turned towards the centre of the curve, and its side equal to the thickness of the arches: whereas in the new vault, the section taken in the same manner, forms a rectangle equal in breadth to the side of an octagon inscribed in the square pier, and of a depth which may exceed that of the old groin in any proportion, (see *b*, Fig. 2.) Now, the strength of an arch, in its different points, is measured by the greatest weight which it is able to carry on those points without breaking; that is, it is in a ratio compounded of the triplicate ratio of the secant of the angle of the curve's inclination to the horizon, in its various points, and the reciprocal simple ratio of the radius of curvature in the same points. But since the relative strength of arches is to be determined by comparing them in their weakest parts, (namely the crown,) the strength of any arch at the crown will be reciprocally as the radius of curvature at that point, since the angle of the curve's inclination to the horizon at that point is always 0° 0′; or reciprocally as the span of the arches when the rise of them is the same, their thicknesses being supposed equal. From this it will be evident, that the strength of the diagonal ribs and groins will be directly as the areas of their sections, and distances of the centres of gravity from the place where the fracture would end, and reciprocally as the spans of the arches: that is, if A represent the area of the section, G the distance of its centre of gravity, and S the span of the arch; then the strength of one arch to that of another will be as $\frac{A\,.\,G}{S}$.

Let the side of the square pier be $= a$; then the thickness necessary for the side arches will be $= \frac{a}{4}$, which, consequently, will be the side of the square section of the groins in the old arch; its area, therefore, will be $= \frac{a^2}{16} = A$, and its half diagonal $= \frac{1}{2}\sqrt{\frac{a^2}{8}} = G$. The distance of the piers being $4.5\,a$, the span of the diagonal groins will be $= \sqrt{2 \times (4.5\,a)^2} = 6.364\,a = S$; we have therefore $\frac{A\,.\,G}{S} = \frac{\frac{a}{32}\sqrt{\frac{a^2}{8}}}{6.364}$ for the strength of the old groin.

The side of the square pier remaining still $= a$ in the new arch, the breadth of the rib $= \sqrt{2\,a^2} - a$, which is the side of an octagon inscribed within the pier, the thickness proper for the rib will be $= \frac{a}{3}$: then will $A = \frac{a^2\sqrt{2} - a^2}{3}$; $G = \frac{a}{6}$; and $S = 5.364\,a + \sqrt{2\,a^2}$; consequently $\frac{A\,.\,G}{S} = \frac{a^2\sqrt{2} - a^2}{122.004}$, the strength of the new rib.

If we assume $a = 4$ feet 8 inches, (the dimensions assigned by Mr Alexander to the piers of the groined vaults at the London dock tobacco warehouses,) the strength of the old groins will be to that of the new ribs as 5.44 to 10.64, which is nearly 2 to 1 in favour of the new construction; and this will be the case while the same proportions are preserved, whatever may be the extent of the arch.

If the side arches, with their spandrils, and the loading on the floor above, be cut by parallel vertical planes, (as at S, Fig. 2,) the sections will be to each other as their chords *c d* nearly; which being less in the new vault than in the old, on account of the greater breadth of the ribs, the weight incumbent on those ribs (which always tends to destroy their equilibrium) is just so much less in the former than in the latter, and consequently their tendency to fracture is diminished in the same proportion. Plate CCLXXXIV. Fig. 2.

It may not be improper to observe, that Dr Hutton recommends the stones of the wall, or spandril over the extrados of the voussoirs of an arch, to be bonded into the stones of the pier, and with one another; because the pier will then carry part of their weight, and thereby oppose a greater power of resistance to the thrust of the arch. For the same reason, it would be equally advisable, in the new method of building groined vaults, to carry up at the same time the diagonal ribs, side arches, and spandrils, well bonding the whole together into one solid mass; which will render vaults built in this manner a valuable acquisition in warehouses and other large buildings, where the greatest weights are to be sustained.

GRONINGEN, a town in Holland, and capital of the province of the same name. It is intersected by the river Hunes, which passes through it in a northerly direction to the sea. The town is large, rich, strong, and populous, and is adorned with many excellent buildings. It is nearly round, and is surrounded with good ramparts, a wall, and ditches, and has a citadel. Its university was founded in 1614, and endowed with the revenues of several monasteries The harbour can contain many vessels, which enter it by a canal about nine miles from the sea. It carries on a considerable trade in butter, horses, and horned cattle. There are some breweries in the town.

GROSE, Francis, a celebrated antiquarian, was born in 1731, and was the son of a jeweller at Richmond, who died in the year 1769, and left his son an independent fortune. He entered into the Surrey militia, and was appointed adjntant and paymaster; and such was his love of dissipation, that he soon squandered away the fortune which his father had accumulated. The distress to which he was now reduced, compelled him to have recourse to his talents; and having a fine taste for drawing, he began to collect materials for his *Views of Antiquities in England and Wales*, a work which he began to publish in numbers in 1773, and which was completed in 1776. Other two volumes, including Guernsey and Jersey, were completed in 1787. The success of this work induced him to embark more deeply as an author. In the summer of 1789, he made a tour through Scotland; and in 1790, he began to publish, in numbers, his *Antiquities of Scotland*, which were completed in two volumes 4to. In the year 1791, Mr Grose set out for Ireland, with the view of collecting materials for an account of the antiquities of that country; but soon after his arrival at Dublin, he was seized with an apoplectic fit, of which he died, on the 6th of May 1791, about the 60th year of his age. Mr Grose was remarkable for his good humour, conviviality, and friendship. He was extremely corpulent, and altogether singular in his external appearance. A likeness of him, at full length, is given in his Olio, published after his death.

The following is a list of his works: 1. The Antiquities of England and Wales, 8 vols. 4to. and 8vo. 2. The Antiquities of Scotland, 2 vols. 4to. and 8vo. 3. The Antiquities of Ireland, 2 vols. 4to. and 8vo. 4. A Treatise on Ancient Armour and Weapons, 4to, 1785. 5. A Classical Dictionary of the Vulgar Tongue, 8 vols. 1785. 6. Military Antiquities; being a History of the English Army from the Conquest to the present time, 2 vols. 4to, 1786, 1788. 7. The History of Dover Castle, by the Rev. William Daniell, 4to, 1786. 8. A Provincial Glossary, with a Collection of local Proverbs and popular Superstitions, 8vo, 1788. 9. Rules for drawing Caricatures, 8vo, 1788. 10. Supplement to the Treatise on Ancient Armour and Weapons, 4to, 1789. 11. A Guide to Health, Beauty, Honour, and Riches; being a collection of humorous Advertisements, pointing out the means to obtain those blessings; with a suitable introductory Preface, 8vo. 12. The Olio; being a Collection of Essays in 8vo, 1793.

GROTIUS, Hugo, one of the most profound and enlightened scholars, and one of the most remarkable men of his age, was born at Delft in the United Netherlands, on the 10th of April 1583. The name in Dutch is *De Groot* or *the Great*; and as it had for many ages been the patronymick of one branch of his ancestors, the circumstances which led to its adoption are unknown. But few families have better merited such a distinction, if greatness be estimated not by external rank and honour, but by those intellectual and moral endowments, which far surpass in value all the gifts of fortune. The family of Grotius had been illustrious at Delft for four centuries, and he himself in the estimation of his own age and of posterity, pre-eminently merited the surname of *Great* among the *great*. He did not descend, however, in the uninterrupted male line from that family; for it is related, that about the year 1430, Dederic De Groot, burgomaster of Delft, and a highly distinguished member of the family, had an only child, a daughter named Eremgard, whom he left a wealthy heiress. This young lady was sought in marriage by Cornelius Cornetz, who sprung from that branch of the noble family of Cornetz, which, under the Dukes of Burgundy, had emigrated from France into Holland. The lady favoured his addresses, but under this stipulation, that should there be any children of the marriage, they should take the name of her and her ancestors, *De Groot*. The first who, in conformity to this agreement, bore her name, was Hugh, grandson of Dederic, and grandfather of the subject of this article. One of the sons of this Hugh was Cornelius De Groot, born in Delft in 1544. After acquiring much learning at his native place, he prosecuted his studies, literary and mathematical, with great ardour at Louvain and Paris. He delighted in the philosophy of Plato. He then applied himself to the civil law at Orleans, and on his return to Delft, betook himself to the bar, and afterwards filled several important offices. In 1575 he was appointed professor of philosophy in the university of Leyden, which dates its origin from about that time, and which has since been so celebrated in the republic of letters. He afterwards taught the civil law in that seminary, and evinced his preference for the quiet pursuits of learning, by refusing a seat in the great council of the States, though that appointment was repeatedly pressed on his acceptance. He died without issue in 1601. Hugh De Groot had another son, John, who also studied law. He was appointed burgomaster of Delft, and afterwards curator of the university of Leyden. He was an elegant scholar and a poet. But his chief claim to the remembrance of posterity is, that he was the father of our Hugo Grotius, to whom it is now proper to direct our attention.

This illustrious man was born, as we already stated, at Delft in 1583. His mother's name was Alide Overschie, and the family to which she belonged was of some note. Endued by nature with admirable talents, he enjoyed from his infancy the advantage of an excellent education. When he was only seven years of age, he was placed under the tuition of masters, with whom he made such extraordinary progress, that before he had completed his ninth year he composed verses which obtained the approbation of the learned. At twelve he was so great a proficient in the knowledge of the classics, and of *belles lettres*, that he was qualified to pursue his studies at the university. He was accordingly sent in 1595 from Delft to Leyden, where he spent three years in the study of mathematics, philosophy, theology, and law, and excelled in the knowledge of each of these sciences. He was only fifteen years old when he wrote a commentary on a very difficult Latin poet, Marcianus Capella. The celebrated statesman, John Barnevelt, attorney-general of the republic of Holland, having been, in 1598, appointed ambassador to France, the young Grotius accompanied him thither. Henry the Fourth, who then reigned in France, gave him most gratifying marks of his esteem. The monarch presented him with a gold chain, and a portrait of himself; and it is said that he was so highly pleased with such attention, that he caused his own portrait to be engraved, adorned with these tokens of royal favour. While he remained in France, he obtained the degree of Doctor of Law at the early age of sixteen.

On his return to Holland, Grotius, in compliance with his father's desire, entered on the profession of law; and at the age of seventeen, he began to plead with distinguished ability and success. He retained his fondness, however, for classical and literary pursuits, and continued to prosecute his general studies with ardour in those intervals of leisure which his laborious profession allowed, and which supplied the place of recreation, chiefly by affording a change of employment. When he was in his 24th year, he was appointed attorney-general of Holland, Zealand, and West Friezland, and filled his high office with such talents and integrity, that the salary attached to it was augmented.

In 1613 he removed to Rotterdam, to engage in the duty of pensionary, or chief magistrate of that city, as successor of the recently deceased Elias Barnevelt, brother of John, his early patron and friend. At this time, religious controversy ran high in the United Provinces between the Calvinists, or Gomarists as they have been called, from Francis Gomar of Bruges, and the Armenians, especially with respect to grace and predestination. Grotius, amidst the heat of the contending parties, conducted himself with such prudence and moderation, as to retain for a considerable time the respect of both. He was also admitted into the assembly of the states of Holland; and as he had written in defence of the right of the Dutch to trade with India, he was sent to England, to adjust the differences which had arisen between the merchants of the two countries. He succeeded in the object of his mission, and received marks of regard from James I. At his return home, he found the United Provinces divided and distracted by quarrels about religion; and while he had the affliction to see that true patriot and able politician John Barnevelt sacrificed to a faction, under the pretence of treason and heresy, to gratify its own ambitious projects, Grotius himself most narrowly escaped sharing his melancholy fate. Barnevelt was tried by twenty-six commissioners deputed from the Seven Provinces, and, in terms of the sentence of this cruel tribunal, was beheaded in 1619. Grotius, who had been warmly attached to him, and who was suspected, by the bigots of the day, of favouring the Armenians, was involved in his disgrace. He was arrested in August 1618, and in May following was condemned to perpetual imprisonment, and to have all his property confiscated. He was strictly confined in the castle of Louvestein, near Gorcum. "Here he remained," says Dumourier, "without any other consolation than the company of his wife, and of books which his friends were permitted to send to him. A large trunk was usually sent filled with books, which he returned after having devoured them, (*apres les avoir devorés,*) and it was during this imprisonment that he translated Stobœus. But his confinement lasted only about two years, as he was happily delivered from it by the address of his wife, Mary Reygelsberg.* She having remarked, that his guards (tired with frequently searching the great chest filled with linen or books, that passed between the prison and Gorcum) allowed it at length to be transmitted without opening it, advised her husband to place himself in it, after having made holes with a wimble in the part of it over his face, to allow him to breathe. He entered into the scheme, and was thus carried to the house of one of his friends at Gorcum, whence he went to Antwerp by the ordinary conveyance, after having passed through the market-place at Gorcum, disguised as a mason with a rule in his hand. His wife, who had so dexterously managed the affair, pretended that her husband was much indisposed, in order to afford time for his escape; but when she supposed him to be in a place of safety, she told the guards that the bird was flown. It was at first intended to prosecute her, with a view of having her confined in her husband's stead; but she was liberated by a majority of votes, and she was universally praised for having restored her husband to freedom. This took place in March 1621." Dumourier *Memoires de Hollande.* Grotius thus happily delivered, secretly left Antwerp in the following month, and repaired to France, where he experienced powerful protection, and was introduced to Louis XIII. who bestowed on him a pension of 3000 livres, which he enjoyed for about ten years. Prince Maurice, the enemy of Barnevelt, and persecutor of Grotius, died in 1625; and it is a circumstance highly honourable to Grotius, that in his History of the Netherlands, from the departure of Philip II. till 1608, which was not published till after the author's death, he relates the splendid achievements of this prince with the utmost fidelity, and without alluding to the harsh treatment which he had suffered from him. The brother of Maurice, Prince Henry Frederic, entertained the most friendly disposition towards Grotius, and would gladly have recalled him, but was deterred by the jealousy of his political opponents, which still existed with unabated force.

Many attempts were in the mean time made, but, happily for the best interests of learning and humanity, without success, to excite prejudice against him in the breast of his powerful protector Louis. That prince was not to be influenced by such unworthy efforts; but, on the contrary, his respect for Grotius increased, by observing the unabated love which the illustrious exile bore towards his ungrateful country. He employed much of his time while in France in reading and composition, and increased the resentment of his enemies who then prevailed in Holland, by his admirable defence of the deposed magistrates.

In 1631, his pension from the French court was withdrawn, whether from motives of public economy, or from ministerial pique, or from what other cause, cannot be ascertained. He soon after ventured to return to Holland, confiding in the friendship of Prince Henry Frederic. But, through the malice of his enemies, he was condemned anew to perpetual exile. Finding himself cruelly compelled to leave his native land, which he still fondly loved, he repaired to Hamburgh, where he received the most gratifying offers of protection from the kings of Denmark, Poland, and Spain, accompanied with solicitations from each, that he would attach himself to his court. He preferred, however, the patronage of Gustavus Adolphus, king of Sweden, whose death, in 1632, obliged him for some time to remain unemployed in Hamburgh. Queen Christina fulfilled the wishes and intentions of her predecessor; and in 1634, appointed Grotius one of her counsellors. She soon after nominated him to be her ambassador at the court of France. This new diplomatic appointment displeased Cardinal Richelieu, then prime minister of Louis XIII. and he used his influence with Oxenstern, the chancellor of Sweden, to have him recalled. Grotius, who had remained in retirement at St Denis till the ulterior pleasure of the Swedish court should be known, made his formal entry into Paris as Swedish ambassador in March 1635. After having spent eleven years in France, he was, in consequence of his own request, recalled, and having occasion to pass through Holland in his way to Sweden, he was received at Amsterdam with every mark of respect and honour; for many of his enemies had retired, or were dead, and several of his friends were restored to offices of public trust. The account which he gave to the Queen of Sweden of the affairs connected with his embassy, pro-

* Dumourier writes her name Reygelsberg, as in the text; but in a marginal note in Bayle's Dictionary, she is called Reygersbergen.

ved highly satisfactory; and anxious as he was to retire from public life, she would have gladly retained him in her councils; but the jealousies of her courtiers inducing him to persist in his desire, she at length consented. She made him, when on the eve of his departure, a present of twelve thousand rix-dollars. Stress of weather driving the vessel in which he embarked for Holland upon the coast of Pomerania, he was put ashore in a bad state of health, intending to finish his journey by land. He was unable to proceed farther than Rostock. Calumnies, with regard to the soundness of the religious principles of Grotius, and the state of his mind at his death, were officiously published by his enemies; but they are satisfactorily confuted by John Questorpius, professor of theology, and minister of Rostock. This learned and pious man wrote a letter, which is still extant, giving a pleasing account of the chearful resignation and Christian piety by which the close of his valuable life was characterized. He expired at Rostock, on the 28th of August 1645, in the 63d year of his age. The remains of this great and good man were embalmed, and removed to Delft, where they were committed to the sepulchre of his ancestors. His wife appears to have survived him. He left three sons and a daughter. The eldest son Cornelius, who wrote elegant Latin verses, was for some time employed by Oxenstern in Sweden. The second, Dederic, was aide-de-camp to Duke Bernard of Weimar, and was assassinated in a tavern by his valet. The youngest, Peter, was appointed by the Elector Palatine to be his resident with the states general; and, by the favour of the De Wits, he was made pensionary of Amsterdam. After having been employed in different political embassies for Holland, he was tried for alleged offences against the state, and was acquitted. He died in retirement at the age of seventy. Cornelia, the daughter of Grotius, was married to M. de Mouthas, who served with eclat in Holland; but being involved in the fall of the De Wits, he quitted that country in 1672.

The multitude of works which Grotius left behind him on various subjects, prove him to have been an universal and profound scholar, and a man of the most indefatigable industry. It is not without astonishment that we contemplate the literary labours of one, whose private misfortunes and public duties might have been supposed to leave him little inclination, and less leisure, for the calm pursuits of philosophy and science. His mind was amply stored with the treasures of ancient and modern learning, and his excellent memory enabled him to retain and employ, as occasion might require, the knowledge which he derived from his books. It is indeed related of him by Borreman, in proof of his wonderful memory, though we must be permitted to doubt the accuracy of the anecdote, that Grotius having been present at the review of a regiment, recollected the name of every individual belonging to it.

It would be tedious to give a catalogue of the works which are known to have proceeded from his pen, most of which were published during the life of the author, as they amount to seventy-four or seventy-five. As his writings, however, exercised a powerful influence, not only over his contemporaries, but have continued, and still continue, to influence the policy of nations, and the opinions of scholars and philosophers throughout the civilized world, we shall mention the names of some of the most remarkable, and add a few occasional reflections on their value. Considering him, then, as an author, we may, for the sake of arrangement, notice some of those compositions which exhibit him respectively as a scholar and poet, a patriot, a philosopher, a philanthropist, and a theologian. It is to be premised, that his works were generally written in the Latin language, which in his time, and for ages after, formed the chief medium of communication among the learned of all the countries of Europe.

In viewing Grotius as a scholar and a poet, we may mention the following works:

1. *Poemata nonnulla, seu Characteris Pontificis Romani*, &c. &c. 4to, 1599.

2. *Marciani, M. F. Capellæ Satyricon, seu de Nuptiis Philologiæ et Mercurii, libri duo emendati et notis illustrati*, 8vo, 1600. This learned publication, from so young an author as Grotius, was among the first things that brought him into notice, and gave a most auspicious promise of his future greatness.

3. *Mirabilium anni* 1600, *quæ Belgas spectant*, &c.; a poem in 4to.

4. *Adamus Exul*, tragœdia, 8vo, 1601. This work was printed when the author was only eighteen, and about seven years before the birth of Milton. Whether or not this tragedy may have suggested the idea of *Paradise Lost*, or how far he, Milton, may have availed himself of it, we have not at present the means of ascertaining But the choice of this subject by two such eminent contemporaries, is an interesting coincidence in the history of literature

5. *Christus patiens*, tragœdia, 8vo, 1608. This tragedy was translated into English by George Sandys, with notes, in 1640. A German writer used it as a model for the illustration of the rules of tragedy; and Curpzovius, Professor of Poetry at Wittemberg, made it the theme of some of his lectures.

6. *Commendatio Annuli*, (a poem) 4to, 1609 7. *Lucani Pharsalia*, cum notis, 4to, 1614. 8. *Exerpta ex Tragœdiis et Comœdiis Græcis*, &c.

In the biographical sketch, we have had occasion to mention the ardent love of country which characterized Grotius, amidst all the sufferings and varieties of his life; and we noticed two of his works relating to his native land, the one of a historical, the other of a commercial nature. The title of the latter of these, and of the answer to it, are curious, and particularly when we consider them in connection with the political events and speculations which have marked the close of the eighteenth, and the opening of the nineteenth century, both on this and the other side of the Atlantic. It is called *Mare Liberum, seu de jure quod Batavis competit, aut Indica commercia*, 8vo, 1609. It was at first printed anonymously, was then translated into Dutch, and passed through many editions. After the lapse of some years it was answered by John Seldon, in a composition entitled *Mare clausum, seu de dominio maris*, Lond. 1635. To this attack, Grotius, in so far as we have been able to discover, made no reply. Grotius published in 4to, A. D. 1610, his work *De Antiquitate Reipublicæ Batavicæ*. Also, a Discourse pronounced in the Senate of Amsterdam, upon the views of the States of Holland respecting the Reformed Religion. In the Dutch language, 4to, 1616.

But it behoves us now to speak of the great work upon which the fame of Grotius chiefly rests, which exhibits him as a citizen of the world, and which forms the beginning of a great era in the history of political philosophy. The work to which we allude was written in France, at the instigation of his friend Peireskius, and printed at Paris, in 4to, in 1625, entitled *De Jure Belli et Pacis*. The President Jean Jacques de Mesmes gave him the use of his country house Balagni, that he might have leisure and retirement for the composition of this work. The author dedicated it to Louis XIII. and he quickly attained by it a splendid height of popularity and fame. It was revised and improved by Grotius, and translated into many languages. Under this title he has attempted to give a complete system of natural law, and to evolve from the mass of precedents and particular statutes, which constituted the chief study of the lawyers of his time, many of those general maxims which should enter into the principles of legislation, and regulate inter-national transactions, as well as to point out their foundation and sanctions in the nature of man, and in the constitution of human society. His work partakes, in some respects, of the prejudices of the age in which it was written, and, particularly, of an overstrained reverence for the institutions of the Roman law. It is also overloaded with quotations and authorities from classical writers, from the Mosaic law, from other parts of scripture, and from various writers sacred and profane, by which the mind of the reader is often perplexed rather than enlightened; and the diffuseness of the notes forms a curious contrast to the brevity and obscurity of the text. Puffendorff, for whom a professorship was formed at Heidelberg, for the express purpose of extending the knowledge of the doctrines of Grotius, is deemed the most eminent of his disciples and commentators. These doctrines have been since taught almost to our own day, in the most celebrated universities of Europe, and, in the opinion of respectable judges, form the foundation of the ethical and political philosophy of the present times. Bayle has justly remarked, that Grotius must be deemed particularly fortunate as an author; and that, fifty years after his death, this work obtained for him an honour, which was not bestowed upon the ancients till after many ages, namely, that he appeared in it *cum commentariis variorum*.

We have space only farther to mention, that, besides several treatises connected with religion and the controversies of the day, Grotius distinguished himself by a popular and a philosophical work in defence of Christianity. The first of these was entitled, Proofs of the True Religion. It was written in Dutch verse, with the benevolent designs of furnishing innocent and useful employment to the minds of his sea-faring countrymen in long and tedious voyages; and of enabling them to maintain their stedfastness in their own faith, and, as opportunities might occur, to explain and recommend it to the foreigners with whom they might have intercourse. The other work to which we have alluded, is the celebrated treatise *De Veritate Religionis Christianæ*, which was published at Paris in 1639, and dedicated to his friend Bignonius. The plan of this work is comprehensive, the style frequently obscure, and the notes unnecessarily copious and minute. Yet, as it was among the first works of the kind which were published, and as it contained much new and excellent argument and illustration, it has been translated into all the European languages, referred to in most works on the same subject, and preserves its estimation as a standard work on theology at the present day. (*l*)

GROTTO, is a subterraneous fissure or opening in the earth, generally adorned by calcareous incrustations, which produce a brilliant effect when illuminated by torches.

Mountainous and volcanic countries, or those regions which are partitioned into many islands, more frequently exhibit grottos, caverns, or fissures, than low or level grounds. They are also common in places subject to earthquakes, and have the greatest extent and intricacy in countries where huge masses of limestone abound.

The most celebrated grotto for beauty, size, and magnificence, is that of ANTIPAROS, an island of the Mediterranean, already described in the previous part of this work; and that which is reputed next to it is of recent discovery in the island of Skye, among the Hebrides of Scotland. It had been long known to the islanders, that the mouth of a cavern called *Slochd Altriman*, or the *Nursling Cave*, opened among the cliffs overhanging the sea on the south-west shore, and that a particular tradition was annexed to its history. But none ventured to explore its recesses, until, in the year 1808, the masculine intrepidity of a lady, Mrs Gillespie, exposed to more timid adventurers what has been called one of the most remarkable phenomena, which exists in the structure of the earth.

Grotto of Antiparos.

Grotto in the island of Skye.

This cave comes under the particular description of a grotto; for, it may be observed, that a cave and a cavern, between which some authors even make a distinction, properly implies a subterraneous vacuity without incrustations. The land above *Slochd Altriman* is of moderate height; but, from the shore consisting entirely of perpendicular rocks, the entrance can be reached on foot only at low water, and then with particular difficulty. When the tide is up, however, a boat can easily approach it, unless the wind should render such an attempt dangerous from sunken rocks, and dislocations of stony masses from the cliffs. The grand access to the cave is formed by two immense walls of free stone, separated thirty feet asunder, rising above 100 feet in perpendicular height, and stretching out in a straight line from the shore. Here the tide flows in about 400 feet; but, at low water, the bottom is rough, and covered with slippery weeds. These obstructions being surmounted, a magnificent rugged arch, of a Gothic form, is presented to the spectator, and on one side an inferior cave with many lateral crevices. This great aperture is embellished with innumerable dark green stalactites of various sizes; some descending to the ground, and forming pillars overgrown with moss, which, with the intermixture of vivid foliage, brown heath, and wild flowers, produces an interesting combination. Close to the entrance of this grotto, there is, as it were cut out of the stone, a small fountain of pure water, surrounded by rocky pillars, and the water collected in the cistern is derived from the exudation of the rock above. A passage about nine feet broad, and from fifteen to twenty in height, conducts the visitor almost on a perfect level for twenty yards, when a steep ascent for 55 feet leads up a bank of earth, sand, and small broken whinstone, another acclivity now commences, more difficult to overcome, of irregular surface, resembling a solid cascade, or frozen snow, and sparkling with crystallizations. Advancing a few yards, the principal entrance to the interior grotto is gained, eight feet broad, and twelve in height, universally white as marble, and variously decorated with beautiful incrustations. Thousands of icicles of pure white spar are suspended from the roof like the festoons of a curtain, giving the whole a finished appearance. The breadth, on proceeding still farther, enlarges to ten feet, and the height to forty, while the white marble spar continues rough and uneven; and it is only after traversing thirty-five feet of this gallery, that the proper excavation, which has been denominated the *Spar Cave*, is reached. It consists of a circular vacuity about twenty feet in diameter, with a lofty roof, and a pool at the bottom, contained in a marble cistern. But the whole is said to exhibit the most brilliant spectacle which imagination can conceive. The sparry concretions are innumerable, and in every variety of form; while the lights, by which the specta-

Grotto in the island of Skye.

tor examines them, are reflected from a thousand glittering points. Many of the surrounding objects, formed by the calcareous depositions, are compared to animate and inanimate substances of various descriptions. To the right is the resemblance of a monk, as if kneeling on a cushion, with uplifted hands, and large as life. Behind it appear several semblances of busts; and at a distance are seen the images of various animals, together with an exact representation of a fleece. But among the whole, the monk excites the greatest attention. The head is bare, after the monastic fashion; the face is supposed to be distinct; the shoulders are in just proportion; and the drapery of the robe enveloping the body is alike beautiful and correct. Figures of vegetables are every where formed; and numerous columns, some apparently supported by distorted beings, seem to sustain the roof, which resembles a pure white cloud suspended in the air. Portions of it, however, descend in stalactites; which, together with the crystals in the interstices of the columns, emit fine coruscations from the lights below.

Another rugged declivity, similar to that which conducted the spectator to the cave, leads down to the pool, which is sixty-five feet in circuit, five feet deep, and of cooler temperature than the external atmosphere. It resembles a large marble bath of pellucid water, the bottom and sides being of the purest white. It occupies so much of the base of the grotto, that a person cannot walk round it. On its margin the spectator finds himself standing in a magnificent apartment, wholly consisting of the most brilliant spar glittering on all sides, and emitting myriads of rays, which are reflected from the bottom of the pool. In some grottos and caverns of other countries, there is a constant supply of water, which is generally discharged by a stream running towards the entrance; but here there is no visible outlet, and the quantity of water in this reservoir is not observed to decrease. Crossing the pool on a plank, a gallery of great height, but only three feet wide, is found, which leads to farther passages imperfectly explored. Its entrance is formed by two large columns of pure spar; that on the left of rustic conformation, six feet in circumference, and sixteen high; but that on the right rather resembles a work of art. It is of more surprising structure, and more elegant appearance, than any of the figures which the spar of this grotto has assumed. The shaft is twenty feet in length, nearly cylindrical, and its thickness in general about two feet and a half. It stands on a regular circular base rising from the floor, and projecting about twelve inches round its circumference. A series of sections seems to constitute the whole column, each twenty-two inches in length, and divisible into two distinct portions; the upper one being a crystallized mass of stalactites, while, in its general aspect, the under part resembles the foliated carvings of the Corinthian or Composite capital inverted. On more minute inspection, this division is found to display the most methodical arrangement of structure, in the formation and insertion of the foliage of sparry concretion; and the interstices of the leaves are of such dimensions, as to admit of complete inspection of the interior of the column, which proves a combination of the same foliated incrustations as the exterior. Passing by these pillars, the width of the gallery is somewhat enlarged, the sides still exposing elegant and numberless crystals, emitting a dazzling lustre. The floor also is of white marble, but of more singular conformation than in any other part of the cavity. Part of it rising from the rest resembles a piece of lace, and consists of many concretions on one side, while the other is quite smooth, and entirely covered with shining crystallizations, the waved interstices of which are full of water. These beautiful productions abruptly cease at the distance of about 250 feet from the mouth of the cave, and the bare black rock is exposed. Although farther recesses exist, they have not yet been explored.

Several singularities regarding this remarkable grotto being peculiarly interesting, ought not to be overlooked. Its formation is concluded to have resulted from the separation of immense dykes of whinstone, while freestone constitutes both the floor and the roof. Although no considerable stratum of limestone is seen in the neighbourhood, there is a prodigious accumulation of spar entirely calcareous within. The crystallizations are of the most complete kind, free from every imperfection, and white and beautiful. Water is constantly exuding from the whole roof; and it is likewise universally suffused over the incrusted surface of the spar, which is always moist to the touch. But this humidity augments the brilliancy of the coruscations, and is the source of the water contained in the marble cistern. The endless variety in which the sparry incrustations appear, is one of the greatest ornaments of the grotto; and the infinite combinations and modifications of it are alike brilliant and interesting. Sometimes it is disposed in foliage or flowers; sometimes in busts or columns; and the interior, of tubulated stalactites, is studded with innumerable crystals converging towards the centre. It may seem idle to speak of traditions of the ninth century, but we shall only observe in illustration of the name *Slochd Altriman* or the *Nursling Cave*, that it is said to have afforded refuge to a youthful female, who had become the victim of a feud which estranged the parents of her and her lover, the young chief of Colonsay. Separated from him, she was delivered of a son, who was carried to *Slochd Altriman*, whither his mother retired to nurse his infancy; and thence the name of Nursling Cave.

Penpark Hole.

On the 17th of March 1775, the Rev. Mr Newnham, a young clergyman of Bristol cathedral, accompanied by a gentleman and two ladies, went to visit a chasm in the ground called Penpark Hole, about three miles from that city. Wishing to sound its depth with a line, he advanced a short way into the upper part of the opening declivity, which is not steep, in order to give it a freer cast, and, for greater security, held by the twig of a tree, spreading across the chasm. Unhappily, in accomplishing this, his feet slipped, owing to the humidity of the earth, and he was precipitated headlong into a frightful abyss, before the eyes of his terrified companions. An accident so distressing, gave birth to many speculations respecting the caverns where it had happened, particularly as the body of the sufferer was long the object of a fruitless search; but at last some hardy adventurers having resolved on descending, discovered a great accumulation of water at the bottom, and a stone thrown down being interrupted in its fall, disclosed the spot where the body still floated, 39 days after the catastrophe. It is difficult to explain the figure of this, or indeed of any other cavern, without drawings; therefore we shall briefly observe, that the access to Penpark Hole is by two separate chasms in the ground, leading by a declivity to the interior. After passing different lateral vacuities, one of which has a spacious vaulted roof, the adventurer reaches the most extensive recess, branching into an oblong irregular space, 225 feet long, by 123 in width. Below it are other recesses, and the bottom of the whole, which, if we rightly understand the description, is more than 200 feet from the surface of the earth, is covered with water, varying in depth from 6 to 50 feet, but clear, and good, and free from any peculiarities. All the cavities are of extremely irregular formation, in general presenting a rocky surface, or sparry incrustations, and the floor is described as in some places to consist of "a kind of white stone, enamelled with lead ore." The subterraneous communication between the external mouths is extremely narrow, and was first explored by Mr White, a land-surveyor, who, with much hazard and difficulty, forced his way through, by crawling on his belly. But even now, should a stone be displaced in the undertaking, the adventurer would inevitably be buried alive. Penpark Hole was visited in 1669 by Captain Sturmey, and in 1682 by Captain Collins. The former was accompanied by a miner, who, penetrating one of the galleries to a considerable distance, exclaimed that he had found a rich mine; but his joy was suddenly converted to astonishment, for he returned affrighted by the sight, as he said, of an evil spirit. No inducement could prevail on him to revisit the place, and Captain Sturmey himself sickened four days after and died. In consequence of the accident above related, it was more particularly examined by several individuals; but more minutely by Mr Catcott and Mr White, the latter of whom has drawn a section of it.

