4362. A common cause of injury to the banks of rivers is produced during floods. A tree or branch carried down by a stream, and deposited, or accidentally fixed or retained, in its banks, will repel that part of the stream which strikes against it, and the impulse (counteracted more or less by the general current) will direct a substream against the epposite bank. The effect of this continual action against one point of the opposite bank is, to wear out a hole or breach; and immediately above this breach it is customary to place a protecting pier to receive the impulse of the substream, and reverberate it to the middle of the general stream. But if this pier is not placed very obliquely to the substream, as well as to the general stream, it will prove injurious to the opposite bank by diecting a subcurrent there as great as the first; and, indeed, it is next to impossible to avoid this; so much so, that Smeaton, in almost every instance in which he was consulted in cases of this sort, recommended removing the obstacle where that could be done, and then throwing loose stones into the breach.

4363. Injuries by floods, according to Marshal, are to be remedied in two ways; the one is to sheath the injured banks of the bays $(fig. 671 \cdot a, b, c)$ with such materials

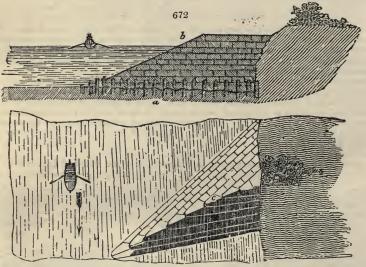

as will resist the circuitous current; and let the river remain in its crooked state. The other, to erect piers (d), to parry off the force of the current from the bank, and direct it forward; with the twofold intention of preventing further mischief, and of bringing back the course of the river to its former state of straightness. It is to be observed, that the operation of guarding the immediate bank of a sharp river bend, against a heavy current meeting with great resistance, by sheathing it with stones, is generally a work of much

difficulty and expense, even where materials can be easily procured: while that of diverting the current by a pier may frequently be accomplished at a comparatively small cost; and its effect be rendered infinitely more salutary and permanent. For it is plain that, if the accidental obstruction mentioned had been timely removed, no bad effect would have ensued: and the river would have continued its direct course. Or if, through neglect, it had been suffered to remain awhile, until its mischief was discoverable; even then, if it had been moved from its station to the opposite side of the river, and placed in the part affected, this small counterpoise might have recovered the balance of the current, and directed it into its wonted channel; and, in almost any case, by judiciously placing, in a similar manner, a pier or other obstruction proportioned to the magnitude of the power to be counteracted, the like effect may be produced.

4364. In the use of piers great caution is requisite, for a very little reflection will show that they are more likely to increase than to remedy the evil they are intended to cure. We have seen the injurious effects of such piers on the Tay and the Dee; and on a part of the Jed near Crailing they are so numerous, that the stream is, to use a familiar phrase, bandied about like a foot-ball, from one shore to the other; behind every pier an eddy is formed, and if the stream does not strike the pier exactly, a breach in the bank takes place. Many of these piers have, in consequence, been taken down. The use of such piers can only be justified where the obstruction, from ill-neighbourhood or some such cause, cannot be removed from the opposite bank; or where, as is sometimes the case, it arises from an island of sand or gravel thrown out by the river near its middle, which, however absurd it may appear, the interested parties cannot agree as to who may remove. The case of buildings also being in danger may justify such a pier for immediate protection; but if such breaches are taken in time, a few loads of loose stones dropped in the breach, as recommended by Smeaton, will effect a remedy without the risk of incurring or occasioning a greater evil.

4365. In the construction of piers, attention is required to secure the foundation, either by first throwing in a quantity of loose stones, which the water will in a great measure dispose of so as to form a flat surface; or by the use of piles either under, or in single or double rows around, those parts of its base in contact with the river. (fig. 672. a.) The elevation (b), where the current is not required to act with great violence on the opposite shore, ought to be bevelled back on all sides exposed to the water, towards the middle of the structure (c). In the most important cases stones are the only fit materials, and these

should be regularly jointed and laid in cement according to the best practice of masonry. But, in general, a case of wicker work, of the proper shape, may be filled in with loose stones, some earth, together with the roots of such plants as Tussilago Petasites, E'lymus arenains, Galium, &c. These will form a barrier of considerable durability for some years, and probably till the evil is so far subdued that, when the wicker case decays, its contents will have sufficiently consolidated to effect the object without further care. If not, the wicker case may be renewed. In ordinary cases, a mere wicker hedge projecting into the water will effect the object without further trouble.

4366. The sheath, or land-guard of loose stones, which Marshal recommends, and which, in effect, is the mode already mentioned (4362.) as preferred by Smeaton, is applicable to the following cases: — First, where the river, in the part required to be bent, is confined, by rocks or otherwise, to an unalterable channel, as it frequently is in subalpine situations; and, secondly, where a deep pool occurs in that part, at low

water, so as to render it difficult to get a proper foundation for a pier. Where the foot of the injured bank is covered with a pool at low water, shelve off the brink of the bank, and shoot down loose stones from the top of it; suffering them to form their own slope, in the action of falling, and by the operation of succeeding floods: continuing to pour them down, until the bank be secured, at least from minor floods, and then slope back the upper part, to give freedom to floods of greater magnitude.

back the upper part, to give freedom to floods of greater magnitude.

4367. When the channel of a rapid river is narrow, and the banks undermined and washed away by the torrents, what Marshal terms the land-guard is to be used.

4368. In forming a land-guard for this purpose, he says, the foundation should be laid pretty deep, to guard against any accidental scoopings from the floods. The wall ought to be carried up dry, or without mortar, the stones being laid with their ends outward, their inner ends pointing to the same centre, like those of an arch, and to be backed with gravel, or earth, rammed in firmly behind, as the facing is carried up. The coping or uppermost course of the stones is to be securely bound, with thick tough sods (8 or 10 inches deep), whose surfaces, when beaten down, ought to lie even with that of the stonework; and similar sods require to be laid, with a gently rising slope, until they unite smoothly with the natural turf of the land to be defended; so that the waters of floods, when they rise above the stonework, may have no abruptness to lay hold of, but may pass away smoothly over the surface of the land, as they commonly do over smooth greensward, without injury. Finally, the stones are to be beaten forcibly into the bank, with a rammer, a mallet, or a small battering-ram, adapted to the purpose; thus rendering the whole compact and firm, to resist the current. Where vacancies or fissures still appear, long splinters of stone are to be driven in, as wedges, to increase the firmness, and prevent the current from tearing out an unguarded stone. It follows, of course, that the largest and longest of the stones ought to be used where the greatest resistance is known to be required.

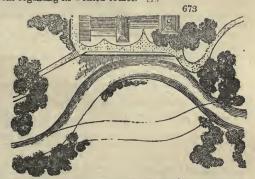

4369. The repairs of a butwark of this sort, like every other species of river fence, require to be retreded to from time to time, especially after great floods. If the foundation be laid bare, it requires to be recovered with rough gravel, or with stones thrown loosely against it. If any of the facing ston

SUBSECT. 2. Changing the Courses of Rivers, deepening their Beds, or raising their Waters to a higher Level.

4370. A river whose course is in a straight line, or nearly so, hardly ever makes any encroachment on its banks, except perhaps very large rivers, when they rise above their usual level, either by an increase in their own waters, or from their flow being in some degree interrupted by the tides. Hence, whenever a river is narrow in its channel and winds considerably, any mischief it commonly occasions may be prevented by deepening and

straightening the course of the stream. (Code of Agr. p. 319.)
4371. The alteration of the course of a river or brook is attended with difficulty and expense, according to the particular circumstances. In a simple case, in which one straight cut only is required, the principal difficulty, and that which requires the best skill of the artist, lies in directing the current of the first flood, out of the old into the new channel: but if a bend of the old channel can be made use of, this difficulty may be said to vanish. The mouth of the new cut receives the current with a straight course; consequently, if it be made of sufficient capacity, the river, in a flood, can have no propensity left towards its old channel: and the loose materials which rise in forming the mouth of the new cut, will generally be sufficient to turn the stream at low water into it. But if a suitable bend cannot be approached by the new cut, a directing pier will be required to bend the flood current, and give it a straightforward course into the new channel: a watertight dam being formed between the point of the pier and the firm bank of the new channel to prevent the water from regaining its wonted course.

4372. An entirely new bed or channel, however, is much to be preferred where it can be obtained: for in an altered course, when the stream passes alternately through new soil and through a part of its old bed, its action on surfaces which are so different in regard to induration ends, if great care is not taken, in holes and gulleys in the new bank, which require to be constantly filled up with loose stones thrown in, and left to be fixed by the pressure and motion of the water. In the

case of a river passing near a house (fig. 673.) this is sometimes of great importance.

4373. Cutting the new channel is merely a work of manual labour; being attended with no other difficulty than what may arise from the expense, which will depend on the size of the river, the nature of the ground to be cut through, and the value of labour in the given district. It is mostly to be ascertained with sufficient accuracy by previous calculations. (See 3323.)

4374. The size of the new cut, on account of its greater depth, may be small, compared with that of the

old channel. For the current of floods, by carrying off the earthy particles with which they come in contact, will soon enlarge it. It is nevertheless right to give ample room in the new channel, lest the first flood should prove high, and, by bursting its bounds, force its way back to its former course.

4375. A new river course requires to be carefully attended to, during a few years after it is opened, to see that its channel preserves its straightness, and that no breaches are made or threatened in its banks. Considering the uncertainty of extraordinary floods, it cannot be said to be out of danger in less than three years: hence it becomes prudent, when a work of this nature is contracted for, or undertaken to be done by measurement at an estimated price or prices previously agreed upon (as it generally ought), that the undertaker should agree to preserve the straightness of the channel, and uphold its banks during that or some other time fixed upon; and to deliver them up, at the end of the term, in the state and condition specified in the contract.

4376. A case of straightening the course of a river is given in The Code of Agriculture. The waters,

condition specified in the contract.

4376. A case of straightening the course of a river is given in The Code of Agriculture. The waters, which in their crooked course were formerly almost stagnated, now run at the ordinary rate of the declivity given them. They never overflow their banks. Cattle can now pasture upon those grounds in which they would formerly have been swamped. The surface of the water being now in general four, and sometimes six feet below that of the adjacent fields, this cut serves as a general drain to the whole valley; so that three hundred acres of meadow may be converted into arable land; sixty acres of moss may be improved into meadow; and five hundred acres of arable land are rendered of double their former value. (p. 319.)

4377. Raising rivers to a higher level.

As rivers and streams may require to be deepened for the purpose of drainage, so may their waters require to be raised for the purpose of irrigation, impelling machinery, or producing cascades or waterfalls for the purpose of ornament. Dams or wears for this purpose should be constructed so as to form a segment of a circle across the bed of the stream, with the convex side pointing up the stream, and the ends abutting against a natural or artificial bank (fig. 674.) By this construction, the force of the

water, however great, will be effectually resisted, and the structure remains secure. greater the slope towards the upper side, the better, but the lower side should be nearly perpendicular, that the water may fall over it without coming in contact with the face

of the building. (fig. 675.) The wall (a) should be built of regularly hewn stone, as should the abutments (b); next the wall there should be a mass of clay as a puddle (c), and above that gravel or earthy

matter of any kind to a considerable slope (d). Beneath the dam a considerable por-

tion ought to be paved (e). (Gen. Rep. Scot. vol. ii. p. 669.)

4378. Heads, or banks of earth, for the confinement of water in artificial lakes or ponds, are often constructed at great expense, and, not being properly formed, often break out, and occasion considerable damage. The error in their construction is commonly owing to the want of breadth at the base in proportion to their height, and their not having a sufficient slope towards the water, nor a proper section of puddle in the (Ibid.)

4379. Heads of loose stones of a large size (fig. 676.) may be had recourse to in slow

running rivers not subject to high floods, and where there is such a superabundance of water that no loss is sustained by the quantity which flows through the stones. Where it is required to retain the whole of

the water, a puddle bank should be carried up the middle of the dam. (Ibid.)

CHAP. III.

Irrigation, or the Improvement of Culturable Lands and Farmeries by the means of Water.

4380. The improvement of lands by water is of three kinds: - irrigation, or the application of water to the surface of the soil, and especially of grass lands, as a species of culture; warping, or the covering of the soil with water to receive a deposition of earthy matter; and the procuring or preserving of water by wells, reservoirs, and other means, for the use of farmeries, live stock in the fields, or the domestic purposes of the farmer or cottager.

Sect. I. Irrigation, or the Preparation of the Surface of Lands for the profitable Application of Water.

4381. Irrigation in its different forms may be considered an operation of culture as well as of permanent improvement. It is accordingly in many cases effected by tenants, but always, as in the case of improving wastes, in consequence of extraordinary encouragement from the landlord, by long leases, money advanced, or other advantages.

4382. The application of water to the surface of lands for the purpose of promoting vegetation has been practised, as we have seen (141.), from the earliest ages in warm countries. Solomon made him gardens, and orchards, and pools of water to water therewith the wood that bringeth forth the trees. (Ecclesiastes.) The art was taught by nature in the overflowing of the Nile and other rivers. Water is an essential article for the culture both of the cereal and pasture grasses, and indeed of most herbaceous crops, in all the tropical climates, and even in a great degree in the South of Europe. In the greater part of Italy and Spain, few crops are raised without being irrigated; and even in the south of France, potatoes, maize, madder, and sometimes vines, and orange trees, (as at Hieres,) have water applied to their roots, by furrows and other gutters and trenches formed on the surface. The system of watering grass lands was revived in Italy in the ninth century, and seems to have been practised in a few places in Britain from the time of the Romans; there being meadows near Salisbury which have been irrigated from time immemorial. In 1610, the public attention was called to it by Rowland Vaughan, in a work entitled, "Most improved and long experienced Water Works; containing the manner of summer and winter drowning of meadow and pasture, by the advantage of the least river, brook, fount, or water mill adjacent; thereby to make those grounds (especially if they be dry) more fertile ten for one."

4383. Irrigation in former times, and in all countries, however imperfect, was probably much more frequent than it is now. In light and gravelly tracts of country, the greatest difficulty in farming was to procure a sufficient supply of fodder for their cattle in winter. Meadows were therefore indispensable, and to increase the crop of hay, watering in a dry spring, and immediately (in dry summers) after the first crop was off, was constantly followed. Since the practice of sowing artificial grasses, and the introduction of the turnip husbandry, the custom of watering has been in such situations given up; not only because it has become less necessary than it was heretofore, but because watered meadow hay is of inferior quality as well as value in the market. It is nevertheless true that the herbage of very coarse boggy meadows is improved, and that of cold meagre soils is

accelerated and increased by it.

4384. But the principal scientific efforts in watering lands have been made during the latter end of the last and beginning of the present century, in consequence of a treatise on the subject by George Boswell, published in 1780, and various others by the Rev. Thomas Wright, of Auld, in Northamptonshire, which appeared from 1789 to 1810. The practice, however, has been chiefly confined to England, there being a sort of national prejudice, as Loch has observed (Improvements on the Stafford Estates, &c.), against the practice in Scotland, though its beneficial effects may be seen as far north as Sutherland, where rills on the sides of brown heathy mountains never fail to destroy the heath plants within their reach, and these are succeeded by a verdant surface of grasses. A valuable treatise on the subject of irrigation in Scotland, by Dr. Singer, will be found in The General Report of Scotland, vol. ii. p. 610. In England the best examples of watering are to be found in Gloucestershire and Wiltshire. In our view of this subject, we shall first consider the soils and situations suitable for irrigation, and next the different modes of effecting it, known as flooding, irrigating, warping, irrigation on arable lands, and subterraneous irrigation.

Subsect. 1. Soils and Situations suitable for Watering.

4385. The theory of the operation of water on lands we have already developed. It appears to act as a medium of conveying food, as a stimulus, as a consolidater of mossy soils, as a destroyer of some descriptions of weeds or useless plants, and as the cause of warmth at one season, and of a refreshing coolness at another. From these circumstances, and also from what we observe in nature, there appears to be no soil or situation, nor any climate, in which watering grass-lands may not be of service; since the banks of streams between mountains of every description of rock, and in every temperature from that of Lapland to the equator, are found to produce the richest grass. One circumstance alone seems common to all situations, which is, that the lands must be drained either naturally or by art. The flat surfaces on every brook or river, after being covered with water during floods, are specifly dried when they subside, by the retiring of the waters to their channel.

4386. The most proper soils for being watered are all those which are of a sandy or gravelly friable nature, as the improvement is not only immediate, but the effects more

powerful than on other descriptions of land. There are also some strong adhesive sour wet lands, such as are common in the vicinity of large rivers, which are also capable of being improved by watering; but the beneficial effects are not in such cases so soon produced as on the first sorts, nor is the process so advantageous to the farmer, on account of the very great expense to which he must, in many cases, be put by previous draining. There are some other lands, as those which contain coarse vegetable productions, as heath, ling, rushes, &c. which may likewise be much improved by watering. It must be kept constantly in mind, in attempting this sort of improvement, that, the more tenacious the soil is, the greater should be the command of water for effecting the purpose; as a stream, capable of watering fifteen or twenty acres of light dry land, would be found to be beneficial in but a small degree when applied to watering half the same quantity of cold clayey ground such as in its natural state abounds with coarse plants. On all soils of the latter kind a considerable body of water for the purpose of floating them is required to produce much benefit, and where a sufficient quantity cannot be procured, this mode of improvement will seldom answer the farmer's intention or be advantageous in the result.

asset intention or be advantageous in the result.

4387. Smith, an experienced irrigator, supposes that "there are only a few soils to which irrigation may not be advantageously applied: his experience, he says, has determined, that the wettest land may be greatly improved by it, and also that it is equally beneficial to that which is dry." (Obs. on Irrigation, &c.) But, as many persons unacquainted with the nature of irrigation may be more inclined to the latter supposition than the former, he explains the reason of wet land being as capable of improvement from flooding as that which is completely dry. It is, that, in the construction of all water meadows, particular care must be taken to render them perfectly dry when the business of floating shall terminate; and that the season for floating is in the winter and not in the summer, which those who are unacquainted with the process have too generally supposed. All peat bogs are certainly of vegetables of the bog would, under due management upon the surface, produce such grasses, or other vegetables of the bog would, under due management upon the surface, produce such grasses, or other vegetables, as are usually grown by the farmer; and he has hitherto had reason to think that this may be considered as a general rule for determining the situation of any experiments with water. The lands that permit of this sort of improvement with the most success are such as lie in low situations on the borders of brooks, streams, or rivers, or in sloping directions on the sides of hills.

4388. The purity of the water to be used in irrigation is supposed by some to be

4388. The purity of the water to be used in irrigation is supposed by some to be a matter of the first importance; but it is now fully proved, by the accurate experiments of an able chemist, and by the extraordinary growth of grasses in Pristley meadow, in Bedfordshire, that ferruginous waters are friendly to vegetation, when properly applied. (Smith's Observations on Irrigation, p. 28.) Lead or copper never does good, and it is well known, that waters of that description, after they have been brought into fields, by levels cut at a considerable expense, have again been diverted, and suffered to flow in their original channels. Waters impregnated with the juices that flow from peat-mosses, are consistered by many not worth applying to the soil. It is objected to them, that they are soon frozen, that they convey no material nutriment, and that they are commonly loaded with such antiseptic substances as, instead of promoting, will retard vegetation. (Dr. Singer's Treatise, p. 579.) It is urged, on the other hand, that a want of sufficient slope in the meadow, or of proper management in regard to the water, may have occasioned the disappointments experienced in some cases, when bog-waters have been applied. (Derbyshire Report, vol. ii. p. 463.)

4389. The advantages of watering lands must, in a material degree, depend on the It is evident that the benefit to be derived from this process in Sweden, for climate. example, where the summers are short, must be greatly inferior to what it is in Lombardy, where grass grows all the year; and that in Perthshire, where grass ceases to grow for at least three and often four months in the year, it must be much less than in Gloucestershire or Ireland, where its growth is not interrupted above a month or six weeks, and sometimes not at all: most grasses vegetating in a temperature of 33 or 34 degrees. Still, however, as the most luxuriant pastures are found on lands naturally watered, both in Sweden and Perthshire, it would appear worth while to imitate nature in cold as well as in warm countries. According to many writers on the subject, the benefits attending watering in England are immense. In Davis's Survey of Wiltshire, it is calculated that 2000 acres of water meadow will, on a moderate estimate, produce, in four or five years, 10,000 tons of manure, and will keep in permanent fertility 400 acres per annum of arable land.

4390. Watering poor land, especially if of a gravelly nature, is stated in The Code of Agriculture to be by far the easiest, cheapest, and most certain mode of improving it. "Land, when once improved by irrigation, is put in a state of perpetual fertility, without any occasion for manure, or trouble of weeding, or any other material expense. It becomes so productive, as to yield the largest bulk of hay, besides abundance of the very best support for ewes and lambs in the spring, and for cows and other cattle in the autumn of every year. In favourable situations, it produces very early grass in the spring, when it is doubly valuable; and not only is the land thus rendered fertile, without having any occasion for manure, but it produces food for animals, which is converted into manure, to be used on other lands, thus augmenting, in a compound proportion, that great source of fertility." Were these advantages more generally known, or more fully appreciated, a large proportion of the kingdom might become like South Cerney, in Gloucestershire, where every spring, or rivulet, however insignificant, is made subservient to the purpose of irrigation, fertilising, in proportion to its size, either a small quantity or a large tract of land. (Gloucestershire Report, p. 280.)

4391. Irrigation by liquid manure may occasionally be practised in the neighbourhood of towns and cities to the greatest advantage. In the neighbourhood of Edinburgh, we

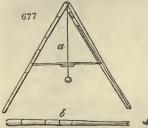

are informed by Stephens, upwards of 200 acres are so irrigated from the principal common sewer, and that, although the formation of these meadows is irregular, and the management very imperfect, the effects of the water are astonishing: they produce crops of grass not to be equalled, being cut from four to six times a year, and the grass given green to milch cows.

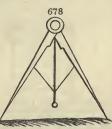

Subsect. 2. Implements made Use of in Watering Lands; and the Terms of Art peculiar to such Operations.

4392. The principal instruments made use of in the preparation of lands for watering

are the following:

4393. The level, of which different descriptions have already been given, is necessarily employed to take the level of the land at a distance, compared with the part of the river, &c. whence it is intended to bring the water, to know whether it can or cannot be made to float the part intended to be watered. Bringing the water after them to work by is found very useful in undertakings of this nature, especially when on a large scale, though the workmen too frequently dispense with it. In drawing a main, they begin at the head, and work deep enough to have the water to follow them; and in drawing a tail drain, they begin at the hower end of it, and work

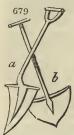

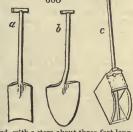

upwards, to let the water come after them. The level should, however, be made use of, as being more certain and correct. being more certain and correct. Brown, an experienced irrigator in the west of England, recommends a level (Fig. 677. a), which when not in use imay be closed (b) like a walking-stick. There is also a compass level (Fig. 678.), which may be used in the same way.

4394. A line and reel, and a breast-plough, or turf spade (fig. 211.), are likewise absolutely necessary. The use of the two former are well known; but as the line is mostly used in the wet, it should for this purpose be larger and stronger than those employed in gardening. The turf spade should be of the best description, being principally employed in cutting turfs for the sides of the channels.

4395. The spades made use of in this sort of work (fig. 679.) should have the stems considerably more crooked than those of any other kind; the bit being of iron, about a foot wide in the middle, terminating in a point; a thick ridge running perpendicularly down the middle, from the stem almost to the point; the edges on both sides

almost to the point; the edges on both sides should be drawn very thin, and as they are obliged to be kept very sharp, they should be often ground and whetted. This necessarily wears them away, and they soon become narrow; they are then used for the narrow trenches and drains, whilst new ones are used for the wider. From the stems being made crooked, the workmen, standing in the working position in the bottom of the trench or drain, are en-

in the bottom of the trench or drain, are enabled to make it quite smooth and even. Shovels of different forms (fig. 680. a, b), and a scoop for lifting water (c), are also requisite.

4396. The crescent (fig. 679. b) is a tool made like the gardener's edging fron, only much larger, having the form of a crescent, being very thin and well steeled, with a stem about three feet long, and a cross handle to bear upon. It is used for tracing out the sides of the mains, trenches, drains, &c.

4397. The turf knife (fig. 681.) has a cimeter-like blade, with a tread for the foot (a) and a bent handle (b): it is used for the same purpose as the crescent, and by some

631 4398. Wheelbarrows also become necessary to remove the clods to flat places: they may be open, without sides or hinder parts.
4399. Handbarrows are likewise sometimes made use of where the ground is too soft to admit of wheelbarrows, and where clods require to be removed during the time

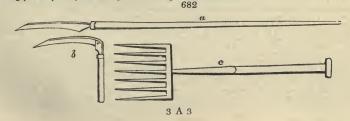

the meadow is under water.

the meadow is under water.

4400. Three-wheeled carts, &c. are necessary, when large quantities of earth are to be removed, particularly when it is carried to some distance.

4401. Scylhes, of different sorts (fig. 682. a, b), are required to mow the weeds and grass, when the water is running in the trenches, drains, &c. The crooks (b) should be made light, and have long stems, to reach wherever the water is so deep that the workmen cannot work in it.

4402. Besides these, forks (c), and long four or five tined hacks, are requisite to pull out the roots of the sedge, rushes, reeds, &c. which grow in the large mains and drains.

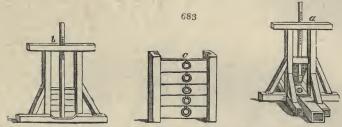

4403. Stout targe waterproof boots, having tops so as to draw up half the length of the thigh, are indispensable; they must be large enough to admit a quantity of hay to be stuffed down all round the legs, and be kept well tallowed, to resist the running water for a length of time.

4404. The terms made use of are various:

4405. A wear is an erection across a river, brook, rivulet, main, &c., made often of timber only, sometimes of bricks, or stones and timber, with from two to eight or ten thoroughs (openings) to let the water through, according to the breadth of the stream. Its height is always equal to the depth of the stream compared with the adjacent land. Its use is, when the hatches are all in their proper places, to stop the whole current, that the water may rise high enough to overflow the banks, and spread over the adjoining land; or, by stopping the water in its natural course, to turn it through mains cut for conveying it another way to water some distinct lands. way, to water some distant lands.

4406. A sluice (fig. 683. a, b) is made exactly as a wear, only it has but one thorough; for if there are

more than one, it becomes a wear.

4407. A trunk is a covered sluice, being a necessary construction in all cases where two streams of water are to cross each other, to serve as a bridge for that stream which is to pass over or under the other.

other.

4408. A carriage is a sort of small wooden or brick aqueduct, built open, for the purpose of carrying one stream over another, and is the most expensive conveyance belonging to the business of watering.

4409. A drain sluice, or drain trunk, signifies such as are placed in the lowest part of a main, as near to the head as a drain can be formed, and situated low enough to drain the main, &c. It is placed with 4409. A train strice, or drain trunk, signifies such as are placed in the lowest part of a main, as uear to the head as a drain can be formed, and situated low enough to drain the main, &c. It is placed with the mouth at the bottom of the main, being let down into the bank; and from its other end a drain is cut to communicate with the nearest trench-drain. It is a contrivance to carry off the leakage through the hatches when they are shut down, to convey the water to other grounds, or to repair the main, &c. 4410. Hatches (fg. 683.c) are floodgates, variously constructed. A particular kind, which has about a foot to take off; so as to permit the water to flow over that much of the hatch where it appears to be useful in irrigation, has been employed, but is not found to answer. They are best when made whole. They may be made of any timber, but oak and elm are the best.

4411. Head main is a term used to signify a ditch drawn from the river, rivulet, &c. to convey the water out of its usual current to water the lands laid out for that nurrose through the means of lesser mains.

4411. Head main is a term used to signify a ditch drawn from the river, rivulet, &c. to convey the water out of its usual current to water the lands laid out for that purpose, through the means of lesser mains and trenches. The head main is drawn of various breadths and depths, according to the quantity of land to be watered, to the length, or to the fall or descent of the land it is cut through. Smaller mains are frequently taken out of the head main, at, or nearly at, right angles, to which they are usually cut. They are much smaller than the head main, and this constitutes the only difference. The use of both the large and small mains is to feed with water the various trenches which branch out into all parts of the

are much smaller than the head main, and this constitutes the only difference. The use of both the large and small mains is to feed with water the various trenches which branch out into all parts of the meadow. These smaller mains are by some called carriages, but improperly, for it is confounding them with the open trunk, called by that name, as seen above.

4412. The trench is a narrow shallow ditch, for conveying the water out of the mains to float the land. It ought always to be drawn in a straight line from angle to angle, with as few turnings as possible. It is never made deep, but the width is in proportion to the length it runs, and the breadth of the pane between it and the trench drain. It narrows gradually to the lower end.

4413. The trench drain is cut parallel to the trench, and as deep, when necessary, as the tail drain water will admit. It ought always to be cut, if possible, so as to come down to a firm stratum of sand, gravel, or clay: if the latter, a spade's depth into it will be of great advantage. Its use is to carry away the water immediately after it has run over the panes from the trench. It need not be drawn up to the head of the land, by five, six, or more yards, according to the nature of the soil. Its form is the reverse of the trench, being narrower at the head, or upper part, and gradually wider, till it comes to the lower end and empties itself into the tail drain.

4414. The tail drain is a receptacle for all the water that runs out of the other drains, not so situated as to empty themselves into the river; and therefore it should run nearly at right angles with the trenches, but, in general it is drawn in the lowest part of the ground, and used to convey the water out of the meadow where there is the greatest descent. This is generally found in one of the fence ditch is mostly used, at once fencing the meadow and draining it.

4415. A pane of ground is that part of the meadow which lies between the trench and the trenches, and drained by the trench drains, consequently there is

every part of each pane an equal quantity of water.

4418. A gutter is a small groove cut out from the tails of those trenches, where the panes run longer at one corner than the other. Its use is to carry the water to the extreme point of the pane. Those panes which are intersected by the trench and tail drains meeting in an obtuse angle, want the assistance of these gutters to convey the water to the longest side; and when, from insufficient levelling, some parts of the panes lie higher than they ought, a gutter is drawn from the trench over that high ground, which otherwise would not be overflowed. Without this precaution, unless the flats were filled up (which ought always to be done when materials can be had), the water would not rise upon it: and after the watering season was past, those places would appear rusty and brown, whilst a rich verdure would overspread the others; at hay-time, also, the grass in those places would be scarce high enough

for the scythe to touch it, whilst that around them, which had been properly watered, would from its luxuriance lie down. Though this method of treating such places is mentioned, their existence ought always to be reprobated; for every inequality in water meadows should either be levelled down or filled up. Here the irrigator's skill is shown, in bringing the water over those places to which it could not rise of itself, and in carrying it off from others where it would otherwise stagnate.

4419. Catch drain is a term sometimes applied to a method made use of to irrigate the land when the water is scarce, and the method is this: when a meadow is pretty long, and has a quick descent, the water is made to run swiftly down a drain or drains, in which it is stopped at different distances so as to spread it over the adjoining surface. (See fig. 686. p. 798.)

4420. The bed of a river, main, trench, &c., is the bottom of it.

4421. Pond means water standing upon the land, or in the tail drain, trench drains, &c., so as to injure the ground near them; and is occasioned sometimes by the flats not having been properly filled up; and at other times, when, a ware being shut close, to water some high ground above it, the water is thrown back upon the ground contiguous. In this case the lesser evil, whichever it is, must be borne with.

is thrown back upon the ground contiguous. In this case the lesser evil, whichever it is, must be borne with.

4422. A turn of water means so much land in a meadow as can be watered at one time. It is done by shutting down the hatches in all those wears where the water is intended to be kept out, and opening those that are to let the water through. The quantity of land to be watered by one turn must vary with the size of the river, main, &c. as well as with the plenty or scarcity of water.

4423. The head of a meadow is that part into which the river, main, &c. first enters; and the tail of a meadow is that part out of which the river, &c. last passes.

4424. The upper side of a meain, or trench, is that side which (when the main or trench is drawn at, or nearly at, right angles with the river, &c.) fronts the part whence the river entered. Consequently the lower side is the reverse.

1806 A 1816 is the reverse.

4125. The upper pane in a meadow is that pane which lies upon the upper side of the main, or trench, drawn at right angles with the river; that is, when the river, &c. runs north and south, entering at the north, and the mains and trenches are drawn east and west, all those panes which lie on the north side of the main, &c. are called the upper panes, those on the south side are called the lower. But it may be noticed, that where the mains, trenches, &c. run parallel with the river, the panes on either side are not distinguished from each other. distinguished from each other.

4426. Meadows are of two sorts: flowing, calculated for a flat country; and catch-work, for sloping grounds.

44:7. Flowing meadows. Where the ground is flat, the soil is formed into beds, or broad ridges, like those met with at bleachfields. They are commonly from 30 to 40 feet wide, and nine or ten poles in length; as, in such situations, the great object is, when once brought on, to be able to carry off the water quickly. Hence it is necessary to throw up the land in high ridges, with drains between them. More of the failures in irrigation arise from the ridges not being sufficiently high, and the slopes not being sufficiently steep, than from any other cause. (Code.)
44:28. Catch-work meadows. It is difficult to give an intelligible written description of the mode of making these meadows. To be properly understood, the operation must be seen. It may, however, in general be remarked, that the system is calculated for sloping grounds, and that, after the water is brought from the original stream, into a new cut, it is stopped at the end, on as high a level as the case admits of, by which means it is made to fill the trench, and run over at the side, flooding the land below. But as the water would soon cease to run equally, and would wash the land out in gutters, it has been found necessary to cut small parallel trenches, at the distance of from 20 to 50 feet, coatch the water again (hence the name originated), and the same plan of spreading or diffusing is continued, until the water reaches the main drain at the bottom of the meadow. It is a great advantage attending the catchwork system, that it is not only less expensive, but the same quantity of water will do much more work. (Code.)

Subsect. 3. Preparation of Surfaces for Irrigation.

4429. Artificial irrigation, Smith observes, is produced by diverting the water of a brook out of its accustomed channel (where there is a fall) in such a manner that, the new watercourse being kept nearly level, the space between the old and new channel may be floated; the water being brought upon the land by the new channel and taken away by Thus a constant discharge and succession of water is maintained, without such an accumulation as would make it appear bright upon the land, or without such a deficiency as would leave any part of it not perfectly floating; for the art of irrigation may be most properly called floating, not soaking nor drowning. Soaking the soil, similar to the effects produced from a shower of rain, is not sufficient for the general purposes of irrigation, nor will damming up water, and keeping it stagnant upon the surface,

like that in a pond, or on the fens, produce the desired effect.

4430. Stagnating water on land may properly be called drowning, because it drowns or covers all the grass, thereby rendering the plants beneath it in some degree aquatic, or the herbage disposed to make such a change; whereas the herbage of a water meadow should, by the construction and good management of the latter, enjoy the full benefits of both the elements of air and water. Practice has proved that there is no better method of doing this than by keeping water passing over the surface of the land with a brisk current; not so brisk as to wash away the soil, and yet in sufficient quantity to cover and nourish the roots, but not too much to hide the shoots of the grasses: hence appears the nicety of adjusting the quantity of water; and hence it also appears, that one main drain to bring the water on the upper side of the mead, and another on the lower side to take it away, will not be adequate to all the purposes of such an accurate regulation. If the space between the upper channel or main feeder and the lower one or main drain, should therefore be wider than is proper for the good adjustment of the water, that is, so that every part of the space shall have enough water passing over it and no part too much, then that space must be divided into smaller spaces by intermediate drains, which shall catch and re-distribute the water. As the water is brought by the main feeder upon the higher

side of a piece of ground which slopes towards the main drain, and down which sloping surface the water will run very readily, it does not, to persons unacquainted with irrigation, at first sight appear necessary to make such a number of intermediate catch drains; but it is proved by experience, that, however regular the slope of ground may appear to the eye, the water will find a number of irregularities, forcing itself into gutters or channels, and defeating the purposes of irrigation; in the hollow places by excess, and in high ones by the want of water. Hence the water, which was scattered over the surface of the first space, being all collected in the catch drain, may by the skill of the floater be let out upon those parts of the bed below which appear to need the most assistance.

4431. The work should always be well formed at first in all cases of improvements of this nature. Temporary means of making dams and hatches to divert the water out of its usual channel may, says Smith, suffice to try an experiment, or for a tenant who has but a short term in the grounds to be irrigated; but every land-owner who enters upon such work in this temporary manner sadly mistakes his own interest: indeed, it is frequently more difficult to repair than to renew upon large streams, when the foundations are often destroyed by the force of the water. The same principle holds good upon small streams, and even in the drains and feeders of a water meadow. Wherever the channels are so constructed as to make a fall, or much increase the rapidity of the stream, it is constantly disposed to wear away the sides of its channel, or undermine a dam. To repair these defects, land must be dug away and wasted each time it is replaced, with the loss of labour. The consequent ill management of the water renders it more advisable, and perhaps cheaper, to make all such works of masonry. When works are well done at first, the owner ever finds much pleasure in viewing them; and even the labourers feel much more interested in their good management.

4432. The expenses of making a water meadow are not easily estimated. Much depends on the original state of the ground, the size and fall of the streams to be used, the cost of hatches, and length of the main feeders which may be necessary for diverting the water out of its original channel, and even upon the charge for levelling land, which differs materially. Some soils are much harder and more difficult to move than others, and, in certain situations, building materials are very scarce and dear. This last circumstance must make a considerable variation in the price of the hatches, where the stream is large. It is also impossible to tell, with any degree of certainty, what proportion these expenses should bear to the quantity of land irrigated, for some situations will require much more masonry than others.

4433. Before entering upon the execution of a water meadow, it is necessary to consider fully, whether the stream of water to be made use of will admit of a temporary wear or dam to be formed across it, so as to keep the water up to a proper level for covering the land without flooding or injuring other adjoining grounds; or if the water be in its natural state sufficiently high without a wear or dam; or can be made so by taking it from the stream higher up more towards its source; and by the conductor keeping it up nearly to its level till it comes upon the meadow or other ground; and still further, whether the water can be drawn off the meadow or other ground in as rapid a manner as it is brought on. Having, in addition to these, an attention to all such other difficulties and obstructions as may present themselves, from the lands being in lease, through which it may be necessary to cut or form the mains or grand carriers, from the water being necessary for turning mills, from the rivers or brooks not being wholly at the command of the irrigator, and from small necks of land intervening so as to prevent the work from being performed to the greatest advantage, the operator may be in a situation to commence his operations.

4434. In order to have an equal distribution and prevent waste, Smith states, that no part of a meadow, either in catch-work or beds, should be so formed as to be floated directly from the main feeder; but all the main feeders should be kept high enough to discharge the water into the small feeders with considerable velocity and through a narrow opening. The motion of water is truly mechanical: it requires a great deal of ingenuity, and a perfect knowledge of lines and levels, to make it move over the ground in a proper manner. No two pieces of land being exactly alike, renders it still more difficult to set out a water meadow; but even if the figure of two pieces be alike, the inequalities of surface will probably vary. Each meadow, therefore, requires a different design, unless the landowner makes up his mind to the heavy expenses of paring off banks, and filling up such hollows as may be necessary to reduce it to some regular method; the construction to be varied according to the nature of the ground. This constitutes the difference between the water meadows of Berkshire and Devonshire. Those of the latter are upon small streams carried round the sides of the hills, and are chiefly catchwork; those of the former, being near large rivers and boggy ground, are thrown up into ridges to create a brisk motion in the water, and also for the essential purpose of draining off all superfluous moisture, which might be injurious to the grasses when shut up for feeding or mowing. Where there is much floating to be done with a little water, or rather where the great fall of a small stream will admit of its being carried over a vast quantity of ground and used several times, it is desirable to employ it in such

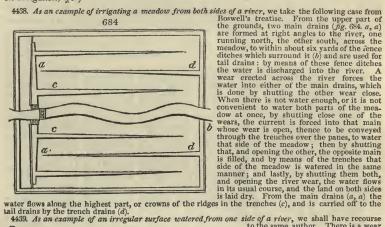

a way as that the earthy particles it may contain may be deposited as equally as possible over the whole surface to be irrigated. But it is to be observed, that this mode of applying water must not be exhibited as a perfect model. If it should answer the purpose of a coat of manure, upon such an extent of ground, it is all that can be expected, and will amply repay the expense. Losing fall is wasting water.

4435. The drains of a water meadow require no greater declivity than is necessary to carry the water from the surface: therefore the water ought to be collected and used again at every three feet of the fall, if it be not catch-work. It is sometimes difficult to do this in bed-work meads; but where the upper part of the meadow is catch-work or in level beds, and the lower part not too much elevated, it may be done. By collecting and using the water again in the same piece of ground before it falls into the brook, a set of hatches is saved; and it is not necessary to be very particular about getting the upper part into high ridges, since that part of the meadow which is near the hatches generally becomes the best, and the lower end of the field, being often the wettest or most boggy in its original state, requires to be thrown up the highest. If the land is of a dry absorbent nature before floating, it is not necessary that it should be thrown up into high beds, but merely as much inclined as will give the water a current.

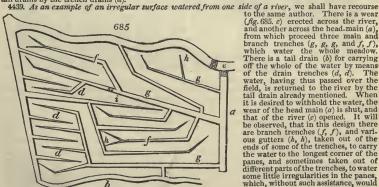

4436. Inclined planes are absolutely necessary for the purpose of irrigation. To form these between straight and parallel lines, it is necessary to dig away land where it is too high, and move it to those places where it is too low, to make such a uniformity of surface. The new made ground will of course settle in hollows proportioned to the depth of loose matter which has been recently put together, but this settlement will not take place until the new soil has been completely soaked and dried again; therefore these defects cannot be remedied before the second or third year of watering: it will therefore require more skill to manage a water meadow for the first three or four years, than afterwards.

fore require more skill to manage a water meadow for the first three or four years, than afterwards.

4437. Properly to construct a water meadow is much more difficult than is commonly imagined. It is no easy task to give an irregular surface that regular yet various figure which shall be fit for the overflowing of water. It is very necessary for the operator to have just ideas of levels, lines, and angles; a knowledge of superficial forms will not be sufficient; accurate notions of solid geometry (obtained from theory or practice) are absolutely necessary to put such a surface into the form proper for the reception of water, without the trouble and expense of doing much of the work twice over. (Obs. on Irrigation, &c.)

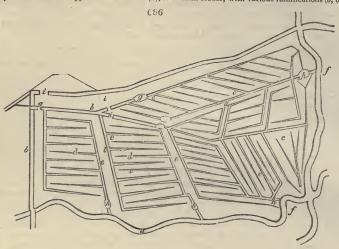

water into either of the main drains, which is done by shutting the other wear close. When there is not water enough, or it is not

from which proceed three main and from which proceed three main and branch trenches $(g_1, g_2, g_3, \text{ and } f_1, f_2)$, which water the whole meadow. There is a tail drain (b) for carrying off the whole of the water by means of the drain trenches (d_1, d_2) . The water, having thus passed over the field, is returned to the river by the tail drain already mentioned. When it is desired to withhold the water, the water of the head main (p) is shut, and wear of the head main (a) is shut, and we at of the river (e) opened. It will be observed, that in this design there are branch trenches (f, f), and various gutters (h, h), taken out of the ends of some of the trenches, to carry the water to the longest corner of the panes, and sometimes taken out of panes, and sometimes taken out of different parts of the trenches, to water some little irregularities in the panes, which, without such assistance, would not have any water upon them. There not have any water upon them.

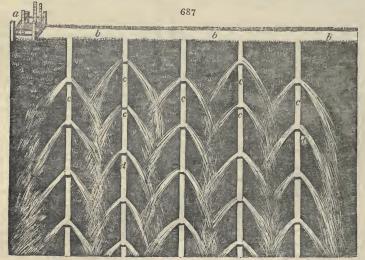

is a sluice (i) erected at the end of one of the small mains, to force the water into the branch trench adjoining (f), that being the highest ground.

4440. A very complete piece of irrigation (fig. 686) was formed for the Duke of Bedford, by Smith, at Pristley. The water is supplied from a brook (a), to a main feeder, with various ramifications (b, b); the

surface is formed into ridges (c, c), over which the water flows, and is carried off by the drains in their furrows (d, d), to the main drains (e, e), and to the brook at different places (f, f). There are bridges (g) over the main federes, small arches over the main discharging drains (h), and three hatches (i).

4411. As an example of catch-work watering, we may refer to a case (fg, 681), given in a recent work

by John Brown. (Treatise on Irrigation, 1817.) In this the field of operations being on the steep side of a hill, a main carrier is led from the sluice (a), directly across the declivity (b), and lateral feeders (c) taken out from it at regular distances. These feeders have stops of turf, at regular distances (d), by which means the water is dispersed. After watering a space of from twenty to forty feet in breadth, it is again collected by the small drains in the furrows, and returned lower down to another feeder. The advantage of this method, Browne observes, "relates more materially to the sides of hills, and to porous soils that are by some thought incapable of being watered. The chief point is to get the water to the highest level possible; and in case the soil be porous, one main carrier only will require puddling, in order to prevent the water from sinking away: when that is done, no difficulty whatever is found in taking it in small streams vertically, or directly down the slope (c), and putting stops (d) to arrest its progress occasionally, which will throw it on each side; and when those stops are placed on above another, it will have the effect of spreading the water on the land, somewhat similar to a fan when extended. The stops need only be sods or turfs, one laid lengthways in the gutter, and one across it, which may be raised or lowered according to the declivity: these sods or turfs will require probably a small wooden peg to fasten them at first; and by the time the land requires a second watering, the roots of the grass will have sufficiently fastened them; and they need not be removed, unless occasionally for the purpose of watering any separate part below, when the stream may be too small to water the whole piece at once; and the small cuts for conveying the water will be less expensive in cleaning, not being so liable to choke up as

those carried on what is termed horizontal or level gutters. In some places in Essex, it is the practice to irrigate during winter by means of the water of occasional floods. Sometimes this water is obtained from the ditches along the sides of the roads, and from the drainages of villages; and in these cases is more or

the ditches along the sides of the roads, and from the drainages of vinages; and in these cases is more or less enriched by earthy materials.

4442. As an example of the benefit of flooding, we refer to Loch Ken, in Kircudbrightshire, the most striking instance known in Great Britain of advantage being derived from the initiadations of a lake. At the head of that beautiful piece of water, there is a flat of about £40 statute acres, which is rendered, by flooding, one of the richest spots in Scotland. Many acres in it produce at the rate of three tons of hay each, and some parts of it have been eropped with grain for twenty-five years in succession, without any manure, except what it receives from the inundations it experiences. These, however, leave behind them a variety of enriching substances. (Statistical Account of Scotland, vol. iv. p. 260.)

The ancient and now obsolete practice of flooding, or, as 4443. Floating upwards. it was termed, of floating upwards, was practised in various parts of the kingdom. For that purpose, the water was penned, in times of floods, by means of a dam or floodgate across the bottom of the meadow or flat to be watered. The waters were not suffered to remain long upon the land, but were let off as soon as it was judged that they had deposited their sediment. The benefit arising from this method of using floodwaters, it is said, was considerable; but when the improved mode of irrigation by floating ridges was introduced, and found more advantageous, the other was discontinued. (Marshal's Midland Counties, Minute 27.)

4444. Watering land by machinery. If the land be put in a proper form for irrigation, and supplied with a good stream at proper seasons, there can be no difference from the method of getting it on the surface; and if all other circumstances are equally favourable, the same fertility may be expected from water thrown up by a drain-mill, as from that which runs from a brook. (Smith's Observations on Water Meadows, &c. p. 93.) A cheap and effectual power for raising water in sufficient quantities to flow about ten acres at a time, would be an invaluable acquisition; for a productive water meadow is probably the true mark of perfection in the management of a farm. (Middlesex Report, p. 322.)

4445. Sea water. Smith suggests the idea of employing machinery to raise not only fresh but even sea water for irrigation. (Observations, p. 87.) It is well known how much all kinds of stock are improved by salt marshes, and how beneficial to them is a moderate quantity of saline matter. There are many parts of the kingdom where, by the aid of machinery, these advantages might be obtained at a moderate expense.

(Code.)

4446. The expense of irrigation varies according to the nature of the work. Where the catch-work system is practicable, in favourable situations, the forming may be done as low as ten shillings per acre. This fact is, in many cases, decisively in favour of this natural and simple mode, which requires also much less water, and often answers fully as well as flat flooding. (General Report, vol. ii. p. 598.) The expense of bed-work, as it is called, is, however, considerable. If the ground to be flooded be smooth on its surface, or in regular ridges, and if the water can easily be brought to the meadow, with a temporary wear, supposing the extent to be almost twenty acres, it may be done at from 51. to 101. per acre: but if the land be of large extent, with an irregular surface; if a large conductor and a proper wear shall be required, with hatches both in it and also in the feeders; and if the aid of a professional person, to lay out and oversee the work, be necessary (which is generally the case), the expense will vary from 10l. to 20l. per acre. (General Report, vol. ii. p. 598.) Nay, in Wiltshire, where they are anxious to have their meadows formed in the most perfect manner, with that regularity which the nice adjustment of water demands, the expense per acre has amounted to 40%. Observations on Irrigation, p. 56.)

4447. Objections to irrigation have been made on the supposition that it renders a country unhealthy; but as the water is continually kept in motion, this is not likely to be the case, and indeed is found not to be so in Gloucestershire, Lombardy, and other places where it is extensively practised. It is also thought that though the produce may be increased, it becomes in a few years of so coarse a nature, mixed with rushes and water plants, that cattle frequently refuse to eat it; and when they do, their appearance proclaims that it is far from being of a nutritious quality. (Rutland Report, p. 114.) But this objection is never applicable to meadows skilfully made and properly managed; and whenever the grasses are coarse, if intended for hay, they should be cut earlier. Rushes and water plants are proofs that the meadow lies too flat and is ill managed.

(Code.)

4448. The principal impediments to irrigation are the claims of different individuals on one stream, as millers, canal owners, &c.; the intermixture of property and interests;

and the existence in some cases of adverse leases.

4449. The formation and arrangement of surfaces for irrigation, however simple in principle, is in practice one of the most difficult operations of agricultural improvement. Whoever, therefore, contemplates extensive and intricate works of this kind will find it desirable to call in the assistance of a professor and contractor of reputation. In Gloucestershire there are a class of men known as "flooders," who have under them a company of men accustomed to every part of the work, and who accompany their chief to execute works in any part of the country.

SECT. II. Warping, or the Improvement of Land by muddy Water.

4450. Warping is a mode of fertilising lands by depositing a coat of mud on their surface. This may be practised on the borders of large rivers and estuaries into which sea tides flow, or where floods are frequent; provided, however, that in either case the waters contain alluvial matters in a state of suspension. According to the best information that can be obtained (Marshal, in R. Econ. of York., 1788. Day, West Riding Report, p. 171.), warping was first practised on the banks of the Humber, by one Barker, a small farmer at Rawcliff, between 1730 and 1740: it was afterwards extended by Richard Jennings, of Armin, near Howden, in 1743; but, till about the year 1753, it was not attempted by any other person. It was first brought into notice by Marshal, in 1788, and subsequently in the Report of the West Riding of Yorkshire, and is now practised by various proprietors and farmers on the Humber, the Trent, and other rivers. It has been long practised in Italy in a manner something different from that employed in this country. It may be considered as of Egyptian origin.

4451. The theory of warping is thus given by Arthur Young: -

4452. The water of the tides that come up the Trent, Ouse, Dun, and other rivers which empty themselves into the great estuary of the Humber, is muddy to an excess; insomuch that in summer, if a cylindrical glass, twelve or fifteen inches long, be filled with them, it will presently deposit an inch, and sometimes more, of what is called warp. Where this warp comes from is a dispute: the Humber, at its mouth, is clear water; and no floods in the countries washed by the warp rivers bring it, but, on the contrary, do much mischief by spoiling the warp. In the very driest seasons and longest droughts, it is best and most plentiful. The improvement is perfectly simple, and consists in nothing more than letting in the tide at high water, to deposit the warp, and permitting it to run off again as the tide falls: this is the aim and effect: but to render it efficacious, the water must be at command, to keep it out and let it in at pleasure; so that there must not only be a cut or canal made to join the river, but a sluice at the mouth to open or shut, as wanted; and, that the water may be of a proper depth on the land to be warped, and also prevented from flowing over contiguous lands, whether cultivated or not, banks are raised around the fields to be warped, from three or four to six or seven feet high, according to circumstances. Thus, if the tract be large, the canal which takes the water, and which, as in irrigation, might be called the grand carrier, may be made several miles long: it has been tried as far as four, so as to warp the lands on each side the whole way, and lateral cuts made in any direction for the same purpose; observing, however, that the effect lessens as you recede from the river; that is, it demands longer time to deposit warp enough for producing benefit.

4453. The effect of warping is very different from that of irrigation: for it is not the water that works the effect, but the mud; so that in floods and in winter the business ceases; and it is not the object to manure the soil, but to create it. The nature of the land intended to be warped is not of the smallest consequence: bog, clay, sand, and peat, are alike eligible; as the warp raises it in one summer from six to sixteen inches thick, and in the hollows or low places, two, three, or four feet, so as to leave the whole piece level. Thus a soil of any depth you please is formed, which consists of mud of a vast fertility, though containing not much besides sand and gravel.

4454. The method of executing the work is described in the following manner by Lord Hawke, in The Agricultural Survey of the West Riding of Yorkshire: —

Hawke, in The Agricultural Survey of the West Riding of Yorkshire: —

4455. The land to be warped must be banked round against the river. The banks are made of the earth taken on the spot from the land: they must slope six feet; that is, three feet on each side of the top or crown of the bank, for every foot perpendicular of rise: their top or crown is broader or narrower, according to the impetuosity of the tide, and the weight and quantity of water; and it extends from two feet to twelve: their height is regulated by the height to which the spring tides flow, so as to exclude or let them in at pleasure. In these banks, there are more or fewer openings, according to the size of the ground to be warped, and to the choice of the occupier; but in general they have only two sluices; one called the floodgate, to admit, the other, called the clough, to let off, the water gently: these are enough for ten or fifteen acres. When the spring tide begins to ebb, the floodgate is opened to admit the tide, the clough having been previously shut by the weight of the water brought up the river by the flow of the tide. As the tide ebbs down the river, the weight or pressure of water being taken from the outside of the clough next the river, the tide water that has been previously admitted by the floodgate opens the clough again, and discharges itself slowly but completely through it. The cloughs are walled on each side, and so constructed as to let the water run off, between the ebb of the tide admitted and the flow of the next; and to this point particular attention is paid. The floodgates are placed so high as only to let in the spring tides when opened: they are placed above the level of the common tides. Willows are also occasionally planted on the front of the banks, to break the force of the tides, and defend the banks by raising the front of them with warp thus collected and accumulated; but these willows must never be planted on the banks, as they would destroy them by giving the winds power to shake them.