Derbyshire caverns.

Great Britain abounds with caverns, and especially the county of Derby. Here there are no less than 28 of some celebrity, and some of lesser note. Several have already been alluded to in our notice of that county, as that stupendous recess now converted from a rude and coarse appellation, to the Devil's Cave, or Peak Cavern, Elden Hole, and Poole's Hole, whence we shall restrict our observations to an abstract of Sir Richard Sullivan's adventure in the Three Mile Cavern.

Three Mile cavern.

This is an immense vacuity that has partly been effected by art, and which receives its name from its supposed extent. The descent is accomplished with much difficulty for 420 feet, and introduces the spectator to two or three lofty caverns, beautifully enamelled with spar. "Penetrating still farther," Sir Richard says, "we forced our way with infinite struggles, through a narrow space between two rocks, and thence getting on our hands and knees, were, for the full distance of a mile, obliged to crawl without ever daring to lift up our heads, the passage being both low and craggy; and as it was likewise filled with mud, dirt, and a multitude of bits of rock, our progress was painful indeed; we still, however, hoped for something better. On we accordingly proceeded, till a dreadful noise rumbling along the horrible crevices of the cave, gave us to understand we were near a river. To this then we hurried; but description is inadequate to any thing like a representation of the scene; a vast ocean seemed roaring in upon us; in some places bursting with inconceivable impetuosity; and at others falling through dreadful chasms, burst into shaggy forms to give it vent." It appears that this subterraneous stream is deep, and has a long course; but whether it is absorbed in the earth, or finds a passage to the surface, is not explained. After having underwent many dangers and difficulties, not unattended with personal injury, the author concludes his narrative in these words: "Altogether the depth we had descended was about 140 fathoms, or 980 feet, and the length about three miles, according to the miners calculation. Neither at this distance were we at the end; a passage still continued; but so filled with water, and so full of peril, that the miners themselves were averse to further trial." Possibly the number and size of British grottos and caverns, exceed those within the same bounds of any other country with which we are acquainted; nor are we aware that any spacious recess, (with the exception of the cave in Kentucky,) opening directly from the earth, has been penetrated 2250 feet, as the Devil's Cave of Derbyshire.

Madison's cave.

In the limestone country of Virginia in North America, are several caverns of some extent, among which the most celebrated is Madison's cave on the north side of the Blue Ridge. Its entrance is about two-thirds high in a moderately elevated hill, into which it extends about 300 feet, branching out into subordinate caverns, sometimes ascending a little, but more generally descending, and at length terminates at different places in two basons of water of unknown dimensions, that are never turbid. The vault of this cave is of solid limestone, from 20 to 40 or 50 feet high, through which water perpetually percolates; and trickling down its sides, has incrusted them with elegant drapery, or dripping from the top, generates conical stalactites both above and below.

Great cavern in Kentucky.

Another cave, about 8 or 9 miles long, and with many branches, has lately been discovered in Kentucky. It is covered with stalactites; and a very remarkable mummy was found within it at a considerable distance from its mouth. See KENTUCKY, where we propose to give a full account of this interesting cavern.

Grottos in India.

Besides those curious excavations on the western coast of the Indian peninsula, some interesting caverns occur in that great range of mountains, which, traversing Cochin China, penetrates the neighbouring countries. The inhabitants retreat thither, or conceal their effects in them during the time of war, and they are also kept concealed to avoid the expensive visits of the great men of the country. A naturalist, the late historian of these regions affirms, would here find ample scope for observation: the caverns are full of petrifactions and crystallizations of various colours: immense halls are formed, wherein may be seen the resemblance of altars or thrones; and quantities of fruits appear ready to drop from their trees. One most remarkable grotto traverses a mountain throughout: its entrance and its exit being terminated by two fertile plains. The bottom is covered with water, which may be navigated by vessels; and the roof, which is very lofty in some places, decreases elsewhere to 8 or 10 feet. There is another in the same chain of mountains of vast extent, but abounding in deleterious exhalations; and the water of a canal covering its bottom, is dangerous to be drank. No one has hitherto ventured to explore its most distant extremities.

Grottos in Italy.

In various parts of Italy, we find several famous grottos, though less celebrated for their extent than from some other peculiarities; and although known by the name of grottos, no crystallizations are seen in some of them. In Naples there is a spacious cavity, called *Grotto dei Funaioli*, or the Rope Makers Grotto, because its entrance has long been devoted to this useful purpose. The roof exhibits a rent, said to be the effects of lightning, and in other respects presents a menacing but imposing aspect, though the inhabitants carry on their operations in the most perfect confidence.

The grotto of Pausilippo near Naples, is a great excavation, partly artificial, penetrating the mountain of that name 2316 feet. It is 89 feet high in the most lofty part, 24 where lowest, and about 22 in breadth, traversing volcanic tufa. The date of its formation is

Grouse || Guadalaxara.

unknown; but in modern times, Don John of Arragon, Viceroy of Naples, and Peter of Toledo, under Charles V. brought it to its present state, and now it serves for an ordinary, though disagreeable road from the city, with a glimmering light from two apertures above.

Grotto del Cane.

In the side of a hill, beside the lake Agnano, in Italy, there is an artificial excavation, unskilfully executed, called the *Grotto del Cane.* It is of limited dimensions, being only twelve feet deep, four broad, and nine in height at the entrance, but always decreasing as it recedes. The celebrity of this grotto, which has long been known, is owing to pestilential exhalations arising from the earth; and it receives its name from the animal which is usually selected to demonstrate their presence. If a dog be brought within the sphere of the deleterious vapour, which remains within eighteen inches of the surface, its respiration immediately becomes affected—the abdomen contracts—the eyes are fixed—and the tongue, now of a livid hue, hangs out during the first minute, while, in the next, the animal is totally deprived of motion. Death would inevitably follow, but, on being speedily withdrawn, the lungs resume their play, and the creature gradually recovers its wonted strength and vigour; nevertheless a severe shock is sustained, as the same dog cannot support the experiment above twelve or fifteen times without destruction; in which event it dies in convulsions. The Abbe Nollet, on stooping to inhale the vapour, felt as if he had swallowed boiling water on the first inspiration, yet producing no painful sensations. On lowering his face, a kind of suffocation was experienced; and probably, had the experiment been continued longer, dangerous consequences would have ensued. The vapour is whitish, and possesses some degree of heat: It never rises above eighteen inches from the earth; and a torch immersed in it is extinguished, while the black smoke rolls over its surface without penetrating deeper. GROUSE. See Ornithology *Index.*

GRUYERES, is the name of a small town of Switzerland, in the canton of Friburg. It is situated at the foot of the mountains of this canton. The territory of Gruyeres, is 8 or 10 leagues long and 4 broad; and it is principally celebrated for the excellence of its cheese, which is esteemed the best in Switzerland. The best is made in the pastures of Molesson, and in the mountains of the vallies of Bellegarde and Charmey. It sells at 2½ louis per quintal; and the merchants of the country sell it at 6 batz, or 18 French sous per pound. There are large magazines of this cheese at Bulle, a town about a league from Gruyeres. The view from the summit of the Mollesson, which is near the town, is very grand. It may be ascended in three or four hours.

GRYLLUS. See Entomology.

GUADALAXARA, an intendancy of New Spain, and part of the kingdom of New Gallicia, is situated between 19° and 23° North Latitude. Its greatest breadth, from the port of San Blas to the town of Lagos, is 100 leagues; and its greatest length from south to north 118 leagues. It is traversed from east to west by the Rio de Santiago, a considerable river, which communicates with the lake of Chapala. It contains two cities, six villas, and 322 villages. The principal city Guadalaxara, the residence of the intendant, the bishop, and the high court of justice, is situated on the left bank of the Rio de Santiago, and contains about 20,000 inhabitants. San Blas, a sea port, and the residence of the marine department, is situated at the mouth of the Santiago, and is a very unhealthy place. The eastern part of the province is the Table Land, and western declivity of the Cordilleras of Anahuac. The maritime district, especially towards the great bay of Bayonne, is covered with forests, and supplies excellent timber for ship-building. The interior of the country enjoys a temperate and salubrious climate. The Volcan de Colima, in the northern extremity of the province, is the most western of the volcanoes of New Spain, which are placed in one parallel on the same line. It is estimated to be 10,000 feet in height, but is rarely covered with snow. The lake of Chapala, in the vicinity of Guadalaxara, is nearly 160 square leagues in extent. The superficial extent of the province is 9612 square leagues; and the population in 1803 was 630,500, which gives 66 inhabitants to the square league. The value of its agricultural preduce in 1802, consisting in maize, wheat, cochineal, &c. amounted to £ 568,531 sterling; and the value of its manufacturing industry, composed chiefly of woollen and cotton stuffs, tanned hides, and soap, was estimated at £ 722,351. The revenues of the bishop are 90,000 double piastres. This province abounds in silver mines, and affords excellent pastures. On the coast, in 21° 28′ North Latitude, are the three Marias islands, the most northern of which is about 13 miles in length, and 9 in breadth, surrounded by white rocky cliffs; and another, about 24 miles in circuit, separated from the last by a strait six miles broad, and which Dampean called Prince George's island, abounds in vegetable productions, but is deficient in fresh water. See Humboldt's *Political Essay on the Kingdom of New Spain,* vol. ii. and *Mod. Univ. Hist.* vol. xxxix. (q)

Guadaloupe.

GUADALOUPE, the largest and one of the most valuable of the Caribbee islands, lies between Antigua and Martinique. Its length is between 60 and 70 British miles, and its greatest breadth about 25. The middle of the island is situated in about 16° 20′ North Latitude, and 62° West Longitude. Guadaloupe has somewhat of the form of a crescent, and may be considered rather as consisting of two islands than of one; for it is divided into two parts by a narrow strait called Salt River. For a short distance on each side of this strait, the breadth of the island is not more than four miles. By this remarkable channel, the sea on the north-west communicates with the sea on the south-east. Its breadth varies from about thirty to eighty yards; and it is navigable for vessels not exceeding fifty tons burden. The north-west of the island is divided into Basseterre and Cabesterre; the eastern division of it is named Grandeterre. That portion of the island from which the whole takes its name, is, towards the middle, full of high and rugged rocks, where the climate is so cold, and the soil so barren, that little vegetation is to be seen. Over the summit of these rocks, the mountain called La Souffriere, or the brimstone mountain, rises to a great height. This mountain of sulphur continually sends forth, through various apertures, a thick black smoke, frequently mingled with sparks of fire. It is of a singular form, being divided into two parts by a remarkable channel, navigable by boats. There are many marks of volcanoes in other parts of the island. On a part of the western shore, the sea is so hot at a small distance from the beach, as to boil eggs; and the sand on being stirred, emits a

Description

strong sulphureous odour. The island contains a boiling fountain, and a hot marsh, which is very deceitful, and dangerous to strangers. The islands, of which Guadaloupe is the chief, were discovered by Columbus in his second voyage, when he visited Dominica, Guadaloupe, and Antigua. But they were at that time neglected by the Spaniards in their eager lust of dominion and gold on the larger islands, and on the American continent, the unexplored treasures of which were then opening to their ambition.

History.

No European nation had taken possession of Guadaloupe, when an expedition of five or six hundred Frenchmen, under two adventurous leaders, arrived from Dieppe in June 1635. The new settlers soon commenced a war with the native Caribs, for the purpose of supplying themselves with provisions, of which their own exertions could not yet produce a sufficient quantity for their subsistence. Many of these poor, simple and undisciplined people, unable to maintain a regular struggle with their more skilful invaders, retired to some of the other islands. Others of them concealed themselves in the natural strongholds and recesses of their own, and having previously destroyed their plantations and stores, their superior knowledge of the country enabled them to sally out unexpectedly, and to inflict vengeance on such straggling parties of their oppressors as fell in their way. After a struggle, which was kept up with various success, and which at length produced a terrible famine, a peace was patched up between the contending parties in 1640; and the remnant of Europeans, who had escaped the calamities which they had drawn on themselves, were joined by some discontented sailors and colonists from St Christophers. The superior advantages of Martinique as a sea-port, induced many adventurers to leave Guadaloupe, and pass over to that island; and from this time the French administration bestowed for some years almost exclusive attention on the latter, which became the seat of government of the French islands. For the first sixty years of its occupation by the French, Guadaloupe made little progress; but in the course of the ensuing fifty-five, its improvement was as rapid as it had formerly been slow. In April 1759, the island was conquered by the English. In July 1763, it was restored to its former owners in a highly improved condition. The French government now began to see the value of this settlement, and an independent government was given to it. The island was taken by the British in April 1794, but was retaken by the French under Victor Hughes in February 1795.

Early in 1810, an English expedition, the naval part of which was conducted by vice-admiral Sir A. Cochrane, and the military force by lieutenant-general Sir G. Beckwith, prepared with the design of attacking Guadaloupe and St Eustatius, was ready to commence operations. It was completely successful; and thus the enemy were deprived of the last of their possessions in the Columbian islands.

Guadaloupe continued under the power of the British crown till 1813, when in a treaty dated March 3d, between his Britannic Majesty and the King of Sweden, it is agreed, that this valuable colony should be ceded to the latter, in consideration of an engagement on his part to furnish a force of 30,000 men, in aid of the allied powers against France. Swedish commissioners were accordingly sent, to make arrangements for taking possession of the island; but in consequence of certain political causes not yet fully explained, it was restored to its old possessors the French, at the restoration of Louis XVIII. in terms of the general treaty of peace, signed May 30th 1814. On the return of Bonaparte from Elba in 1815, General Boyer, the governor, hoisted the three-coloured flag. After the second restoration of the Bourbons, he was condemned to death, but the sentence has been commuted into twenty years imprisonment. The sum of one million sterling was the compensation given to Sweden, for our non-fulfilment of the stipulation by which it was to be delivered into her hands. The general astonishment and indignation of the people of Great Britain and Ireland, on finding, that by one of the articles in the treaty with Louis, the slave trade was to be permitted to be carried on by the French for five years, in this island and Martinique, which British generosity had restored, are not easily described. Petitions poured in upon both Houses of Parliament, and addresses to the Prince Regent from every part of the united kingdom. In consequence of these petitions, Lord Castlereagh, the British negociator, was employing all his influence and skill in order to undo what he had done, and to induce the government of Louis to receive these islands under the express condition, that the odious traffic should instantly be definitively and for ever abolished by France. The consideration of this subject was taken up by the congress assembled at Vienna. But there appeared every reason to believe, that our benevolent endeavours would have failed of success, when the irruption of the exiled usurper into France once more transferred this island to the sovereignty of Napoleon Bonaparte. By a stroke of policy, intended at once to show his power, and to conciliate the people of England, he issued a decree as soon as he felt himself replaced on his trembling throne, by which he declared the slave trade to be abolished in the French islands. In doing so indeed, he made no kind of allusion as to the immorality and wickedness of the traffic with Africa. Besides, he knew that while the war should continue, and England ride triumphant on the sea, he could carry on little foreign trade of any kind, and that these islands would probably fall speedily into our hands; so that the sacrifice he appeared to make of interest to duty, was in fact only a nominal one, and as his decree was expressed just as coldly as if he had been prohibiting the importation of flax or grain, he could easily, he well knew, and without any appearance of gross inconsistency, by another of his imperial decrees, restore the trade, on the ground of alleged expediency, whenever he might be able to derive any advantage from the renewal. This decree of Bonaparte, however, though no one could be deceived as to its motive, had a happy effect on the great cause; for when Louis was a second time restored to his throne in summer 1815, and when these islands, once more in the power of England, were to be delivered up to France, the example of Bonaparte himself could be quoted, to shame the new government into accordance with our wishes. Indeed England had now the means and the right to enforce compliance with her request. Accordingly Louis, soon after his return, by a royal decree, declared the French slave trade to be definitively and absolutely abolished.

Commerce.

The unsettled state of this island, may probably have prevented any very accurate estimate either of its trade or population since the French revolution. In the year 1700, the population amounted only to about 382 indigenous inhabitants or Caribs; 325 free negroes; and 6725 slaves.

In 1755, there were

Whites	9643
Slaves	41,140
Sugar houses	334

Guadaloupe || Guam.

Banana trees	2,028,520
Ditches of manioc	32,577,950
Horses	4946
Mules	2924
Asses	125
Beeves	13,916
Sheep and goats	11,162
Swine	2444

In 1767, France received from Guadaloupe,

Fine sugar	140,418 quintals.
Raw sugar	23,603
Coffee	34,205
Cotton	11,955
Cacao	456
Ginger	1884
Campeachy wood	2529
Confections	24 boxes.
Liqueurs	165 boxes.
Potassia	34 casks.
Skins	1202 No.

These articles were sold in the colony for 7,103,838 livres, while the articles imported from France cost 4,523,884 livres, leaving a balance in favour of the colony of 2,579,954 livres.

In 1767, Guadaloupe contained

Whites	12,700
Blacks, or free Negroes	1350
Slaves	100,000
Horses and mules	9220
Horned cattle	15,740
Sheep, swine, and goats,	25,400

It possessed at the same time,

Feet of cacao	449,622
Feet of cotton	11,974,046
Feet of coffee	18,799,680
Sugar houses	388

In the year 1775, eighty-one vessels returned to France loaded with the following produce:

		Value in Europe.
Raw sugar	188,384 quintals.	7,137,930 livres.
Coffee	63,029	2,993,860
Indigo	1438	1,222,529
Cacao	1023	71,651
Cotton	5193	1,298,437
Skins	727	6973

and some other articles of minor importance.

The value of the imports and exports, was in

	Imports.	Exports.
1767	livres 4,523,884	7,103,838
1788	5,362,000	15,053,000

Several of the productions of Guadaloupe were formerly sent to Martinique; and America received some of its liqueurs, and other commodities, and sent in return, wood, cattle, flour, and cod fish.

In 1789, the population of all descriptions was about 104,000. The island is well stored with horned cattle, sheep, horses, &c. and produces a vast abundance of sugar, coffee, rum, ginger, cocoa, logwood, &c.

GUIACUM. See Chemistry, vol. vi. p. 124, Sect. xxiv.

GUAM, or Guahon as it is called by the natives, is an island in the eastern seas, forming one of the group denominated Ladrones, or Marianne islands. According to the computation of the Spaniards, it is about 120 miles in circuit, apparently flat and even from a distance, but the east coast, on nearer approach, is found to be high and shelving, fenced with steep rocks which oppose the perpetual beating of the sea. Here there is no anchorage; but the west side is divided into small low and sandy bays, one of which, called Umata, constitutes a good harbour for a few vessels, and is defended by a battery of twenty guns. The surface of the island gradually rises from the shore to nearly the middle. The rocks are chiefly granitic; and the centre of the pebbles, found on the beach, contains various coloured crystals. Several vallies are interposed between the shore and the inland parts, where vegetation becomes profuse. They appear to have been the bed of so many currents; and their soil consists of sandy earth, mixed with decaying madrepores, from which the sea seems to have withdrawn. The interior, however, is of extreme fertility, abounding with all that can be desired for the use of man. Numerous fountains spring from the rocks, and in their course form transparent pools, shaded by trees, always preserving an agreeable freshness amidst the heats of the climate. But there are no rivers of importance; the other waters being either torrents from among the hills, or inlets of the sea.

Productions.

No portion of the globe is more copiously supplied with vegetables than Guam; and here our celebrated circumnavigator Dampier first discovered the bread-fruit, an invaluable plant, which affords subsistence to so many thousand islanders of the South Pacific Ocean. The forests are full of guavas, bananas, cocoas, oranges, and limes. Capers are produced in abundance from a shrub, indigenous to the soil, of beautiful appearance, flourishing throughout the year, and exhaling a delightful odour. From hence it has been transplanted to the Philippine islands. Two species of banana are thought peculiar to Guam; one of dwarfish size, only three feet in height, but producing a fruit so much superior to all the rest, that its cultivation has been recommended in the European tropical colonies; the other is the wild banana, a large tree, the fruit of which is not eatable. Of the cocoa tree there are three kinds: *first*, the common species, disseminated throughout India, bearing a nut, which is a great article of subsistence; *secondly*, a middle-sized tree, which is lower, the nut having a tender shell and a kernel tasting like an artichoke bottom; *thirdly*, the black cocoa tree, rising at most to eight or ten feet in height, with a nut perfectly round, about three inches in diameter, and very delicate. This last affords oil more abundantly than the others, as also coir for cordage, and the leaves of all the three are equally suitable for thatching huts, and making mats.

Animals.

Fish is plentiful on the shores of the island, though frequently of a poisonous quality, originating, it has been conjectured, either from their feeding on the polypi of madrepores and coral, or other marine animals. It is affirmed, that the very taste of the coral is imparted to them. Turtle are large and numerous; besides which the streams of Guam afford abundance of aquatic tribes peculiar to themselves. But the facility with which subsistence of a different description is obtained, renders that which may be derived from the waters quite of secondary consideration, and it is little sought after.

It has never been explained, what are the birds and quadrupeds which are indigenous to the island. A few cattle, that were carried thither long ago, have multiplied exceedingly, and run wild in the uninhabited districts. They are large, and well fed, and exhibit one remarkable feature common to those resuming their original state, in almost all being white, with black ears. It is known, that in Great Britain the few which remain unmixed from distant ages, and have preserved their pristine ferocity, retain along with it the same peculiarity, which is of much interest to the zoologist. Some years ago, the Spaniards transported a large spe-

Guam. cies of deer from the Philippines to Guam, which undergoes so great a change along with the season as scarcely to be recognizable as the same animal. From December to May, its winter coat is long, thick, and of a grey colour; but from the month of May, the hair is brown, or almost yellow, smooth, and shining, having three black streaks on the back, interspersed with white. It multiplies in the woods, which are also well stocked with wild hogs.

Native inhabitants. Dampier describes the natives of this island as "strong bodied, large limbed, and well shaped. They are copper coloured like other Indians; their hair is black and long; their eyes meanly proportioned; they have pretty high noses; their lips are pretty full; and their teeth indifferent white. They are long visaged, and stern of countenance; yet we found them to be affable and courteous." These people have a great tendency to corpulency, and are very subject to leprosy, or a kind of cutaneous disease, especially in the wet season, or between June and October. They are particularly characterized by mildness and hospitality, which have enabled their invaders to make deeper encroachments on their liberty, than if they had displayed a more repulsive disposition. They are indolent, prone to intoxication, and fond of music, dancing, and cock-fighting. The Spaniards have rendered them acquainted with agriculture; and, to facilitate their labours, they tame the wild cattle, which are trained to carry loads throughout the island. Several are kept for this purpose by most families, becoming perfectly tractable, and as quiet as horses. They are guided by a halter penetrating the septum of the nose, to which they grow accustomed in a fortnight. No part of the industry of the natives of Guam appears to have existed anterior to their conquest; they have either been explicitly taught, or acquired what they practise from example. Some of the mechanical arts are practised by them in carpentry, smith work, brick-making; and they fabricate cloth, cordage, and even cables, for the Acapulco galleons from the wild banana, which are reputed of superior strength to those manufactured of the best European

Canoes. hemp. But there is one branch of the arts in which they have remained stationary since the discovery of their island, namely, the construction of their canoes; and this has arisen less from want of skill to make the alteration, than from their having already adopted the best possible form of which their local situation admitted. Celebrated navigators have repeatedly expressed their admiration of these vessels, which are equally calculated to keep the sea, and to take advantage of the prevalent winds. Some of their canoes are forty feet long, hollowed out of the trunk of a single tree, and very narrow. A piece two inches deep is sewed on as a washing board to raise it higher; "but, what is very singular, one side of the boat is made perpendicular like a wall, while the other side is round, and made just as other vessels are with a pretty full belly." The ends are sharp; each serves for a prow; and the neighbouring islands frequented by the natives lying chiefly north and south, and the wind being almost constantly east, the rounded side is found on the lee. But there is, besides, an outrigger projecting from the side, necessary to steady so narrow a vessel, and at the extremity is a log of wood, in shape resembling another canoe, though much smaller. A single mast stands in the middle, with a triangular sail, which, when taken in, is rolled around a yard at the bottom. No canoes are better adapted for sailing. A French navigator assures us, that, with a fair wind, they go at the rate of nine miles an hour, a distance said to be augmented to fifteen under the most favourable circumstances. Dampier observes, "I did here, for my own satisfaction, try the swiftness of one of them. Sailing by our log, we had 12 knots on our reel, and she run it all out before the half minute glass was half out, which, if it had been no more, is after the rate of 12 miles an hour; but I do believe she would have run 24 miles an hour." He was told of one of them having been sent express to Manilla, and performing the voyage, which is about 400 leagues, in the space of four days. However it is understood, that, although the best sailers known, the canoes of Guam are not safe at sea; but should an accident happen, the natives are so expert at swimming, they are capable of repairing it in the water. The companions of M. Marion observe, that "the form of these embarcations is such, as would do honour to a shipbuilder among people who have made the greatest progress in the knowledge of navigation. This form has been imitated from no model, because it differs from all those which men inhabiting different parts of the world have given to their vessels."

The inhabitants of Guam are dispersed in twenty-one native establishments, chiefly on the coast, and the town of Agana, situated about twelve miles north-east of the harbour. All the Indian families are agricultural, and each has a small portion of land subdivided into fields or gardens; but the interior of the island is still in a state of nature, covered with thick woods, affording excellent timber for the construction of houses or vessels. The town stands on the shore, at the base of some hills of moderate elevation, in a fine district full of springs, and watered by a small rivulet. Its streets are laid out in a straight line; and the houses, built for the most part of wood, stand on posts about three feet above the ground, and are roofed with tiles or palm leaves. But all the public edifices are constructed of brick. There is a fine church here decorated after the Spanish fashion; and two or three convents or colleges occupied by monks, one of which was established for the education of Indians. The religious establishment of Guam was formerly vested in the Jesuits, who, on the suppression of their order, were supplanted by the Augustines; and besides Agana, there are two or three other cures in different parts of the island. The government house is spacious. There is a royal magazine tolerably well stored, and barracks for 500 men. This being the only Spanish colony in the Ladrones, was preserved with considerable care; however, its chief and most important improvements were derived from the governor Tobias, who was at its head about forty years ago. He taught the natives the proper means of cultivating the land; he planted rice, maize, indigo, sugar canes, and cotton, all of which succeeded admirably, and the maize in particular produced an incredible return. To give them a proper example, this paternal governor formed gardens and plantations, where all necessary vegetables were cultivated, along with the most delicious fruits. He established a kind of cotton manufacture, and caused salt pits to be dug. Further, he instituted a school for the gratuitous education of the native children of both sexes, where they were instructed in reading, writing, and arithmetic, as also vocal and instrumental music; whence strangers have been agreeably surprized, in finding practised musicians assisting the celebration of divine worship in a place so remote from the civilized world. Finding it necessary to provide the island with a sufficient force to protect itself, he formed a militia of 200 Indians, among whom were four Spanish captains, while the remainder of the officers were chiefly Mestees, or

Town of Agana.

Guam.

the mixed race of Spaniards and natives from the Philippines. But to preserve these troops from the hazard of idleness, and to procure them ample subsistence, they were occupied in cultivating a tract called the Royal Domain, separate from all other property. By such humane and prudent measures, while the natives are reclaimed to habits of industry, their principles and morals, aided by an innate placid disposition, undergo an absolute alteration; yet this patriotic individual was afterwards persecuted by the clergy of Manilla.

History.

The history of Guam is marked by some singular and interesting features. It was discovered in the year 1521, by Magellan, who ascertained that it belonged to a cluster of nine principal islands, and a number of smaller islets, which he first called *De Velas*, from the sails of the canoes, but afterwards *Ladrones*, from the propensity of the natives to theft. Guam appeared to enjoy a delightful climate; it was covered with fruits, and afforded the means of supporting a colony; therefore the Spaniards having already established themselves in the Eastern Seas, resolved upon making a settlement here. The inhabitants were a wild and savage race; but equally savage with themselves, the Europeans, in usurping their territories, carried fire and sword along with them. In violating the religion of their fathers, they endeavoured to inculcate the principles of Christianity; but instead of adhering to its mild and benevolent doctrines, they practised the most horrible cruelties to enforce belief. While their rude opponents might have been gained by conciliation, a war of extermination was unrelentingly prosecuted, because their demands, alike ungenerous and unjust, were resisted. At this early period, the nine islands of the group were calculated to contain 60,000 inhabitants, of whom 20,000 belonged to Guam. But they gradually fell under the barbarity of their invaders, too well skilled in warfare. After a long interval of suffering, a measure was at length adopted by the natives, which is scarcely to be paralleled in history: They resolved to allow their race to be extinguished in themselves, that posterity might not be able in their misery to reproach them with existence. Thus the women drank deleterious potions to procure abortion at the moment, and to prevent their having any future offspring; and this outrage against nature was so obstinately persisted in, that about 60 years ago, the total population of the group had decreased to 800 or 900 persons. The Spaniards, however, had awakened from their error, and learning the benefit of conciliation, found means to collect the whole in the island of Guam. There it continued to augment during twenty years, to about 1500, since which time we have no further accounts of it; but most probably it is much more considerable, or part may have colonized the neighbouring islands. During these convulsions the invaders did not escape with impunity, and on one occasion when the natives rose upon them, all the missionaries were massacred; but on another, when their numbers were small, they proved unsuccessful, and all except 100 evacuated the island, leaving the Spaniards in peaceable possession of it. Afterwards they became accustomed to the yoke, and a quiet, peaceable, and inoffensive race has now sprung up to promote instead of resist the objects of the settlers.

Guam is of importance as a Spanish establishment, from its position and great fertility: the galleons from Acapulco to Manilla, so much the object of capture to hostile nations, were wont to put in here for refreshments, besides which, a vessel came annually from the Philippines. It is said that the natives of the neighbouring islands have become more warlike of late, and seem disposed to make conquests of other territories; but whether they disturb the European colonies is not explained. In concluding these observations, we may cite the words of a French navigator, who made a short residence in Guam, which will satisfactorily illustrate its properties. "In traversing this island, we discovered how lavish nature has been of picturesque and agreeable places. Enchanting spots were met with in our excursions, where she had bestowed every thing, and where the hand of man had made no arrangements. Ennui was banished: here all was united for the enjoyment of solitude: verdure, shade, coolness, and the perfume of flowers: crystalline fountains were seen springing from the rocks: the song of innumerable birds was heard: and groves appeared of cocoas, bread-fruit, oranges, citrons, and an infinity of fruits interspersed among the foliage of trees, all cultivated by the operation of nature alone. Here, too, they presented a pleasing disorder, which art has never been able to imitate. I could not quit this delightful abode without regret, where life might be passed in satisfaction."

It seems doubtful whether the actual position of Guam is completely ascertained. Dampier, after a very long run, lays it down in Latitude 13° 21′ North, Longitude 125° 11′ West: later navigators place it in 13° 25′ North Latitude, and 155° 10′ East Longitude; and La Perouse, probably from observation, fixes the harbour of Umata in 13° 10′ North Latitude. (*c*)

Guamanga.

GUAMANCA, Guamanga, or Huamanga, is the name of a city and province in Peru. The city was originally founded by Pizarro in 1539, as a middle station for the trade between Lima and Cusco. It was built at first on the site of an Indian village of the same name; but, in memory of a victory gained over the Ynca, was called by the Spaniards San Juan de la Vittoria. It was situated in the vicinity of the Andes, in a barren district; but, after the subjugation of the Peruvians, was removed to its present site, in 13° South Lat. in a more fertile territory, about sixty leagues east-south-east from Lima. It stands upon the declivity of a mountainous ridge, not remarkable for its height; but still so far above the rivers, as to be scantily supplied with water. About twenty noble families reside in the centre of the town, in spacious houses of a considerable height, built partly of stone, and covered with tiles, and surrounded with extensive gardens. It is skirted with suburbs of Indian habitations, which are chiefly built of stone, and, though low in the walls, as is generally the case in the inland towns of South America, yet add considerably to the appearance of the city. It contains a splendid cathedral, and a seminary for the service of the church, under the title of St Christopher; a university, with professors of philosophy, divinity, and law, and endowed with privileges equal to that of Lima; and also several chapels and convents, a hospital, and a college of Jesuits. It is governed by a corregidor, assisted by the principal nobility, who form a corporate body, out of which are chosen the alcaldes, to superintend the several departments of the police of the city, and the jurisdiction of the province.

The province or diocese lying eastward of Lima, is of very considerable extent, and is divided into the following districts:—Guamanga, which contains the capital of the province, is very fertile and populous. Its climate is temperate, and it abounds in various kinds of grain, fruit, and cattle. It contains several mines, but few of them are worked; and its agricultural wealth is fortunately the principal object of attention to the inhabitants. A principal part of its commerce consists in bend leather, for the soles of shoes; and great quan-

Guamanga, Guanaxuato. tities also of conserves and sweetmeats are prepared for exportation.—Guanta, about four leagues north-west of the city of Guamanga, and about thirty leagues in length, is likewise a temperate and fruitful district. It is diversified by numerous heights, woodlands, and broken glens rich in fruits and pastures. Its silver mines, which were formerly very rich, are now almost exhausted; but there are still many of lead; and this metal, together with salt and provisions, are its principal articles of trade.—Vilcas Guaman, about seven leagues south-east of Guamanga, is celebrated for its esculent vegetables and fine pastures, and breeds vast quantities of cattle. The natives are employed in various manufactures, particularly woollen stuffs, which are carried to Cusco and other provinces. There is still remaining in this district one of the old Indian fortifications.—Andaguaylas, to the south of Guamanga, extends about twenty miles eastward, between two branches of the Cordillera, and is watered by a number of small rivers descending from the hills. This extensive valley produces all kinds of fruit and grain, particularly maize and sugar cane. It is one of the most populous districts in the country; and in it many of the wealthier inhabitants of Guamanga have large sugar plantations.—Guanca Velica, or Huanca-Belica, commencing about thirty leagues north of Guamanga, is a bleak, hilly, and barren district. It produces little fruit or grain, and its inhabitants are supplied with provisions from the neighbouring countries. It is chiefly celebrated for an immense and apparently inexhaustible mine of quicksilver, to the working of which the inhabitants owe their chief subsistence. In the mountains are many shells and marine substances; and in a river near the principal town such large petrifactions are formed, that they are frequently used in building houses and other works.—Angares, about twenty leagues west-north-west from Guamanga, and about twenty leagues in extent, is tolerably temperate and fruitful, and yields vast herds of all kinds of cattle.—Castro Virreyna, south-west of Guamanga, is of very various temperature, but in its bleakest parts its greatest wealth is found. This consists in the wool of a species of sheep called Vicunna, which had been improvidently hunted down for the sake of its fleece, and which is now to be found only in the coldest heathy spots.—Parina-Cocha, about twenty leagues south of Guamanga, is fertile in grain, and rich in pastures; and its mountains contain several mines of gold and silver, which yield these metals in great abundance, and supply its principal article of commerce.—Lucanas, about thirty leagues south-south-west of Guamanga, is of a cold temperature, but its vegetable productions are abundant, and its herds of cattle numerous. It abounds in rich mines of silver, and is the centre of a very considerable commerce. See Ulloa's *Voyage to South America*, vol. ii.; and Playfair's *Geography*, vol. vi. (*q*)

GUANAXUATO, an intendancy of New Spain, lies between the 20° 55′ and the 21° 30′ North Lat. and is wholly situated on the ridge of the Cordillera of Anahuac. Its length, from the lake of Chapala to the north-east of San Felipe, is fifty-two leagues, and its breadth, from the Villa de Leon to Celaya, is thirty-one. Its principal cities are, Guanaxuato, or as it is also called Santa Fe de Gonnajoato, in 21° 0′ 9″ North Lat. built by the Spaniards in 1554, surrounded with mines, and containing 70,600 inhabitants; Salamanca, a neat little town situated in a plain; Celaya, in which are several splendid buildings, and particularly a magnificent church of the Carmelites; Villa de Leon, in the midst of a highly fruitful district; and San Miguel el Grande, celebrated for its industrious inhabitants, who are employed in cotton manufactures. The province, which is part of the old kingdom of Mechoacan, was first cultivated by the Europeans in the sixteenth century, who expelled the Indian tribes of hunters and shepherds, and supplied their place with colonies of Mexican or Aztec Indians. During a considerable period agriculture made greater progress than mining, and during the seventeenth and eighteenth centuries, most of the mines were entirely abandoned. But, during the last forty years, the mines of Guanaxuato have yielded a greater metallic produce than Potosi, or any other mine in the two continents; and it is now the first mining district in America. Of the situation and products of its mines, a minute description is given by M. Humboldt, both in the historical account of his travels, and in his *Political Essay on New Spain*, vol. iii. p. 169. One of these mines alone, that of Valentiana, which has been known only for forty years, has sometimes furnished, in one year, as much silver as the whole kingdom of Peru. This fine province also is, relatively, the most populous in New Spain. Its superficial extent is only 911 square leagues, and it contains 517,300 inhabitants, which gives 586 to every square league. The principal natural curiosity in this province, are the hot wells of San Jose de Comangillas, which issue from a basaltic opening, and of which the temperature was found to be 205°.3 of Fahrenheit. See Humboldt's *Political Essay on New Spain.* (*q*)

Guatimala. GUATIMALA, one of the three audiences or kingdoms into which Mexico or New Spain was formerly divided, lies between 7½° and 22° North Lat. extending upwards of 300 leagues along the south coast, and in no place exceeding 160 in breadth. It is in some parts extremely narrow, and on the north coast is deeply indented by the Bay of Honduras. It has been divided into thirteen provinces, according to some accounts, and according to others into eight. The latter of these is here adopted, because it best corresponds with the map given in this work, and also because the limits of the thirteen departments have not hitherto been accurately ascertained.* Veragua, the most southern province, and bordering on Panama, is about fifty leagues from west to east, and from nine to twenty-seven in breadth. It was discovered by Columbus in 1502, and was granted to him and his posterity as a reward of his services. Its coasts are low, and full of brushwood; but the interior parts are hilly, covered with forests very imperfectly explored, but known to abound in rich silver mines. Its principal river Veragua is remarkable for the verdant hue of its waters; and from this circumstance its discoverer gave it the name of Verdes Aquas. Its principal towns are, Conception, considered as the capital of the province, a small place situated near a river of the same name; Santiago al Angel, built in 1521, but frequently destroyed and restored; Santa Fé, a small town and bishop's see in the middle of the province; and Pueblo Nuevo, or New Town, situated in an unhealthy spot at the mouth of a river, about twenty-three leagues south-west of Santa Fé. There are besides upwards of thir-

* The celebrated traveller M. Humboldt has furnished a complete description of the modern division of New Spain into Intendencies; but he has not touched upon the portion comprehended in Guatimala, for which he mentions that he had no data, and which we can therefore describe only under its ancient divisions.

Guatimala.

teen villages inhabited by Indians. Costa Rica, or Rich Coast, north-west of Veragua, is from fifty to sixty leagues in length, and forty in breadth. It consists chiefly of mountainous and woody deserts, and is thinly inhabited and little cultivated. Its mines were formerly productive, but have been abandoned on account of the difficulty of working them; and its chief articles of trade are hides, honey, and wax. Its principal town is Cartago, a small place and Bishop's see in the interior of the province, where the governor resides. Nicaragua, in 12° North Latitude, is about 80 leagues in length, and 50 in breadth, running from north-west to south-east, between Costa Rica and Honduras. It consists for the most part of high woody mountains, in which are some volcanoes, but no mines. There is a large lake, 200 miles in circumference, in the south-west, which communicates with the Atlantic ocean by the river St Juan. Its vallies are well watered, and its principal products are timber of great size, cotton, sugar, honey, wax, cochineal, and fruits. Its chief towns are Leon de Nicaragua, a place of considerable trade, on the north-west border of the lake, several leagues from the south coast; and Granada, a populous and trading town on the west border of the lake, near a rugged volcanic mountain. The eastern coast is surrounded with shoals, and has no proper harbour. Honduras, in 15° North Latitude, extends 180 leagues along the south border of the gulf of that name, and from 25 to 50 from north to south. It is well watered by many streams which run northward into the gulf, and which, overflowing their banks in the rainy season, render the soil extremely fertile. Its bay, which includes a compass of 500 miles, is of dangerous navigation; but celebrated for the excellent logwood, which abounds on its flat and marshy shores. There are several islands along the coast of this bay; one of which particularly, Rattan, about 10 leagues in length, was long the resort of pirates, till the British established a colony upon it, for the protection of the trading vessels. The chief towns of the province are, Valladolid, a bishop's see, a small inland town in a pleasant valley; St Jago, 100 miles east of Valladolid, Truxillo, 125 north-east, and Puerto de Cavallos, about 90 north-west, all formerly places of considerable trade, but now greatly deserted. The British established a settlement in 1730 on the Black river, 26 leagues east of Cape Honduras, and another on a navigable river near Cape Gracias da Dios, where there is a secure and spacious road for ships. Guatimala, in 14° North Latitude, bordered on the south and west by the Pacific Ocean, is a province of considerable importance. Its surface is mountainous, and it is extremely subject to earthquakes; but its vallies are remarkably fruitful, abounding in grain, sugar, cotton, various dyeing drugs, especially indigo of a superior quality, and the richest pastures, stocked with incredible multitudes of cattle. Its capital, St Jago, or Guatimala, a bishop's see and the seat of a university, is a considerable trading town. It formerly stood in a delightful valley, not far from the west coast, but was repeatedly destroyed by tremendous earthquakes and volcanic eruptions; and was at length removed to a beautiful plain about 8 leagues from its former site. Nearly 30 leagues to the south-east is Sansonata, or Trinidad, which is the nearest proper harbour for ships from Panama and Peru trading with St Jago. Vera-paz, or Coban, in 16° North Latitude, at the bottom of the bay of Honduras, and north of Guatimala, is about 35 leagues in length, and 30 in breadth. It is a mountainous country, covered with forests; but a few cultivated tracts yield plentiful crops of maize. Cotton, wool, cocoa, honey, wax, and gums, are its chief articles of trade. It contains no towns of any importance; and Vera-paz, the governor's residence on the bank of a river running south-east to Golfo Dolce, Acarabatlan, a small place to the westward, esteemed for its musk melons, and Robinal, a trading village in the pleasant valley of St Nicolas, are scarcely worthy of being noticed. Chiapa, north-west of Vera-paz, in 16½° North Latitude, is of a triangular form, and each of its sides extends about 65 leagues. It abounds in hills covered with forests, and has two rivers, the Chiapa, running eastward to the bay of Campeachy; and the Samasinta, which traverses the eastern part from south to north. It has no mines of gold or silver; and its riches consist in grain, fruits, and pastures. Its principal town, Cividad Real, a bishop's see, is situated in a valley surrounded by mountains, about 90 leagues north-north-west of Guatimala, and trades in cotton, cocoa, and cochineal. There are several Indian towns in this province, of which the most populous is Chiapa dos Indos, about 12 leagues westward of Cividad Real, situated in a valley watered by the river Tabasco. The natives of this diocese obtained, through the mediation of the Bishop Casas, exemption from slavery, with other signal privileges. Soconusco lies between Chiapa and the Pacific Ocean, and is about 35 leagues in length and 30 in breadth. It is a mountainous country, but has no mines. It is covered with forests, and its vallies produce indigo, cocoa-nuts, fruits, and pastures. The only settlement worthy of notice is Guevitlan, or Soconusco, which is the residence of the Spanish governor, and is situated near the coast of the South Sea, about 40 leagues south of Chiapa. See *Modern Universal History*, vol. xxxix; and Playfair's *Geography*, vol. vi. (q)

GUAXACA, or more properly OAXACA, is the name of a city and intendancy in Mexico, or New Spain. The city, which is the ancient Mexican Huaxyacac, was called Antiquera at the time of the conquest. It is situated in an extensive and populous valley, about 80 leagues south-east of Mexico. It carries on a considerable trade, and is particularly celebrated for it excellent chocolate. It is handsomely built, and contains a very fine cathedral, but is open and unfortified. It is a bishop's see, and in 1792 contained 24,000 inhabitants. The province of Guaxaca lies in 17° North Latitude, reaching from sea to sea, extending about 90 leagues along the south coast, 30 along the Mexican Gulf, and from 30 to 70 in breadth. Its climate presents a perpetual spring, and it is one of the most delightful countries in that quarter of the globe. Its mountainous districts, composed of granite and gneiss, are rich in mines of gold, silver, and lead. Its plains are highly fertile, and yield abundance of sugar, cochineal, fruits, grain, and various useful productions. Its relative population is equal to that of European Russia, and it has been long advancing in civilization. Throughout the whole province, vegetation is extremely vigorous, especially halfway down the declivity, in the temperate region, where the rains are very copious from May to October; and, at a small village, about three leagues from the capital, is an enormous trunk of *Cupressus disticha*, which measures 118 feet in circumference; but upon a narrow inspection is evidently composed of three united stems. Many remains of ancient Mexican structures are to be seen in the province, especially at San Antonio de los Cues, a populous place on the road from Orizaba to Guaxaca, and at a village named Mitla. In this last mentioned place, which was formerly called Miguitlan, Oaxaca. Guayaquil. a word signifying in the Mexican language, a place of sadness, are the ruins of an extensive palace, constructed over the tombs of the kings, and to which the sovereign used to retire for some time on the death of a son, a wife, or a mother. This palace, or rather sepulchre, consists of three edifices placed symmetrically in a very romantic situation. The principal structure, which is in the best preservation, is nearly 131 feet in length, and the distribution of the apartments bears a strong analogy to what has been remarked by the French *savans*, in the monuments of Upper Egypt. A stair, formed in a pit, leads down to a subterraneous apartment, which is 88 feet by 26, and which, as well as the exterior walls of the edifice, is covered with those ornaments generally called *grecques*, such as meanders, labyrinths, &c. some of which are in Mosaic, of small porphyry stones. Several curious paintings have been found in these ruins, representing warlike trophies and sacrifices; but the most striking object is a vast hall, of which the ceiling is supported by six porphyry columns, about 16 feet in height. These columns, the only ones found in the new continent, bear strong marks of the infancy of the art, having neither base nor capital, but simply a contraction of the upper part. Besides the capital, there are several other towns in the province, the principal of which is Tecoantepec, about 40 leagues south of Guaxaca, at the bottom of a bay on the coast of the Pacific Ocean. It is a small town, with a good fishing harbour, and an open road for ships; but the port is impeded by a dangerous bar. It is likely, however, to become a place of greater importance, by the increase of the indigo trade from Guatimala. The family of Hernan Cortez bears the title of Marquis of the valley of Oaxaca, a property containing 4 villas, 49 villages, and 17,700 inhabitants. There are 306 secular ecclesiastics in the province, and 342 regulars. The revenues of the bishop amount to 18,000 double piastres. See Humboldt's *Political Essay on the Kingdom of New Spain*. (*q*)

GUAYAQUIL, a city and province in the kingdom of Quito. The city is the second of Spanish origin in the empire of Peru; and was first built about the year 1535, near the gulf of Charapoto, but, in 1693, it was removed to its present situation, on the west bank of the river Guayaquil, in 2° 11′ 21″ South Latitude, about 63 miles from Quito, and 188 from Lima. It extends along the side of the river nearly half a league, and is divided into an old and new town, both of which contain about 2000 houses, which are built of brick or wood, covered with tiles or thatch, but, on account of the numerous conflagrations by which it has suffered, the latter covering is now prohibited. The ground on which the new town stands, is composed of a spongy chalk, and is every where so level, that, in the rainy season, it becomes utterly impassable either on foot or on horseback, and the communication of the inhabitants is effected chiefly by means of large planks, which soon becoming slippery, afford a very inconvenient path. The place is defended by three forts, two on the river close by the town, and a third behind it guarding the entrance of a ravine. All the churches and convents are built of wood, on account of the softness of the soil, except the church of St Domingo in the old town, which is of stone; and the country supplies timber well adapted for these purposes, being extremely hard, and capable of retaining its solidity either in the mud, or under the water. The city and its jurisdiction are under a corregidor, who is subordinate to the president and audience of Quito, and holds his office during five years; the police is conducted by ordinary Alcaldes; and the ecclesiastical government is lodged in the Bishop of Quito's vicar, who is generally also the priest of the town. It contains a small college of Jesuits, and an hospital without any endowments. The inhabitants of Guyaquil, including the strangers who are drawn thither by commerce, are computed at 20,000; and many of the principal people are Europeans, who have married and settled in the place. All who are capable of bearing arms are enrolled in companies of militia, according to their rank or cast. Though the heat of the climate is equal to that of Panama or Carthagena, yet it is a remarkable circumstance, that the Spanish inhabitants are extremely fresh coloured, and their children universally fair, having light hair and eye-brows. They are accounted the handsomest people in all Peru, and are said to be equally distinguished by the elegance and politeness of their manners. As the river is brackish near the city, good water is extremely scarce, especially during summer, and is brought from a distance of four or five leagues, by means of boats resembling rafts. The fish also in its immediate vicinity is neither good nor plentiful; but great quantities of the most excellent kinds, particularly shell-fish, are brought from the neighbouring coasts, and constitute a principal part of the food of the inhabitants. As wheat is scarce, and the bread from it also badly made, different kinds of roots have been employed as substitutes, particularly unripe plantains cut into slices and roasted. The inhabitants affect great splendour in their formal entertainments; and their dishes are a succession of high-seasoned ragouts snd sweetmeats, always beginning with the latter. Their liquors, on these occasions, are grape-brandy, cordials, and wine. Weak acid punch is much used by both sexes, in the forenoon and evening, as a refreshing and wholesome drink, and as a necessary mode of correcting the disagreeable qualities of the water. Melons and water melons are brought in great abundance to the city during the summer season. From the month of May to December, the air is remarkably serene and delightful; and the cool breezes, which blow from the mountains from mid-day till five or six o'clock next morning, tend greatly to refresh the earth and the atmosphere. But during the other half of the year, the climate is intolerable to strangers, the heat greater than at Carthagena, the rains continual, the country overflowed, the insects and other vermin extremely numerous, and even venomous. They are said to be so abundant in the city, that it is impossible to keep a candle burning except in a lantern, as it would otherwise be extinguished in a few minutes by the multitudes flying around it. Tertian fevers prevail much at this season, which the inhabitants, from a prejudice against the use of the bark, (though originally discovered in the province,) suffer to prey upon their constitutions, till they often become incurable. They are very subject also to cataracts and other distempers of the eyes, which often terminate in total blindness, and which some have ascribed to the aqueous exhalations during winter from the chalky soil. The city carries on a considerable trade, and exports native produce, of which the chief article is cocoa, to the value of 550,000 piastres annually; while the amount of imports is 1,200,000 piastres. The province of Guayaquil extends about 60 leagues from north to south, and about 45 from east to west; and is divided into seven departments or lieutenancies, for each of which the

Guayaquil. corregidor appoints a deputy governor, but whose authority must be confirmed by the audience of Quito. These are Puerto Viejo, a poor and thinly inhabited district, abounding in wood, producing a little cotton, and formerly noted for a considerable pearl fishery in the bay of Manta.—Punta de Santa Elena, a low fertile country, full of salt works, but chiefly remarkable for possessing the purple dye so highly esteemed among the ancients, and which is simply the blood of a species of shell fish growing on the rocks. The threads, after being drawn through this liquor, are tinged at first with a milky hue, which changes into green, and then into a vivid purple, which does not fade by wearing, and is rather improved by washing.—Puna, a low flat island in the mouth of Guayaquil river, about seven leagues square, covered with thickets of mangrove trees.—Yaguache, around the mouth of a river of the same name, which falls into the Guayaquil, has no towns of note, but the country is populous, and produces much excellent wood.—Babahoyo, is a large district, subject to great inundations during winter, but productive in cotton, rice, Guinea pepper, and other fruits, especially in plantations of cacao. Large droves of horses, mules, and black cattle, which are kept in the mountains during the wet season, are brought down when the land is dry, and fattened on the plant called gamalotte, which, resembling barley in its blade, grows in such luxuriance as entirely to cover the plains, even to the height of 7 or 8 feet.—Baba, a very extensive district reaching to the skirts of the Cordillera, abounds chiefly in the cacao tree, which delights in a watery soil, and which here grows frequently to the height of 20 feet. The gathering of its fruit and drying of its seed forms the principal trade of the inhabitants. Daule has many large orchards, and extensive corn fields, plantations of cacao, cotton, and sugar cane, but is chiefly distinguished by the excellence of its tobacco. Throughout the whole province of Guayaquil numbers of cattle are reared, especially where there are mountainous tracts to afford a retreat during the season of the inundations. The woody parts are much infested with insects and noxious animals. The river of Guayaquil, which is the principal channel of the commerce of the country, is navigable for the space of 24 leagues, from the isle of Puna at its mouth to the town of Babahoyo, where all the goods intended for the Cordillera, or proceeding thence, must be entered. This river is frequently swelled by torrents from the mountains; and, as these floods are continually shifting the sand banks, its navigation is uncertain, and requires constant sounding. It is navigated principally by *balzas*, or rafts, which are made of a soft, light wood, and which are of various sizes, but frequently carry 400 or 500 quintals. (See Balza.) The principal articles of the cargoes exported from the province are cacao, timber, salt, and cattle, tobacco, wax, Guinea-pepper, drugs, and ceibo-wool. This last is the product of a high and tufted tree, and bears a greater resemblance to silk than either to cotton or wool. It is chiefly used to fill mattresses, and has this remarkable property, that when compressed by dampness, yet, if laid in the sun, it swells again, and often with such force as to stretch the covering of the mattress. The imports are wine, brandy, oil, and dried fruits from Peru; bays, flour, papas, bacon, hams, cheese, and similar articles, from Quito; iron and cordage from New Spain; and European goods from Panama. But the principal profits of the Guayaquil traders arise from the commercial exchanges between Lima and Quito, which pass in the course of its river, especially in the summer season, when the goods can be conveyed between the mountainous districts and the shipping. The banks of the river are covered with habitations, as the inhabitants thus enjoy the advantages both of fishing and of agriculture. These houses, like the greater part of what are built in the province, are chiefly of timber, and raised upon posts 12 or 15 feet from the ground, on account of the general inundations during winter. In that season, the inhabitants of the level districts pass from house to house by means of canoes, which even the children are able to manage with extraordinary dexterity. The river of Guayaquil supplies the numerous inhabitants of its borders with abundance of fish; and the Indians after harvest set sail in their balzas with their families, and employ several weeks in fishing; moving from one creek to another, according to their success. Besides using harpoons and nets, they employ in the smoother creeks a certain herb called *barbasco*, which they chew, mix with bait, and scatter on the water. The juice of this herb is so powerful, that it often kills the smaller fish when they eat of it; and so stupifies the larger, that they float on the surface, and are taken up without any trouble. The increase of the fish is greatly hindered, by the multitudes of alligators which frequent the river and the adjacent plains; and some of which are fifteen feet in length. They are not ferocious, and uniformly flee at the approach of a man; but they often devour the calves, colts, and even the children when wandering near the river in the dusk; and it is said, that after once tasting human flesh, they become more ravenous, sometimes watching an opportunity to drag the boatmen, while asleep, into the water. The gallinazo, a bird about the size of a pea-hen, and very common in the hot climates of South America, furnishes a useful check to the increase of the alligators by its activity in destroying their eggs. Concealed among the branches of a tree, it silently watches the female alligator till she has laid and covered her eggs in the sand. As soon as she is gone, the bird darts upon the spot, and, assisted by a multitude of its tribe, who readily join the fortunate discoverer, uncovers the nest, and devours the eggs. See Ulloa's *Voyage to South America*, vol. i. (*q*)

GUAYRA. See Caraccas, vol. v. p. 424.

GUERCINO. The original name of this celebrated artist was *Giovanni Francisco Barbieri*. Malvasia relates, that in his infancy he lost the sight of his right eye, and that from this accident he acquired the name by which he is now generally known. He was born at the village of Cento, in the territory of Ferrara; and little doubt remains that he never received any regular instructions in painting but what he derived from two very obscure artists in his own country, namely, Gio. Batista Cremonini, and Benedetto Gennari. It has been affirmed, indeed, that he was taught in the school of the Carracci; but this supposition is rendered improbable by a variety of circumstances, and by none more than the peculiarities of his different styles, all of which are at variance with the principles of that school. It is more than likely, however, that he derived much advantage from studying the magnificent picture of Lodovico Carracci at the Capuchins at Cento; but for the great proficiency which he attained, he must be considered as chiefly indebted to the strength of his own genius, and to the careful study of nature. The tendency of his mind began to shew itself at an early age; and it is recorded of him, that when only ten years old, he painted a picture of the Virgin, in the façade of his

Guercino.

father's house, which would not have disgraced a more mature age, and a more practised hand. When premature talent is found to ripen into great excellence, we too readily give credit to the stories which blind admiration delights to record of childhood already atchieving what belongs to experience and age. And when his biographers relate that this picture of Guercino, at the age of ten, with such a subject as the Virgin, was actually a picture of *extraordinary excellence*; we may safely class it among those innumerable instances of a like nature, in which exaggeration sets not only what is probable, but what is possible also, at defiance.

In the course of his practice, Guercino adopted three different styles, which he followed at different periods. The first is not distinguished either by accuracy or grace of design; and in respect of colouring and effect, is violent, inharmonious, and harsh. It is a bad imitation of Michael Angelo Caravaggio, whose works at that time were held in high estimation. Dissatisfied with his attainments, he visited the celebrated schools of art at Rome, at Venice, and Bologna, and by great study and observation, he changed and improved his manner; and his second stile is free from many of the faults which are observable in his previous works. He still retained that vivid contrast of light and shade which distinguishes the productions of Caravaggio; and, like him, his outlines are generally lost, and blended in the *fondo*, but he now far surpassed him in grandeur of composition, and in dignity of character. His females are remarkable for elegant and fascinating beauty. His men, however, are not always free (even in this his best and most valued manner) from a degree of vulgarity and individuality, which probably arose from too strict an adherence to the mode from which he painted. Among the great performances which he executed at this period, we may reckon the picture of St Petronilla, formerly in St Peter's, and lately removed from the gallery of the Louvre; the Aurora, in the Villa Ludovisi; his St Philip of Neri; his St Glena; and his fine picture of the Resurrection. In a similar style of bold design, and magically forcible effect, both of colouring and of light and shade, he executed his grand undertaking of the Dome at St Piacenza, in which he has carried fresco painting to a high degree of perfection. The late Mr Barry, in a letter dated at Bologna, to Sir Joshua Reynolds, speaks in terms of the highest praise of the pictures by Guercino, at that time in the church of St Gregorio. Speaking of the solemn colouring in the works of Ludovico Carracci, "Guercino," says he, "has much of this manner in his fine pictures at St Gregorio, with this difference, that I observe in Guercino more mellowing and *fuoco* in the colouring;" and he regrets that this great artist should ever have departed from the grave majestic tone which he then practised. Like the great painter to whom he is thus compared, one great excellence of Guercino, is the clearness of his deepest shadows. In his best works, he admitted a very large proportion of shadow; yet, notwithstanding their breadth and deep repose, every object which it envelopes is as distinctly seen as it would be in nature. Nothing is lost, nothing is left ambiguous.

From this style, however, he was at an advanced period of his life tempted to deviate. The manner of colouring which Guido had adopted, remarkable for sweetness, openness, and delicacy, was become the subject of great admiration; and Guercino, in attempting to rival the peculiarities of style so widely different from his own, lost all that stamped him an original genius, and fell into a manner of comparative imbecility. In this last manner, were his pictures of the Annunciation at Forli, the Prodigal in the royal palace at Turin, and the Marriage of the Virgin in St Paterniano, at Faro.

This laborious artist left an incredible number of works. In the list given by Malvasia, he enumerates 106 altar-pieces for the churches, 144 large historical pictures, besides his great fresco works, and his numerous portraits and landscapes in private collections. He left also a vast number of drawings, which are held in great estimation. The etchings which he executed, nine in number, are very spirited. He died in 1666, aged 76. (*l*)

Guericke. Guernsey.

GUERICKE, Otto. See Pneumatics, *History of.*

GUERNSEY, the *Sarnia* of the ancients, is an island belonging to Great Britain. It is one of the Channel islands, lying within the bay of St Michael, and about seven leagues from the coast of Normandy. This island is of a triangular shape. Its extreme length is about $7\frac{1}{2}$ miles, and its greatest breadth about 4 miles. It is about 21 miles in circuit. According to the recent account of it given by Dr Macculloch, it is elevated to the south, and shelves towards the north. The southern coast is bounded by high cliffs, stretching along part of the eastern coast. The rest of the eastern coast, and the northern coast, consist of a number of flat bays, separated by ridges of lofty rocks. Dr Macculloch conceives the island to be divided by an imaginary line, drawn from the town of St Peter's Port to Pezeries. A level tract, broken only by cairns and rocky hillocks, lies to the north of this line. This tract comprehends an inundation of more than 60 years standing, which covers three hundred acres. It was formerly quite dry before the time of low water, but has lately been embanked and drained. Towards the south of the imaginary line, the country forms a higher stratum, everywhere intersected by deep glens and narrow vallies of various directions. With the exception of two or three narrow caves, which form the mouths of small vallies intersecting the high land, the lofty cliffs which bound the southern tract are continuous. There are here few detached rocks, but the northern coast is covered with them. Dr Macculloch observed, that the island is entirely of granitic formation; that the southern division consists wholly of gneiss; and that the rocks which form the northern point, exhibit various kinds of granite, or granitel. At the foot of a rocky steep near Prevolet Point, is a curious cave called *La Cave Mahie*. It is above 200 feet in depth; and from an entrance 9 or 10 feet wide and 6 high, it extends from 50 to 60 feet in height and breadth, ending in granite points.

General structure.

The soil of Guernsey, which is decomposed gneiss, is very fertile, and is well watered by springs and rivulets. Agriculture is carried on with great care. The lands are inclosed with stone fences. The seats of the gentry, and the farm-houses and cottages, which are very handsome, are agreeably situated among orchards and gardens. The ordinary food of the inhabitants, is a soup made of cabbage, pease, flour, and a few slices of green bacon. Their beverage is cyder. The produce of the island is nearly the same as that of the west of England. The fruits are very fine. Pigs are fed in winter on parsnips; and the butter, pork, and veal, are in the highest perfection. Red and grey mullets, mackarel, congor eels, and lobsters, are caught in great abundance round the island. Coals are imported; but the principal fuel of the poorer inhabitants is sea-weed, the ashes of which are used as manure by the farmers.

Soil and agriculture.

The climate of Guernsey is mild and temperate, and

Climate.

Guernsey.

is not subject to excessive heats or colds. The winters and springs are moist, and high winds often prevail.

Religious and political state.

Guernsey is divided into ten parishes, each of which is divided into several vintons, for the better management of affairs. The island is in the diocese of Winchester, and province of Canterbury. The convention of the state, consists of the governor, a bailiff, 12 jurats appointed by the king, who administer the laws, which are quite different from ours. These officers hold their places during pleasure; and they judge in all civil and criminal cases excepting high treason. The governor receives tythes of all kinds of grain. He has under him a lieutenant-governor, who is called the constable of the castle. The prevailing religion is that of the church of England, though the followers of Wesley are numerous. The Catholics are very few in number.

Principal town St Peter's Port.

The only town in the island is St Peter's Port. It originally consisted of a narrow street of high houses, but the buildings have been extended across a ravine over the surrounding heights. The lower streets are narrow, dirty, and irregular. The principal church, built in 1312, is of granite. It has Gothic mouldings, though no pointed arches. Its exterior is handsome. Its porch is remarkable for the depth and extent of its mouldings; and its tower is a great ornament from the pier and road It contains some good modern monuments. The new court-house is handsomely built of granite, and fitted up with suitable offices for the preservation of a few records. The new prison, built after the model of the debtors' gaol at Manchester, is very spacious and commodious. The work-house, or hospital, is supported by an endowment, and by an assessment on lands and houses. The harbour affords sufficient shelter and security to shipping. The keys and the piers are immense masses of rough masonry formed of granite, and extending out into the harbour. These walls are paved, and have parapets, and they inclose a space of several acres. The harbour and the road are exposed to the south-east. Harbours for vessels of light tonnage occur on the north and west sides of the island, at the creeks of Bazon, L'Accousse, Ferminer, St Sampson, and the west passage. The market-house for meat and vegetables, is a large building erected in an open square. Two large and handsome rooms have been fitted up above the market-house, for the public assemblies and entertainments, which are held monthly during the gay season. There is also a small theatre here. An ascent of about 100 steps, leads from the level of the market-place up the side of a ravine to the new town, where there are many good and open streets, one of which, called George Row, contains several elegant houses. The government house, the public walks at L'Hivreur, and the college founded by Queen Elizabeth, are the only other objects of interest.

Ancient castles.

There were formerly four castles in the island, viz. Castle Cornet, the Castle in the Marshes, Vale Castle, and the Castle of Notre Dame. Castle Cornet is situated on a rock of gneiss often approaching to granite, and intersected by veins of quartz, trap, and felspar, curved and mixed in various ways. This rock is about a quarter of a mile from the shore, and near Port St Peter's. It is scarcely accessible but on one side. It is surrounded with an outer wall of great thickness, flanked by several machicolated towers, and the keep has been converted into casemates. Elizabeth enlarged it with a lower line of curtain and bastions; and barracks and accommodation for a numerous garrison have since been formed. It is now defended by a considerable quantity of heavy artillery.

Guernsey, Guiana.

The Castle in the Marshes appears to be very ancient. It is encircled with a double wall of granite, and has an outer and inner ditch, and a keep in the Norman form.

The Vale Castle, which is also ancient, stands upon a commanding eminence, near St Sampson's harbour. It was once reckoned to be strong, but it has now only a surrounding wall, with flanking towers, and a portal. There are barracks for a garrison; and several pieces of cannon on the ramparts, command a passage called the Russel. The castle of Notre Dame, and that of Rocquane, no longer exist.

Manufactures and commerce.

The inhabitants are chiefly employed in agriculture, and in the cultivation of their gardens and orchards, from which great quantities of excellent cyder are made. The only manufacture is that of woollen goods. They are allowed to import 1000 tons of wool annually from England, which is made into stockings, waistcoats and breeches. Lobsters are the only fish which is exported. Guernsey was, before the establishment of the London Docks, the grand depot of all the foreign wines and brandies. Towards the bay of St Sampson's, there is a fine rock of grey or black granite, which is exported in large quantities to London and Portsmouth. It is called the Guernsey or St Sampson's stone, and being hard and tough, it is admirably adapted for building and paving, as it easily breaks into square masses before the hammer. Dr Macculloch could not obtain any physical or historical evidence that emery was a production of this island, as has been generally stated. Every part of the coast of Guernsey is fortified with strong batteries and breast works. The number of houses in St Peter's is about 800, and the population of the island about 15,000.