4456. The season for warping begins in the month of July, and continues during the summer; and as this sort of business can only be performed at that season, every occasion of having it executed should be embraced, by having the work in perfect repair, that every tide may be made to produce its full effect. With regard to the advantage of doing this work in the summer months, it may be remarked that at these times the lands not only become the soonest dry, a circumstance which must always fully take place before the process of cultivation can be carried on; but the tides are less mixed with fresh water, in which condition they are constantly found the most effectual.

4457. The expense of this mode of improving lands must differ much in different cases, according as the circumstances of situation and distance vary; but it can seldom exceed

12l. or 15l. the acre, according to Young, and in most instances it must be greatly below such estimates.

such estimates.

4458. That no estimate can be made without viewing the situation of the lands to be warped, and the course and distance it will be necessary to carry the warp to such lands, is remarked by Day, in the Agricultural Survey of the same district 1st, The situation of the lands must be considered; 2d, The quantity of land the same drains and cloughs will be sufficient to warp; 3d, The expense of building the cloughs, cutting the drains, embanking the lands, &c. An estimate of these expenses being made, it will then be necessary to know the number of acrees such cloughs and drains will warp, before any estimate can be made; as the greater the quantity of land the same cloughs and drains will warp, the lighter the expense will be per acre. In Day's opinion, there is a great deal of land in the country capable of being warped at so small an expense as from 4t, to 8t, per acre, which is nothing in comparison to the advantages which arise from it. He has known land raised in value by warping, from 5t, to upwards of 40t, and 50t, per acre. The greatest advantages arise upon the worst land, and the more porous the soil the better, as the wet filters through, and it sooner becomes fit for use. The advantages of warping are very great; as, after lands have been properly warped, they are so enriched thereby that they will bring very large crops for several years afterwards without any manure; and, when it is necessary, the lands might be warped again, at a very trifling expense, by opening the old drains, and would bring crops in succession for many years, with very little or no tillage at all, if the lands were kept free from quick grass and other weeds, which must be the case in all properly managed lands; besides, the drains which are made for the purpose of warping, which is another very great advantage in low lands.

4459. The best mode of cultivating new-warped land must depend principally on the nature of the warp and of the subsoil. In the Code of Agriculture it is recommended to sow it with clover, and to let it lie under that crop for two years, in order that it may be brought into a state fit for corn. Even though fallowed, it does not answer to sow land with wheat immediately after it is warped; but after white or red clover for two years, a good crop of wheat may generally be relied on. Nor is it proper, when land is warped, to plant it with potatoes, or to sow it with flax, being at first of too cold a nature; though, if the land be not too strong for potatoes, these crops may answer, after it has been for two or three years in cultivation. In the quality of warped land, there are most essential differences; some will be very strong, and in the same field some will be very friable. The land nearest the drain is in general the lightest, owing to the quantity of sand that is deposited as soon as the water enters the field: the land farthest from the drain is in general the best. The produce of warped land varies much, but in general it may be stated as abundant. (Code, 315.)

Subsect. 1. Irrigation of Arable Lands, and Subterraneous Irrigation.

4460. The irrigation of arable lands is universal in warm countries, and even in the south of France and Italy. The land is laid into narrow beds, between which the water is introduced in furrows during the growth of the crop, and absorbed by the soil. In other cases the crop is grown in drills, and the water introduced in the furrow between each row. In this mode of irrigation no collecting drains are required, as the whole of the water laid on is absorbed by the soil. The principal expense of the operation is that of preparing the lands by throwing the surface into a proper level or levels. The main or carrier is conducted to the higher part of the field, and the rest is easy. A particular description of the practice, as carried on in Tuscany, is given by Sigismondi. (Agr. de la Toscane.) Some account also of the practice in Italy and the East Indies will be found in our outline of the agriculture of these countries. (267 and 921.) In the General Report of Scotland, vol. iii. p. 361. it is stated, that a field of waste land, which had been flooded during winter with stagnant water, was thus, without manure, rendered capable of yielding a good crop of oats; but this is more of the nature of warping than of that description of irrigation which is practised in warm countries on arable lands, during the growth of the crop.

4461. Subterraneous irrigation appears to have been first practised in Lombardy, and first treated of by Professor Thouin. (Annales du Musée, &c.) It consists in saturating a soil with water from below, instead of from the surface, and is effected by surrounding a piece of ground by an open drain or main, and intersecting it by covered drains communicating with this main. If the field is on a level, as in most cases where the practice is adopted in Lombardy, nothing is more necessary than to fill the main, and keep it full till the lands have been sufficiently soaked; but if it lies on a slope, then the lower ends of the drains must be closely stopped, and the water admitted only into the main on the upper side: this main must be kept full till the land is soaked, when the mouths of the lower drains may be opened to carry off the superfluous water. The

practice is applicable either to pasture or arable lands.

4462. In Britain, subterraneous irrigation has been applied in a very simple manner to drained bogs and morasses, and to fen lands. All that is necessary is to build a sluice in the lower part of the main drain where it quits the drained grounds, and in dry weather to shut down this sluice, so as to dam up the water and throw it back into all the minor open drains, and also into the covered drains. This plan has been adopted with success, first, as we believe, by Smith, of Swineridge Muir, in Ayrshire, and subsequently by Johnston, in the case of several bog drainages executed by him in Scotland.

It is also practised in Lincolnshire, where it was introduced by the advice of the late engineer Rennie, after the completion of a public drainage at Boston.

Sect. III. Artificial Means of Procuring Water for the Use of Live Stock.

4463. Water is supplied by nature in most parts of the British isles, and retained with little art both at farmeries and in fields. There are exceptions, however, in different districts, and especially in chalky soils, gravels, and some upland clays. In these cases water is procured for cattle by some of the following means:—By conducting a stream from a distant source, as in a work of irrigation; by collecting rain-water from roads, ditches, or sloping surfaces, in artificial ponds, or reservoirs; by collecting it from the roofs of buildings, and preserving it in covered cisterns; by sinking a well, or a pipe,

either in the field or the farm-yard; and by artificial springs.

4464. An artificial stream will in most cases be found too expensive an operation to be undertaken for the supply of drinking-water for live stock; but this purpose may frequently be combined with that of watering lands or driving machinery. North Riding of Yorkshire, there is a tract extending for many miles entirely destitute of water, except what flows along the bottoms of the deep valleys by which it is intersected; and little relief could consequently be afforded, by streams thus distantly and inconveniently situated, to the inhabitants of the uplands, or their cattle. About the year 1770, a person of the name of Ford devised the means of watering this district, by means of rills brought from the springs that break out at the foot of the still loftier moorland hills that run parallel to, and to the north of, this tract, in some instances at the distance of about ten miles. The springs he collected into one channel, which he carried, in a winding direction, about the intervening space, according to its level, and along the sides of the valleys, until he gained the summit of the arid country which he wished to supply with water; and when this was accomplished, the water was easily conveyed to the places desired, and also to the ponds in all the fields, over a considerable tract of ground.

4465. Collecting rain-water from roads, &c. in ponds or drinking pools. Formerly, it is probable, something of this art was practised throughout the kingdom: most villages, and many old farmsteads, have drinking pools for stock, which appear to have been formed or assisted by art. In strong-land grazing districts, pits have evidently been dug, to catch the rain-water fortuitously collected by furrows and ditches, or by landsprings. On the chalk hills of the southern counties, the art has been long esta-

blished, and continued down to the present time.

4466. An improved practice was introduced on the wolds or chalk hills of Yorkshire by Robert Gardner, of Kilham, which gained an establishment towards the end of the last century, and has spread rapidly over the adjacent heights, with great profit to the country. In every dry-land situation, it may be practised with high advantage to an estate, and is well entitled to attention.

4467. The mode of constructing these collecting ponds is described in The Annals of Agriculture (vol. vi.), and illustrated by a section. (fig. 688.) The ground plan is circular, and generally forty or fifty feet in

diameter, and the excavation is not made deeper in the centre than five feet. This

deeper in the centre than five feet. This excavation being cleared out, a layer of clay (a, b, c) sufficiently moistened, is to be carefully beaten and trod down into a compact and solid body of about the thickness, is finely and uniformly spread. Next is another layer of clay of about one foot in thickness (a), which is to be trodden and rammed down as the former. Upon this are spread stones or coarse gravel (e), of such thickness as may prevent the pond receiving any injury from the treading of cattle, which would otherwise break through the body of the clay and lime, and by so doing let out the water. After this, the pond will remain five feet deep and forty-five feet in diameter; the size they are usually made.

4468. Brick-clay is by no means required for the ponds; any earth sufficiently tenacious to bear beating into a solid compact body, though not approaching to a pure clay, will answer the purpose very well.

well

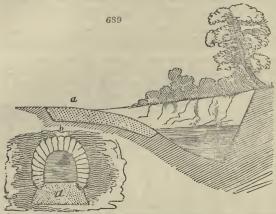

well.

449. The preferable situation to make the pond is a little valley, or at the bottom of a declivity, or near a high road, in which situation a stream of water may be brought into it after sudden showers or thaws, the object being to get it filled as soon as possible after it is made, that the sun and winds may not crack the clay. If it is not likely to be filled soon, some straw or litter must be spread over it; but in general, after it is once filled, the rains that fall in the course of the year will keep it full, no water being lost otherwise than by evaporation and the consumption of cattle.

4470. The whole execulence of the pond depends upon the time: care must be taken to spread it regularly and uniformly over the surface of the lower bed of clay. It is well known that ponds made of clay alone, however good its quality, and whatever care may be bestowed in the execution, will requently not hold water: these, with the above precautions, rarely fail. By what means the lime prevents the loss of water is not exactly known: one of these two is probably the cause: either the lime prevents the loss of water is not exactly known: one of these two is probably the cause: either the lime prevents the loss of water the clay in search of the water: certain, however, it is, that, with lime thus applied, ponds may be made in sand, however porous, or on rocks, however open, in neither of which situations are they to be depended upon when made with clay alone. On this mode of making ponds for the use of live stock, there are several circumstances of the process more fully detailed in The Rural Economy of Yorkshire.

4471. In constructing ponds in loamy soils, all that is necessary is to coat the bottom over with clay or loam to the depth of eighteen inches or two feet, and then to puddle or work this well with water till it becomes a homogeneous layer impenetrable to that element. If clay or loamy earth cannot be obtained, any earth not very much inclined to sand may be substituted, but it will require more labour

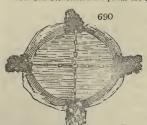

On clayer soils very little more is necessary than smoothing the surface of the excavation, and perhaps watering it and beating it to a smooth surface with rammers. The pond being now formed, the next operation is to coat it over with coarse gravel to the depth of at least eighteen inches; or, what is preferable, chalk and flints with gravel; or, best of all, to causeway or pave it. It is also very desirable

to pave or gravel the sur-face for the breadth of at least two yards round the pond, in order to prevent the cattle from poaching it

when they come to drink.

4472. On clayey soils an
economical mode of forming ponds is often adopted, where gravel or stone for paving is scarce. It consists in employing the horse-shoe form as the ground plan of the excavation, and cutting all the sides steep, or at an angle of 45 or 50 degrees, except the part answering to the heel of the shoe (fig. 689 a), which is well gravelled or paved, as the only entrance for the cattle. The extrance for the cattle. cavated earth serves to raise the high side of the pond (b) which is generally guarded by a fence, or a few trees. The disadvantage of such ponds is, that one is required for every field, or at least for every two fields;

whereas a pond sloped on all sides may supply four fields, or even a greater number. (fig. 690.)

4473. The Gloucestershire ponds are made either of a square or a circular shape, and generally so situated as to furnish a supply to four fields. (fig. 690.) Three layers of clay, free from the smallest stone or gravel, are so worked in as to form an impenetrable cement. The whole is afterwards covered with sand, and finished with pavement. (Gloucestershire

covered with sand, and finished with pavement. (Gloucesterskire Report, p. 31)
474. The Derbyshire artificial meers, or cattle ponds, are made in their dry rocky pastures, with great success. Having selected a low situation for the purpose, they form an excavation ten or twenty yards across, and spread over the whole a layer, about five inches thick, of refuse slaked lime and coal cinders; then they spread, trample, and ram down a stratum of well tempered clay, about four inches thick; and upon this they spread a second bed of clay, in a similar manner, of the same thickness; the whole of the bottom and edges of the meer is then paved with rubble stones; and small rubble stones, several inches thick, are spread upon the pavement. (Derbyshire Report, vol. i. p. 494.)
4475. The situation of field ponds, where practicable, should be at the intersection of fences, so that one may serve as many fields are best situation in every case, because it may happen that water

This, however, cannot be the best situation in every case, because it may happen that water be collected. At the same time a low situation is not always desirable, because it may be so

cannot there be collected.

cannot there be collected. At the same time a low situation is not always desirable, because it may neso circumstanced that too much dirty water may run into it during rains.

4476. Trees are frequently planted round ponds, and with seeming propriety, as their effect is beautiful, and they shade the water from the direct influence of the sun during summer; but in autumn their leaves certainly tend to render the water impure for a time. As most leaves are of an astringent quality, perhaps there may be no injury sustained by cattle from drinking such water at first; but after some time the leaves begin to decay, and occasion a sort of fermentation, which, till it subsides in the beginning of frosty weather, renders the water somewhat unhealthy and very unsightly. Leaves therefore ought to be drawn off with long open rakes as they fall from the trees.

Wells, where no better method of procuring water can be devised, may be resorted to, both for fields and farmeries; but the great objection to them is the labour required to pump up or otherwise raise the water, and the consequent risk of neglect. Before proceeding to dig a well, it ought first to be determined on whether a mere reservoir for the water which oozes out of the surface soil is desired or obtainable, or a perpetual spring. If the former is the object in view, a depth of fifteen or twenty feet may probably suffice, though this cannot be expected to afford a constant supply, unless a watery vein or spring is hit on: if the latter, the depth may be very various, there being instances of 300 and 500 feet having been cut through before a permanent supply of water was found. (Middlesex, Surrey, and Hampshire Reports.)

was found. (Muddlesex, Surrey, and Hampshire Reports.)

4478. The art of well-digging is generally carried on by persons who devote themselves exclusively to that department. The site being fixed on, the ground-plan is a circle, generally of not more than six or eight feet in diameter: the digger then works down by means of a small short-handled spade, and a small implement of the pick-axe kind; the earthy materials being drawn up in buckets by the hand or a wind-lass, fixed over the opening for the purpose. Where persons conversant with this sort of business are employed, they usually manage the whole of the work, bricking round the sides with great facility and readiness; but in other cases it will be necessary to have a bricklayer to execute this part of the business. 4479. Steining. There are two methods of building the stone or brick within the well, which is called the steining. In one of these a circular ring is formed, of the same diameter as the intended well; and the timber of which it is composed is of the size of the brick-courses with which the well is to be lined. The lower edge of this circle is made sharp, and shod with iron, so that it has a tendency to cut into the ground; this circular curb is placed flat upon the ground, and the bricks are built upon it to a considerable height, like a circular wall. The well-digger gets within this circle, and digs away the earth at the bottom; the weight of the wall then forces the kirb and the brick-work with which it is loaded to descend into the earth, and as fast as the earth is removed it sinks deeper, the circular brick wall being increased or raised at top as fast as it sinks down; but when it gets very deep, it will sink no longer, particularly if

it passes through soft strata; in this case, a second kirb of a smaller size is sometimes begun within the first. When a kirb will not sink from the softness of the strata, or when it is required to stop out water, the bricks or stones must be laid one by one at the bottom of the work, taking care that the work is not left unsupported in such a manner as to let the bricks fall as they are laid: this is called under-pinning.

480. Noxious air. Well-diggers experience sometimes great difficulty from a noxious air which fighs the well, and suffocates them if they breathe it. The usual mode of clearing wells of noxious air is, by means of a large pair of bellows, and a long leathern pipe, which is hung down into the well to the bottom and free his torsed down by working the hellows.

and fresh air forced down by working the bellows.

481. The use of the auger is common in well-digging, both in ascertaining before commencement the nature of the strata to be dug into, and also in course of digging for the same purpose; and because, by boring in the bottom of a well to a considerable depth, the spring is sometimes hit upon, and digging ren-

boring in the bottom of a well to a considerable depth, the spring is sometimes hit upon, and digging rendered no longer necessary.

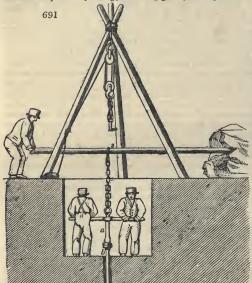

483. The use of the borer alone may procure an adequate supply of water in particular situations. This mode appears to have been long resorted to in this and other countries. From what we have already stated as to the disposition of strata, the conditions requisite for its success will be readily conceived; viz. watery strata connected with others on a higher level: the pressure of the water contained in the higher parts of such strata on that in the lower will readily force up the latter through any orifice, however small. All that is necessary, therefore, is to bore down to the stratum containing the water, and, having completed the bore, to insert a pipe, which may either be left to overflow into a cistern, or it may terminate in a pump. In many cases, water may be found in this way, and yet not in sufficient quantity and force to rise to the surface; in such cases a well may be sunk to a certain depth, and the auger-hole made, and the pipe inserted in it in the bottom of the well. From the bottom it may be pumped up to the surface by any of the usual modes. the surface by any of the usual modes

the surface by any of the usual modes.

4483. As an example of well-digging combined with boring, we give that of a well dug at a brewery at Chelsea, Middlesex, in 1793. The situation was within 20 or 30 feet of the edge of the Thames, and the depth 394 feet, mostly through a blue clay or marl. At the depth of nearly fifty feet a quantity of loose coal, twelve inches in thickness, was discovered: and a little sand and gravel was found about the same depth. The well-digger usually bored about ten, fifteen, or twenty feet at a time lower than his work as he went on; and on the last boring, when the rod was about fifteen feet below the bottom of the well, the man felt, as the first signal of water, a rolling motion, something like the gentle motion of a coach passing over pavement: upon his continuing to bore, the water presently pushed its way by the side of the auger with great force, scarcely allowing him time to withdraw the borer, put that and his other tools into the bucket, and be drawn up to the top of the well. The water soon rose to the height of two hundred feet. 4434. In a case which occurred in digging a well at Dr. Darwin's, near Derby, the water rose so much higher than the surface of the ground, that, by confining it in a tube, he raised it to the upper part of the house. (Rees's Cyclopædia, at. Well, and Derbyshire Rep.)

4485. The process of boring the earth for spring water has of late been practised, with great success, in various parts of England, chiefly by a person named Goode, of Hunt-In the neighbourhood of London, many fountains of pure spring-water have lately been obtained by these means. We may particularly name those at Tottenham, Middlesex, and Mitcham, Surrey, both of which afford a continuous and abundant flow of water, at one time equal to about eight gallons per minute, but now reduced to a much smaller quantity, in consequence of the great number of holes that have been bored into the supplying strata.

4486. The operation of boring for water (fig. 691.) is thus performed: - The situation of the intended well

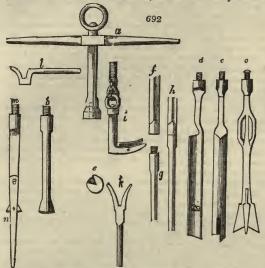

being determined on, a circular hole is generally dug in the ground, about six or eight feet deep, and five or six feet wide. In the centre of this hole, the wide. In the centre of this hole, the boring is carried on by two workmen, assisted by a labourer above. (fig. 691.) The implements used may either be those of Goode, already described (§ 2507.) as the best, or any other instruments in repute. For variety's sake, we shall here describe the process by the instruments formerly in most general use about London. most general use about London. The handle (fig. 691. a) having a female screw in the bottom of its iron shank, a wooden bar or rail passing through the socket of the shank, and a ring at top, is the general agent, to which all the boring implements are to be attached. A chisel (b) is first employed, and connected to this handle by its screw at top. If the ground is tolerably soft, the weight of the two workmen, bearing upon the cross-bar and occasionally forcing it round, will soon cause the chisel to penetrate; but if the ground is hard or strong, the workmen strike the chisel down with repeated blows, so as to pick their way, often changing their situation by walking round, which breaks the stone, or other hard substances, that may happen to obstruct its progress.

4487. The labour is very considerably reduced by means of an elastic wooden pole placed

horizontally over the well, from which a chain is brought down, and attached to the ring of the handle. This pole is usually made fast at one end as a fulcrum, by being set into a heap of heavy loose stones; at the other end the labourer gives it a slight up and down vibrating motion, corresponding to the beating motion of the workmen below,

by which means the elasticity of the pole in rising lifts the handle and picker, and thereby very considerably diminishes the labour of the workmen.

4488. When the hole has been thus opened by a chisel, as far as its length would permit, the chisel is withdrawn, and a sort of cylindrical auger (c) attached to the

handle (a), for the purpose of drawing up the or broken stones, which have been disturbed by the chisel. A section of this auger (d) shows the internal valve. The auger being introduced into the hole, and turned round by the workmen, the dirt or broken stones will pass through the aperture at bottom (shown at e), and fill the cylinder, which is then drawn up, and discharged at the top of the auger, the valve preventing its escape at bottom.

4489. In order to penetrate deeper into the ground, an iron rod (f) is now to be attached to the chisel (b), by screwing on to its upper end, and the rod is also fastened to the handle (a), by screwing into

The chisel, having thus become lengthened by the addition of the rod, is its socket. again introduced into the hole, and the operation of picking or forcing it down is carried on by the workmen as before. When the ground has been thus perforated, as far as the chisel and its rod will reach, they must be withdrawn, in order again to introduce the auger (c), to collect and bring up the rubbish, which is done by attaching it to the iron rod, in place of the chisel. Thus, as the hole becomes deepened, other lengths of iron rods are added, by connecting them together (f and g when joined form h). necessity of frequently withdrawing the rods from the hole, in order to collect the mud, stones, or rubbish, and the great friction produced by the rubbing of the tools against its sides, as well as the lengths of rods augmenting in the progress of the operation, sometimes to the extent of several hundred feet, render it extremely inconvenient, if not impossible, to raise them by hand. A tripedal standard is therefore generally constructed, by three scaffolding poles tied together, over the hole (fig. 691.), from the centre of thich a wheel and axle, or a pair of pulley blocks, are suspended, for the purpose of hauling up the rods, and from which hangs a forked hook (i). This forked hook is to be brought down under the shoulder, near the top of each rod, and made fast to it by passing a pin through two little holes in the claws. The rods are thus drawn up, about seven feet at a time, which is the usual distance between each joint, and at every haul a fork (k) is laid horizontally over the hole, with the shoulders of the lower rod resting between its claws, by which means the rods are prevented from sinking down into the hole again, while the upper length is unscrewed and removed. In attaching and detaching these lengths of rod, a wrench (1) is employed, by which they are turned round, and the screws forced up to their firm bearing.

4490. The boring is sometimes performed for the first sixty or a hundred feet, by a chisel of two and a half inches wide, and cleared out by a gouge of two and a quarter diameter, and then the hole is widened by another tool (m). This is merely a chisel, four inches wide, but with a guide (n) put on at its lower part, for the purpose of keeping it in a perpendicular direction; the lower part is not intended to pick, but to pass down the hole previously made, while the sides of the chisel operate in enlarging the hole to four inches. The process, however, is generally performed at one operation, by a chisel four inches wide (b), and a gouge of three inches and three quarters (c).

4491. Placing and displacing the lengths of rod is done every time that the auger is required to be introduced or withdrawn; and it is obvious that this must of itself be extremely troublesome, independently of the labour of boring; but yet the operation proceeds, when no unpropitious circumstances attend it, with a facility almost incredible. Sometimes, however, rocks intercept the way, which require great labour to penetrate, but this is always effected by picking, which slowly pulverises the stone. The most

unpleasant circumstance attendant upon this business is, the occasional breaking of a rod in the hole, which sometimes creates a delay of many days, and an incalculable

labour in drawing up the lower portion.

4492. When the water is obtained in such quantities and of such quality as may be required, the hole is dressed or finished by passing down it the diamond chisel (o): this is to make the side smooth previously to putting in the pipe. This chisel is attached to rods, and to the handle, as before described; and in its descent the workmen continually walk round, by which the hole is made smooth and cylindrical. In the progress of the boring, frequent veins of water are passed through; but as these are small streams, and perhaps impregnated with mineral substances, the operation is carried on until an aperture is made into a main spring, which will flow up to the surface of the earth. This must, of course, depend upon the level of its source, which, if in a neighbouring hill, will frequently cause the water to rise up and produce a continued fountain. But if the altitude of the distant spring happens to be below the level of the surface of the ground where the boring is effected, it sometimes happens that a well of considerable capacity is obliged to be dug down to that level, in order to form a reservoir, into which the water may flow, and from which it must be raised by a pump: while, in the former instance, a continued fountain may be obtained. Hence, it will always be a matter of doubt, in level countries, whether water can be procured which would flow near to or over the surface: if this cannot be effected, the process of boring will be of little or no advantage, except as an experiment to ascertain the fact.

4493. In order to keep the strata pure and uncontaminated with mineral springs, the hole is cased for a considerable depth with a metallic pipe, about a quarter of an inch smaller than the bore. This is generally made of tin (though sometimes of copper or

lead), in convenient lengths; and as each length is let down, it is held by a shoulder resting in a fork, while another length is soldered to it, by which means a continued pipe is carried through the bore as far as may be found necessary, to exclude land-springs, and to prevent loose earth or sand from falling in and choking the aperture. (Newton's Journal, vol. vi. p. 146.)

4494. The manner of forcing down lengths of cast-iron pipe, after the bore is formed, is this: —The pipe (fig. 693. a) has a socket in its upper end, in which a 693 block of wood (b) is inserted. From this block a rod (c) extends upwards, upon which a weight (d) slides. To the weight (d) cords are attached, reaching to the top of the bore, where the workman al-

attached, reaching to the top of the bore, where the workman alternately raises the weight and lets it fall, which, by striking upon the block (b), beats down the pipe by a succession of strokes; and when one length of pipe has by these means been forced down, another length is introduced into the socket of the former. Another tool for the same purpose (fig. 694.) is formed like an acorn, the point of the acorn strikes against the edge of the pipe, and by that means it is

forced down the bore.

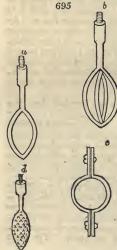

4495. Wrought-iron, copper, tin, and lead pipes, are occasionally used for lining the bore; and as these are subject to bends and bruises, it is necessary to introduce tools

for the purpose of straightening their sides. One of these tools (fig. 695. a) is a bow, and is to be passed down the inside of the pipe, in order to press out any dents. Another tool for the same purpose (b) is a double bow, and may be turned round in the pipe for the purpose of straightening it all the way down. A pair of clams (c) is used for turning the pipe round in the hole while driving.

4496. In raising pipes, it is necessary to introduce a tool

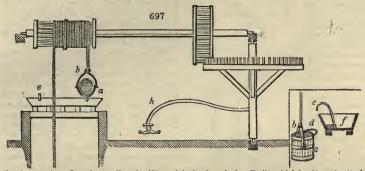

to the inside of the pipe, by which it will be held fast. The pine-apple stool for this purpose (d) has its surface cut like a rasp, which passes easily down into the pipe, but catches as it is drawn up, and by that means brings the pipe with it. There is a spear for the same purpose (fig. 696) which easily enters the pipe by springing; at the ends of its prongs there are forks which stick into the metal as it is drawn up, and thereby raise it.

4497. Mr. Goode suggests the employment of long baskets with valves opening upward in their bottoms, for the purpose of drawing water from these wells when the water will not flow over the surface; also lift-pumps, with a succession of buckets, for the same purpose. (Newton's Journal, vol. viii. p. 249.)

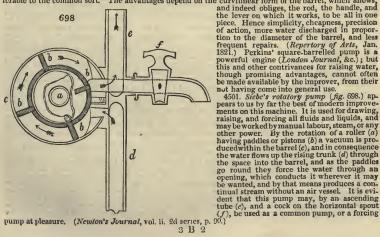

4498. Mommon has invented a new apparatus for guiding the operation of boring, which seems very ingenious; but we are not aware that it has yet been adopted in practice. Engravings, accompanied by a copious description, will be found in the Mechanics' Magazine, vol. iv.; in which work are also various other articles on the same subject.

4499. Of the various modes of raising water from deep wells, the pump is the most convenient, and the ever and bucket the most simple. When a constant supply is wanted from a very deep well, machinery fig. 637.) may be erected over it, and driven by an old horse or ass. While one bucket is filling, the

other is emptying. In order to effect the filling of the bucket, the handle (b), which is of iron, is attached by iron swivel rivets, on which it readily turns, below the centre of gravity of the bucket (c). In order that it may empty itself, a horizontal handle (d) is attached, which, when the filled bucket attains a certain height, is caught by a hook (c) fixed in the trough which conveys away the water raised (f). The horse or ass may be made to work in this machine without the attendance of a man, by the following training:— Attach a bell to the lever of draught (h); use eye-blinders to prevent the animal from seeing whether or not any one is in attendance, and from becoming giddy by going constantly round. Put the animal in motion, and the bell will not stop ringing till he stops. The moment he stops, and the bell ceases to ring, apply the whip severely. Continue to do this every time the animal stops, till the two hours' labour are completed; then unyoke and feed. After one or two hours, or whatever period may be deemed necessary for rest and refreshment, yoke again, and proceed as before. Go on in this way for two days, and the terror of receiving chastisement when the bell ceases to ring, will have frightened the animal into a habit of working two hours at a time without attendance. This mode is practised successfully in France, Italy, and Spain. (Cours, &c. Art. Puit à Roue.)

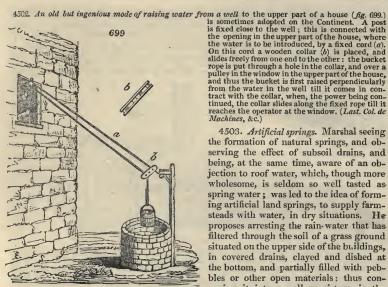

4500. Pamps are of various kinds, as the lifting-pump; the forcing-pump, for very deep wells; the suction pump; and the rotatory pump, a recent invention for such as do not exceed thirty-three feet in depth, and of which there are several varieties, but by far the best is that by Siebe. A good pump for urine pits or reservoirs, where the water is not to be raised above twenty-eight or thirty feet, is that of Robertson Buchanan, author of A Treatise on Heating by Steam, &c.; because this pump will raise drainings of dunglillis, the contents of cesspools, privies, &c., or even water thickened by mud, sand, or gravel. "The points in as is often the case with the common and chain pumps: that the valves are not commed to any particular dimensions, but may be made capable of discharging every thing that can rise in the action-piece without danger of being choked; and that if, upon any occasion, there should happen to be an obstruction in the valves, they are both within the reach of a person's hand, and may be cleared at one, without the disjunction of any part of the pump. It is a simple and durable pump, and may be made either of metal or wood, at a moderate expense." Where clear water only is to be raised, Aust's (of Hoxton) curvilinear pump is preforable to the common sort. The advantages depend on the curvilinear form of the barrel, which allows,

and indeed obliges, the rod, the handle, and the lever on which it works, to be all in one piece. Hence simplicity, cheapness, precision of action, more water discharged in proporof action, more water discharged in propor-tion to the diameter of the barrel, and less frequent repairs. (Repertory of Arts, Jan. 1821.) Perkins' square-barrelled pump is a powerful engine (London Journal, &c.); but this and other contrivances for raising water, though promising advantages, cannot often be made available by the improver, from their

not having come into general use.

4501. Siebe's rotatory pump (fig. 698.) appears to us by far the best of modern improvements on this machine. It is used for drawing, raising, and forcing all fluids and liquids, and raising, and forcing all fluids and liquids, and may be worked by manual labour, steam, or any other power. By the rotation of a roller (a) having paddles or pistons (b) a vactum is produced within the barrel (c), and in consequence the water flows up the rising trunk (a) through the space into the barrel, and as the paddles go round they force the water through an opening, which conducts it wherever it may be wanted, and by that means produces a continual stream without an air vessel. It is evident that this numn may, by an ascending

reaches the operator at the window. (Last. Col. de Machines, &c.)

4503. Artificial springs. Marshal seeing the formation of natural springs, and observing the effect of subsoil drains, and being, at the same time, aware of an objection to roof water, which, though more wholesome, is seldom so well tasted asspring water; was led to the idea of forming artificial land springs, to supply farmsteads with water, in dry situations. He proposes arresting the rain-water that has filtered through the soil of a grass ground situated on the upper side of the buildings, in covered drains, clayed and dished at the bottom, and partially filled with pebbles or other open materials: thus conveying it into a well or cistern, in the

manner of roof water: and by this means uniting, it is probable, the palatableness of spring water with the wholesomeness of that which is collected immediately from the atmosphere.

4504. Water for common farm-yard and domestic purposes may be obtained in most situations, by collecting that which falls on the roofs of the farmery and dwelling-house. This is done by a system of gutters and pipes, which, for the farmery, may lead to a cistern or tank under ground; and for the family, that from the roof of the dwelling-house may be conducted to a tub. According to Waistell, a sufficient supply of water has been collected from the roof of a cottage to answer every purpose of the family during the dryest season, by preserving the water so collected in a tank. The quantity of water that falls annually upon every hundred superficial feet, or square of building, is about 1400 gallons. Before using the water so collected, it should be filtered; and it seems very desirable that it should undergo this operation before it enters the tank.

4505. The operation of filtering may be performed in various ways: -

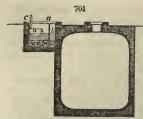

4505. The operation of filtering may be performed in various ways:—

4506. A very simple mode is by having two casks two or three feet high, and of any convenient width (fig. 700.) One of these casks (a) may receive the water from the roof, or from any other supply; the other (b) should have a false bottom (c) perforated with holes and covered with flannel; on this flat bottomed equal quantities of sand and charcoal may be laid to the depth of twelve or fourteen inches, and covered with another false bottom similar to the first (a); the remainder of the cask will contain the filtered water, which may either be awanted by a cock (c), or allowed to pass into an underground tank by the same means. The grosser impurities will always be deposited at the bottom of the filtering tank (b), and these may be drawn off at pleasure by a cock (f), placed immediately above the bottom of the barrel. The sand and charcoal may also be freed from any impurities will descend through the filter and clear it. The advantage of having two barrels for the purpose of filtering the water from a roof is partly to retain a larger quantity, on the supposition that there is not a reservoir or tank under ground, and partly to admit of supplying the first barrel, from ponds or other sources, in seasons when the roof is unproductive. Where the water is to be preserved in a tank under ground, only one barrel (b) is necessary, the pipe from the roof (g) proceeding, in that case, at once to the bottom of the filtering barrel, and entering where, in the case of two barrels, the junction-pipe (b) enters. In all cases of preserving water, whether filtered or unfiltered, it is of great importance to preserve a steady and a low temperature, and for this purpose an underground reservoir is highly desirable.

4507. The best form for a tank, according to Waistell, is a circular plan; the bottom in the form of a flat dome reversed, and the ton also domical, with an opening left in the centre of sufficient size to admit

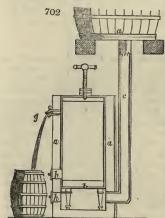

reservoir is highly desirable.

4507. The best form for a tank, according to Waistell, is a circular plan; the bottom in the form of a flat dome reversed, and the top also domical, with an opening left in the centre of sufficient size to admit a man to clean it out occasionally. The tep of this opening should be a little above the surface of the ground, and should be covered with an oak flap, with several holes bored in it for ventilation: or the cover may be an iron grating, horizontal, and a little elevated, or conical. These tanks may be constructed of various dimensions: the depth and width should be nearly equal; a hole should also be left for the service-pipe, or that which conveys the water into the tank, and also for the pipe for the pump, if the water be drawn out by that means. The water may be filtered previously to its entering the tank; the hole for the service-pipe ought, therefore, to be near the top, and on that side most convenient for the filtering chamber; this may be about four feet in diameter, and three feet deep; across this, about twelve

inches from the side next the tank (fig. 701.) a slate partition from the top to within about six inches from the bottom, should be fixed; at the bottom of the box should be put clean coarse sand or pounded charcoal, about a foot in thickness. The pipe or opening from the filter to the reservoir should be of ample dimental than the product of the pr opening from the filter to the reservoir should be or ample dimensions, and be made at about eighteen or twenty inches from the bottom, in the small division or space behind the slate (b). Above this opening, and in any part most convenient (w), in the large division of the filter, should be an opening or drain to carry off the water when the tank is full. This filter should also have a cover,

as often as may be cleaned out, and fresh sand or other purifiers put in as often as may be found requisite. Of course the water as it comes from the roof is to be first conveyed into the large division of the filtering chamber, on the opposite side to the slate partition (c), and passing through the sand it rises in the small division purified, when it is fit to pass into the tank. If there are two or more of these filtering chambers, or if they are of greater depth, the water may be passed through the greater quantity of sand, &c. in them, and be still more purified. Both the tanks and the filters should be water, tight; if constructed of brick, the inner course may be built with Roman cement, and afterwards the whole of the inside covered with a coat of about three quarters of an inch thick. Water, from drains formed in the ground for the purpose of collecting it for domestic purposes, may be purified, by passing it through a sand filter previously to its entering the tank or reservoir. Sponge and flannel may also be used as filters. In constructing tanks of the above description, care must be taken to have the earth to have the earth closely filled around the brick-work, and to allow sufficient time for the work to get properly settled, previously to admitting any great weight of water." (Agricultural Buildings, p. 15.) 4308. Filtering water on a large scale may be effected by emptying one pond into another on a lower level, through a conduit of any kind filled with gravel, sand, and charcoal.

• has been invented, but we are unable to say how far it has succeeded: it, atany rate, will succeed well with fresh water, and, we have no doubt, to a certain extent also with that of the sea. Fig. 702. a a is a cylindrical vessel of wood, or any other suitable material, which is lined on the inside with cement as far as the filterer extends; b is the bottom of the filterer, formed with a grating, which is supported by the rame of a stool; c is a pipe extending from the under part of a cask (a), containing the salt water, and which pipe opens to the lower part of the vessel a a below the filterer. Over the grating (b) there are placed several thicknesses of woven horse-hair, or a quantity of wool, and above this the vessel is filled with sand. On the top of the sand there is a plate (e) like a piston pressing upon the sand and keeping it vessel is filled with sand. On the top of the sand there is a plate (e) like a piston pressing upon the sand and keeping it compact, the plate being held down by a screw (f). The salt water thus delivered from the cask (d) by the pipe (e), fills the lower part of the vessel (a), and by the superincumbent pressure of the column descending from the cask, the water is forced upwards through the mass of sand, and runs off at the cock (g) in a purified state. There are man holes (h, h) for the purpose of getting access to the interior when it is required to remove the sand or other matters, and the internal surface of the filterer is rendered rough in order to prevent the water from sliding up the sides of the vessel, instead of passing through the sand. (Newton's Journal, vol. 1.2d series, p. 158.)

4510. The distillation of palatable water at sea has been effected by P. Nicole, of Dieppe, by simply causing the steam arising from boiling sea water in a still to pass through a stratum of coarsely powdered charcoal, in its way to the con-

stratum of coarsely powdered charcoal, in its way to the condenser, or worm-tub. (Mechanics' Magazine, vol. iv. p. 280.)

paving-stones, are much better than those made of wood, and lined with lead. (Waistell's Agricultural Buildings, p. 15.)

CHAP. IV.

Improvement of Lands lying Waste, so as to fit them for Farm-Culture.

4512. Of waste lands, many descriptions are best improved by planting, and therefore are to be considered as disposed of in that way in the laying out or arrangement of an estate; but there are others which may be more profitably occupied as farm-lands, and it is the preparing or bringing of these into a state of culture, which is the business of the present chapter. Such lands may be classed as mountainous or hilly grounds, rocky or stony surfaces, moors, bogs, or peat-mosses, marshes, woody wastes or wealds, warrens or downs, and sea-shores or beaches. In the improvement of these, many of the operations are such as are performed by temporary occupiers or farmers; but, as in this case such occupiers have always extraordinary encouragement from the landlords, either in the shape of a low rent, of money advanced, of long leases, or of all of these; we consider it preferable to treat of them as permanent, or fundamental improvements, than to consider them as parts of farm-culture. The delusive prospects of profit, from the improvement of wastes, held out by speculative men, have an unhappy tendency to produce disappointment in rash and sanguine adventurers, and ultimately to discourage such attempts as, with judicious attention to economy, would, in all probability, be attended with great Those who are conversant with the publications that have lately appeared on this subject must be aware with what caution the alleged results of most of these writers

ought to be examined; and how different has been the experience of those who have ventured to put their schemes in practice, from what they had been led to anticipate. (Gen. Rep. Scot.)

Sect. I. Mountainous and hilly Grounds and their Improvement.

4513. The upper parts of mountains may be considered as among the least improvable parts of the earth's surface, from the impossibility of ever ameliorating their climate. "The highest peaks and ridges are mostly naked granite, slate, or volcanic productions. Their more elevated sides, and the tops of those of moderate height, are usually covered by a thin soil, producing a short dry herbage, which is frequently mixed with a dwarf, or stunted heath. Where the soil is not injured by moisture, these are best calculated for sheep. When the height of mountains exceed 800 feet of elevation above the level of the sea, unless covered either with natural woods or artificial plantations, they can only be profitably used in pasture." (Code.)

4514. The hills, or lands less elevated than mountains, have, in general, a deeper and moister soil, and produce a more luxuriant herbage, but of a coarse quality; hence they are better adapted for small hardy cattle. Though the summits of hills are generally unfit for raising grain, yet the plough is gradually ascending along their sloping sides, and within the last thirty years many thousand acres in such situations have been re-

claimed in the United Kingdom.

4515. Steep lands along the sides of rivers and small streams are often inaccessible to the plough, and unfit for tillage. The more rugged of these are well calculated for woods or coppice; while those in more favourable situations and climates may be converted into orchards. (Code of Agr. 161.)

SECT. II. Rocky or Stony Surfaces.

4516. Rocky and stony lands are common in the valleys of a hilly or mountainous country, and sometimes, as in Aberdeenshire, they cover immense tracts of flat surface.

4517. When rocks protrude from the surface here and there in fragments of a few tons, and it is considered desirable to render the field or scene fit for aration, the only mode is to rend them asunder by gunpowder, and then carry off the fragments for walls, drains, roads, or buildings; or, if they are not wanted for these or any other purpose, to bury them so deep in the ground as to be out of the reach of the plough. rise in considerable masses of several poles in diameter, it will generally be found preferable to enclose and plant them. Clefts and crevices are found in all rocks which have been long exposed to the air and weather, and in these may be inserted young plants, or seeds, or both. Such masses being enclosed by rough stone walls, formed from the more detached fragments, or from loose stones, will grow up and be at once highly ornamental and useful as shelter. It is true they will interrupt the progress of the plough in a straight line, but not more so than the rock if left in a state of nature. When a rocky surface is not intended to be ploughed, all that is necessary is to remove as many of the solitary rocks as possible, and either enclose and plant the rest, or cover them with

4518. The stones which impede the improvement of land are either loose, thrown up when the land is trenched, or ploughed; or fixed in the earth, and not to be removed without much labour and expense.

4519. Lose stones may often be converted into use for the purpose of forming covered drains, of constructing walls or fences, or of making and repairing the roads on the farm or in the neighbourhood; and, on these accounts, are sometimes worth the trouble of collecting. They may be removed, with the least inconvenience, when the land is fallowed. Where lose stones are of a moderate size, they are sometimes found advantageous rather than detrimental, as in the stone-brash soils of Somersetshire and other districts. They prevent evaporation, and thus preserve moisture in the soil. Hence the old remark, that farmers have been induced to bring back again to their corn-fields those very stones they have been induced to carry off (Code).

tricts. They prevent evaporation, and thus preserve moisture in the soil. Hence the old remark, that farmers have been induced to carry off. (Code.)

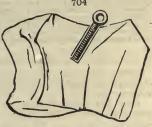

4520. Where stones are large and fixed in the earth, if they appear above the surface, they should be removed before the ploughing of the waste commences; but where they are concealed under the surface, various modes to get rid of them have been adopted. In some parts of Yorkshire, the whole surface is gone over with sharp prongs, which, at the distance of every twelve or fourteen inches, are thrust into the ground to the depth of about a foot, to ascertain where stones are to be met with. The spot is marked by a twig, and the stones are removed before the land is ploughed. Sometimes the plough is used without such previous examination, and the place marked where stones are encountered, that they may be taken away; and sometimes, in order to discover and remove such stones, the land is trenched by the spade (Communications to the Board of Agriculture, vol. ii. p. 253.)

4521. Stones above the surface may be avoided by the ploughman, though not without loss of ground; but stones under the surface are often not discovered till the plough is drawn against them, and perhaps broken, by which a day's work is sometimes lost. A wooden bolt, however, to unite the horse-trees to the chain of the plough, may prevent mischief by giving way. Clearing the ground from stones not only prevents such mischiefs, but is attended with actual profit. When removed, they may be used for various purposes, and are often less expensive than if dug, or purchased at a quarry. The soil round a large stone is likewise, in general, the best in the field, and is bought at a low rate by the expense of taking out the stone, as the plough has thus access to all the land around it. In stony land the ploughmust proceed slowly, and cannot perform half so much work as it ought to do; but, after such impediments have been removed, the field may be ploughed with the usual facility and cheapness, and ha mu

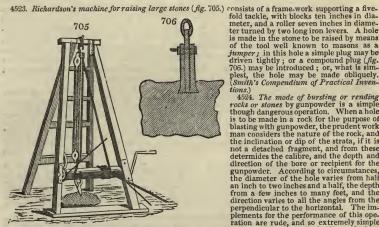

4522. There are various modes of getting rid of stones. These are generally of such a size as to admit of being conveyed away in carts or other vehicles calculated for the Some ingenious artificers have constructed machines for raising them, when On some occasions, pits have been dug close to large stones, and the latter have large.

been turned into the former, at such a depth as to lie out of the reach of the plough: but it is frequently necessary to reduce their size by the force of gunpowder before they can be removed. Loose stones are commonly moved by levers, and rolled on a sledge; but sometimes they are raised by a block and tackle attached to a triangle with a pair of callipers to hold the stone (fig. 703.) The stone may also be raised by boring a hole in it

obliquely and then inserting an iron bolt with an eye (fig. 704.), which, though loose, will yet serve to raise the stone in a perpendicular direction.

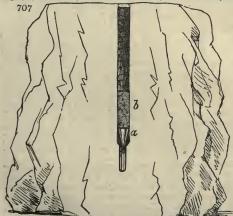

ter turned by two long iron levers. A hole is made in the stone to be raised by means of the tool well known to masons as a of the tool well known to masons as a jumper; in this hole a simple plug may be driven tightly; or a compound plug (fig. 70c.) may be introduced; or, what is sim-plest, the hole may be made obliquely. (Smith's Compendium of Practical Inven-

4524. The mode of bursting or rending rocks or stones by gunpowder is a simple though dangerous operation. When a hole is to be made in a rock for the purpose of blasting with gunpowder, the prudent work man considers the nature of the rock, and the inclination or dip of the strata, if it is not a detached fragment, and from these determides the calibre, and the depth and direction, of the borger recipient for the not a detactive and the depth and direction of the bore or recipient for the gunpowder. According to circumstances, the diameter of the hole varies from half an inch to two inches and a half, the depth from a few inches to many feet, and the direction varies to all the angles from the propositional to the horizontal. The impropositional to the horizontal the manufacture of the correction of the horizontal the manufacture of the horizontal that we have the correction of the horizontal that we have the horizontal that have

perpendicular to the horizontal. The implements for the performance of this operation are rude, and so extremely simple easily performed, that, in the space of a few weeks, an intelligent labourer may become an expert quarrier. A writer in the Mechanics' Magazine has proposed to increase the effect of the gunpowder, by widening the lower extremity of the bore, and this he thinks may be effected, after the bore is made of the proper ength, by introducing an instrument with a jointed extremity which would work obliquely.

4525. The government of ramming frequently gives rise to accidents; but a recent improvement, that of using a wadding of loose sand, or of

using a wadding of loose sand, or of any earthy matter in a dry state, answers all the purposes of the firmest ramming or wadding. It has been used for upwards of ten years at Lord Elgin's extensive mining operations at Charlestown in Fifeshire, and also in removing immense bodies of rock from the Calton hill at Edinburgh, by Stevenson, an eminent engineer, whose article on the subject of blasting, in

article on the subject of blasting, in the Sup. to the Encyc. Brit. deserves the attention of such as use the process in working quarries or clearing rocky or stony grounds.

4596. Dr. Dyce of Aberdeen has communicated to Dr. Brewster's Journal an account of a cheap and effectual method of blasting granite took which deserves the particular enectual method of bussting grantic rock, which deserves the particular attention of the owners and workers of quarries. It is beautifully scien-tific, and may be summed up under the three following heads: viz. I. To lepite the gunpowder at the bottom of the observed we may of substitute. of the charge, by means of sulphuric acid, charcoal, and sulphur. 2. To take advantage of the propelling power

of gunpowder, as is done with a cannon ball, only, instead of a spherical ball, to employ one of a conical form (fig. 707.), by which the full effect of the wedge is given in every direction at the lower part of the charge, but particularly downwards 3. And, in the last place, to add to the effect of the whole, to insure a fourth part of the depth of the bore at the bottom (b) to be free from the gunpowder; so that, when inflamation ensues, a red heat may be communicated to the air in the lower chamber, whereby it will be expanded to such a degree as to have the power of at least one hundred times the atmospheric pressure, and thereby give this additional momentum to the explosive power of the gunpowder. (Dr. Breunster's Edin. Journ., Oct. 1836, p. 343, and Gard. Mag. vol. ii. p. 467.)

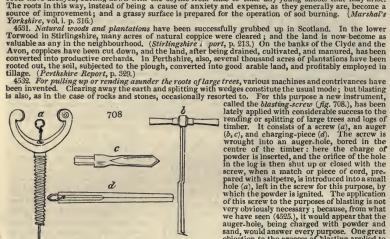

4571. The Assances close the mouth of the hole by driving in with a mallet a stout wooden plug some inches in length, through which a touch-hole is bored. Between the powder and the lower part of the plug, an interval of several inches is left. The communication is perfected by means of a tin tube filled with powder, and passing through the centre of the plug. (Monthly Magazine.)

SECT. III. Improving Woody Wastes or Wealds.

4528. With surfaces partially covered with bushes and stumps of trees, ferns, &c., the obvious improvement is to grub them up, and subject the land to cultivation according to its nature.

4529. The growth of large trees is a sign that the soil is naturally fertile. It must also have been enriched by the quantity of leaves which in the course of ages have fallen and rotted upon the surface. Such are the beneficial effects of this process, that after the trees have been cut down, the soil has often been kept under crops of grain for a number of years without interruption or any addition of manure: but land thus treated ultimately becomes so much reduced by great exhaustion, that it will not bear a crop worth the expense of seed and labour. (Comm. to the Board of Agr., vol. ii. p. 257.) It is evident, however, that this deterioration entirely proceeds from the improvident management previously adopted. In reclaiming such wastes, the branches of the felled trees, are generally collected and burnt; and the ashes, either in whole or in part, are spread on the ground, by which the fertility of the soil is excited. Indeed, where there is no demand for timber on the spot, nor the means of conveyance to any advantageous market, the whole wood is burnt, and the ashes applied as manure.

4530. Much coppice land has been grubbed up in various parts of England, and brought into tillage. Sometimes woods are grubbed for pasture merely. In that case the ground should be as little broken as possible, because the surface of the land, owing to the dead wood and leaves rotting time out of mind upon it, is much better than the mould below. It soon each interconduction. possible, occause the surface of the land, owing to the dead wood and leaves rotting time out of mind upon it, is much better than the mould below. It soon gets into good pasture as grass land, without the sowing of any seed. (Comm. to the Board of Agr. vol. iv. p. 42.) But by far the most eligible mode of converting woodland into arable is merely to cut down the trees, and to leave the land in a state of grass until the roots have decayed, cutting down with the scythe from time to time any young shoots that may arise. The roots in this way, instead of being a cause of anxiety and expense, as they generally are, become a source of improvement; and a grassy surface is prepared for the operation of sod burning. (Marshal's Yorkshire, vol. i. p. 316.)

of this screw to the purposes of blasting is not very obviously necessary; because, from what we have seen (4525.), it would appear that the auger-hole, being charged with powder and sand, would answer every purpose. One great objection to the process of blasting applied to the rending of timber is, the irregular and necessary to resort to this mode of breaking up large trees, when cut down and left in inaccessible situations, where a great force of men and implements cannot easily be procured or applied; and certainly it is one of the most effectual modes of tearing their stools or roots in pieces. (Sup. Encyc. Brit. art. Blasting.)

4533. Land covered with furze, broom, and other shrubs, is generally well adapted for cultivation. The furze, or whin (U lex europæa), will grow in a dense clay soil; and where found in a thriving state, every species of grain, roots, and grasses, may be cultivated with advantage. The broom, on the other hand, prefers a dry, gravelly, or sandy soil, such as is adapted for the culture of turnips. A large proportion of the arable land, in the richest districts of England and Scotland, was originally covered by these two plants; and vast tracts still remain in that state, which might be profitably brought

under cultivation. For this purpose, the shrubs ought to be cut down, the ground trenched, or the plants rooted out by a strong plough, drawn by four or six horses, and the roots and shrubs (if not wanted for other purposes), burnt in heaps, and the ashes spread equally over the surface. (Com. to the Board of Agr. vol. ii. p. 260.) In many places, shrubs and brushwood may be sold for more than the expense of rooting them out. When coal is not abundant, and limestone or chalk can be had, the furze should be employed in burning the lime used in carrying on the improvement. (Oxfordshire Report, p. 232.) It requires constant attention, however, to prevent such plants from again getting possession of the ground, when restored to pasture. This can best be effected, by ploughing up the land occasionally, taking a few crops of potatoes, turnips, or tares in rows, and restoring it to be depastured by sheep. In moist weather, also, the young plants should be pulled up and destroyed. (Code.)

4534. Fern (Ptèris and Osmunda) is a very troublesome weed to extirpate, as, in many soils, it sends down its roots into the under stratum, beyond the reach of the deepest ploughing; but it is a sign of the goodness of any soil where it grows to a large size.

June and July are the best seasons for destroying it; the plants are then full of sap, and should be frequently cut. They are not, however, easily subdued, often appearing after a rotation of seven years, including a fallow, and sometimes requiring another rotation, and repeated cutting, before their final disappearance can be effected. Lime in its caustic state is peculiarly hostile to fern; at the same time, this weed can hardly be completely eradicated but by frequent cultivation, and by green crops assisted by the hoe.

(Oxfordshire Report, pp. 234. 240.)

4535. The heath (Erica) is a hardy plant, palatable and nutritious to sheep; and under its protection coarse grasses are often produced. When young, or in flower, it may be cut and converted into an inferior species of winter provision for stock; but where it can be obtained, it is desirable to have grass in its stead. For this purpose, the land may in some cases be flooded, and in others the heath may be burned, and the land kept free from stock for eighteen months; in consequence of either of these modes, many new grasses will spring up, from the destruction of the heath, and the enriching quality of the deposit from the water or the ashes. The improvement is very great; more especially if the land be drained, and lime or compost applied. (Gen. Rep. of Scot. vol. ii. p. 359.) But if the land be too soon depastured, the grasses being weak and tender, the sheep or cattle will pull them up with their roots, and will materially injure the pasture. (Statistical Account of Scotland, vol. iv. p. 465.) Where it is proposed to cultivate the land for arable crops, the lime applied should be in a finely powdered state, highly caustic, and as equally spread as possible. (Com. to the B. of Agr. vol. ii. p. 264.) Lime in a caustic state is an excellent top dressing for heath. is astonishing to see white clover spring up, after lime has been some time applied, on spots where not a green leaf could be detected before.

4536. Paring and burning is a speedy and effectual mode of bringing a surface covered with coarse herbage into a state of culture. Some have recommended making a compost of the pared surface, with lime; or building folds or earthen walls of the sods, which, by the action of the atmosphere, become friable and fertile; but these processes are slower and not so effectual as paring and burning. In coarse rough pastures, ant-hills frequently abound, which are effectually destroyed by paring and burning. (Code.)

SECT. IV. Moors and their Improvements.

4537. Moorlands are of various descriptions. Sometimes they are in low and mild situations, where the upper soil is thin or scantily supplied with vegetable mould, and where the bottom or under-stratum is impervious and barren: these, in general, may be reclaimed with more or less advantage, according to the proximity of manure or markets, and of other means of improvement. Sometimes, on the contrary, they are in situations much elevated above the level of the sea; where the surface is covered with heath and other coarse plants, and frequently encumbered with stones: such moors are seldom worth the expense of cultivation, and from their height are only calculated for woods or pasturage.

4538. Moors not placed in high or bleak situations, where the surface is close-swarded, or covered with plants, and where the subsoil is naturally either not altogether wet, or capable of being made sufficiently dry at a moderate expense, may not only be reclaimed, but can often be highly improved by the common operations of farm culture, by paring

and burning, by fallow and liming, or by trenching or deep ploughing.

4539. Vast improvements on different sorts of moory lands have been made in Yorkshire where there are immense tracts of moors. It is stated in The Agricultural Report of the North Riding of Yorkshire, that an improvement was made upon Lockton Moor, on a quantity of land of about seventy acres, which would not let for more than 1s, per acre before it was enclosed. Of this forty-eight acres were pared and burnt, and sown with rape, except about an acre sown with rye; the produce about sixty quarters. The rye grew very strong, and in height not less than six feet, and was sold, while standing, for five guineas the acre. The land was only once ploughed, otherwise the crop of rape would probably have been much better. One hundred and twenty chaldrons (each thirty-two bushels) of lime were ploughed into the

field; which, for want of more frequent ploughing, was probably not of the service it otherwise might have been. Part of the land was afterwards sown down with oats and grass seeds; the former of which afforded but a moderate crop, the latter a very good one, and has since produced two loads, 120 stones each, per acre. The seeds sown were rye-grass, rib-grass, white clover, and trefoil; of these, the first succeeded amazingly, the others not so well; potatoes throve very well; turnips not equal to them. A farm-house has been built upon it, which now, alng with five acres more of the same kind of land, is let on lease at thirty pounds per annum. The soil consisted, in general, of benty peat, upon red gritstone, with a mixture of clay upon limestone; this last is, in some places, at a considerable depth, in others, sufficiently near the surface for lime to be burnt on the premises.

4540. Finlayson's rid-plough (§ 2605.) has been found a valuable implement in breaking up heath and moorlands, in Scotland.

Sect. V. Peat Mosses, Bogs, and Morasses, and their Improvement.

4541. Mossy and boggy surfaces occupy a very considerable portion of the British In Ireland alone there are of flat red bog, capable of being converted to the general purposes of agriculture, 1,576,000 acres; and of peat soil, covering mountains, capable of being improved for pasture, or beneficially applied to the purposes of plantation, 1,255,000 acres, making together nearly three millions of acres. Mossy lands, whether on mountains or plains, are of two kinds: the one black and solid; the other

spongy, containing a great quantity of water, with a proportion of fibrous materials.

4542. Black mosses, though formerly considered irreclaimable, are now found capable of great melioration. By cultivation, they may be completely changed in their quality and appearance; and, from a peaty, become a soft vegetable earth of great fertility. They may be converted into pasture; or, after being thoroughly drained, thriving plantations may be raised upon them; or, under judicious management, they will produce crops of grain and roots; or, they may be formed into meadow-land of considerable

4543. Flow, fluid, or spongy mosses, abound in various parts of the British Isles. Such mosses are sometimes from ten to twenty feet deep, and even more, but the average may be stated at from four to eight. In high situations, their improvement is attended with so much expense, and the returns are so scanty, that it is advisable to leave them in their original state; but where advantageously situated, it is now proved that they may be profitably converted into arable land, or valuable meadow. If they are not too high above the level of the sea, arable crops may be successfully cultivated. Potatoes, and other green crops, where manure can be obtained, may likewise be raised on them with advantage.

4544. Peat is certainly a production capable of administering to the support of many valuable kinds of plants: but to effect this purpose, it must be reduced to such a state, either by the application of fire, or the influence of putrefaction, as may prepare it for their nourishment. In either of these ways, peat may be changed into a soil fit for the production of grass, of herbs, or of roots. The application of a proper quantity of lime, chalk, or marl, prepares it equally well for the production of corn. (Code.)

4545. The fundamental improvement of all peat soils is drainage, which alone will in a few years change a boggy to a grassy surface. After being drained, the surface may be covered with earthy materials, pared and burned, fallowed, dug, trenched, or rolled. The celebrated Duke of Bridgewater covered a part of Chatmoss with the refuse of coal-pits, a mixture of earths and stones of different qualities and sizes, which were brought in barges out of the interior of a mountain; and, by compressing the surface, enabled it to bear pasturing stock. Its fertility was promoted by the vegetable mould of the morass, which presently rose and mixed with the heavier materials which were spread upon it. (Marshal on Landed Property, p. 46.)

4546. The fenny grounds of Huntingdonshire are in some cases improved by applying marl to the surface. Where that substance is mixed with the fen soil, the finer grasses flourish beyond what they do on the fen soil unmixed; and when the mixed soil is ploughed, and sown with any sort of grain, the calcareous earth renders the crops less apt to fall down, the produce is greater, and the grain of better quality of no value, has thus been rendered worth from 2l. to 3l. and even 4l. per acre. The horses upon this land must either be equipped with wooden clogs, or the work performed in froxy weather, when the surface of the moss is hard. Coarse obdurate clay (provincially till) is peculiarly calculated for this process; as, when it is blended with poden clogs, or the work performed i

(Code.)
4548. Rolling peaty surfaces has been found to improve them. The greatest defect of soft soils is, that the drought easily penetrates them, and they become too open. The roller is an antidote to that evil, and the expense is the only thing that ought to set bounds to the practice of this operation. It also tends to destroy those worms, grubs, and insects, with which light and fenny land is apt to be infested. The roller for such soils ought not to be heavy, nor of a narrow diameter. If it is weighty, and the diameter small, it sinks too much where the pressure falls, which causes the soft moss to rise before and behind the roller, and thus, instead of consolidating, it rends the soil. A gentle pressure consolidates moss, but too much weight has a contrary effect. A roller for moss ought therefore to be formed of wood, the cylinder about four feet diameter, and mounted to be drawn by two or three men. Three small rollers working in one frame, (fig. 709.), have sometimes been so drawn. When horses are employed, they ought to have clogs or pattens, if likely to sink. The offener the rolling is performed, on spongy soils as long as the crops of corn or grass will admit of it, the better, and the more certain is the result.

4549. An extensive tract of most in the county of Lancaster has been recently improved by the celebrated Roscoe of Liverpool, in a very spirited and skilful manner. Chatmoss in that county is well known; its length is about six miles, its greatest breadth about three miles, and its depth may be estimated from ten to upwards of thirty feet. It is entirely composed of agate of vegetable matter, disorganised and inert, but preserved by certain causes from putrefaction. On the surface it is light and fibrous, but becomes more dense below. On cutting to a considerable depth, it is found to be black, compact, and throughout the whole moss the least intermixture of sand, regetable. About 1796 or 1797, Roscoe began to improve Trafford moss, a tract of three hundred acres, lying two miles east of Chatmoss; and his operations on it seem to have been so successful as to encourage him to proceed with Chatmoss. In the improvement of the latter, he found it unnecessary to incurs of heavy an expense for drainings as he had done in different or heavy and expense for drainings as he had done in draw the water had drawn towards it from a distance of fifty to a hundred yards, he conceived that if each drain had to draw the water only twenty-five yards, they would, within a reasonable time, undoubtedly answer the purpose. The whole of the moss was therefore laid out on the following plan:—arry from east to west, through the whele extent of my portion of the moss. This road is about three miles long and thrity-six feet wide; it is bounded on each side by a main drain, seven from each drain diverge, at fifty yard, distance from each drain diverge, at fifty yard, distance from each drain diverge, at fifty yard, distance from each from the troad, and is of an indefinite length, according as the boundary of the moss. Thus, each field contains fifty yards in front to the road, and is of an indefinite length, according as the boundary of the moss varies. These field drains are four feet wide at the top, one foot at he bottom, and four fe

stricta, and other plants, whose matted roots are almost imperishable. The moss being thus brought to a tolerably dry and level surface, I then plough it in a regular furrow sit inches deep- and as soon as possible after it is thus turned up, it inches deep- and as soon as possible after it is thus turned up, it inches deep- and as soon as possible after it is thus turned up, it inches deep- and as soon as possible after it is thus turned up, it inches deep- and as soon as possible after it is thus turned up, it inches deep- and as soon as possible after it is thus turned up, it inches deep- and as soon as possible after it is thus turned up, it inches deep- and as soon as possible after it is thus turned up, it is an additionally an additional and the archaed and the second and the second and the archaed and the horse-scriftle or scarrifier, according to the nature of the bring down the navigable river Irwell, to the borders of the bring down the navigable river Irwell, to the borders of the bring down the navigable river Irwell, to the borders of the bring down the navigable river Irwell, to the borders of the bring down the navigable river Irwell, to the borders of the bring down the navigable river Irwell, to the borders of the bring down the navigable river Irwell, to the borders of the reason and the second the second and the second the second and as a second better to the farmer with green crops, as potatose, turnips, &c. but with any kind of grain; and as wheat has, of late, paid better to the farmer first, copy, for reimbursing the expense."

4502. The expense of the several ploughings, with the burning, sowing, and harrowing, and of the mark and manure, but exclusive of the seed, and also of the previous drainage and general charges, amounts to 181. 5, per arce; and in 1812, on wheat, then worth a guinea per bushel, and on another pleo wheat, then worth a guinea per bushel, and on another pleo wheat, then worth a guinea per bushel, and on another pleo wheat, then worth a guinea per bushel, and on anot

4554. An anomalous mode of treating peat bogs was invented and practised by the late Lord Kaimes, which may be applicable in a few cases. This singular mode can be adopted only where there is a command of water, and where the subjacent clay is of a most fertile quality, or consists of alluvial soil. A stream of water is brought into the moss, into which the spongy upper stratum is first thrown, and afterwards the heavier moss, in small quantities at a time; the whole is then conveyed by the stream into the neighbouring river, and thence to the sea. The moss thus got rid of, in the instance of Blair Drummond, in Perthshire, was, on an average, about seven feet deep. Much ingenuity was alplayed in constructing the machinery, to supply water for removing the moss, previously to the improvement of the rich soil below. It required both the genius and the perseverance of Lord Kaimes to complete this scheme; but by this singular mode of improvement, about 1000 English acres have been already cleared, a population of above 900 inhabitants furnished with the means of subsistence, and an extensive district, where only snipes and moorfowl were formerly maintained, is now converted, as if by magic, into a rich and fertile carse, or tract of alluvial soil. (Code.) In The General Report of Scotland, Appendix, vol. ii. p. 38., and at p. 326 of this work, will be found a detailed account of this improvement.

4555. Moss has been converted into manure by fermentation with stable dung, and with this article joined with whale oil. In the Highland Soc. Trans., vol. vil., an account is given (p. 147.) of several experiments of this kind by W. Bell, Esq.:—A layer of moss a foot thick was formed after the material was tolerably dry, in the month of June; above this a layer of moss thicker than the first; on this last layer a ton of coarse whale oil was poured, and the whole was completely covered up with moss. In ten days the whole mass came freely into heat; in about eight weeks it was turned, and continued to ferment freely; in a f

duced.

4556. Peat may be charred and rendered fit to be used like charcoal in cookery and other domestic purposes, in the same way as wood or coal is charred, and in much less time. For ordinary purposes, it is charred by some families on the kitchen fire, thus: — Take a dozen or fifteen peats, and put them upon the top of the kitchen fire, upon edge: they will soon draw up the coal fire, and become red in a short time; after being turned about once or twice, and done with smoking, they are charred, and may be removed to the stoves: if more char is wanted, put on another supply of peat, as before mentioned. By following this plan, you keep up the kitchen fire, and have at the same time, with very little trouble, a supply of the best charred peat, perfectly free of smoke; and the vapour is by no means so nosious as charcoal made from wood. Peats charred in this way may be used in a chafer, in any room, or even in a nursery, without any danger arising from the vapour. It would also be found very fit for the warming of beds; and much better than live coals, which are in general used full of sulphur, and smell all over the house. (Farm. Mag. vol. xvii.)

SECT. VI. Marshes and their Improvement.

4557. A tract of land on the borders of the sea or of a large river is called a marsh: it differs from the fen, bog, and morass, in consisting of a firmer and better soil, and in being occasionally flooded. Marshes are generally divided into fresh-water marshes and salt-water marshes; the latter sometimes called saltings or ings: freshwater marshes differ from meadows, in being generally soaked with water from the subsoils or springs.

4558. Fresh-water marshes are often found interspersed with anable land, where springs rise, and redundant water has not been carried off; and may be improved by a course of ditching, draining, and ploughing. Where large inland marshes are almost constantly

covered with water, or the soil is extremely wet, they may be drained, as large districts in the fens of Lincolnshire have been, and made highly valuable. The object, in that case, is, by embankments, draining, and other means of improvement, to convert these marshes into pasture or meadow, or even arable lands; and where such improvements cannot be accomplished, the most useful woody aquatics, as willows, osiers, &c., may be grown with advantage.

4559. Romney marsh is one of the most extensive and fertile fresh-water marshes in Britain. It contains nearly 24,000 acres; besides which Walland marsh and Dinge marsh, which are comprised within the walls, contain, the former 12,000, and the latter 8,000 acres. Boys informs us that "the internal regulations of these marshes are committed to the superintendence of expenditors. These are appointed by the Commissioners of Sewers, and are to take care that the repairs of the walls are maintained in due order, and that the costs attending the same be levied on each tenant according to the number of acres occupied by him; for which purpose they are to cause assessments to be made out, with the names of the occupiers, and the rateable proportions to be borne by them respectively; and these rates, which must be confirmed by the commissioners, are termed scots; and that when any occupier refuses to pay his scot, the expenditors can obtain a warrant from the commissioners, empowering them to distrain for the same, as for any other tax." These marshes are both appropriated to the purposes of breeding and feeding.

4560. Salt water marshes are subject to be overflowed at every spring tide, and at other times, when, from the violence of the wind or the impetuosity of the tide, the water flows beyond its usual limits. Their goodness is in a great measure analogous to the fertility of the adjoining marshes; and their extent differs according to the situation. Embankments, as it is remarked in The Code of Agriculture, are perhaps the only means by which they can be effectually improved, especially when they are deficient in pasture. However, where pasture abounds, they are in some cases more valuable than arable lands, the

pasture operating as a medicine upon diseased cattle.

4561. Marshes on the Thames. In The Agricultural Survey of Kent it is asserted, that great profit is made by the renters of marshes bordering on the Thames, in the neighbourhood of London, from the grazing of horses, the pasture being deservedly accounted salubrious to that useful animal. Such horses as have been worn down by hard travel, or long afflicted with the farcy, lameness, &c., have frequently been restored to their pristine health and vigour, by a few months' run in the marshes, especially on the saltings; but as every piece of marsh land in some measure participates of this saline disposition, so do they all of them possess, in a comparative degree, the virtues above mentioned, and for this reason the Londoners are happy to procure a run for their horses, at 4s. or 5s. per week. Another method practised by the graziers in the vicinity of London is, to purchase sheep or bullocks in Smithfield at a hanging market, which, being turned into the marshes, in the lapse of a few weeks are not only much improved in flesh, but go off at a time when the markets, being less crowded, have considerably advanced in price; and thus a twofold gain is made from this traffic. Many of the wealthy butchers of the metropolis are possessed of a tract of this marsh land, and, having from their constant attendance at Smithfield, a perfect knowledge of the rise and fall in the markets, they are consequently enabled to judge with certainty when will be the proper time to buy in their stock, and at what period to dispose of them.

4562. In various districts of the island situated on the borders of the sea, or near the mouths of large rivers, there are many very extensive tracts of this description of land, which by proper drainage and enclosure may be rendered highly valuable and productive. This is particularly the case in Somersetshire and Lincolnshire. In the former of these counties, vast improvements have, according to Billingsley, as stated in his able Survey, been effected by the cutting of ditches, for the purpose of dividing the property, and the deepening of the general outlets to discharge the superfluous water. Many thousand acres which were formerly overflowed for months together, and consequently of little or

no value, are now become fine grazing and dairy lands.

SECT. VII. Downs and other Shore Lands.

4563. Downs are those undulating smooth surfaces covered with close and fine turf met with in some districts on the sea-shore; the soil is sometimes sandy, and at other times clay or loam. In inland situations there are also down lands, as in Wiltshire, Lincolnshire, and Yorkshire; in the latter two counties they are called wolds.

4564. Sandy downs on the sea-shore are often more valuable in their natural state than after cultivation. In a state of nature they frequently afford good pasture for sheep and rabbits, and at other times produce grasses that may be used as food for cattle, or as litter. But the great object should be to raise plants which contribute to fix these soils, and to prevent them from being drifted by the winds, which often occasion incalculable

mischief. The most suitable plants for the purpose are, the E'lymus arenarius, Juncus arenarius, Arúndo Dònax, Onònis spinòsa, Gàlium vèrum, Tussilàgo Petasites, and a variety of other creeping-rooted plants and grasses. Of woody plants, the elder is one of the best for resisting the sea breeze, and requires only to be inserted in the sand in large truncheons. Where the sands on sea-shores are mixed with shells, and not very liable to drift, if they can be sheltered by fences or an embankment, and sown with white clover, it will be found both an economical and profitable improvement.

4565. The drift-sands of the outer Hebrides have in some places been consolidated and covered with verd-

Plebrides have in some places been consolidated and covered with verdure by "square pieces of turf, cut from solid sward, and laid upon the drifting surface, in steep places nearer to each other, and in less inclined places at a greater distance: on very rapid declivities the turfs are placed in contiguity. These turfs, although separated by intervals of a foot or so of sand, are not liable to be buried, except in very exposed places." (Quar. Jour. Agr. vol. 1, 7.15.) N. Macleod, Exq. of Harris, has "Guarde and brought into useful permanent pasture above 120 acres of useless drifting sand, by planting it with Ardindo arenària (fig. 710.) in 1819. The operation is performed in September, by cutting the plants "about two inches below the surface with a small thin-edged spade, with a short handle, which a man can use in his right hand, at the same time taking hold of the grass with his left; other persons carrying it to the blowing-sand to be planted in a hole, or rather a cut, made in the sand, about eight or nine inches deep, (and deeper where the sand is very open and much exposed,) by a large narrow-pointed spade. A handful of Arúndo arenària, or bent grass, was put into each of these cuts, which were about twelve inches distant, more or less, according to the exposure of the situation. When properly fixed in the blowing-sand, the roots begin to grow and spread under the surface, in the course of a month after planting. This grass is relished by cattle in summer, but it is of greater value, by preserving it on the ground for wintering cattle: it would be injudicious to cut it, because it will stand the winter better than any other grass, and is seldom covered with snow. Neither wind, rain, nor frost will destroy it; but the old grass naturally decays towards the latter end of spring and the beginning of summer, as the new crop grows. White and red clover will grow spontaneously among this grass in the course of a few years, provided it is well secured. (Trans. Hight. Soc. vol. vi. p. 265.)

4566. Poor sandy soils in inland districts are not unfrequently stocked with rabbits. When the productions of arable lands are high, it is found worth while to break up these

warrens and cultivate corn and turnips; but it frequently happens that, taking the requisite outlay of capital, and the expenses and risk into consideration, they do not pay so well as when stocked with rabbits. Such lands are generally well adapted for plant-711 ing; but in this, as in every other case

where there is a choice, circumstances must direct what line of improvement is to be adopted.

4567 Shores and sea beaches of gravel and shingle, without either soil or vegetation, are perhaps the most unimproveable spots of any; but something may be done with them by burying the roots of the arenarious grasses along with a little clay or loamy earth. these, the best is the Arundo arenaria and E'lymus arenarius (fig. 711. a), already mentioned; and E. geniculatus (b) and sibíricus (c) would probably succeed equally The last grows on the sandy wastes of Siberia, and the preceding is found on the shores of Britain.

CHAP. V.

Improvement of Lands already in a State of Culture.

4568. A profitable application of many of the practices recommended in the chapters of this and the foregoing Book may be made to many estates which have been long under cultivation. It is certain, indeed, that the majority of those who study our work will have that object more in view than the laying out or improvement of estates ab origine. Few are the estates in Britain in which the farm lands do not admit of increased value.

by rectifying the shape of fields, adjusting their size, improving the fences, draining the soil, or adding to the shelter; and few are the farmeries that may not be rendered more commodious. Of this, we shall give a few examples, after we have stated the general principles and modes of proceeding.

Sect. I. General Principles and Modes of Procedure, in improving Estates already more or less improved.

4569. The groundwork of improvement, on which a practical man may tread with safety and full effect, is an accurate delineation of the existing state, together with a faithful estimate of the present value, of the lands, and other particulars of an estate to be improved. A general map of the appropriated lands, readily exhibiting the several farms and fields as they lie, and showing the existing watercourses, embankments, fences, and buildings; the woodlands, standing waters, morasses, and moory grounds; the known mines and quarries; together with the commonable lands (if any) belonging to the estate, forms a comprehensive and useful subject of study to the practical improver. him, what the map of a country is to a traveller, or a sea-chart to a navigator. estate is large, a faithful delineation of it will enable him in a few hours to set out with advantages, respecting the connections and dependencies of the whole and its several parts. which, were he deprived of such scientific assistance, as many days, weeks, or months could not furnish. If on the same plan appear the rental value of each field or parcel of land, and the annual produce of each mine, quarry, woodland, and productive water, in its present state, the preparatory information which science is capable of supplying may be considered as complete; and it remains with the artist to study with persevering attention the subject itself, in order to discover the species of improvements of which it is susceptible, and the suitable means of carrying them into effect.

4570. The species of improvements incident to landed property are numerous. They may, however, be classed under the following heads: — the improvement of the outline, and general consolidation of an estate by purchase, sale, or exchange: the improvement of the roads; of the mines and minerals; of the towns, villages, mills, and manufactories; of the waters; of the woods and plantations; and of the farmeries and farm lands. This last subject is the most common, and to it we shall devote the succeeding section. To discuss the other species of improvement, as applied to old estates, would necessarily include so much of what has already passed in review in the foregoing Book, as to be

wearisome to the reader.

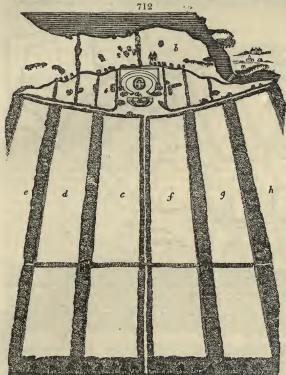

SECT. II. Improvement of Farmeries and Farm Lands.

4571. Farm lands are of more or less value according to the means of occupying them. Arable lands in particular require buildings and other conveniences proportioned to the size of a farm. We frequently see tenants curbed in their operations, and incurring a waste of produce, through the want of sufficient homestalls. On the other hand, we sometimes observe a prodigality of expenditure on farm buildings; thus not only sinking money unnecessarily, but incurring unnecessary expenses in subsequent repairs, by extending homesteads beyond the sizes of farms. In some cases, therefore, it will be found necessary to curtail the extent of farm buildings, as large barns; in others to enlarge the yards, and in many to add and re-arrange the whole. The subject therefore may be considered in regard to design and execution; but as we have already treated fully on laying out new farmeries, we shall here offer only a few general remarks as to alterations.

4572. In improving the plan of a farmery, the given intention is first to be maturely considered, and the several requisites to be carefully ascertained. The given site is next to be delineated, so as to show the existing buildings, yards, roadways, and entrances; and then, by maturely studying the plan alternately with the site itself, the improver is to endeavour to trace out the most suitable alterations; all the while keeping in view the perfection of arrangement, the situation and value of the existing buildings, and the expenses of alteration; reconsidering the subject repeatedly, until the judgment be fully satisfied. It is much easier to plan and erect a new farmstead, than to improve one which is already erected. The former requires science and ingenuity only; the latter good sense and judgment also.

4573. In executing improvements on old farmeries, some difficulty occurs as to the incorporation of new and old materials. If the situation and plan are likely to be of permanent approval, the new erections may be made in the most substantial manner; keeping it in view that the old, which are repaired at the time, may afterwards be wholly renewed. But if the repairs and improvements are not to extend further than the duration of a lease, or till, by the expiration of various leases, some general plan of improvement can be determined on, then old materials may be used, or less permanent structures may be erected.

4574. As an example of adding part of a newly-enclosed common-field to a small anciently enclosed grass-farm (fig. 712), we give:
the following case:
4575. The farmery (a)

and ancient enclosed fields (b), are separated from the common field by a road, and bounded on the other side by a lake. The soil is a soft black earth on a gravelly subsoil, the surface a gentle slope towards the lake. The farm-house is supposed to be already placed in this ancient part; and the oblarge portion of the com-mon field, when enclosed, to each ancient farm, as to get a fair rent for the lands at the least expense. The soil of this common field is a light poor sand, with nearly a flat surface. The circumstances of the country are favourable to large farms, the climate is dry, and the situation such as to require shelter. The number of acres to be enclosed and added to this farm is 1200. These this farm is 1200. These will be most advantage. ously cultivated in six shifts of, 1, turnips (c); 2, barley (d); 3, artificial grasses (c); 4 and 5, the same (f,g); 6, wheat or oats (h). Each shift is proposed to be separated by a plantation for shelter. by a plantation for shelter, and no inferior divisions made. In two the plantations are fieldbarns, sheds, &c. where the corn grown on one-half of the arable lands is threshed by a moveable threshing-machine, and the straw consumed by cattle. There are cottages at each of these barns for

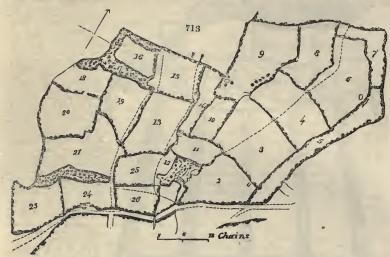

labourers to attend to the stock, &c. The ridges in each of the breaks or shifts are supposed to extend their whole length; or they may be ploughed as if the whole break were only one ridge, by which means not a moment is lost in turning at the ends, &c. Hereford or Devon oxen are supposed the beasts of labour on this farm.

4576. In place of the above rotation, wheat may be added after the second year of artificial grasses, and one shift kept entirely under saintfoin. This saintfoin division must of course be changed every sixth or seventh year. However, if a proper mixture of artificial grasses is sown, such as red, white, and yellow clover, rib-grass, burnet, saintfoin, timothy, cocksfoot, rye-grass, and soft-grass, the produce will be superior to that from either saintfoin or lucern alone, on a soil such as this, or even perhaps on any soil. Every agriculturist of observation must be aware that the efforts of annual and biennial plants are powerful for a few years at first, and that they uniformly produce a greater bulk than perennials: the latter seem to compensate for this temporary bulk by a steady durable produce.

4577. The old pasture near the house is supposed to be irrigated from the upper part of the lake, by a cut passing near the house. These pastures are particularly advantageous for early lambs, milch cows, &c. and for stock in general in seasons of great drought.

4578. Correcting the outlines of fields is one of the most obvious sources of amelioration on many, perhaps on most, estates. The advantages of proper sized and shaped enclosures have been fully pointed out, when treating of laying out farm lands, and in altering existing fences the same principles must be steadily kept in view; for though, unless by a total eradication of all the existing fences, every requisite may not be attainable, yet such a number may be gained as amply to compensate for the expense. In altering the shape and size of fields, besides the advantages resulting from the improvement in form, it will generally be found that a number of culturable acres may be added to the farm in proportion to the crookedness and width of the fences. Better drainage and roads will also be obtained, and where ornament is an object, a park-like appearance may be produced by leaving a single trees as part of what may have stood in the eradicated hedge-rows.

4579. As an example of improving the shape and size of fields, we shall refer to a farm of 350 acres, situated in Middlesex. (fig. 713.) In this case, the fields were larger than usual, but the fences were in

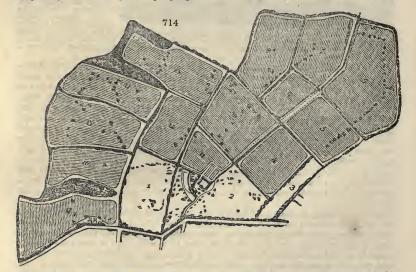

many parts from ten to fifteen yards in width, more resembling strips of copse wood than fences, as they contained hazel, dogwood, black and white thorns, wild roses, brambles, and a variety of native shrubs. The lines of these fences were so ill calculated for carrying off the surface-water, that in one half of the fields there were open gutters for the discharge of the water collected in the hedge-row ditches.

The lines of these fences were so ill calculated for carrying off the surface-water, that in one half of the fields there were open gutters for the discharge of the water collected in the leedge-row ditches.

4580. In the centre of one field (25), for example, above an acre was rendered waste by the water from other fields (19, 20, and 21), which water, it is curious to remark, might, if led over the same acre agreeably to the principles of irrigation, have produced annually at least two loads and a half of good hay, in place of annually rendering the produce of this acre unmarketable. The water of some fields (as 16, 18, and part of 19,) ran in a diagonal direction through another (15), two acres of which might have been irrigated by it to advantage.

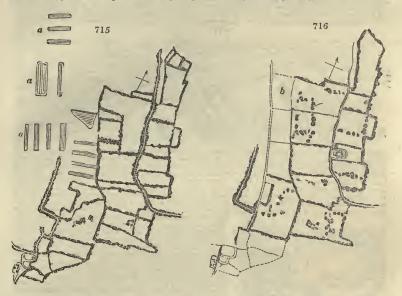

gated by it to advantage.

4581. In the farm, when altered (fig. 714.), the fields are more uniform in shape and size; their sides are parallel, and better adapted for ploughing the lands in straight ridges. All the surface-water is

carried off by the open fence drains. Access is had to every field by the shortest possible road from the farmery. Only two-thirds of the number of gates formerly required are requisite. Fifty acres are rendered useful which were formerly lost, or pernicious, by occupying space for which rent was paid, and by harbouring insects and noxious weeds; and as much rich vegetable earth is obtained from the old hedge banks as, spread abroad in every direction, may be said to manure at least ten acres. The whole is more open and healthful; and, from the number of single trees thrown into the fields, more elegant, and bearing a greater resemblance to a park. A part near the house (1, 2, 3) is in permanent pasture, and the rest (4, 5, 6, &c.) under a course of fallow, wheat, clover, beans, and wheat.

4582. As an example of altering the fields and consolidating a farm, we submit the case of a meadow rank with the arable lands in a common field state. (fig. 715.) By an act of enclosure, these scattered arable lands (a) were exchanged for others adjoining the meadow grounds (fig. 716. b), and the whole rendered states are the scattered arable lands (a) were exchanged for others adjoining the meadow grounds (fig. 716. b), and the whole rendered states are the scattered arable lands (a) were exchanged for others adjoining the meadow grounds (fig. 716. b), and the whole rendered arable lands (a) were exchanged for others adjoining the meadow grounds (fig. 716. b).

dered more compact and commodious. This farm, being intersected by a public lane, affords an example in which no private roads are wanted. The size and shape of the fields were improved, and the broad fences reduced as in the preceding case, and attended with the same advantages in an agricultural point

4695. But though in altering broad fences there are obvious and indisputable advantages to the farmer, yet, as justly observed by Loch, gain is not every thing. "The fences on the Marquess of Stafford's estates," he says, "were liable to the same objection which is applicable to a great proportion of the counties of England. They are not composed of quick, at least but in a scanty degree; they for the most part consist of bushes, growing from the stump of every sort of forest-tree, intermixed with planted on high and dry mounds, and thus are subject to constant decay. They occupy too much ground, provided agricul-

ture alone were the occupation of life. But as they give great protection, when they thrive, to the game, they become an important object of preservation, inasmuch as every thing must be of consequence which contributes to the sport, and has the effect of relating the gentry of England much upon their estates. For this reason, it may occasionally he proper to consider of the best way to preserve these hedges at the least expense, in place of substituting more perfect ones in their agricultural improvements of sog great and so wealthy a country." Such are Mr. Loch's ideas on game and hedges.

4584. When farm-lands are exposed to high winds, insterspersing them with strips or masses of plantation is attended with obviously important advantages. Not only are such lands rendered more congenial to the growth of grass, and corn, and the health of pasturing animals, but the local climate is improved. The fact, that the climate may be thus improved, has, in very many instances, been sufficiently established. astonishing how much better cattle thrive in fields even but moderately sheltered than they do in an open exposed country. In the breeding of cattle, a sheltered farm, or a sheltered corner in a farm, is a thing much prized; and, in instances where fields are taken by the season for the purpose of fattening, those most sheltered never fail to bring the highest rents, provided the soil is equal to that of the neighbouring fields which are not sheltered by trees. If we enquire into the cause, we shall find, that it does not altogether depend on an early rise of grass, on account of the shelter afforded to the lands by the plantations; but likewise that cattle, which have it in their power, in cold seasons, to indulge in the kindly shelter afforded them by the trees, feed better; because their bodies are not pierced by the keen winds of spring and autumn, neither is the tender grass destroyed by the frosty blasts of March and April. (Plant. Kal. p. 121.)

4585. The operation of skreen plantations, in exposed situations, Marshal observes, is not merely that of giving shelter to the animals lodging immediately beneath them; but likewise that of breaking the uniform current of the wind,—shattering the cutting blasts, and throwing them into eddies; thus meliorating the air to some distance from them. Living trees communicate a degree of actual warmth to the air which envelopes them. Where there is hie there is warmth, not only in animal but in vegetable nature. The severest frost rarely affects the sap of trees. Hence it appears, that trees and shrubs properly disposed, in a bleak situation, tend to improve the lands so situated, in a threefold way, for the purposes of agriculture; namely, by giving shelter to stock; by breaking the currents of winds; and by communicating a degree of warmth or softness to the air, in calmer weather.

4586. The proper disposal of skreen plantations for this purpose is in lines across the most offensive winds, and in situations best calculated to break their force. Placed across valleys, dips, or more open plains, in bleak exposures, they may be of singular use; also on the ridges, as well as on the points and hangs, of hills.

4587. The width of skreen plantations ought generally to be regulated by the value of the land for agricultural uses, and the advantages of the situation for the sale and delivery of timber. In ordinary cases, from two to four statute poles may be considered as an eligible width.

4588. The form of plantations for shelter, however, will not in every case be that of a stripe or belt of uniform width. In hilly, rocky, and other situations, different forms will suggest themselves, according to the situation and the objects in view. In rocky abrupt sites (fig. 717.) the plantation will consist of a

number of masses (a, b, c), of forms determined by the rocks and precipices, among which some of the most valuable pasture may be left as glades (d, c), for use, effect, and for the sake of game. Strips and hedges for sheltering, or separating arable lands, should be formed as much as possible in straight and parallel lines, in order not to increase the expense of tillage by short and irregular turnings. Straight parallel strips, on irregular surfaces, have a more varied appearance at a distance, than strips ever so much varied on a flat surface; for, in the former case, the outline against the sky is varied as much as that on the earth. In extensive hilly pastures, in which it is often desirable to produce shelter, and at the same time to plant only the most rocky and unproductive spots, the forms may be of the most irregular description; and by planting chiefly on the eminences and slopes (fig. 718), shelter will be most alleground rendered productive in copse or timber, and the greatest richness and picturesque beauty conferred on the landscape. There are some fine examples of this in the hilly districts of Fifeshire: there, on many estates where nothing was sought for but profit and shelter, the greatest beauty has been produced; and the picturesque tourist now passes through glades and valleys, pastured by well-fed cattle and sheep, enlivened by rocks, thickets, hanging woods, and occasional rills and lakes. Fifty years ago scarcely a tree was to be seen, and only the most inferior descriptions of live stock.

live stock.

4589. The species of woody plants best adapted for shelter, are the rapid-growing and evergreen trees, as the Scotch pine; and such as are at the same time clothed with branches from the ground upwards, as the spruce fir, are the best of all trees for shelter, unless the situation is very elevated.

attained in an eminent degree, and almost in perpetuity.

4592. In deep-soiled vale districts, which not unfrequently want shelter, skreens of oak might be managed in a similar way. Hollies, or other hardy evergreens, planted as underwood, in groves of either of the above descriptions, would, if suitable situations were assigned them, assist much in this intention.

4593. A tall impervious fence is, for the purpose of shelter to pasturing stock, hearly equal to a depth of coppice wood, and infinitely preferable to an open grove of timber trees; beside its additional use as a fence. There appears one species of fence which is peculiarly adapted to this purpose. This is the coppice mound hedge of Devonshire and South Wales; namely, a high wide bank or mound of earth, planted with coppice woods. This becomes, immediately on its erection, a shelter and a guard to pasture grounds.

4594. The method of forming fences of this kind is to carry up a stratum of earth, between two sod facines, "battering," or leaning somewhat inward, to the required height; and to plant on the top the roots and lower stems of coppice plants, gathered in woods or on waste grounds; or nursery plants adapted the roots of the roots (in the usual practice of Devonshire), a suf-

ficient fence is thus immediately formed against ordinary stock. But if the bank be lower, or if nursery plants be put in, a slight guard run along the outer brink on either side, and leaning outward over the face of the mound, is required (especially against sheep) until the plants get up. If a hedge of this kind be raised as a plantation fence (especially on the lower side of a slope), the outer side only requires to be faced with sods; the hedge plants being set in a rough shelving bank, on the inner side.

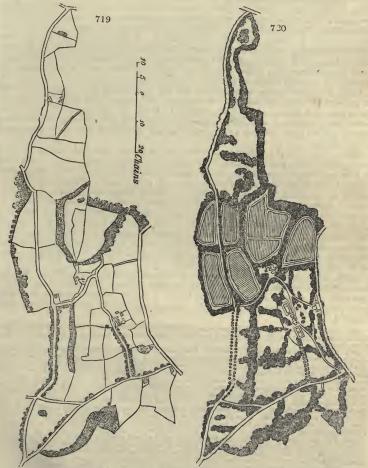

4595. The species of hedge woods, proper for mound fences, depends entirely on the soil and situation. On mounds of bad soil, in a bleak situation, the furze alone affords much shelter, and a good fence. The sides being kept pruned, so as to show a close firm face rising above the top of the bank, it is a secure barrier, even against the wilder breeds of Welsh sheep. The beech is commonly planted in high exposed situations; and in places more genial to the growth of wood, the hazel, the ash,

and the ook are the ordinary plants of bedse mounds. The willow tribe have a quality which recommends them, in situ-ations where they will flourish; they grow freely from cuttings, or truncheons set in the ground; whereas, to secure the growth of ordinary coppies woods, rooted plants are required. The rock-willow (Salix caprea) will grow in high and dry situ-

been is commonly planted in agn exposed situations; and in atoms. places more genial to the growth of wood, the haze, the ash, 4596. On thin-soiled stony surfaces, tall mounds are difficult to raise; and there stone walls are not only built at a small expense, but are convenient receptacles for the stones with which the soil is encumbered. But a stone wall, unless it be carried up to an inordinate height, at a great expense, is useless as a skreen; and may be said to be dangerous as such, in a bleak exposed situation, for as sone as the drifting snow has reached the top of the wall, on the windward side, it pours over it, and inevitably buries the sheep which may be seeking for shelter on the leeward side. Hence, in a situation where shelter is required, it is necessary that a stone fence should be backed with a skreen plantation.

4597. To plant trees for shade may in some cases be requisite for agricultural purposes. Where this is the ease, close plantations are seldom desirable, a free circulation of air being necessary to coolness; therefore trees with lofty stems, and large heads pruned to single stems, are preferable: the oak, elm, chestnut, and beech, for thick shade; the plane, acacia, and poplar, for shade of a lighter degree.

4598. An example of sheltering a hill farm by plantation, and at the same time improving the shape and size of fields, shall next be given. No farming subject affords better opportunities of introducing hedge-rows, and strips of planting, than hill-farms. The one under consideration (fig. 719.) is a small estate farmed by its owner: it consists of nearly 370 acres; and is situated in an elevate, picturesque part of a central English county. The soil is partly a flinty loam or chalk, and partly a strong rich soil, incumbent on clay. The fields are very irregular, bounded by strips of timber and copose. By the alterations and additions proposed (fig. 720.), all the most hilly and distant spots will be kept in permanent pasture; and the exposed and abrupt places, angles, &c. plante

4599. On hill farms in Scotland, where shelter cannot be given to grass and stock by plantations, small circular inclosures have been adopted for that purpose. The diameter of these circles is from 10 to 30

feet, the height of the wall six or eight feet, and a conical roof is placed on them, and covered with turf; but many inclosures of this kind are formed without roofs. They are called in Selkirkshire stells, and were brought into notice, in 1822, by Captain, now Lord Napier, in his Treatise on Store Farming, a work to which we shall have recourse in a subsequent section.

CHAP. VI.

Execution of Improvements.

4600. The mode in which improvements are executed is a point of very considerable importance, and may materially affect their success as well as their expense. We shall first consider the different modes of execution, and next offer some general cautions to be kept in view in undertaking extensive works.

Sect. I. Different Modes of procuring the Execution of Improvements on Estates.

4601. The necessary preliminary to the execution of an improvement, is a calculation of the advantages to arise from it, and an estimate of the expense of carrying it into effect. If the former, taken in their full extent, do not exceed the latter, the proposed alteration cannot, in a private view, be considered as an improvement. The next point to be ascertained is the practicability, under the given circumstances of a case, of executing the plan under consideration. There are three things essential to the due execution of an im-1st, an undertaker, or a person of skill, leisure, and activity, to direct the undertaking; 2d, men and animals with which to prosecute the work; 3d, money, or other means of answering the required expenditure. A deficiency in any one of these may, by frustrating a well-planned work after its commencement, be the cause not only of its failure, but of time, money, and credit being lost. - Improvements may be executed by the proprietor, either directly; gradually, by economical arrangements; or remotely, to a certain extent, by moral and intellectual means.

4602. To execute improvements directly, all that is necessary is to employ a steward or manager of adequate abilities and integrity, and supply him with the requisite plans, men, and money. This will generally be found the best mode of forming new roads, new plantations, opening new quarries or mineral pits, altering the course of waters, and all such creations or alterations as are not included in the improvement

of farm lands.

4603. To procure the gradual execution of improvements on farm lands, various arrangements may be made with the tenants: for example, by granting long leases; letting them find the requisites of improvement, and take the advantages during their terms; by granting shorter leases, with a covenant of remuneration for the remainder of such improvements as they have made, at the time of quitting; by granting leases, at a low rent, for the first years of the term, to give the tenants time and ability to improve at their own expense; by advancing money to tenants at will, or, which is the same, making allowances of rent for specified improvements, to be executed by them under the inspection and control of the manager, they paying interest for the money advanced or allowed; by employing workmen on tenanted farms; the tenants in like manner paying interest on the money The usual interest, till lately, was six per cent.; thus estimating the value of the improvement at sixteen years' purchase.

4604. The moral and intellectual means of improving farm lands consists, as Marshal has observed, in enlightening the minds of tenants. Though this mode is but of slow operation, and respects improvements in modes of culture, rather than such as require great outlay; yet it deserves notice in this place, as necessary to second the efforts of the

landlord.

4605. Farmers, as moral and intellectual agents, may be divided into reading men, and illiterate beings: the first class derive hints for improvement from books; but the second can only, if at all, derive benefit

the first class derive hints for improvement from books; but the second can only, if at all, derive benefit from example.

4606. With respect to improving farmers by books,—agricultural newspapers, magazines, and county surveys, are probably what would be read with most eagerness; and as such works abound in statements of what actually has taken place in different situations, by farmers like themselves, perhaps they are the most likely to stimulate to exertion. Historical relations of the agriculture of other countries are also generally interesting to agriculturists; and though no great professional benefit is to be derived from them, yet they tend to enlarge and liberalise the mind, and promote a taste for knowledge. Under these circumstances, it may be worthy of consideration whether an agricultural library might not be established in the steward's office, on very extensive estates, for the use of tenants and all other persons belonging to the estate who chose to read from it. Itinerating libraries for the use both of farmers and their servants, or, indeed, of whoever chooses to use them, have for some time been established, and extensively used in East Lothian, and they are gradually being adopted in other counties both in Scotland and England. (Gard. Mag. vol. ii., 9.376.)

4607. The establishment of schools for the children of the lower class of tenants, and of cottagers of every description, is an obvious and important source of moral and intellectual improvement; and considering it as decided by experience and the most competent judges, that the education of the lower classes will tend greatly to their amelioration and the benefit of society at large, we are of opinion that, wherever they are not already established, they should be introduced. Working schools, somewhat in the German manner, both for boys and girls, would also be a material improvement in such districts as are behind in a taste for cleanliness, fireside comforts, cookery, and dress.

4608. Examples as stimuli to improvement may be exhibited in various ways: by letting a farm to a tenant of superior energy, or from a more improved district; by exhibiting improved implements an operations on one particular farm; by an itinerant ploughman of abilities, accompand by a smith and carpenter, and with some implements, to go round the estate and instruct each tenant on his own farm; and finally, and perhaps preferably, by inducing every farmer to make a tour into some other district

once a year.

4009. In addition to these modes, appropriate as we consider for two different classes of tenants, Marshal suggests the following as calculated to insure a spirit of improvement among all farmers not of sufficient energy and intelligence. They are to be adopted in various ways, by a proprietor, or by the manager of an estate, who has a knowledge of rural affairs, and who possesses the good will and confidence of its townstre.

an estate, who has a knowledge of rural affairs, and who possesses the good will and confidence of its tenantry.

4610 By personal attention alone much is to be done. By reviewing an estate, once or twice a year; by conversing with each tenant in looking over his farm; and by duly noticing the instances of good management which rise to the eye, and condemning those which are bad; vanity and fear, two powerful stimulants of the human mind, will be roused, and an emulation be created among superior managers; while shame will scarcely fail to bring up the more deserving of the inferior ranks. If, after repeated exhortations, an irreclaimable sloven be discharged as such, and his farm given to another, professedly for his superior qualifications as a husbandman, an alarm will presently be spread over the estate, and none, but those who deserve to be discharged, will long remain in the field of bad management.

4611. Even by conversation, well directed, something may be done. If, instead of, on the one hand, collecting tenants to the audit, as sheep to the shearing, and sending them away, as sheep that are shorn; or, on the other, providing for them a sumptuous entertainment, and committing them to their fate in a state of intoxication; a repast suited to their conditions and habits of life were set before them; and, after this, the conversation bent towards agriculture, by distributing presents to superior managers, and specifying the particulars of excellence for which the rewards or acknowledgments were severally bestowed; a spirit of emulation could not fail to arise among the higher classes; while the minds of the lower order of tenants, and of the whole, would be stimulated and improved by the conversation.

4612. By encouraging leading men in different parts of a large estate, men who are looked up to by ordinary tenants; by holding out these as patterns to the rest; by furnishing them with the means of improved constructions: and, in recluse and backward districts, much may be done by tempting good husbandme

4613. By an experimental farm, to try new breeds of stock, new crops, new implements, new operations, and new plans of management; such as ordinary tenants ought not to attempt, before they have seen them tried. To this important end, let the demesne lands of a large estate, or a sufficient portion of them, be appropriated to a nursery of improvements, for the use of the estate; to be professedly held out as such, and be constantly open to the tenants; more particularly to the exemplary practitioners, the leading men of the estate, just mentioned; who, alone, can introduce improvements among the lower classes of an ignorant and prejudiced tenantry; it is in vain for a proprietor attempt it. On the contrary, the attempt seldom fails to alarm, disgust, and prevent the growth of spontaneous improvements. ments.

contrary, the attempt seldom fails to alarm, disgust, and prevent the growth of spontaneous improvements.

4614. Under the present plan of demessue farming, the tenants see expensive works going forward, which they know they cannot copy, and hear of extraordinary profits, byparticular articles, which they are certain cannot be obtained by any regular course of business. They therefore conclude that the whole is mere deception, to gain a pretext for raising the rents of their farms above their value. Whereas, if the demessne lands were held out, as trial grounds, for their immediate benefit, and conducted, as such, in a manner intelligible to them, they would not fail to visit them. Instead of large proprietors attempting to rival the meanest of their tenants, in farming for pecuniary profit, which, on a fair calculation, they rarely, if ever, obtain; let their views in agriculture be professedly and effectually directed toward the pecuniary advantages of their tenants; for from these alone can their own arise, in any degree that is entitled to the attentions of men of fortune. Instead of boasting of the price of a bullock, or the produce of a field, let it be the pride of him who possesses an extent of landed property, to speak of the flourishing condition of his estates at large, the number of superior managers that he can count upon them, and the value of the improvements which he has been the happy means of diffusing among them. Leave it to professional men, to yeomanry and the higher class of tenants, to carry on the improvements, and incorporate them with established practices; to prosecute pecuniary agriculture in a superior manner, and set examples to inferior tenantry. This is strictly their province; and their highest and best view in life. It has been through this order of men, chiefly or wholly, that valuable improvements in agriculture have been brought into practice, and rendered of general use.

4615. The possessor of an extent of territory has higher objects in view, and a more elevated station t

SECT. II. General Cautions on the Subject of executing Improvements.

4616. No work can be prudently commenced until the plan be fully matured, not in idea only, but in diagrams, and in models, if the subject requires them; in order that every bearing and every hinge may be sufficiently foreknown: the site of improvement being reverted to, again and again, with the draught or the model in hand, until the judgment be satisfied and the mind be inspired with confidence. If a proprietor have not yet acquired sufficient judgment within himself, let him consult some one man, or one council of men, in whose knowledge and judgment he can confide; and thus fix a rallying point. Having brought his plan to a degree of maturity, in this private manner, he may then venture to publish it; and endeavour to improve it, by the advice of its friends, and the animadversions of its enemies.

4617. If a proprietor wants judgment himself, and a friend to supply it, let him not attempt the more difficult works of improvement. Yet how often we see, both in public and private life, men engaged in arduous undertakings, embarked on the wide ocean of usiness, without rudder or compass to guide them, depending on casual information, o help them on their way! They are consequently ever of opinion with the last persons hey converse with. Such men's decisions and operations are always wrong: and for an obvious reason. They consult those who are best able to inform them, first; and receive their last impressions from those who are least capable to give them. Men who have neither judgment in themselves, nor any standard of practice to rally at, are liable to be led astray by the plausible schemes of theorists, the greater part of whom know nothing of the practical part of business, and who, by their calculations, both of expense in the outlay and of profit in the return, deceive both themselves and their friends or employers: some also may have sinister designs in view; though we believe the errors of speculative men are in most cases owing to their being endowed with more imagination than judgment.

4618. The execution of the different improvements of which an estate has been found susceptible being determined on, it is always advisable to begin with one which is obvious; which may be effected with the greatest certainty; which will repay most amply the expenses of carrying it into effect; or which leads to other improvements, as embankment, drainage, &c. To attempt a doubtful project, while plans which are obvious and certain remain unexecuted; to try experiments before the list of known improvements has been gone through; is seldom to be recommended, though it might sometimes

turn out to be right.

4619. All rural operations are more or less public, and as it were performed on a stage; and spectators fail not to criticise. If an experiment should prove abortive, or a proposed improvement turn out to be false, the ardour of the improver will be liable to be damped, his people to be discontented (as partaking in the discredit), and the expecting public around him to be disappointed. A few miscarriages, in the outset, might frustrate the best intentions and the most profitable schemes. But if, by prosecuting plain and certain improvements, a man once gain his own confidence, as well as that of the people about him, he may then venture to explore less beaten paths; and this he will be able to do with greater caution, and more probability of success, by the experience already gained; this being a further motive for pursuing the line of conduct here suggested.