See Dicey's *History of Guernsey*; Grose's *Antiquities of England and Wales*; and Macculloch's *Account of Guernsey*, in the *Transactions of the Geological Society*, vol. i. p. 7.

Situation and extent.

GUIANA, an extensive country in South America, is bounded by the river Orinoco on the north, by the river of the Amazons on the south, by the Atlantic Ocean on the east and north-east, and by New Granada on the west. It is nearly of a triangular form, and is computed to contain 250,000 square miles. It extends along the coast from the mouth of the Orinoco to that of the Maranon or Amazons river, about 700 miles; and stretches inland from east to west about 1200. The Orinoco is known to communicate by several branch-streams with the Maranon; and one of these, called the Yupura, is considered as the western verge of Guiana. It is therefore completely an insulated tract, and is probably capable of being circumnavigated.

Discovery and history.

The discovery of Guiana has been attributed by some to Columbus in the year 1498, and by others to the Spanish navigator Vasco Nunes, who, after ascertaining Cuba to be an island, landed in 1501 on the continent of South America; and, having traced the coast from the Orinoco to the Maranon, comprehended the whole tract in that extensive country, to which, in contradistinction to Cuba and the adjacent islands, he gave the general name of Terra Firma. But, though originally seen by the Spaniards, Guiana was little known, till it was visited by Sir Walter Raleigh in the year 1595; who not only explored the coast, but also sailed up the river Orinoco about 600 miles in quest of the imaginary El Dorado. Several English buccaneers next re-

Guiana. sorted to the coast; and, in 1634, about sixty persons, partly English and partly French, under the command of a Captain Marshall, were found in Surinam cultivating tobacco, and making trading voyages to the neighbouring coasts. In 1650, this voluntary settlement was taken under the protection of Great Britain, and Lord Willoughby of Parkham was appointed governor; but, in 1667, it was taken by the Dutch, and finally ceded to them by the treaty of Westminster in 1674, in exchange for the province of New York. Similar settlements were gradually made by other powers, on different parts of the coast: and the country of Guiana has thus been distributed by geographers into four distinct divisions; viz. Spanish Guiana, Dutch Guiana, French Guiana, and Portuguese Guiana. Spanish Guiana extends along the coast about thirty leagues from the mouth of the Orinoco to Cape Nassau, and runs inland about 150 leagues on the south of the Orinoco; Dutch Guiana lies between Cape Nassau and the river Maroni; French Guiana between the Maroni and the river Carapana; and Portuguese Guiana, between the Carapana and the river of the Amazons. The more inland part of the country, behind these settlements, may be considered as a fifth division, and called Indian Guiana. Of these, Spanish Guiana is by far the most extensive and valuable possession. Its breadth, indeed, for the space of 80 leagues eastward, does not exceed 30 leagues; but it afterwards widens to more than 150 leagues, running along the back of the Dutch and French possessions, till it reaches the equinoctial line, which separates it from the Portuguese territories. It is divided into Upper and Lower Guiana, of which the river Caroni may be considered as the separating boundary. Lower Guiana is intersected in all directions by numerous rivers, which from time immemorial have contributed to increase the vegetable mould on its surface, so that in point of fertility it is not surpassed by any other portion of territory in the American continent. But, for the space of 30 leagues from the coast, it is completely occupied by the Caribs, the most ferocious of the Indian tribes, who have hitherto massacred every Spanish missionary or settler, who ventured to approach their habitations; and whose hostility to the Spaniards, the Dutch have been accused of fomenting, for the purpose of extending their commerce along the coast of Spanish Guiana. The city of Saint Thomas, the capital of Spanish Guiana, is situated on the right bank of the Orinoco, about 90 leagues from the mouth of the river; and is the residence of a governor and a bishop. Its streets are regularly built and well paved; and its climate pure and healthy; but its port is incommodious, and its distance from the coast unfavourable to its commercial prosperity. From this port of Guiana, were exported, from 1791 to 1794, 10,380 oxen, and 3140 mules, all either bred in the province or brought from Varinas; and, in return, were imported 200 negroes, and 349,448 piastres in specie. From 1791 to 1795 the silver exported to Europe amounted to 25,203 piastres, and the commodities to 363,397 piastres. But this commerce is said to have greatly diminished. The population of Spanish Guiana, exclusive of the portion occupied by the Caribs near the coast, is estimated only at 34,000, of which 19,425 Indians are under the jurisdiction of the missionaries, 6575 reside in the capital, and the remaining 8000 are scattered through the different villages. Farther particulars respecting the political and ecclesiastical state of this province will be found under the articles CARACCAS and ORINOCO; and for an account of the other European settlements on the coast of Guiana, we refer to the articles BERBICE, CAYENNE, DEMERARY, SURINAM, &c. In the present article we confine ourselves to such topics as may be considered common to them all, especially to the natural history of Guiana, comprising its soil, climate, native productions, original inhabitants, &c.

Division.

Spanish Guiana.

Aspect.

Guiana was originally called by some navigators the wild coast; and its shores, accessible only by the mouths of its rivers, are every where covered by dangerous banks, quicksands, rocks, and impenetrable thickets. Its appearance from the sea is wild and uncultivated; and it is so low and flat, that, even where there are plantations along the coast, there is nothing visible at first, but a continued forest standing close to the beach; so that the country appears as a cluster of trees growing out of the water. The European settlers, particularly the Dutch, attempted at first to cultivate the banks of the rivers, at a considerable distance from the coast; but, by the example of the British, were persuaded to extend their plantations along the shore, where the soil is remarkably fertile, and adapted for every variety of tropical production. The ground, for a considerable way up the country, is every where level; and so low, that, during the rainy season, it is usually covered with water nearly two feet in height. This renders the soil so rich, that, on the surface, for 12 feet in depth, it is a stratum of perfect manure, and has been actually carried to Barbadoes for that purpose. In some places, 30 crops of rice can be raised in succession; whereas, in the West India islands, not more than two is ever expected from the richest lands. The whole country is intersected by deep swamps or marshes, numerous rivers, and extensive savannahs. The interior has been little explored; but, in proceeding inland, it becomes more hilly, and the soil poorer, sometimes rocky, and often sandy. It is covered with immense forests, rocks, and mountains; and, in some of the latter, a variety of mineral substances are found. The most prominent objects are a lake called Parima, whose extent varies with the seasons; and a chain of mountains called Mei, nearly parallel with the form of the coast. From these mountains, rivers flow in every direction; some, like the Essequibo, falling into the Atlantic; some, like the Caroni, joining the Orinoco; and others, like the Rio Blanco, uniting with the river of the Amazons.

Soil.

Climate.

The climate of Guiana is the mildest and most salubrious of any tropical country hitherto inhabited by Europeans. This has been ascribed principally to the regular blowing of the trade-wind over the surface of a vast tract of ocean, which thus carries a perpetual stream of cool air over Guiana from east to west; while, on the opposite coast of Africa, the same equatorial wind, coming over land, is heated with the sultry vapours of sandy deserts. Besides this general flow of the whole atmosphere in a westerly direction, there is a daily lateral fluctuation, termed the sea-breeze and the land-breeze; the former, which is the cooler of the two, blowing from the north-east during the day, temperating the ardour of noon; and the latter, which is the warmer of the two, blowing from the south-east during the night, preventing too rapid a chillness. The range of the thermometer on the coast, during the whole year, is from 72 to 87; and, between two or three hundred miles up the country, it is from 65½ to 84. Instead of the cold and the warm seasons of Europe, the year is divided by the rainy and the dry seasons, which may be termed the winter and summer of the country. But, in Guiana, there may be said to be annually two winters or wet seasons, and two summers or dry seasons, which are distinguished from each other by the appellation of the *greater* and the *smaller*, referring not to the intensity of the heat, or the violence of the rains in the one more than the other, but to their duration. The long wet season begins about the middle of April, declines in August, and ceases in September; when the short dry season commences, and continues till the middle of November. Then comes on the short wet season, which lasts till the middle of January, when the long dry season appears, which does not terminate till the middle of April. During this last period, especially in the month of March, the weather is most pleasant, the atmosphere clear and pure, the climate genial and cool. There are frequent variations in these stated periods; and the changes are generally accompanied with tremendous storms of thunder and lightning, which sometimes prove fatal both to the inhabitants and the cattle of the country. In the wet season, though the rain falls in torrents, yet it is generally in the afternoon; and in the dry season, there is rarely a drought, but showers occasionally come during the night. The earth is thus, during the whole year, adorned with perpetual verdure, the trees loaded at the same time with blossoms and ripe fruit; and the whole presenting to the view a delightful union of spring and of summer. There are no hurricanes to destroy the crops of the planter; and rarely are any earthquakes felt in the level districts.

Diseases. There are few contagious disorders in Guiana; and by temperate living, together with proper care to avoid the mid-day heat and evening dews, Europeans have been able to preserve a state of excellent health in the country. The principal disease is fever, in a variety of forms and degrees, from the simple intermittant to the dreaded yellow fever. A prickly heat, or scarlet eruption, is frequently experienced, which causes extreme itching, but is considered rather as friendly to health. The stings of the musquitoes or gnats are often succeeded by large pimples, which are apt to be converted by scratching into troublesome ulcers. The ring-worm consists of long scarlet spots, chiefly about the face and neck, and is prevented from spreading by the immediate application of lime-juice mixed with gun-powder. The chigoe, or jigger, is a kind of sand-flea, which lodges under the toe-nails, between the skin and the flesh, and unless extracted as soon as the itching which they occasion is felt, are apt to produce very deep and fretting ulcers. The yaws, a dreadful disorder resembling the small-pox, and covering the body with large ulcers, is extremely infectious, but seems peculiar to the negro race. Dry gripes, bloody flux, and dropsy, are also frequent.

Vegetable productions. The vegetable productions of Guiana are exceedingly numerous, and many of them particularly worthy of notice, both as objects of curiosity and as articles of utility. The trees in the forests grow to an immense size, many of their trunks rising to the height of 100 feet, and throwing out at the lower extremity a number of flattened projections, which surround the stem like supporting buttresses, and form deep recesses, capable sometimes of affording shelter to 10 or 12 persons. Mountain cabbage. The mountain cabbage, unrivalled in the vegetable world, has a straight tapering trunk 100 feet in height, and 7 or 8 feet in circumference, branches 20 feet in length, diverging in a horizontal direction, palmated narrow leaves above 2 feet long, a green husky pod 20 inches in length at the clefts of the lower branches, full of nuts, which are the seeds of the plant; and, on the summit of the trunk, the cabbage, consisting of thin white strata, and resembling an almond in taste. Silk cotton tree. The silk cotton tree, generally growing to the height of 100 feet, with a trunk 12 feet in circumference, and free of branches for the space of 70 feet, bears a pod full of silky filaments. Red mangrove tree. The red mangrove tree, growing in marshy places, rises from a number of roots, which appear several feet above ground, before they are joined together to form the main trunk, which is generally tall and large, hard, and good for building; and numerous ligneous shoots, without leaves or branches, descend from the stem and the lateral boughs towards the ground, where they take root, and like props or pillars, afford support to the tree in its watery soil. Cocoa nut tree. The cocoa nut tree, growing to the height of 60 or 80 feet, but seldom perfectly straight, bears fruit at the age of six or eight years. Pipeira tree. The pipeira tree, about 70 feet high, and 9 in circumference, affords a weighty durable timber, and bears a small round fruit of a farinaceous nature, which is sometimes used by the Indians as food. Among a variety of other valuable forest trees, growing to the height of 50 feet, may be mentioned the Iron wood tree. iron-wood tree, so called from its hard and heavy wood, which is used for clubs, windmills, and similar purposes; Bullet tree. the bullet-tree, which has a dark coloured wood, spotted with small white specks, very durable, and so weighty as to sink in salt water; Launa tree. the launa tree, which bears a fruit like an apple, yielding a purple coloured juice, employed by the Indians in painting their bodies; Mahogany. the mahogany tree, resembling the cedar, and preferring a rocky soil; Tonquin bean tree. the tonquin bean tree, which bears the sweet-smelling pulse of that name, and some of which sometimes grow to the height of 70 or 80 feet; Cassia fistula. the cassia fistula, covered with a light brown bark, and bearing pods 18 inches long, containing a sweet pulp resembling treacle. Of a smaller size are the bourracoura, or Letter wood tree. letter wood tree, which contains a heart of a deep red colour, marked with black spots, hard, ponderous, capable of the finest polish, and highly valued for its beauty; Hiarree. the hiarree tree, which grows near rivers, and generally at a distance from other trees, esteemed a strong poison, even the smoke of the wood when burning proving fatal to animal life; the cocoa tree, which bears a pod of the size and shape of a melon, containing rows of nuts in its longitudinal cavities.

Fruit trees. Guava. The most valuable fruit trees are the guava, which bears a round fruit of a light yellow colour, the internal part of which is a red pulp generally made into jellies, and the external part resembling the substance of an apple, employed in tarts, &c.; Tamarind. the tamarind tree, which grows to a considerable size, and produces its fruit in a large pod; the aviato or avogato pear tree, resembling a walnut tree, and bearing a delicious fruit like a large pear of a pale green colour, and yellow pulp, similar in taste and flavour to the finest peach; the female poppau, which produces an oval-shaped fruit, about six inches in length; plantains, bananas, pine apples, &c. Shrubs. Among the useful shrubs, we can only particularize the cotton bush, which produces two crops annually; the coffee bush, which also bears two crops, each tree yielding about a pound and a half at a crop; Castor bush. the palma christi, or castor bush, which bears nuts of a triangular form, covered with a thin brown fur, the kernels of which yield by expression the well known castor oil; the cassava shrub, of which the roots are ground into meal, and formed into an excellent bread; but the bitter cassava, though it becomes a wholesome food when boiled or baked, is in its raw state a fatal poison. Of many curious plants may be mentioned the Aloe. aloe, of which there are various kinds; the caruna shrub, bear-

Guiana.

Silk-grass plant.

ing a nut, of which the kernel is used by the Indians as a slow poison; the curretta, or silk-grass plant, a species of aloe, the leaves of which contain a saponaceous pulp, used in washing, mixed with fine and strong white filaments, which when properly cleaned, can scarcely be distinguished from threads of silk, and are employed in making nets, cords, &c.; the siliqua hirsuta, a slender creeping plant like the vine, bearing pods resembling the common pea, covered with fine stiff pointed hairs, which, upon being applied to the skin, produce an intolerable sensation of itching; troolies, or leaves of an enormous size, from 20 to 30 feet in length, and about 2 or 3 in breadth, growing from a short root close to the ground, and used as a thatch for houses, which they protect from the heaviest rains, and last for many years; nibbees, a kind of ligneous rope, without any foliage, growing to an immense length, and from 3 to 18 inches in circumference, sometimes entwining themselves together to the thickness of a ship's cable, and at other times interweaving themselves like nets, so as to intercept the game in their course, frequently climbing to the tops of the loftiest trees, and again descending to take root in the earth, often coiling themselves so closely around the trunks of the trees, as completely to check their growth, and so extremely tough as to be used by the natives for fastening the posts and thatch of their huts.

Troolies.

Nibbees.

Roots.

The roots most deserving of notice, are the ipecacuanha, the ginger, and the Indian yam, which last is about eight inches in length, and six in circumference, of a reddish purple colour, and affords an agreeable farinaceous food.

Animals.

The native animals of Guiana are not yet fully ascertained; and its unexplored forests contain, in all probability, many animated beings, which are but very imperfectly known to the zoologist. Many of the domestic animals, the bull, the cow, the ass, the hog, the sheep, &c. have been imported from the old continent; and some of these, having escaped into the woods, have run wild and multiplied rapidly. Most of them, however, have greatly degenerated both in size and in flesh, in consequence, it is conjectured, of the perpetual perspiration to which they are exposed, and the coarseness of the grass on which they feed. The sheep, particularly, are remarkably diminutive, and their wool converted into straight hair. The hogs, on the contrary, are large and fat, and superior to those of Europe. The goats are large and beautiful animals, common in all parts of the country; often kept on the plantations, where they breed quickly, and yield much milk. The poultry are as plentiful and excellent as in any part of the world. A smaller species of domestic hen with rumpled or inverted feathers, is reared by the natives in the inland parts of the country, and is considered as natural to Guiana.

Domestic animals.

Beasts of prey.

The beasts of prey, which abound in the forests of this country, though numerous, are not remarkably formidable to the human race. The most powerful is the tiger, of which there are several kinds; the jaguar, which resembles the African species, and sometimes measures six feet from the nose to the root of the tail, is very strong and ferocious, frequently attacking the cows, horses, and young negroes on the plantations; the couquar, or red tiger, resembling a grey hound in shape, but larger in size, and equally fierce as the last mentioned; and the tiger cat, a beautiful creature, not much larger than the domestic cat of Europe, but destructive and untameable like the rest of its kind. This is a ferocious little creature, called the crabbo-dago, not much larger than a common cat, and supposed to be the same with what Buffon calls the grison or grey-weasel, which is never glutted with blood, but murders whatever comes in its way, whether quadrupeds, fowls or reptiles, if it is able to vanquish them. There are various kinds of monkeys, but no apes in Guiana. The natives affirm, that the ouran-outang, five feet in height, is found in the woods, but no European has ever seen any of these animals in the country. Of the others, the most remarkable are, the quato, which has a naked face, a nose like that of a negro, deeply sunken eyes, large ears, and, excepting its long tail, bears a great resemblance to the human form; the howling baboon, which is about the size of a small bull dog, has a long black beard, and is chiefly remarkable for assembling in large crowds, and uttering a most disagreeable howl or yell, which is continued for a long time, and which is said to be a sure sign of approaching rain; and the saccawinkee, or schacomingky; sometimes called the lion monkey, a small and delicate creature, only about five or six ounces in weight, which perches like a bird upon the forefinger, and is frequently brought down to the plantations by the natives for sale, has a small head, round smooth ears, oval face covered with fine white hair, a tail much longer than its body, long bushy black hair, especially around its neck, like the main of a lion, is extremely susceptible of cold, and though frequently tamed, seldom lives longer than a few months. The coatimondi or Brasilian weasel, shaped like a dog, often as large as a fox, and resembling that animal in cunning, is a great destroyer of the poultry; and, equalling the monkies in the faculty of climbing trees, commits great ravages among bird nests. One of the most extraordinary animals in Guiana is the great ant-bear, which often weighs from 150 to 200 lbs. and measures not less than eight feet from the snout to the tip of the tail. It has a small head, covered with hair as soft as velvet, and a tail immensely large, flat, and covered with long hair like that of a horse, and as strong as the bristles of a hog, with which, during a shower, or when attacked, or when asleep, he protects his whole body. His feet are armed with long claws, with which he can defend himself against any dog, and even against the tiger, and never quits his hold while he has life. He has a long slender tongue, resembling a worm, sometimes almost two feet in length, and moistened with saliva of a sweetish taste, which he thrusts into the ants' nests, who settle upon it in crowds, when he draws it into his mouth, renewing the operation till no more are to be found. There are found in Guiana the porcupine, the armadillo, the sloth, several kinds of opossum, wood-rats, and hedge-hogs.

Coatimondi.

Ant-bear.

Deer.

There are two kinds of deer, the largest of which, called bajew, are about the size of an English buck, and feed in great numbers in the savannahs; the smaller species, called wirreboeerra, are remarkably nimble, have no horns, and make the most delicate venison. The paccarara, or Indian coney, is common in all parts of Guiana, and greatly resembles the hare in shape and size; is very prolific, and easily taken; and its flesh, which is much like that of a rabbit, forms a principal part of the food of the natives. There are several kinds of wild hogs in the forests, particularly the pingos, or warree, resembling small English hogs, found in herds of 300 or more, running always in a line, and easily knocked on the head. A larger kind, called eras-pingos, are armed with strong tusks, and, when wounded or obstructed in their course, become extremely ferocious. But both these kinds are supposed to be merely

Wild hogs.

Guiana. the domestic hog of Africa or Europe in a wild state; and the only species indigenous in Guiana, is the piccaree, or Mexican hog, which is about 3 feet in length, without either tusks or tail, and is particularly remarkable, from having on its back, above the hind legs, a cavity about an inch deep, filled with a white fetid fluid, which, unless cut out as soon as the animal is killed, infects the whole flesh, so as render it unfit for being used as food. They are found in large herds in the drier and mountainous parts of the country; and their flesh is greatly admired by the natives. There is a great variety of lizards, of which the most remarkable is the guana, about three feet in length, and generally found among the shrubs and fruit trees. Its eggs, which are deposited in the sand, are reckoned excellent food; and its flesh particularly is esteemed a great delicacy, resembling in taste that of a chicken.

Amphibiæ. Tapira. The amphibious animals are very abundant in Guiana; of which we can only slightly notice the tapira, resembling the hippopotamus, but not larger than an ass, with the head of a horse, and a considerable prolongation of the upper lip, excessively thick skin, bristly mane, and short tail, feeds on grass and aquatic herbs, and its flesh is accounted superior to the finest ox beef, but it is rarely procured, as the animal is extremely shy, and plunges into the water upon the least alarm; the manatee, or sea cow, about 16 feet or more in length, with a head like that of a hog, nostrils like an ox, breasts like those of a woman, and a tail like that of the whale, seldom quits the water entirely, and its flesh, which is very fat, tastes much like veal; the alligator, or cayman, found sometimes 20 feet in length, but generally harmless, and even in water seldom attacking a man, as long as he keeps himself in motion; the laubba, which seems to be the same with what others call the paca, or spotted cavey, or aquatic hare, is peculiar to this part of the world, about the size of a sucking pig or large cat, with the head of a pug dog, extremely fat, and resembles the finest pork, feeds on herbs and grain, takes refuge in the water when pursued, swimming a long time at a short distance from the surface, so that it is often shot under water with arrows; the pipa, a kind of toad or frog, sometimes as large as an ordinary duck, a creature of a hideous appearance, covered with a brown shrivelled skin, and chiefly remarkable for the uncommon loudness of its voice; but still more for the peculiar manner of its propagation, the young being hatched in watery cells on the back of the female, or, according to others, placed there by the assistance of the male after they have become tadpoles, and continuing to nestle there till the second transformation is completed.

Sea cow. Alligator. Laubba. Pipa.

There are many snakes in Guiana, of which the best known are the rattle-snake, whip-snake, and dipsas; the papaw, or ammodytes, a harmless and beautiful creature, from three to five feet in length, which is revered by the natives as a sacred object; the oroocookoo, supposed to be the same with the small laboia, the bite of which has been known to prove fatal in a few minutes; and the aboma, an amphibious animal, delighting in low marshy places, found upwards of 20 feet in length, and said, when fully grown, to be from 30 to 40 feet long, and from 3 to 4 in circumference at the thickest part of the body. Its bite is not considered as venomous, and it is a sluggish unwieldy creature, but seizes its prey by surprize, and devours deer, hogs, or even the tyger without difficulty, entangling and crushing them in its grasp, besmearing them with saliva, and swallowing their bodies entire.

Papaw. Aboma.

Birds. The birds most commonly found in Guiana are the vulture, eagle, owl, falcon, butcher bird; parrots of various kinds; large and beautiful mackaws, some of which are about the size of a capon, toucan, pelican, wood-pecker, green sparrow, tiger bird, a kind of heron of a reddish colour, spotted with black; flamingo found in flocks on the banks of rivers, and so tame as frequently to mix with the poultry on the plantations; agame, or trumpeter, a kind of turkey peculiar to the country, and often domesticated; sun-bird, resembling the English partridge, and sometimes kept in the houses to destroy the ants; peacock-pheasant, or powese, resembling in size and flavour an English turkey; kishee-kishee, about the size of a sparrow, adorned with most beautiful plumage, and sometimes brought by the Indians from the interior of the country; the mocking bird, which hangs its nest, (about 14 inches in length, and 8 in circumference,) at the extremity of the twigs of the remotest branches, as a security from the monkies; and the humming bird, which is found here in great number and variety: the most common of these, of a green and crimson colour, is not bigger than a large cherry, and the smallest, of a black and green colour, with a golden tuft on its head, nearly a third less than the last mentioned, sometimes weighs little more than 50 grains. There are bats of a large size, some of which have been found to measure thirty-two inches between the tips of the extended wings, and which are known to open the veins in the feet of persons asleep, and to suck the blood till they are satisfied.

Flamingo. Kishee-kishee. Humming bird. Bats.

Fish. The fish caught on the coast are far from being delicate, as the water is extremely muddy for several leagues from the shore. The most remarkable of the salt water fish is the low-low, about six inches in length, and three in circumference; and the largest of the fresh water fish is the barroketa, about three feet long, and two in circumference, resembling a salmon, white, fat, and delicate. The peri, another fresh water fish, about 18 inches long, and of a flat form, has a large mouth armed with long sharp teeth, and is said to attack persons when bathing in the rivers. The frog fish is one of the greatest curiosities in Guiana, and is said to pass by regular gradations, through the form of a frog, a frog fish, and lastly a fish, but is affirmed by Stedman to proceed rather in the opposite direction, from a fish to a frog, and to be probably nothing else than a kind of tadpole, which grows to a large size before undergoing its usual transformation; in the fish state, it is about eight or ten inches long, without scales, and exceedingly fat and delicate. The galvanic eel is very common in the rivers of this country, generally about three feet in length, and 12 inches in circumference, though sometimes found of a much larger size; it comes frequently to the surface of the water, as if to inhale the air, and its flesh is esteemed delicate food by the natives. Multitudes of crabs are found in the bottoms of the muddy streams; and a large land crab, much used as food by the natives, abounds on the banks of the sea, at the mouth of the rivers.

Frog fish.

Insects. Insects abound in Guiana in vast numbers, owing to the continued warmth of the climate, which both favours their production, and prolongs their existence; and continually flying in the faces, or crawling about the bodies of the inhabitants, are the most intolerable pest of the country, especially to new settlers from Europe. Musquitoes are inconceivably numerous during the rainy season, particularly on the coast, and on the banks of rivers; and are said to prevail most in places, which are in a state of progress from a wild to a completely

Guiana. cultivated condition. The juice of lemons or limes, mixed with water and applied to the skin, is at once the best remedy for their stings, and a tolerable preservative against their attacks. Cock-roaches are found from one to two inches in length, which make their way into chests and boxes, and besides destroying cloths of every description, render every kind of victuals which they attack utterly disgusting, by the nauseous smell which they leave behind. As this creature is seldom seen to fly, the best preservative against its ravages is to place the boxes or trunks upon empty wine bottles, kept free from dust, so as by their smoothness to render its ascent more difficult. Ants of many different kinds are extremely numerous, and prove very destructive to the stores, (especially of sugar,) in the plantations. Their immense nests of black earth, built on the trunks of the trees, are often so high as to resemble large black bears at a distance; and some of their hillocks on the ground have been seen as high as 15 or 20 feet, and nearly 100 feet in circumference. Some of these insects are above an inch in length, and cause great pain by their bite. A small species, called the fire-ant, which flies in great numbers, occasions a burning sensation resembling that produced by boiling water, supposed to proceed from some venomous fluid injected into the wound. There are two kinds of fire-flies, the smallest of which seen only during night, emits sparks of fire at intervals; but the larger kind, which is more than an inch in length, affords so steady and clear a light, that two or three of them put into a glass will enable a person to read or write without difficulty. The bees of Guiana are very small, of a black colour, and armed with powerful stings; and one species, mentioned by Stedman, which builds its nest in the roofs of houses, is said to attack every stranger with the greatest fury, while it never molests the regular occupiers of the habitation in which it has taken up its abode. The grasshopper tribe is sufficiently numerous; but two kinds are peculiarly worthy of notice, one called "the walking leaf," from its wings, about three inches in length, being so folded on its back, as to give it a close resemblance to a brown leaf; the other, called in Surinam "Spaanse-juffer," has a body about seven inches in length, not thicker than a common quill; has no wings, but is mounted like a spider on six legs, nearly six inches long, and has on its head four antennæ, two of which are about five inches in length. An enormous and hideous looking spider, called the bush-spider, is found in the forests; and is of such a size, that one of them, when put into a case bottle eight inches high, actually reached the top with some of its claws, while its feet were resting on the bottom. It feeds upon all kinds of insects, and is said even to suck the blood of young birds. Its bite is so venomous, as to be supposed to prove sometimes fatal, and always at least occasions a fever. The groe-groe, or palm-tree worm, about three inches long, and thick as a man's thumb, of a light yellow colour, with a black head, breeds in the cabbage tree after it is cut down, is roasted and eaten as a great delicacy, equal to the finest marrow; and sometimes its fat, melted and clarified, is used instead of butter. There are centipedes above six inches in length, which move with equal rapidity backwards or forwards, and whose bite is venomous. Scorpions, also, are frequently found among old trees and rubbish; but their sting, though very painful, and apt to occasion fever, is said not to be mortal.

Insects. Cock-roaches. Ants. Fire-ant. Bees. Grasshoppers. Bush-spider. Palm-tree worm. Centipedes. Scorpions.

For an account of the native human inhabitants of this country, we refer to the general description of the American Indians, given under the article America; and shall only notice here, in a cursory manner, the particular tribes which occupy the interior of Guiana, but occasionally visit the European settlements on the coast. The chief of these are the Caribs, Accawaws, Arrowawes, and Worrows. The Caribs inhabit that part of the coast which lies between the Essequibo and the Orinoco, and are by far the most numerous, warlike, and active of the natives. Their stature is taller, their complexion lighter, and their features more sprightly and agreeable than those of the other tribes. They are also more industrious, and, besides the ordinary Indian occupations of hunting and fishing, they cultivate fields of plaintains and cassava around their dwellings. They carry on constant hostilities against the Spaniards; but are considered as allies of the Dutch. They frequently go to war also with the other tribes; and, in some instances, have been known to devour their enemies slain in battle. The Accawaws inhabit the inland districts behind the Caribs, and adjacent to the sources of the Essequibo, Demerary, and Berbice. They bear a nearer resemblance in their persons to the Caribs than the other tribes; but are more grave in their aspect and manners, and remarkable for their superior cunning. They are also addicted, more than any of their neighbours, to the use of poison, both against their enemies, and those of their own people who may have done them any injury. The Worrows occupy the coast between Demerary and Surinam, and are much darker in their colour, disagreeable in their aspect, and dirty in their habits, than any of the other tribes. They are said to be extremely pusillanimous and lazy, scarcely exerting themselves to provide any other clothing than the bark of trees, or to procure any better food than crabs and fresh water. The Arrowawes reside behind the Worrows, at the back of the settlements of Surinam and Demerary, and are described as the most gentle in manners, lively in temper, and handsome in person, of all the Indians of Guiana. They are remarkably friendly to the Europeans, and peaceable in their intercourse with the other Indian nations. Besides these four tribes, who are most frequently seen at the settlements on the coast, other two have been mentioned, namely, the Taiiras, residing on the sea-coast between Surinam and the river Amazon, who are said to be extremely numerous, but peaceable and indolent, resembling very much the Worrow tribe; and the Piannacotaws, who live far inland, and are violent enemies to all Europeans, with whom they obstinately refuse to have any kind of intercourse. It has long been the policy of the Dutch settlements to cultivate the friendship of these native tribes; and an annual sum is expended in purchasing blue cloth, beads, hatchets, ribbons, and other ornaments and implements as gifts to their Indian neighbours. They come down to the colonies occasionally in small parties, and make engagements to cut wood, an operation at which they are remarkably expert; but they soon become impatient of the restraint of regular industry; and sometimes take their departure suddenly without any apparent reason. They frequently appear also as traders, bringing as their merchandize, cotton hammocks, canoes, baskets, wax, balsam of capivi, arnotto, wild nutmeg, wild cinnamon, parrots, monkeys, ebony, and other curious woods; for which they receive, in return, chequered cloth, fire-arms, gunpowder, hatch-

Guiana. Natives. Caribs. Accawaws. Worrows. Arrowawes. Taiiras. Piannacotaws.

ets, knives, scissars, looking-glasses, fish-hooks, combs, needles, pins, beads, &c. One of their favourite purchases is rum, which they swallow with eagerness till they become completely intoxicated; but it is generally observed, that one half of the party keep themselves sober to watch their drunken friends, who afterwards perform the office of guards in their turn. Sometimes they bring down the prisoners whom they have taken in war, and sell them as slaves; but these captives serve only for show, as they absolutely refuse to work; and, if treated harshly, particularly if beaten, they pine and languish, refusing even to take food, till they finally die of want or dejection. The native Indians have a strong dislike of the negroes, whom they regard with contempt as an inferior race, and are generally ready to render assistance to the colonists in suppressing insurrections among the slaves, or apprehending the runaways. It is strongly recommended that every inducement should be offered to encourage their intercourse with the settlements; and that fairs should be held, at certain fixed seasons, for their barter trade, which might thus be greatly increased to the mutual advantage of both parties.

See Depon's *Travels in South America*; Pinckard's *Notes on the West Indies*; Bolingbroke's *Voyage to the Demerary*; Stedman's *Narrative of the Expedition against the Revolted Negroes of Surinam*; Bancroft's *Natural History of Guiana*; and *Letters to Dr Pitcairn*, published in 1766. (*q*)

GUIDO. See Rheni.