4620. All works of improvement should be executed with vigour. Many falter in the midst of well-planned works, either, through the want of foresight or of business-like exertion; in consequence, the money already expended lies dead, and the works are injured by the delay. Some works, as embankments and drainages, may be ruined by the slightest neglect or relaxation; and, indeed, as Marshal observes, we see, in every department of the kingdom, these and other works deserted, and left to moulder into nuisances

or disreputable eyesores.

4621. In carrying on a work, execute every thing substantially, and in a workman-like manner. Too often a false economy leads to the subversion of this principle. To save a few pounds in the first cost, materials of an inferior quality are laid in, or a quantity used insufficient to give the required substance and strength to the work. By either of these imprudences, its duration is abridged; and the eventual loss, by repairs and renewal, may be ten times greater than the sum injudiciously saved in the original erection. Nevertheless, to increase the evil of these ill-judged savings, inferior workmen are employed; or sufficient workmen at inferior prices, at which they cannot afford to make good work, nor can a superintendent urge them to make it under such circumstances. Consequently the work is ill performed, its duration is still more abridged, and a further loss is incurred by injudicious saving.

4622. There are cases in which temporary works only are required. A lease-tenant, for instance, wants to make an improvement which will last as long as his lease, without caring about its further duration. In such a case, it may be well-judged frugality and admissible "cleverness in business," to work up cheap materials in a cheap way: but it seldom can be right in the proprietor of a hereditary estate, whose interest in it may be said to be perpetual, to proceed in the same manner. His best policy is to take favourable opportunities of laying in good materials at moderate prices; to use them when duly seasoned; and to employ good workmen at such prices as cannot furnish an excuse

for bad workmanship, and will warrant him to enforce good.

4623. Accomplish one work before another is commenced. A work may be considered as accomplished when the chief difficulties are surmounted, and the chief cost expended; and, till this is the case, it cannot be prudent to embark in another. By avoiding embarrassments, the execution of improvements becomes a present pleasure, as well as a source of future profit; no half-finished works are left as monuments of disgrace to an estate and its owner; no time nor interest of money is lost; every work is brought into action and profit as it is finished; and if, as it frequently will happen with the most prudent calculators, the estimated sum has been exceeded, due time may be taken to let the fund of improvement accumulate, so as to enable it to discharge the arrear, and to furnish, as wanted, the estimated sums requisite for the succeeding work.

BOOK IV.

MANAGEMENT OF LANDED PROPERTY.

4624. The management of an extensive landed estate, like that of every other great property, is a business both of talent and integrity. In former times, when every proprietor may be said to have cultivated the whole of his agricultural territory, it constituted his whole occupation, when not engaged in war; or required a host of managers, if he was a man of the first rank. On the continent, and especially in Russia and Hungary, where estates are of enormous extent, and wholly farmed by the proprietor, the largest estates, as we have seen (621.), are managed by a court of directors, and an executive department, with a numerous body of superintendent officers, artists, and artisans. A better system is now adopted in this country, in consequence of the creation of professional farmers, who, taking large portions of territory from the owner for a certain number of years at a fixed rent, and on certain stipulations for mutual security, occasion little more trouble to the proprietor, during that period, than receiving payments. Hence it is that the management of estates in Britain, though important, is a more simple business than in any other country.

4625. Where there are only tenanted holdings, the business of management is very simple; where there are woodlands, it requires a person to look after that department; and where there are waters, quarries, and mines, a greater number of subordinate officers are requisite. But what often occasions most expense, and at the same time is attended with the least profit, is the management of the abstract rights belonging to an estate; such as manorial rights, quit-rents, and other feudal or antiquated trifles or absurdities, which require courts to be holden, and lawyers and other officers to be called in to assist. The only British author who has digested the business of managing estates into a regular system is Marshal, and we shall follow him in considering this subject: — 1st, as to the superintendents on the executive establishment of an estate;

and, 2dly, as to the general business of management.

CHAP. I.

Superintendents, or Executive Establishment of an Estate.

4626. Though every man who cannot manage his own estate in all important matters, deserves to lose it, yet, as extensive proprietors generally have their properties situated in different parts of the country, and have, besides, public duties to attend to, certain subordinate managers become necessary. In The Code of Agriculture it is stated, that no individual having a large estate is equal to the task of managing it, unless he is in the prime of life, dedicates his whole time to the business, and gives up every other occupa-It is there stated to have been found expedient, by the proprietor of an estate of great extent, to nominate two or three commissioners to assist him in its management. Under the superintendence of such commissioners, it is said, the affairs of a great property would be as well conducted as on the best managed small or moderate-sized estates; while the duties of the proprietor would principally be to carry the exercise of true benevolence into effect, which would consist in softening severe decisions; or in granting those marks of approbation and reward which, when bestowed by the proprietor himself, are the most likely to produce beneficial consequences. (Code, &c. App. 58.) Such may be the case on a few estates in the British isles not yet brought into a regular system of improvement, and about to be remodelled, of which a grand example occurs in the immense property of the Marquess of Stafford; but, in the great majority of cases, to each estate a manager of qualifications suited to its extent and duties, and a general receiver and controller in the capital or metropolis (if the proprietor and his banker cannot effect these duties between them) are all that is requisite. We shall first offer a few remarks on the qualifications and duties of managers, and next on the place of business and its requisites.

SECT. I. Steward or Manager of an Estate, and his Assistants.

4627. The head manager of an estate ought unquestionably to be the proprietor himself, or his representative, if a minor or otherwise incompetent. Next to the proprietor is his acting man of business, with proper assistants; together with such professional men as advisers as the circumstances of business may render necessary. A tenanted estate differs widely from other species of property; as giving power and authority over persons as well as things. It has, therefore, a dignity and a set of duties attached to it,

which are peculiar to itself. A man who receives ten thousand pounds a year from the public funds, for instance, is an insulated being, compared with him who receives the same income from landed property, and who is one of society's best members, provided his affairs are judiciously conducted. On the contrary, if, regardless of the dignity and the duties of his station, he lives but to dissipate his income, leaving the government of his estates and their inhabitants to those whose interest and honour are unconcerned in their welfare, or to those whose best interests lie in their derangement, he becomes at once an enemy to himself, to his family, and to the community. As unpardonable it would be in the possessor of a kingdom to be ignorant of state affairs, and unmindful of the ministers who reside about his court; or in the commanding officer of a regiment to be a stranger to his men, a priest to his parishioners, or a shepherd to his flock; as for the possessor of a tenanted estate to be ignorant of territorial concerns, and a stranger to his lands and their occupiers.

4628. Though it be an essential part of the duty of a man of fortune to be intimately acquainted with his own affairs, it does not follow that he should be absorbed in them, and neglect his duties as a superior member of society. In all matters of government and command, subordination is essential to good order and success. A commander in chief does not act as pioneer, nor does a naval commander reef his sails, or heave his anchor. Each has his subordinate officers to convey his commands, and men to execute them. But it is essentially necessary that the former should be well acquainted with military, the latter with naval, affairs. Every heir apparent, therefore, to a large landed property, should be regularly, or at least more or less, bred up in the knowledge of rural affairs, so as to fill with honour and profit the high station he has in view. But if the possessor of an estate has not been fortunately initiated in the knowledge which belongs to his station, the task of acquiring it is far from great.

4629. On a large estate we generally find a resident manager, a land steward, a man who has some knowledge of what is termed country business, and who acts under the control of his employer, or of a confidential friend, who is more conversant in rural concerns; or perhaps of a law agent, who knows less of them; or such residing steward, especially of a detached estate which lies at some distance from the residence of its proprietor, acts without control. In the last case, if he is a man of judgment, it is fortunate both for the landlord and tenant: but, on the contrary, if such possessory manager wants those requisite qualifications, the consequence becomes mischievous to the lands, their occupiers, their proprietors, and the community.

4630. The requisite acquirements of an acting manager, according to Marshal, are, a knowledge of agriculture, surveying, planting, some knowledge of mechanics, natural history, and skill in accounts. Agriculture is the only firm foundation on which the other required attainments can be securely reposed. It is not more essentially valuable in the superintendence than in the improvement of an estate. It is difficult to become an accurate judge of the value of lands without a practical knowledge of their uses; nor can any man without it properly appreciate the management of occupiers, much less assist them in correcting their errors, and improving their practice.

4631. Land-surveying is a requisite qualification. Not so much, however, for the purpose of measuring and mapping an estate at large, as for checking and correcting the works of professional men, as well as to assist in laying out its lands to advantage.

4632. Planting, and the management of woodlands, are acquirements that cannot be dispensed with. Nor should his knowledge and attention be confined to the surface of the estate entrusted to his care; he ought to have some acquaintance with natural history chamistry, and avnorimental philosopy to the surface.

Nor should his knowledge and attention be confined to the surface of the estate entrusted to his care; he ought to have some acquaintance with natural history, chemistry, and experimental philosophy, to enable him to form just notions on the subject of the subterrene productions which it may contain.

4633. Some knowledge of mechanics, and other sciences that are requisite to the business of an engineer, may be highly useful in prosecuting the improvements incident to landed property.

4634. A competent knowledge of rural architecture, the doctrine of the strength of materials, and the superintendence of artificers, may be said to be of daily use.

4635. A thorough knowledge of accounts is essentially requisite to the manager of a landed estate.

4636. He should be a man of good character, of upright principles, and conciliatory manners; to set an example of good conduct to the tenants, and to become their common counsellor and peace-maker, in those trifling disputes which never fail to arise among the occupiers of adjoining land; and which too frequently bring on serious quarrels and lawsuits, that end in the ruin, not only of themselves, but of the tenements they occupy. A proprietor has, therefore, an interest in checking such disputes in the bud; and no man can do this with so much effect as a manager in whom they have a proper confidence, and who possesses a due share of popularity on the estate. who possesses a due share of popularity on the estate.

4637. The acting manager requires certain assistants on a large estate; especially if it lies in detached and scattered parts. Those in general use are a ground officer and clerk.

4638. A land-reeve, woodward, or ground officer, is required on each district or department of a large estate; to attend not only to the woods and hedge-timber, but to the state of the fences, gates, buildings, private roads, driftways, and watercourses; also to the stocking of commons (if any), and encroachments of every kind; as well as to prevent or detect waste and spoil in general, whether by the tenants of the estate, or others; and to report the same to the manager.

4639. The office-clerk, book-keeper, or under steward, is employed to form registers,

make out rentals, &c. and keep the accounts of the estate; as well as to assist the manager in his more active employments; also to act as his substitute in case of sickness, or absence; and to become his successor in the event of his death, or other termination of

his stewardship.

4640. A law assistant, solicitor, or attorney, may next be considered as requisite to the good management of a landed estate. For although much is to be done by judicious regulations, and the timely interposition and advice of a resident manager, such are the frailties of human nature, that, in a state of civilised society, and of property, legal assistance will sometimes be necessary. The error of country gentlemen consists, not in employing lawyers, but in committing the management of their landed estates to them. The employment of law agents as land stewards, however, is not without some reason. Farmers are not for the most part sufficiently skilled in accounts for taking the charge of a large estate; and such of them as are capable, are commonly men of capital, and would not exchange their situation for the less independent one of a land steward. The division of labour, in the case of large estates, is not without its use, and is recognised in practice. A law agent collects the rents and keeps the accounts, often on a very small salary; and in questions of a practical nature, such as the valuation of new leases, the modes of cropping, &c. he advises with a surveyor or land valuer. After all, however, a well chosen land-steward to reside upon the estate, and to consult, when necessary, with a lawyer, must be the best plan, even though his salary be higher than that of the law agent, who commonly acts for several proprietors, does not reside on any of their estates, and very likely, as we think, cannot do them justice.

4641. In the feudal system, under which every manor court was a court of law, we may perceive the origin of law land-stewards. It is allowed by the best agricultural writers in Europe (Chateauvieux, Thaer, Thouin, Mathieu de Dombasle, Sigismondi, Jovellanos, Young, Marshal, Brown, Coventry, &c.), that these men by their rigid adherence to precedent in the clauses of leases, have contributed most materially to retard the

progress of agricultural improvement.

4642. The land-surveyor is another professional man, whom the superintendent of an estate may want to call in occasionally. Not merely to measure and map the whole or parts of the estate, but to assist in matters of arbitration, and the amicable settlement of disputes; or to act himself, as valuer or referee.

SECT. II. Land Steward's Place of Business, and what belongs to it.

4643. A manager's place of business may be considered in regard to its situation, accommodations, and appropriate professional furniture.

4644. The situation of the place of business should be under the roof of the proprietor's principal residence; round which, and in its neighbourhood, some considerable parts of his estates may be supposed (as they ever ought) to lie. If a large bulk of his property lie at too great a distance for tenants to attend at the principal office, and if on this he has a secondary residence, an inferior office is there required for such detached part. And it may be laid down as a rule, in the management of landed property, Marshal observes, that every distant part of an estate ought to have a place upon it (be it ever so humble) in which its possessor may spend a few days comfortably; to diffuse over it a spirit of good order and emulation. He has known the most neglected and almost savage spot, such as are many landed estates in Ireland, reclaimed and put in a train of improvement by this easy method.

4645. The accommodations requisite for a principal office are, a commodious business room, a small ante-room; and a safe-keep, or strong room, fire proof, for the more valu-

able documents.

4646. The professional furniture with which an office of this description requires to be supplied are maps, rental-books, books of valuation, register, legal papers, and some others.

others.

4647. A general map of the whole estate on a large scale is an obvious requisite; and portable separate maps, with accompanying registers and other descriptive particulars, are useful in proportion as improvements may be in contemplation.

4648. Books of valuation are essential, especially where there are numerous small holdings on short terms. In these registers are contained the number, name, admeasurement, and estimated value of each field, and of every parcel of land, as well as of each cottage or other building not being part of a farm-stead, on the several distinct parts or districts of the estate. The valuations being inserted in columns, as they arise, whether by general surveys, or incidentally, headed with the names of their respective valuers, so that whenever a farm is to be relet, these columns may be consulted, and its real value fixed in a resurvey with the greater exactness.

4649. A general register of timber trees, consecuod, and young plantations is particularly wanted where there is much hedgerow timber. Marshal directs to specify in this register the number of timber trees in each wood, grove, hedgerow, and area, with the species, number, and admeasurement of each tree. He also recommends separate pocketbooks, containing the particulars of each division, or of a number of contiguous divisions, for the occasional use of the manager and woodreeve.

4650. Contracts, agreements, accounts, letters on business, and other documents, should be intelligibly endorsed, dated or numbered, and arranged so as to be easily referred to. A book of abstracts, or heads of papers of greater importance, should be made out to be referred to on ordinary occasions, and likewise

to serve as an index to the originals, which require a more secure repository than a common business-

4651. Legal documents, such as title deeds, legal decisions, awards of arbitration, counterparts of leases, securities, cash, bills, passed accounts, &c., as being the most important objects, should be carefully depo-

sted in the safety-chest or strong room.

4652. Portable registers of the tenanted lands, in convenient pocket volumes, with maps on a small scale heading every farm, are, according to Marshal, who seems to have looked upon tenants as placed in a state of continual hostility with their landlords, a most invaluable description of books both for the manager and his employer. Two opposite pages being appropriated to each farm with its map, the following information should be significant. should be given : -

Name of the farm and its number of acres. The name of the tenant and the existing rent.

The tenancy; if on lease, the term of expiring. Any extraordinary covenant of the lease.

The number of cottages let with the farm, The number of timber trees growing on it. The number of orchard trees growing on it.

The eligibility of the plan and circumstances of the farm. The eligibility of the occupier.
The eligibility of the present rent.
The state of the buildings, fences, and gates,

roads, and watercourses. The state of cultivation, and condition of the live

4653. Add, among other things, the following, viz.: -

The repairs more immediately wanted.
The improvements of which the whole is suscep-

The agreements entered into with the tenant,

The permissions granted him. The injunctions delivered to him.

With a hint as to his personal character, and the number and general character of his family.

With any other incident or occurrence respecting the farm or its occupier, that requires to be remembered; and with references to the books and papers which may pertain to the several particulars; thus having at one view a complete abstract of the history and present state of every farm, together with the particulars of attention which each will require will require.

number and general character of his family. Will require.

4654. The trouble of forming an abstract of this kind, or of renewing it when filled, or in order to adapt it to the varying circumstances of the several farms, is inconsiderable, compared with its uses, which are not only obvious in theory, but are fully established in practice. On returning to an estate, after twelve months' absence, Marshal has generally found, that, by consulting a register of this sort, and, through its means, making systematic enquiries respecting the incidents that have occurred on the several farms during his absence; he, in this summary way, and before he entered upon a fresh view, became better acquainted not only with the general interests, but with the more ordinary business, of the estate, than the acting manager, who had constantly resided upon it, without such a remembrancer. This abstract or remembrancer, he says, ought not to comprehend tenanted farms only; but should comprise woodlands, quarries, the demesne, &c. in hand; as well as the more important improvements going on: each of which ought to have its separate folio assigned it. To a proprietor, or his confidential friend, who only goes over his estate occasionally, such an intelligent companion is essentially serviceable. He cannot profitably direct, nor safely advise with, an acting manager, or other agent or officer of the estate, until he has consulted so infallible an oracle. The utility of such a register, while a proprietor is absent from his extate, if he can be said to be so, with such a faithful mirror in his possession, is too obvious to require explanation. explanation.

explanation.

4655. Among the instruments necessary for a manager's office, may be included those requisite for surveying, mapping, levelling, measuring timber, and every description of country work, together with boring machines, draught measurers, weighing scales, some chemical tests, models, and such other articles as may be required or rendered useful by particular circumstances.

4656. An agricultural library may be considered an essential requisite; including works on rural architecture, the prices and measuring of work, and other fluctuating matters; and one of the best encyclopedias of universal knowledge. We have already suggested an important use to which such a library might be applied. might be applied.

4657. Such an establishment and place of business as has been described, we agree with Marshal in thinking, many will consider as in some degree superfluous or extravagant. In many cases we admit it would be so; but it is impossible to determine what things can be done without, unless a particular case were given. Such a minute register of farms, for example, would be quite ridiculous on an estate in East Lothian, where tenants are of sufficient wealth and respectability of manners to be treated as men; and not watched and schooled like those which Marshal seems generally to have in view. As tenants of land become enlightened, they will be very differently treated from what in many places they are at present. As a proof of this, we have only to compare one district of country with another. In East Lothian, Berwickshire, and some other parts of Scotland, the farmers are as intelligent as their landlords; and the transactions which take place between them resemble the transactions which take place between one mer-is sunk in ignorance, he ranks with the labourer, and occupies his farm by a sort of sufferance. It is a pity that the ignorance and seclusion of such men do not admit of their comparing their state with that of others possessing no greater capital, but more knowledge and skill: it is a pity, we say, for the sake of their children, whom they might thus be induced to educate.

CHAP. II.

Duties of Managers of Estates.

4658. The various duties of the manager, or the proprietor, of a landed estate, may be considered under the heads of general business, business with tenants, and auditing accounts.

Sect. I. General Principles of Business considered relatively to Land-Stewardship.

4659. The first and most general principle, in this and every other department of business, is to embrace readily the several matters as they occur; and not to put them off from time to time, until they accumulate, and render the task difficult and irksome. The only artifice, it may be said, which a man of character can well employ in business is that of endeavouring to render it pleasurable; and, by meeting it cheerfully, as it rises, or as it becomes ripe for despatch, this desirable end will generally be attained: for, in that state a man not only enters upon it with pleasure himself, but he will generally find his opponent in the same temper of mind. Whereas, through delay, misunderstandings, idle tales, and groundless surmises are liable to intervene; the minds of both to be soured; a distant coolness to take place between them; and a barrier to be raised, which, though altogether imaginary, nothing but the mystic wand of the law may be able to remove.

4660. There are three distinct methods of conducting business. The first is that in which the parties meet, with fair intentions, to find out the point of equity, and there to close. In the second, they enter upon business, guarded with cunning, and armed with trick and artifice, as gamblers draw round a table, to take every advantage, fair or otherwise, which they can effect with impunity. The last method lies in the courts of law and equity.

and equity.

4631. A business founded on honourable intentions is the only one in which a man of honour can voluntarily appear. Here honest men come, as indifferent persons, to arbitrate the matter in reference. In every settlement between man and man, there is a point of equity and right, which all good men are desirous to find; and when men of liberal minds fortunately meet and join in the search, it is seldom difficult to be discovered. Should some little difference of opinion arise, let them call in an umpire to decide between them; or leave the whole to the decision of three capable and disinterested men.

4632. A man of strict integrity may become entangled in business with a man folsoer principles. In this case, it behoves him to be upon his guard; but still to enter into the negotiation with temper and civility. There is even a politeness in affliars of business which cannot be departed from on any occasion. Interruptions and schisms frequently arise, especially between men who are of keen sensibility, and who (though passably honest) are tenacious of their own interests, from mere matter of punctillo. The mind of either being once soured by neglect, or urfled by disrespectful behaviour, the smooth path of peaceful negotiation is broken up, a spirit of warfare is roused, and advantages are taken, or attempted, which calm reason would not have suggested. Hence, when men of unequal degree are brought together in business, it is incumbent on the superior to set the example of liberality and civility of demeanour.

4633. In extreme cases there is no resource but the law; and here the most that an honest man can do is to procure, without loss of time, the best advice; and to spare no exertion or useful expense in bringing the dangerous and tormenting business to a speedy conclusion. Not only is a man's property endangered, while it is tossed on the troubled sea of the law; but his time and attention are led astray, and his peace of mind is liable to be broken in upon, thus deranging his ordinary concerns, an

4664. In forming connections in business, select the man who has a character to lose. This principle should be invariably acted on: for if a man of established good character be properly treated, and determinately closed in with in case he demur or swerve from the right line of conduct, he will not forfeit his good name by doing a disreputable action; and must therefore come forward to the point of equity and justice.

SECT. II. Management of Tenants.

4665. The general treatment of tenants and cottagers may be considered as the most important part of every land-steward's occupation: it includes the mode and conditions of letting lands, and the time and manner of receiving rents. The idea of a landlord or his agents managing his tenants does certainly on the face of it appear an absurdity. The tenant is not more obliged to the landlord than the landlord is to the tenant; and therefore both parties being on an equality in point of obligation, the one ought not to require or have the power to manage the other. This power is given, however, by the ignorance of one of the parties, and the existing monopoly in favour of the other; and till these are done away with, by education and political changes, the ignorant part of farmers will always be managed by their landlords.

Subsect. 1. Proper Treatment of Tenants.

4666. On every large hereditary estate, there are established customs and usages, to which the proprietor and the occupiers consider themselves mutually amenable, though no legal contracts may subsist between them. Even where imperfect leases, or other legal agreements exist, still there is generally much left for custom and usage to determine. Though some of these may be improper, yet they ought to be strictly observed by its superintendent, until better can be placed in their stead; not merely on the score of moral justice, but, in the same observance, to set an example of integrity and good faith to the tenants. If a superintendent imprudently break through a custom or a covenant, what can he say to a tenant who follows his example?

4667. A manager ought to set an example to the tenants under his care of liberality and kindness. This is more especially applicable to the case of cottagers and others who rent small holdings. There are numberless small favours which he can bestow upon them without loss, and many with eventual advantage to the estate. A spirited improving tenant should be refused nothing that he can reasonably ask; should have favours voluntraily conferred upon him, not merely as a reward for the services which he individually is rendering the estate, but to induce its other tenants to follow his example, and to make known to the whole that their conduct is observed, and distinctions made

between good and bad managers.

4668. Estates, like men, have their good and bad characters. No skilful farmer who has a capital to lose, will take up his residence on an estate of known bad character. On the contrary, when once an estate has acquired the character of good faith and proper treatment of its tenantry, men of money and spirit will ever be anxious to gain a footing there. Besides, the character of an estate will ever involve that of its possessor: and, setting income at naught, it surely behoves a man of property to pay some attention to the character of his estates; for what can well add more to the permanent respectability of a family of rank or fortune, than having its estates occupied by a wealthy and respectable tenantry?

4669. In a state of civilised society and property, one of the great arts of life is to teach character and interest to go hand in hand, and on ordinary occasions to endeavour to turn every incident, as it fortuitously occurs, to their mutual advantage. If a tenant of capital and an improving spirit be found upon an estate, give him due encouragement, for the purposes already explained. On the contrary, if another is found to possess refractory habits, to swerve from his engagements, or to injure the lands in his occupation, it is but common prudence to take the first legal and fair opportunity of dismissing him, and supplying his place with another who is better qualified to fill it; not more with a view of rescuing his particular farm from further injury, and of making an example of him in terror to others of similar habits, than to preserve and heighten the character of

the estate.

4670. These remarks may be considered as applicable chiefly to small tenants, or such as from ignorance and want of leases may be considered in a state of bondage. ought never to be in the power of a landlord to make "an example of a tenant in terror to others;" it is enough if this power be left to the laws. A tenant who rents a farm on certain conditions, and fulfils them, is, in point of obligation, on an equality with his landlord; neither is obliged to the other: and while the one does not require those acts of kindness and liberality which Marshal inculcates, the other is not entitled to that submission and slavish deference so common among tenants at will, and indeed most others in England. It is justly observed by Brown (Treat. on Rur. Aff.) that the moral excitement, or degree of encouragement, given to the tenant for improving the ground put under his occupation, is regulated entirely by the terms or conditions of the lease under which he holds possession. If the conditions be liberal and judicious, and accommodated to the soil and situation of the land thereby demised to the tenant, all that is obligatory upon the proprietor is faithfully discharged. But when matters are otherwise, when the tenant possesses under a short lease, when the covenants or obligations are severe in the first instance and ultimately of little avail towards forwarding improvement, it may reasonably be inferred that the connection is improperly constituted, and that little benefit will thence follow either to the public or to the parties concerned. The proper view of a lease is, that it is merely a mercantile transaction reduced to writing, in which both parties are on an equal footing.

Subsect. 2. Business of letting Farms.

4671. There are three methods of letting a farm: putting it up to public auction, and taking the highest bidder for a tenant; receiving written proposals, and accepting the highest offer; and asking more rent for it than it is worth, haggling with different chapmen, and closing with him who promises to give the most money, without regard to his eligibility as a tenant. After a variety of obvious remarks, Marshal concludes, that "seeing in every situation, there is at all times a fair rental value, or market price of lands, as of their products, there appears to be only one rational, and eventually profitable, method of letting a farm; and this is, to fix the rent, and choose the tenant. In the choice of a tenant every body knows the requisite qualifications to be, capital, skill, industry, and character. The respective advantages of these qualities are amply developed in The Treatise on Landed Property.

Subsect. 3. Different Species of Tenancy.

4672. The different holdings in use in Britain are at will, from year to year, for a term of years, or for a life or lives.

4673. The tenant holding at will, or until the customary notice be given by either party to the other, is without any legal contract, or written agreement; the only tie between the owner and the occupier being the custom of the estate or of the country in which it lies, and the common law of the land. This may be considered as the simple holding which succeeded the feudal or copyhold tenure; but which is now fast coing into disease.

fast going into disuse.

4674. Holding from year to year, under a written agreement, with specified covenants, is a more modern

usage, and becoming more and more prevalent in some parts of England, and among small tenants, even where leases for a term of years were formerly granted.

4675. Leases for a term of years, as seven, fourteen, twenty-one, or a greater number of years, certain; but without the power of assignment, unless with the consent of the lessor.

4676. Leases for lives; as, one, two, three, or more, without the power of assignment. In Britain, life leases of this description are now rarely granted. In Wales and Ireland they are still prevalent; the rent being there sottled according to the value of the land at the time of letting; as on granting a lease for a term. In the western extreme of England, what are termed life leases are still common: but they are rather pledges for money taken up, or deeds of sale for lives, than leases; for nearly the whole of the estimated sale value of the land, during the life term, is paid down at the time of purchase, the seller reserving only a quit rent, or annual acknowledgment.

4677. A lease for a term of years, or for two or more lives, can alone be favourable for the progress of agriculture. A farmer holding at will, or from year to year, may plough, sow, and reap; but he will, if a prudent man, be very careful not to make improvements, well knowing that the first effect would be a rise of rent or a notice to quit. Leases for a single life have the great disadvantage of uncertainty in duration, both as to landlord and tenant; and though the latter may insure a certain sum on his life for the benefit of his family, yet it were better that he should lay out that money in improving the farm. Leases on lives, renewable, are for all purposes of culture as good as freehold; but they have this disadvantage to a tenant, that they require a considerable part of his capital paid down, and a further draught on his capital on the falling in of any of the lives. the first of these payments would embarrass the great majority of professional farmers, and disable them from bestowing proper cultivation on the soil; but to a farmer with a surplus capital no description of lease can be better, as he lays out his surplus capital at the market rate of interest, and is, as it were, his own annuitant. To the landlord such leases cannot be advantageous; because, there being fewer who can compete for them, lands let on these conditions do not fetch their full price.

4678. The fundamental principle on which both the duration and conditions of leases are established is evidently this: - A agrees to lend to B a certain article for his use for an equivalent in money; but such is the nature of this article, that, in order to use it with advantage, B must possess it during a considerable time: he, therefore, requires a security from A to that effect; and A on his part requires a security from B that he will return the article at least in as good condition as when it was lent to him. The term of years for which the article is to be lent, and the precautions taken to insure its return without deterioration, are founded on experience, and vary according to the peculiar circumstances of lender and borrower. In general, however, this is obvious, that where the period of lending is not sufficient for profitable use, or the conditions required for ensuring the lender an undeteriorated return of the article unreasonable, the value of the

loan or rent will be proportionably diminished. (Sup. Enc. Brit. art. Agr.)

4679. In recurring to what actually exists in the best cultivated districts, we shall quote the excellent observations of an experienced farmer and approved public writer: - " The general principle which should regulate the connection between landlord and tenant seems to be, that while the farm ought to be restored to the owner at the expiration of the tenant's interest, at least without deterioration, the tenant should be encouraged to render it as productive as possible during his possession. In both of these views, a lease for a term of years is scarcely less necessary for the landlord than for the tenant; and so much is the public interested in this measure, that it has been proposed by intelligent men, to impose a penal tax on the rent of lands held by tenants at will.

4680. That the value of the property is enhanced by the security which such a lease confers on the tenant will be put beyond all doubt, if the rents of two estates for half a century back are compared; the one occupied by tenants at will, and the other by tenants on leases for a moderate term, and where the soil and situation are nearly alike in every respect. If the comparison be made between two tracts originally very different in point of value, the advantages of leases will be still more striking; while that which is held by tenants at will remains nearly stationary, the other is gradually, yet effectually, improved, under the security of leases, by the tenants' capital; and, in no long period, the latter takes the lead of the former, both in the amount of the revenue which it yields to the proprietor, and in the quantity of produce which it furnishes for the general consumption. The higher rents and greater produce of some parts of Scotland than of many of the English counties, where the soil, climate, and markets are much more favourable, must be ascribed to the almost universal practice of holding on leases in the former country, in a much greater degree than to any of the causes which have been frequently assigned. Less than a century ago, what are now the best cultivated districts of Scotland were very far behind the greater part of England; and, indeed, had made very little progress from the time of the feudal system. It is not fifty years since the farmers of Scotland were in the practice of going to learn of their southern neighbours an art, which was then very imperfectly known in their own country. But in several parts of England advanced; and at present exhibit very generally, a happy contrast to their condition in the middle of the last century. last century.

last century.

4631. In respect to farmers themselves, it cannot be necessary to point out the advantages of leases. It may be true, that, under the security of the honour of an English landlord, tenants at will have been continued in possession from generation to generation, and acquired wealth which he has never, like the landholders of some other countries, attempted to wrest from them. But there are few individuals in any rank of life, who continue for a length of time to sacrifice their just claims on the altar of pure generosity. Something is almost always expected in return. A portion of revenue in this case is exchanged for power, and that power is displayed not only in the habitual degradation of the tenantry, but in the control over them, which the landlord never fails to exert at the election of members of parliament, and on all other political emergencies. No prudent man will ever invest his fortune in the improvement of another person's property, unless, from the length of his lease, he has a reasonable prospect of being reimbursed

with profit; and the servility which holding at will necessarily exacts is altogether incompatible with that spirit of enterprise which belongs to an enlightened and independent mind.

4682. Every measure which has a tendency to fetter the productive powers of the soil, must deeply affect the public at large, as well as depress one of the largest and most valuable classes. It is clearly their interest, that corn and other provisions should be supplied in abundance, and the people of England may justly complain of the want of leases, as one of the principal causes which check the improvement

may justly complain of the want of leases, as one of the principal causes which check the improvement of their own territory.

4683. What ought to be the term of a lease can only be determined by a reference to the circumstances of each particular case. Lands naturally rich, or such as have already been brought to a high degree of fertility, requiring no great investment of capital, and returning all or nearly all the necessary outlay within the year, may be advantageously held upon short leases, such as perhaps give time for two, or at most three of the rotations or courses of crops to which the quality of the soli is best adapted. The practice of England in this respect is extremely various, almost every term, from twenty years downwards, being found in different parts of it. In Scotland, by far the most common period is nineteen years, to which it was formerly the practice, in some places, to add the life of the tenant. In that country, even when it is thought expedient to agree for a much longer term, this is still expressed in periods of nineteen years, a sort of mysterious cycle, which seems to be no less a favourite with the courts of law than with landholders and farmers. Yet this term is somewhat inconvenient, as it can never correspond with any number of the recognised rotations of arable land. number of the recognised rotations of arable land.

number of the recognised rotations of arable land, 4684. A lease for twenty years, it has been maintained by several writers, is not sufficient to reimburse a tenant for any considerable improvements, and landholders have often been urged to agree to a much longer term, which, it is alleged, would be not less for their own interest than for that of the tenant. This is a question which our limits do not permit us to discuss; but, after viewing it in different lights, assisted by the experience of long leases in different parts of Scotland, we cannot help expressing some doubts of their utility, even in so far only as it regards the parties themselves; and we are decidedly of opinion, that a greater produce will be brought to market, from any given extent of land held on successive leases of twenty years, for half a century, than if held on one lease of that duration, whether the term be specified, or indefinite as is the case of a lease for life. As a general mode of tenure, leases for lives seem to us particularly objectionable.

4883 The great any any agency of a lease are so well known in Scotland, that one of ther best agricultural

or indefinite as is the case of a lease for life. As a general mode of tenure, leases for lives seem to us particularly objectionable.

485. The great advantages of a lease are so well known in Scotland, that one of her best agricultural writers, himself a landed proprietor, has suggested a method of conferring on it the character of perpetuity, to such an extent as, he thinks, would give ample security to the tenant for every profitable improvement, without preventing the landlord from resuming possession upon equitable terms, at the expiration of every specified period. But the author of this plan (Lord Kaimes), in his ardent wishes for the advancement of agriculture, at that time in a very backward state in his native country, seems to have overlooked the difficulties that stood in the way of its adoption; and the great advance in the price of produce, and consequently in the rate of rents, since his lordship wrote, have long since put an end to the discussion which his proposal excited. For a form of a lease on his plan, the reader may cousuit Bell's Treatise on The Gentleman Farmer, recently published.

4686. Long leases granted upon condition of receiving an advance of rent at the end of a certain number of years have been granted; but covenants of this kind, meant to apply to the circumstances of a distant period, cannot possibly be framed in such a manner as to do equal justice to both parties; and it ought not to be concealed, that, in every case of a very long lease, the chances are rather more unfavourable to the landholder than to the farmer. If the price of produce shall continue to rise as it ado one, till very lately, for the last forty years, no improvements which a tenant can be expected to execute will compensate the landlord's loss; and if, on the other hand, prices shall continue to rise as it ado one, till very lately, for the last forty years, and the lands will necessarily revert to the proprietor, as has been the case of late in many instances. Hence a landholder, in agreeing to a long l

between the parties.

Subsect. 4. Rent and Covenants of a Lease.

4688. To avert the evils of fixed money rents, and long leases, both to landlords and tenants, the best mode known at present is the old plan of corn rents. This plan was first revived in 1811, by a pamphlet published in Cupar, which attracted considerable attention, and has led to the adoption in various parts of Scotland, of a mixed mode of paying rents, partly in corn or the price of corn, and partly in money. In hilly districts, wool, or the price of wool for an average of years, is sometimes fixed on instead of corn. We shall quote from the same intelligent writer on the duration of leases, his sentiments on corn rents, and subjoin his observations on covenants.

on corn rents, and subjoin his observations on covenants.

4689. Though the most equitable mode of determining the rent of lands on lease, would be to make it rise and fall with the price of corn; yet a rent paid in corn is liable to serious objections, and can seldom be advisable in a commercial country. It necessarily bears hardest on a tenant when he least able to discharge it. In very bad seasons, his crop may be so scanty, as scarcely to return seed and the expenses of cultivation, and the share which he ought to receive himself, as the profits of his capital, as well as the quantity allotted to the landlord, may not exist at all. Though, in this case, if he pays a money rent, his loss may be considerable, it may be twice or three times greater if the rent is to be paid in corn, or according to the high price of such seasons. In less favourable years, which often occur in the variable climate of Britain, a corn rent would, in numerous instances, absorb nearly the whole free or disposable produce, as it is by no means uncommon to find the gross produce of even good land reduced from twenty to fifty per cent. below an average in particular seasons. And it ought to be considered, in regard to the landlord himself, that his income would thus be doubled or trebled, at a time when all other classes were suffering from scarcity and consequent dearth; while, in times of plenty and cheapness, he might find it difficult to make his expenses correspond with the great diminution of his receipts. It is of much importance to both parties, that the amount of the rent should vary as little as possible from any unforeseen causes, though tenants in general would be perhaps the most injured by such fluctuations.

4690. To obviate these and other 'objections to a corn rent, and to do equal justice at all times to both landford and tenant, a plan has been lately suggested for converting the corn into money, adopting for its price, not the price of the year for which the rent is payable, but the average price of a certain number of years. The rent, according to this plan, may be calculated every year, by omitting the first year of the series, and adding a new one; or, it may continue the same for a certain number of years, and then be fixed according to a new average. Let us suppose the lease to be for twenty-one years, and then be fixed according to a new average. Let us suppose the lease to be for twenty-one years, and then be fixed according to a new average price of the crop of that year, and of the six years preceding. If it be meant to take a new average for the second and every succeeding year's rent, all that is necessary is, to strike off the first of these seven years, adding the year for which the rent is payable, and so on during all the years of the lease. But this labour, slight as it is, may be dispensed with, by continuing the rent without variation for the first seven years of the lease according to the average price of the seven years of the lease according to the average price of the seven years is use xpired, to continue for the next seven years. Thus, in the course of twenty-one years, the rent would be calculated only three times; and for whatever quantity of corn the parties had agreed, the money payments would be equal to the average price of the seven years preceding it; and the price of the least seven years of the lease itself, and of the seven years preceding it; and the price of the least seven years of the lease itself, and of the seven years preceding it; and the price of the least seven years of the lease itself, and of the seven years preceding it; and the price of the least seven years of the lease itself, and of the seven years preceding it; and the price of the least seven year of the le

a lease as we have mentioned.
4693. The corn-rent plan, in the case of much longer leases, will no doubt diminish the evils which we think are inseparable from them, but it cannot possibly reach some of the most considerable. Its utmost effect is to secure to the landholder a rent which shall in all time to come be an adequate rent, according to the state of the least and the mode of cultivation known at the date of the lease. But it can make no provision that will apply to the enlargement of the gross produce from the future improvement of the lands themselves, or of the disposable produce from the invention of machinery and other plans for economising labour. And the objections just stated, in reference to a lease of twenty-one years, evidently apply much more forcibly to one of two or three times that length. Old corn-rents, though much higher at urssent than old money-rents are seldom or never so high as the rents that could now be paid on a apply much more forcibly to one of two or three times that length. Old corn-rents, though much might at present than old money-rents, are seldom or never so high as the rents that could now be paid on a lease of twenty-one years. But, independently of these considerations, which more immediately bear upon the interests of the parties themselves; one insuperable objection to all such leases is, that they partake too much of the nature of entails, and depart too far from that commercial character which is most favourable to the investment of capital, and consequently to the greatest increase of land produce

nost favourable to the investment of capital, and consequently to the greatest increase of land produce.

4694. The most recent opinions on this subject are in favour of a money rent, or of a rent formed partly from the average prices of produce, and partly of money, but somewhat complicated in its arrangement, and therefore not likely to come into general use. There seems, indeed, no essential reason why rents in agriculture should not be regulated on the same general principle as rents in commerce; and were it not for the extraordinary fluctuation that has taken place in the currency of the country within the last forty years, it is more than probable no such alteration of principle would ever have been thought of. The reader who wishes to enter more at length into this subject, may consult the most recent works on political economy, and especially M*Culloch's Principles. He will also find a paper on the subject, of some practical value, in the Second edition of his Principles of Political Economy, with reference to corn rents, observes, that the disturbing effects of changes in the value of money are averted, at the same time that the effect of those which occur in the cost of producing corn are mitigated. This plan, he adds, is, however, defective, inasmuch as it obliges the tenant to pay more than the fair value of his farm in scarce years; while, on the other hand, it has the effect of improperly reducing the landlord's rents in years of unusual plenty. A simple device has, however, been fallen upon, which has gone far to reduce these defects: this consists in fixing a maximum and a minimum price, it being declared in the lease that the produce to be paid to the landlord shall be converted into money, according to the current prices of the year; but that, to whatever extent prices may rise above the maximum price fixed in the lease, the landlord shall have no claim for such excess of price. By means of this check, the tenant is prevented from paying any great excess of rent in scarce years. And to prevent

4696. The terms of payment of rent differ a little in different districts and countries. Rents, in Scotland, are paid either previously to the first crop being reaped, when they are called fore-rents; or they are paid

subsequently to the reaping, when they are termed back-rents. In England, it is believed that, with a few exceptions in the border counties, back-rents are not in use. The effect of these rents is, to afford a long credit to the tenant; it is assumed that his means of paying any year's yent are chiefly derived from the also of the crop of that year, and hence he is allowed to reap and sell the crop, in order to pay the rent; thus, if he enters at Whitsunday, 1859, and at separation of crop 1859 from the ground, his first term's they are the paying any year's yent are chiefly derived from the ground of the paying and the paying a

in our best cultivated counties.

4700. For the last four years of a lease, the same covenants are generally sufficient, only they require to be applied with more precision. Instead of taking for granted, that the proportion of the farm that cannot be under corn, will be properly cultivated, from the tenant's regard to his own interest, it becomes necessary to take him bound to this effect in express terms; the object generally being to enable the tenant, upon a new lease, to carry on the cultivation of the lands, as if the former lease had not terminated. What these additional stipulations should be, must depend in part on the season of the year at which the new lease commences, and in part on the course of crops best adapted to the soil, and the particular circumstances of every form.

new lease commences, and in part on the course of crops best adapted to the soil, and the particular circumstances of every farm.

4701. With respect to the form of a lease, as no one form would suit every district, nothing specific can be laid down with advantage. The lawyers of every estate have particular forms, and it is easy for them, in concert with the proprietor or manager, to obliterate useless or injurious restrictions, and substitute such as may be deemed best for the estate, or in harmony with the progress of the age. (Sup. Encyc. Brit. art. Agr.)

Subsect. 5. Receiving Rents.

4702. The business of receiving the rents and profits of a landed estate, simple as it may seem, is subject to analysis, and entitled to consideration. Indeed, on large properties, on which not farm rents only, but various other profits, are to be received, as cottage rents, tithe compositions, chief rents, and, perhaps, quit rents of copyhold lands; the business becomes so complex as to require to be methodised and simplified, in order to obtain the requisite facility and despatch. This is generally best effected by appointing distinct days, or distinct parts of the day, for each receipt, so that the different tenants

and suitors may know their hours of attendance.

4703. The business of holding manor courts depends on whether they are held of right, or merely by custom. If the copyhold tenure is so far worn out in any manor, that there are not two ancient or feudal tenants remaining within it, the court has lost its legal power; it cannot by right take cognizance of crimes, nor enforce amerciaments. Nevertheless, manorial courts have their uses, in regulating farm roads, driftways, and watercourses, and in preventing nuisances of different kinds within a manor; and it is generally right to preserve the custom of holding them for these purposes.

4704. Where copyhold courts remain in force, and where legal forms are to be observed, a law "steward of the manor" is proper to hold them. It is not necessary, however, that courts of this kind should interfere with the receipt of farm rents; or that a business of this nature should in any way clash with the general receivership of the estate. Employ an attorney to hold courts, as a surveyor to arbitrate disputes, or an engineer to plan

works of improvement.

4705. The propriety of having fixed days for receiving the rents of farms is evident; and some consideration is required to determine on the season of the year for holding them, so as not to oblige the farmer to forced sales of his produce. In England and Ireland, farm rents are generally due at Lady-day and Michaelmas, and in Scotland at Candlemas and Lammas. But the proper times of paying them depend on the marketable produce of an estate, and on the season of the year at which it goes in common course, and with the best advantage, to market. A tenant should never be forced to sell his produce with disadvantage; nor, when he has received his money for it, ought he to be at a loss for an opportunity of discharging his debt to his landlord. On corn-farm estates, or those whose lands are kept in a state of mixed cultivation, which comprise the great mass of farm lands in this kingdom, Michaelmas may be considered as one of the worst times of the year, at which to call upon tenants for their rents. It is at the close (or, in the northern provinces, perhaps at the height) of harvest, when the farmers' pockets are drained by extra labour, and when they have not yet had time to thresh out their crops to replenish them; nor is the summer's grass at that season yet consumed, nor off-going stock, perhaps, yet ready for market. In Norfolk, Marshal found the end of February, or beginning of March, a very fit time to pay the half year's rent due at Michaelmas; and June for paying those due at Ladyday. In some districts of the north it used to be the custom not to demand the first half year's reut, till the tenant was a year in his farm, by which means he had the use during his lease of nearly a year's rent in addition to his actual capital. But farmers there being now considered as possessed of more wealth than formerly, the first half year's rent of the lease is paid nine months after possession, and the last half year's rent of the term on or immediately before its expiration.

4706. The proper days for receiving rents are to be determined by the local circumstances of an estate and the district in which it lies; more especially by the fairs of the neighbourhood at that season, and by other stated times at which the tenants are accustomed, in conformity with the practice of the country, to receive for their dairy produce or other articles delivered in to dealers; and should be fixed immediately after these

days of embursement.

4707. On the subject of arrears, a good deal has been said by Marshal; but it is one of those which may very safely be left to the good sense and discretion of the proprietor or his manager.

SECT. III. Keeping and Auditing Accounts.

4708. Clearness and brevity constitute the excellence of accounts, and these excellencies are only to be obtained by simplicity of method. Where lands lie in detached estates so as to require different receivers, a separate account is necessarily required for each receivership; but to preserve this simplicity and clearness, it is necessary that the several sets should be in precisely the same form.

4709. The groundwork of the accounts peculiar to a landed estate is the rent-roll: from this receiving rentals are to be taken, and with these and the miscellaneous receipts and disbursements incident to the estate, an account current is to be annually

made out.

4710. In the receiving rental the particulars which a receiver wants to see at one view, when receiving the rents of an estate under judicious management, where rents are regularly received, and where occupiers pay taxes and do ordinary repairs, are few; the name of the farm, the name of the tenant, and the amount of his half year's rent, only are required: but upon an estate, on which arrears are suffered to remain, and on which matters of account are liable to take place, a greater number of particulars are necessary; as the name of the farm, of the tenant, his arrears, his half year's rent, any other charge

against him, any allowance to be made him, and the nett sum receivable, leaving a blank for the sum received and another for the arrear left.

4711. Accounts current are required to be delivered in annually by the acting manager, who ought generally to be the receiver. If the current receipts and disbursements are numerous, as where extensive improvements are going on, and woods, mines, quarries, &c., in hand, such accounts may be given in monthly, which will show the progress of the several concerns, and simplify the business at the end of the year.

4712. On the best managed estates it is usual, besides the books which have been mentioned, to keep a ledger; opening separate accounts for farm lands, woods, mines, quarries, waters, houses and their appurtenances, public works, &c.: and where a proprietor has several detached estates, besides such accounts being kept on each, one master ledger contains accounts for the whole property. This, indeed, is nothing but an obvious application of mercantile book-keeping to territorial property, the advantages of which cannot but be as great in the one case as in the other.

4713. In auditing estate accounts, the rent accounts are to be checked with the arrears of the preceding year; the column of rents with the rent-roll, corrected up to the last term of entry in order to comprise the fresh lettings; and the columns of account with the particulars, those of allowances being signed by the respective tenants.

4714. The monthly accounts of receipts and disbursements, as well as the annual payments, are to be compared with vouchers. The receipts are checked by deeds of sale, contracts, and other written agreements, the awards of referees, or the estimates of surveyors, the market prices of produce, &c.; the receiver, in every case, identifying the person from whom each sum was received. Each disbursement requires a direct and sufficient voucher, endorsed and numbered, with a corresponding number affixed to the charge in the account, so that they may be readily compared.

4715. The most essential part of the office of an auditor is that of entering into the merits of each receipt and payment; and considering whether the charges correspond with the purposes for which they are made; and whether the several sums received are adequate to the respective matters disposed of; by these means detecting, and thence-forward preventing, imposition and connivance. This, however, is an office which no one but a proprietor, or other person, who has been conversant with the transactions that have taken place upon the estate, and who has a competent knowledge of rural concerns, can properly perform. It may therefore be right to repeat, that if a proprietor has not yet acquired a competent knowledge of his own territorial concerns, to form an adequate judgment of the different entries in his manager's account, he should call in the assistance of those who are conversant in rural affairs, to enable him to judge of any particular parts that may seem to require it; and should not set his hand to an account which he does not clearly understand, nor authorise another to sign it, who may have less knowledge than himself of its merits.

BOOK V.

SELECTION, HIRING, AND STOCKING OF FARMS.

4716. FARMS or lands let out to men who cultivate it as a business or profession exist in all highly civilised countries. Sometimes the farmer or tenant pays to the proprietor or landlord a proportion of the produce, determined yearly, or as the crops ripen; and sometimes he pays a fixed quantity of produce, or labour, or money, or part of each of these. In Britain, where farming, as a profession, is carried to a higher degree of perfection than in any other country, the connection between landlord and tenant is regularly defined by particular agreements and general laws; and the latter, on entering on a farm, engages to pay a fixed sum for its use for a certain number of years. This sum is fixed according to the estimated value of the land; but being fixed, and for a certain time, it admits of no abatement in proportion to the quantity or value of the produce, as in the proportional or metayer system general in most countries (265. and 596.); and hence the necessity of a farmer maturely considering every circumstance connected with a farm before he becomes its tenant. The subjects of consideration form the business of this Book, and naturally divide themselves into such as relate to the farm, to the farmer, and to the landlord. Some of the subjects, being treated of in the preceding Book, will be but slightly noticed, though, as connected with the object of the present, they could not be altogether omitted.

CHAP. I.

Circumstances of a Farm necessary to be considered by a proposed Tenant.

4717. Whoever intends to become a professional or rent-paying farmer will, in searching for a farm, find it necessary to attend to a great variety of considerations. Those of the greatest importance may be included under climate, soil, and subsoil, character of surface, topographical position, extent, buildings, roads, fields, tenure, rent, and outgoings. In The Code of Agriculture, a more valuable collection of facts as to these points is brought together than in any other work, and from it, therefore, we shall select the greater part of the following sections.

Sect. I. Climate, in respect to farming Lands.

4718. The climate of a farm is one of the circumstances over which human art has less control than over any other; and a farmer who has but a temporary interest in his possession may be considered as incapable of exercising any influence over it. He may improve the soil and subsoil by draining and culture; and the buildings, roads, and fences by additions and alterations; but it is for the landlord to attempt improving the

climate by planting, and for a future generation to enjoy the effects.

4719. Sufficient attention, it is said in The Code of Agriculture, "is rarely paid by the farmer to the nature of the climate in which his operations are carried on. Unless the system he adopts be calculated for the weather his crops are likely to experience, every exertion will often terminate in disappointment. The system that is proper for warm and dry situations is not suitable for cold and wet ones; and in a bleak and backward climate, the nature of the soil ought not only to be attended to, but the utmost care ought to be paid to the early sowing of the earliest varieties of seed. Even the species of stock to be bred or kept on a farm should, in a great measure, be regulated by the Hence, this is a subject which the diligent farmer will invariably study with the greatest solicitude. Climate and soil, Curwen justly remarks, are, above all other considerations, those which the farmer ought constantly to keep in view." (Report to the Workington Society.)

4720. In considering the climate of a country, the following points are of peculiar importance: - Its general character, and the means of its improvement; its local heat; the light it furnishes; the quantity of its moisture; the prevailing winds; its position, whether maritime or inland; the regularity of the seasons; the phenomena to which it is liable; the productions best suited to it; the expenses it may occasion in cultivation; and its suitableness for the introduction of exotic plants and animals.

4721. The general character of a climate not only depends on position or latitude, but likewise on the elevation of a country above the level of the sea; its general aspect; the vicinity to mountains, forests, bogs, marshes, lakes, and seas; the nature of the soil and subsoil, and the power which the former possesses of retaining heat and moisture; the direction of the winds; the length of time the sun continues above the horizon; the difference of temperature between the day and the night; and the extent of dry surface in the neighbourhood. The result of these particulars combined form what may be called the general character of climate. Some of the causes of an unfavourable climate cannot be remedied by any human effort; in other cases, art may effect much; but that art is generally such as the farmer can seldom undertake, unless with a very long lease. Ameliorations of this sort, therefore, belong to the landlord. landlord.

seaon undertake, unless with a very long lease. Amenorations of this sort, increase, declared the landlord.

4722. The importance of heat, as a stimulus to vegetation, cannot be doubted. It is at a certain degree of heat that vegetation commences, and it becomes nearly stationary when the temperature falls below it. There are, comparatively speaking, but few plants calculated for very cold countries, and these are seldom valuable; whereas, in warm and temperate regions, the variety is great, and their value unquestionable. Indeed, such is the offict of cold, that, while the thermometer is below forty degrees of heat, the strongest plants become torpid, and remain in that state while it continues. Revived by the warmth of spring, and strengthened by the heat of summer, they acquire fresh life and vigour, and are thus better enabled to withstand the rigours of the succeeding winter.

4723. An increased temperature, when not carried to excess, will augment the quantity of nutritive matter in a plant, or improve the quality of fruit grown under its influence. Thus, English barley, of equal weight, is more valuable than the Scotch, because, from growing in a warmer climate, and enjoying the advantage of a greater quantity of sprints, or of malt liquor. It thence acquires more saccharine matter, and produces a greater quantity of sprints, or of malt liquor. It is also proved, by the experiments of Sir Humphry Davy, that wheat, ripened in a more regular and warmer clime, contains more of that valuable article called gluten, than the same species of grain when raised in England.

4724. The average heat of the year is not, however, of so much importance to the growth of plants, as its duration, and its steadiness at a certain degree, during the season when the grain is ripening. This gives the uniform climates of the Continent a great advantage over our variable seasons, in the production of the more delicate sorts of fruit; which, in this island, are often injured by the frosts in spring, and seldom ripen in a northern

duration.

4725. The quantity of solar light which a climate furnishes, is likewise an important object of enquiry. Light is essential to increase the proportion of starch or farina; to complete the formation of oils in plants; and to give to fruits their proper colour and flavour. It has also the effect of augmenting saccharine matter, insomuch that those sugar-canes which are exposed to the sun have more of that important ingredient than when they grow under shade. Nor ought the observation to be omitted, that darkness and light have effects directly opposite upon vegetables. Darkness favours the length of the growth, by keeping up the pliancy of their parts; light consolidates them, and stops growth, by favouring maturation. Hence, in the northernmost regions, plants go through all their stages of growth at a time when the sun no longer quits the horizon; and the light, of which they thus experience the unremitting effect, hardens them before they have time to lengthen. Their growth is therefore quick, but of short duration. They are robust, but undersized. (Mirbel.) It has been remarked also, that a soil, not retended to the sun to be supplied to the sun of the sun

tive, will be more productive in a wet climate than in a dry one. Hence, in the western coasts of England, as in Lancashire, where the quantity of rain that falls annually varies from forty to sixty inches, a siliceous sandy soil is much more productive than the same species of soil in the eastern districts, where seldom more than from twenty-five to thirty-five inches of rain fall in a year. In wet climates, also, even wheat and beans will require a less coherent and absorbent soil than in drier situations. At the same time, weather moderately dry is the most favourable to a great produce of corn; and the blossoms of wheat, in particular, set best if no rain falls in the flowering season. 4726, The importance of moisture to vegetation is obvious to every one. Water constitutes a large proportion of every plant, and is the vehicle of the food of plants held in solution. Hence, without so essential an ingredient, they must either become stunted in their growth or perish. In dry weather, when vegetation seems at a stand, no sooner do showers of rain fall, than a rapid growth of every kind of herbage immediately succeeds, even on poor dry soils, where otherwise, however well manured, vegetation would make but slow progress.

immediately succeeds, even on poor dry soils, where otherwise, however well manured, vegetation would make but slow progress.

4727. The quantity of rain that falls annually in any country is a very inferior consideration, when compared with that of the general and equable distribution of that quantity throughout the several days and months of the year. A great quantity, at the same time, is rather hurfful than beneficial; whereas those moderate, but golden showers, which regularly fall on a soil calculated to receive them, are real sources of fertility. It is by this that the character of a climate, whether were or dry, is chiefly determined, and the operations of agriculture are principally influenced.

4728. The utility of a moist atmosphere, with a view to vegetation, is, in some respects, peculiarly remarkable. Thus, in wet climates, as on the western coasts of England, Scotland, and Ireland, crops of grain and potatoes are found to exhaust the soil less than in dry situations. Oats in particular are impoverishing in a greater degree in dry climates, than in moist ones; and in the former, should be sown much earlier than in the latter.

4729. The disadvantages of a wet climate to a farmer, more especially if accompanied with a retentive

much earlier than in the latter, 4729. The disadvantages of a wet climate to a farmer, more especially if accompanied with a retentive soil, are very great. It is calculated, that in the richest district in Scotland, the Carse of Gowrie, there are only about twenty weeks in the year fit for ploughing; whereas in several parts of England, they have thirty weeks, and in many cases more, during which this essential operation can be performed. Hence ploughing must be much more expensive in the one case than in the other. 4730. The season of the year in which rain abounds is likewise of much importance. An excess is prejudicial in any season, but is peculiarly so in autumn, when it often lodges the grain by its violence, or by its long continuance prevents the corn from being properly harvested. The hopes of the husbandman are thus blasted, and the fruits of his toil and industry are frequently diminished, and sometimes entirely last lost

lost.

4731. Dews have a great effect in furnishing plants with moisture; and, indeed, without their aid, vegetation, in warm and dry climates, could not go on. Even in temperate regions dews are beneficial. In Guernsey, on the coast of Normandy, the autumnal dews are singularly heavy, so much so that, in the middle of a hot day, the dew-drops are not quite exhaled from the grass. From this moisture the aftergrass receives great benefit. Dr. Hales estimated the quantity of dew that fails in one year at three and a half inches; Dalton, at nearly five inches. In this matter, however, it is not easy to be correct.

4732. The prevailing winds have a great influence on the character of a climate, and a powerful effect on vegetation. When they pass over a large expanse of water, they are usually of a warmer or higher temperature in winter, than those which blow over high lands; more especially if sucil come from countries covered with snow. Hence the east and north-east winds, which have passed over the coldest regions of Europe, are much colder than the west and south-west winds, which blow over the Atlantic Ocean, and they oftener occasion blights. The former are comparatively drier, unless when accompanied by those thick mists, called haars, arising from the copious evaporation of the Gernan Ocean. The latter are loaded with the vapours of the Atlantic, and often, from excess of moisture, are rendered prejudicial. The strength of the prevailing winds, or the violence with which they act, more especially during harvest, ought likewise to be considered. If they are very violent, they are apt to affect the crops, and of course it becomes an object to suit the produce to them; and to form fences, enclosures, and plantations accordingly. ingly

ought likewise to be considered. If they are very violent, they are apt to affect the crops, and of course it becomes an object to suit the produce to them; and to form fences, enclosures, and plantations accordingly.

4733. A maritime position occasions a more equal temperature in a climate. Where a great body of land is exposed to the heating rays of the sun, the air becomes much warmer than it would if resting upon a small body of land, contiguous to, or surrounded by, the ocean. On the other hand, as the sea always preserves nearly the same temperature, and, except in the most northern regions, is never frozen, it communicates warmth, in the cold seasons of the year, to the air passing over it, which had been cooled in its passage over continents covered with ice and snow. Hence islands are more temperate than continents. It appears, indeed, that the thermometer has not so great a range on the sea coast, as in the more inland parts of Great Britain, even at an elevation of 400 feet above the level of the sea. Of the influence of proximity to the sea many proofs might be brought forward. It is in consequence of this circumstance, that the city of Moscow, which is situated somewhat farther south than Edihburgh, experiences winters much more severe. Another effect of a maritime position is, that strong winds which blow from the sea are sometimes accompanied by salt spray or vapour, which is injurious to crops of grain, and the leaves of trees; but when it comes in moderation, those saline particles, with which the westerly winds are loaded, contribute to the verdure of the fields in pasture.

4734. The nature of the inland position is also of much importance. The relative position of the neighbouring hills occasions a material difference of climate, exposing some districts to great severity of weather, and, by protecting others from that disadvantage, greatly promoting their fertility.

4735. In many countries the seasons of collimate, as we first and the accountry of the weather, and, by protecting others fro

must remain completely waste, in a warm one may be rendered productive. Thus, where the climate is adapted to the culture of the vine, rocks, which in Great Britain, and in colder countries, would in general be of little or no worth, in the southern provinces of France may yield as much in valuable produce as the cultivated land in their neighbourhood. The real excellence of a climate, however, depends on its yielding, in perfection and abundance, the necessaries of life, or those which constitute the principal articles of food for man, and for the domestic animals kept for his use. In this point of view, a meadow is much more productive, and in some respects more valuable, than either a vineyard or a grove of oranges; though the one may be situated in a cold and variable climate, and the other in a country celebrated both for its regularity and warmth of temperature.

4739. Even the nature of the articles raised depends upon the climate. Thus, in many elevated parts, both of England and Scotland, wheat cannot be grown to advantage, and in some of the high-lying districts of the latter, it has never been attempted. In several of the northern counties, it has been found necessary to sow, instead of the two-rowed barley, the inferior sort called bear or big; and oats, from the hardy quality of the grain, are found to be a more certain and more profitable species of corn than any other; while in humid districts peas or beans cannot be safely cultivated, from the periodical wetness of the autumn. On the whole, without great attention to the nature of the climate, no profitable system can be laid down by any occupier of land.

4740. An inferior climate greatly augments the expenses of cultivation; because a number of horses are required for labour during the short period of the year, when the weather will admit of it, which, at other seasons, are a useless burden upon the farm. When to this are joined an unevourface and an inferior quality of soil, arable laud is of little value, and yields but a trifling rent.

474

Sect. II. Soil in respect to farming Lands.

4743. The necessity of paying attention to the nature and quality of the soil need not be dwelt upon. By ascertaining the qualities it possesses, or by removing its defects, the profits of a farmer may be greatly increased. He must, in general, regulate his measures accordingly, in regard to the rent he is to offer; the capital he is to lay out; the stock he is to keep; the crops he is to raise; and the improvements he is to execute. Indeed, such is the importance of the soil, and the necessity of adapting his system to its peculiar properties, that no general system of cultivation can be laid down, unless all the circumstances regarding the nature and situation of the soil and subsoil be known; and such is the force of habit, that it rarely happens that a farmer who has been long accustomed to one species of soil will be equally successful in the management of another. From inattention to the nature of soils, many foolish, fruitless, and expensive attempts have been made to introduce different kinds of plants, not at all suited to them; and manures have often been improperly applied. This ignorance has likewise prevented many from employing the means of improvement, though the expense was trifling, and within their reach. From ignorance also of the means calculated for the proper cultivation of the different soils, many unsuccessful and pernicious practices have been adopted. Soils may be considered under the following general heads: - Sandy; gravelly; clayey; stoney; chalky; peaty; alluvial; and loamy, or that species of artificial soil into which the others are generally brought by the effects of manure, and of earthy applications, in the course of long cultivation.

of earthy applications, in the course of long cultivation.

4744. Though sandy soils are not naturally valuable, yet being easily cultivated, and well calculated for sheep, that most profitable species of stock, they are often farmed with considerable advantage; and when of a good quality, and under a regular course of husbandry, they are invaluable. They are easily worked, and at all seasons; they are cultivated at a moderate expense; are not so liable to injury from the vicissitudes of the weather; and in general they are deep and retentive of moisture, which secures excellent crops even in the driest summers. The crops raised on sandy soils are numerous, such as turnips, potatoes, carrots, barley, rye, buck-wheat, peas, clover, saintfoin, and other grasses. This species of soil, in general; has not strength enough for the production of Swedish turnips, beans, wheat, flax, or hemp, in any degree of perfection, without much improvement in its texture, the addition of great quantities of enriching manure, and the most skilful management. In Norfolk and Suffolk it is found, that poor sandy soils, unfit for any other purpose, will, under saintfoin, produce, after the first year, about two tons per acre of excellent hay, for several years; with an after-grass, extremely valuable for weaning and keeping lambs. How much more beneficial than any crops of grain that such soils usually yield! (Young's Kaderad. 123.) 4745. The fertility of sandy soils is in proportion to the quantity of rain that Islo, combined with the frequency of its recurrence. As a proof of this, in the rainy climate of Turin, the most prolific soil has from severaly soils differ materially from sandy, both in their texture and modes of management. They are frequency soils differ materially from sandy, both in their texture and modes of management. They are frequently composed of small soft stones, sometimes of flinty ones; but they often contain granite; limestone, and other rocky substances, partially, but not very minutely decomposed. Gravel, be

4747. A gravelly soil, free from stagnant water, gives such an additional warmth to the climate, that egetation is nearly a fortnight earlier than where other soils predominate. About Dartford and Blackheath, in Kent, such soils produce early green peas, winter tares, rye, autumnal peas, and occasionally wheat, in great perfection.

heath, in Kent, such soils produce early green peas, winter tares, rye, autumnal peas, and occasionally wheat, in great perfection.

4748. Gravelly soils, in a wet climate, answer well for potatoes; in Cornwall, in a sheltered situation, with a command of sea-and, and of sea-weed, they raise two crops of potatoes in the same year.

4749. Poor gravelly soils full of springs, and those sulphureous, are very unfriendly to vegetation; and are better calculated for wood than for arable culture.

4750. The stony, shaley, or stone-brash soils of Gloucestershire, and the midland counties of England, are much mixted with small stones, but have more frequently sand, or clay, or calcareous loam, in their composition than gravelly soils, and are therefore generally preferable.

4751. A clayer soil is often of so adhesive a nature that it will hold water like a dish. In a dry summer, the plough turns it up in great clods, scarcely to be broken or separated by the heaviest roller. It requires, therefore, much labour to put it in a state fit for producing either corn or grass, and it can only be cultivated when in a particular state, and in favourable weather. Though it will yield great crops under a proper system of management, yet, being cultivated at a heavy expense, requiring stronger instruments and stouter horses, it is seldom that much profit is obtained, unless when occupied by a judicious and attentive farmer. The best management of clay soils is that of the Lothians. There they are found well calculated for growing crops of beans, wheat, oats, clover, and winter tares but are not adapted for barley, unless immediately after a fallow; nor for potatoes, unless under very peculiar management. In regard to turnips, they do not usually thrive so well in clays, as in soils which are more free and open: but it is now ascertained, that the Swedish, and above all the yellow, turnip may be raised in them with advantage; that the quality is superior; that if they are taken up early, the soil is not inpured; and that there is n

Cheshire and Derbyshire for the dairy.

4752. On reclaimed peat-bogs, oats, rye, beans, potatoes, turnips, carrots, cole-seed, and white and red clover, may be cultivated. Wheat and barley have succeeded on such lands, after they have been supplied with abundance of calcareous earth; and the florin grass (Agróstis stolonifera) seems likewise to be well adapted to that description of soil in a warm climate. In Leicestershire, and other counties, they have great tracts of meadow-land; these are, in many instances, the sites of lakes filled up, and the soil is composed of peat and sediment; the peat originally formed by aquatic vegetation, and the sediment brought down by rains and streams from the upland. This soil is admirably calculated for grass.

4753. The fens in Cambridgeshire, Lincolnshire, and several other districts in England, consist of peat and sediment

and sediment.

4735. The fens in Cambridgeshire, Lincolnshire, and several other districts in England, consist of peat and sediment.
4734. Chalky soils principally consist of calcareous matter mixed with various substances, in greater or less proportions. Where clayey or earthy substances are to be found in such soils in considerable quantities, the composition is heavy and productive; where sand or gravel abounds, it is slight, and rather unfertile. The crops chiefly cultivated on chalky soils are peas, turnips, barley, clover, and wheat; and, however much the soil is exhausted, it will produce saintfoin.
4735. Chalky soils are in general filter for titlage than for grazing; for, without the plough, the peculiar advantages derived from this soil by saintfoin could not be obtained. The plough, however, ought not to extend to those fine chalky downs (called ewe leases in Dorsetshire), which, by a very attentive management during a number of years, have been brought to a considerable degree of fertility as grazing land, and which are so useful to sheep in the winter season. A chalky soil that has been in tillage permits water to pass through it so freely in winter, and is so pervious to the sun's rays in summer, that it is the work of an age to make it a good pasture of natural grasses, more especially when the chalk lies near the surface. Hence, in the western counties of England, several thousands of acres of this soil, though not ploughed for thirty years, have searcely any grass of tolerable quality upon them, and are literally worth nothing. Such soils ought to be laid down with saintfoin.

4736. Alluvial soils are of two sorts; one derived from the sediment of fresh, and the other from that of salt water. Along the sides of rivers, and other considerable streams, water-formed soils are to be met with, consisting of the decomposed matter of decayed vegetables, with the sediment of streams. They are in general deep and fertile, and not apt to be injuried by rain, as they usually lie on a bed of open gravel. They are commonl

carried off by floods.

4757. Altuvial soils, arising from the operations of salt water, called salt marshes in England, carses in Scotland, and polders in Holland and Flanders, are composed of the finest parts of natural clay, washed off by running water, and deposited on flat ground, on the shores of estuaries, where they are formed by the reflux of the tide, and enriched with marine productions. They generally have a rich level surface, and being deep in the staple, they are well adapted for the culture of the most valuable crops. Hence wheat, barley, oats, and clover are all of them productive on this species of soil; which is likewise peculiarly well calculated for beans, as the tap-root pushes vigorously through it, and finds its nourishment at a great depth. From the great mass of excellent soil, the fertility of these tracts is nearly inexhaustible; but, from their low and damp situations, they are not easily managed. Lime, in considerable quantities, is found to answer well upon this species of soil.

4758. The term boamy soil is applied to such as are moderately cohesive, less tenacious than clay, and more so than sand. Loams are the most desirable of all soils to occupy. They are friable; can in general be cultivated at almost any season of the year; are plouphed with greater facility, and less strength than clay; bear better the vicissitudes of the seasons; and seldom require any change in the rotation adopted. Above all, they are peculiarly well adapted for the convertible husbandry; for they can be changed, not only without injury, but generally with benefit, from grass to tillage, and from tillage to grass.

4759. As to the comparative value of soil, it has been justly remarked, that too much can hardly be paid for a good soil, and that even a low rent will not make a poor one profitable. The labour of cultivating a rich and a poor soil is nearly the same; while the latter requires more manure, and consequently is more expensive. Poor soils, at the same time, may have such a command of lasting manures, as lime or marl, or even of temporary sorts, like sea-weed, or the refuse of fish, as may render them profitable to cultivate. It is a wise maxim in husbandry, that the soil, like the cattle by which it is cultivated, should always be kept up in good condition, and never suffered to fall below the work it may be expected to perform.

SECT. III. Subsoil relatively to the Choice of a Farm.

4760. On the nature of the under-stratum depends much of the value of the surface soil. On various accounts its properties merit particular attention. By examining the

subsoil, information may be obtained in regard to the soil itself; for the materials of the latter are often similar to those which enter largely into the composition of the former, though the substances in the soil are necessarily altered, by various mixtures, in the The subsoil may be of use to the soil, by supplying its deficourse of cultivation. ciencies and correcting its defects. The hazard and expense of cultivating the surface are often considerably augmented by defects in the under-stratum, but which, in some cases, may be remedied. Disorders in the roots of plants are generally owing to a wet Subsoils are retentive or porous. or noxious subsoil.

or noxious subsoil. Subsoils are retentive or porous.

4761. Retentive subsoils consist of clay, or marl, or of stone beds of various kinds. A retentive clayey subsoil is in general found to be highly injurious. The surface soil is soaked with water, is ploughed with difficulty, and is usually in a bad condition for the exertion of its vegetative powers, until the cold sluggish moisture of the winter be exhaled. By the water being retained in the upper soil, the putrefactive process is interrupted, and manures are restrained from operating, consequently the plants make but little progress. Hence, its grain is of inferior quality, and when in grass its heroge is coarse.

4762. A stony subsoil, when in a position approaching to the horizontal, is in general prejudicial, and, if the surface-soil be thin, usually occasions barrenness, unless the rock should be limestone; and then the soil, though thin, can easily be converted into healthy pastures, and, in favourable seasons, will feed a heavy stock. They will also produce good crops of corn, though subject to the wire-worm.

4763. A porous subsoil is uniformly attended with this advantage, that by its means all superfluous moisture may be absorbed. Below clay, and all the variety of loams, an open subsoil is particularly desirable. It is favourable to all the operations of husbandry; it tends to correct the imperfections of too great a degree of absorbent power in the soil above; it promotes the beneficial effects of manures; it contributes to the preservation and growth of the seeds; and ensures the future prosperity of the plants. Hence it is, that a thinner soil, with a favourable subsoil, will produce better crops than a more fertile one incumbent on wet clay, or on cold and non-absorbent rock. Lands whose substratum consists of clean gravel or sand can bear little sun, owing to their not having the capacity of retaining moisture, and their generally possessing only a shallow surface of vegetable mould. In England this soil was formerly called rye-land, being ripening may be secured.

SECT. IV. Elevation of Lands relatively to Farming.

4764. The elevation of lands above the level of the sea has a material influence on the kind and quality of their produce. Land in the same parallel of latitude, other circumstance being nearly similar, is always more valuable in proportion to the comparative lowness of its situation.

4765. In the higher districts the herbage is less succulent and nourishing, and the reproduction slower when the land is in grass; while the grain is less plump, runs more to straw, is less perfectly ripened, and the harvest is also later when the produce is It has been calculated that in Great Britain sixty yards of elevation in the land are equal to a degree of latitude; or, in other words, that sixty yards perpendicularly higher, are, in respect of climate, equal to a degree more to the north. In considering the crops to be raised in any particular farm, attention ought therefore to be paid to its height above the level of the sea, as well as to its latitude. In latitude 54° and 55°, an elevation of 500 feet above that level is the greatest height at which wheat can be cultivated with any probable chance of profit; and even there the grain will prove very light, and will often be a month later in ripening than if sown at the foot of the hills,

4766. The usual maximum of elevation may be reckoned between 600 and 800 feet for the more common sorts of grain; and in backward seasons the produce will be of small value, and sometimes will yield nothing but straw. It is proper, at the same time, to remark, that in the second class of mountains in the county of Wicklow, in Ireland, where no other grain is considered to be a safe crop, rye is cultivated with success. Where the soil is calcareous, however, as on the Gloucestershire and Yorkshire wolds, from the superior warmth of that species of soil, compared to cold clays or peat, barley grows in great perfection at an elevation of 800 feet above the level of the sea. Some experiments have been made to resise core, come a travel a bigher elevation on the celebrated mountain Skiddaw. In Cumbaland have raise corn crops, at even a higher elevation, on the celebrated mountain Skiddaw, in Cumberland, but

raise corn crops, at even a magnet canada, with the more remote parts of Scotland, so as to yield 4767. The greatest height at which corn will grow, in the more remote parts of Scotland, so as to yield any profit to the husbandman, is stated to be at 500 feet above the level of the sea. At the same time corn has been produced, in other districts of that country, at still higher elevations, in particular at the

Doubruch, in Braemar, Aberdeenshire 1294
Lead-hills, in Lanarkshire 11864
led on high elemetrs. Feet above the Level of the Sea. - 600 - 760 Parish of Hume, in Roxburghshire Upper Ward of Lanarkshire

4768. These and other instances of land being cultivated on high elevations, however, are merely small spots, richly manured, and, after all, producing nothing but crops of inferior barley and oats, and seldom fully ripe or successfully harvested. It is chiefly where the soil is sandy or gravelly, that corn will answer in Scotland on such elevated situations; and even then, only when the seasons are propitious, and when there are local advantages, favourable to warmth and shelter, in the situation of the lands.

Sect. V. Character of Surface in regard to farming Lands.

4769. A hilly irregular surface, whether at a high or low elevation above the sea, is unfavourable to farming. The labour of ploughing, carrying home produce, and carrying out manure, is greatly increased; while the soil on the summit of steep hills, mounts, or declivities, is unavoidably deteriorated. On the sides of slopes the finer parts of the clay and mould are washed away, while the sand and gravel remain. Hence the soil in such

districts often wants a proper degree of tenacity for supporting corn crops. A great part of the manure that is applied in such situations is likewise soon lost. From

various causes, also, they are colder than the plains.

4770. Many extensive countries have no perceptible rise. These have their advantages from uniformity of soil, where it is rich. In other districts, the surface is of a waving description, an inequality which contributes much to the ornament of the country, by the agreeable relief which the eye constantly meets with in the change of objects; while the universal declivity which prevails more or less in every field is favourable to the culture of the land, by allowing a ready descent to any water with which the surface may be encumbered.

SECT. VI. Aspect in regard to farming Lands.

4771. Aspect, in hilly or mountainous districts, is an important subject of attention to the farmer; more especially where the climate is unfavourable. It is proved in a variety of instances, both in the central highlands of Scotland, and in other parts of the kingdom, that where the aspect of a hill is towards the north, the soil is more fertile than when it lies with a southern exposure. This is attributed to the variations from frost to thaw in the spring months, which are greater in a southern than in a northern aspect. Hence, while the soil to the north remains locked fast, and secured from waste, the other is loosened by the sun, and carried off by showers falling in the intervals of thaw.

4772. Soils which face the south are more liable to have their substance carried away by heavy rains, which are generally impelled from the south and south-west. But though the soil to the north often produces the heaviest crops of grass and hay, yet from possessing a more genial climate, and from the earlier and more powerful action of the sun, both corn and grass are harvested earlier on land which has a southern than on that which has a northern aspect; and superiority of quality thus compensates for any

inferiority in the quantity of the produce.

SECT. VII. Situation of Farm Lands in regard to Markets.

4773. No farming can go on without markets. The system of farming to be adopted on any particular farm, and the expense attending it, must materially depend on its situation in regard to markets; to the facility with which its produce can be conveyed, where a contiguous market is wanting; to vicinity to manure, to fuel, and to water.

4774. The advantages resulting from vicinity to a market, or to a large town, by which that is insured, are very great. Some crops, as those of potatoes, turnips, and clover, are frequently sold on the ground, without any farther trouble or expense to the farmer; and great quantities of manure may be purchased at a moderate expense. In such situations also there is a ready sale for every article the farm can produce; and the articles sold are not only brought to market at a small expense, but the payment is immediate. For all these reasons, it is contended, and apparently with justice, that the neighbourhood of a capital is the most profitable spot to farm in, notwithstanding the high rent of land, and the great expense

of labour.

of labour.

175. Where markets are not at hand, the farmer ought to take into consideration what articles will best suit those at a distance to which his produce must be sent. In such a situation, unless there are facilities for the conveyance of so bulky an article as corn by good roads, or by water-carriage, it is advisable, instead of cultivating grain, to attend either to the dairy husbandry, or to the breeding of stock which can be fattened in other districts where good markets are more numerous. This plan, by which the dairy, the breeding, and the fattening of stock, are made distinct professions, is highly beneficial to the country at large. Stock can be reared cheaper in remote districts than where land is dear and labour high. On the other hand, the purchaser of lean stock avoids the expense and risk of breeding great numbers of animals. His attention is not distracted by a multiplicity of objects; he can alter his system from cattle to sheep, or from sheep to cattle, as is likely to be most profitable; his business is simplified, and the capital he lays out is speedily returned. The division of professions between breeding and feeding (though they may be united in circumstances peculiarly favourable), is on the whole a most important link in the progress of agricultural prosperity.

4776. In regard to facility of conveyance, the state of public roads, bridges, iron rail-ways, canals, rivers rendered navigable, and harbours, deserves the consideration of the farmer, and will most materially influence the value of produce.

influence the value of produce.

4717. The situation of the furm in regard to manures, for an easy access to lime, chalk, marl, sea-weed, &c. is of essential advantage to cultivation. The price at which these articles can be purchased, their quality, their distance, and expense of conveyance, are likewise of importance. Farms, for example, possessing the advantage of sea-weed contiguous and in abundance, can pay from fifteen to twenty per cent, more rent per acre than otherwise could be afforded.

4718. Vicinity to fuel in the cold and moist regions of Europe are important considerations to the farmer. In the same county, even in England, the difference of expense is often material. In the Hebrides, from the moistness of the climate, the expense of fuel is reckoned equal to a third part of the rent of the land; and farmers who pay, in some cases, 1500, per amnum, would give 2000, if the landlord would supply them and their servants with fuel.

4719. Where a farmer is under the necessitu of using neat, from the labour attending the cutting.

and their servants with fuel.

4779. Where a farmer is under the necessity of using peat, from the labour attending the cutting, spreading, drying, and conveying it from a distance, several weeks of his horses and servants are devoted to that sole purpose; and much valuable time is lost, which ought to have been employed in the cultivation of his farm. It has been well remarked, that many farmers, to save five guineas on coal, often expend twenty, in thus misapplying the labour of their horses.

4780. Where wood is used, it occupies a great deal of ground that might often be cultivated to advantage, and it is not of a lasting quality. Coal is preferable, for general purposes, to every other species of fuel; and besides its domestic application, its superiority for burning lime, that important source of fertility, or calcareous clay, also of much value to the farmer, is an object of great moment. The tenant, therefore, who resides in the neighbourhood of coal, more especially if limestone or calcareous substances are at no great distance, farms at less expense, can afford to pay a higher rent, and may derive more profit from the land he cultivates, than if in these respects he were differently circumstanced.

SECT. VIII. Extent of Land suitable for a Farm.

4781. The extent of ground which a farmer proposes to occupy demands due consideration. If it be beyond his capital to cultivate or improve, he can derive no profit by taking it.

On the other hand, a small occupation may not be worthy of his attention.

4782. Farms as to size may be divided into three sorts: small farms under 100 acres; moderate-sized farms, from 100 to 200 acres; large farms, from 200 to 1000 acres, and upwards, of land fit for cultivation. The expense of labour is now so great, and the rent of land so high, that the profits of a small farm are not sufficient, with the utmost frugality, or even parsimony, to maintain a family with comfort.

frugality, or even parsimony, to maintain a family with comfort.

4783. Moderate-sized farms are well calculated for the dairy system, for the neighbourhood of large towns, and where capital is not abundant. There are few trades in which a small capital can be employed to a greater advantage than in a dairy farm, yet there is no branch of agriculture where such constant and unremitting attention is required. That is not to be expected from hired servants; but it is in the power of the wife and daughters of the farmer to perform, or at any rate to superintend, the whole business, and without their aid it cannot be rendered productive.

4784. Moderate-sized farms are general in the neighbourhood of towns. This necessarily results from the high rents paid in such situations; the shortness of the leases usually granted of land near towns; and the necessity the farmer is under of selling, in small quantities, the articles, the articles on the farmer is under of selling, in small quantities, the articles of produced on his farm. On this subject it has been remarked, that farmers in the vicinity of large towns resemble retail shop-keepers, whose attention must be directed to small objects, by which a great deal of money is got, the greater part of which would be lost, without the most unremitting attention. The farmer at a distance from markets, who cultivates on a great scale, may be compared, on the other hand, to a wholesale trader, who, as his profits are less, requires a greater extent of land, for the purpose both of engaging his attention, and of enabling him to support that station of life in which he is placed. There is this difference also between farmers in the neighbourhood of towns, and those who reside at a distance from them, that the former find it more profitable to sell their produce, even such bulky articles as turnips, potatoes, clover, hay, and straw, than to fatten cattle for the butcher; and they are enabled to do so, without injury to their farms, as they can procure dung in return.

4785. Farm

Sect. IX. Tenure on which Lands are held for Farming.

4786. Perpetual tenures, or absolute property in land, can never come into consideration with a farmer looking out for a farm. A proprietor cultivating his own property cannot, in correct language, be said to be a farmer; for to constitute the latter an essential requisite is the payment of rent.

requisite is the payment of rent.

4787. The leases on which lands are let for farming are for various terms, and with very different covenants. The shortest lease is from year to year, which, unless in the case of grass lands in the highest order, and of the richest quality, or under some other very peculiar circumstances, no prudent man, whose object was to make the most of his skill and capital, would accept of. Even leases for seven or ten years are too short for general purposes; a period of fourteen or fifteen years seems to the shortest for arable lands, so as to admit of the tenant paying a full rent; but fourteen years, when the lands to be entered on are in bad condition, are too few, and twenty-one years much better for the true interests of both parties. In farming, however, as in every other occupation where there are more skill and capital in want of employment than can find subjects to work on, farms will be taken under circumstances, both in regard to leases and rent, that are highly unfavourable to the farmer; and if they do not end in his ruin will keep him always poor, and probably not only pay less interest for his capital than any other way in which he could have employed it, but also infringe on its amount. The rapid depreciation of currency which took place in Britain during the wars against the French deceived many farmers, and flattered them for a time with the gradual rise of markets year after year. However high land might be taken at the commencement of a lease, it was always considered a consolation that it would be a bargain by the time it was half done; and that the farmers' fortune would be made during the last few years of its endurance. When the currency of Britain was permitted to find its level with that of other countries, the delusion ceased, and the majority of farmers were partially or wholly ruined.

4788. In regard to the covenants of a lease, it is necessary that there should be such in every one as shall protect both landlord and tenant. Certain general covenants in r

SECT. X. Rent.

4790. The rent of land, in a general point of view, must always depend on a variety of circumstances; as the wealth of the country; its population; the price of produce; the amount of public and other burdens; the distance from markets; the means of conveyance; the competition among farmers; and other less important considerations: but the rent of any particular farm must be regulated by the nature of the soil; the duration

of the tenure, and the covenants contained in the lease; the capital to be invested by the farmer in its culture; and the expenses to which he is liable.

4791. The rent of poor land cannot possibly be the same as in the case of fertile lands. The labour of ploughing, harrowing, sowing, &c., when the land is in cultivation, is nearly the same, and yet the produce is greatly inferior, not only in quantity, but in quality. Indeed, where the produce is inconsiderable, or the quality much inferior, the whole, or nearly the whole, may be swallowed up by the expense of labour, and no rent whatever can be afforded, more especially in adverse seasons.

4792. The duration of the tenure must have a considerable effect in fixing the rent. No farmer can afford to pay the same sum for land on a short as if he held it on a long lease. The covenants, also, which are in fact a species of rent, must influence the money payments.

4793. Rent must also depend on the capital invested in the cultivation of the farm. Thus, if a farmer can lay out only 44. Of capital per acre, he may not be able to afford for it a higher rent than 10s, per acre; if he lays out 7t. he may pay 14s.; and with a capital of 10t, per acre, he may be enabled to pay 18s. or 20s. of rent.

or 20s. of rent.

4794. The proportion of produce which should be paid as rent, is a question that has long been considered as abstruse, mysterious, and very difficult to resolve. Some have supposed that one fifth was a reasonable proportion, while others contend for a fourth, or even a third part of the produce of arable land. But all former calculations on this subject are rendered fallacious by the effects of modern improvements. The rent ought certainly to depend upon the amount of the disposable produce; and that produce in grain is greatly augmented, both by a diminution of the consumption on the farm, effected by improved implements, and a more correct arrangement of labour, and likewise a better cultivation of the land in tillage. Hence, while the price of wheat has greatly advanced during the last twenty years, above the average price of the preceding twenty, the rent of lahad has not only risen, but in a higher proportion. More grain, and that of a better quality, has been produced on the same extent of land, and a greater amount of disposable surplus has gone to market. Out of this surplus disposable produce, it is evident that the rent must be paid. But it is difficult to divide its amount between the landlord and tenant, as so much depends upon the seasons, and on the prices of the different articles which the farm produces. In bad seasons also, every deficiency of produce, in the acres set apart for supporting home population, must be made up from the disposable surplus; nor is it possible to apply the same rules to all situations, soils, and climates, in all the various districts of an extensive country. It may be proper, however, to give some general idea of the proportion of produce paid as rent in Scotland and in England.

4795. In Scotland, the following table states what is considered to be a fair proportion, where the land and the statistical content of the proportion of the consumption of the consumption of the consumption of the death as the back of the west extent for the proportion.

England.

4795. In Scotland, the following table states what is considered to be a fair proportion, where the land is cultivated. One of the most scientific agricultural writers, and, at the same time, one who has had much experience in farming, informs us that "this table is a statement of Sir John Sinclair, who wishes to subject every thing to petty regulation; and that there is no such proportion recognised in Scotland:"—

Per acre.
-£3 11 0
- 1 13 0 Where land produces 101. 10s. per acre per annum, one third, or

Where land produces 61. 12s. per acre per annum, one fourth, or

Where land produces only 44.5s. per acre per annum, one fifth, or

1 13 0

Where land produces only 44.5s. per acre per annum, one fifth, or

0 17 0

4796. In regard to grazing farms, they are let on principles totally different from the arable; namely, according to the quantity of stock they can maintain; and as they are not liable to the same expense of management, both the landlord and the tenant receive larger shares of the produce than in the case of

arable farms.

4797. The England, the tenant is allowed, on arable land, what is considered to be one moiety of the surplus, after defraying the expenses of cultivation, the taxes to which he is liable, and every other outgoing. Hay land requires much less of his attention; and for this he only obtains one third of the surplus. But the profits of grazing depending much on superior judgment in buying and selling stock, as well as skill in preventing or curing their diseases, the grazier is entitled to a share of the surplus, fully equal to that of his landlord. It has been contended, as a general principle, that as both expense of cultivating land, and the value of its produce, are infinitely various, a farmer ought to calculate what profit he can make on his whole farm, without entering into details; it being of little consequence to him whether he pays at the rate of 10t. or 10s, per acre, provided he makes an adequate interest on the capital invested. That is certainly a fair criterion on which a tenant may calculate what he ought to offer; but a landlord, in estimating the rent he ought to insist on, will necessarily take into his consideration the produce that his land is capable of yielding, and what proportion of it, or of its value, at a fair average, he has reason to expect, under all the circumstances of the case.

4798. Tithe. In Scotland there is no tithe. In England, compositions for tithes are computed as six is to twenty-two; so is the composition for tithe to the rent: so that land averaging 10t. 10s, per acre would,

to twenty-two; so is the composition for tithe to the rent: so that land averaging 101. 10s. per acre would,

according to Sir John Sinclair's calculation, be charged for

£2 11 71 19 41 Rent Composition for tithe £3 11 0

4799. What the profits are to which a farmer is entitled, is a question much disputed. The proper answer is simply this: — The common profits of capital invested in other commercial undertakings. As the subject, however, will bear talking about, let us hear what is said in the Code on this subject. On the one hand it is contended, that the produce of land is of such universal and absolute necessity to the existence of mankind, that it is not reasonable it should yield to him who raises it more than a fair profit. On the other hand it is urged, that a farmer is entitled to be fully recompensed for the application of a considerable capital, exposed to the uncertainty of the seasons, when it is managed with economy, and conducted with industry and skill; and it has also been observed, that it is seldom more money is got by farming than an adequate interest for the capital invested. This is owing to competition, the articles produced being in numberless hands, who must bring them to market; and necessity, the goods of the farmer being in general of a perishable nature, on the sale of which he depends for the payments he has to make, and the subsistence of his family. To prove how moderate the profits of farming in general are, it appears from the most careful enquiries, that on arable farms they rarely exceed from ten to fifteen per cent, on the capital invested, which is little enough, considering that few employments are more subject to casualties than farming, or require more uniform attention. Some arable farmers, possessed of superior skill and energy, and who have got leases on reasonable terms, may clear from fifteen to twenty per cent, it while others, who are deficient in these qualities, or pay too high rents, frequently become insolvent. Certain it is, that the great majority of farmers merely contrive to live and bring up their families; adding little or nothing to their capital, but that nominal addition which takes place in consequence of the depreciation of the currence. quence of the depreciation of the currency.

quence or the depreciation of the currency.

4800. In grazing farms the case is different; as they are attended with less expense of labour, and produce articles of a more luxurious description, for which a higher price will be given. Hence, in such farms, fifteen per cent, and upwards is not unusual. Besides, the grazier is more of a trader than the mere arable farmer; is frequently buying as well as selling stock; and sometimes makes money by judicious speculations, though occasionally, from a sudden fall of stock, his losses are considerable. The grazier who breeds superior stock, and thence incurs great expense, is cartainly well entitled to more than common profit for his skill and attention.

4801. For the mode in which rent should be paid, and the terms of payment, we refer to the succeeding

Taxes and other Burdens which affect the Farmer.

4802. Farmers are subjected to the payment of various taxes besides the rent paid to the landlord; some of them imposed for local purposes, and others for the general expenses The real amount of such burdens every careful tenant ought accurately They may be classed under the following to know before he bargains for his lease. heads: parochial, national, and miscellaneous.

heads: parochial, national, and miscellaneous.

4803. Parochial taxes are for the support of the clergyman, for the maintenance of the poor, and, in Scotland, for providing a parochial schoolmaster. The mode of supporting the clergy in England, by paying them a tenth part of the produce of the land in kind, is highly injurious to agriculture, and a bar to improvement. It is a great bar to improvement, because an improving farmer, one more enlightened or more spirited than his neighbours, would pay more tithe by means of his outlay and his exertions, but it is not certain that he would likewise receive more profit. The produce would be more, but the expense would be greater. Nothing can be more obnoxious than a law by which, when a person expends a large sum, either in reclaiming wastes, or augmenting the fertility of land already cultivated, he should be under the necessity of yielding up one tenth of its produce to a person who has a been liable to no share of the expense, who has run none of the risk, and who has sustained none of the labour attending the improvement. A commutation of tithe, therefore, instead of its being exacted in kind, would be one of the greatest benefits that could be conferred on agriculture; and there is not the least difficulty in effecting it, by giving to the tithe-owner either a proportion of the land, or by converting the tithe into a perpetual corn rent. Both these plans have been adopted in a variety of cases, by local acts in England, and they ought now to be enforced as a general system.

4804. An assessment for the maintenance of the poor is another parochial burden, which is annually increasing, and which, if not speedily regulated upon proper principles, will inevitably absorba very large proportion of rent in England. Indeed, there are instances where, between the years 1815 and 1822, it has absorbed the whole. This tax is the most dangerous of all for the farmer, on account of its fluctuation; and, indeed, it may be said that it never falls, but continually rises. During

4805. The tithes and the poor-rates are charges upon the land, and in fact come from the landlord's pocket rather than from the tenant's; but in their operation are often oppressive to the tenant, by rising pocket rather than from the tenant's; but in their operation are often oppressive to the tenant, by rising in the course of the lease much higher than they were at the commencement; and as a farmer's rent is always considered by the overseer to be his income, he is charged on that; while the tradesman, who realises three times the amount, is only charged to the poor on the amount of rent of his house.

4806. In Scotland, the poor are in general maintained by voluntary contributions; but when these are not found to be sufficient, the proprietors of the parish, with the clergyman and vestry, or kirk-session, are directed to make a list of the indigent persons in the parish, and then to impose an assessment for their relief, one half to be paid by the proprietors, and the other half by the tenantry.

4807. The national burdens in general, as the duties on houses and windows, and other assessed taxes, or assessments for the support of militia-men's wives and families, for the conveyance of vagrants, or the prosecution of felons, fall no heavier upon the farmer than upon other classes of the community. 4808. There are various miscellaneous burdens affecting the farmer, as statute assessments for properly applied, cannot be

4808. There are various miscellaneous burdens affecting the farmer, as statute assessments for bridges, which are of such public utility, that moderate rates for their maintenance, properly applied, cannot be objected to: statute labour on the highways; constable dues, which are sciolom of much moment; charges of the churchwardens, including the repairs of the church; and in some populous parishes, there is sometimes a burial ground tax. All these are paid by the occupiers. In some places, also, there is a sewer tax, chargeable on the landlords, where it is not otherwise settled by express contract.

4869. The vexations to which farmers in England are subjected, from various uncertain burdens, operate as a premium to Scottish agriculture. It is ingeniously and justly remarked, that physical circumstances are much more favourable to agriculture in England than in her sister country; but these advantages are counteracted by the accumulation of moral evils, which might be removed if the legislature were to bestow on matters connected with the internal improvement of the country, and the means for promoting it, a portion of that attention which it's of requently gives to the amelioration or improvement of our foreign possessions. It ought to have been the business of the late Board of Agriculture to endeavour to prevail on the legislature to relieve agriculture from its moral and political evils; but, instead of this, they set about procuring and distributing statistical and professional information, comparatively of very inferior utility; and after receiving from government nearly 50,000d, or, for any thing we know, more, left agriculture where they found it. Even in the particular line which the Board adopted, Marshall was a much more effectual instrument of agricultural improvement.

SECT. XII. Other Particulars requiring a Farmer's Attention, with a View to the Renting of Land.

4810. A variety of miscellaneous particulars require consideration before a prudent farmer will finally resolve to undertake the cultivation of a farm; as, the nature of the property on which the farm is situated; in particular, whether the estate is entailed, and to what extent the possessor of the estate is authorised to grant a lease; the character of the landlord, and, in case of his decease, that of his family, and of those whom they are likely to consult; the real condition of the farm in regard to the enclosures, drainage, buildings, &c.; the crops it has usually produced, and the manner in which it has been managed for some years preceding; the general state of the district, in regard to the price of labour, and the expense of living; the character of its inhabitants, in particular of the neighbouring farmers and labourers, and whether they are likely to promote or to discourage a spirit of improvement; the probability of subletting to advantage in case of not liking the situation, of finding a better bargain, or of death. The chances of settling one's family; as of marrying daughters, or of sons' making good marriages. The social state of the farmers, or those that would be considered one's neighbours; the number and

tone of clergy, and lawyers; the game, and the chances of disputes concerning it; the morals of the serving class; schools, places of worship, &c. It is evident, that in hardly any one instance can all the circumstances above enumerated be favourably combined. But the active and intelligent farmer will not be discouraged by the obstacles he may have to surmount; but will strenuously endeavour, by exertion, industry, and perseverance, to overcome the difficulties he must unavoidably encounter. These are vague generalities, and may be thought too commonplace for a work of this description; but the young farmer on the look-out for a farm may not be the worse for having his memory refreshed by them.

CHAP. II.

Considerations respecting Himself, which a Farmer ought to keep in view in selecting and hiring a Farm.

4811. Whoever intends to embrace farming as a profession, will be less likely to meet with disappointment, if he previously examines a little into his own disposition and talents; and weighs his expectations against ordinary results. Nor is it less essential that he should estimate justly the extent to which his capital may be adequate, and keep regular accounts.

Sect. I. Personal Character and Expectations of a professional Farmer.

4812. Every one who proposes to farm with success, Professor Thaer observes, ought to unite energy and activity, to reflection, to experience, and to all necessary knowledge. It is true, he says, farming has long been considered as an occupation fit for a young man incapable for any other, and such have sometimes succeeded; but this has always been chiefly owing to a fortunate concurrence of circumstances, which it is not now very easy to meet with.

4813. The practice of agriculture consists of an infinite number of particular operations, each of which appears easy in itself, but is often for that very reason the more difficult to execute to the precise extent required; one operation so often interferes with another. To regulate them according to the given time and strength, and in such a way that none is neglected, or causes the neglect of others, requires at once a great deal of attention and activity, without inquietude; of promptitude without precipitation; of general views, and yet with an extreme attention to details.

4814. To casualties and accidents no business is so much exposed as farming; and therefore, to enjoy an ordinary degree of happiness, Professor Thaer considers it essential that the farmer possess a certain tranquility of mind. This, he says, may either be the result of a naturally phlegmatic habit of body, or of elevated views in religion or philosophy. These will enable him to bear with every misfortune arising from adverse seasons, or the death of live stock; and only permit him to regret accidents which result from his own neglect.

from his own neglect.

from adverse seasons, or the death of live stock; and only permit him to regret accidents which result from his own neglect.

4815. The expectations of profit and happiness which a young farmer has formed ought to be well weighed against the profits and happiness of farmers in general. However superior a farmer may consider his own talents and abilities, he may rest assured there are a number as skilful and adroit as himself, and just as likely to realise extraordinary advantages. Let none therefore engage in farming, thinking to make more money than other farmers similarly circumstanced with himself. If from a happy concurrence of circumstances he is more than usually successful, so much the better, and let him consider it as partly owing to good fortune as well as good farming; but never let him set out on the supposition of gaining extraordinary advantages with only ordinary means.

4816. The profits of farming are much exaggerated by people in general; but it may be asserted as an unquestionable fact, that no capital affords less profit than that employed in farming, except that sunk in landed property. This is the natural result both of the universality of the business and of its nature. Farming is every where practised, and every one thinks he may easily become a farmer, hence high rents, which necessarily lessen the profits on capital. From the nature of farming, the capital employed is returned seldom. A tradesman may lay out and return his capital several times a year; but a farmer can never, generally speaking, grow more than one crop per annum. Suppose he succeeds in raising the best possible crops in his given circumstances, still his profits have an absolute limit; for if an ordinary crop be as five, and the best that can be grown be as seven, all that the most fortunate concurrence of circumstances will give is not great, and is easily foreseen. It is hardly possible for a farmer, paying the market price for his land, to make much more than a living for himself and family. Those few who have excee

4818. The most likely persons to engage in farming with success are the sons of farmers, or such others as have been regularly brought up to the practice of every part of agri-They must also have an inclination for the profession, as well as a competent understanding of its theory or principles. Books are to be found every where, from which the science of the art is to be obtained; and there are eminent farmers in the improved districts who take apprentices as pupils.

4819. In The Husbandry of Scotland, the case is mentioned of Walker, of Mellendean, an eminent

farmer of Roxburghshire, renting about 2866 acres of arable land, and distinguished for his skill in agriculture, who takes young men under him as apprentices, and these, instead of receiving wages, have uniformly paid him ten pounds each. Some of them remain with him two years, but the greater number only one. They eat in his kitchen, where they have always plenty of plain wholesome food. He takes none who are above living in that way, or who will not put their hands to every thing going forward on the farm. He has sometimes been offered ten times the above sum, to take in young gentlement to eat and associate with his own family; but that he has uniformly declined. These young men have an opportunity of attending to every operation of husbandry, as practised on Walker's farm; and are taught to hold the plough, to sow, to build stacks, &c.

Sect. II. Capital required by the Farmer.

4820. The importance of capital in every branch of industry is universally acknowledged, and in none is it more requisite than in farming. When there is any deficiency in that important particular, the farmer cannot derive an adequate profit from his exertions, as he would necessarily be frequently obliged to dispose of his crops for less than their value, to procure ready money; and it would restrain him from making advantageous purchases, when even the most favourable opportunities occurred. An industrious, frugal, and intelligent farmer, who is punctual in his payments, and hence in good credit, will strive with many difficulties, and get on with less money than a man of a different character. But if he has not sufficient live stock to work his lands in the best manner, as well as to raise a sufficient quantity of manure; nor money to purchase the articles required for the farm; he must, under ordinary circumstances, live in a state of penury and hard labour; and the first unfavourable season, or other incidental misfortune, will probably sink him under the weight of his accumulated burdens. Farmers are too generally disposed to engage in larger farms than they have capital to stock and cultivate. This is a great error; for it makes many a person poor upon a large farm, who might live in comfort and acquire property upon one of less extent. No tenant can be secure without a surplus at command, not only for defraying the common expenses of labour, but those which may happen from any unexpected circumstance. When a farmer farms within his capital, he is enabled to embrace every favourable opportunity of buying when prices are low, and of selling when they are high.

4821. The amount of capital required must depend upon a variety of circumstances; as whether it is necessary for the farmer to expend any sum in the erection, or in the repair, of his farm-house and offices; what sum an in-coming tenant has to pay to his predecessor, for the straw of the crop, the dung left upon the farm, and other articles of similar nature; the condition of the farm at the commencement of the lease, and whether any sums must be laid out in drainage, enclosure, irrigation, levelling ridges, &c.; whether it is necessary to purchase lime, or other extraneous manures, and to what extent; on the period of entry, and the time at which the rent becomes payable, as this is sometimes exacted before there is any return from the lands, out of the actual produce of which it ought to be paid; and, lastly, on its being a grazing or an arable

farm, or a mixture of both.

4822. In pasture districts, the common mode of estimating the amount of capital necessary is according to the amount of the rent; and it is calculated that, in ordinary pastures, every farmer ought to have at his command from three to five times the rent he has agreed to pay. But in the more fertile grazing districts, carrying stock worth from 201, to 301, and even upwards, per acre (as is the case in many parts of England), five rents are evidently insufficient. When prices are high, ten rents will frequently be required by those who breed superior stock, and enter with spirit into that new field of speculation

be required by those who breed superior stock, and enter with spirit line that he does not specially and enterprise.

4823. The capital required by an arable farmer varies, according to circumstances, from 5t. to 10t. or even 1425. Per acre. An ignorant, timid, and penurious farmer lays out the least sum he can possibly contrive; and consequently he obtains the smallest produce or profit from his farm. The profit, however, will always increase, when accompanied by spirit and industry, in proportion to the capital employed, if judiciously expended. At the same time, attention and economy cannot be dispensed with. It is ill-judged to purchase a horse at forty guiness, if one worth thirty can execute the labour of the farm; or to lay out sums unnecessarily upon expensive harness, loaded with useless ornaments. Prudent farmers also, who have not a large capital at command, when they commence business, often purchase some horses still fit for labour, though past their prime, and some breeding arraes, or colts; and in five or six years, they are fully supplied with good stock, and can sometimes sell their old horses without much loss. In every case, such shifts must be resorted to, where there is any deficiency of capital.

without much loss. In every case, such shifts must be resorted to, where there is any deficiency of capital.

4824. A mixture of arable and grass farming is, on the whole, the most profitable method of farming. Independently of the advantages to be derived from the alternate husbandry (which are always considerable), the chances of profit are much more numerous from a varied system than where one object is exclusively followed. Where this mixed mode of farming is practised, the farmer will frequently rely on the rurchase of lean stock, instead of breeding his own; and derives great advantage from the quickness with which capital thus employed is returned. But, in that case, much must depend upon judicious selection. In general it may be said, that to stock a turnip-land arble farm, will require, at this time (1830), 51. or 61. and a clay-land farm from 71. or 81. per acre, according to circumstances.

4825. This capital is necessarily divided into two parts. The one is partly expended on implements, or stock of a more or less perishable nature, and partly vested in the soil; for this farmer is entitled to a certain annual gain, adequate to replace, within a given number of years, the sum thus laid out. The other is employed in defraying the charges of labour, &c. as they occur throughout the year; the whole of which, with the interest, should be replaced by the yearly produce. These two branches of expense on a farm are the first to be attended to, both in order of time, and in magnitude of amount.

CHAP. III.

Choice of Stock for a Farm.

4826. The stocking of a farm may be considered as including live stock, implements, servants, and seed. A considerable portion of a farmer's capital is employed in manures, tillages, labour, &c.; but a farm being once engaged, the above are the only descriptions of stock which admit of a choice.

SECT. I. Choice of Live Stock.

4827. The animals required by a farmer are of two kinds; such as are employed to assist in labour; and such as are used to convert the produce of the farm into food, or other disposable commodities.

Subsect. 1. Live Stock for the Purposes of Labour.

4828. The animals of labour used in British farming are exclusively the horse and the ox. Much difference of opinion formerly prevailed, as to which of these two animals should be preferred; and the preference has generally been given by speculative writers to the ox, and by practical farmers to the horse. Lord Kaimes in the last century, and Lord Somerville in the present, may be considered the principal advocates for the ox. To their arguments, and to all others, the following objections have been stated by the able author of the supplement to the 6th edition of The Gentleman Farmer; and they may be considered as conveying the sentiments, and according with the practice, of all the best informed and most extensive British farmers.