GUILDFORD, a borough and market town of England, in Surrey. It is the county town, and is situated on the side of a considerable chalk hill on the east bank of the Wey. This river is crossed by a stone bridge of five arches, which was lately widened with brick, and the centre arch enlarged to allow barges to pass. The town is large and well built, and consists principally of one excellent and spacious street, which, from the declivity of its situation, is particularly striking to strangers. Guildford contains three parish churches. Trinity church is situated on the top of the hill, and on the south side of the high street. The foundation stone was laid in 1740, and it was completed in 1763. It is a handsome brick structure, 82 feet long, and 52½ broad. The tower, which is also of brick, is about 90 feet high, and contains eight bells. St Mary's church is a very rude and ancient building, consisting of chalk, flint, pebbles, and rubble stones, coarsely put together. St Nicholas's church, which stands on the west bank of the Wey, is an ancient building of chalk and stone. The other public buildings and institutions are the hospital, the free grammar school, the town or guildhall, the theatre, and the gaol. The hospital, built in 1619, is a brick building, inclosing a quadrangular space of 66 feet broad, and 63 deep, with a noble tower gate, with four turrets, at its entrance. It was founded by George Abbot, archbishop of Canterbury, for the maintenance of a master, twelve brethren, and eight sisters. The free grammar school, built of brick and stone, was built in 1557, and is 65 feet long and 22 broad. The town or guildhall, is a spacious building, with a turret on the top. It was erected in 1683, and is 44 feet long. The hall was formerly used at the assizes; but in 1789, Lord Onslow and Lord Grantley purchased the Red Lion Inn, and on one part of the ground erected a room 40 feet long, 30 broad, and 20 high, in which the judges now sit. The theatre was built near this room a few years ago. The gaol, rebuilt of stone in 1765, is near St Mary's church. There is also here a charity school, a Roman Catholic chapel, and meeting houses for the Baptists, Presbyterians, and Quakers: a cold bath was erected at a house near the bridge, by Lord Grantley in 1775. There is a fine circular race course about two miles east of the town. A plate of 100 guineas, given by William III. and three subscription plates, exclusive of matches, are run for in Whitsun week. The castle of Guildford, one of the principal objects in the town, is situated about 300 yards southward of the high street. The keep is now the chief part that remains. It is a quadrangle 47 feet by 45½, and 70 feet high. The walls are ten feet thick. On the west side of the keep may be seen the outer gate of the castle. The ruins occupy at present about five acres. In the chalky cliff on which the castle is situated, is a series of caverns. One of these caverns is 45 feet by 20 wide, and 9 feet high. This town formerly enjoyed a considerable share of the clothing trade; but a small part of it only remains. The trade of the place consists chiefly in sending timber and corn to London by the Wey, and in supplying the surrounding villages with their requisite merchandize. A direct communication has lately been made with Brighton and the coast of Sussex by a turnpike road to Horsham, and a fund has been raised for joining the river Wey and the Arun, so as to form a navigable line from London to the sea at Little Hampton.

The town is supplied with water by means of an engine, which discharges it into a reservoir at the foot of Poyle hill, from which it is carried by pipes to the houses of the inhabitants.

The following is the population abstract for the borough for 1811.

Inhabited houses	495
Number of families	596
Families employed in agriculture	46
Do. in trade and manufactures	434
Males	1382
Females	1592
Total population	2974
Increase since 1801	340

See the *Beauties of England and Wales*, vol. xiv. p. 251.

GUILLOTINE, is the name of an instrument of death, invented by Dr Guillotin of Lyons, a member of the National Assembly of France, and used during all the horrors of the French revolution. M. Louis, a celebrated surgeon in Paris, is said to have been rewarded with 2000 livres for a dissertation on the advantages of the guillotine; and the inventor himself suffered death by his own instrument in the reign of Robespierre.

The hands of the sufferer being tied behind his back, he is fixed to a plank standing vertically, not reaching higher than his neck. This plank is suddenly brought by machinery into a horizontal position, and moved below the loaded axe, which descends with a slanting edge, and severs the head from the body.

An instrument of a similar kind seems to have been first used at Halifax in Yorkshire. It was introduced into Scotland under the name of the *Maiden* by the Regent Morton, who accidentally saw it in use when passing through Halifax; and one of these instruments is still to be seen in Edinburgh, in the Museum of the Society of the Antiquaries of Scotland.

GUINEA.

Guinea.

Boundaries and extent.

GUINEA, is a maritime district in the south-west part of Africa, to which various limits are assigned by different nations. The Dutch consider it as extending from Cape Blanco, 21° North Lat. to Cape Lopez, in 1° South Lat. making Sierra Leona, in 8½° North Lat. the boundary between North and South Guinea. The Portuguese include under the general name, the whole of the coast from Cape Ledo or Tagrin, 8° North Lat. to Cape Negro, 16° South Lat. making Cape Lopez the division between Upper and Lower Guinea. According to the French, Guinea lies betwixt Cabo Monte, 11½° West Long. and Cape Lopez; and, by the English, the tract between the mouth of the river Gambia, 12½°, and Cape Palmas, 4° North Lat. is called North Guinea; while South Guinea reaches from Cape Palmas to Cape Lopez. By the greater part of geographers, Upper Guinea is limited to that part of the coast which runs from east to west about 500 leagues, comprehending Sierra Leona, Malaguetta, or the Grain Coast, the Ivory Coast, the Gold Coast, the Slave Coast, and the kingdom of Benin. Of Lower Guinea, in the more confined application of the name, extending from the kingdom of Benin to Cape Lopez, very little is known except the line of coast; and we have only to refer our readers to the map of Africa in this work, for the names and situations of its principal districts. The southern division, between Cape Lopez and Cape Negro, has been explored, and occupied chiefly by the Portuguese; and its different countries, ANGOLA, BENGUELA, CONGO *Proper*, and LOANGO, are described under separate articles. It is to Upper Guinea, that our attention is at present to be directed, and particularly to that portion of it which is generally denominated Guinea Proper, comprehending the Ivory, Gold, and Slave Coasts. BENIN has been already noticed; and SIERRA LEONA will form the subject of a distinct article.

Grain Coast.

The interior of the Grain country is very little known, and its line of coast may be described in a few words. It is sometimes called the Pepper Coast, and Malaguetta, from the long pepper of that name; but generally the Grain Coast, from the grain of paradise with which it abounds. It extends about 100 leagues from Cape Mesurado to the vicinity of Cape Palmas; and is in general low, flat, covered with forests, and watered by numerous streams. The principal places along the coast, are Rio Junco, or Rio del Punto, about 50 miles east of Cape Mesurado, a shallow stream, about 500 paces broad at its entrance, flowing through a level and delightful tract of country, which is inhabited by a peaceable and industrious people, who are principally employed in making salt and cultivating rice, and who trade in cotton cloth, sea horse teeth, skins of wild beasts, and slaves;—the country of the Foljas, or Pholeys, a powerful tribe, who are noted for the superior elegance of their speech, and whose territories are partly watered by the Junco;—Tabo-Dragon, a large and populous village on the east bank of the Tabo, or Rio Corso, where the merchants of Dieppe established a factory;—Rio Sestos, about 50 miles from Rio Junco, said to be navigable by small barks for 25 miles, has several villages at its mouth and on its banks; and the inhabitants, called Quabo-monou, are a pacific and well-proportioned race, subsisting on millet, fruits, and fish;—Sanguin, Baffa, Setuna, Batoua, Cape Sino, Sestro-krou, Wappo, Great Sestro, &c. all villages along the coast, of which the last mentioned is the most populous, and most noted for its trade in pepper and ivory, and is situated near Rio das Escravas. The Grain Coast is generally bordered with shoals; and its staple commodities are long pepper, leather, ivory, gold-dust, and slaves.

Ivory Coast.

The Ivory Coast extends about 110 leagues from west to east, from Cape Palmas to Cape Apollonia, in a low strait line, with few bays or islands; but a foul bottom and high surf prevent vessels from anchoring or landing upon any part of it with safety. Cape Palmas, formed by two hills covered with palms, in 4° 25′ North Lat. and 12° East Long. has a small gulf behind it, where vessels may be sheltered from the south wind. Grova, a few miles eastward of Cape Palmas; Tabo-Duno, where there is a commodious road for shipping; Drevin Petri, a considerable village about 50 leagues east of Cape Palmas; Giron, on the border of a well-watered meadow; Lahou, a populous town frequented by Europeans, and abounding in provisions, and from which, eastward to Cape Apollonia, the coast is commonly called the country of the Quaquas; Gammo, a place to which the inhabitants of the interior bring down their articles of traffic; Sueiro d'Acosta, where there is a small road for ships; Issini, where the French built a fort at the beginning of the 18th century; Assoko, about five or six miles from the sea coast, and said to contain about 1000 inhabitants; Albiani and Tabo, environed with plantations of palm trees; Akani Mina, in the vicinity of Cape Apollonia, are the principal villages on the coast, and most of them are situated on the borders of rivers. The soil of the lower and maritime tracts produces cotton, indigo, cocoa nuts, fruits, rice, and other grain. The chief articles of trade are gold, ivory, salt, cotton, palm-wine, and oil. All sorts of tame animals, abound in the country; and immense numbers of elephants, tigers, panthers, serpents, &c. are found in the forests. This level coast is bounded by mountains well covered with wood, and where the vallies are generally fertile and populous.

Gold Coast.

The Gold Coast commences a few leagues westward of Cape Apollonia, and terminates at Rio Volta, an extent of about 350 miles, lying between 4° 40′, and 5° 40′ of North Lat. and between the meridian and 3° West Long. Cape Apollonia is low on the coast, but rises into three hills, covered with trees, and seen from a great distance at sea. The first fort on the windward part is Apollonia, about three miles eastward of the Cape, situated in a spacious plain, which is bounded towards the interior by a fine lake of fresh water, about six miles in circumference, and full of fish. In this lake, a small village is erected on wooden piles, the inhabitants of which are said to have been exiles from the interior, who were not allowed to build upon the land. Along the whole coast of Apollonia, the surf is exceedingly dangerous, and there are no creeks or harbours. This territory or state extends about 100 miles along the coast, and probably not more than 20 inland. The next settlement is Axim, which belongs to the Dutch, and forms part of the extensive and fertile country of Ahantah. The fort, originally built by the Por-

Guinea. Gold Coast.

tuguese, and called Fort Anthony, stands up on a promontory, which forms the western part of Cape Three Points. The landing is here perfectly safe, and may be approached by boats in the dry season without any danger. About four leagues from Fort Anthony is Fort Fredericksburgh, first erected by the Prussians, but afterwards sold to the Dutch, and now in ruins. At three leagues distance is Accoda, another Dutch settlement; and three leagues farther is Dix Cove, belonging to the British, advantageously situated at the entrance of a small cove, which is capable of admitting vessels of 40 tons at high water. Boutry, Taccorary, and Succondee, all Dutch settlements, lie at the distance of a few miles from each other; and the last mentioned forms the extremity of the Ahanta country, which is the richest and best provided with harbours of all the Gold Coast. It stretches farther inland than Apollonia, and is bounded by the Warsaw and Dinkara states. About three leagues from Succondee is Chamah, where the Dutch have a small fort called Sebastian, supposed to have been originally built by the Portuguese. About eight miles from Chamah, is Commenda, where the British and Dutch have settlements and forts, and where the inhabitants are chiefly employed in supplying vessels with canoes and canoe men for trading on the leeward coast. About 9 miles from Commenda, is Elmina, the most respectable fortress on the Gold Coast, and the head-quarters of the Dutch settlements. The town is large, and some of the houses built of stone. The river admits vessels of 100 tons at high water, which can unload under the walls of the castle. The inhabitants consist of traders, fishermen, and a few mulatto mechanics. The population amounts to about 15,000; and a considerable trade is carried on, particularly in gold and slaves. About 9 miles from Elmina, is Cape Coast Castle, the principal British fort and settlement on the Gold Coast. It was built by the Portuguese, who ceded it to the Dutch, from whom it was taken in 1665. It has been considerably improved and strengthened by the African Company; and the castle is capable of making a powerful resistance on the side towards the sea. The town is irregular, and the houses chiefly built of clay. The population amounts to 8000; and the trade consists chiefly in gold. The adjoining country is called Fetu, and is subject to the Fantee state. During the existence of the slave trade, the countries from Cape Coast to Acra were the great centre of that nefarious traffic, which brought a rapid accumulation of wealth to the native traders in every town and village, the result of which was a spirit of idleness, licentiousness, and turbulence, which threatened the overthrow of all order and security in the settlement. About four miles from Cape Coast, is a Dutch fort called Nassau, situated at a village named Mouree. About six miles from Mouree, is the British fort Anamaboa, the most compact and well built in the country; and the town, in its former flourishing state, contained at least 15,000 inhabitants. But it was destroyed in a war with the Ashantees, a powerful people in the interior; and the abolition of the slave trade, in which it formerly bore a principal share, is likely to retard its re-establishment. About three miles from Anamaboa is the town of Cormantine, where the Dutch have a fort called Amsterdam, originally built by the British, and the first that was erected on the Gold Coast. About six leagues eastward is Tantumquerry, where landing is very difficult; and, nine miles farther, is the district of Assam, or Apang, where the Dutch have a small fort, and where the coast is more accessible. About 8 miles from Assam is the town of Winnebah, where there is a small fort belonging to the British, and where the landing is generally safe. The town has been reduced, by wars and other casualties, from a population of 4000 to 2000, and was formerly a part of the Agoona country, which has recently fallen under the power of the Fantees. About three leagues from Winnebah is the Dutch fort of Berracoe; and nine leagues farther west is Acra, where there are settlements of the British, Dutch, and Danes. Acra is an independent state, which formerly belonged to the kings of Aquamboe, but has at present most intercourse with the Ashantees. It is the most healthy situation on the Gold Coast; and the inhabitants are more civilized than most of their neighbours. About 32 miles from Acra, is a small British fort named Pram Pram; and 8 miles farther, is the Danish fort of Ningo, around which the country is level and fertile, abounding in game, and in a large breed of horned cattle. About 36 miles from Ningo is Adda, where there is a Danish fort, and is situated on the left bank of the Rio Volta, which terminates the Gold Coast. This river runs nearly north-west and south-east, separating the countries of Aquamboe and Aquapim, and is navigable for small craft to the distance of 100 miles from its mouth. See Acra, Anamaboa, and Aquamboe.

Slave Coast.

The slave coast extends from Rio Volta to Rio Sagos, which separates it from the kingdom of Benin. It reaches about 50 leagues from west to east, and contains the following districts or provinces: Koto, lying between Rio Volta and Cape Monte, which is a flat, sandy territory, little frequented. Near Cape Pucalo, is a village named Quilta, where there is a British fort; and at a little distance is Koto, the capital of the country. Popo or Papa, about 10 leagues in length, between Cape Monte and Juida, is low and sandy, in some places marshy, and generally inaccessible on the coast. At the mouth of the Tari is a village of the same name, and a Dutch factory. Juida or Whidah extending several leagues, is more fertile and populous than the districts already noticed; and at the mouth of one of its rivers, called Euphrates, is a port where ships may unload, though not without considerable inconvenience from the surf. Near this river, but about two leagues from the shore, is a populous town named Sabi or Xavier, where merchants resort. At the mouth of another river, named Jaquin, are British, Portuguese, and Dutch settlements, in an island called Gregoi. Ardra extends about 15 leagues along the coast, and is a fertile but insalubrious tract. Foulaon, Assem, Jago, and Appak are the names of its principal villages. Whidah and Ardrah have been long subject to the king of Dahomy, a powerful state in the interior. The principal trade of the slave coast consists in salt, palm-oil, and slaves. See Ardrah and Dahomy.

Aspect of the country.

There are several tracts along the coast of Guinea of a sandy and sterile nature, without any other trees than the palm; but the general appearance of the country from the sea is that of an immense forest, with a few high grounds covered with lofty trees, and the thickest underwood. Many of the vallies are richly planted, and extensive plains may be seen, beautifully studded with natural clumps of trees and bushes. In the more inland parts, where the moisture is more abundant than on the coast, the woods are almost impenetrable, on account of their luxuriant growth; and the surface of the ground is completely concealed by shrubs and

Guinea.

herbs. The rivers generally run in a very winding direction, and in some places overflow their banks during the wet season, forming large stagnant ponds.

Soil.

The soil varies considerably along the coast, from a light sand or gravel, to a fine black mould and loamy clay; but it is more uniformly rich and productive towards the interior of the country. For the space of six or eight miles from the sea may be found soil of every description, suited to every kind of cultivation.

Climate.

The climate is not so hot as in many other parts of Africa, nearer the tropics; and it is generally observed that the countries on the equator, from five to six degrees on either side of it, are the most temperate in the tropical regions of Africa. The temperature is found in these countries to be affected, not merely by the latitude, but by various other causes; and is always cooler where the soil is good, cultivation extensive, and the country open, with high lands in the vicinity. At Cape Coast, though accounted the hottest situation on the Gold Coast, the thermometer is usually, during the hottest months, from 85 to 90 degrees of Fahrenheit. At Winnebah and Acra, it is seldom known to exceed 87; and, during the months of June, July, August, not higher than 78 degrees.

Seasons.

The seasons, as in other tropical countries, may be distinguished into wet and dry; or rather into two wet and one dry period. The first wet season commences in the end of May, or beginning of June, when the rains fall with great violence, and without intermission for several days. Strong breezes commonly follow this first deluge, and the rains are seldom very heavy during the remainder of the wet season, which terminates with the month of July. Then begins the foggy season, which is extremely unhealthy, especially in low, swampy, or woody situations, and continues for two or three weeks. About the month of October, the second rainy season begins; but the rains do not fall with so much violence as the first, nor are they succeeded by mists and foggy weather. The dry season begins with November, and continues during the remainder of the year to the month of May; but, in the course of this period, the coast is visited with violent storms of wind, generally denominated tornadoes and harmattans. Tornadoes * commonly commence in March, and cease with the beginning of the first rains; but sometimes blow before or after the second rains or preceding a harmattan. They invariably come from the eastward, and are generally experienced a day or two after the full and change of the moon. Their approach is sufficiently indicated by vivid and successive flashes of lightning in the east, attended with thunder and heavy clouds, and by the clear and bluish appearance of the horizon. Their nearer approach is announced by the darkening of the horizon, especially in the eastern hemisphere, the increase of the lightning, and, finally, as an immediate prelude to the tempest, by a solemn stillness and entire calm in the lower part of the atmosphere, while the upper regions appear in dreadful commotion. A gentle air is then perceived, which is almost instantaneously succeeded by violent gusts of wind, usually accompanied with rain; and seldom continuing above half an hour or fifty minutes. Tremendous peals of thunder, and torrents of rain, for the space of two or more hours, terminate the storm. During its continuance, the thermometer suffers a rapid depression of five degrees or more; the air is subsequently cooled, vegetation refreshed, and the human constitution invigorated. A harmattan † is an easterly wind, which prevails in the months of December, January, and February, along the coast from Cape Verd and Cape Lopez. It comes on indiscriminately at any time of the day, or of the tide, or of the moon; and continues, sometimes one or two days, sometimes five or six, and sometimes even fifteen or sixteen. It is always accompanied by a fog or haze, which occasions a considerable obscurity, and renders the sun, which appears only a few hours about noon, of a mild red colour. Extreme dryness is another attendant of a harmattan, and, during its continuance, no moisture is perceived in the atmosphere, or any falling of dew on the earth. All vegetation is checked, and the more tender plants are completely destroyed. The grass becomes like hay, and the most vigorous ever-greens droop under its influence. Its parching effects are severely felt on the external parts of the body, particularly the eyes, nostrils, lips, and palate, which become dry and uneasy. Drink is often required, not so much to quench thirst, as to remove a painful aridity in the fauces; and, though the air is cool, a troublesome sensation of prickly heat is felt on the skin. If the wind should continue for four or five days, the scarf-skin generally peels off from the hands and face, and even from the whole of the body. Notwithstanding these disagreeable effects, it is found, on the coast of Guinea, to be highly conducive to health, restoring persons labouring under dysenteries, fevers, or any debilitating evacuations, arresting the progress of epidemics, and apparently preventing even the artificial communication of infection. ‡

Vegetable productions.

The principal vegetable productions of the coast of Guinea, are maize, millet, rice, yams, cassada, potatoes, pulse, plantains, guavas, bananas, chillees, &c. The sugar cane grows spontaneously, to a tolerable size; and the cotton shrub is found in a wild state. The indigo plant is common in many parts of the coast; and black pepper has been discovered in the inland districts. European cabbage and eschallots are cultivated in some places; and a mucilaginous vegetable, called *encrumah*, the same as the ockra of the West Indies, (*Heluscus esculentus,*) is very plentiful in the country. Besides the ordinary tropical fruits, there is one of a very nutritious nature, called *enteraba*, which is much used, and is about the shape and size of the largest onions. The silk-cotton tree is found in every part of the coast, and grows to a majestic size, so as to furnish excellent materials for the formation of canoes. There is a great variety of useful timber in the country, but the palm-tree is the most profitable to the natives. Of the leaf they make rope, thread, nets, fishing lines, &c. From the fruit they express an oil of great delicacy, which is used in all their dishes, and, when eaten fresh, is equal to excellent butter. The kernel contains a hard pulpy substance, which is sometimes roasted and eaten by the women, as promoting corpulency. From the trunk of the tallest species, which sometimes reach 100 feet in height, they draw an intoxicating liquid which they call palm-wine, and which is procured by inserting a reed into a hole at the top of the tree, through which the liquor flows into an earthen pot. A similar liquid, of a more agreeable flavour, and less intoxicating qua-

* The name *tornadoe* is supposed to be a corruption of the Portuguese word *trevado*, a thunder storm.

† Supposed to be a Fantee word, pronounced by the natives *harmanta*, and said by them to signify a cold dry wind.

‡ It appears to be the same kind of wind as the *sammiel* of Egypt, and the *sirocco* of the Mediterranean.

Guinea.

lity, is procured from the low-palm; but, in order to procure it, the tree is generally dug up, and the trunk heated by fire, that the juice may flow more abundantly. This wine is drunk in a state of effervescence, and will not keep above a few hours.

Minerals.

The mountains of Guinea, as far as they have been examined, are in general granitic and schistous, and are filled with mines of gold and iron. The latter of these metals is little known to the natives, and Europeans have not thought it their interest to instruct them in the subject; but the first has been sought from time immemorial, and is likely to become a still more extensive object of traffic, in proportion as the exportation of human beings shall cease.

Gold mines.

Gold is found in these mountains in a primitive state, between two layers of a granite, finer, more solid, and more highly coloured than the rest of the rock; but the natives, unacquainted with the art of mining, and unprovided with proper tools for the purpose, have never attempted to work it in these places. They confine their operations to digging at the base of the mountains, where the schistous beds and banks of granite are more friable, and washing the sands in the beds of rivers and water courses at the bottom of the hills, when the rain water has run off. In digging, they work downwards, as if forming a well; or sometimes make a ditch about 20 or 30 feet deep, till they become alarmed for the crumbling down of the earth. They generally begin to find the gold at the depth of three feet; and, as they advance in the work, put the lumps of the metal into pouches which are fixed round their waists. Pieces are sometimes found of a considerable size, and the king of Ashantee is said to possess a lump of native gold, so large that four men are required to lift it. The earth, which is thrown out in the course of the digging, is laid in heaps at the side of the pit, and is carried by other labourers, chiefly women and children, to the nearest river, where it is washed in bags or wooden bowls, and the particles of gold afterwards separated from the heavier parts, which remain in the vessel. This ore is sometimes so rich, that a piece of it, weighing four or five ounces, has been known, when pounded and washed, to produce about four pennyweights of gold dust; and the general fertility of the mines may be estimated from the circumstance of the slaves employed by the king of Ashantee in 1790, engaging to supply him with half an ounce a-day for each labourer. The gold-finders, who wash the sands on the banks of rivers, and the sea-shore, are less successful in their researches, and it is generally the women only who are thus employed; but this precious metal, it is sufficiently ascertained, is very abundant in the interior of the country, and the mines may be considered as still virgin mines.

Animals.

The animals of Guinea are numerous, but only such as are common to the western coast of Africa. The ordinary domestic animals, dogs, cats, sheep, goats, and hogs, are plentiful in most places; and poultry, particularly, is found in great abundance. There are horned cattle in some parts of the coast, especially in Apollonia, but only in the possession of the chiefs. The wild animals are buffaloes, tiger cats, leopards, hyænas, jackals, antbears, porcupines, monkeys, deer, hares, squirrels, musk-cats, alligators, lizards, land-crabs, chameleons, guanos, scorpions, centipedes, and a variety of snakes. The hippopotamus is occasionally seen on the banks of the river Volta. The feathered tribe in a wild state are extremely various; and the smaller birds, particularly, are remarkable for the beauty of their plumage. The lakes and rivers abound with mullet and other kinds of fish; oysters and prawns are plentiful in some places; and turtles are not uncommon. There is a variety of excellent fish on the coast, which is procured in abundance, during the dry season, when the surf is least violent.

Natives.

There are several distinct nations along the coast of Guinea; but their general customs are so extremely similar, that they may be described as one people. The most powerful tribes are found in the interior of the country, and they are, in many respects, superior to those who inhabit the maritime districts. The two most extensive of these kingdoms are Dahomy (see DAHOMY) and Ashantee, both of which have made their power at times severely felt on the coast. The former is described in a preceding article; but very little was known of the latter, till its king appeared on the coast, in a war against the Fantees in 1807; when the discipline and bravery of the army, and the order and regularity of the court, evinced a considerable degree of civilization. The following account of an interview between the governor of the British fort at Annamaboe and the king may furnish some idea of this people. " The governor was obliged to visit each man of rank, before he could be received by the king; a ceremony that could not be prudently denied, and which occupied some time; for those men had their several courts, and collectively had formed an extensive circle. Every one of them was seated under a huge umbrella, surrounded by attendants and guards, with young persons employed in fanning the air, and dispersing the flies." " After the ceremony of visiting those persons was over, the governor was conducted towards the king, who was surrounded by a number of attendants, whose appearance bore evident marks of riches and authority. Chairs, stools, axes, swords, flutes, message-canes, &c. were either of solid gold, or richly adorned with that metal. Those dazzling appearances, added to damask, taffety, and other rich dresses, gave a splendour to the scene, highly interesting. When the governor approached the king, and when an interchange of compliments had passed, the air resounded with the noise of musical instruments, such as drums, horns, and flutes. After some conversation, during which much politeness was observed in the behaviour of the king, the governor wished this ceremonial visit to be returned, &c.—The king was of the middle size, well-formed, and perfectly black, with regular features, and an open and pleasing countenance. His manner indicated understanding, and was adorned with gracefulness; and in all respects he exceeded the expectations of every person. His dress was plain; it consisted of a piece of silk wrapt loosely about him; a wreath of green silk ornamented his head; his sandals were neatly made, and curiously studded with gold. He was not distinguished by any gold ornaments as his attendants were." *

Government and laws.

The kingdoms along the coast are considerably different in respect of government. Among some tribes, as in Apollonia and the Slave Coast, it is absolute monarchy; in others, as in the Ahanta country, a kind of aristocracy; and in others, as among the Fantees, it consists of a variety of forms, according to some of which the power is lodged in the hands of the community at large, as in a democracy;

* Meredith's Account of the Gold Coast.

Guinea.

and in others, as in Acra, it is a mixture of aristocracy and democracy. In this last mentioned country, the inhabitants of different states are known to unite occasionally for general safety under the absolute command of individuals, as in a dictatorship; and, when the danger is past, to revert to their accustomed forms of government. The laws consequently differ considerably in the form of administration, according to the nature of the government; but. during the continuance of the slave trade, the most trifling offence was every where examined with the utmost strictness, and almost every punishment was commuted into slavery. The prevailing penalties are fines, or servitude, which are almost the same punishment, as every convict, if unable to pay his fine, becomes a slave. Even murder, though by law generally punishable with death, may be compensated by the payment of seven slaves, or their value; but if the person murdered should have been of any consequence or authority, the law of retaliation is enforced, and much bloodshed ensues. In the Fantee country the laws are more rigorous than in any other part of the coast. If any person be detected in the act of committing the most trifling theft, he forfeits his freedom; and if the article stolen should be valuable, his family becomes involved in his fate. If any one, either by accident or design, should kill a hog, a goat, even a hen, or any other animal which is the property of another, he loses his liberty, unless he can soften the injured party by presents. The law against witchcraft is peculiarly severe, and extends to all under the same roof with the offender, as they are supposed to possess some portion of the evil influence; but, since the abolition of the slave traffic, few convictions of this kind have taken place, and the rigour of the laws respecting trifling offences has begun to relax. Another oppressive law, peculiar to the Fantee country, deserves to be noticed, chiefly as demonstrating the baneful effects of the same odious trade in human beings. If a person become involved in debt, and was either unable or unwilling to pay, the creditor was at liberty to "panyar," that is, to seize and confine any person or persons belonging to the family, or the town, or even the country of the debtor; and these captives, if opportunity offered, were sold as slaves without any delay or ceremony. During the time of the slave trade, this custom was often practised under false pretexts of debts or offences, and many innocent persons forcibly seized, and instantly sold by private individuals, without any possibility of redress.

In the monarchical state of Apollonia, the right of succession devolves on the son of the king's sister. The reigning sovereign is the sole administrator of justice; and passes sentence without the advice of any of his subjects; but, if the accused be a person of rank, he generally receives a message requiring him to prove his innocence by the ordeal. This consists in swallowing a portion of a certain bark, accounted poisonous, which, if rejected from the stomach, is a token of innocence, but if retained, (in which case it commonly proves fatal,) it is an evidence of guilt. In the more mixed governments, as in the Fantee country, the administration of justice and of public affairs resides principally in the pynins or elders, who are elected by the public voice, and sometimes succeed by hereditary right. They are the oracles of the laws, which they commit to memory with extraordinary correctness; and, in the trial of causes, they act at once as judges and jurors. They assemble their courts in the market-place, where both parties are attentively heard, witnesses regularly examined, and sentence duly pronounced. They have a share in all fines and forfeitures, and generally receive a present of rum when any cause of importance is brought before them. If the condemned party think himself aggrieved, he may appeal to the elders of another town or district, and sometimes to the governor of the neighbouring European fort. The natives are said to plead their causes with much ability, and to accompany their words with suitable and energetic gesture. In consequence of the strictness of the laws, crimes are extremely rare; but, during the prevalence of the slave trade, when false accusations and false witnesses abounded, condemnations occurred every day. But, though the natives rarely commit thefts against the property of their countrymen, every thing belonging to a white man is considered as a fair object of plunder. In cases of slander or evil speaking, a peculiar trial, called "brandeeing," is instituted between the parties. The injured person repairs to the market-place with a portion of spirits, and invites his accuser to make good his assertions, who is obliged to produce an equal quantity of liquor before he can obtain a hearing. The person found guilty is required to make a pecuniary compensation to the other; and the spirits, which in the case of wealthy individuals sometimes exceed a hundred gallons, go to the elders, and the friends of the person who is acquitted.

Religion.

The religion of the natives of Guinea is not easily described. They have some notion of a Supreme Being; but their worship consists in a mass of strange and unmeaning superstitions, of which they do not attempt to give any account. They do not generally engage in any external worship; and though, on certain days, they abstain from their ordinary employments, they have no reason to assign, except that it has been the custom. In some places there is an annual sacrifice of a deer to the divinity. They seem to hold the moon in greater veneration than the sun, and welcome her appearance with great rejoicings. Their system of belief, however, is little else than a constant fear of some malignant influence, and a superstitious confidence in certain charms to avert the dreaded evil. Their object of worship, whatever it be, bears the undefinable name of Fetish, a word which some suppose to be derived from the Portuguese *fetischo*, witchcraft; but which is applied with great latitude to any thing sacred, prohibited, unlucky, or unaccountable, and is considered as equivalent to the "Obi" of the West Indies, perhaps also to the "taboo" of the South Sea islands. In Acra, the principal image, or deity, is a large mass of solid gold in the form of a human head. In the Fantee capital, Abrah, their chief object of adoration, is denominated, Woorah, woorah! Agah, nannah! that is, Master, master! Father of all! But every town or village has its own favourite idol, and even in every house is some object emblematic of a divinity. The Fetishmen or women, who are considered as alone possessed of any knowledge, are not only the priests, but also the lawyers and physicians of the country. They are supposed to have communications with the demon or Fetish, and to be able to instruct their votaries in every case of actual or apprehended evil. Their good offices must be procured by presents, which are often of considerable value, and are appropriated to their own use. They are usually connected with persons in power, and are frequently useful in enforcing the authority of the laws. Where there is no monarch, and the government is lodged in the community, these persons assume great consequence, and render it hazardous for any one to

Guinea. withstand their influence, or to be guilty of any neglect towards the Fetish.

Languages. There are innumerable languages and dialects along the whole of the west coast of Africa; but the most prevalent in Guinea is the Fantee, which is understood from Apollonia to Acra, and to a considerable distance inland. It is soft and harmonious; but has never been reduced to writing. The following specimen gives the proper names of men and women, according to the day of the week on which they were born.

Days of the week.	Men.	Women.
Sunday	Quashie	Aquishervah
Monday	Cudjoe	Adjuah
Tuesday	Quabino	Abinabah
Wednesday	Quacoe	Eccoah
Thursday	Quow	Abbah
Friday	Couffee	Effuah
Saturday	Quamina	Ambah.

Character of the natives. The natives of the coast of Guinea are in general extremely similar in their physical qualities, and in their prevailing customs; but differ considerably in their dispositions and morals. The diversity in this respect is ascribed, with sufficient probability, to their intercourse with Europeans, and especially to the degree in which they engage in the slave trade; but seems also to arise partly from the form and character of the native governments. In most of the districts they are tall, well formed, with the usual negro features, thick lips, and flat noses. On the Grain Coast, especially in the western parts, they are mild, peaceable, honest, and industrious; but on the Ivory Coast they have become deceitful and cruel. In Apollonia, they are extremely courteous, hospitable, and brave; but generally reserved in their manners, a circumstance which has been attributed more to the despotic form of their government than their natural disposition. In the Ahantah country, they are friendly in their manners, and more free in conversation than the Apollonians, but less hospitable and courteous. The people of Chamah and Commenda are very turbulent and ferocious, addicted to frequent quarrels, and much inclined to maltreat Europeans. Those of Elmina have generally been found to be civil and peaceable; but some recent instances have occurred of their ferocity when roused by provocation. The Fantees are generally an indolent, ferocious, and faithless people; and their petty chiefs are extremely avaricious and deceitful, watching every opportunity to gratify their vicious passions. The natives of the Agonna country, especially around Winnebah, have long been noted for every species of licentiousness, living entirely by plunder, and displaying a degree of ferocity unparalleled in any other part of the coast. In Acra and Adampe, the inhabitants are remarkably indolent, addicted to drunkenness, and full of deceit; but those of Acra have been considerably improved by their intercourse with the Ashantees, a powerful people in the interior, already mentioned, and who manifest a greater attention to the rules of decency and morality than any other tribe yet discovered in the country.

"Notwithstanding some years acquaintance with the natives," (says Mr Meredith, referring principally to the Gold Coast,) "I find it no easy matter to lay down their true character; for they appear to us in a variety of forms, according to the nature of our intercourse with them, and to their employment. Those persons who are indifferent to exceed a further intimacy with Europeans, than an interchange of commodities will admit of, are to be viewed in the true light of peddling traders. When there is a prospect of a good bargain to be obtained, every species of low cunning and mercenary artifice is practised to acquire it. They accommodate themselves with much ingenuity and facility to our humours and fancies; every attitude, every expression, is carefully recommended by flexibility and supplication; yet they carefully avoid (showing) too great a desire of obtaining what would turn out profitable or advantageous to them; and, when they know that their wishes are not to be gratified as easily as was expected, disappointment is carefully concealed, and a seeming indifference is preserved in their behaviour."—"They may be justly pronounced as possessing all the chicanery inseparable from their calling, and are not readily outwitted. Those who gain a livelihood by fishing, are a laborious people; and our knowledge of them extends a little further than of the trader, because they are employed frequently by us as canoemen and labourers. When thus employed, they perform their duty with cheerfulness; and, if encouraged, will go through a vast deal of labour; but they must be treated with exactness and punctuality. When they call for any customary allowance, or for payment, they do not like to be put off, and expect that their labour should meet with its instant reward. If they be not punctually attended to, they become neglectful, and inattentive to the interest of their employer. They are much addicted to that vice (theft), which prevails in almost every part of the world, and are very expert in the practice of it, particularly as to small articles which they can easily conceal. Men who follow an agricultural life, and who chiefly inhabit the inland parts, will be found more uniform in their conduct than the traders or fishermen. To consider them in a general view, and to make allowances for the failings attached to the uncivilized part of mankind, they may be considered a well-meaning set of men. They are divested of that low cunning and deceitful artifice, known and practised by those who gain a livelihood by a more intimate connection with Europeans. They possess no small share of honesty, sincerity, and benevolence; and are strangers to the corrupt and licentious conduct plainly to be seen among the inhabitants of the water side."—"The natives of the sea coast, from a more immediate connection with Europeans we should suppose, are more inclined to industry than those inland; but it will be found that real industry prevails more uniformly inland, and vice is less encouraged. Every person on the coast appears very diligent in acquiring the profits of his occupation; but profligacy, drunkenness, and debauchery, are practised to a pernicious extent."

Manners and customs. Young persons of both sexes generally go naked till the age of puberty, (which takes place in males at the age of twelve, and in females at ten,) except a girdle about the loins, with a small slip of cloth affixed to it for the sake of decency. Dress. The dress of both sexes is nearly alike, and consists in a piece of cloth, about four yards long and two broad, wrapped loosely around them; but, when engaged in any occupation, part of it is folded about the loins, and the remainder hanging down, covers the lower part of the body. The more wealthy, especially when they travel, are provided with hats, and sometimes with sandals. The women generally have their breasts uncovered; and their garment is fastened round their middle by a girdle or zone called tombah, which is supported behind by folds of cloth, forming a protuberance, in proportion to the age and rank of the

4

wearer. Women of quality have likewise a number of silver keys suspended by a ring to the front of the girdle. The women also wear bracelets and necklaces of gold and beads, and frequently oval brass rings on their ankles. Both sexes are remarkably attentive to the decoration of their heads, and cut the hair with great nicety and taste. Some of the men allow the hair to grow on the chin, and occasionally wear whiskers and mustaches. The old men shave the whole of the head, leaving only one or two locks behind, to which they commonly keep a piece of gold suspended. The Fantees are distinguished from the other natives by small scarifications on the upper part of the cheek bones, and on the back of the neck. Both the men and women among this tribe are remarkably cleanly, and generally wash their whole bodies twice a day. The Fetish men, especially in Acra, are habited in white, a colour which is held in great veneration in all parts of the country, as emblematic of purity and perfection. The principal article of food in the Fantee country is bread, which is unleavened, and made of maize or Indian corn. In all their dishes, pepper is a necessary ingredient. Their chief mess consists of fish or poultry made into soup, with fresh palm oil, pepper, salt, and eschallots; and with this high-seasoned dish they eat bread, or yams and plantains made into a pudding. The men and women generally eat separately; and seat themselves in small parties round a bowl of soup, into which they alternately dip some bread or pudding. They do not drink during their meals; but, after finishing the repast, sometimes indulge freely in the use of palm wine or spirits. The houses are commonly made of bamboo, and plaistered with a strong loamy clay, with which also the floors are laid. The towns and villages are generally surrounded by a strong fence of bamboo cane, as a protection against wild beasts.

Arts and manufactures are in a very low state among the natives. They make canoes, baskets, mats, bills, hoes, fishing nets, hooks, lines, &c. and some of them work as masons and carpenters. The women, who are literally the slaves of the men, perform most of the laborious offices, such as grinding corn, procuring food and water, every thing in short except fishing and planting. In the Ahantah country particularly, the people are much inclined to agriculture, which is in a very rude and defective state; but, in many of the maritime villages, besides acting as fishermen, they used to procure their subsistence, in a great measure, by hiring themselves as canoe men to the slave ships bound to the leeward coast. Their canoes are of various sizes, requiring from 3 to 21 oars, or rather paddles; and some of the larger have a platform in the bottom, with an awning erected over the fore part of the deck, for the shelter of the passengers. These canoes are made of the trunks of the silk cotton tree, shaped and hollowed by a very simple iron instrument like a large chisel, answering either as axe or adze, according to the form of its handle. The wood of these trees, especially when green, is soft, and easily worked; when dry, almost as light as cork; and sometimes large enough to make a canoe paddled by twenty men, and carrying four puncheons of liquor. Those who are acquainted with the management of these canoes, conduct them through the high surf on the coast with great dexterity. On coming ashore, they watch the sea when on the point of breaking, and betake themselves to steering, by keeping the flat part of the paddle parallel to the canoe, and giving it a quick motion, moving it nearly at right angles with the canoe; and, when it is on the summit of the wave which is ready to break, this quick motion is discontinued, the paddle kept firmly in a parallel position, and the canoe, steadily balanced and directed in a straight course, flies on shore with amazing velocity.

Travelling. In travelling by land, Europeans make use of a large cotton hammock, which is slung from a bamboo pole about nine feet long, and covered by a cloth in such a manner, that the person carried in it may either sit up or lie down. For a distance of 25 or 30 miles, this conveyance requires six or eight bearers, two of whom carry it by turns; and, if well supplied with rum, will travel at the rate of five miles an hour. When a party of Europeans travelling in this way arrive at a town or village, they are met by the men in their war dresses, jumping and firing their muskets heavily loaded with powder almost in the faces of the visitors; a ceremony which is not without hazard, from the occasional bursting of the pieces, and which it is necessary nevertheless to requite by a present of liquor and gunpowder.

Amusements. The recreations of the younger part of the people consist chiefly in dancing and singing; and they are in most places fond of music. Their instruments consist of drums of various forms and sizes; horns made of the tusks of young elephants, and sounding like a bugle; and flutes made of a large reed, about four feet in length, open at both ends, and producing a soft and plaintive note.

Marriages. Polygamy prevails in every part of the coast, and every man may have as many wives as he can maintain; but the first wife has the sole management of the domestic affairs within the house, besides acting as a watch over the fidelity of the rest. Mothers have the entire disposal of their daughters in marriage, and their consent must be procured by presents. After the payment of a certain sum, which is regulated by custom, the young woman is dressed according to her rank with rich cloths, valuable beads and ornaments of gold; and conducted by the female relatives to the house of her husband, where she is formally received by his relations and friends. On the following day she receives visits, and must continue to appear in her wedding dress for a week.

Funerals. The Fantees, and most of the other tribes, bury their dead within their houses; and they are very reluctant to leave the spot where their relatives are interred. If any one die in a state of insolvency, his body does not receive the rites of burial till his debts are discharged; and the corpses of persons guilty of suicide are burned, unless a considerable sum be paid to the elders for permission to commit them to the earth. In Apollonia funerals are in general solemnized by a mixture of condoling and carousing; and every friend of the deceased contributes something expressive of regard for his memory. Cloth, spirits, and gunpowder, are lavished on these occasions; and, till the body be deposited in the ground, there is a continual succession of dances, songs, volleys of guns, and lamentable exclamations. These customary revellings, however, are performed by persons hired for the purpose, and, after the interment, the habitation of the deceased exhibits sufficient tokens of real affliction. The dead body is exposed for several days to public view, decorated with ornaments and valuable articles; and, when buried, gold, rich cloths, and other things of value, are put into the grave. At the funeral of any person of eminence, some of his slaves, generally the old and infirm, are offered in sacrifice. "In the year 1800," says Mr Me-

Guinea. redith, "when a king of Apollonia died, one or two human beings were sacrificed every Saturday, until the grand ceremony took place, which did not happen till six months after his decease. On that occasion, upwards of fifty persons were sacrificed, and two of his youngest wives were put into the grave. The lid of the coffin was covered with human blood, and gold dust sprinkled upon it, and much gold and rich cloths were deposited in the grave.

Diseases. The diseases incident to the natives of Guinea are, leprosy, which is greatly dreaded, and generally considered incurable; though, in its milder form, and when early attended to, it is sometimes removed. It is in some places supposed to be contagious, and the sufferers are excluded from society. The natives employ chiefly vesicating and excoriating substances in the milder cases. Yaws, appearing in white crusted spots on the skin, not a common but a very infectious disease, and though repressed for a time, is never radically cured. Elephantiasis, an enormous hard swelling of the legs, which is also incurable. Smallpox, which causes great ravages wherever it appears, and to which the natives in general apply no remedy; but, in some parts of the coast, inoculation is practised, and the puncture usually made at the wrist. Guinea-worm, peculiar to the sea coast, and supposed to be occasioned by drinking water full of animalculæ, as it is seldom experienced in places provided with good water. It is considered by others as rather produced by absorption through the pores of the skin, as persons are known to receive it by going to the pools for water, and by infection from others. The legs are the most common seat of the disease, though occasionally it has appeared in other parts of the body. The worm itself appears no bigger than a large woollen thread, of a whitish colour, and rather flattened in its form; but some have been extracted above thirteen feet in length. Much pain is felt before it protrudes through the skin, and an inflammatory tumour is produced, through which the creature makes its appearance. The natives then apply a slip of wood to the sore; and, when the worm comes in contact with it, they carefully turn it round, so as to wind the worm upon it, leaving it suspended in this situation, that the weight may draw it out more speedily. If the animal is broken, the part remaining in the flesh generally recedes, and may not reappear for months; and, unless properly managed, much pain and dangerous sores are often the consequence.—Enlarged scrotum, supposed to be caused by an immoderate use of palm wine.—Dysentery, which the natives treat with great success, by administering drastic purgatives, followed by stimulating astringent clysters, making use of suppositories, keeping the patient warm, and frequently imbrocating the loins and belly with a composition of pepper.—Ophthalmia, which though not common, is troublesome at some seasons, but chiefly occasioned by excesses in living; and is treated by the natives only with topical remedies, inserting lime juice into the eye, and drawing blood from the temples.—Fevers, which are most prevalent after the periodical rains; and, excepting a few external applications, such as ablutions with warm water, and rubbing the body with certain herbs, are left by the natives to the powers of nature.—Rheumatism, a common disorder, successfully removed by tepid applications and warm clothing.—Internal inflammations, pleurisies, and pulmonary diseases, are very general during the rainy season. The medical practitioners of the country are principally females, whose skill is transmitted from one generation to another, and who perform the operations of scarification and cupping with great dexterity, as well as discover considerable botanical knowledge in the selection of herbs and plants. The male physicians are generally ranked among the Fetish men, and are much greater empyrics than the women, imposing upon the credulity, or working upon the imaginations of their patients, by pretending to expel the evil influence, or extract the supposed cause of their sufferings.

Climate. The insalubrity of the climate to Europeans is understood to have been greatly exaggerated, and to be chiefly owing to their own excesses and neglect of proper precautions. The climate of Guinea is greatly superior to that of Guiana, which lies under the same parallel; and any part of the coast, if cleared and improved, would not be less healthful, it has been affirmed, than Barbadoes, the most salubrious of the West India islands. Strangers arriving in the country are directed, by Mr Meredith, to avoid, as much as possible, the meridian sun, by keeping within doors from eight o'clock in the morning to three in the afternoon, but to take regular exercise before and after these hours; to travel during the night with heavy clothing to protect the body from the dews, or, if necessitated to go out in the day-time, to use an umbrella, and place a handkerchief or two between the head and the hat, to rub the body well with coarse cloths, and put on warm clothing after getting wet, and, if much exposed to rain, to bathe in salt water, but never to apply spirits to the surface of the body; to use cold bathing frequently, to practise early rising, to take animal food only once a day, and to wear flannel next the body; to counteract the damp air of the wet season by heavy clothing, warm apartments, and even occasional fumigation of the rooms with vinegar, sulphur, or tobacco; and, in the dry months of December and January, to be more attentive to exercise in the open air, temperance in living, and the use of cooling laxatives. Persons just arrived in the country are particularly warned to be sparing in diet, refraining from salt meat, and freely using vegetables and acid fruits; to drink also sparingly, using chiefly rum and water, wine and water, lemonade, &c.; to take the cold bath every day, and avoid the heat of the sun as much as possible; and to keep the body gently open by means of salts, cream of tartar, or similar cooling purgatives, of which a dose should be taken every week for two months, till the constitution becomes habituated to the climate.

Trade. Europeans have hitherto made no attempt to extend their commerce to the interior of the country; but, with the exception of slaves, (which must soon cease, it is hoped, to be enumerated among articles of traffic,) have confined themselves to a very limited coast-trade. The articles of which it consists are chiefly pepper, palm oil, cowries, ivory, gold; in exchange for which, they import lead, iron, fire-arms, gunpowder, tobacco, spirits, tobacco-pipes, vessels of brass, woollens and cottons of British manufacture, and especially East India cotton goods, which are most esteemed in the country. All the ivory is procured from the interior, and, in all the inland countries, gold is found in considerable quantities. The native traders penetrate to a great distance into the interior in quest of these articles, or rather they pass through numerous hands from nation to nation till they reach the commercial establishments on the coast; but all the people, concerned in this inland traffic, are extremely mysterious in their operations, and very reluctant to communicate the slightest intelligence on the subject. It is only gold-dust that they sell to the Europeans, as they generally convert into ornaments the solid pieces, and even hold them sacred, if tolerably large. The gold of this country, whether in grains or in dust, is extremely pale, though very pure; and greatly resembles the filings of yellow copper, with which it is sometimes fraudulently mixed. This alloy is easily discovered by means of aqua fortis; but it is sometimes also imperfectly cleaned from the sand, which is of a quartzose nature, and which requires a keen eye, a glass, or even the crucible to detect its presence. The native brokers or gold-takers are extremely skilful in this commerce, and know with the utmost precision the value of what they sell; but they are often equally well versed in the arts of knavery, requiring to be trusted with great caution, and only upon good recommendation. In Apollonia, it is said, the trader is more secure, either from exactions or impositions, and his person is considered as sacred. The gold trade is understood to have diminished considerably of late, in consequence of the more powerful princes having attempted to secure a monopoly for themselves, by compelling the weaker to renounce the working of their mines. Cowries and gold form the current medium of exchange, especially the former, as being easily reduced to the smallest sums. Forty cowries make a string; fifty strings a head, which is equal to one ackey of gold; and sixteen ackies make an ounce, which is valued at four pounds sterling.* The price of gold never fluctuates; and it is commonly estimated to yield in Europe a profit of 25 per cent. Much attention has recently been directed to the improvement and civilization of this and other tracts on the western coast of Africa; and a more interesting topic could scarcely be presented to enlightened humanity, than an enquiry into the most effectual means of promoting the benevolent object. It has been suggested, in general, to extend our trade inland, by forming alliances with the princes, and placing residents in the principal towns; thus reaching the resources of the country, securing the confidence of the natives, and enlarging the demand for European manufactures;—to encourage the progress of cultivation, by protecting planters from Europe, and directing the industry of the natives to the production of new articles of export;—to annihilate absolutely every vestige of the slave trade, to establish schools for the instruction of the people, and to exercise, in the vicinity of our settlements, as much controuling power of government as possible, for introducing salutary regulations, and enforcing orderly obedience.† "There exists no country in the world," says the French mineralogist De Montfort, "so susceptible of general cultivation. We know that certain districts of Africa are fertile in corn, and grain of every kind grows there intermixed with sugar-canes lately introduced, and which protect the grain from hail. The plants of India, Europe, America, Australasia, or the fifth portion of the globe, will flourish there in perpetual spring, and the animals of all climates can be easily naturalized. The negroes, whose respect for the whites is extreme, notwithstanding what they have suffered from them, will cheerfully give up their lands to be cultivated by us." *Philosophical Magazine*, vol. xlvi. p. 302. See Meredith's *Account of the Gold Coast*; Smith's *Voyage to Guinea*; Peuchet's *Dict. De la Geog.*; and Playfair's *Geography*. (*q*)

GUITAR, *Guitarra* Spanish, *Chitarra* Italian, from *Cithara*, is the name of a musical instrument, commonly strung with wire; but in Spain, the guitars are always strung with catgut or bowel strings, which gives them a much finer tone. The Guitar seems to have been introduced into Spain by the Moors, and has at particular times been more or less in use in almost every part of Europe.

GULF STREAM, is the name given to a constant current in the ocean, produced by the trade winds, which are constantly blowing from east to west. This current, coming from the Pacific and Indian Oceans, passes round the Cape of Good Hope, and, after going along the coast of Africa, it crosses to America towards the equator. It is there divided, and reflected southwards to the Brazils, and running along the shores of Guiana and Terra Firma, it passes through the Caribbean Sea, and coasts along the Gulf of Mexico. Issuing from the Gulf between Cape Florida and the island of Cuba, it traverses the coasts of East Florida, the United States, New Brunswick, and Nova Scotia, and advances eastward to the banks of Newfoundland, where it turns off to the south-east and runs through the Western Islands, from which it goes to the coast of Africa, and in a southerly direction along that coast, till it supplies the place of the waters carried away to the west by the trade winds. "It is perhaps on account of these currents," says Dr Thomas Young, "that the Red Sea is found to be about 25 feet higher than the Mediterranean.‡ Their direction may possibly have been somewhat changed in the course of many ages, and with it the level of the Mediterranean also, since the floor of the cathedral at Ravenna is now several feet lower with respect to the sea than it is supposed to have been formerly; and some steps have been found in the rock of Malta, apparently intended for ascending it, which are at present under water." M. Humboldt remarks, "that the Gulf Stream is occasioned by the current of rotation, (trade winds,) which strikes against the coasts of Veragua and Honduras, and ascending towards the Gulf of Mexico between Cape Caloche and Cape St Antoine, issues through the canal of Bahama. It is owing to this motion, that the vegetable productions of the Antilles are carried to Norway, Ireland, and the Canaries."

The general breadth of the Gulf Stream is about 50 or 60 miles. Sir Charles Blagden, in a voyage to America in the year 1774, found that the water of the Gulf Stream was from 6° to 11° warmer than the waters of the sea through which it ran. The heat at its commencement in the Gulf of Florida was about 82°, and it lost 2° for every 3° of latitude in going northwards. It continued sensible off Nantucket.

The Gulf Stream may be easily distinguished from the other waters of the ocean, by the gulf-weed with which it is every where interspersed, and by its not sparkling in the night. In high latitudes it is always covered with a thick fog. Its breadth is diminished by north-east and east winds, which also increase the rapidity of its motion, and drive it nearer the coast. A

* It is said that a labouring man, during the plentiful season, from September to May, can subsist abundantly on two strings, or twopence farthing a day; and that the usual pay of a labourer is from two to three ackies per month, *i. e.* from 10s. to 15s. currency.

† For the best views of this interesting subject, the readers may be referred to the *Reports of the African Institution*; and the accounts of these publications in the *Edinburgh Review*.

‡ The observations of the French engineers make it 6 toises or 38 feet.

contrary effect is produced by north-west, and west winds.

The Gulf Stream passes at the distance of about 75 miles from the coast of the southern states of America. This distance, however, augments as it advances northwards. Its common velocity is about three miles an hour, and it takes about 20 days to run from Cape Florida to Newfoundland.

See Franklin's *Maritime Observations* in the Transactions of the American Philosophical Society, vol. ii. p. 314. This paper contains a chart of the Gulf Stream, principally from the observations of Captain Folger. Blagden *On the Heat of the Water in the Gulf Stream* in the Phil. Trans. 1781, page 334. Pownall's *Hydraulic and Nautical Observations,* 4to, London, 1787. This last work also contains a chart of the Gulf Stream. Rennel, *Phil. Trans.* 1793, vol. lxxxiii. p. 8. Young's *Natural Philosophy,* vol. i. p. 587; and Morse's *Geography.* See also PHYSICAL *Geography.*

GUMS. See CHEMISTRY, vol. vi. p. 108, 121—128.

GUM *Amber.* See AMBER, and CHEMISTRY, p. 124.

GUM *Ammoniac.* See CHEMISTRY, page 128. This gum should be chosen full of drops or tears, dry, brittle, easily softened by the fire, reducible to a white powder, and of a sharp taste and smell. When thrown on live coals, the drops should burn away in a flame. In 1804, the quantity imported by the East India Company was 81 cwt. and the price per cwt. £3, 11s. 1d. In 1805, the quantity was 333 cwt. and the price £1, 12s. 2d. In 1806, 81 cwt. were imported at the price of £1, 8s. 2d. And in 1807, 59 cwt. were imported at the price of £1, 15s.

GUM *Anime.* See CHEMISTRY, p. 123. This gum should be chosen in large pieces, clear and transparent. When laid on a red hot iron it melts, flames, and burns quickly away with a fragrant smell, leaving a few light coloured ashes. Small dark coloured and opaque pieces should be rejected. The quantity imported by the East India Company from 1804 to 1808, was

	Cwt.	Average Price per Cwt.
1804	166	£6 8 11
1805	452	7 5 8
1806	268	4 19 2
1807	986	4 6 7
1808	1099	1 15 3

This gum is often sold for gum copal.

GUM *Arabic.* See CHEMISTRY, Sect. v. p. 108. In choosing this gum, great care should be taken that it is not mixed with another kind of gum, generally in larger pieces, which, instead of dissolving completely in water, only swells in it. The following quantities were imported by the East India Company from 1804 to 1808:

	Cwt.	Average Price per Cwt.
1804	1767	£4 12 1
1805	3931	4 1 11
1806	1534	2 17 8
1807	6565	2 6 10
1808	1382	2 3 3

GUM *Assafœtida.* See CHEMISTRY, p. 128. The use of this gum was introduced by the Arabians about 1000 years ago. It should be chosen clear, fresh, strong-scented, and of a pale reddish colour. When broken, it should have a resemblance to marble; and by exposure to the air, it should turn of a violet red colour. That which is soft, black, and foul, is adulterated. The following quantities were imported by the East India Company from 1804 to 1808:

	Cwt.	Average Price per Cwt.
1804	141	£3 15 2
1805	157	5 11 2
1806	82	3 12 8
1807	40	3 12 6
1808	72	3 17 9

GUM *Bdellium,* is a gum which is brought from Persia and the East Indies. It has a reddish brown colour externally, but is like glue internally. The loose drops in which it is brought home are sometimes as large as hazel nuts, but often less than a pea. They are commonly of an irregular shape. It is moderately heavy and hard, and grows tough in the mouth. It readily takes fire, burns with a bright white flame, and crackles, throwing out small fragments. It dissolves completely in vinegar.

GUM from *Botany Bay.* See CHEMISTRY, p. 123.

GUM *Caoutchouc.* See CAOUTCHOUC, and CHEMISTRY, Sect. xxvi. p. 126.

GUM *Cherry Tree.* See GUM *Prunus Avium.*

GUM *Copal.* See CHEMISTRY, p. 123.

GUM *Dragon's Blood.* See GUM *Sanguis Draconis.*

GUM *Dragon.* See GUM *Tragacanth.*

GUM *Elemi.* See CHEMISTRY, p. 123. This gum is obtained from the East Indies, as well as from Canada and Spanish America. The East India elemi is semitransparent, of a pale yellow colour inclining to green, and is bought in cakes of 2 or 3 lbs. each, wrapped up in flag leaves. That which is soft, with a strong smell and a bitterish taste, is the best. The hard and dark coloured is never good.

GUM *Euphorbium,* is the concrete resinous juice of a prickly shrub, which grows in Malabar and various parts of India. The irregularly shaped tears of which it consists, sometimes enclose thorns, twigs, &c. The best kind is dry, clear, and of a bright light yellow colour; and is so sharp to the taste, that a small piece held a short time in the mouth will inflame it.

GUM called *Frankincense.* See GUM *Olibanum.*

GUM *Galbanum.* See CHEMISTRY, p. 127, and GALBANUM.

GUM *Gamboge,* or *Gumgutt.* See CHEMISTRY, page 128, and GAMBOGE.

GUM *Guiacum.* See CHEMISTRY, Sect. xxiv. p. 124.

GUM *Juniper,* the same as GUM *Olibanum,* which see.

GUM *Labdanum.* See CHEMISTRY, p. 123, and LABDANUM.

GUM *Lac.* See CHEMISTRY, p. 123, and LAC.

GUM *Manna.* See CHEMISTRY, p. 108.

GUM *Mastich.* See CHEMISTRY, page 122, and MASTICH.

GUM *Myrrh.* See CHEMISTRY, p. 128, and MYRRH.

GUM *Olibanum,* or *Frankincense.* See CHEMISTRY, p. 128, and OLIBANUM.

GUM *Opium.* See CHEMISTRY, Sect. xviii. p. 117, and OPIUM.

GUM *Opoponax.* See CHEMISTRY, p. 128, and OPOPONAX.

GUM *Prunus Avium.* See CHEMISTRY, p. 109.

GUM *Sagapenum.* See SAGAPENUM.

Gums, Gun-Flints.

Gum *Sandarach*. See Chemistry, p. 123.

Gum *Sanguis Draconis*. See Chemistry, page 126. Dragon's blood in drops is preferable to that which is obtained in cakes, being more pure and compact. Genuine dragon's blood readily melts and flames, but is not soluble in water. The following quantities were imported by the East India Company:

	Cwt.	Average Price per Cwt.
1804	53	£11 0 0
1805	103	3 13 0
1806	26	9 19 11
1808	19	11 6 9

Gum *Scammony*. See Chemistry, page 128, and Scammony.

Gum *Senegal*. See Chemistry, p. 109. This gum exudes from a prickly shrub, of the same genus with that from which gum arabic is obtained. It is chiefly used by calico printers, and in other trades where gums are employed. It dries more slowly than gum arabic.

Gum *Tacamahac*. See Chemistry, p. 123.

Gum *Thus*, or *Frankincense*. See Gum *Olibanum*, and Olibanum.

Gum *Tragacanth*, or Gum *Dragon*. See Chemistry, p. 109.

There are many other gums than those which have been mentioned, but they are not of much importance as articles of commerce. Dr Francis Buchanan informs us, that gums are collected between Seringapatam and Bangalore from the following trees:

Andersonia panshmoum. (Dr Roxburgh's MSS.)
Melia azadirachta.
Chirongia glabra. (Dr Buchanan's MSS.)
Mangifera Indica.
Cassia auriculata.
Ægle marmelos.
Shorea jala. (Dr Buchanan's MSS.)
Chloroxylon dupada. (Do.)
Bomboc gossypinum.

See Buchanan's *Journey from Madras*, &c. vol. i. p. 169. See also Milburn's *Oriental Commerce*, passim.

GUN-Flints, are small pieces of flint cut into regular shapes, for the purpose of setting fire by their collision against a piece of steel, to the priming of fowling pieces, muskets, &c.

The first stones used for this purpose were a kind of compact pyrites, or marcasite, and they were long known by that name. The species of stone used in the greater part of Europe, is called by Wallerius *silex ignarius*, and by Linnæus *silex cretaceus*. In Germany it was called *flins* or *vlins*; in the Swedish and Danish *flinta*; and in English *flint*. This name is said to be of great antiquity, as the Wends had a Pagan deity which they placed on a stone called *flynsteiu*. From the word flint arose the names of *flintgewehr*, *flint*, or *flinte*, which the Germans have given to guns fired by that stone. Stones seem to have been first used about the middle of the 16th century.

The manufacture of gun flints has been long kept a profound secret; and we are indebted to Dolomieu for the first exposition of the method employed in France.

The masses of flint which are best fitted for this purpose, are of a convex surface, approaching to globular. The knobbed and branched flints are commonly full of imperfections. The best flint nodules are generally between 2 and 20 pounds weight. They should be unctuous, or rather shining internally, with a grain so fine as to be imperceptible to the eye. The colour should be uniform in the same nodule, and may vary from honey yellow to a blackish brown. The fracture should be smooth and equal, and the fragments slightly conchoidal; and the transparency should be such as to allow letters to be distinguished through a thickness of one-fourth of a line when laid close to the paper. When flints do not possess these properties, either naturally, or after a long exposure to the air, they are rejected by the workmen.

Gun-Flints.

Tools for making gun-flints. Plate CCLXXXIV.

Four tools are necessary in the manufacture of gun flints. 1. An iron hammer with a square head, a handle seven or eight inches long, and not exceeding two pounds in weight. This instrument is shewn in Fig 3. Plate CCLXXXIV. 2. A hammer of well-hardened steel, with two points, a handle seven inches long, and from 10 to 16 ounces in weight. The handle must pass through in such a manner that the two points may be nearer the hand of the workman than the centre of gravity of the mass. This hammer is represented in Fig. 4. 3. A disk hammer, or roller, like a solid wheel, or the section of a cylinder, two inches and four lines in diameter, and not exceeding 12 ounces in weight. It is made of steel, not hardened, and has a handle six inches long, which passes through a square hole in the centre. It is shewn in Fig. 5. 4. A chisel, tapering and bevelled at both ends. It should be made of steel, not hardened, and six, seven, or eight inches long, and two inches wide. This chisel is represented in Fig. 6. This is set on a wooden block, which is also used, as a bench for the workman. A file is necessary for restoring the edge of the chisel. With these tools the flints are formed in the following manner, which we have abridged from Dolomieu's Memoir.

1. *To break the block.* The workman seated on the ground, places the nodule of flint on his left thigh, and applies slight strokes with the square hammer, to divide it into smaller pieces of about a pound and a half each, with broad surfaces, and almost even fracture.

2. *To cleave or chip the flint.* The workman holds the piece of flint in his left hand, not supported, and strikes with the pointed hammer, No. 2. on the edges of the great planes produced by the first breaking, by which means the white coating of the flint is removed in the form of small scales, and the mass of the flint itself laid bare in the manner represented, Fig. 7. After which he continues to chip off similar scaly portions from the pure mass of the flint. These scaly portions are nearly one inch and a half wide, two inches and a half long; and their thickness in the middle is of about two lines. They are slightly convex below, and consequently leave in the part of the flint from which they were separated, a space slightly concave, longitudinally bordered by two rather projecting straight lines, or ridges, Fig. 8. These ridges, produced by the separation of the first scales, must naturally constitute nearly the middle of the subsequent piece; and such scales alone as have their ridges thus placed in the middle are fit to be made into gun flints. In this manner the workman continues to split or chip the mass of flint in various directions, until the defects usually found in the interior render it impossible to make the fracture required, or until the piece is reduced too much to receive the small blows by which the flint is divided.

3. *To shape the gun flint.* Five different parts may be distinguished in a gun flint. 1*st*, The sloping facet, or bevel part, which is impelled against the hammer of the lock of the gun. Its width should be from two to

Gun-Flints. three-twelfths of an inch; if it were broader it would be too liable to break: and if more obtuse the scintillation would be less brisk. *2dly*, The sides or lateral ridges, which are always rather irregular. *3dly*, The back, or the part opposite the tapering edge: this is the thickest part of the flint. *4thly*, The under surface, which is uninterrupted and rather convex. And, *5thly*, The upper facet, or small square facet between the tapering edge and the back, which receives the upper claw of the cock; it is slightly concave. In order to fashion the flint, those scales are selected that have at least one of the above-mentioned longitudinal ridges: The workman fixes on one of the two tapering borders to form the striking edge; after which, the two sides of the stone that are to form the lateral edges, as well as the part which is to form the back, are successively placed on the edge of the chisel, in such a manner that the convex surface of the flint which rests on the fore-finger of his left hand is turned towards that tool. He then with the roulette applies some slight strokes to the flint, just opposite the edge of the chisel underneath; by which means the flint breaks exactly along the edge of the chisel.

4. *To trim the flint.* The last operation is to *trim*, or give the flint a smooth and equal edge; this is done by turning the stone, and placing the edge of its tapering end on the chisel, in which situation it is completed by five or six slight strokes with the roulette. See Fig. 9.

Plate CCLXXXIV. Fig. 9.