4829. The first objection to oxen is, that they are unfit for the various labours of modern husbandry,—for travelling on hard roads in particular,—for all distant carriages,—and generally for every kind of work which requires despatch: and what sort of work often does not in this variable climate? A great part of a farmer's work is indeed carried on at home; and it may still be thought that this may be done by oxen, while one or more horse teams are employed in carrying the produce to market, and bringing home manure and fuel. But it is unnecessary to appeal to the author of The Wealth of Nations, to prove the impracticability of this division of labour, unless upon very large farms; and even on these the advantages of such an arrangement are at best extremely problematical. The different kinds of farmwork do not proceed at the same time; but every season, and even every change of weather, demands the farmer's attention to some-particular employment, rather than to others. When his teams are capable of performing every sort of work, he brings them all to bear for a time upon the most important labours of every season; and when that is despatched, or interrupted by unfavourable weather, the less urgent branches are speedily executed by the same means. This is one cause, more important perhaps than any other, why oxen have ceased to be employed; for even ploughing, which they can perform better than any other kind of work, is scarcely ever going forward all the year; and for some months in winter, the weather often prevents it altogether.

4830. Another objection is, that an ox team capable of performing the work of two borses, even such kind of work as they can perform, consumes the produce of considerably more land than the horses. If this be the case, it is of no great importance, either to the farmer or the community, whether the land be under oats, or under herbage and roots. The only circumstance to be attended to here is, the carcase of the ox: the value of this, in stating the consumption of produce, must

4830. Another objection is, that an ox team capable of performing the work of two horses, even such kind of work as they can perform, consumes the produce of considerably more land than the horses. If this be the case, it is of no great importance, either to the farmer or the community, whether the land be under oats, or under herbage and roots. The only circumstance to be attended to here is, the carcase of the ox: the value of this, in stating the consumption of produce, must be added to the value of his labour. He consumes, from his birth till he goes to the shambles, the produce of a certain number of acres of land; the return he makes for this is so much beef, and so many years' labour. The consumption of produce must therefore be divided between these two articles. To find the share that should be allotted to each, the first thing is to accertain how many acres of grass and roots would produce the same weight of beef from an ox, bred and reared for beef alone, and slaughtered at three or four years old. What remains has been consumed in producing labour. The next thing is to compare this consumption with that of the horse, which produces nothing but labour. By this simple test, the question, viewing it upon a broad national ground, must evidently be determined. Every one may easily make such a calculation suited to the circumstances of his farm; none that could be offered would apply to every situation. But it will be found, that if even three oxen were able to do the work of two horses, the advantages in this point of view would still be on the side of the horse; and the first objection applies with undiminished force besides.

force besides.

4831. The money-price of the horse and ox, it is evident, is merely a temporary and incidental circumstance, which depends upon the demand. A work ox may be got for less than half the price of a horse, because there is little or no demand for working oxen; while the demand for horses by manufactures, commerce, pleasure, and war, enhances the price of farm-horses, as well as of the food they consume. Those who wish to see horses banished from all sorts of agricultural labour, would do well to consider where they are to be reared for the numerous wants of the other classes of society. Besides, if two oxen must be kept for doing the work of one horse, it ought to be foreseen, that though beef may be more abundant than at present, there will be a corresponding deficiency in the producin of mutton and wool. A greater portion of the arable land of the country must be withdrawn from yielding the food of man directly, and kept under cattle crops, which, however necessary to a certain extent for preserving the fertility of the soil, do not return human food, on a comparison with corn crops, in so great a proportion as that of one to six from any given extent of land of the same quality.

4832. The demand for oxen is confined almost every where to the shambles; and by the improvements of modern husbandry, they are brought to a state of profitable maturity at an early age. No difference in price at setting to work, — no increase of weight while working, — no saving on the value of the food consumed, can ever make it the interest of tillage farmers generally to keep oxen as formerly, till they are eight or ten years old. They judiciously obtain the two products from different kinds of animals, each of them from the kind which is best fitted by nature to afford it, — the labour from the horse, and the beef alone from the ox. And though the price of the horse is almost wholly sunk at last, during the period of his labour he has been paying a part of it every year to a fund, which, before his usual term expires, becomes sufficiently large to indemnify his owner. The ox, on the other hand, is changed three or four times during the same

period; and cach of them gives nearly as large a carcase for the food of man as if his days had been unprofitably prolonged in executing labour, from which he has been gradually exempted in Britain, in France, and in other countries, very nearly in proportion

to the progress of correct systems of husbandry.

4833. The description of horse which a farmer ought to choose will depend chiefly on the soil of the farm, and partly also on the quantity of road-work. Stiff lands require obviously a heavier and more powerful breed than such as are light and hilly. latter case, two of the best breeds are the Clevelands and Clydesdale, or some local cross with these breeds. In general, it is not advisable to procure horses from a climate materially different from that where they are to remain; and therefore, for various reasons, a prudent farmer will look out for the best in his neighbourhood. Often, however, he is obliged to take the stock of his predecessor; and this he can only get rid of or improve to his mind by degrees. The farm-horses in most parts of England are much too cumbrous and heavy, and are more fitted for drawing heavy drays or waggons in towns than for the quick step required in the operations of agriculture.

4834. The objections of Davis of Longleat to the using of large heavy-heeled horses, in preference to the smart, the active, and the really useful breeds, merit particular attention. In some situations, the steepness of the hills and the heaviness of the soil require more than ordinary strength; but, in such cases, he maintains that it would be better to add to the number of horses than to increase their size. Great horses maintains that it would be better to add to the number of horses than to increase their size. Great horses not only cost proportionably more at first than small ones, but require much more food, and of a better quality, to keep up their flesh. The Wiltshire carter also takes a pride in keeping them as fat as possible; and their food (which is generally barley) is given without stint. In many instances, indeed, the expense of keeping a fine team of horses amounts nearly to the rent of the farm on which they are worked. They are purchased young when two years' old colts, and sold at five or six years of age for the London drays and waggons. The expense of their maintenance is very seldom counterbalaced by the difference of price, more especially as such horses are gently worked when young, that they may attain their full size and beauty. In ploughing light soils, the strength of a dray-horse is not wanted; and in heavy soils, the weight of the animal does injury to the land.

Choice of Live Stock for the Purposes of breeding or feeding. Subsect. 2.

4835. The most desirable properties of live stock destined for food are considered in The Code of Agriculture, in respect to size, form, a tendency to grow, early maturity, hardiness of constitution, prolific properties, quality of flesh, a disposition to fatten, and lightness of offal.

be distinguished by a general fulness and rotundity of shape; that the chest should be broad, for no animal whose chest is narrow can easily be made fat; that the carease should be deep and straight; that shows a diseased state, and the control of the control o

are exempted from various diseases, such as having yellow fat, and being blackfleshed, defects so injurious to stock.

4845. The prolific quality of a breed is a matter deserving attention. The females of some breeds both bear more frequently than usual, and also have frequently more than one at a birth. This property runs more strikingly in sub-varieties, or individual families; and though partly owing to something in the habits of animals, and partly to their previous good or bad treatment, yet in some degree seems to depend upon the seasons, some years being more distinguished for twins than others. In breeding, not only the number, but the sex of the offspring, in some cases, seems to depend upon the female parent. Two cows produced fourteen females each in fifteen years, though the bull was changed every year: it is singular, that when they produced a bull calf, it was in the same year. Under similar circumstances, a great number of males have been produced by the same cow in succession, but not to the same extent.

4846. By the quality of their flesh, breeds are likewise distinguished. In some kinds it is coarse, hard, and fibrous; in others of a finer grain or texture. In some breeds, also, the flavour of the meat is superior; the gravy they produce, instead of being white and insipid, is high coloured, well flavoured, and rich; and the fat is intermixed among the fibres of the muscles, giving the meat a streaked, or marbled appearance. Breeds whose flesh have these properties are peculiarly valuable. Hence two animals of nearly the same edgree of fatness and weight, and who could be fed at nearly the same expense to the husbandman, will sell at very different prices, merely from the known character of their meat.

4847. A disposition to fatten is a great object in animals destined for the shambles. Some animals possess this property during the whole progress of their lives, while in others it only takes place at a more advanced period, when they have attained their full growth, and are furnished at the

on that subject can only arise from want of proper discrimination. Fat meat is unquestionably more nourishing than lean, though to digest this oily matter there are required, on account of its difficult solubility, a good bile, much saliva, and a strong stomach; consequently none, except those who are in the most vigorous state of health, or who are employed in hard labour, can properly digest it. Though fat meat, however, is unfit for general consumption, yet experiments in the art of fattening animals are likely to promote useful discoveries; and though, in the course of trying a number of experiments, errors and excesses may be committed, yet on the whole advantage may be derived from the knowledge thus to be obtained. As the bone also gains but little in the fatting animal, and the other offal becomes proportionably less, as the animal becomes more fat, the public has not sustained much loss by over-fatted animals. To kill even hogs till they are thoroughly fat, is exceeding bad economy. An ox or cow, though the little fiesh it has may be of good quality, yet presents, when lean, little but skin and bone; and it slaughtered in that state, would neither indemnify the owner for the expense of breeding and maintaining it, nor benefit the public. A coarse and heavy-fleshed ox, which would require a very long time and much good food to fatten, may be slaughtered with most advantage while rather lean. It is not, however, so much the extent of fat, as the want of a sufficient quantity of lean flesh, of which the consumer complains; for it cannot be doubted, that the lean flesh of a fat animal is better in quality, and contains more nourishment, than the flesh of a lean animal.

4849. Handling well. The graziers and butchers in various parts of the kingdom have recourse to feeling the skin, or cellular membrane, for ascertaining a disposition to fatten; and since Bakewell directed the public attention so much to breeding, that practice has become more generally known. Handling cannot easily be defined, and can only

4851. The Rev. Henry Berry, who has paid much attention to the subject of breeding and feeding cattle, and written several valuable papers on the subject in the British Farmer's Magazine, seems to prefer for general purposes the improved short-horns. "These cattle," he says, "at three years old, are equal to Hereford cattle at four years old; and they are bred from cows which prove much more profitable for the dairy than the Herefords." At the same time, he admits that the Hereford cattle are excellent to purchase with a view to fattening, because in a lean state at four years old they will of course not bear an increased price in proportion to the increased time required to render one of them equal to a short-horn of three years. For breeders, therefore, he decidedly recommends the short-horns; and he has given an interesting history of this breed of cattle for the last eighty years, the period which has elapsed since it attracted attention. It was imported from Holland to the banks of the Tees; or, at least, it is the result of a cross between the breed so imported and the native breed of that district. (Improved Short-Horns, &c. By the Rev. Henry Berry. 2d edit. 1830.)

SECT. II. Choice of Agricultural Implements, Seeds, and Plants.

4852. The variety and excellence of agricultural implements is so great, that the prudent farmer, in regard to these, as well as in every other branch of his art, must study economy. He should not incur an unnecessary expense in buying them, or in purchasing more than are essentially requisite, and can be profitably used. This maxim ought to be more especially attended to by young improvers, who are often tempted, under the specious idea of diminishing labour and saving expense, to buy a superfluous quantity of implements, which they afterwards find are of little use. (Coventry's Disc. p. 47.) It is remarked by an intelligent author on matters of husbandry, that a great diversity of implements, as they are more rarely used, prove in general a source of vexation and disappointment, rather than of satisfaction, to the farmer.

4853. The different implements required by the farmer are: those of tillage; for drilling or sowing the first part of the former for realing corn; for mowing and harvesting hay; of conveyance; for draining; for harnessing stock; for rolling land; for the dairy; and, for

ing hay, of conveyance; for draining; for harnessing stock; for rolling land; for the dairy; and, for miscellaneous purposes.

4834. In purchasing implements, the following rules are to be observed: they should be simple in their construction, both that their uses may be more easily understood, and that any common workman may be able to repair them when they get out of order; the materials should be of a durable nature, that the labour may be less liable to interruption from their accidental failure; their form should be firm and compact, that they may not be injured by joilst and shaking; and that they may be more safely worked by country labourers, who are but little accustomed to the use of delicate tools. In the larger machines, symmetry and lightness of shape ought to be particularly attended to: for a heavy carriage, like a greaf horse, is worn out by its own weight, nearly as much as by what he carries. The wood should be cut up and placed in a position the best calculated to resist pressure; and morties, so likely to weaken the wood, should, as much as possible, be avoided; at the same time, implements should be made as light as is consistent with the strength that is necessary. Their price should be such, that farmers in moderate circumstances can afford to buy them; yet for the sake of a low price, the judicious farmer will not purchase articles either of a finney fabric or a faulty form; and implements ought to be suited to the nature of the country, whether hilly or level, and more especially to the quality of the soil; for those which are calculated for light land will not answer equally well in soils that are heavy and adhesive. (Code.)

4855. In the choice of seed corn, regard must be had to procure it from a suitable soil and climate, and of a suitable variety. A change from one soil to another of a different

quality, is generally found advantageous; but this is not always the case as to climate. Thus, some of the varieties of oats, as the Angus oat, which answers well in most parts of Scotland, is found not to fill in the ear, but to shrivel up after blossoming, in the south In like manner, the woolly-chaffed white wheats of Essex and Kent rot in the ear when grown in the moist climate of Lancashire. In settling on a farm in a country with which the farmer is little acquainted, he will often find it advisable to select the best seed he can find in the neighbourhood, and probably to resift it and free it from the seeds of weeds and imperfect grains. Particular care is requisite in selecting the seed of the bean and pea, as no crop depends more on the variety being suited to the soil Thus, on hot gravelly soils in the south, the late grey pea would produce little haulm and no pulse; but the early varieties, or the pearl pea, will produce a fair proportion of both.

4856. The only small seeds the farmer has to sow on a large scale, are the clovers, grasses, the different varieties of turnip, and probably the mangold wurzel and carrot. No expense or trouble should be spared to procure the best turnip seed; as if that is either mixed by impregnation with other varieties of the Brássica tribe, or has been raised from a degenerate small-rooted parentage, the progeny will never come to any The same may be said of carrot or mangold seed, raised from small misshapen Even rape seed should be raised from the strongest and largest rooted plants, as these always produce a stronger progeny.

roots. Even rape seed should be raised from the strongest and largest rooted plants, as these always produce a stronger progeny.

4857. The selection and propagation of improved agricultural seeds has till lately been very little attended to. But the subject has been taken up by Mr. Sinclair of New Cross, Mr. Shirreff of Mungos Wells, Mr. Gorrie of Raitia nather and we have little doubt some greatly improved varieties of our more useful field plants will be the term and we have little doubt some greatly improved varieties of our which seed was saved, been improved in nutrificus all and, by suddous lection of the roots from which seed was saved, been improved in nutrificus all and, by suddous lection of the roots from which seed was saved, been improved in nutrificus all and provement by indicatoes and swedish turnip. Mr. Shirreff says, "appear to be susceptible of farther improvement by indicatoes and seed to the country is susceptible, by the propagation of genuine seeds of the best varieties of plants, one remarkable feature of such an improvement is, that it could be carried into effect without any additional investment of capital, or destruction of that already employed. It would require, in the first instance, only a slight degree of observation amongst practical farmers to select the best varieties of plants, or even seed of a good and a bad variety of a plant, is og great, that it does not seem instance, be clear gain to the occupiers, and ultimately to the owners of land. The difference of produce, arising from sowing the seed of a good and a bad variety of a plant, is og great, that it does not seem inconsistent with probability to state, that the gross agricultural produce of the country might be augmented, in the course of a few years, through the agency of improved seeds, to the amount of seven per cent; and as the farmer's home consumption of produce, by such means, would be increased nearly ten per cent, what an enormous fund this forms for maintaining the unagricultural part of the population, an

inferior herbage into nutriment of a different description; grasses and roots are the raw materials, butcher's meat the manufactured commodity."

4860. The importance of attending to varieties of cultivated plants has been ably pointed out by Mr. Bishop, at once a scientific botanist and an experienced practical gardener. "By means of varieties" he says, "the produce of our gardens and fields are not only increased in a tenfold degree, but the quality of the produce is improved in a still greater proportion. In them we perceive the labour and assiduity of man triumphing over the sterility of unassisted nature, and succeeding in giving birth to a race of beings calculated to supply his wants in a manner that original species never could have done. The difference between varieties that have sprung from the same species fits them for different purposes, and for different soils, situations, and climates. Some, by reason of their robust natures, are winter vegetables; and others, by being early, are spring vegetables; while some are in perfection in summer, and others in autumn. The fruit produced by some is fit to eat when pulled off the tree; while the fruit of others is valuable by reason of its keeping till that season, when Nature rests to recruit her strength. Thus, in edible plants and fruits, we are supplied with an agreeable change throughout the year, from a difference in varieties that have sprung from the same species. In the earlier ages of the world, no idea could have been entertained of the

excellence some varieties have attained over their originals. Who, upon viewing the wild cabbage that grows along our sea-coast, would ever imagine that cauliflower or broccoil would have been produced by the same? Or who would expect the well-formed apple of a pound's weight from the verjuice plant in our hedges? Many instances might be noticed of original species that are scarcely fit to be eaten by the beasts of the field, the varieties of which afford a nutritious and wholesome food for man. Upon comparing the original variety of the Daicus Carota, the Pastinaca sativa, and some others indigenous to our climate, with their varieties produced by culture, we are struck with their great inferiority, and cannot help reflecting on the hapless condition of that hungry savage who first taught us their use; for nothing short of the greatest privation could ever have led to that discovery. Indeed, nothing is more obvious, upon comparing original species with their varieties produced by culture, than that we, by means of the latter, enjoy a vegetable food far preferable to that of our forefathers; a circumstance from which it may be inferred that posterity is destined to enjoy a better than that which we do now. For although it is reasonable to believe that there exists a degree of excellence attainable by varieties over the species where the posterity is destined to enjoy a better than that which we do now. For although it is reasonable to believe that there exists a degree of excellence attainable by varieties over the species of cultivate have sprungs, yet as that degree is unknown, and as it is probably beyond the power of man, of cultivate have sprungs and the power of the power o

benefits mankind derive from the varieties produced by culture are numerous and important, and that the discovery of those of merit is an object highly deserving of our attention." (Bishop's Causal Botany.)

4803. The varieties of wheat and barley in general cultivation, Mr. Gorrie observes, are "not numerous; but were 2 part of that attention paid to the production of new and improved varieties of field-beans, peas, oats, barley, and wheat, which is now almost wasted on live stock, the same success might follow, and varieties of each of these useful species of grain might be found as far surpassing those now in cultivation as the modern breeds of horses and cattle surpass those of former days. To effect this, a simple process only is necessary. When any two varieties are intended to be used in 'crossing,' it is necessary that they should be sown at such periods as may render them likely to flower at the same time; and we would recommend that such plants should be sown or transplanted into flower-pots, particularly the variety to be used as the female breeder. The parts of fructification of all the Cerealia tribe are composed of a stigma, or fringed substance, which crowns the embryo grain; three anthers or male parts, which have either a purple or yellow colour; and firm, small, round, or rather longish cylindrical knobs, with a hollow line longitudinally along the middle, on the side farthest from the filament which supports these anthers. Allowing that there are six plants, say of wheat, in a pot to be imprepated, let the variety possessing the greatest proportion of desirable qualities be selected for the male, from a field or otherwise, and, before the anthers of all the ears growing on the plants in the popened by a slight touch of the forefinger; cut off the anthers of all the ears growing on the plants in the popened by a slight touch of the forefinger; cut off the anthers of all the ears growing on the plants in the pot, and then take the male parts of the variety wished to be improved, which have been vol. i. p. 17.)

vol. i. p. 17.)

4864. Grain, seeds, and roots intended for reproduction are not required to have come to the same degree of maturity on the plant, as when intended for meal or other products to be consumed as food. The cause of this has never been satisfactorily explained; all that is alleged being the conjecture, that the cotyledons of the seed are better fitted for entering the vessels of the minute plant, when they are not of such a farinaceous nature, as when these cotyledons are more mature. "That grain not perfectly matured is fully qualified for seed, is evident from places situated near rivers or lakes, where the grain is some seasons is subject to be what the people who cultivate such situations term blasted or middewed. This happens in autumn, before the grain is matured, and is probably caused by fogs or damps which arise from the water. This blast discolours the straw, and renders it so friable that it will hardly bind itself; the grain never receives any more nourishment, is shrivelled and light, and soon assume a ripe appearance, and so small a quantity of farinaceous matter will be contained in the grains, that a sheaf, after being reaped, will feel as light in the hand as if it had been previously threshed; and yet, for as bad as it appears, it is commonly taken for seed, and never fails to give a luxuriant crop, provided it escape the following autumn." (Ibid.)

9 E. 2

4865. Of the plants which the farmer has to choose for stock, the chief is the potato; and every one knows that no circumstances in the soil, climate, or culture will compensate for planting a bad sort. The potato requires a climate rather humid than otherwise, and rather moderate and equable in temperature than hot: hence the best crops are found in Lancashire, Dumfriesshire, and Ayrshire in Britain, and in Ireland, where the climate is every where moist. Excellently flavoured potatoes are also grown on mossy lands in most parts of the country. The prudent farmer will be particularly careful in choosing this description of plant stock, and also in changing it frequently, so as to ensure prolificacy and flavour. The general result of experience is decidedly in favour of unripe tubers for the purpose of propagation. A number of important papers on this subject will be found in the first and second volumes of the Gardener's Magazine, all confirmatory of the advantages of selecting tubers which are immature.

SECT. III. Choice of Servants.

4866. On the moral and professional character of his servants much of the comfort of the farmer depends; and every one who has farmed near large towns, and at a distance from them, knows how great the difference is in every description of labourers. servants required in farmeries are, the bailiff or head ploughman, common ploughmen, shepherds, labourers of all-work, herdsmen, and women. Sometimes apprentices and pupils are taken; but their labour is not often to be much depended on.

4867. A bailiff is required only in the largest description of farms, occupied by a professional farmer; and is not often required to act as market-man. In general young men are preferred, who look forward to higher situations, as gentlemen's bailiffs or land Most farmers require only a head ploughman, who works the best pair of horses, and takes the lead of, and sets the example to, the other ploughmen in every

description of work.

4868. Ploughmen should, if possible, be yearly servants, and reside upon the farm; if married, cottages should be provided for them. Weekly or occasional ploughmen are found comparatively unsteady; they are continually wandering from one master to another, and are very precarious supports of a tillage farm: for they may quit their service at the most inconvenient time, unless bribed by higher wages; and the farmer may thus lose the benefit of the finest part of the season. Where ploughmen and day labourers, however, are married, they are more to be depended upon than unmarried domestic servants, more especially when the labourer has a family, which ties him down to regular

4869. The mode of hiring servants at what are called public statutes, so general in many parts of England, is justly reprobated as having a tendency to vitiate their minds, enabling them to get places without reference to character, exposing good servants to be corrupted by the bad, promoting dissipation, and causing a cessation of country business for some days, and an awkwardness in it for some time afterwards. When hiring servants, it would be extremely important, if possible, to get rid of any injurious perquisites, which are often prejudicial to the interests of the master, without being of any advantage For instance, in Yorkshire and in other districts it is a custom to give farm servants liquor both morning and evening, whatever is the nature and urgency of Nothing can be more absurd than permitting a ploughman to stop for half an hour in a winter day to drink ale, while his horses are neglected and shivering with

4870. The following plan of maintaining the hinds or ploughmen in the best cultivated districts in Scotland, is found by experience to be greatly superior to any other mode hitherto adopted.

hitherto adopted.

4871. Proper houses are built for the farm servants contiguous to every farmstead. This gives them an opportunity of settling in life, and greatly tends to promote their future welfare. Thus also the farmer has his people at all times within reach for carrying on his business.

4872. The farm servants, when married, receive the greater part of their wages in the produce of the soil, which gives them an interest in the prosperity of the concern in which they are employed, and in a manner obliges them to eat and drink comfortably; while young men often starve themselves in order to save money for drinking or clothes, in either of which cases they are deficient in the requisite animal strength. At least under this mode of payment they are certain of being supplied with the necessaries of life, and a rise of prices does not affect them; whereas, when their wages are paid in money, they are exposed to many temptations of spending it which their circumstances can ill afford, and during a rise of prices they are sometimes reduced to considerable difficulties. From the adoption of an opposite system, habits of sobriety and economy, so conspicuous among the farm servants of Scotland, and the advantages of which cannot be too highly appreciated, have arisen and still prevail in these districts.

4873. A most important branch of this system is, that almost every married man has a cow of a moderate size kept for him by the farmer all the year round. This is a boon of great utility to his family. The prospect of enjoying this advantage has an excellent effect upon the morals of young unmarried servants, who in general make it a point to lay up as much of their yearly wages as will enable them to purchase a cow and furniture for a house when they enter into the married state. These savings, under different circumstances, would most probably have been spent in dissipation.

4874. They have also several other perquisites, as a piece of ground for potatoes and flax (about one-eighth part of an acre for each);

4875. There are nowhere to be met with more active, respectable, and conscientious servants than those who are kept according to this system. There is hardly an instance of their soliciting relief from the public. They rear numerous families, who are trained to industry and knowledge in the operations of agriculture, and whose assistance in weeding the crops, &c. is of considerable service to the farmer. They become attached to the farm, take an interest in its prosperity, and seldom think of removing from it. Under this system every great farm is a species of little colony, of which the farmer is the resident governor. Nor, on the whole, can there be a more gratifying spectacle than to see a large estate under the direction of an intelligent landlord, or of an agent competent to the task of managing it to advantage; where the farms are of a proper size; where they are occupied by industrious and skifult tenants, auxious to promote, in consequence of the leases they enjoy, the improvement of the land in their possession; and where the cultivation is carried on by a number of married servants enjoying a far competence and rearing large families, sufficient not only to replace themselves, but also, from their surplus population, to supply the demand and even the waste of the other industrious classes of the community. Such a system, there is reason to believe, is brought to a higher degree of perfection and carried to a greater extent in the more improved districts of Scotland than perhaps in any other country in Europe. (Code, &c.)

4876. A shepherd is of course only requisite on sheep farms; and no description of farm servant is required to be so steady and attentive. At the lambing season much of the farmer's property is in his hands, and depends on his unwearied exertions early and

late. Such servants should be well paid and comfortably treated.

4877. The labourers required on a farm are few; in general, one for field operations, as hedge and ditch work, roads, the garden, cleaning out furrows, &c.; and another for attending to the cattle, pigs, and straw-yard, killing sheep and pigs when required, &c. will be sufficient. Both will assist in harvest, hay-time, threshing, filling dung, &c. These men are much better servants when married and hired by the year, than when

accidental day labourers.

4878. The female servants required in a farmery are casual, as haymakers, turnip hoers, &cc.; or yearly, as house, dairy, and poultry maids. Much depends on the steadiness of the first class; and it is in general better to select them from the families of the married servants, by which means their conduct and conversation is observable by their parents and relations. A skilful dairy-maid is a most valuable servant, and it is well when the cattle-keeper is her husband; both may live in the farmer's house (provided they have no children), and the man may act as groom to the master's horse and chaise, and assist in brewing, butchery, &c. In the cheese districts, men often milk the cows, and manage the whole process of the dairy; but females are surely much better calculated for a business of so domestic a nature, and where so much depends on cleanliness.

4879. Farmer's apprentices are not common, but parish boys are so disposed of in some parts of the west of England, and might be so generally. They are said to make the best and steadiest servants; and indeed the remaining in one situation, and under one good master for a fixed period, say not less than three years, must have a great tendency to fix the character and morals of youth in every line or condition of life.

4880. Apprentices intended for farmers are generally young men who have received a tolerable education beforehand, and have attained to manhood or nearly so. These pay a premium, and are regularly instructed in the operations of farming. We have already alluded to the example of Walker, who considers such apprentices, notwithstanding the care required to instruct them, rather useful than otherwise. (Husb. of Scot. vol. it., p. 106.)

4881. To train ploughmen to habits of activity and diligence is of great importance. In some districts they are proverbial for the slowness of their step, which they teach their horses; whereas these animals, if accustomed to it, would move with as much ease to themselves in a quick as in a slow pace. Hence their ploughs seldom go above two miles in an hour, and sometimes even less; whereas, where the soil is light and sandy, they might go at the rate of three miles and a half. Farmers are greater sufferers than they imagine by this habitual indolence of their workmen, which extends from the plough to all their other employments, for it makes a very important difference in the expense of labour. (Code.)

CHAP. IV.

General Management of a Farm.

4882. The importance of an *orderly systematic mode of managing* every concern is sufficiently obvious. The points which chiefly demand a farmer's attention are the accounts of money transactions, the management of servants, and the regulation of labours.

SECT. I. Keeping Accounts.

4883. It is a maxim of the Dutch, that "no one is ever ruined who keeps good accounts," which are said in The Code of Agriculture to be not so common among farmers as they ought to be; persons employed in other professions being generally much more attentive and correct. Among gentlemen farmers there is often a systematic regularity in all their proceedings, and their pages of debtor and creditor, of expense and profit, are as strictly kept as those of any banking-house in the metropolis. But with the generality of farmers the case is widely different. It rarely happens that books are kept by

1997

them in a minute and regular manner; and the accounts of a farmer, occupying even a large estate, and consequently employing a great capital, are seldom deemed of sufficient importance to merit a share of attention equal to that bestowed by a tradesman on a concern of not one-twentieth part of the value. There is certainly some difficulty in keeping accurate accounts respecting the profit and loss of so uncertain and complicated a business as the one carried on by the farmer, which depends so much on the weather, the state of the markets, and other circumstances not under his control; but the great bulk of farming transactions is settled at the moment; that is to say, the article is delivered and the money instantly paid; so that little more is necessary than to record these properly. In regard to the expenses laid out on the farm, an accurate account of them is perfectly practicable, and ought to be regularly attended to by every prudent and industrious occupier.

4894. To record pecuniary transactions is not the only object to be attended to in the accounts of a farmer. It is necessary to have an annual account of the live stock, and of their value at the time; of the quantity of hay unconsumed; of the grain in store or in the stack-yard; and of the implements and other articles in which the capital is invested. An account, detailing the expense and return of each field, according to its productive contents, is likewise wanted, without which it is impossible to calculate the advantage of different rotations, the most beneficial mode of managing the farm, or the improvements of which it is susceptible. Besides the obvious advantages of enabling a man to understand his own affairs, and to avoid being cheated, it has a moral effect upon the farmer of the greatest consequence, however small his dealings may be. Experience shows that men situated like small farmers (who are their own masters, and yet have very little capital to manage or lose,) are very apt to contract habits of irregularity, procrastination, and indolence. They persuade themselves that a thing may be as well done to-morrow as to-day, and the result is, that the thing is not done till it is too late, and then hastily and imperfectly. Now nothing can be conceived better adapted to check this disposition than a determination to keep regular accounts. The very consciousness that a man has to make entries in his books of every thing that he does, keeps his attention alive to what he is to do; and the act of making those entries is the best oossible training to produce active and pains-taking habits.

4835. Trotter's method of farm book-keeping. A very original, concise, and accurate mode of keeping farm accounts has been invented by Alexander Trotter, Esq. of Dreghorn. Though the merits of this mode seem to be acknowledged by all who understand it, yet they do not appear to be of that nature to bring it into general use. This, however, may depend partly, or even wholly, on the ignorance or prejudices of those fo

4896. These forms may be useful, by directing the attention of farmers to the particulars of which they should keep an accurate record; but as to any particular system of accounts applicable to farmers a good deal of delusion seems to prevail, as if the established modes in general use among mercantile men would not answer. In fact, there is no correct mode of keeping accounts but by the principles of double entry.

4897. The account books for a common farmer may be, a cash-book for all receipts and payments, specifying each; a ledger for accounts with dealers and tradesmen; and a stock book for taking, once a year, an inventory and valuation of stock, crop, manures, tillages, and every thing that a tenant could dispose of or be paid for on quitting his farm. Farming may be carried on with the greatest accuracy and safety, as to money matters, by means of the above books, and a few pocket memorandum books for labourers' time, jobs, &c. With the exception of a time-book, such as we have before described (3383), we should never require more, even from a proprietor's bailiff; many of whom the nine forms just given (4887) would only puzzle, and some we have known them lead to the greatest errors and confusion. Munro's Guide to Farm Book-keeping (Edin. 12mo. 1821) may be recommended to the practical farmer; but no form of books, or mode of procedure will enable a farmer to know whether he is losing or gaining but that of taking stock.

4898. A form for a cattle stock account has been recommended by Sir Patrick Murray, of which it may be useful to present a specimen. This form, Sir Patrick observes, has been kept at his estate of Ochtertyre, in Perthshire, for twenty-two years, and found perfectly adapted to the purpose in view; being sufficiently simple in form to be understood by every farm manager, and sufficiently comprehensive in particulars to embrace all the requisite details. They may be either made up quarterly, half-yearly, or yearly.

Sir Patrick adopts the half-yearly mode.

SECT. II. Management of Servants.

4900. In former times, farm servants lived at the same table with their masters, and that is still the practice in those districts where the farms are small. On moderate-sized, and on large farms, they are usually sent to a separate table; but of late a custom has been introduced of putting them on board-wages. This is a most pernicious practice; which often leads them to the ale-house, corrupts their morals, and injures their health. better plan, with a view of lessening trouble, to board them with the bailiff; but it is still more desirable for the farmer to have them under his own eye, that he may attend to their moral conduct. He will find much more useful assistance from the decent and the orderly than from the idle and the profligate.

4901. The best mode of managing yearly married servants, whether ploughmen or labourers, we conceive to be that already referred to (4870) as practised in Northumberland, and other northern counties. Marshal (Review of Bailey's Northumberland) calls it a remain of feudal times; but certainly, if it be so, it appears one of those remains which should be carefully preserved. We may challenge the empire to produce servants and farm operations equal to those where this system is adopted. The great excellence of the

system consists on its being founded in the comfort of the servant.

4902. The permanent labourers on a farm ought to be treated in the same manner as the ploughmen; and indeed it is much to be wished, for the sake both of humanity and morality, that all married labourers, who live in the country, should have gardens attached to their cottages, if not a cow kept, and a pig and fowls, in the manner of the Scottish ploughmen. Some valuable observations on this subject will be found in The Husbandry

of Scotland.

4903. Temporary labourers, or such as are engaged for hay-making, reaping, turniphoeing, &c. are for the most part beyond the control of the farmer, as to their living and lodging. It is a good practice, however, where hay-making and reaping are performed by the day, to feed the operators, and to lodge on the premises such of them as have not homes in the neighbourhood; providing them with a dry loft and warm blankets. Piece or job-work, however, is now becoming so very general, in all farm operations performed by occasional labourers, that attention to these particulars becomes unnecessary, and the farmer's chief business is to see that the work be properly done.

4904. A day's work of a country labourer, is ten hours during the spring, summer, and autumn quarters. Farmers, however, are not at all uniform in their hours of working during these periods. Some begin at five o'clock, rest three hours at midday, during the more violent heat of the sun, and fill up their day's work by beginning again at one o'clock, and ending at six in the evening. Others begin at six, and end at six, allowing half an hour at breakfast, and an hour at dinner. But although these are the ordinary hours, both for servants and labourers, during the more busy seasons of the year, yet neither of them will scruple to work either sooner or later, when occasion requires. In regard to the winter months, the hours of labour are from the dawn of morning, as long as it is light, with the allowance of about half an hour at mid-

day for dinner.

4905. That the rate of labour must in a great measure depend upon the price of grain, is a general principle. In England, the value of a peck of wheat, and in Scotland, of a peck of oatmeal (being the principal articles of subsistence of the lower orders of the people in the two countries), were long accounted an equivalent to the daily pay of a In both countries, however, the price of potatoes has, of late years, had a considerable influence on the rate of labour; and in England, the effects of the poor laws have tended to keep down that rate below the increased price of provisions, and thus have deranged the natural progress of things. It has been ascertained, that a man, his wife, and from two to three children, if wheat is their habitual food, will require ten gallons weekly. When they live on bread, hard-working people ought to have the best kind, as that will furnish the most nutrition. How, then, could a labourer and his family exist upon wages of from 6s. to 9s. per week, when wheat is from 8s. to 10s. or 12s. per bushel? The difference is compensated by the poor-rates, a most exceptionable mode of making up the deficiency; for labour would otherwise have found its own level, and the labourer would have obtained the price of a bushel and a half of wheat weekly.

4906. In Scotland, the rate of labour has increased beyond the price of provisions. Prior to 1792, the average price of a peck of oatmeal was 1s. 1d., and the average price of a day's labour in summer 1s. 1\frac{1}{2}d., which nearly corresponded with the principle above stated: but the average price of a peck of oatmeal in 1810 was 1s. 3\frac{3}{2}d., whilst the average price of a day's labour was 1s. 10\frac{1}{2}d.; which shows, in a most satisfactory manner, the very great improvement that has taken place in the lot of the labouring classes in that part of the United Kingdom. (Gen. Rep. vol. iii. p. 962.)

4907. The practice of giving labourers grain, \$c. at a cheap rate was adopted by George 111., who carried on farming operations to a considerable extent, allowing his labourers flour at a fixed price, whatever wheat might sell for. This benevolent system has been practised by several gentlemen farmers, some of whom have allowed bread, and others a daily quantity of milk, at moderate prices. The same system is general in several of the western counties, as in Dorset, Devon, and Cornwall, where the labourers have a standing supply of bread-corn; of wheat at 6s. and of barley at 3s. per bushel. In some of the midland

counties the day-wages are regulated by the price of the best wheaten bread: thus the price of a half-peck loaf forms the day-wages for out-of-door farm servants. Of late years this rule has been departed from in favour of the labourers: thus, when bread is at 1s. 8d. the half-peck, then wages are 1s. 10d.; and when at 2s., the wages are 2s. 4d.

4908. Most descriptions of country labour, performed without the aid of horses, may be let by the job. Farey, in his excellent Report of Derbyshire, informs us, that besides all ordinary labour, the late John Billingsley, of Ashwick Grove, in Somersetshire, let his ploughing, harrowing, rolling, sowing, turning of corn when cut, hay-making, &c. by the acre; from which he found great advantages, even where his own oxen and horses were used by the takers of the work. Whether we regard despatch, economy, perfection of rural works, or the bettering of the condition of the labourers therein, nothing will contribute so much to all these as a general system of letting works at fair and truly apportioned prices, according to the degree of labour and skill required in each kind of work. Few persons have doubted that despatch and economy are attainable by this method; but those who have indolently or improperly gone about the letting of their labour, have uniformly complained of its being slovenly done, and of the proneness of the men to cheat when so employed. Such frauds are to be expected in all modes of employment, and can only be counteracted, or made to disappear, by competent knowledge and due vigilance in the employer, or his agents and foremen, who ought to study and understand the time and degree of exertion and skill, as well as the best methods, in all their minutiæ, of performing the various works they have to At first sight these might seem to be very difficult and unattainable qualifications in farmers' bailiffs or foremen, but it is nevertheless certain, that a proper system and perseverance will soon overcome these difficulties. One of the first requisites is, the keeping of accurate and methodical day-accounts of all men employed; and, on the measuring up and calculating of every job of work, to register how much has been earned per day, and never to attempt abatement of the amount, should this even greatly exceed the ordinary day's pay of the country; but let this experience gained operate in fixing the price of the next job of the same work, in order to lessen the earnings by degrees, of fully competent and industrious men, to $1\frac{3}{4}$ or $1\frac{1}{4}$ times the ordinary wages when working by the day.

by the day.

4009. Form the men into small gangs, according to their abilities and industry, and always set the best gang about any new kind of work, or one whose prices want regulating: encourage these by liberal prices at first, gradually lowering them; and by degrees introduce the other gangs to work with or near them at the same kind of work. On the discovery of any material slight of or deceptions in the work, at the time of measuring it, more than their proportionate values should be deducted for them, and a separate job made to one of the best gangs of men, for completing or altering it: by which means shame is made to operate, with loss of earnings, in favour of greater skill, attention, and honesty in future. When the necessity occurs of employing even the best men by the day, let the periods be as short as possible, and the prices considerably below job earnings; and contrive, by the offer of a desirable job to follow, to make it their interest and wish to despatch the work that is necessary to be done by the day, in order to get again to piece-work. The men being thus induced to study and contrive the readlest and best methods of performing every part of their labour, and of expending their time, the work will unquestionably be better done than by the thoughtless drones who usually work by the day. And that these are the true methods of bettering the condition of the labourers, Malthus has ably shown in theory; and all those who have adopted and persevered in them have seen the same in practice. (Farey's Derbyshire, vol. iii. 192)

Sect. III. Arrangement of Farm Labour.

4910. The importance of order and system we have already insisted on (3370), and the subject can hardly be too often repeated. To conduct an extensive farm well is not a matter of trivial moment, or one to the management of which every man is competent. Much may be effected by capital, skill, and industry; but even these will not always ensure success without judicious arrangement. With it, a farm furnishes an uninterrupted succession of useful labour during all the seasons of the year; and the most is made that circumstances will admit of, by regularly employing the labouring persons and cattle, at such works as are likely to be the most profitable. Under such a system it is hardly to be credited how little time is lost, either of the men or horses, in the course of a whole year. This is a great object; for each horse may be estimated at three shillings per day, and each man at two shillings. Every day, therefore, in which a man and horse are unemployed occasions the loss of at least five shillings to the husbandman.

4911. As the foundation of a proper arrangement, it is necessary to have a plan of the farm, or at least a list of the fields or parcels of land into which it is divided, describing their productive extent, the quality of the soil, the preceding crops, the cultivation given to each, and the species and quantity of manure they have severally received. The future treatment of each field, for a succession of years, may then be resolved on with more probability of success. With the assistance of such a statement, every autumn an arrangement of crops for the ensuing year ought to be made out; classing the fields or pieces of land, according to the purposes for which they are respectively intended. The number of acres allotted for arable land, meadow, or pasture, will thus be ascertained. It will not then be difficult to discover what number of horses and labourers will be

required during the season for the fields in culture, nor the live stock that will be necessary for the pasture land. The works of summer and harvest will likewise be foreseen,

and proper hands engaged in due time to perform them.

4912. A farmer should have constantly in view a judicious rotation of crops, according to the nature and quality of his soil, and should arrange the quantity and succession of labour accordingly. Team labour, when frost and bad weather do not intervene, should be arranged for some months; and hand labour, for some weeks, according to the season of the year. " A general memorandum list of business to be done," may therefore be useful, that nothing may escape the memory, and that the most requisite work may be brought forward first, if suitable to the state of the weather. In this way the labour will go on regularly, and without confusion; while, by a proper attention, either a distribution of labour, or an occasional consolidation of it, may be applied to every part of the farm.

4913. As general rules, connected with the arrangement, and the successful management of a farm, the following are particularly to be recommended: -

4914. The farmer ought to rise early, and see that others do so. In the winter season breakfast should be taken by candle-light, for by this means an hour is gained which many farmers indolently lose; though six hours in a week are nearly equal to the working part of a winter day. This is a material object, where a number of servants are employed. It is also particularly necessary for farmers to insist on the punctual performance of their orders.

4915. The whole farm should be regularly inspected, and not only every field examined, but every beast seen, at least once a day, either by the occupier, or by some intelligent servant.

4916. In a considerable farm, it is of the utmost consequence to have servants specially appropriated for each of the most important departments of labour; for there is often a great loss of time, where persons are frequently changing their employments. Besides, where the division of labour is introduced, work is executed not only more expeditiously, but also much better, in consequence of the same hands being constantly employed in one particular department. For that purpose, the ploughmen ought never to be employed in manual labour, but regularly kept at work with their horses, when the weather will admit of it.

admit of it.

admit of it.

4917. To arrange the operation of ploughing, according to the soils cultivated, is an object of essential importance. On many farms there are fields which are soon rendered unfit to be ploughed, either by much rain or by severe drought. In such cases, the prudent farmer, before the wet season commences, should plough such land as in the greatest danger of being injured by too much wet; and before the dry period of the year sets in, he should till such land as in the greatest danger of being rendered unfit for ploughing by too much drought. The season between seed-time and winter may be well occupied in working soils intended to be sown with beans, oats, barley, and other spring crops. On farms where these rules are attended to there is always some land in a proper condition to be ploughed, or to be worked by the improved harrows or grubbers; and there is never any necessity either for delaying the work. or performing it improperly.

worked by the improved harrows or grubbers; and there is never any necessity either for delaying the work, or performing it improperly.

4918. Every means should be thought of to diminish labour, or to increase its power. For instance, by proper arrangement, five horses may do as much labour as six perform, according to the usual mode of employing them. One horse may be employed in carting turnips during winter, or in other necessary farm-work at other seasons, without the necessity of reducing the number of ploughs. When driving dung from the farm-yard, three carts may be used, one always filling in the yard, another going to the field, and a third returning; the leading horse of the empty cart ought then to be unyoked, and put to the full one. In the same manner, while one pair of horses are preparing the land for sowing turnips, the other three horses may be employed in carrying the dung to the land, either with two or three carts, as the situation of the ground may happen to require. By extending the same management to other farm operations, a considerable saving of labour may be effected.

4919. Previously to engaging in a work, whether of ordinary practice, or of intended improvement, the best consideration of which the farmer is capable ought to be given to it, till he is satisfied that it is advisable for him to attempt it. When begun, he ought to proceed in it with much attention and perseverance, until he has given it a fair trial. It is a main object, in carrying on improvements, not to attempt too much at once; and never to begin a work without a probability of being able to finish it in due season.

due season.

4920. By the adoption of these rules, every farmer will be master of his time, so that every thing required to be done will be performed at the proper moment, and not delayed till the season and opportunity have been lost. The impediments arising from bad weather, sick servants, or the occasional and necessary absence of the master, will, in that case, be of little consequence, nor will they embarrass the operations to be carried on; and the occupier will not be prevented from attending to even the smallest concerns connected with his business, on the aggregate of which his prosperity depends.

Sect. IV. Domestic Management and personal Expenses.

Young farmers beginning house-4921. On domestic affairs a hint may suffice. keeping, like most others in similar circumstances, are apt to sink too great a proportion of their capital in furniture, and furnishing riding-horses, carriages, &c.; and some-times to live up to, or even beyond, their income. We do not mean that farmers should not live as well as other men of the same property; but merely that all beginners should live within their income. Even in the marketing expenses care is requisite; and the prudent farmer will do well, every penny or sixpence he lays out, to reckon up in his mind what that sum per day would amount to in a year. The amount will often astonish him, and lead to economy and, where practicable, retrenchment. Franklin has inculcated, is the only certain way of accumulating money.

4922. In regard to housekeeping, it is observed in The Code of Agriculture, that the safest plan is, not to suffer it to exceed a certain sum for bought articles weekly. annual sum should be allotted for clothing, and the personal expenses of the farmer, his wife and children, which ought not to be exceeded. The whole allotted expense should be considerably within the probable receipts; and, if possible, one eighth of the income annually received should be laid up for contingencies, or expended in extra improvements on the farm.

BOOK VI.

CULTURE OF FARM LANDS.

4923. THE business of farming consists of the culture of vegetables, and the treatment or culture of animals; in practice these are generally carried on together, but may be more conveniently treated of apart. In this Book, therefore, we confine ourselves to the culture of vegetable, and shall consider in succession the general processes of culture; the culture of corn and pulse; of roots and leaves; of herbage plants; of grasses; and of manufactorial plants.

CHAP. I.

General Processes common to Farm Lands.

4924. Among general processes, those which merit particular notice in this place are, the rotation of crops, the working of fallows, and the management of manures. The theory of these processes has been already given in treating of soils and manures (PART II. Book III.); and it therefore only remains to detail their application to practice under different circumstances.

SECT. I. Rotation of Crops suitable to different Descriptions of Soils.

4925. The proper distribution of crops, and a plan for their succession, is one of the first subjects to which a farmer newly entered on a farm requires to direct his attention. The kind of crops to be raised are determined in a great measure by the climate, soil, and demand, and the quantity of each by the value, demand, and the adjustment of farm labour.

4926. In the adjustment of farm labour, the great art is to divide it as equally as pos-ple throughout the year. Thus it would not answer in any situation to sow exclusively sible throughout the year. autumn crops, as wheat or rye; nor only spring corns, as oats or barley; for by so doing all the labour of seed-time would come on at once, and the same of harvest work, while the rest of the year there would be little to do on the farm. But by sowing a portion of each of these and other crops, the labour both of seed-time and harvest is divided and rendered easier, and is more likely to be done well and in season. But this point is so obvious as not to require elucidation.

4927. The succession or rotation of crops is a point on which the profits of the farmer depend more than on any other. It is remarked by Arthur Young, that agricultural writers, previously to the middle of the eighteenth century, paid little or no attention to They recite, he says, courses good, bad, and execrable in the same tone, as matters not open to praise or censure, and unconnected with any principles that could throw light on the arrangement of fields. The first writer who assigned due importance to the subject of rotations seems to have been the Rev. Adam Dickson, in his Treatise on Agriculture, published in Edinburgh in 1777; and soon afterwards Lord Kaimes, in his Gentleman Farmer, illustrates the importance of the subject: both writers were probably led to it by observing the effects of the Norfolk husbandry, then beginning to be introduced to Berwickshire. But whatever may have been the little attention paid to this subject by former writers, the importance of the subject of rotations, and the rule founded on the principles already laid down, that culmiferous crops ripening their seeds should not be repeated without the intervention of pulse, roots, herbage, or fallow, is now "recognised in the practice and writings of all judicious cultivators, more generally perhaps than any other." (Edit. of Farmer's Mag.)

4998. The system of rotations is adapted for every soil, though no particular rotation can be given for any one soil which will answer in all cases; as something depends on climate, and something also on the kind of produce for which there is the greatest market demand. But wherever the system of rotations is followed, and the several processes of labour which belong to it properly executed, land will rarely get into a foul and exhausted state, or at least, if foul and exhausted under a judicious rotation, "matters would be much worse were any other system followed."

4929. The particular crops which enter into a system of rotation must obviously be such as are suited to the soil and climate, though, as the experienced author so often quoted observes, "they will be somewhat varied by local circumstances, such as the proximity of towns and villages, where there is a greater demand for turnips, potatos, hay, &c. than in thinly peopled districts. In general, beans and clover, with rye-grass, are interposed between corn crops on clavey soils; and turnips, potatoes, and clover with rye-grass on dry loams and sands, or what are technically known by the name of turnip soils. A variety of

other plants, such as peas, tares, cabbages, and carrots, occupy a part, though commonly but a small part, of that division of a farm which is allotted to green crops. This order of succession is called the system of alternate husbandry; and on rich soils, or such as have access to abundance of putrescent manure; it is certainly the most productive of all others, both for food for man and for the inferior animals. One half of a farm is in this course always under some of the different species of cereal grasses, and the other half under pulse; roots, cultivated herbage, or plain fallow.

4830. But the greater part of the arable land of Britain cannot be maintained in a fertile state under this management; and sandy soils, even though highly manured, soon become too incohesive under a course of constant tillage. It therefore becomes necessary to leave that division or break that carries cultivated herbage to be pastured for two years or more, according to the degree of its consistency and fertility; and all the fields of a farm are treated thus in their turn if they require it. This is called the system of convertible husbandry, a regular change being constantly going on from aration to pasturage, and vice versā.

system of convertible husbandry, a regular enange being constantly going on from artion to pasturage, and vice versā.

4931. Not to repeat the same kind of crop at too short intervals, is another rule with regard to the succession of crops. Whatever may be the cause, whether it is to be sought for in the nature of the soil or of the plants themselves, experience clearly proves the advantages of introducing a diversity of species into every course of cropping. When land is pastured several years before it is brought again under the plough, there may be less need for adhering steadily to this rule; but the degeneracy of wheat and other corn crops recurring upon the same land every second year for a long period, has been very generally acknowledged. It is the same with what are called green crops; beans and peas, potatos, turnips, and in an especial manner red clover, become all of them much less productive, and much more liable to disease, when they come into the course, upon the same land, every second, third, or fourth year. But what the an especial manner red clover, become all of them much less productive, and much more liable to disease, when they come into the course, upon the same land, every second, third, or fourth year. But what the interval ought to be has not yet been ascertained, and, from the great number of years that experiments must be continued to give any certain result, probably cannot be determined until the component parts of soils, and particularly the sort of vegetable nourishment which each species of plant extracts from the soil, have been more fully investigated.

4932. A change of pariety as well as of the species, and even of the plants of the same variety, is found to be attended with advantage; and in the latter case, or a change of seed, the species and variety being the same, the practice is almost universal. It is well known, that of two parcels of wheat, for instance, as much alike in quality as possible, the one which had grown on a soil differing much from that on which it is to be sown, will yield a better produce than the other that grew in the same or a similar soil and climate. The farmers of Scotland accordingly find that wheat from the south, even though it be not, as it

mate. The farmers of Scotland accordingly find that wheat from the south, even though it be not, as it usually is, better than their own, is a very advantageous change; and oats and other grain brought from a clayey to a sandy soil, other things being equal, are more productive than such as have grown on sandy soil. (Supp. Encyc. Brit. art. Agr. 144.)

4933. The following are examples of rotations suited to different soils, as given in Brown's excellent *Treatise on Rural Affairs.* The basis of every rotation, he says, "we hold to be either a bare summer fallow, or a fallow on which drilled turnips are cultivated, and its conclusion to be with the crops taken in the year preceding a return of fallow or drilled turnips, when of course a new rotation commences.

4934. Rotation for strong deep lands. According to this rotation, wheat and drilled beans are the crops to be cultivated, though clover and rye-grass may be taken for one year in place of beans, should such a variety be viewed as more eligible. The rotation begins with summer fallow, because it is only on strong deep lands that it can be profitably practised; and it may go on for any length of time, or so long as the land can be kept clean, though it ought to stop the moment that the land gets into a contrary condition. A considerable quantity of manure is required to go on successfully; perhaps dung should be given to each bean crop; and if this crop is drilled and attentively horse-hoed, the rotation may turn out to be one of the most profitable that can be exercised.

4935. Rotation for loans and clays. Where it may not be advisable to carry the first rotation into execution, a different one can be practised, according to which labour will be more divided, and the usual grains more generally cultivated; for instance, the following, which used to be common in East Lothian:—

 Fallow, with dung.
 Wheat. 2

Beans drilled and horse-hoed.
 Wheat.