The whole operation of making a gun flint is performed in less than one minute. A good workman is able to manufacture a thousand good chips or scales a day, (if the flint nodules be of a good quality;) and in the same manner he can fashion 500 gun flints in a day, so that, in the space of three days, he is able to cleave and finish a thousand gun flints without farther assistance.

In this manner, five or six blows with the hammer are sufficient to produce a perfection of figure which would require more than an hour's labour, if the faces were formed by grinding them against harder substances; and less than a farthing will pay for a gun flint from the hand of the workman, though fifty times that sum would be insufficient to purchase it, if it were formed in any other way.

When the gun flints are completed, they are sorted into two classes, fine and common flints, and according to their application into flints for pistols, fowling-pieces, and muskets. A good gun flint will give 50 strokes without being unfit for service. They are sold in France at from four pence halfpenny to seven pence per hundred. They cost twice as much in Italy, and, in 1745, when they were exported from the department of the Loire and Cher to Lyons, Strasburg, and St Quintin, they cost 12 francs per thousand, or one shilling per hundred.

The manufacture of gun flints in France, employed above 800 of the inhabitants in the communes of Noyers, Couffy, and Meunes, in the department of the Loire and Cher. The mine, which is four leagues square, is thirty or forty feet deep, and thirty million of flints manufactured here were stored up in 1794. They are also made in the communes of Lye, in the department of the Indre, of Maysse and St Vincent, in the department of Ardeche, and at Cerilly in the department of the Yonne. Dolomieu received the information contained in the preceding article from Stephen Buffet, who emigrated from the commune of Meunes to the banks of the Seine, where he carried on his profession for above 30 years.

Gun flints are made also in the territory of Vicenza, and in one of the cantons of Sicily. They were manufactured in great quantities at Stevensklint in Zeeland. They are also manufactured at Purfleet in Kent, and in various other parts of England in a very superior stile.

See Dolomieu's Memoir in the *Memoires de l' Institut.* vol. iii. p. 148; in the *Journal des Mines*, No. xxxiii. p. 693; and in Nicholson's *Journal*, vol. i. 8vo. p. 88. In the *Journal des Mines*, No. xxxiii. p 713, and 719, will also be found a Memoir by M Solivet, and observations by M. Tonellier on the manufacture of gun flints in the commune of Cerilly. See also the *Hanoverian Magazine* for 1772; and Beckmann's *History of Inventions*, vol iv. p. 609, &c.

Gun-making. GUN-MAKING is the art of manufacturing small arms, for the purposes of war and the chace. The name harquebuss, which was first given to small arms, is said to have been derived from the Italian word *arcobousa*, or bow with a hole, and the instrument was successively designated harquebuss, hackbut, hand-gun, match lock, musket, snaplance, petrinal, firelock, carabine, and fowling-piece; hence the workmen acquired the appellation from the French harquebussiers; and the British gun-smiths, and gun-makers.

History of gun-making. The first application of gunpowder to small arms, appears to have been made by the Germans soon after the invention of cannon; for in 1471 we find that Edward the IV. brought over into England 300 Flemings, armed with hackbuts or harquebusses. The Spaniards are said to have, so early as the reign of Philip the II., adopted them in the army; and that monarch caused them to be made of a large calibre, and so heavy that a forked rest was requisite to level them in taking aim. They were used at the siege of Rhige, and by the Emperor and Pope Leo in 1521. The French had availed themselves of this arm, in 1667, to the extent of four harquebusses in each company of their army. England appears to have been earlier apprized of their superiority over the weapons then in use. Harquebuss soldiers formed a part of their forces in 1540; and Peter Van Collins is mentioned by Stowe, as the first gunsmith, in 1543. By an act of Henry the VIII. the length of the hand, gun stock, and barrel, is directed not to exceed one yard; and that of the hackbut three quarters of a yard. By a statute of Elizabeth, they are ordered to be made all of one size and calibre, from which they acquired the name of culivers, a light kind of matchlock, fired without a rest; and their price was fixed at 13 shillings and sixpence, with flask, touch-box, laces and mould. In James the First's reign, the price was fixed at 14 shillings and ten pence. Charles the Second directs the musket barrel not to be under three feet in length, and to receive a ball of twelve in the pound; and in 1638, he grants a charter to the gun-smiths of London, by the name of master wardens, and society of gun-makers; at which period they made wheel and snap-lance locks. The Scotch used the harquebuss or match-lock soon after its invention, from their intimate correspondence with France and Flanders; yet we have no certain information of their having any artists in that profession sooner than 1640, when they became incorporated with the hammermen of Edinburgh, as a pendicle of the lock-smith art. The city guard were armed with muskets or harquebusses in 1682, the expence of purchasing and maintaining of which was directed to be defrayed from the money exacted from those who entered burgess. After the union of the two kingdoms, the manufacture of small arms, (if ever carried on to any extent,) seems to have been confined to a few individuals. From the records of the hammermen, it appears that in 1715 there were only two, viz. Murdoch Grant, and John Simpson; and in 1741 there was only one in the profession. Since that period, however, greater encouragement has been given to that art in Edinburgh, there being at the present time (1816) six master gun-makers, who employ about thirty workmen; and there is one in a few of the principal towns in Scotland. This business has been carried on to a very considerable extent, in England, by private individuals; and government, within these few years, has established extensive manufactories at Lewisham, and in the Tower of London, employing about 500 workmen, who complete at the rate of 5000 stand of muskets every week: Expert workmen have been paid seven guineas and upwards for their week's labour. The London gun-makers, who are employed in the making of fowling-pieces, rifles, and pistols, amount to about forty-three, and they have not less than 300 people in their service. Birmingham is the place where all kinds of fire-arms are manufactured to the greatest extent; although it is to be regretted that the effect of competition has introduced a superficial style of working, which is greatly detrimental to the character of the article, and to its extension as a branch of commercial export.

The manufacture of a gun is performed by the following workmen, viz. barrel forger, borer and filer, lock forger and filer, furniture filer, ribber and breecher, rough stocker, screwer together, polisher, and engraver, in all ten different persons, few of whom can execute any other branch of the art but one. Most of the principal towns in England have one or two master gun-makers, but none of them carry on the business in all its different branches, except London, Birmingham, and Edinburgh. The makers of the first and last cities have the highest prices for their guns, single fowling-pieces being from 15 to 30 guineas, and double ones from 35 to 70 guineas; indeed, to such a perfection has this instrument been brought, of late years, by the British artists, that it cannot be doubted but that they are greatly superior to every other nation in Europe; although we have learned that, at the Versailles manufactory, under the first consul's special patronage, fowling-pieces were made at the high price of 800 guineas. Instances, however, can be produced where London makers have had a thousand guineas for one gun. The variety and ingenuity in the construction of small arms, in order to gain peculiar advantages, are so various and extensive, that it would be very difficult to enter into any details upon the subject: We shall, however, enumerate a few of the different kinds of guns which are in use: guns with one barrel to discharge from one to three balls successively; magazine guns that prime and load by one motion, and discharge from 10 to 20 balls in succession; double guns, with their barrels placed perpendicular, horizontal, and to turn round a centre; three, four, and seven barreled guns; harpoon guns; muskets and carabines, &c.

Gun barrel.

The gun barrel.—The length, shape, and bore of gun barrels, have materially changed as the instrument became more generally used and better understood. Hence we find, in different countries and at different periods, their lengths fluctuating from six feet to 25 inches, and their diameters from half an inch to one and a quarter inch: They are generally cylindrical, but in some instances square, internally and externally with chambers at the breech to contain the powder, as is the case with all the Asiatic matchlocks of most ancient construction. The Spaniards were the first people in Europe who excelled in the manufacture of barrels, remarkable for lightness and safety: Possessing finer iron from their smelting their ores with wood; and being sensible that the more it is wrought by heating and hammering, the purer it becomes, they naturally resorted to the old nails extracted from the shoes of their horses and mules. Juan Sanchez di Mirvena, is the first that forged the barrel in separate pieces, in the reign of Philip IV.; and so highly were the Madrid makers esteemed, in 1720, that the French gave 1000 livres, or £43, 13s. sterling, for the barrels of Nicholas Biz, Juan Beler, and Juan Fernendez. About the year 1650, we find Lazerino Cominazio, of Brescia, in high repute. France has also had her eminent workmen, such as Nicol le Clerc, Des Champs, Jean Franc Renet, and Henry Renet, all of Paris, whose barrels are still much prized. The British are now, however, confessedly much superior to every other people in the manufacture of this article. They have, of late, introduced many ingenious improvements, such as patent steel barrels, and narrow and wire-twist barrels, with a beautiful application of the fibres of the metal in welding, so as to resemble exactly the Damascus steel of Persia, or what is seen in the finest arms of Indian workmanship. At first the European barrels were all of one diameter throughout, until within these 30 years, that a London tradesman obtained a patent for a chambered breech, which, though it possessed peculiar merit, was nothing but a copy from the principle of the carronade, and both are obviously borrowed from the Indian matchlock; hence his privilege of original invention being untenable, this construction became general in a few years, and still continues, with some slight variation, to the present period.

In forming the common gun barrel, the workmen begin by heating and hammering out a bar of the best iron, into the form of a flat ruler, thinner at the end intended for the muzzle, and thicker at that for the breach, the length, breadth, and thickness of the whole plate being regulated by the intended length, diameter, and weight of the barrel. This oblong plate is then, by repeated heating and hammering, turned round a cylindrical rod of steel, called a mandril, whose diameter is considerably less than the intended bore of the barrel. The edges of the plate are made to overlap each other about half an inch, and are welded together by heating the tube in lengths of two or three inches at a time, and hammering it with very brisk but moderate strokes, upon an anvil which has a number of semicircular furrows in it, adapted to barrels of different sizes. The heat required for welding is the bright white heat which immediately precedes fusion, and at which the particles of the metal unite and blend so intimately with each other, that when properly managed, not a trace is left of their former separation. Every time the barrel is withdrawn from the forge, the workmen strike the end of it once or twice gently against the anvil in an horizontal direction; this operation, which is called jumping, serves to consolidate the particles of the metal more perfectly, as well as to disengage the scoria from the inside and outside of the tube, and to obliterate any appearance of a seam. The mandril is then introduced into the bore, or cavity; and the barrel being placed in one of the furrows or moulds of the anvil, is hammered very briskly by two persons; the forger all the while turning it round in the mould, so that every point of the heated portion may come equally under the action of the hammer. These heatings and hammerings are repeated until the whole of the barrel has undergone the same operation, and is rendered as perfectly continuous as if it had been bored out of a solid piece. Twisted barrels are now generally used for the finest fowling-pieces, the method of fabricating of which is as follows. Four bars of stub iron, two feet in length, half an inch in breadth, and the first two bars half an inch thick or more, according to the size of the barrel, are previously prepared. An old barrel being welded to the extremity of one of those bars for a handle, it is heated and turned round like a cork-screw, by means of the hammer and anvil; after this, the turns of the spiral are united by heating the tube two or three inches at a time to a bright white heat, and striking the end of it several times against the anvil in a horizontal direction, with considerable force: This is called jumping the barrel, and the heats given for that purpose jumping heats: A mandril is immediately introduced into the cavity, and a quick light hammering is kept up on the welding part, until the ridges raised at the seams by the jumping are flattened, and the piece appears sound. As soon as one bar is rounded and jumped in this manner, another is welded to it, and treated in the same way, until the four pieces are united and form one tube: The old barrel is then cut off as being no longer requisite, and the operation of heating and hammering is frequently repeated in its whole length, until its external figure is correctly acquired, and the metal has arrived at the utmost closeness of fibre in all its parts. It is a circumstance of considerable importance with respect to a gun barrel, that it should be forged as nearly as possible to its weight when finished, so that very little may be taken away in the boring and filing; for as the outer surface, by having undergone the action of the hammer more immediately than any other part, is rendered more compact and pure, the less that is removed the better will the barrel be.

Process of boring.

The next process is the boring, the apparatus for which is either driven by a water wheel, steam engine, or the hand, according to the extent of the manufacturer's demand. This operation consists in giving to the barrel its proper calibre. The boring bit is a rod of iron, somewhat longer than the barrel, one end being fitted into the socket of the crank, and the other furnished with a cylindrical plug of tempered steel, about an inch and a half long, and having its surface cut with spiral grooves, flat at bottom, and a quarter of an inch in breadth. This form gives the bit a very strong hold of the metal, and the threads sharp at the edges, scoop out and remove every roughness and inequality from the inside of the barrel, and render the cavity smooth and equal throughout. Several bits, each a little larger than the preceding one, are afterwards successively passed through the barrel in the same way, until it has acquired the intended calibre. After this the fine boring bit is introduced, being a similar rod to the former, with a square bar of tempered steel, 10 or 12 inches long at its extremity, and finely sharpened on one of its sides; on the opposite side is placed a semicircular slip of wood, of a size sufficient to fill up with the bit the entire diameter of the barrel, two of its edges only acting on the tube, which passing through its whole length, and kept well oiled, is frequently repeated, and the bore enlarged by small slips of paper placed between the wood and the bit, until the inside presents a perfectly equal and polished surface. The trueness of the bore is then proved, either by a steel or leaden plug passed through its whole length. The next step towards completing the barrel is the operation on its exterior surface, which in common barrels is done by grinding on a large stone; two steel pins being inserted into the mouth and breach of the tube, and smaller than its diameter. The workman holding them in his hands, presses the barrel to the stone, which revolving on the pins, grinds off the inequalities left by the hammer; after which it is passed to another person who files and smooths it from one end to the other. The best barrel makers do not grind, but turn their barrels on a lathe, which is well calculated to insure that perfect equality of thickness on which the strength and safety of the piece so greatly depend. The filing and smoothing is afterwards performed in the usual manner. The imperfections to which gun barrels are liable, and which render them dangerous to use, and apt to burst, are the *chink*, *crack*, and *flaw*. The first is a small rent in the direction of the length of the barrel, the second across it, and the third is a scale or plate adhering to the barrel, by a narrow base, from which it spreads out like the head of a nail from its shank, and when separated leaves a pit or hollow in the metal. Chinks or flaws are of much worse consequence than the crack in fire-arms, the expansive force of the powder being exerted more upon the circumference than the length of the barrel; the flaw is much more frequent than the chink, the latter scarcely ever occurring but in plain barrels, formed out of a single plate of iron. The proof of gun-barrels, both musket and fowling pieces, as established by Government and the Gunmakers Company of London, is a ball that fits the diameter of the piece, and a charge of powder of equal weight, which being fired, either bursts the barrel, or demonstrates its soundness and safety. Some gunmakers are in the habit of following this test, by a water proof, in order to ascertain if the pores of the metal continue perfectly secure. Pistol barrels are forged in one piece, two at a time, joined by their muzzles, and are bored before they are cut asunder, by which means there is not only a saving of time and labour, but a greater certainty of the bores being the same.

Rifle barrels.

Rifle barrels are of modern invention: The Germans have the merit of this contrivance. The rifle barrels of Kuchanrieter senior of Ratisbon are in the greatest esteem; and so fond are the Germans of excelling in the use of the rifle, that it has become one of their principal amusements, in which all ranks of society frequently indulge. Every town and village has their practising ground, or butts, where small prizes are competed for, with an accuracy of aim that is truly surprizing. The Americans have also, from their habits of hunting, acquired great correctness in the use of rifle guns; and within these few years our government has introduced them into the army; the ninety-fifth regiment being peculiarly clothed, and armed with that weapon. The manufacture of rifles, in their first formation, is exactly similar to that of other barrels, except that their external form is generally octagonal.

Process of rifling.

The process of rifling is as follows; the barrel being previously bored, and finished to a true cylindrical form, is placed on the rifling machine, an instrument formed on a square plank of wood seven feet long, to which is fitted a tube about an inch in diameter, with spiral grooves deeply cut internally through its whole length, and to which is attached a circular plate, about five inches diameter, accurately divided in concentric circles, into from five to ten equal parts, and supported by two rings affixed to the plank, in which it revolves; an arm connected with the dividing plate, and pierced

Gunmaking.

with holes, through which a pin is passed, regulates the change of the tube in giving the proper number of rifles to the barrel. An iron rod with a moveable handle at one end, and a steel cutter in the other, passes through the rifling tube. This rod is covered with a core of lead one foot in length, and the barrel is firmly fixed by means of two rings on the plank standing in a straight line to the tube. The rod is then repeatedly drawn through the whole length of the barrel, until the cutter has formed one groove to the proper depth; the pin being shifted to another hole in the dividing plate, the operation of grooving is continued until the whole number that was required is complete. The barrel is then taken out of the machine and finished. This is done by casting on the end of a small iron rod a core of lead, which, when coated with fine emery and oil, is drawn for a length of time by the workman from one end of the barrel to the other, till it has acquired a high degree of smoothness and polish. The process is then complete, and the barrel is ready for the ribber and breacher, &c. The best degree of spirality is found to be half a turn in a length of three feet.

Gun lock.

The Lock, was originally a cleft piece of iron, moving on a pin fixed into the stock. The match was held in the cleft, and conveyed into the priming in the pan: A lever carried down the under part of the stock, and projecting at its extremity, served for a trigger. This simple contrivance was followed by the wheel-lock, so called from a small solid wheel of steel, nearly a quarter of an inch in thickness, and one and a half in diameter, cut on its edge with grooves, and notched transversely. The upper part of the circumference of this wheel rose up through the middle of the pan: It had an axis placed in its centre, to which a chain was attached, connecting itself to the extremity of a strong spring on the outside of the lock-plate, and the whole was fixed to the barrel by screws passing through the stock. Its application was by turning the wheel with a key, or spanger, which rolled the chain round its axis, and drew up the spring to its full tension. By this movement, a slider that covered the pan containing the priming, retired from over it, so as to permit the dog, which held the flint, to place itself on the edge of the wheel, which being let off by the trigger, the rapid revolutions of the wheel elicited fire from the flint, and inflamed the priming. See Fig. 8. To this succeeded the *Snaplance*, in which a motion was given to the dog, or cock, and a moveable plate of steel, called the frizel, or hammer, was placed vertically above the pan to receive the action of the flint. Numerous important advantages were acquired by this improvement over the wheel-lock, first, by securing the priming until the instant the piece was to be fired; and by increasing the quickness of its action and the lightness of its construction, &c. The great perfection to which this part of a gun has been carried within these 40 years in Britain, justly acquired the profession an acknowledged celebrity over every other nation. The important requisites in a gun lock are, that the action of the cock be as rapid as possible, and that it should be so placed that on uncovering the pan, the flint may point into the centre of the priming, and as near to it as possible, without touching it. The main-spring should have a smooth and active motion; the hammer-spring should be light, and should give a slight resistance to the cock on its striking the steel, which ought to move on a roller; and the temper should not be too hard or too soft, the one extreme being known by a roughness on its surface, and the other by the flint's making scarcely any impression on it, and producing little or no fire. The inside of the lock ought to be freed and swivelled, and the tumbler and seer of steel, and also the nails, should be tempered.

Plate CCLXXXV. Fig. 8.

A very great improvement in the construction of gun-locks has lately been made by the Rev. Mr Forsyth, minister of Belhelvie, in Aberdeenshire. This ingenious gentleman contrived and made with his own hands a lock to fire without a flint, and by percussion alone to inflame certain powders. This contrivance possesses so many advantages over the present lock, (even in its most perfect state) that it will ultimately supersede it entirely. Although it is not more than five or six years since it was made public; yet both the German and Prussian gun-makers have adopted it, and there is little doubt it will become general here, so soon as his patent expires. The great advantages of this discovery are, the rapid and complete inflammation of the *whole* charge in the chamber of the barrel, a prevention of the loss of force through the touch-hole, perfect security against rain or damp in the priming, no flash from the pan, and less risk of accidental discharge of the piece than when the common lock is used.

Forsyth's lock. Plate CCLXXXV. Figs. 1—4.

This lock is represented in Figs. 1, 2, 3, 4, of Plate CCLXXXV. It consists of a hammer or dog-head H, and a magazine MN. This magazine MN, a section of which is shewn in Fig. 3. consists of a roller A round which the magazine is moveable as about an axis, one end of which is screwed into the breach of the barrel, as shewn in Fig. 4. The roller is perforated through its axis by a channel *m*, Fig. 4. which communicates with the chamber S of the gun. On the upper side of the roller is a pan B, which communicates by a hole in its centre with the channel *m*, and consequently with the chamber of the piece. The priming powder, which consists of *three* parts of the hyper-oxymuriate of potash, *one* part of sulphur, and *one* part of charcoal, is put into the cavity C of the magazine, which will hold 40 primings. The opposite cavity D contains the steel punch and spiral spring E. When this punch is pressed down, it strikes the pan B, and is again raised from the pan by the elasticity of the spiral spring. F, F are the screws between the points of which, and the cork fixed on the inside of the magazine, the grease for oiling the roller is contained. In order to use this lock, the magazine is brought into the position shewn in Fig. 1. where the cavity containing the priming powder is above the pan. A small portion of the powder therefore falls into the pan. The magazine is then turned round into the position of Fig. 2. where the steel punch is uppermost at M. The hammer H being raised, and the trigger being pulled, it gives a blow to the steel punch, which strikes the priming powder in the pan, and inflames it by the concussion. The flame having no other exit, passes along the channel *m*, Fig. 4. and inflames the charge. One of the great advantages of this lock is, that it may be used during rain, and the piece will go off even if the lock is immersed in water.

Simplification of Forsyth's lock.

A very elegant simplification of this lock has been made, by giving the magazine MN a horizontal instead of a rotatory motion. The magazine is connected with the hammer by a lever, so that when the hammer is raised, or the piece cocked, the lever pulls the magazine over the pan, and fills it with priming. When the hammer is let go, by pulling the trigger, the magazine is moved from the priming pan, and the powder is inflamed by the percussion of the extremity of the hammer. This form of the lock, however, is not water proof.

Stock and mounting.

The Stock and Mounting of Guns has assumed a great variety of forms, and not only the figure, but the mode of holding small arms has undergone a change; the

Gunmaking.

straight stocked match-lock being placed under the right arm, the crooked short hagbut and the poitrinal on the breast, and the modern musket at the right shoulder. Guns of sport, till within these thirty years, were made very crooked in the stock, and no regard was then paid to the balance of the piece; since that period straight stocks have been universally adopted, and the length of the stock has been accommodated to the stature of the person for whom it is made. For a view of various constructions of small arms, see Plate CCLXXXV.

GUNNERY,

Gunnery.

Is the art of constructing and using great guns, for the purpose of hitting a distant object, with shot or shells, discharged from the gun by the explosive force of gunpowder.

In the present article we propose to confine ourselves to the theory of gunnery, as founded on the mathematical doctrine of projectiles, corrected and modified by experimental investigations. The art of constructing and mounting great guns, and the description of the apparatus connected with them, will form a separate article under the head of Ordnance.

HISTORY.*

History.

The Italians seem to have been the first people that directed their attention to the subject of the motion of cannon shot. Nicholas Tartaglia, a Venetian, who was born at Brescia, published at Venice, in 1537, his *Nuova Scienza*, and in 1546 his *Quesiti e Invenzioni diverse*, in both of which he treats the subject of projectiles. In the last of these works, he gives an account of the calibre rod, or artillery measuring rod, of which he seems to have been the inventor. In another work, translated into English by Cyprian Lucas, and entitled *Colloquies concerning the Art of Shooting in Great and Small Pieces of Artillery*, Lond. 1588, he has entered more minutely into the subject. Having no knowledge of the practical part of artillery, Tartaglia investigated the subject theoretically upon fallacious principles, and can scarcely be considered as having done any great service to this branch of science. He is supposed, however, to have discovered that projectiles may be thrown to the greatest distance when they are projected at an angle of 45 degrees; and, in opposition to the notion of practical gunners, he maintained that no part of the path of a cannon ball was a straight line, but that it was like the surface of the sea, which, though to all appearance a plane, was nevertheless a portion of a circle described by the radius of the earth. Tartaglia appears also to have been the inventor of the gunner's quadrant.

The researches of Tartaglia, imperfect and unsatisfactory as they were, had the merit of directing the attention both of military engineers and mathematicians to this curious subject. Many fallacious theories of the motions of cannon shot were brought forward, and Ufano, Galeus, Ulrick, and several other writers, published tables of the comparative ranges of military projectiles, that were quite irreconcileable with experiment.

Collado's experiments.

The first experimental examination of this subject was made by M. Collado, a Spaniard, who served as an engineer with the Spanish army in Italy. In his work entitled *Practica Manuale de Artiglieria*, Venice, 1586, which was first published in Italian and afterwards in Spanish, he has given for each point of the gunner's quadrant the ranges of a falconet which carries a three pound shot. Mr Robins remarks, that it is manifest, from the number, that the falconet was not loaded with the usual quantity of powder. The following are Collado's results:

Points of the Gunner's Quadrant.	Angle of Elevation.	Range in paces, or common steps.
0	0° point blank	268
1	$7\frac{1}{2}$	594
2	15	794
3	$22\frac{1}{2}$	954
4	30°	1010
5	$37\frac{1}{2}$	1040
6	45	1053
7	$52\frac{1}{2}$ between the 3d and 4th range.	
8	60 between the 2d and 3d range.	
9	$67\frac{1}{2}$ between the 1st and 2d range.	
10	75 between the 0 and 1st range.	
11	$82\frac{1}{2}$ the ball fell very near the piece.	

Bourne's experiments.

The next experiments which were made on this subject, appeared in the *Art of Shooting in Great Ordnance*, a work which was published in 1643 by Mr William Bourne. He assumes unity as the range for a point blank shot, and ascertains the ratio of the ranges at different elevations. Bourne does not mention the nature of the piece which he used, but Mr Robins presumes that it must have been a small one. The following Table contains the results given in Chap. vii. of the above work:

Angles of Elevation.	Ranges.
0	1.000
5	2.222
10	3.366
15	4.366
20	4.833
36	Greatest range when a strong wind favours the motion of the projectile.
42	Greatest range in a calm day.
45	Greatest range when a strong wind opposes the motion of the projectile.

Eldred's experiments.

A very admirable series of experiments were made early in the 17th century, by our countryman Eldred, who was for many years master gunner at Dover castle. His earliest experiments are dated 1611; but the book which contains them, entitled *The Gunner's Glasse*, was not published till 1646. His experiments, which are very numerous, were made with great care, and the principles on which he proceeded were simple

* An account of the invention and history of Artillery will be found under that article.

History.

and tolerably correct. He has published the actual ranges of different pieces of artillery, at small elevations, not exceeding ten degrees, and among these are some trials made with the famous cannon called the *basilisk*, a piece 23 feet long, and well known to those who visit Dover castle. He found that this gun, which carries a 10 lb. shot, ranged 3600 feet with 18 lb. of powder, at an inclination of 2°, and 6000 feet at an elevation of 43°

Discoveries of Galileo.

The subject of gunnery was now destined to receive the most important improvements from the genius of Galileo. By the application of mathematics to the doctrines of motion, he has given the form of a science to this branch of natural philosophy, and has enabled us to ascertain every thing that relates to the flight of military projectiles, on the supposition that they are discharged in a non-resisting medium. His *Discursus et Demonstrationes Mathematicæ*, &c. which contains these fine investigations, were published in 1638. They are given in the fourth dialogue, entitled *De Motu Projectorum*, and occupy fourteen propositions, in which he has proved that a projectile must describe a parabolic curve by the combination of the force of gravity with the force of projection, and has shewn how to compute the distance to which the body will be thrown, the time of its flight, and the momentum with which it falls, when projected in a given direction, and with a given velocity. Galileo was perfectly sensible that the resistance of the air would produce a considerable change in these results, and he has described a method of discovering the magnitude of the effects which this resistance would produce on the motion of a bullet at some given distance from the gun.

The opinions which prevailed at this time respecting the extreme rarity and tenuity of the air, prevented philosophers and military engineers from availing themselves of this important part of Galileo's work. They anticipated no great variation from the theory, and accordingly we find it to have been, for a long time, the received opinion, that all projectiles moved in a parabolic curve.

Experiments of Anderson.

This erroneous opinion was stoutly maintained by our countryman Anderson, in his treatise *Of the Genuine use and effects of the Gun*, published in 1674. This work is founded on the Galilean theory; and its author boldly undertakes to overturn all objections that can be urged against the parabolic motion of projectiles.

Of Blondel.

A similar notion is maintained by M. Blondel, in his *L'Art de jetter les bombes*, which appeared at Paris in 1683. He applies the doctrines of Galileo to the flight of shells and bullets of every kind; and after a long discussion relative to the air's resistance, he concludes that it is too minute to affect the accuracy of his deductions.

Experiments of Halley.

The celebrated Dr Halley held the same false opinion. He was, however, not merely misled by a belief in the extreme tenuity of the air; but he was confirmed in his errors by some very imperfect experiments. After treating of the motion of projectiles, (See *Phil. Trans.* 1685, No. 179. p. 3.) he observes, that "these rules would be rigidly true, were it not for the resistance of the medium, by which not only the direct impressed motion is continually retarded, but likewise the increase of the velocity of the fall, so that the spaces described thence are not exactly as the squares of the times; but what this resistance of the air is, against several velocities, bulks, and weights, is not so easy to determine. It is certain that the weight of air to that of water is nearly as 1 to 800; whence its weight to that of any project is given. It is very likely, that to the same velocity and magnitude, but of different matter, the resistance will be reciprocally as the weights of the shot; as also, that to shot of the same velocity and matter, but of different sizes, it should be as the diameters reciprocally; whence, generally, the resistance to shot with the same velocity, but of different diameters and materials, should be as their specific gravities into their diameters reciprocally; but whether the opposition to different velocities of the same shot be as the squares of those velocities, or as the velocities themselves, or otherwise, is yet a more difficult question. However it be, it is certain that in large shot of metal, whose weight many thousand times surpasses that of the air, and whose force is very great in proportion to the surface, this resistance is scarcely discernible; for by several experiments made with all care and circumspection, with a mortar-piece, extraordinarily well fixed to the earth on purpose, which carried a solid brass shot of 4½ inches diameter, and of about 14 lb. weight, the ranges above and below 45 degrees were found nearly equal; if there were any difference, the under ranges went rather the farthest; but those differences were usually less than the errors committed in ordinary practice, by the unequal goodness and dryness of the same sort of powder, by the unfitness of the shot to the bore, and by the looseness of the carriage.

In a smaller brass shot, of about 1½ inch diameter, cast by a cross-bow, which ranged it at most about 400 feet, the force being much more equal than in the mortar-piece, this difference was found more curiously and constantly, and most evidently the under ranges exceeded the upper. From which trials I conclude, that although, in small and light shot, the opposition of the air ought and must be accounted for; yet in shooting of great and weighty bombs, there need be very little or no allowance made; so that these rules may be put in practice, to all intents and purposes, as if this impediment were absolutely removed."

Subsequent experiments by Anderson.

Although the opinion which we have been considering was entertained chiefly by speculative writers, yet those who made extensive experiments on the motion of projected bodies, began to suspect some lurking error. Anderson, whom we have already mentioned, as a keen abettor of the parabolic theory, had occasion to make a number of new experiments on the ranges of shells discharged with small velocities, which he published in 1690, in his treatise entitled, *To hit a mark.* He found that the track of shells and bullets was much less incurvated in the first part of their path than they ought to be, on the Galilean theory; but instead of supposing the theory practically incorrect, or conjecturing that the deviations were produced by the resistance of the air, he imagined that the shell or bullet was discharged from the gun to a certain distance in a right line, and that gravity only began to deflect it into a parabolic curve at the end of this line, which he calls the *line of the impulse of the fire*, and which he supposes to be the same at all elevations. By giving a proper magnitude to this imaginary line, he was always able to reconcile the ranges of any two shells projected at different elevations; though, as Mr Robins remarks, he would have found it impossible to reconcile the irregularities of three or more ranges.

Newton on the resistance of the air.

So deeply rooted was the erroneous notion that the air offered only an unappreciable resistance to moving balls, that the publication of Sir Isaac Newton's *Principia*, in which the resistance of the air in slow motions is ascertained and confirmed by experiment, was not able to correct it. By extending the law for slow motions to those in which the velocity was very great, it was obvious that the resistance opposed to cannon balls

History.

Newton on the resistance of the air.

was too great to be overlooked; though it did not amount, by the calculation, to that enormous degree which was afterwards deduced from direct experiment. Newton has not attempted to investigate, in a direct manner, the path which a body will describe when projected into the atmosphere with a given velocity, and in a given direction. He shews, however, the particular state of density in the air, which will agree with the motion of a body in any curve whatever; and, by the application of the principle to curves, which have some resemblance to the path of a projectile, he finds it differing little from what may be considered as the path of a body projected in our atmosphere. In the second edition of the *Principia*, which appeared in 1713, he corrects some of the oversights into which he had formerly been led; and he shews that a projectile, moving in a medium, whose density varies according to certain laws, and acted upon by a force directed to the centre of the earth, will describe an eccentric spiral, whose properties he describes.

Bernoulli's investigations.

The complete solution of this problem was not obtained till Dr Keill challenged John Bernoulli to determine the curve described by a body projected through a medium resisting as the square of the velocity. The Swiss geometer very soon gave a much more general solution than was demanded, independent of any limitation of the law of resistance, of the law of gravity, or of the law of density, provided that they were capable of being expressed algebraically. Dr Brook Taylor gave a solution of the problem in its limited form.

Labours of Huygens.

In the year 1690, the celebrated Huygens published a treatise on Gravity, in which he endeavoured to prove, from a series of experiments, that projectiles discharged through the air with great velocity, described paths very different from a parabola. The inconsistency of the Galilean theory, with the practice of artillery, was now particularly noticed by M. Ressons, a French artillery officer, who drew up a memoir on the subject, and presented it to the Academy of Sciences. * In this memoir, which was entitled *Methode pour tirer les bombes avec succes*, he attempts to shew that the theory is of very little service in the use of mortars, and that the theoretical path of projectiles is justly described in the works of Blondel; yet by directing mortars according to that theory, he could never obtain results that had the slightest agreement with it.