Barley.
 Clover and rye-grass.
 Oats or wheat.

3. Beans, drilled and horse-hoed.

This rotation is excellently calculated to insure an abundant return through the whole of it, provided dung is bestowed upon the clover stubble. Without this supply the rotation would be crippled, and inferior crops of course produced in the concluding years.

4936. Rotation for clays and loams of an inferior description. This rotation is calculated for soils of an inferior description to those already treated of.

Fallow, with dung.
 Wheat.

3. Clover and rye-grass. 4. Oats.

Beans, drilled and horse-hoed.
 Wheat.

According to this rotation, also in use in East Lothian, the rules of good busbandry are studiously practised; while the sequence is obviously calculated to keep the land in good order, and in such a condition as to ensure crops of the greatest value. If manure is bestowed either upon the clover-stubble or before the beans are sown, the rotation is one of the best that can be devised for the soils mentioned.

4937. Rotation for thin clays. On thin clays gentle husbandry is indispensably necessary, otherwise the soil may be exhausted, and the produce unequal to the expense of cultivation. Soils of this description will not improve much while under grass; but unless an additional stock of manure can be procured, there is a necessity of refreshing them in that way, even though the produce should in the mean time be comparatively of small value. The following rotation is not an improper one:

1. Fellow, with days.

Fallow, with dung.
 Wheat.

3. Grass pastured, but not too early eaten.
4. Grass.

5. Grass. 6. Oats.

2. Wheat.

4. Grass.

6. Goats.

This rotation may be shortened or lengthened, according to circumstances, but should never extend further in point of ploughing than when dung can be given to the fallow-break. This is the keystone of the whole; and if neglected the rotation is rendered useless.

4938. Rotation for peat earth soils. These are not friendly to wheat, unless aided by a quantity of calcareous matter. Taking them in a general point of view, it is not advisable to cultivate wheat, but a crop of oats may almost be depended upon, provided the previous management hase in judiciously executed. If the subsoil of peat earth lands is retentive of moisture, the process ought to commence with a bare summer fallow; but if such are incumbent on free and open bottoms, a crop of turnips may be substituted for fallow; according to which method, the surface will get a body which naturally it did not possess. Grass on such soils must always occupy a great space of every rotation, because physical circumstances render regular cropping utterly impracticable.

circumstances permit the land to be broken up, when oats are to be

1. Fallow, or turnips with dung.
2. Oats of an early variety.
3. Clover, and a considerable 4. Pasture for several years, till

repeated.

4939. Rotation for light soils. These are easily managed, though to procure a full return of the profit which they are capable of yielding, requires generally as much attention as is necessary in the management of those of a stronger description. Upon light soils, a bare summer fallow is seldom called for, as cleanliness may be preserved by growing turnips, and other leguminous articles. Grass also is of eminent advantage upon such soils, often yielding a greater profit than what is afforded by culmiferous

Turnips.
 Spring wheat, or barley.

Clover and rye-grass.
 Oats or wheat.

2. Spring wheat, or barley.

4. Oats or wheat.

This is a fashionable rotation; but it may be doubted whether a continuance of it for any considerable period is advisable, because both turnips and clover are found to fall off when repeated so often as once in four years. Common red clover will not grow every four years, unless gypsum be restored to the land. Perhaps the rotation would be greatly improved were it extended te eight years, whilst the ground, by such an extension, would be kept fresh and constantly in good condition. As, for instance, were seeds for pasture sown in the second year, the ground kept three years under grass, broke up for oats in the sixth year, drilled with beans and peas in the seventh, and sown with wheat in the eighth; the rotation would then be complete, because it included every branch of husbandry, and admitted a variety in management generally agreeable to the soil, and always favourable to the interest of cultivators. The rotation may also consist of six crops, were the land kept only one year in grass, though few situations admit of so much cropping, unless additional manure is within reach.

4949. Rotation for sandy soils. These, when properly manured, are well adapted to turnips, though it rarely happens that wheat can be cultivated on them with advantage, unless they are dressed with alluvial compost, marl, clay, or some such substances as will give a body or strength to them, which they do not naturally possess. Barley, oats, and rye, the latter especially, are, however, sure crops on sands, and in favourable seasons will return greater profit than can be obtained from wheat.

1. Turnips well manured consumed on the ground.

3. Clover and rye-grass.

3. Clover and rye-grass. 4. Wheat, rye, or oats. Turnips well manured consumed on the ground. 2. Barley sown with clover and rye-grass.

By keeping the land three years in grass, the rotation would be extended to six years, a measure highly advisable.

4941. These examples are sufficient to illustrate the subject of improved rotations; but as the best general schemes may be sometimes momentarily deviated from with advantage, the same able author adds, that "cross cropping, in some cases, may perhaps be justifiable in practice; as, for instance, we have seen wheat taken after oats with great success, when these oats had followed a clover crop on rich soil; but, after all, as a general measure, that mode of cropping cannot be recommended. We have heard of another rotation, which comes almost under the like predicament; though, as the test of experience has not yet been applied, a decisive opinion cannot be pronounced upon its This rotation begins with a bare fallow, and is carried on with wheat, grass for one year or more, oats, and wheat, where it ends. Its supporters maintain that beans are an uncertain crop, and cultivated at great expense; and that in no other way will corn, in equal quantity and of equal value, be cultivated at so little expense as according to the plan mentioned. That the expense of cultivation is much lessened, we acknowledge, because no more than seven ploughings are given through the whole rotation; but whether the crops will be of equal value, and whether the ground will be preserved in equally good condition, are points which remain to be ascertained by experience." (Brown on Rural Affairs.)

4942. As a general guide to devising rotations on clay soils, it may be observed, that winter or autumn sown crops are to be preferred to such as are put in in spring. Spring ploughing on such soils is a hazardous business, and not to be practised where it can possibly be avoided. Except in the case of drilled beans, there is not the slightest necessity for ploughing clays in the spring months; but as land intended to carry beans ought to be early ploughed, so that the benefit of frost may be obtained, and as the seed furrow is an ebb one, rarely exceeding four inches in deepness, the hazard of spring ploughing for this article is not of much consequence. Ploughing with a view to clean soils of the description under consideration has little effect, unless given in the summer months. This renders summer fallow indispensably necessary; and without this radical process, none of the heavy and wet soils can be suitably managed, or preserved in a good

4943. To adopt a judicious rotation of cropping for every soil, requires a degree of judgment in the farmer, which can only be gathered from observation and experience. The old rotations were calculated to wear out the soil, and to render it unproductive. To take wheat, barley, and oats in succession, a practice very common thirty years ago, was sufficient to impoverish the best of land, while it put little into the pockets of the farmer; but the modern rotations, such as those which we have described, are founded on principles which ensure a full return from the soil, without lessening its value, or im-Much depends, however, upon the manner in which the poverishing its condition. different processes are executed; for the best arranged rotation may be of no avail, if the processes belonging to it are imperfectly and unseasonably executed. The best farmers in the northern counties now avoid over-cropping or treating land in any way so as to exhaust its powers, as the greatest of all evils.

The working of Fallows. SECT. II.

4944. The practice of fallowing, as we have seen in our historical view of Greek and Roman agriculture, has existed from the earliest ages; and the theory of its beneficial

effects we have endeavoured to explain. (2175.) The Romans with their agriculture introduced fallows in every part of Europe; and two crops, succeeded either by a year's fallow, or by leaving the land to rest for two or more years, became the rotation on all soils and under all circumstances. This mode of cultivating arable land is still the most universal in Europe, and was prevalent in Britain till the middle of the last century; but as a crop was lost every year they occurred, a powerful aversion from naked fallows arose about that time, and called forth numerous attempts to show that they were unnecessary, and consequently an immense public loss. This anti-fallowing mania, as it has been called, was chiefly supported by Arthur Young, Nathaniel Kent, and others, members or correspondents of the Board of Agriculture: it was at its greatest height about the beginning of the present century, but has now spent its force; and after exhausting all the arguments on both sides, as an able author has observed, "the practice does not appear to give way, but rather to extend."

4945. The expediency or inexpediency of pulverising and cleaning the soil by a bare fallow, is a question that can be determined only by experience, and not by argument. No reasons, however ingenious, for the omission of this practice, can bring conviction to the mind of a farmer, who, in spite of all his exertions, finds, at the end of six or eight years, that his land is full of weeds, sour, and comparatively unproductive. Drilled and horsehoed green crops, though cultivated with advantage on almost every soil are probably n general unprofitable as a substitute for fallow, and after a time altogether inefficient. It is not because turnips, cabbages, &c. will not grow in such soils, that a fallow is resorted to, but because, taking a course of years, the value of the successive crops is found to be so much greater, even though an unproductive year is interposed, as to induce a preference to fallowing. Horse-hoed crops, of beans in particular, postpone the recurrence of fallow, but in few situations can ever exclude it altogether. On the other hand, the instances that have been adduced, of a profitable succession of crops on soils of this description, without the intervention of a fallow, are so well authenticated, that it would be extremely rash to assert that it can in no case be dispensed with on clay soils. stances of this kind are to be found in several parts of Young's Annals of Agriculture; and a very notable one, on Greg's farm of Coles, in Hertfordshire, is accurately detailed in the sixth volume of The Communications to the Board of Agriculture.

4946. The principal causes of this extraordinary difference among men of great experience, may probably be found in the quality of the soil, or in the nature of the climate, or in both. Nothing is more vague than the names by which soils are known in different districts. Greg's farm, particular, though the soil is denominated "heavy arable land," and "very heavy land," is found so suitable to turnips, that a sixth part of it is always under that crop, and these are consumed on the ground by sheep; a system of management which every farmer must know to be altogether impracticable on the wet tenacious clays of other districts. It may indeed be laid down as a criterion for determining the question, that wherever this management can be profitably adopted, fallow, as a regular branch of the course, must be not less absurd than it is injurious, both to the cultivator and to the public. It is probable, therefore, that, in debating this point, the opposite parties are not agreed about the quality of the soil; and, in particular, about its property of absorbing and retaining moisture, so different in soils that in common language have the same denomination.

denomination.

4947. Another cause of difference must be found in the climate. It is well known that a great deal more rain falls on the west than on the east coast of Britain; and that between the northern and southern counties there is at least a month or six weeks' difference in the maturation of the crops. Though the rain falls on the west than on the east coast of Britain; and that between the northern and southern counties there is at least a month or six weeks' difference in the maturation of the crops. Though the soil, therefore, be as nearly as possible similar in quality and surface, the period in which it is accessible to agricultural operations must vary accordingly. Thus, in the south-eastern counties of the island, where the crops may be all cut down, and almost all carried home by the end of August, much may be done in cleansing and pulverising the soil, during the months of September and October, while the farmers of the north are exclusively employed in harvest work, which is frequently not finished by the beginning of November. In some districts in the south of England, wheat is rarely sown before December; whereas in the north, and still more in Scotland, if it cannot be got completed by the end of October, it must commonly be delayed till spring, or oats or barley be taken in place of wheat. It does not then seem of any utility to enter farther into this controversy, which every skilful cultivator must determine for himself. All the crops, and all the modes of management which have been proposed as substitutes for fallow, are well known to such men, and would unquestionably have been generally adopted long ago, if, upon a careful consideration of the advantages and disadvantages on both sides, a bare fallow was found to be unprofitable in a course of years. The reader who wishes to examine the question fully may consult, among many others, the following:— Young's Annals of Agriculture, and his writings generally; Hunter's Georgical Essays; Dickson's Practical Agriculture; Sir H. Davy's Agricultural Chemistry; The Agricultural Chemistry of Chaptal; Brown's Treatise on Rural Affairs; The County Reports; The General Report of Scotland, and the Quarterly Journal of Agriculture, vol. ii. p. 90.

4918. The importance of naked fallows has been ably pointed out by a writer in the work last referred to. "In order," h

the greatest facility which a farmer possesses of cleaning his land or keeping it clean, under a green crop, is by a turnip one, on a light soil resting on an open bottom, in a dry season. This last instance amounts, in fact, to all the boasted possibility of keeping land clean by green crops, without the amounts of the control of the process of the control of the

the support of late crops; all which practices approach locally Jour. Ag. vol. ii. p.105.)

4949. Fallows unnecessary on friable soils. However necessary the periodical recurrence of fallow may be on retentive clays, its warmest advocates do not recommend it on turnip soils, or on any friable loams incumbent on a porous subsoil; nor is it in any case necessary every third year, according to the practice of some districts. On the best cultivated lands it seldom returns oftener than once in six or eight years; and in favourable situations for obtaining an extra supply of manure, it may be advantageously dispensed with for a still longer period. (Suppl. to Encyc. Brit. art. Agr.)

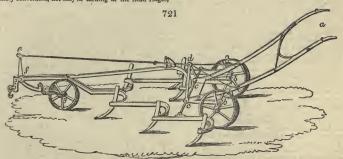

4950. The operation of fallowing, as commonly practised in England, is, in usefulness and effect, very different from what it ought to be. In most places the first furrow is not given till the spring, or even till the month of May or June; or, if it is given earlier, the second is not given till after midsummer, and on the third the wheat is sown. Land may rest under this system of management; but to clean it from weeds, to pulverise it, or The farmer in some cases purto give it the benefits of aeration and heat, is impossible. posely delays ploughing his fallows, for the sake of the scanty bite the couch and weeds afford to his sheep; and for the same reason, having ploughed once, he delays the second It is not to be wondered at, that under such a system, the theoretical agriploughing. culturist should have taken a rooted aversion from what are thus erroneously termed fallows. The practice of the best farmers of the northern counties is very different, and that practice we shall here detail.

that practice we shall here detail.

4951. A proper fallow invariably commences after harvest; the land intended to be fallowed getting one ploughing, which ought to be as deep as the soil will admit, even though a little of the till or subsoil is brought up. This both tends to deepen the cultivated, or manured, soil, as the fresh accession of hitherto uncultivated earth becomes afterwards incorporated with the former manured soil, and greatly facilitates the separation of the roots of weeds during the ensuing fallow process, by actaching them completely from any connection with the fast subsoil. This autumnal ploughing, usually called the winter furrow, promotes the rotting of stubble and weeds; and, if not accomplished towards the end of harvest, must be given in the winter months, or as early in the spring as possible. In giving this first ploughing, the old ridges should be gathered up, if practicable, as in that state they are kept dry during the winter months; but it is not uncommon to split them out or divide them, especially if the land had been previously highly gathered, so that each original ridge of land is divided into two half ridges. Sometimes, when the land is easily laid dry, the furrows of the old ridges are made the crowns of the new ones, or the land is ploughed in the way technically called crown-and-furrow. In other instances, two ridges are ploughed together, by what is called casting, which has been already described. After the field is ploughed, all the interfurrows, and those of the headlands, are carefully opened upby the plough, and are afterwards gone over effectually by a labourer with a spade, to remove all obstructions, and to open up the water furrows into the fence ditches, wherever that seems necessary, that all moisture may have a ready exit. In every place where water is expected to lodge, such as dishes, or hollow places in the field, cross or oblique furrows are drawn by the plough, and their intersections carefully opened into each other by the spade. Wherever it appears

cross-ploughed; and after lying till sufficiently dry to admit the harrows, it is harrowed and rolled repeatedly, and every particle of the vivacious roots of weeds brought up to view, carefully gathered by hand into heaps, and either burnt on the field, or carted off to the compost heap. The fallow is then ridged up, which places it in a safe condition in the event of bad weather, and exposes a new surface to the harrows and roller; after which the weeds are again gathered by hand, but a previous harrowing is necessary. It is afterwards ploughed, harrowed, rolled, and gathered as often as it may be necessary to reduce it into fine tilth, and completely to eradicate all root-weeds. Between these successive operations, repeated crops of seedling weeds are brought into vegetation, and destroyed. The larvæ likewise of various insects, together with an infinite variety of the seeds of weeds, are exposed to be devoured by birds, which are then the farmer's best friends, though often proscribed as his bitterest enemies.

but whenever an obstruction is met with in the ground, arising from rocky, retentive, or other impenetrable soils. In such of these as would completely interrupt the progress of the ordinary instrument, this proceeds with ease, by merely being lifted more or less over them. The operation is performed by the more or less over them. The operation is performed by the ground of the series of the

4955. When effectually reduced to fine tilth, and thoroughly cleaned from roots and weeds, the fallow is ploughed end-long into gathered ridges or lands, usually fifteen or eighteen feet broad. If the seed is to be drilled, the lands or ridges are made of such widths as may suit the construction of the particular drill-machine to be employed. If the seed is to be sown by hand, the lands or ridges are commonly formed into what are called single or double cast ridges; the first of four paces or steps, and the latter of eight steps in width. These widths are found the most convenient for a one-handed sower. An expert sower can, however, measure his handful to almost any width; but the above long experience has made the standard. After the land has been once gathered by a deep furrow, proportioned to the depth of the cultivated soil, the manure is laid on, and evenly spread over the surface, whether muck, lime, marl, or compost. A second gathering is now given by the plough; and this being generally the furrow upon which the seed is sown, great care is used to plough as equally as possible. After the seed is sown and the land thoroughly harrowed, all the inter-furrows, furrows of the headlands, and oblique or gaw furrows, are carefully opened up by the plough, and cleared out by the spade, as already mentioned, respecting the first or winter ploughing. or winter ploughing.

4957. The expense of fallowing may appear, from what has been said, to be very considerable, when land has been allowed to become stocked with weeds; but if it be kept under regular management, corn alternating with drilled pulse or green crops, the subsequent returns of fallow will not require near so much labour. In common cases, from four to six ploughings are generally given, with harrowing and rolling between, as may be found necessary; and, as we have already noticed, the cultivator may be employed to diminish this heavy expense. But it must be considered, that upon the manner in which the fallow operations are conducted, depend not only the ensuing wheat crop, but in a great measure all the crops of the rotation. (Supp. to Encyc. Britart. Agr. 128.)

Sect. III. General Management of Manures.

4958. The manures of animal, vegetable, or mineral origin have been already described, and their operation explained. (2224.) But a very few of these substances can be obtained by farmers in general; whose standard resources are farm-yard dung and lime, and composts of these with earth. It is on the management of these that we propose to deliver the practice of the best British farmers.

Subsect. 1. Management of Farm-yard Dung.

4959. The basis of farm-yard dung is straw, to which is added, in its progress through the farm-yard, the excrementitious substances of live stock. From every ton of dry straw, about three tons of farm-yard dung may be obtained, if the after-management be properly conducted; and, as the weight of straw per acre runs from one ton to one and a half, about four tons of dung, on an average of the different crops, may be produced from the straw of every acre under corn. (Husbandry of Scotland, vol. ii.) Hence (it may be noticed) the great importance of cutting corn as low as possible; a few inches at the root of the stalk weighing more than double the same length at the ear.

4960. The conversion of straw into farm yard dung in the farmery, is thus effected: —The straw is served out to cattle and horses in the houses and fold-yards, either as provender or litter, and commonly for both purposes; turnips in winter, and green clover in summer, are given to the stock both in the houses and yards: on this food the animals pass a great deal of urine, and afford the means of converting the straw into a richer manure than if it were eaten alone. All the dung from the houses, as they are cleaned out, is regularly spread over the yards in which young cattle are left loose, where litter is usually allowed in great abundance; or over the dunghill itself, if there is one at hand. This renders the quality of the whole mass more uniform; and the horse-dung, which is of a hot nature, promotes the decomposition of the woody fibres of the straw.

into a richer manure than if it were eaten alone. All the dung from the houses, as they are cleaned out, are regularly spread over the yards in which young cattle are left loose, where litter is usually allowed in great abundance; or over the dunphil itself, if there is one at hand. This renders the quality of the of the woody fibres of the straw.

4951. The preparation of the contents of the farm-yard for laying on the land, is by turning it over; or, what is preferable, carting it out to a dunphil. The operation of carting out is usually performed during the frosts of winter; it is then taken to the field in which it is to be employed, and neatly built in dunphils the frosts of winter; it is then taken to the field in which it is to be employed, and neatly built in dunphils what is add up in this manner early in winter, is commonly sufficiently prepared for turning in fluid to the control of accelerating the decomposition of the straw, yards till spring, it is necessary to turn it one or oftener, for the purpose of accelerating the decomposition of the straw yards to the mass. When dung is applied to fallows in July or August, preparatively to autumn-sown wheat, a much less degree of putrefaction will suffice than for some time, the woody fibre is gradually broken down in the course of the winter, and the nourishment of the plants continued till apring, or later, when its efficts are most beneficial.

4802. Management of stable dauge. There is a most valuable paper on this subject by Lord Meadow-bank, in the second volume of the Came is the Board of Agr. "His lordship has ever found, that, instead simperfectly fermented, but nevertheless when the process is going on at such rate as that it must competed." Percy gardener knows, that the dung used in hobeits has little effect in comparison of fresh dung; and every farmer knows, that the dung used in hobeits has little effect in comparison of fresh dung; and every farmer knows, that the dung used in the soil that is completed. Every gardener knows, that the dung

the stale of their cattle towards the dung pit, which, by this contrivance, it keeps constantly supplying." (Comm. B. Agr. vol. ii.)

4964. In the application of farm-yard dung to land under tillage, particular attention is paid to the cleanness of the soil; and to use it at a time when, from the pulverisation of the ground, it may be most intimately mixed with it. The most common time of manuring with farm-yard dung is, therefore, either towards the conclusion of the fallowing operations, or immediately before the sowing of fallow crops. If no dung can be procured but what is made from the produce of the farm, it will seldom be possible to allow more than ten or twelve tons to every acre, when the land is managed under a regular course of white and green crops; and it is thought more advantageous to repeat this dose at short intervals, than to give a larger quantity at once, and at a more distant period in proportion. (General Report of Scotland, vol. ii. p. 517.) Farm-yard dung, it is well known, is greatly reduced in value by being exposed to the atmosphere in small heaps, previously to being spread, and still more after being spread. Its rich juices are exhaled by the sun, or washed away by the rains, and the residuum is comparatively worthless. This is in an especial manner the case with long fresh dung, the far greater part of which consists of wet straw in an entire state. All careful farmers, accordingly, spread and cover in their dung with the plough, as soon as possible after it is brought on the land.

4965. The use of fresh dung is decidedly opposite to the practice of the best farmers of turnip soils; its inutility, or rather injurious effects, from its opening the soil too much, is a matter of experience with every one who cultivates drilled turnips on a large scale. As the whole farm-yard dung, on such land, is applied to the turnip crop, it must necessarily happen that it should be laid on in different stages of putre-faction; and what is made very late in spring, often after a very slight fermentation, or none at all. The experience of the effect of recent dung is accordingly very general, and the result, in almost every case, is, that the growth of the young plants is slow; that they remain long in a feeble and doubtful state; and that they seldom, in ordinary seasons, become a full crop, even though twice the quantity that is given of short muck has been allowed. On the other hand, when the manure is considerably decomposed, the effects are immediate, the plants rise vigorously, and soon put forth their rough leaf, after which the beetle or fly does not seize on them; and in a few weeks, the leaves become so large, that the plants probably draw the greatest part of their nourishment from the atmosphere. Though it were true, therefore, that more nutritive matter is given out by a certain quantity of dung, applied in a recent state, and allowed to decompose gradually in the soil, than if applied after undergoing fermentation and putrefaction, the objection arising from the showness of its operation would, in many instances, be an insuperable one with farmers. But there seems reason to doubt if fresh strawy manure would ferment much in the soil, after being spread out in so small a quantity as has been already mentioned; and also if, in the warm dry weather of summer, the shallow covering of earth given by the plough would not permit the gaseous matters to escape to a much greater amount than if fermentation had been completed in a well-built covered dungfaill.

4966. Another great objection to the use of fresh farm-yard dung is, that the seeds and roots of those plants with which it commonly abounds spring up luxuriantly on the land; and this evil nothing but a considerable degree of fermentation can obviate. The mass of materials consists of the straw of various crops, some of the grains of which, after all the care that can be taken, will adhere to the straw; of the dung of different animals voided, as is often the case with horses fed on oats, with the grain in an entire state; and of the roots, stems, and seeds of the weeds that had grown among the straw, clover, and hay, and such as had been brought to the houses and fold-yards with the turnips and other roots given to live

4967. The degree of decomposition to which farm-yard dung should arrive, before it can be deemed a profitable manure, must depend on the texture of the soil, the nature of the plants, and the time of its application. In general, clayey soils, as more tenacious of moisture, and more benefited by being rendered incohesive and porous, may receive manure less decomposed than well pulverised turnip soils require. Some plants, too, seem to thrive better with fresh dung than others, potatoes in particular; but all the small-seeded plants, such as turnips, clover, carrots, &c. which are extremely tender in the early stage of their growth, require to be pushed forward into luxuriant vegetation with the least possible delay, by means of short dung.

4968. The season when manure is applied, is also a material circumstance. In spring and summer, whether used for corn or green crops, the object is to produce an immediate effect, and it should therefore be more completely decomposed than may be necessary when laid on in autumn for a crop whose condition will be almost stationary for many months. (Sup. Ency. Brit. art. Agr.)

4969. The quantity of putrescent manure requisite for each acre of land during each year is estimated, by Professor Coventry, at five tons per acre annually. That quantity being supplied, not annually, but in quantities of twenty tons per acre every four years, or twenty-five tons per acre every five years. (Quar. Jour. Agr. vol. ii. p. 335.)

Subsect. 2. Lime, and its Management as a Manure.

4970. Lime is by far the most important of the fossil manures; and, indeed, it may be asserted, that no soil will ever be fit for much which does not contain a proportion of this earth, either naturally or by artificial application. Next to farm-yard dung, lime is in most general use as a manure, though it is one of a quite different character; and when judiciously applied, and the land laid to pasture, or cultivated for white and green crops alternately, with an adequate allowance of putrescent manure, its effects are much more lasting, and, in many instances, still more beneficial, than those of farm-yard dung. Fossil manures, Sir H. Davy observes, must produce their effect, either by becoming a constituent part of the plant, or by acting upon its more essential food, so as to render it more fitted for the purposes of vegetable life. It is, perhaps, in the former of these

3 F 3

ways that wheat and some other plants are brought to perfection, after lime has been applied, upon land that would not bring them to maturity by the most liberal use of dung This being an established fact may be considered one of the greatest importance to all cultivators.

4971. With regard to the quantity of lime that ought to be applied to different soils, it is much to be regretted that Sir Humphry Davy has not thought proper to enter fully into the subject. Clays, it is well known, require a larger quantity than sands or dry It has been applied accordingly in almost every quantity from 100 to 500 bushels or upwards per acre. About 160 bushels are generally considered a full dressing for lighter soils, and 80 or 100 bushels more for heavy cohesive soils. One of the greatest advantages arising from the use of lime on gravelly or sandy soils, is its power of absorbing moisture from the air, which is in the highest degree useful to the crops in dry summers.

4972. In the application of lime to arable land, there are some general rules commonly attended to by diligent farmers, which we shall give nearly in the words of a recent

publication.

- 1. As the effects of lime greatly depend on its intimate admixture with the surface soil, it is essential to have it in a powdery state at the time it is applied.

 2. Lime having a tendency to sink in the soil, it should be ploughed in with a shallow furrow.

 3. Lime may either be applied to grass land, or to land in preparation for green crops or summer fallow, with almost equal advantage; but, in general, the latter mode of application is to be preferred.

 4. Lime ought not to be applied a second time to moory soils, unless mixed up as a compost, after which the land should be immediately laid down to grass.

 5. Upon fresh land, the effect of lime is much superior to that of dung. The ground, likewise, more especially where it is of a strong nature, is more easily wrought; in some instances, it is said, the saving of labour would be sufficient to induce a farmer to lime his land, were no greater benefit derived from the application than the opportunity thereby gained of working it in a more perfect manner. (General Report application than the opportunity thereby gained of working it in a more perfect manner. (General Report of Scotland, vol. ii. p. 536.)
- 4973. In liming for improving hilly land, with a view to pasture, a much smaller quantity has been found to produce permanent and highly beneficial effects, when kept as much as possible near the surface, by being merely harrowed in with the seeds, after a fallow or green crop, instead of being buried by the plough.
- fallow or green crop, instead of being buried by the plough.

 4074. The successful practice of one of the most eminent farmers in Britain cannot be too generally known in a matter of so great importance to farmers of such land, especially when lime must be brought from a great distance, as was the case in the instance to which we are about to allude. "A few years after 1754," says Dawson, "having a considerable extent of outfield land in fallow, which I wished to lime previously to its being laid down to pasture, and finding that I could not obtain a sufficient quantity of lime for the whole in proper time, I was induced, from observing the effects of fine loam upon the surface of similar soil, even when covered with bent, to try a small quantity of lime on the surface of this fallow, instead of a larger quantity ploughed down in the usual manner. Accordingly, in the autumn, about twenty acres of it were well harrowed, and then about fifty-six Winchester bushels only of unslacked lime were, after being slacked, carefully spread upon each English acre, and immediately well harrowed in. As many pieces of the lime, which had not been fully slacked at first, were gradually reduced to powder by the dews and moisture of the earth, to mix these with the soil, the land was sagin well harrowed in three or four days thereafter. This land was sown in the spring with oats, with white and red clover and ryegrass seeds, and well harrowed without being ploughed again. The crop of oats was good; the plants of grass sufficiently numerous and healthy; and they formed a very fine pasture, which continued good until ploughed some years after for corn. About twelve years afterwards, I took a lease of the hilly farm of Grubbet; many parts of which, though of an earthy mould tolerably deep, were too steep and elevated to be kept in tillage. As these lands had been much exhausted by cropping, and see and the hilly farm of Grubbet; many parts of which, though of an earthy mould tolerably deep, were too steep and elevated to be kept in

4975. The conclusions which Dawson draws from his extensive practice in the use of lime and dung, deserve the attention of all cultivators of similar land.

Imme and dung, deserve the attention of all cultivators of similar land.

1. That animal dung dropped upon coarse benty pastures, produces little or no improvement upon them; and that, even when sheep or cattle are confined to a small space, as in the case of folding, their dung ceases to produce any beneficial effect, after a few years, whether the land is continued in pasture, or brought under the plough.

2. That even when land of this description is well fallowed and dunged, but not limed, though the dung augments the produce of the subsequent crop of grain, and of grass also for two or three years, that thereafter its effects are no longer discernible either upon the one or the other.

3. That when this land is limed, if the lime is kept upon the surface of the soil, or well mixed with it, and then laid down to pasture, the finer grasses continue in possession of the soil, even in elevated and exposed situations, for a great many years, to the exclusion of bent and moss. In the case of Grubbet hills, it was observed, that more than thirty years have now elapsed. Besides this, the dung of the animals pastured upon such land adds every year to the luxuriance, improves the quality of the pasture, and augments the productive powers of the soil when afterwards ploughed for grain; thus producing, upon a benty outfield soil, effects similar to what are experienced when rich infield lands have been long in pasture, and thereby more and more enriched.

4. That when a large quantity of lime is laid on such land, and ploughed down deep, the same effects will not be produced, whether in respect to the permanent fineness of the pasture, its gradual ameliora-

will not be produced, whether in respect to the permanent fineness of the pasture, its gradual amelioration by the dung of the animals pastured on it, or its fertility when afterwards in tillage. On the contrary, unless the surface is fully mixed with lime, the coarse grasses will in a few years regain possession of the soil, and the dung thereafter deposited by cattle will not enrich the land for subsequent tillage.

Lastly. It also appears from what has been stated, that the four-shift husbandry is only proper for very-rich land, or in situations where there is a full command of dung. That by far the greatest part of the land of this country requires to be continued in grass two, three, four, or more years, according to its

natural poverty; that the objection made to this, viz that the coarse grasses in a few years usurp possession of the soil, must be owing to the surface soil not being sufficiently mixed with lime, the lime having been covered too deep by the plough. (Farmer's Magazine, vol. xiii., 9.9.)

Sect. IV. Composts and other Manures.

4976. Mixing farm-yard dung, in a state of fermentation, with earth, in which there is much inert vegetable matter, —as the banks of old ditches, or what is collected from the sides of lanes, &c., - will bring this inert, dead matter, consisting of the roots of decayed grasses and other plants, into a state of putridity and solubility, and prepare it for nourishing the crops or plants it may be applied to, in the very manner it acts on peat. Dung, however, mixed with earth, taken from rich arable fields which have been long cultivated and manured, can have no effect as manure to other land that the same earth and dung would not produce applied separately; because there is generally no inert matter in this description of earth to be rendered soluble.

4977. Mixing dung, earth, and quick-lime together, can never be advisable; because quick-lime will render some of the most valuable parts of the dung insoluble. (See 2290.) It will depend on the nature of soil or earth, whether even quick-lime only should be mixed with it to form compost. If there be much inert vegetable matter in the earth, the quick-lime will prepare it for becoming food for the plants it may be applied to; but if rich earth be taken from arable fields, the bottoms of dung-pits, or, in fact, if any soil full of soluble matter be used, the quick-lime will decompose parts of this soluble matter, combine with other parts, and render the whole mass less nourishing as manure to plants or crops than before the quick-lime was applied to it. Making composts, then, of rich soil of this description, with dung or lime, mixed or separate, is evidently, to say no more of it, a waste of time and labour. The mixture of earths of this description with dung produces no alteration in the component parts of the earth, where there is no inert vegetable substances to be acted on; and the mixture of earth full of soluble matter with dung and quick-lime, in a mass together, has the worst effects, the quick-lime decomposing and uniting with the soluble matter of the earth, as well as that of the dung; thus rendering both, in every case, less efficient as manures, than if applied separately from the quick-lime, and even the quick-lime itself inferior as manure for certain soils, than if it had never been mixed with the dung and earth at all. (Farmer's Magazine, vol. xv. p. 351.)

4978. Mixing dung in a state of fermentation with peat, or forming what in Scotland are called Meadowbank middens (2241.), is a successful mode of increasing the quantity of putrescent manure. The peat, being dug and partially dried, may either be carted into the farm-yard and spread over the cattle court, there to remain till the whole is carted out and laid upon a dunghill to ferment; or it may be mixed up with the farmyard dung as carted out. If care be taken to watch the fermenting process, as the fire of a clay-kiln is watched, a few loads of dung may be made to rot many loads of Adding lime to such composts does not in the least promote fermentation, while it renders the most valuable parts of the mass insoluble. Adding sand, ashes, or earth, will, by tending to consolidate the mass, considerably impede the progress of

fermentation.

4979. Bone manure. Crushed bones were first introduced to Lincolnshire and Yorkshire, about 1800, by a bone merchant at Hull; and the effect has been, according to a writer in the British Farmer's Magazine, vol. iii. p. 207., to raise wild unenclosed sheepwalks from 2s. 6d. or 5s. to 10s. 6d. or 20s. an acre. The quantity at present laid on is 12 bushels per acre drilled in, in the form of dust, with turnip seed. The turnips are fed off with sheep, and succeeded by a corn crop, and by two crops of grass. It seems to be generally admitted, that bone dust is not beneficial on wet retentive soils, as continued moisture prevents decomposition; but in all descriptions of dry soils it never fails of success. On the poor soil, or chalk or lime-stone of the woolds of Lincolnshire and Yorkshire, the turnip crops are said to equal those of any part of England; and the barley, though coarse, to produce a greater quantity of saccharine matter than even the brightest Norfolk samples. (Brit. Farm. Mag. vol. iii. p. 208.)

4980. The Doncaster Agricultural Association appointed a committee, in 1828, to make enquiries, and report the result of them, on the use and advantages of bones as a manure. The report is full of interest, and highly satisfactory as to the great value of this species. The following is a summary of deductions from the details collected:—

1. That ones which have undergone the process of fermentation are decidedly superior to those which have not expended superior to those which have undergone the process of fermentation are decidedly superior to those which have not done so have not superior to those which have undergone the process of fermentation are decidedly superior to those which have not done so.

have not done so. 5. That the quantity should be about 25 bushels of dust, or 40 bushels of large, increasing the quantity if the land be impoverished.

6. That upon clays and heavy loams, it does not yet appear that bones will answer.

4981. Salt, nitre, and other manures have been already treated of in Part II. at sufficient length. It is clear that both salt and nitre may be advantageously used in many cases. Nitre continues to be a good deal used in Hertfordshire, on which it is sown at the rate of 1½ cwt. per acre. It has been tried at this rate in Scotland to wheat and to grass, and the effect is said to have been wonderful. Salt has been extensively used with almost every crop at different rates, from 20 to 40 bushels per acre; and it appears in many, if not in most, cases to have proved useful. (Quar. Jour. Agr. vol. i. p. 208., and Highl. Soc. Trans. vol. i. p. 147.)

CHAP. II.

Culture of the Cereal Grasses.

4982. The corn crops cultivated in Britain are, wheat, rye, barley, and oats. Other culmiferous plants, as the maize, millet, and rice, have been tried with partial success in warm districts, but they have no chance of ever becoming general in our climate. The best description of the different species and varieties of Cereàlia cultivated in Europe will be found in Metzger's Europæische Cerealien in Botanischer und Landwirthschaftlicher Hinsicht, &c. Heidelberg, 1824. Folio, 20 plates. The plates are exceedingly well executed; and there are popular as well as scientific descriptions, with synonyms in all the

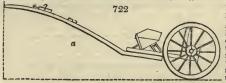

European languages.

4983. On the culture of culmiferous plants, a few general remarks may be of use to the young farmer. Culmiferous plants, particularly wheat and rye, like most others, have two sets of roots. The first originate with the germination of the grain, are always under the soil, and are called the seminal roots; the second spring from the first joint which is formed near the surface of the soil, and from that joint strike down into the soil; these are called the coronal roots. The coronal roots appear chiefly intended for drawing nourishment from the soil; and, as Professor Martyn has observed, are judiciously placed for this purpose, the richest part of all soils being on or near the surface. These fibres are of larger diameter, more succulent, and never so long as the seminal. From these facts, as to the roots of culmiferous plants, some important hints may be derived regarding their culture. The use of stirring the surface in spring to facilitate the extension of the coronal roots, is obvious; the immediate effect of a top-dressing is also apparent, and also that manures may be ploughed in too deep to give the full amount of their beneticial effects to corn crops or grasses. Sageret, a scientific French agriculturist, proved experimentally, that where any of the grains or grasses are etiolated immediately after germination, by growing too rapidly, or by being sown too thick or in too warm a season, the first joint from which the coronal or nourishing roots spring is raised above the ground, and in consequence either throws out no roots at all, or so few as to nourish it imperfectly; in which case it either dies before it comes into flower, or before the seed is matured. (Mem. de la Soc. Ag. de Seine, tom. ii.)

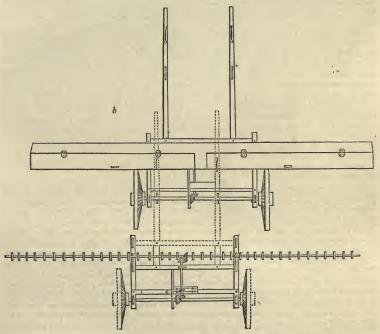

4984. Whether corn ought to be sown broadcast or in drills, is a question which has given rise to considerable discussion. The cultivation in rows of such plants as admit of intertillage during the summer months, is known to supersede the use of a summer fallow on lighter soils. "In truth, the row culture of certain green crops is one of the greatest improvements of modern agriculture, and should be extended by every effort of instruction and example. By no other means yet known to us can so large a produce be raised from land under constant tillage, so beneficial a rotation of crops be adopted, or so great an economy be practised in the application of manures. But, while the advantages are thus apparent with regard to the application of this species of culture to our preparatory green crops, it does in no degree follow that advantages equally great will result from its application to our crops of white corn. The analogy, as it regards the nature of the plants which form the subject of cultivation, does not hold. The cereal grains send forth numerous shoots or suckers, and the goodness of the crop mainly depends on the vigour and number of the shoots which they send forth. The other kind of crops do not, generally speaking, tiller like wheat, barley, or oats, but rise from one stem. Reasoning from these principles, we should infer that the former class of plants should be cultivated in that manner in which they are best suited to summer tillage; that is, in rows: the latter in that manner in which the seed is most equally deposited in the upper stratum of the soil, which is in broadcast. The opinions, however, of intelligent agriculturists are not agreed as to the superiority in practice of the broadcast over the row system, even as it relates to the cereal grains. The farmer of Norfolk, or of the light soils of Sussex, will contend as strenuously for the superiority of the row system as the farmer of East Lothian for the broadcast system; and cach may be right as it regards the application of the principle to the circumstances of his own situation. The question which is to be settled, however, is, -- Which of the two systems

is to be regarded as the rule in husbandry, and which the exception? Now, — independently of the circumstances just adverted to, and judging only from the greater extent to which the broad-cast system is carried on in the country; from the fact of the row system having declined in favour in districts where it had once been most extensively practised; and from its having recently ceased to make progress in general practice, — we should be inclined to hold that, with respect to the cereal grains, the rule of agriculture is the broad-cast system, and the exception the row system. The cases falling under the exception may be, and doubtless are, very numerous and important. There are many light soils in which the seeds require to be deposited at a considerable and cqual depth, and this the drill-machine effects better than sowing on the surface; and there are many thin cold clays which tend to throw out the plants, the best remedy for which is thought to be deep sowing."

4985. The sowing of corn from the hand, "however, is known to be attended with some uncertainty; being dependent for the accuracy of the execution upon the skill and attention of the sowers. The regularity of the work is also affected by winds; and, unfortunately, the means rarely exist of detecting the degree of inaccuracy in the work until too late to correct it." As a remedy for these inconveniences, we have already described a broad-cast hand drill (2576.), and shall here introduce a horse machine for the same purpose (fig. 722 a. b.), that has been for some years employed in "the agriculture of Northumberland, North Durham, and some of the southern counties of Scotland for sowing broad-cast. As it regards

same purpose (Iig. 722 a. b.), that has been for some years employed in "the agriculture of Northumberland, North Durham, and some of the southern counties of Scotland, for sowing broad-cast. As it regards economy alone, little perhaps is effected by the employment of this machine: its recommendations are the regularity and certainty with which it performs the work, and the rendering of the execution independent of unskilfulness or want of care in the operator." (Quar. Jour. Agr. vol. ii. p. 250.)

"A man and a horse with this machine will sow between 25 and 50 acres in a day. The regular manner in which the seed is disseminated renders less seed necessary than in the common method of sowing by the hand. Besides the advantages arising from a saving of seed, the greater regularity, as it regards their distance from each other, with which the plants spring up, generally renders the crop superior to that sown in the other way. The machine has been described as adapted to the sowing of the common sorts of grain, but it is equally well calculated for sowing the cultivated grasses." (Quar. Jour. Agr. vol. ii. p. 254.)

4986. The preservation of corn after it is threshed and cleaned is generally effected in granaries, where the grain is kept well ventilated by passing it frequently from one floor to another, or through winnowing machines.

4987. It has been proposed and attempted in France to preserve it in pits or dry cells at an equal temperature, and included from the atmosphere; but the experiments now going on for this purpose, more

especially by M. Ternaux at St. Ouen, near Paris, are not yet sufficiently matured to enable us to lay any useful result before the public. That corn has been so preserved in former ages, and that to a considerable extent, is beyond a doubt; and it is equally certain that in the interior of Africa, among the Caffres and other nations, as well as in the south of Russia, in Turkey, and in Egypt, the practice is still employed on a small scale. It may be doubted, we think, whether, with the present population of Europe, it could ever be concertible adopted.

be generally adopted.

be generally acopied.

4988, Preservation of corn in siloes. Some account of the opening of a siloe was lately read to the Agricultural Society of Paris. "The place consisted of an icchouse, and the grain when put in was of the finest appearance, perfectly dried, and in excellent condition. The door had been hermetically sealed; and yet, when opened, a considerable thickness of the mass of corn was found destroyed by weevils, the latter being in such quantity as to occasion an elevated temperature. As part of the same corn had been perfectly well preserved in other siloes, the cause of this deterioration was sought for and a hole was

and yet, when opened, a considerable thickness of the mass of corn was found destroyed by weevils, the latter being in such quantity as to occasion an elevated temperature. As part of the same corn had been perfectly well preserved in other siloes, the cause of this deterioration was sought for, and a hole was found in the lower part which had been made by mice, and which, by admitting air in sufficient quantity, had allowed the weevils originally in the corn to live, and increase their numbers to the degree mentioned. After some observations upon experiments which showed that insects could live for a very long time in vitiated air, a committee was named to ascertain the requisite state of the air, and the circumstances connected in the enquiry with the preservation of grain in these repositories. At another meeting of the society, M. Hachette described the method proposed by M. Clement to prevent the destruction of corn by weevils. It is founded upon a fact observed by him, that these insects cannot live in an atmosphere which contains less than a certain proportion of moisture. He therefore proposes that the corn should be subject to a continued ventilation of air dried by passing over quick-line or chloride of calcium. All the weevils originally in the corn would thus be quickly destroyed." (Recweil Industriet, vol. xii. p. 208.) 4989. The prescruation of corn in the north of Russia may deserve notice more as matter of curiosity, and for supplying ideas on the subject, than for imitation. The corn is dried in small ovens or chambers, which communicate with a larger chamber or oven by small tubes that enter the smaller chambers at the top. The oven is then filled with straw closely pressed, which is lighted and left to consume during the night. Next morning the corn is taken from the smaller chambers, the smoke from the ovens having passed into them and perfectly dried it. This practice has several advantages: the corn is lighter to move, and is kept much easier, without requiring to be constantly turned, bei

4990. The uses to which the straw of corn may be applied are various. Besides food for cattle, litter for animals, thatch, &c., it is bleached and plaited into ribands for forming hats, and bleached, dyed of different colours, split, and glued to flat surfaces, so as to form various works useful and ornamental. Paper is also made from straw; and the same pulp which forms the paper may be moulded into all the forms given to papier maché, medallion portraits, embossed works, &c. Whoever wishes to enter into the details of the great variety of articles that may be manufactured from straw, should consult the Dictionnaire Technologique, art. Paille; or an abridged translation of a part of the article in Gill's Technological Repository, vol. vi. new series, p. 228.

4291. The diseases peculiar to the cereal grasses have been included in the diseases common to vegetables in general. (1671.) They are chiefly the smut, the rust, the mildew, and the ergot; and we shall notice them more at length under the different spe-

cies of corn which are most subject to suffer from them.

4992. The practice of reaping corn before it is perfectly ripe originated in France, and has lately been recommended by M. Cadet de Vaux.

has lately been recommended by M. Cadet de Vaux.

4993. Corn reaped eight days before the usual time, this author says, has the grain fuller, larger, finer, and better calculated to resist the attacks of the weevil. An equal quantity of the corn thus reaped, with corn reaped at the period of maturity, gave more bread, and of a better quality. The proper time for reaping is that when the grain, on being pressed between the fingers, has a doughy appearance like the crumb of bread just hot from the oven, when pressed in the same manner. This does not seem to agree altogether with the experience of some agriculturists in the Carse of Gowrie, Perthshire, where oats intended to be made into meal are always found to yield most when allowed to stand as long as possible. Corn for seed, however, it is acknowledged by the same agriculturists, will answer the purpose perfectly though cut before fully matured. (Perth Miscellany, vol. i. p. 41) If the doctrine of Cadet de Vaux be confined to wheat, it may be perhaps considered as confirmed by the following passage from Waistell:—

"It is well known," he observes, "that wheat produces the most flour and the sweetest bread when threshed out before it has been stacked; and as all corn is more or less injured in both these respects, accordingly as it is more or less heated in the rick, it would be highly desirable totally to prevent its heating or becoming musty, in the ricks. In wet harvests it is sometimes impossible to get orn sufficiently dried; and we see that even in hot and dry harvests, such as that of 1819, a great deal of corn is sometimes spoiled in the ricks: we should, therefore, be extremely cautious to have corn well dried in the field, the ricks made of a moderate size, and raised off the ground, to admit the air to circulate under them, with chimneys to allow a current of air to pass upwards through them, to carry off the hot and musty air from the centre of the rick, which, without such a chimney, has its tendency to heat four-fold greater than one with a chimn

4995. The methods of reaping corn are various. The most general mode is by the sickle, already described (2482. and 2483.); the scythe is also used, more especially for barley and oats; and a reaping machine (2737.) is beginning to be used in some parts of Scotland; in which country an effectual bean-reaping machine (2740.) was in use many years ago. A method of mowing corn much practised in the county of Durham, and possibly Yorkshire, has lately been introduced into Northumberland, but does not appear to make much progress, the low priced Irish reapers doing the work so much more neatly and with less waste, though it costs more money to the owner. The scythe has a cradle similar to that described (405.); it is handled and used differently from the bow and grass scythes, and has only one short handle or "nib" on the " sned," or long handle, for the right hand; the left grasps the " sned " with the palm upwards: this enables the mower, who generally mows "from the corn," to bring the back of the scythe and cradle to the ground, and leave the cut corn in a beautiful state for being put into sheaves. A good workman can do two, and some three acres a day: they charge about 5s. per acre for mowing, binding, and stooking (shocking): this practice may be advantageously followed wherever the crop is not stricken down by rains, particularly barley crops. (C. near Alnwick, in Gard. Mag. vol. vi.)

4996. Frosted corn, like frosted seeds of any sort, may be detected by dissection and comparison with unfrosted corn. By frosted corn is to be understood corn that has been frozen on the plant before it was perfectly ripe, in consequence of which the germ of the future plant or vital part of the seed is deprived of its vitality by the expansion

produced by the freezing of its watery parts.

produced by the freezing of its watery parts.

4997. Frosted oats. The oat being one of the latest corns, and a corn of cold rather than of warm countries, is more liable to be frozen than any other; but fortunately, also, frozen oats are more easily detected than either frozen wheat or barley. The Rev. James Farquharson, who has paid much attention to this subject, and written an elaborate article on it in the Farmer's Magazine (vol. xix.), observes, that every kernel, when stripped of the husk, will be found to exhibit the appearance of a groove on one side. If the bottom of the groove has a smooth clear translucent appearance from end to end; if it is not much shrunk into the substance of the kernel; and if the kernel splits with difficulty in its direction, then we may pronounce the vital part of the seed to be free from injury by frost. If, on the contrary, there is a black speck seen in the groove at the root end of the kernel; if the groove cuts deep into the kernel, so that it may be split in that direction; and if, when the kernel is so split, the blackness, accompanied with a rotten scaly appearance, is seen extending from end to end at the bottom of the groove, then the vital part or future plant may be pronounced entirely unfit for being used as seed.

4998. Frosted barky. The nature of the injury that ripening barley suffers from frost is similar to that suffered by oats. The husk of barley, like that of oats, consists of two unequal parts; the small part covering the groove of the kernel. In sound grain, when dry, the hull is firmly attached to the kernel; but in frosted grain the small part of the hull becomes loose, and feels soft on being pressed; and if, in such grain, this part of the hull be comes loose, and feels soft on being pressed; and if, in such grain, this part of the hull is striped away, a blackness and rottenness, resembling that in frosted oats, will be seen in the bottom of the groove.

4999. Frosted wheat. Upon an attentive inspection of wheat that has been exposed to the frost

5000. The nutritive products of the plants to be treated of in this section, are thus given by Sir H. Davy.

Systematic Names.	English Names. The quantity analysed, of each sort 1000 parts.	Whole quantity of soluble or nutritive matter.	Mucilage or starch.	Saccha- rine mat- ter or sugar.	Gluten or albumen.	Extract, or matter render d insoluble during the opera- tion.
Triticum hybérnum	Middlesex wheat, average crop -	955	765	_	190	.
æstlvum	Spring wheat	940	700	-	240

Wheat. - Tríticum L.; Triándria Digynia L., and Gramíneæ J. Froment, SECT. I. Fr.; Weitzen, Ger.; Grano, Ital.; and Trigo, Span.

5001. Wheat is by far the most important of the cereal grasses, the flour made from its grains or seeds, from the quantity of gluten they contain, making the best bread in the world. A greater proportion of mankind are nourished by rice than by wheat, but there is no grain which comes near wheat in its qualities for bread-making. and maize are comparatively unfit for it, and oats, barley, and rye but imperfectly adapted. Rye, however, comes nearer to wheat in its bread-making qualities than any other grain.

5002. Of what country wheat is a native, is totally unknown; it has been supposed indigenous to Asia and Africa, and unquestionably it is more likely to belong to these parts of the world than any other; but all that can be advanced on this subject is con-Wheat, with the exception it is said of some parts of the southern coast of Africa, is cultivated in every part of the temperate and torrid zones, and in some places as high as 2000 feet above the level of the sea. It has been grown from time immemorial in Britain, but in few places at a greater elevation than 600 feet. the elevation to which any plant can be cultivated always depends on the latitude of the situation.

5003. Species and varieties. (fig. 723.) Botanists reckon seven species of Triticum, which are or may be cultivated for their grains, besides many varieties and subvarieties of those in common culture. The species or subspecies are,

 Trificum æstivum, Summer wheat or spring wheat (a).
 hybérnum, Lammas wheat (b).
 compósitum, Egyptian wheat (c).
 turgidum, Turgid wheat (d) 5 Triticum polonicum, Polish wheat (e).
6. Spelta, Spelt wheat (f).
7. monococcum, One-grained wheat (g).

The first, second, fourth, and fifth sorts are by many botanists considered as only varieties, and it it is doubtful whether the third and sixth may not be the same; the seventh has all the marks of a distinct species, but it is very questionable whether, if much cultivated, it would always continue to produce one row of grains.

much cultivated, it would always continue to produce one row of grains.

5004. The spring or summer wheat (a), Ble de Mars, Fr., is distinguished from that generally sown, by its narrower ears, longer beards, smaller grains, and shorter and more slender straw, and also by its inability to endure our winters. It is commonly sown in April, or even so late a May. It was known to Parkinson in 1666, but has never been much cultivated, except in Lincolnshire. It was tried and given up in Northumberland and Mid Lothian, and also in some counties near Londou. Many varieties of summer wheat were transmitted a few years ago to the president of the Board of Agriculture from the Agricultural Society of Paris, for the purpose of experiment, and were divided among several distinguished agriculturists, (Comm. to the Board of Agr., vol. vii. p. 11.); but there has not yet been time for establishing their comparative merits, or their adaptation to the climate of Britain. Summer, or, as it is often called, spring, wheat has however been long and extensively cultivated in some parts of England, particularly in Lincolnshire; and it is probable may be found a valuable crop in the southern counties; but the trials that have been made in the north, do not seem to entitle it to a preference over winter wheat sown in spring, or even oats or barley, in that climate.