Experiments at Woolwich in 1736.

In the year 1736, a series of experiments was made at Woolwich, in order to determine the length of cannon that could enable them to shoot most efficaciously. These experiments were made with six 24 pounders, cast on purpose, and of the same weight, but varying in length from 8 feet to 10½ feet. These pieces were all loaded alike, with allotments of powder equal to half the weight of the bullet; and five shot were fired from each, at an elevation of 7¼°. The following are the results which were obtained:

Length of Pieces.	June 1st. Medium of Five Ranges.	June 18th. Medium of Three Ranges.	July 2d. Medium of Three Ranges.
Feet.	Yards.	Yards.	Yards.
10½	2486	2614	2406
10	2570	2532	2436
9½	2633	2560	2500
9	2790	2494	2563
8½	2586	2490	2466
8	2438	2473	2452

From the average range of these five shot, the effects of the different lengths were supposed to be deducible. The result of the experiments was, that the pieces of 9 and 9½ feet had the greatest range. Mr Robins has, however, shewn that these experiments are by no means inconsistent with his opinion, that the largest pieces ought to have the greatest range. The ranges with the 9 and 9½ feet guns ought not to differ more than 35 yards from the ranges of the 8 and the 10½ feet guns, according to his theory; and yet with two subsequent trials with the 9 feet gun, the ranges differ no less than 650 yards; and the average ranges made in these successive days differ from each other 300 yards. Hence it is obvious that these experiments differ so much from each other, that they are not sufficient to decide the point for which they were undertaken.

Experiments of the Royal Society of London.

No step of importance seems to have been made in gunnery till the year 1742, when Dr Jurin proposed some questions, which the Royal Society appointed a committee to investigate. The first of these questions was, Whether all the powder of the charge be fired? 2*d*, Whether all the powder that is fired, be fired before the bullet is sensibly moved from its place? And, 3*dly*, Whether the distance to which the bullet is thrown may not become greater or less by changing the form of the chamber, though the charge of powder and all other circumstances remain unchanged? The committee, after numerous experiments, found that all the powder was not fired; that the bullet was sensibly moved from its place, before all the powder that was fired had taken fire; and that a change in the form of the chamber would produce a change in the distance to which the bullet is thrown; the largest chamber of equal capacity always driving the ball farthest. † The committee, however, seem to have made some mistake; for Mr Robins afterwards proved, that the ball has not sensibly changed its place when the powder is fired.

Several experiments were about this time made in France on the ranges of cannon. M. St Remy has given us an account of a series made with pieces of cannon 10 feet in length, of the usual calibre, and elevated at an angle of 45°. The following were his results, the quantity of powder being two-thirds of the weight of the bullet.

	Range in Yards.		Range in Yards.
24 Pounder . . .	4490	8 Pounder . . .	3320
16 Ditto	4040	4 Ditto	3040
12 Ditto	3740		

Pieces of the same calibre as the preceding, but somewhat shorter, had almost the same ranges when fired with only one-half the former charge, or one-third of the weight of the ball in powder. See Remy's *Memoirs of Artillery*, vol. i. p. 69.

Experiments at La Fere by Borda in 1739.

Another series of experiments was made at La Fere, in the year 1739, under the direction of the Chevalier de Borda. They were made with the usual pieces of all the preceding calibres, and were charged with various quantities of powder, and elevated to 4°, to 15°, and to 45°. Experiments were also made with a 24 pounder, at different elevations, from 4° to 45°, and the following results were obtained with a charge of nine libs of powder.

Angle of Elevation.	Actual Range. Yards.	Angle of Elevation.	Actual Range. Yards.
40 . . .	. . . 4100	20 . . .	. . . 3480
35 . . .	. . . 4040	15 . . .	. . . 3350
30 . . .	. . . 3820	4 . . .	. . . 1640
25 . . .	. . . 3650

Experiments at Metz in 1740.

In the year 1740, a series of experiments were made at Metz with great care and attention. In the experiments of La Fere, the medium ranges only were given, but at Metz the result of each trial was set down. The piece which was used was a 24 pounder, 10 feet long. It was charged with different quantities of powder, from 8 to 20 lb. It had always an elevation of 4°; but as it was placed about 78 feet above the plain where the bullets fell, the elevation should be considered as 5°. The following are the results.

Pounds of Powder.	Ranges in Yards.	Pounds of Powder.	Ranges in Yards

Investigations of Benjamin Robins.

Hitherto no general principle had been established by the numerous experiments of which we have given a short account; but the subject of gunnery was now destined to receive the most important improvements from the labours of Mr Benjamin Robins, who published an account of them in 1742, in his *New Principles of Gunnery, containing the determination of the force of Gunpowder, and the investigation of the differences in the resisting power of the air to swift and slow motions.* In this valuable work, he begins by determining the explosive force of gunpowder, (see our article GUNPOWDER, p. 586.) and he found that this force was owing to an elastic fluid like air which existed in a highly condensed state in the powder, and being suddenly separated from it by combustion, expanded and impelled the bullet with prodigious force.

Mr Robins then proceeds to determine the velocity with which gunpowder will impel a shot of a given weight from a cannon of given dimensions; and in order to compare the velocities thus computed with the real velocities, he invented an instrument called the Ballistic Pendulum, by which he was enabled to measure the real velocities of bullets of all kinds with such accuracy, that in the case of a bullet moving with a velocity of 1700 feet per second, the error will never amount to $\frac{1}{150}$th part of the whole.

With this machine he made a great number of experiments, with musket barrels of different lengths, charged with different quantities of powder, and carrying balls of different weights; and the agreement between the calculated and observed velocities is so surprising as to establish his theory on the firmest foundation.

Mr Robins proceeds to point out the changes which take place in the force of gunpowder, from variations in the heat and moisture of the atmosphere: He determines the velocity which the flame of gunpowder acquires by expanding itself, to be 7000 feet per second: He ascertains the manner in which the flame of the powder impels a ball, placed at a considerable distance from the charge; and he enumerates the various kinds of powder, and describes the best methods of examining its goodness.

Mr Robins then treats of the resistance of the air, and of the track described by the flight of shot and shells. He shews, from experiments made with the ballistic pendulum, that at different velocities there was a gradual increase of the resistance over the law of the square of the velocity, as the body moved quicker. He then proves, that a 24 pound ball fired with a full charge of powder, experiences, when it first issues from the piece, a resistance more than 20 times its weight; that the paths of projectiles, when the velocity of projection is considerable, is not nearly a parabola; and that, in their flight, bullets are not only depressed beneath their original direction by the action of gravity, but are frequently deflected to the right or left of that direction by the action of some other force. Robins' *Principles of Gunnery* was translated into German by Euler, who honoured it with learned and valuable commentaries.

Labours of the Chevalier D'Arcy.

About eight or ten years after the publication of Robins' Works, the Chevalier D'Arcy published, in the Memoirs of the Academy for 1751, a Treatise on the Theory of Artillery, in which he gives an account of a series of experiments made with great care. He employed two pendulums, against one of which he fired the ball, while the other, from which the small cannon was suspended, served to measure the recoil. These experiments were afterwards extended, and published in his *Essais d'une Theorie de l'Artillerie*, which appeared in 1760.

Experiments at Turin in 1746.

In the year 1746, between the 7th February and the 30th of March, a series of experiments were made by the officers of artillery at Turin, for the pupose of determining the charges of powder that give the largest ranges. The guns were mounted on a part of the fortifications of the city, where the axis of the piece was 30 feet higher than the level of the country where the

History.

Experiments at Turin in 1746.

shot fell. The guns were fired with their axes always horizontal. The smallest charges were at first used, and increased gradually till the ranges began to diminish. The following Table shows the results of the experiments:

Nature of Guns.	Length of Bore.	Weight.	Weight of Powder.	Range.	Recoil.
	Calibres.	Cwt. qr. lb.	lb. oz.	Yards.	Inches.
4	27	9 1 9	1 4	478	43
			1 10	489	62
			2 1	472	72
8	27	18 2 10	2 7	512	45
			3 5	532	64
			4 2	532	82
16	23	31 3 26	3 5	505	42
			4 6	526	55
			4 15	522	78
32	20	57 2 17	6 9	485	54
			8 12	492	71
			9 13	489	82

From these results it follows, that the charge of powder which gives the longest range is equal to half the weight of the shot in four and eight pounders, and to one-third of its weight in 16 and 32 pounders. The recoil always increases in proportion to the augmentation of the charge. The length of the range increases to a certain point, and afterwards decreases in a much less ratio than the recoil increases. The charge which gives the longest range in pieces of small calibre, is proportionally longer than in pieces of large calibre.

Experiments at Turin in 1750.

In the spring of 1750, the Chevalier Ferrero di Ponsiglione made a series of experiments with pieces of the same calibre and proportions at Turin, for the purpose of ascertaining the charge that gives the longest range when the piece is fired at the greatest elevation its carriage will admit of. The ranges were measured on a flat piece of ground, nearly on the same level with the battery. The shot being rather larger, the windage was less than in the experiments of 1746.

Nature of Guns.		Weight of Powder.	Length of Range.	Recoil.
Pounders.	Elevation.	lb. oz.	Yards.	Inches.
4	14°	2 1	2375	52
		2 8	2219	60
		2 14	2422	70
		3 5	2526	76
8	11°	3 5	2321	46
		4 2	2463	65
		4 15	2486	85
		5 12	2375	102
		6 9	2675	119
16	12°	5 12	2659	71
		6 9	2860	76
		7 3	2663	90
		8 3	2810	97
		9 0	2764	108
		9 13	2892	113
32	11½°	11 8	3172	117
		13 2	3032	120
		14 6	2995	124
		16 6	3220	146
		18 0	3084	168

From these experiments it follows, that the charges that give the longest ranges when cannon are fired from the greatest elevations their carriages will permit, are greater than those which produce the same effect when they are fired horizontally. Several experiments which were some time afterwards made in France, shewed, that in cannon of a large calibre, the charge should be about three-eighths of the weight of a shot. In the month of August 1747, Signior Marandone made a series of experiments for the same purpose, by orders of the Knights of Malta. From these he concluded, that the charge that ought to produce the longest range, must exceed three-eighths of the weight of the shot.

Marandone's experiments.

Signior Mattei, mathematical instrument maker to the King of Sardinia, invented a machine for finding the initial velocity of balls measured near the mouth of the gun; and a number of valuable experiments were made with it by Antoni, of which we shall afterwards give a more particular account. Mattei's machine consists of a horizontal circle, supported by its centre on the upper end of a vertical axis, and serving as a base to a hollow paper drum. This drum is made to revolve by means of a weight at the end of a cord passing over a pulley; and the projectile, thrown in a horizontal direction, traverses the paper drum in two points. The arc described by the system, while the projectile, in traversing the interior of the drum, is measured by the distance of the second point from the diameter which passes through the first. See the Description of Plates, and p. 577.

Mattei's machine for measuring initial velocities. PLATE CCLXVI. Fig. 5.

Another very simple machine for the same purpose, was invented in 1764, by Lieutenant De Butet. "He applies a little plate of metal, provided with a moveable index, to any wheel that turns with an equable motion and sufficient velocity; the index is held at some distance from the circumference of the wheel, by a thread that is stretched across the mouth of the gun. When the gun is fired, the shot breaks the thread and sets at liberty a spring, which instantly presses the index against the wheel, upon which it describes an arch, till it is checked by the impact of the shot against a moveable butt placed at the distance of a few feet: to this effect, one extremity of a rod is fastened to the butt, and the other to the plate; thus the index is drawn back by the rod which follows the movement of the butt, and ceases to describe the arch on the circumference of the wheel. The motion of the wheel, the distance from the muzzle of the gun to the butt, and the arch described by the index being known, it is easy to ascertain the space that the shot passes through in one second of time with an uniform velocity; or, in other words, its initial velocity. To diminish the friction as much as possible, a small groove is made in the part of the wheel that receives the index, and filled with grease, which presents a very slight resistance. By means of this instrument, the time of the shot's passage along the bore of the gun, the initial velocity of shells, and the resistance of the air to their motion, may be determined; if allowance be made for the modifications that must ensue."

De Butet's machine for measuring initial velocities.

In the year 1779, the learned Dr Hutton of Woolwich, in conjunction with several officers of artillery, undertook a series of experiments on the motion of cannon balls. They used ballistic pendulums from 300 to nearly 600 pounds weight, and they employed cannon shot of 1, 2, and 3 pounds weight, and they varied the charge of powder from 2 to 8 ounces. From these experiments, of which a full account was published in the *Philosophical Transactions* for 1778, Dr Hutton deduced the following inferences.

Hutton's experiments at Woolwich in 177[illegible]

History.

...ts of ...utton's ...pi- ...in ...

1. That gunpowder fires almost instantaneously. 2. That the velocities communicated to balls or shot of the same weight by different quantities of powder, are nearly in the subduplicate ratio of those quantities: a small variation in defect taking place when the quantities of powder become great. 3. And when shot of different weights are employed, with the same quantity of powder, the velocities communicated to them are nearly in the reciprocal subduplicate ratio of their weights. 4. So that, universally, shot which are of different weights, and impelled by the firing of different quantities of powder, acquire velocities which are directly as the square roots of the quantities of powder, and inversely as the square roots of the weights of the shot, nearly. 5. It would therefore be a great improvement in artillery to make use of shot of a long form, or of heavier matter; for thus the momentum of a shot, when fired with the same weight of powder, would be increased in the ratio of the square root of the weight of the shot. 6. It would also be an improvement to diminish the windage; for by so doing, one third or more of the quantity of powder might be saved. 7. When the improvements mentioned in the last two articles are considered as both taking place, it is evident that about half the quantity of powder might be saved, which is a very considerable object. But important as this saving may be, it seems to be still exceeded by that of the article of the guns; for thus a small gun may be made to have the effect and execution of another of two or three times its size in the present mode, by discharging a shot of two or three times the weight of its natural ball or round shot: And thus a small ship might discharge shot as heavy as those of the greatest now made use of.

...t Rum- ...expe- ...ts in ...

In the year 1781, Count Rumford instituted a series of experiments with musket barrels. The machinery which he used was ingeniously contrived and well executed, and his object was to determine the initial velocity of bullets, the recoil of the barrel, the effect of firing the charge in different parts of it, and the most advantageous situation for the vent. The following were the principal results which he obtained. He found that when the weights and dimensions of the bullets are the same, their velocities, when discharged from the same piece, are in the subduplicate ratio of the weight of the charges; and he concludes, from numerous experiments, that the vent may be placed in any part of the chamber where it will best answer on other accounts. Hence Count Rumford recommends that the bottom of the bore should be of a hemispherical form; that the vent should be brought directly through the side of the barrel in a line perpendicular to its axis, and pointing to the centre of the hemispherical concavity of the chamber.

In these experiments, the ballistic pendulum of Robins was employed; but in consequence of a suggestion contained in Robins's new principles of gunnery, Count Rumford proposed, and put in practice, another method of determining the velocities of bullets, by suspending the gun in a horizontal position by two pendulous rods, and determining the velocity of its recoil from the arc of its ascent, measured by a ribbon, as in the ballistic pendulum. The velocity of the bullet will be $v = \frac{V - U}{B} \times W$; where W is the weight of the gun, V the velocity of its recoil when fired without a bullet; V the velocity of the recoil when the same charge impels a bullet, B the weight of the bullet, and v its velocity. By comparing the results obtained in this way, with others obtained from the ballistic pendulum, Count Rumford found, that in several cases they agreed, but that in others the differences were so great, that the new method ought not in general to be relied upon.

Dr Hutton's second set of experiments from 1783 to 1791.

Another very extensive set of experiments was undertaken in the year 1783, under the direction of Major Bloomfield, and by the orders of the Duke of Richmond, Master-General of the Ordnance. They were carried on in the summers of 1783, 1784, 1785, 1787, 1788, 1789, 1791, &c. principally with a view to the following objects:

1. To determine the velocity of balls impelled by equal charges, from pieces of different lengths, but of the same weight and calibre.

2. To determine their velocities with different charges, when the weight and length of the gun are the same.

3. To determine the greatest velocity due to different lengths, by making the charge as great as the gun will bear.

4. To determine the effect of varying the weight of the gun, every thing else remaining the same.

5. To determine the penetration of balls into blocks of wood.

6. To determine the ranges and times of flight, and the velocities of balls, by striking the ballistic pendulum at various distances, and to compare them with their initial velocities, in order to ascertain the air's resistance.

7. To determine the effect of wads; of different degrees of ramming; of different degrees of windage, and of different positions of the vent; of chambers and trunnions, and every other circumstance necessary to be known for the improvement of artillery.

These experiments were carried on with great success, excepting in the subject of ranges, which were less regular and uniform than could have been wished. The ballistic pendulum was from 600 to 800 pounds weight. The balls were generally one pound weight, and the powder was increased from one ounce till the bore was quite full.

The following are the general results, as given by Dr Hutton:

General results deduced by Dr Hutton.

"1. That the velocity is directly as the square root of the weight of powder, as far as to about the charge of eight ounces; and so it would continue for all charges, were the guns of an indefinite length. But as the length of the charge is increased, and bears a more considerable proportion to the length of the bore, the velocity falls the more short of that proportion.

2. That the velocity of the ball increases with the charge to a certain point, which is peculiar to each gun where it is greatest; and that, by further increasing the charge, the velocity gradually diminishes till the bore is quite full of powder. That this charge, for the greatest velocity, is greater as the gun is longer, but not greater, however, in so high a proportion as the length of the gun is; so that the part of the bore filled with powder bears a less proportion to the whole in the long guns than it does in the short ones; the part of the whole which is filled being indeed nearly in the reciprocal subduplicate ratio of the length of the empty part. And the other circumstances are as in this Table.

Table of Charges producing the greatest Velocity.

Gun.	Length of the Bore.	Length filled.	Part of the whole.	Weight of the Powder.
Number	Inches.	Inches.		Ounces.
1	28.2	8.2	[illegible]	12
2	38.1	9.5	[illegible]	14
3	57.4	10.7	[illegible]	16
4	79.9	12.1	[illegible]	18

History.

General results deduced by Dr Hutton.

3. It appears that the velocity continually increases as the gun is longer, though the increase in velocity is but very small in respect of the increase in length, the velocities being in a ratio somewhat less than that of the square roots of the length of the bore, but somewhat greater than that of the cube roots of the length, and is indeed nearly in the middle ratio between the two.

4. The range increases in a much less ratio than the velocity, and indeed is nearly as the square root of the velocity, the gun and elevation being the same. And when this is compared with the property of the velocity and length of gun in the foregoing paragraph, we perceive that very little is gained in the range by a great increase in the length of the gun, the charge being the same.

And, indeed, the range is nearly as the 5th root of the length of the bore, which is so small an increase, as to amount only to about one-seventh part more range for a double length of gun.

5. It appears also that the time of the ball's flight is nearly as the range; the gun and the elevation being the same.

6. It appears that there is no sensible difference caused in the velocity or range, by varying the weight of the gun, nor by the use of wads, nor by different degrees of ramming, nor by firing the charge of powder in different parts of it.

7. But a great difference in the velocity arises from a small degree of windage. Indeed, with the usual established windage only, namely, about 1-20th of the calibre, no less than between 1-3d and 1-4th of the powder escapes and is lost. And as the balls are often smaller than that size, it frequently happens that half the powder is lost by unnecessary windage.

8. It appears that the resisting force of wood to balls fired into it, is not constant. And that the depths penetrated by different velocities or charges are nearly as the logarithms of the charges, instead of being as the charges themselves, or, which is the same thing, as the square of the velocity.

9. These, and most other experiments, shew, that balls are greatly deflected from the direction they are projected in, and that so much as 300 or 400 yards in a range of a mile, or almost 1-4th of the range, which is nearly a deflection of an angle of 15°.

10. Finally, these experiments furnish us with the following data to a tolerable degree of accuracy, viz. the dimensions and elevation of the gun, the weight and dimensions of the powder and shot, with the range and time of flight, and the first velocity of the ball.

The experiments made by Dr Hutton in the years 1787, 1788, 1789, and 1791, were principally intended to ascertain the resistance of the air to military projectiles. Balls of 2 inches, 2.78 inches, and 3.55 inches in diameter, were employed, to determine the resistance of very high velocities. They were discharged with velocities from 300 to 2000 feet per second, and were made to strike the pendulum at several different distances from the guns. In all these experiments, the resistances varied nearly as the $2\frac{1}{10}$th power of the velocity, the exponent being 2.028 for a velocity of 200 feet per second, and increasing gradually to 2.136, which it reached when the velocity was 2000 feet per second.

Grobert's apparatus for measuring the initial velocity of projectiles.

In the year 1804, a new machine for measuring the initial velocity of projectiles was proposed and used by Col. Grobert; and a very favourable report of its accuracy was made to the National Institute of France, by Messrs Bossut and Monge. The apparatus consists of a horizontal revolving axis about 34 decimetres long, having at each of its extremities a circle or disc of pasteboard placed perpendicular to the axis. A rotatory motion is communicated to the axes, and consequently to the discs, by means of a weight suspended at the extremity of a rope, which, passing over a pulley 10 or 12 yards above the ground, coils itself about the arbor of a wheel and axle fixed at the same level as the discs. The motion given to the wheel and axle by the descent of the weight is communicated to the axis of the discs by an endless chain passing round the wheel and axle, and also round a pulley on the axis of the discs. The instrument being thus constructed, let us suppose that a ball traverses the two discs when in motion, in a direction parallel to their axes. It is obvious that the hole in each disc will not coincide with one another, and that the angular motion which the second disc has made while the ball was passing between them will be a measure from which the velocity of the ball can be computed. Hence it is necessary to impress upon the discs an uniform and known velocity, and to measure accurately the arch passed over by the second disc during the transit of the ball from the one to the other. In the experiments which were made with this machine, the motion became sensibly uniform when the weight had arrived nearly at the half of the vertical space which it traversed. The following is the formula for calculating the velocity of the ball.

$$V = \frac{2\pi n}{kt} \cdot \frac{r}{a} b, \text{ or}$$

$$V = \frac{6.282\,n}{kt} \cdot \frac{r}{a} b, \text{ in which}$$

V = the velocity of the ball between the discs, considered as uniform;

π = 3.141, the ratio of the circumference to the diameter of a circle;

k = the ratio between the respective numbers of the turns made at the same time by the wheel of the axle, and the pulley of the axis of the discs, which in the following experiments was $\frac{1}{7.875}$;

t = the time employed by the wheel of the axle to make n number of turns;

r = the distance of the hole made by the ball in the second disc from the axis of the discs;

a = the arc passed over by that hole while the disc goes from the one to the other;

b = the distance between the two discs.

The following experiments were made with a horse musketoon, 0.765 metres of interior length. The weight of the ball was 24.7 grammes, and it was projected with half its weight of powder. The mean velocity deduced from these experiments is 390.47; whereas the mean velocity found from experiments with the common infantry musket, 1.137 metre of interior length, was 428, exceeding the former in the ratio of 11 to 10. All the values of a are referred to that of r = 1 metre.

In order to afford the means of traversing the discs by throwing balls in different directions from 0° to 45°, Colonel Grobert gives to each disc a particular horizontal axis, to which a pulley is affixed; and the rotatory motion is communicated by an endless chain to both axes, so that they may perform the same number of revolutions in the same period. The supporter of the second disc is capable of rising vertically, and fixing itself at different heights. The adjustment of this apparatus must, however, be attended with great difficulty.

CHAP. I.

On the Parabolic Theory of Gunnery. *

abolic
l ory of
Cinery.

In the process of our examination of the motions in the solar system, it appears that terrestrial gravity, or the heaviness of common sublunary bodies, is only a particular case of the mutual tendency of all matter towards all matter. It further appears, that a body on the surface of our globe gravitates in a line that is directed very nearly to the centre of the earth; and that the intensity of this gravitation is inversely proportional to the square of its distance from this centre.

Bodies let fall, or projected in any direction on the surface of this earth, move under the influence of this force; and their motions may be computed from the general doctrines of dynamics in the same manner as we computed the motions of the planets. They will either fall in the direction of gravity, or will rise in the opposite direction, or will describe a curve line concave toward the earth, which will be an ellipsis, parabola, hyperbola, or circle, according as the velocity and direction of the projection may have been combined.

But, in the greatest projections that we can make, the force of gravity is so nearly the same in every point of the path, that we may suppose it to be accurately so, without any sensible error, were it ten times greater than it is. Therefore in all disquisitions about projectiles, it would be useless affectation to embarrass ourselves with the variations. None of our projectiles rise a mile in the air, which is about $\frac{1}{3960}$ of the mean radius of the earth, and will occasion a diminution of gravity nearly equal to $\frac{1}{1980}$, a quantity altogether insignificant.

For the same reasons, although the directions of gravity in the different points of the projectile's flight, are lines converging nearly to the centre of the earth, we may consider them as all parallel, because none of our projectiles fly four miles, which produces a convergency of nearly four minutes, a deviation from parallelism which needs not be regarded.

Parabolic Theory of Gunnery.

In general, therefore, we may consider all such projectiles as under the influence of equal gravity acting in lines parallel to the vertical or plumb-line drawn through the place of projection. This reduces the theory of projectiles to a great degree of simplicity.

Accordingly, this is the first department of mechanical philosophy which first received improvement by the application of mathematical knowledge. We are indebted for this fortunate introduction of mathematics into the doctrines of motion, to the celebrated Florentine, Galileo Galilei. This excellent philosopher read his discourses on local motion, about the beginning of the 17th century. Those lectures contain the whole of this doctrine, nearly in the state in which it continued till about the middle of last century. There is no branch of natural philosophy that has met with so much assistance and encouragement, it having been considered in all nations as the foundation of the art of gunnery; an art unfortunately too much connected with the security of every nation. It has therefore been patronised by princes and magistrates—most costly establishments have been made for its cultivation; the mathematicians have occupied themselves with its problems, and more numerous and expensive volumes have been published on this than on any other part of mechanical philosophy. Yet there is none in which so little improvement has been made. Galileo's lessons contain every thing that has been done in a scientific way, till M. Robins, in 1742, gave it a form altogether new.

We shall first consider the perpendicular ascents and descents of heavy bodies; and in the next place, their curvilineal motion when projected in directions deviating from the vertical.

The motion of a falling body is uniformly accelerated, and that of a body thrown straight upward is uniformly retarded.

For the accelerating or retarding force is constant, and therefore the motions are such as were considered in Dynamics.

All the characteristic phenomena of these motions having already been sufficiently considered, all that is wanted for the application to this class of mechanical phenomena, is merely one experimental determination of the accelerative power of gravity, that is, the velocity, or increment of velocity, which gravity will generate in a body by acting on it uniformly during some given time. Galileo, who first demonstrated that an invariable gravity must produce a uniformly accelerated motion, was also among the first who appealed to experiment in all inquiries. We now think lightly of this, and wonder that a man shall think of another argument who has this in his power. But when Galileo began to communicate his knowledge to the world, this was the last support that a philosopher would think of. They had received a parcel of topics from their master, which had been handed down in the schools during many ages; and from these was every thing accounted

* This valuable Chapter was written by the late John Robison, LL. D. F. R. S. E. It was intended to form a part of his *System of Mechanical Philosophy*, and was the last production of that eminent philosopher. It is now published for the first time, with the permission of Mr Murray the proprietor of the MSS. and will appear in the first volume of his *System of Mechanical Philosophy*, now in the press.

for or explained. Aristotle, or his immediate pupils, had said that the velocities of falling bodies increased with their weights; Galileo's doctrine was incompatible with this, and he thought himself obliged to use arguments in his support. He said that if Aristotle's doctrine be true, two crown pieces must fall faster when sticking together than when unconnected, which, said he, is contrary to common experience. Not doubting that he had convinced his audience, he described the experiments which he was to exhibit next day, shewing that in a double time a body would fall four times as far, &c. The experiments were performed in the dome of the great church, before a vast concourse of people, and succeeded most perfectly. Yet so little were the philosophers moved by this kind of argument, that they represented Galileo as a dangerous person, unfriendly to the state; and he was obliged to leave his native city in a few days, and take shelter in Padua. It is very remarkable, that Baliani, one of the first geometers and mathematicians of that age, and who perfectly understood Galileo's speculations on this subject, should teach another doctrine, reviving or supporting an old scholastic assertion, that the velocity of a falling body might be as the space fallen through, calling this motion also a uniformly accelerated motion.

Galileo found more difficulty than one should expect in his endeavours to obtain an exact measure of the power of gravity; and indeed could not obtain one that was satisfactory. But the difficulty of the task, and his struggle to accomplish it, were big with advantages to science. A body falls so fast, that a considerable error in the conclusion arises from a very small error in estimating the time; and the great difficulty was how to estimate the time. It was in this casting about for a measure of a small portion of time that Galileo first thought of the pendulum. His penetrating and sagacious mind enabled him to see that there must be a fixed proportion between the time of a vibration and that of falling through its length, although his mathematical knowledge did not yet enable him to find it out; he saw an immediate consequence of this if true, namely, that the vibrations of two pendulums should be in the subduplicate ratio of the lengths, because this must be the proportions of the times of falling through those lengths. This he would try; and he found that it was so. Delighted with this success, he immediately compared the time of falling from the top of the great dome with that of a pendulous vibration, by making a pendulum of such a length that it performed precisely one vibration in the time of the fall. In this time, the body, moving with the final velocity, would describe a space double of that fallen through. He then counted with patience the number of vibrations made by his pendulum in an interval of time, measured by the transit of two stars. Thus he obtained the time, and the velocity generated in that time by the uniform action of gravity. Galileo made this to be about 31 feet of our measure in a second, and said that it was certainly somewhat more; because his experiments on falling bodies convinced him that their motion is retarded by the air.

These efforts and resources of an ingenious mind are worthy of record, and are instructive to others. But Galileo did not attain the accuracy in this measure that we now possess. The honour of the accurate statement of the time of a pendulous oscillation, and that of the fall through its length, was reserved for Mr Huygens. This proportion was determined by him by a most ingenious and elegant physico-mathematical process. He also gave us the pendulum clock, by which time can be measured with as much accuracy as a line can be divided.

Aided by these inventions, we have now obtained the most precise measure of the accelerating powers of gravity; and we can now say that its intensity is such in the latitude of London, that by acting uniformly on a body for one second of time, it generates in it the velocity of 32 feet two inches per second, and a heavy body falls 16 feet one inch in that time.

These are standard numbers, of continual use in all mechanical discussions, and should be carefully kept in remembrance. Not only so, but we should acquire distinct notions of them in this respect, viz. as standard numbers. Gravity is known to us in two ways; our most familiar acquaintance with it is as a pressure, which we feel when we carry a heavy body. With this we can compare the pressure of a spring, the exertion of an animal, the pressure of a stream of water or wind, the intensity of an attraction, &c. by setting them in opposition and equilibrium. The philosopher, and especially the physical astronomer, and cultivator of the Newtonian philosophy, is well acquainted with gravity as an accelerating and a moving force, capable of accelerating, retarding, or deflecting the body in which it inheres, or on whose intimate particles it acts without intermedium. He can compare the gravity of a stone with that of the moon, or of Jupiter, or with the force that produces the precession of the equinoxes. The general mechanician, observing that all other pressures, such as that of a spring, of an animal, &c. are also moving forces, by combining those two aspects of gravity, makes a most important use of it by comparing other forces with weights, and thence inferring the motions which those forces will produce. Thus, knowing that an arrow $\frac{7}{8}$ oz. weight, by falling 18 inches acquires the velocity of $10\frac{1}{2}$ feet per second, he infers, that when drawn to the head by a bow of 62 pounds, it will be discharged with the velocity of 233 feet per second.

We shall therefore, in future, compare every force with gravity, and express the accelerative power of this standard by 32, meaning that by acting on every particle of a body for a second, it will generate the velocity of 32 feet per second, and cause the body to describe 16 feet with a motion uniformly accelerated. We may find it convenient, on some occasions, to use the numbers 386, and 193, which are the inches in $32\frac{2}{12}$ and $16\frac{1}{12}$ feet.

The questions that interest us at present are those concerning the relations between the time t of any fall, the height h of that fall, and the velocity v that is uniformly acquired in falling; so that when any one of those things is given, the others may be found out.

I. Since the variations of velocity are proportional to the times in which they are produced, we have

$$1' : t'' = 32 : 32\,t''$$
$$\text{and } v' = 32\,t''$$
$$\text{and } t'' = \frac{v'}{32}.$$

N.B. The time t is always supposed to be a number of seconds, and the height h a number of feet, and the velocity v a number of feet uniformly moved over in one second.

A falling body, therefore, acquires an increment of 32 feet per second in every second of its fall, and an ascending body has its velocity lessened as much during every second of its rise. A body *falling* during four seconds, acquires the velocity of 128 feet per second.

But if the body has been projected downward, with the velocity of 100 feet per second, then, at the end of 4″, it is moving at the rate of 228 feet per second.

A body projected straight upwards with the velocity of 160 feet per second, will at the end of the first second of its rise, have the velocity 128. At the end of 2″ it will be moving at the rate of 96 feet per second. Its velocity at the end of the third second will be 64. At the end of the fourth second it will be 32, and at the end of five seconds it will stop, and begin to fall.

The times of the rise and the subsequent fall are equal.

II. Since the heights are as the squares of the times of the fall or ascent, we have

$$1'' : t^2 = 16 : 16\,t^2$$
$$\text{and } h = 16\,t^2 \text{ and } \sqrt{h} = 4\,t.$$
$$\text{also } t^2 = \frac{h}{16}, \text{ and } t = \frac{\sqrt{h}}{4}.$$

A heavy body, falling during four seconds, falls 256 feet.