5005. Of the winter or common wheat (b), Froment blanc, Fr., there are a great number of varieties. Professor Martyn, in Miller's Dictionary, has described forty-nine sorts, and Professor Thaer speaks of a hundred, but affirms that those who describe them know nothing about them, and in all probability include one sort under different names. All the varieties may be reduced to two, the white, and the brown or red grained. As subvarieties, there are the bearded and beardless, the woolly-chaffed, and thin or hairy chaffed, both of the reds and whites. To these some add another variety, which is the springsowing the progeny, after a number of generations, acquires a babit of c

to Villars, is for gruel.

5009. To procure new varieties of wheats, the ordinary mode is to select from a field a spike or spikes from the same stalk, which has the qualities sought for; such as larger grains, thinner chaff, stiffer straw, a tendency to earliness or lateness, &c.; and picking out the best grains from this ear or ears, to sow them in suitable soil in an open airy part of a garden. When the produce is ripe, select the best ears, and from these the best grains, and sow these, and so on till a bushel or more is obtained, which may then be sown in a field apart from any other wheat. In this way, many of the varieties of our common winter wheat have been obtained; as the hedge-wheat which was reared from the produce of a stalk found growing in a hedge in Sussex, by one Wood, about Other varieties have assumed their distinctive marks from having been long cultivated on the same soil and climate, and take local names, as the Hertfordshire red, Essex white, &c.

Essex white, &c.

5010. Marshall, (Yorkshire) mentions a case in which a man of accurate observation, having in a piece of wheat perceived a plant of uncommon strength and luxuriance, diffusing its branches on every side, and setting its closely-surrounding neighbours at defiance, marked it; and at harvest removed it separately. The produce was 15 ears, yielding 604 grains of a strong-bodied liver-coloured wheat, differing, in general appearance, from every other variety he had seen. The chaff was smooth, without awns, and of the colour of the grain; the straws stout and reedy. These 604 grains were planted singly, nine inches asunder, filling about 40 square yards of ground, on a clover stubble, the remainder of the ground being sown with wheat in the ordinary way; by which means extraordinary trouble and destruction by birds were avoided. The produce was two gallons and a half, weighing 204lbs, of prime grain for seed, besides some pounds for seconds. One grain produced 35 ears, yielding 1235 grains; so that the second year's produce was sufficient to plant an acre of ground. What deters farmers from improvements of this nature is probably the mischievousness of birds; from which at harvest it is scarcely possible to preserve a small patch of corn, especially in a garden or other ground situated near a habitation; but by carrying on the improvement in a field of corn of the same nature, that inconvenience is got rid of. In this situation, however, the botanist will be apprehensive of danger from the floral farina of the surrounding crop. But from what observations Marshall has made he is of opinion his fears will be groundless. No evil of this kind occurred, though the cultivation of the above variety was carried on among white wheat.

5011. But the most systematic mode of procuring new varieties, is by crossing groundless. No evil of this kind occurred, though the cultivation of another variety of a different quality. Thus, supposing a farmer was in the habit of cultivating a very good variety, which he wish

1809.

5019. The propagation of wheat by transplanting may be employed to expedite the progress of cultivating a new variety of ascertained excellence. To show what may be gained in time by this mode, we shall quote from The Philosophical Transactions an account of an experiment made by C. Miller, son of the celebrated gardener of that name, in 1766. On the 2d of June, Miller sowed some grains of the common red wheat; and on the 8th of August, a single plant was taken up and separated into 18 parts, and each part planted separately. These plants having pushed out several side shoots, by about the middle of September, some of them were then taken up and divided, and the rest of them between that time and the middle of October. This second division produced 67 plants. These plants remained through the winter, and another division of them, made about the middle of March and the 12th of April, produced 500 plants. They were then divided no further, but permitted to remain. The plants were, in general, stronger than any of the wheat in the fields. Some of them produced upwards of 100 ears from a single root. Many of the ears measured seven inches in length, and contained between 60 and 70 grains. The whole number of ears which, by the process above mentioned, were produced from one grain of wheat, was 21,109, which yielded three pecks and three quarters of clean corn, the weight of which was 470ks. 7 ounces; and, from a calculation made by counting the number of grains in an ounce, the whole number of grains was about 386,840. By this account we find, that there was only one general division of the plants made in the spring. Had a second been made, Miller thinks the number of plants would have amounted to 2000 instead of 500, and the produce thereby much enlarged.

5013. In making a choice from all the species and varieties which we have named, the thin-skinned white wheats are preferred by all the best British farmers whose soil and climate are suitable for this grain, and for sowing in autumn. In late situations, and less favourable soils and climates, the red varieties are generally made choice of; and these are also generally preferred for sowing in spring. Red wheats, however, are considered as at least fifteen per cent. less valuable than the white varieties. No subvariety ever continues very long in vogue; nor is it fitting that it should, as degeneracy soon takes place, and another and better is sought for as a successor. Hence the only recommendation we can give, as to the choice of subvarieties, is, to select the best from among those in use by the best farmers in the given situation, or nearest well-cultivated

5014. The soils best adapted for the culture of wheat, are rich clays and heavy loams; but these are not by any means the only description of soils on which it is cultivated. Before the introduction of turnips and clover, all soils but little cohesive were thought unfit for wheat; but, even on sandy soils, it is now grown extensively, and with much advantage, after either of these crops. The greater part of the wheat crop throughout

Britain, however, is probably still sown upon fallowed land. When it succeeds turnips consumed on the ground, or clover cut for hay or soiling, it is commonly sown after one In Scotland, when wheat is to be sown after clover upon heavier soils, or after grass of two or more years, the land is ploughed twice or thrice, or receives what is called a rag fallow. In Norfolk and Suffolk, wheat is seldom sown after fallow or turnips; but the farmer there thinks himself almost sure of a good wheat crop after a good clover crop. One ploughing only is required, and the seed is dibbled in the flag, as they call it; that is, on the turned-over surface or furrow slice.

as they call it; that is, on the turned-over surface or furrow slice.

5015. On rich clays, wheat may be cultivated almost every second year, provided due care is taken to keep the land clean, and in good condition. A summer fallow once in four, six, or eight years, according to seasons and circumstances, is, however, necessary; and manure should either applied on that fallow for the first crop of wheat, or, what some people think preferable, should be laid on the wheat-stubble for a crop of drilled beans, which ensures the succeeding crop of wheat. If the first crop of beans has been completely cleaned, there is no difficulty in repeating, and even in extending the course; and the crops will be little inferior to those gained at the beginning of the rotation, provided manure has been bestowed to each crop of beans. In this way, when the ground is fallowed every fourth year, two crops of wheat and one of beans are gained from manuring once; when fallowed every fourth year, two crops of wheat and three of beans from manuring twice; and, when fallowed every sixth year, three crops of wheat and three of beans from manuring thrice. In the first-mentioned shift, less manure is bestowed than in either of the others; and, if the soil is of good quality, it will support itself: whereas, in the shifts of six and eight, unless foreign manure be procured, it rarely happens that they can go on successfully for any length of time, without abstracting dung from other parts of the farm on which they are practised. (Brown's Tr. on Rural Affairs.)

5016. In cultivating wheat on thin clays, the rotations just mentioned are inapplicable. A six-course shift of a different kind has, however, been successfully followed by many people; but it requires every branch of the work to be well executed. Ist, a summer fallow, dunged at the rate of twelve or fourteen double loads per acre; 2d, wheat; 3d, grass; 4th, oats; 5th, peas and beans drilled; 6th, wheat. If manure can be given in the middle of the shift, every one of the crops may be

5018. The culture of the soil intended for wheat varies according to its nature, and the preceding and following crops.

preceding and following crops.

5019. On soils really calculated for wheat, though in different degrees, summer fallow is the first and leading step to gain a good crop or crops of that grain. The first furrow should be given before winter, or so early as other operations upon the farm will admit; and every attention should be used to go in as deep as possible; for it rarely happens that any of the succeeding furrows exceed the first one in that respect. The number of after-ploughings must be regulated by the condition of the ground and the state of the weather; but, in general, it may be observed, that ploughing in length and across, alternately, is the way by which the ground will be most completely cut, and the intention of fallowing accomplished. It has been argued, that harrowing clay soils, when summer-fallowed, is prejudicial to the wheat crop; but without discussing this point (such a discussion being unnecessary), it may merely be stated, that, in a dry season, it is almost impracticable to reduce real clays, or to work them too small; and that, even in a wet one, supposing they are made surface-smooth, they will, when ploughed up again, consolidate into clods or big lumps after forty-eight hours' drought, and become nearly as obdurate as ever. It is only on thin soils, which have a mixture of peat earth, and are incumbent on a bottom imprevious to water, that damage is at any time sustained by over-harrowing. Such are generally of a weak texture, and may be broken down with facility by the roller and harrow. If caught by much rain before the pores are in some measure closed, the moisture is greedily absorbed; and being prevented from going downwards by the hardness of the subsoil, the whole surface becomes a kind of mortar or paste, unless previously well ridged 'up; which, to a certain extent, prevents the consequences from being dangerous. These evils, however, must be submitted to by the possessors of such soils, if they want to have them sufficiently fallowed and prepared in a proper manner; for, called for by imperious necessity.

called for by imperious necessity.

5090. When wheat is sown after beans it rarely happens, in this northern climate, that more than one ploughing can be successfully bestowed. Before this is given, it is advantageous to cross-harrow the land, which levels the drills, and permits the ploughing process to be executed with precision. Almost in every case the ridges should be gathered up, so that the furrows may be well cleared out, and the plants preserved from injury during the inclement winter season. Clover land should be neatly ploughed, and well laid over, so that the roots of the grasses may be buried and destroyed; for it frequently happens that crops of wheat, after clover and rye-grass, are greatly injured by inattention to the ploughing process. In short, sowing wheat after clover on clayey soils in Scotland may be considered as the most hazardous way in which that grain can be cultivated. (Brown's Tr. on Rural Affairs.)

5021. The manures best calculated for wheat, are allowed by all agricultural chemists to be animal matters and lime. The former has a direct influence in supplying that essential constituent to wheaten flour, gluten; and the latter azote and lime, both actually found in the straw of wheat. At all events, it is certain that wheat will not thrive on any soil which does not contain lime. In this Sir H. Davy, Chaptal, Professor Thaer, and Grisenthwaite fully agree.

Tessor Infact, and Orisentinvaire unity agrees.

5022. A more abundant supply of manure is generally required for wheat than for any other grain. Professor Thacr says it absorbs more nourishment from the soil than any of the corn tribe; and he calculates (hypothetically, as he allows), that for every 100 parts of nutriment in a soil sown with this grain, 40 will be carried off by the crop. (Principes Raisonnes, tom. iv. art. Froment.) at the same time, too large a dose of manure on land in good tilth is very apt to cause the crop to lodge; and hence some people think it improper to dung rich clays or loams when fallowed, and choose rather to reserve that restorative till the succeeding season, when they are prepared for a crop of drilled beans. Delaying the manuing process for a year is attended with many advantages; because good land, fully wrought, contains such a principle of action within itself, as often causes the first wheat crop to be lodged before it is filled; under which circumstance, the produce is diminished both in quantity and quality. The delay in manuring is, however, attended with disadvantages; because, when dung is kept back till the end of autumn or beginning of winter, to be laid on the stubbles, the weather is often so wet that it cannot be carted on without subjecting the land to injury from poaching, whilst the labour in laying it on is also increased. On thin clays, or even upon soils of the other description not in high condition, there can be no doubt but that the end of summer, and upon summer fallow, is the most proper time for manuring, though it will be found, that an improvident expenditure of dung on such occasions ought always to be steadily avoided. (Broam.)

be found, that an improvident expenditure of dung on such occasions ought always to be steading avoided. (Brown.)

5093. Where manure is abundant, it is stated by some that wheat alternating with a green crop, or indeed any corn crop and a green crop, may be grown alternately for an indefinite time. (Farm. Mag. vol. xxiii, p. 298.) It is alleged by others, that this doctrine is not supported by experience. Constant tillage, they say, wears out the best soils, and the grain degenerates in quality, if not in quantity too. Instances, however, are given in The Communications to the Board of Agriculture of potatoes and wheat having been grown alternately on the same soil for a number of years, and very good crops produced. It may be useful to know that the thing is not impossible.

5024. The climate required to bring wheat to perfection must be such as affords a dry and warm season for the blossoming of the ear, and the ripening of the grain. Wheat will endure a great deal of cold during winter, if sown in a dry or well drained soil; and if it be covered with snow. Hence it is that wheat is sown as far north as Petersburgh Moderately moist weather before the flowering season, and after the and in Sweden. grain is set or formed, is favourable to wheat; but continued heavy rains after the flowering season produce the smut. The dry frosty winds of February and March, and even-of April in some districts, are more injurious to the wheats of Britain than any other description of weather. Hoar frosts, when the plant is in the ear, produce blights; and mildews often result from or follow sultry winds and fogs. Cold, in the blossoming and ripening season in July, even unaccompanied by wind or rain, produces an inferior grain, greatly deficient in gluten; and heat the contrary. The most valuable wheat of Europe, in this respect, is that of Sicily; which Sir H. Davy found to contain much more gluten than the best wheat of Britain.

5025. The season for sowing wheat on clays is generally the latter end of autumn; on early turnip soils it is sown after clover or turnips, at almost every period from the beginning of September till the middle of March; but the far greater part is sown in September and October. For summer wheat, in the southern districts, May is sufficiently early, but in the north, the last fortnight of April is thought a more eligible seed-time. In the cultivation of spring-sown winter wheat, it is of importance to use the produce of spring-sown grain as seed, as the crop of such grain ripens about a fortnight earlier than when the produce of the same wheat winter-sown is employed as spring seed. (Encyc. Brit. art. Agr.)

5026. Seed wheat is prepared for sowing by the process called pickling. According to Brown (Treatise on Rural Affairs, art. Wheat), this process is indispensably necessary on every soil; otherwise smut, to a greater or less extent, will, in nine cases out of ten,

assuredly follow.

assuredly follow.

5027. Though almost all practical farmers are agreed as to the necessity of pickling, yet they are not so unanimous as to the modus operandi of the process, and the article which is best calculated to answer the intended purpose. Stale urine may be considered the safest and surest pickle; and where it can be obtained in a sufficient quantity, it is commonly resorted to. The mode of using it does not, however, seem to be agreed upon; for, while one party contends that the grain ought to be steeped in the urine, another party considers it sufficient to sprinkle the urine upon it. Some, again, are advocates for thoroughly steeping the grain in a pickle made of salt and water, sufficiently strong to buoy up a fresh egg. But whatever difference of opinion there may be as to the kind of pickle that ought to be used, and the mode of using it, all admit the utility of mixing the wetted seed with hot lime, fresh slaked; and this, in one point of view, is absolutely necessary, so that the seed may be equally distributed. It may be remarked, that experience justifies the utility of all these modes, provided they are attentively carried into excution. There is some danger from the first; for if the seed steeped in urine is not immediately sown, it will infallibly lose its vegetative power. The second, viz. sprinkling the urine on the seed, seems to be safest, if performed by an attentive hand; whilst the last may do equally well, if such a quantity of salt be incorporated with the water as to render it of sufficient strength. It may also be remarked, that this last mode is oftener accompanied with smut, owing no doubt to a deficiency of strength in the pickle; whereas a single head with smut is rarely discovered when urine has been used.

5028. An improved mode of preparing wheat for sowing has recently been adopted in the south of Scot-

with snut is rarely discovered when urine has been used.

5028. An improved mode of preparing wheat for sowing has recently been adopted in the south of Scotland, and followed with great success. It is thus described:—"Take four vessels, two of them smaller than the other two, the former with wire bottoms, and of a size to contain about a bushel of wheat, the latter large enough to hold the smaller within them. Fill one of the large tubs with water, and putting the wheat in the small one, immerse it in the water, and stir and skim off the grains that float above, and renew the water as often as is necessary, till it comes off almost quite clean. Then raise the small vessel in which the wheat is contained, and repeat the process with it in the other large tub, which is to be filled with stale urine; and in the mean time wash more wheat in the water tub. When abundance of water is at hand, this operation is by no means tedious; and the wheat is much more effectually cleansed from all impurities, and freed more completely from weak and unhealthy grainsand seeds of weeds, than can be

done by the winnowing machine. When thoroughly washed and skimmed, let it drain a little, then empty it on a clean floor or in the cart that is to take it to the field, and sift quick-lime upon it, turning it over and mixing it with a shovel till it be sufficiently dry for sowing." (Supp. E. Brit. art. Agr.)

5029. The quantity of seed necessarily depends both on the time of sowing and the state of the land; land sown early requiring less than the same land when sown in winter or spring; and poor land being at all times allowed more seed than rich. The quantity accordingly varies from two bushels, or less, to three, and sometimes even to four, bushels per English statute acre. Winter wheat, when sown in spring, ought always to have a liberal allowance, as the plants have not time to tiller much without unduly retarding their maturation. (Supp. &c.) Upon well prepared lands, if the seed is distributed equally, it can scarcely be sown too thin; perhaps two bushels per acre are sufficient; for the heaviest crops at autumn are rarely those which show the most vigorous appearance through the winter months. Bean stubbles require more seed than summer fallows; because the roughness of their surface prevents such an equal distribution; and clover layers ought to be still thicker sown than bean stubbles. sowing in spring ought not to be practised, otherwise the crop will be late, and imperfectly ripened. (Brown.)

5030. The modes of sowing wheat are either broad-cast, drilling, ribbing, or dibbling. The first mode is by far the most general, more especially in the north of England and Scotland, and the seed is for the most part covered by the harrows. No more harrowing, Brown observes, should be given to fields that have been fallowed than what is necessary to cover the seed, and level the surface sufficiently. Ground which is to lie in a brokendown state through the winter, suffers severely when an excessive harrowing is given, especially if it is incumbent on a close bottom; though as to the quantity necessary none

can give an opinion except those who are present.

5031. Ploughing in. Many farmers allege that wheat which is harrowed in is apt to be thrown out in

5031. Ploughing in. Many farmers allege that wheat which is harrowed in is apt to be thrown out in spring; or if not thrown out at that season, that it does not tiller well, and that the stalks are apt to dwindle away and fall down in the flowering season. It is certain that this is the case in many parts of England; and the cause assigned by the northern farmers is the defective manner in which the land is ploughed, by which there is not sufficient covering for the seed. To guard against these evils it is a very general practice in most of the southern counties, when wheat is sown broad-cast, to plough it in with a shallow furrow. This is done even after beans and on clover leys, and is a favourite practice on very opposite soils, as in Norfolk and Middlesex.

5032. Drilling, however, is extensively practised in some districts, and is becoming more general on lands infested with the seeds of annual weeds, especially when sown in spring. A machine which sows at three different intervals, according to the judgment of the farmer, of twelve, ten and a half, or nine inches, is much approved of in the northern districts. It deposits six, seven, or eight rows at once, according to its adjustment to one or other of these intervals, and the work is done with ease and accuracy when the ridges are previously laid out of such a breadth (twelve feet and a half, so to be sown by one bout; the machine going along one side of such a ridge, and returning on the other, and its direction being guided by one of its wheels, which thus always runs in the open furrow between the ridges. If the ran ad a half inch interval be adopted, and it is the most common one in that country, the machine sows seven rows at once, or fourteen rows on a ridge of twelve feet and a half. But the space between the rows war is nome parts still more than this machine admits of; it ought not, however, to be so narrow as to preven hand-hoeing, even after the crop has made considerable progress in growth; and it cannot advantageously be so wide as to admit

rows on a ridge of twelve feet and a half. But the space between the rows varies in some parts still more than this machine admits of; it ought not, however, to be so narrow as to prevent hand-hoeing, even after the crop has made considerable progress in growth; and it cannot advantageously be so wide as to admit the use of any effective horse-hoe.

5033. Ribbing is a mode of sowing common in some places, by which a drill machine is dispensed with, though the same purpose is nearly answered. This we have already adverted to in the section on tillage. The seed is scattered with the hand in the usual broad-cast manner, but as it necessarily falls for the most part in the furrows between the ribs, the crop rises in straight parallel rows, as if it had been sown by a drill machine; after sowing, the ribs are levelled by harrowing across them. This plan has nearly all the advantages of drilling in, as far as it regards exposure to the rays of the sun, and the circulation of air among the plants; but as some plants must always rise between the rows, it is not quite so proper when hoeing is required. (Sup. E. Brid.)

5034. The dibbling of wheat is practised in some parts of Norfolk. The furrow is laid over flat, and a row of holes is made along the middle of each by a man who uses a dibber in each hand. A middling work-man will make four holes in a second. One dibbler is sufficient for three droppers; whence one man and three children are called a set. The dibbler carries on three flags or turned furrows; going on some yards upon one of the outside furrows, and returning upon the other, after which he takes the middle one; and thus keeps his three droppers constantly employed; and at the same time is in no danger of filling up the holes with his feet. The droppers put two or three grains of wheat into each hole; but much time and patience is necessary to teach them to perform the business properly and quickly. An expert dibbler will hole half an acre in a day; though one third of an acre is usually reckoned a good day

consider quite unsuitable to the present improved state of agriculture; but it may sometimes happen, that on rich loamy land, especially in a showery season, there may be no other way of getting in the seed.

5035. The after-culture of wheat, or culture of the growing crop, depends on the manner in which it has been sown.

5036. When wheat is sown broad-cast, the subsequent culture must generally be confined to harrowing, rolling, hand-weeding, or hand-hoeing with a pronged hoe. As grass seeds are frequently sown in spring on winter-sown wheat, the harrows and roller are employed to loosen the soil, and cover the seeds. But these operations, to a certain extent, and at the proper season, are found beneficial to the wheat crop itself, and are sometimes performed even when grass seeds are not to be sown. One or two courses of harrowing penetrate the crust which is formed on tenacious soils, and operate like hand-hoeing in raising a fresh mould to the stems of the young plants. Rolling in spring ought never to be mitted on dry porous soils, which are frequently left in so loose a state by the winter frosts, that the roots quit the soil and perish; and, if the land is rough and cloddy, the roller has a still more beneficial effect than the harrows in pulverising the inert masses, and extending the pasture of the plants. Hand-weeding, so far as to cut down thisties and other long weeds, is never neglected by careful farmers; but the previous culture ought to leave as little as possible of this work to be done when the crop is growing. (Supp.)

5037. When wheat has been drilled, ribbed, or dibbled, the intervals may be heed or stirring will, by the changes it admits of in its double character of drill and horse-hoe, be the sot to use for hooing or stirring; or if a single drill should have been used, the expanding horse-hoe, or Wilkie's brake harrow, may be successfully adopted.

The operation of hoeing or stirring should generally be performed in March, and need not be repeated.

When grass-seeds are to be sown among the wheat, the heeing is an excellent mode of covering them.

Weeding the rows should not be neglected, nor delayed later than the beginning of June. 5036. When wheat is sown broad-cast, the subsequent culture must generally be confined to harrowing,

an excellent mode of covering them. Weeding the rows should not be neglected, nor delayed later than the beginning of June.

5038. Where wheats rise too thin in some places, and too thick in others, whether in rows or broad-cast, the practice of transplanting from the latter to the former has been recommended. This is said to be practised occasionally in Essex and Norfolk, and the time is the end of March. To be attended with success the soil must be in a good state, and the blanks to which the plants are to be transplanted must be stirred up with a trowle or small two-pronged fork. Under such circumstances we have no doubt of the plan being attended with success; but we are certain that without stirring the soil, the operation will not pay for the expense. Blanks are sometimes filled up by sowing summer wheat, dibbling beans, &c but these are obviously bad modes; a better is either to stir the soil well, by the hand pronghoc, and encourage the tillering of the plants, or to stir the soil and then transplant.

5059. Top-dressing wheat crops has been recommended in cases where the land is not in a sufficient state of fertility or preparation to bring the crops to perfection. Substances of both the solid and fluid kinds have been made use of for this purpose; the first consist chiefly of the dung of different sorts of birds, after being brought into a powdery state, bone-dust, soot, peat ashes, and various saline matters. The latter are principally the drainings of dunghills and similar liquid materials. The former should be thinly sown over the crop with as much evenness as possible, as early in the spring as horses can be ad-

The latter are principally the drainings of dunginus and similar induct materials. The former should be thinly sown over the crop with as much eveniess as possible, as early in the spring as horses can be admitted upon the land without injury; and if it can be done when the weather is inclined to be moist, it is the better, a roller may then be passed over the crop with advantage. Where the latter substances are made use of, care should always be taken that the plants be not injured by having too large a quantity applied to them. In this practice the expense should be a primary consideration, and small trials first made where dungs have not been used. The proper season for performing the business is the beginning 5040. When wheat appears too forward and luxuriant, it is sometimes eat-down in April with sheep or even with horses, but this requires great judgment to be effected without injuring the crop.

5041. In harvesting wheat, the best farmers both of Britain and the continent agree, that it ought to be cut before it becomes dead ripe. When this is the case, the loss is considerable, both in the field and stack-yard; and the grain, according to Professor Thaer, produces a less white flour.

Thacr, produces a less white flour.

5042. In ascertaining the proper state, Brown observes, it is necessary to discriminate betwixt the ripeness of the straw, and the ripeness of the grain; for, in some seasons, the straw dries upwards; under which circumstance, a field, to the eye, may appear to be completely if for the sickle, when, in reality, the grain is imperfectly consolidated, and perhaps not much removed from a milky state. Though it is obvious that, under such circumstances, no further benefit can be conveyed from the root, and that nourishment is withheld the moment that the roots die; yet it does not follow, that grain so circumstanced should be immediately cut: because, after that operation is performed, it is in a great measure necessarily deprived of every benefit from the sun and air, both of which have greater influence in bringing it to maturity, so long as it remains on foot, than when cut down, whether laid on the ground or bound up in sheaves. The state of the weather at the time also deserves notice; for, in moist, or even variable weather, every kind of grain, when cut prematurely, is more exposed to damage than when completely ripened. All these things will be studied by the skilful husbandman, who will also take into consideration the dangers which may follow, were he to permit his wheat crop to remain neut till completely ripened. The danger from wind will not be lost sight of, especially if the season of the equinox hypocaches; even the quantity dropped in the field, and in the stack-yard, when wheat cut before it is fully ripe, as less damage will be sustained from acting in this way than by adopting a contrary practice.

5043. The mode of reaping wheat is almost universally by the sickle. When cut, it is usually tied up in sheaves, which it is better to make so small as to be done by bands the length of the straw, than so thick as to require two lengths to be joined for bands. sheaves are set up in shocks or stooks, each containing in all twelve, or, if the straw be long, fourteen sheaves. In the latter case, two rows of six sheaves are made to stand in such a manner as to be in contact at the top, though in order to admit the circulation of air they are placed at some distance below: along this line, two sheaves more are placed as a covering, the corn end of both being towards the extremities of the line. In a few days of good weather the crop is ready for the barn or stack-yard. In the stack-yard it is built either in oblong or circular stacks, sometimes on frames supported with pillars to prevent the access of vermin, and to secure the bottom from dampness; and as soon afterwards as possible the stacks are neatly thatched. When the harvest weather is so wet as to render it difficult to prevent the stacks from heating, it has been the practice to make funnels through them, a large one in a central and perpendicular direction,

and small lateral ones to communicate with it. In the best cultivated counties the use of large barns for holding the crop is disapproved of, not only on account of the expense, but because corn keeps better, or is less exposed to damage of any kind, in a wellbuilt stack.

5044. The threshing of wheat, before machines for that purpose were introduced, was an arduous and difficult task. The expense was very considerable; whilst the severity of the labour almost exceeded the power of the strongest man, especially in unfavourable seasons, when the grain adhered pertinaciously to the ear, and could not, without difficulty, be completely loosened and removed. In such seasons, expense was the smallest consideration which influenced the husbandman; it was the quantity of grain unavoidably lost which occupied his attention; and, as it appeared difficult to find out a remedy, most people considered it as an evil which could scarcely be avoided. In short, the loss was great in almost every case, but greater with wheat than any other grain. thing of this nature, however, may be prevented, now that threshing machines are introduced, provided the feeder is careful, and proportions the quantity on the board to the strength of the impelling power. Wheat, in fact, is now the cleanest threshed grain; because the length of the straw allows it to be properly beat out before it passes the machine, which sometimes is not the case with short oats and barley. If horses are used as the impelling power, thin feeding is necessary, otherwise the animals may be injured; but where wind or water is employed, the business of threshing is executed speedily, completely, and economically. (Brown.)

completely, and economically. (Brown.)

5045. In performing the operation, one man feeds the grain in the straw into the machine, and is assisted by two half-grown lads, or young women, one of whom pitches or carries the sheaves from the bay close to the threshing-stage, while the other opens the bands of every sheaf, and lays the sheaves successively on a small table close by the feeder, who spreads them evenly on the feeding stage, that they may be drawn in successively by the fitted rollers, to undergo the operation of threshing. In the opposite end of the barn or straw-house, into which the rakes or shakers deliver the clean-threshed straw, one man forks up the straw from the floor to the straw-mow, and two lads, or young women, build and tread it down. In a threshing-machine, worked by water or wind, this is the whole expense of hand labour in the threshing part of the operation, and, as a powerful machine can easily thresh from two to three hundred bushels of grain in a working day of nine hours, the expense is exceedingly small indeed. Assuming two hundred and fifty bushels as an average of the work of these people for one day, and their wages to be nine shillings, the expense does not amount to one halfpenny for each bushel of grain. Even reducing the quantity of grain threshed to one hundred and fifty bushels, the easy work of a good machine of inferior size and power, the expense does not exceed three farthings the bushel. But the whole of this must not be charged against the threshing only, the grain being half-dressed at the same time, by passing through one winnowing-machine, which is always attached to a complete threshing-mill; and where a second can be conveniently connected with it, as is commonly the case if the mill is of considerable power, the corn comes down nearly ready for market: so that the threshing, dressing, and building of the straw, with the use of a powerful water-mill, will scarcely cost more than dressing alone when the fall is employed; after every reasonable allowance for the

pilfering, &c.

5047. The produce of wheat must of course vary, according to the soil, climate, culture, and kind grown. Professor Theor says, that in general it gives double the weight of straw that it does of grain; on elevated grounds something less; and on low grounds something more. The yield of grain in some seasons has been under twenty, while in others it is upwards of thirty bushels the acre, the soil and culture being in every respect the same. The average produce of Britain has been estimated at three, three and a half, and four quarters; and one of the largest crops ever heard of, at ten quarters, and the least at one quarter and a half. The proportion which the corn bears to the straw, in Middlesex, is eleven and a half bushels to a load of thirty-six trusses of thirty-six pounds each, or eleven and a half cwt.; no great deviation from Professor Thaer's general esti-

mate, a bushel of wheat weighing about 60 or 61 pounds.

5048. To judge of a sample of wheat, examine by the eye if the grain is perfectly fed or full, plump and bright, and if there is any adulteration proceeding from sprouted grains, smut, or the seeds of weeds; and by the smell, if there is any improper impregnation, and if it has been too much heated in the mow or upon the kiln; and finally, by the feel, to decide if the grain is sufficiently dry, as when much loaded with moisture it is improper for the uses of the miller and baker. In cases where a sample handles coarse, rough, and does not slip readily in the hand, it may be concluded not to be in a condition either for grinding or laying up for keeping. When melilot and wild chamomile abound among the wheat crop, are reaped with it, and undergo fermentation in the rick, the grain will have the flavour of these strong smelling plants. To detect this in the sample, hold the grain close in the hand, moisten it with the breath, and then smell This is the practice at Ampthill and other markets in Bedfordshire.

5049. The yield of wheat in flour is, on an average, thirteen pounds of flour to fourteen pounds of grain. In the chemical analysis of wheat, Sir Humphrey Davy found that one hundred parts of good full-grained wheat, sown in autumn, yield of starch seventyseven, and of gluten nineteen; one hundred parts of wheat, sown in spring, seventy of starch, and twenty-four of gluten. American wheats he found to contain more gluten than the British; and, in general, the wheat of warm climates to abound more in gluten and in insoluble parts, and to be of greater specific gravity, harder, and more difficult to

5050. The uses of wheat in the baking, culinary, and confectionary arts are well known. It is also used for making starch, by steeping the grain and then beating it in hempen bags. The mucilage is thus mixed with the water, produces the acetous fermentation, and the weak acid thus formed renders the mucilage white. After settling, the precipitate is repeatedly washed, and then moulded into square cakes and kiln-dried. In drying, the cakes separate into flakes, as in the starch of the shops. Starch is soluble in hot water, but not in cold; and hence, when ground down, it makes an excellent Its constituents are: carbon, 43.55; oxygen, 49.68; and hydrogen, hair powder. 6.77 = 100.

5051. The uses of wheat straw are various and well known. As fodder it is, according to Professor Thaer, the most nourishing of any; and it makes the best thatch: it is generally preferred for litter, though rye and barley straw are softer: it is used for making bee-hives, horse collars, mattresses, huts, boxes, baskets, and all kinds of what is called Dunstable work; for the cider press; and, among other things, for burning, to procure potash from the ashes. The straw of wheat from dry chalky lands is manufactured into hats for both men and women. For this purpose, the middle part of the tube, above the last joint, is taken; and, being cut into a length of eight or ten inches, is split in two. These splits are then plaited, by females and children, into various kinds of plait or ribands, from half an inch to an inch broad: these, when sewed together according to fancy or fashion, form different descriptions of ladies' bonnets, and the commoner plait and coarser straw of men's hats. The hats are whitened by being placed in the vapour Leghorn hats are made from the straw of a bearded variety of wheat, which some have confounded with rye. It is cultivated on the poorest sandy soils in the neighbourhood of the Arno, between Leghorn and Florence, expressly for this manufacture. It is of humble growth, and not above eighteen inches high; is pulled up when green, and bleached white by spreading and watering on the gravelly banks of the Arno. The straws are not split; but in other respects the manufacture into ribands is the same as at Dunstable in England and in the Orkney Islands.

5052. The Leghan manufacture of wheat straw into the well-known hats has lately been enquired into, and detailed in several publications. The variety of wheat cultivated in Tuscany for this purpose is known as the graw marxuda, or marxolan, or warely of summer wheat with long bearded ears. It is cultivated on the sandy hills on both sides of the vailey of the Arno. The seed is sown in March, very thick, and pulled when the ear is fully shot, but before the grain is formed. It is then 18 inches high, if the crop is good; it is bleached as we do flax, and afterwards tied up in bundles in the same manner, and carried home, to have the part between the ear and the first fruit in the stalk selected, that being the only part used. (Gard. Mag. vol. v. p. 70.)

5053. To obtain the whiteness so much prized, the straw is smoked with sulphur previously to being worked; the platt is also smoked; and, lastly, the hat. About Sienna the process is simply a little sulphur set on fire in the bottom of a large chest, hunches of the straw being placed on long hazel rods across, and the lid shut down. Elsewhere the articles are described as being placed in a small close room, in which a chafing dish of sulphur is placed, and set fire to. Sometimes the operation requires to be done twice before it succeeds.

in which a chafing dish of sulphur is placed, and set fire to. Sometimes the operation requires to be done twice before it succeeds.

5034. The straw for use is classed or stapled like our wool. Children or inferior hands work the coarse thick straw, while good hands work the fine only. Whether fine or coarse, it is only the part on which the spike grows that is made use of; and it is always the same plait, consisting of thirteen straws, which is worked. In the fine plait there is a very great waste of straw, as they reject all that is in the least too thick, and they cut off a considerable part of the straw when it comes near the flower-spike. Fine plait is not accounted good unless very much drawn together; for which end it is worked very wet. The bunches of straw are always put into a small jar, filled with cold water, which stands beside the worker. After being smoked and pressed, the plait is made up into hats by women, who do nothing else; it is not put together by edges, nor overlapped. On the operation of pressing, a great deal depends: there are only two good machines for that purpose in the country. Such is the practice for procuring the hat straw: what they sow for seed is in other ground: not one fourth of the seed is used, and the grain is allowed to come to maturity in the usual way. It is said to be a capital wheat for vermicelli, macaronl, &c., and also for making into bread. (Gard. Mag. vol. v. p. 71.)

5055. The introduction of the grano marzuoto into Brituin has been tried, but not attended with success. Messrs. J. and A. Muir, after various trials, found the straw of rye preferable.

5056. The mode of plaiting is as follows:—The straw being picked, and put into separate bundles, according to their quality, let thirteen of them be taken and tied firmly together by the seed ends; attach them to any thing, such as the back of a chair, to keep them steady; then take hold of the loose end of the bundle, putting six straws into the one hand, and seven into the other. Take the outermost, and with i

parcel as formerly, and in place of it lay in a new straw, which is then to be used exactly as if it

were the old one.

were the old one.

5058. If by chance, in working, any of the straws should break, a thing which can scarcely happen with winle-strase to any but the outermost straw, and to it only through want of attention, it may be remedied without any more trouble than putting in a new one in its place; and though the outside of the plait with the old and new straw should exhibit the appearance of a broken loop, yet, in the knitting up of the work, it can easily be so managed that the defect shall be entirely concealed.

5059. The knitting need not be begun till as much of the plait is made as may be supposed sufficient to form a hat, as an entire hat of any desired shape may be made up of a single piece of plait. About 70 or 80 yards will be sufficient to make a lady's hat.

5060. Outside and inside of the hat. In joining in new straws during the plaiting, the ends of the new and old having been kept on the upper side of the plait, this will therefore be made the inside of the hat. After twisting and turning the plait a little, to make it form the round piece for teop, the plait will be found to lie with the one side to the other, like the teeth of two saws turned to each other; and then so to unite these two opposite sides that they may present the appearance of one piece, begin to sew by putting the needle in through the sort of stitch or loop on the outside of the plait, inserting the needle from below. Take the stitch of the opposite piece in exactly the same way, and, after four or five stitches of each side are taken on the thread, draw it up tightly, so that the stitches of both may be brought firmly the one beside the other. In this manner, in the course of the opperation, it will soon be seen that the place where the seam is can scarcely be discovered from the rest of the plait.

5061. To sew the crown of the hat so that it may be quite plain, every stitch of the one side must not be taken with every one of the other, but every second or third only of one of the sides, till the work get

on a little.

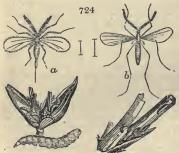

5062. The blocking of a hat may be done with any round piece of smooth stick that will fill it. After the hat is well steeped, and put on the block, it may be made quite smooth by beating it gently with a hammer, (Quar. Jour. Ag. vol. i, p. 294)

5063. The diseases of wheat are the rust, smut, or black mildew, the latter including what is vulgarly called blight. These have been already treated of in our view of the vegetable economy, and we shall merely offer a few practical observations on the smut and mildew.

5064. The proximate cause of smut, in whatever manner the smut may be transmitted from the seed pickle in the ground to the ear, it seems certain, is in general the infection of the seed by the dust of the smut-ball, which B. de Jussieu first conjectured to be Lycoperdon globosum, and which M. Prevost ascertained to be a microscopic vegetable of some sort; and that though the most careful washing, even

tained to be a microscopic vegetable of some sort; and that though the most careful washing, even with the application of caustics, may not in every case insure against smut, yet if the seed be prepared in the way already mentioned, the disease will never prevail to such a degree as to affect materially the value of the crop. This is all that cultivators need to know, and all, perhaps, in the present state of science, that can be known, of the cause and prevention of smut. See an article at length on this subject in the British Farmer's Magazine, vol. iii. p. 176. 5065. Mildew is a much more destructive distemper than smut; and, as it is probably occasioned by a peculiar state of the atmosphere during the periods of flowering and ripening, it is likely to baffle all attempts at prevention. The prevalence of heavy fogs or mist, drizzling rains, and sudden changes in the temperature, have been assigned as the causes of mildew; and as it has been found that open airy exposures are much less affected than low sheltered lands, in years when mildew prevails most generally, the disorder may perhaps be somewhat diminished by drilling, which admits a ircer circulation of air. Spring or summer wheat is less liable to mildew than the winter species, though it does not always escape. Minute parasitical F(nig. Puccinia Gráminis (Exc. of Plants), are commonly detected on the straw of Spring or summer wheat is less liable to mildew than the winter species, though it does not always escape. Minute parasitical F(mig), Puccinia Gráminis (Enc. of Plants), are commonly detected on the straw of mildewed wheat; and there cannot be the least doubt that the barberry bush, and probably several other shrubs on which these F'ingi abound, have a powerful influence in communicating the disease to a certain distance. (Sir Joseph Eankes on Midew, and Com. to the B. of Agr. vol. vii.)

5066. The wheat fly has, of late years, been one of the greatest enemies to the wheat crop in Scotland. In North America this insect, or one of the same family, has been known for many years, more especially in New England; and its alarming ravages are depicted from time to time in the newspapers, under the name of the Hessian fly. In the modern nomenclature, the Rev. W. Kirby informs us that the wheat fly, formerly the Tipula tritici Lin., is now the Cecidomyia tritici (fig. 724. a), and the Hessian fly the generally makes its appearance about the end of June; and, according to appearance about the end of June; and, according to

C. destrictor (b). The wheat fly generally makes its appearance about the end of June; and, according to the observations of Mr. Shirreff, they exist throughout a period of thirty-nine days. The hue of the fly is orange, the wings transparent, and changing colour according to the light in which they are viewed. It lays its eggs within the glumes of the florets, in clusters varying in number from two to ten, or even fifteen; and the larver feed upon the grain. "They are produced from the eggs in the course of eight or ten days: they are at first perfectly transparent, and assume a yellow colour in first perfectly transparent, and assume a yellow colour in a few days afterwards. They travel not from one floret

first perfectly transparent, and assume a yellow colour in a few days afterwards. They travel not from one floret to another, and forty-seven have been numbered in one. Occasionally there are found in the same floret larve and a grain, which is generally shrivelled, as if deprived of nourishment; and although the pollen may furnish the larve with food in the first instance, they soon crowd around the lower part of the germen, and there, in all probability, subsist on the matter destined to form the grain." (Mag. Nat. Hist. vol. ii. p. 450.) The larve are preyed on by the Céraphron destrúctor, an ichneumon fly, which deposits its eggs in the body destruction of the wheat crops attacked by the Cecidomyia. Mr. Shirreff, speaking of this ichneumon, says, "I could not determine if it actually deposits its eggs in the maggot's body; but there can be no doubt, however, of the ichneumon piercing the imaggots with a sting; and, from stinging the same maggot repeatedly, it is probable the fly delights to destroy the maggots, as well as to deposit eggs in their bodies. The carving, also, devours the maggots as food. (Brit. Farm. Mag. vol. iii. p. 493.) Mr. Gorrie estimates the loss sustained by the farming interest in the Carse of Gowrie district alone, by the wheat fly, at 20,000. in 1828, and at 36,000. in 1829. (Perth Miscellany, vol. i. p. 42.) The same writer, in May 1830, thus depicts the prospect of the wheat crop in the Carse of Gowrie:—"The Cecidomyia are still alive in formidable legions. That the flies will this season be in as great plenty as ever, is now quite certain; that in formidable legions. That the flies will this season be in as great plenty as ever, is now quite certain; that in formidable legions. That the flies will this season be in as great plenty as ever, is now quite certain; that in formidable legions. That the flies will this season be in as great plenty as ever, is now quite certain; that in formidable legions. That the flies will this season be in as great plenty as ever, is now quite certa

in the ear; or should the earing take place before the flies appear, then only the late or spring-sown wheats will suffer; but these appear slender chances. We know the history and habits of the insect too well to believe that either mist, or rain, or dew, or drought, will either forward or retard their operations, if the main body appear about the time the wheat comes in the ear. In addition to that vile gnat, our neighbours in the Lothians are threatened with a no less formidable invader in the A'scius pumilarius, which, as we are miormed on respectable authority, have already commenced their depredations, and are thiming the wheat plants rather liberally in that quarter. It, like the Hessian dy in America, attacks the under joints, which become habitations for the young larvæ. As far as our observation extends, this pest has not yet reached us in noticeable numbers." (Country Times, May 17, 1830.)

5067. The culture of summer wheat differs from that of winter or spring-sown winter wheat, in its requiring a more minutely pulverised and rather richer soil. It need not be sown sooner than April, and it advances so rapidly to maturity that it hardly affords time for hoeing (if sown in rows), or harrowing and rolling. When grass or clover seeds are sown on the same ground, they are sown immediately after the wheat, and harrowed in with a light harrow or rolled in. In this respect, and indeed in all others, the preparation of the soil and sowing of this grain are the same as for barley.

5068. The produce of summer wheat, both in grain and straw, is considerably less than that of winter wheat: the straw is only fit for litter or inferior fodder; the flour produced by the grain is rather coarser and darker than that of common wheat. Of course this

sort of wheat cannot, as already observed, be recommended for general culture.

Sect. II. Rye. — Secùle ceredle L.; Triándria Digýnia L., and Gramíneæ J. Seigle, Fr.; Rogon, Ger.; Segale, Ital.; and Centeno, Span. (fig. 725.)

725

Rye, according to some, is a native of Crete; but it is very doubtful whether any country can be now ascertained to be its native soil. It has been cultivated from time immemorial, and is considered as coming nearer in its properties to wheat than any other grain. It is more common than wheat on most parts of the continent, being a more

the bread corn of Germany and Russia. In Britain it is now very little grown, being no longer a bread corn, and therefore of less value to the farmer than barley, oats, or peas. Many consider it the

certain crop, and one which requires less culture and manure.

most impoverishing of all corn crops.

5070. The varieties of rye are not above two, known as winter and spring rye: but there is so little difference between them that spring rye sown along with winter rye can hardly be distinguished from it.

5071. The soil for rye may be inferior to that chosen for wheat: it will grow in dry sandy soils, and produce a tolerable crop; and, on the whole, it may be considered as preferring sands to clays. The preparation of the soil should be the same as for wheat. According to Professor Thaer, rye abstracts 30 parts in 100 of the nutriment contained in the soil on which it is grown.

5072. The climate for rye may be colder than for wheat; but it is rather more injured by rains during winter, and equally injured by moist weather during the flowering

season.

5073. Rye is sown either in antumn or spring, and either broad-cast or in drills: two bushels and a half is the usual allowance when it is sown broad-cast. As it vegetates more slowly than wheat, it should be sown when the soil is dry; a wet soil being apt to rot the grain before it has completely germinated. No pickling or other preparation is

given.

5074. The after culture, harvesting, and threshing are the same as for wheat; and the produce in grain is, under similar circumstances, equal in bulk; but in straw it is greater in rye than in any other grain. Sir H. Davy found, in 1000 parts of rye, 61 parts of starch and five parts of gluten. Professor Thaer says rye is the most nourishing grain next to wheat. It contains an aromatic substance, which appears to adhere more particularly to the husk, since the agreeable taste and smell peculiar to rye bread are not found in that which is made from rye flour that has passed through a very fine bolting-cloth; while the fragrance may be restored by a decoction of rye bran in the warm water used to make the dough. This substance, Thaer says, seems to facilitate digestion, and has an action particularly refreshing and fortifying on the animal frame.

5075. The use of rye is chiefly for bread, especially for gingerbread. It is also used in the distilleries; and the straw is used for the same purposes as that of wheat, except that it is useless as fodder. Some prefer it for thatching and litter, and also for collar-making: it is also employed in Dunstable work. Tanners are said to use it in some

districts.

5076. Rye is sometimes sown as a green crop, with a view of affording some keep for sheep early in the spring, and also for being ploughed in as manure; but that husbandry

must be bad or unfortunate which requires recourse to either mode. In some districts it is customary to sow the head lands of wheat fields with rye, which is said to keep poultry from penetrating to the wheat.

poultry from penetrating to the wheat.

5077. The manufacture of rye straw into plait for hats is a new application, for which the public are indebted to Messrs. J. and A. Muir of Greenock, manufacturers of straw hats in imitation of those of Leghorn. Messrs. Muir had previously tried rye grass, crested dog's-tail grass, sweet-scented vernal grass, and the straw of wheat, raised both from British and foreign seed, without success. At last the idea of employing rye straw was suggested to them; and they now send annually to their establishment in the Orkney Islands (founded by an English gentleman about 1820) "from 40 to 45 bolls, which are sown on about twelve English acres of sandy soil, manured with sea-weed. Several acres of heath for bleaching the straw, and water for steeping it, are required in the neighbourhood of the rye fields. The rye is cut when the seed is beginning to form; and it is necessary to attend to the precise time, for ten days too early or too late produce a considerable difference in the look of the straw. When the rye is cut, women are employed to tie it at the lower extremity in handfuls; it is then put into boxes, and covered with boiling water, in which it remains for half an hour. After this it is spread out upon the heath in a fan form, and turned twice daily, until the bleaching, which takes about ten days, is completed. If exposed to much rain while bleaching, the straw is injured in colour, and rendered very liable to take mildew. It is of great importance to have the crop well housed."—"The seed of the rye is sown in April, in mossy ground, recently rendered arable; and if the season is at all favourable, it comes into flower in July, when it is cut down. The whole stem is then immersed in boiling water, in a trough made for the purpose, and remains in this state for two hours. When taken out, it is spread upon a grass field, and exposed to the sun, till it is properly bleached, which requires from two to four days, according to the weather. When bleached, the stalk is divided i

5078. Rye is less subject to disease than most other grain, and is even sown among wheat and round wheat fields from an idea that it will keep off blight and mildew as well as poultry.

boultry.

5079. The spur or ergot of rye is by some considered as a fungus, a species of Sclerdtium, somewhat analogous to that which produces the smut. It is not peculiar to rye, but it is very seldom found on any other gramineous plant. "It is a production of the seeds; is long, horny, and cartilaginous; and is sometimes straight, at others curved; sometimes it is found more than two inches in leugth. The resemblance of this substance to cocks' spurs has given it the name by which it is distinguished. On breaking a spurred seed, you find within it a substance of a dull white colour adhering to the violet skin that surrounds it. Rye thus attacked cannot germinate. M. Tessier remarked that the most rainy years were the most productive of this disease; that the soils on which most spurred rye grew were most moist; that high grounds were nearly free from them, unless when the furrows prevented he water from running freely off, while the lower parts of the same field produced more than the upper parts." (Brit. Farm. Mag. vol. iii. p. 502.) In France a disease, called the chronic or dry gangrene, has been produced by eating ergot. This disease is also known in Switzerland, where it was observed that most animals refused to eat diseased rye, or rye affected with the cockspur, as it is called. The Royal Society of Medicine at Paris employed M. Tessier, a distinguished agricultural writer and man of science, to go into the countries where the dry gangrene prevailed, and collect a sufficient quantity of the ergot or cockspur rye for experiments. The result confirmed the opinion of those who attributed the disease to the cause assigned. "France afforded, also, a simple explanation of the fact that persons might live for a considerable time upon rye affected with the cockspur, without suffering any sensible injury from its use; since, in all the summals upon which it was tried experimentally, a given quantity was required to produce the specific effect; and they suggested the only measure, that of separating the diseased

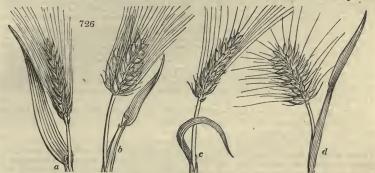

Sect. III. Barley. — Hórdeum L.; Triándria Digýnia L., and Gramíneæ J. L'Orge, Fr.; Gerste, Ger.; Orzo, Ital.; Byg, Dan. and Swed.; and Cebada, Span.

5080. Barley, though less calculated for a bread corn than rye, may be considered as next in value to wheat in Britain. Of what country it is a native is unknown. Some assign it to Tartary, others to Siberia, and even Scotland has been mentioned. It has been cultivated from the earliest antiquity, and was much in use among the Romans, both as food for soldiers and horses. In Sweden and Lapland it is more cultivated than any other grain, on account of its requiring to be so short a period in the soil; sometimes not longer than six weeks, and seldom more than seven or seven and a half. In Spain and Sicily they have two crops a year on the same soil: one is sown in autumn and ripens in May, and the other is sown in May and reaped in autumn. In Britain barley is a tender grain, and easily hurt in any of the stages of its growth, particularly at seed time: a heavy shower of rain will then almost ruin a crop on the best prepared land; and in all the after processes greater pains and attention are required to insure success than in the case of other grains. The harvest process is difficult, and often attended with danger; even the threshing of it is not easily executed with machines, because the corn generally adheres to the grain, and renders separation from the straw a troublesome task.

5081. Species and varieties. (fig. 726.) There are six species and subspecies of his grain in cultivation besides varieties. These are, this grain in cultivation besides varieties.

 Hórdeum vulgàre, Spring barley (a).
 cœléste, Siberian barley.
 hexástichon, Winter barley (b). Hórdeum dístichon, Common or long-eared barley (c).
 dístichon nùdum, Naked barley.
 Zeocriton, Sprat or battledore (d).

The second and fifth sorts are allowed to be subspecies or varieties of the first and fourth, and indeed there can be little doubt that the whole do not constitute more than one species.

5082. The spring barley or early barley (a), Orge carrée, Sucrion de printemps, Fr., is distinguished by its double row of beards or awns standing erect, and its thin husk, which renders it favourable for maltime. This is the sort principally cultivated in the southern and eastern districts of both England and Scotland, Inis is the sort principally cultivated in the southern and eastern districts of both England and Scotland, and of which the farmers make two sorts, viz. the common, and the rath-ripe bare; but these two sorts are in reality the same; for the rath-ripe is only an alteration of the common obarley, occasioned by being long cultivated upon warm gravelly soils. The seed of this, when sown on cold or strong land, will, the first year, ripen near a fortnight earlier than the seed taken from strong land, and therefore the farmers in the vales generally purchase their seed-barley from the warm or gravelly land; for, when preserved in the vales two or three years, it becomes full as late in ripening as the common barley of their own product: on the other hand, the farmers on warm lands are also obliged to procure their seed-barley from the strong lands, otherwise their grain would degenerate in bulk or fulness, which by this change is prevented.

vented.

5083. The Siberian barley, Orge celeste, Fr., and Himmel gerste, Ger., is a variety of early barley with broader leaves, and reckoned more productive than the other. It is much grown in the north of Europe, and was introduced to this country in 1768, but is believed to be now lost or merged in the parent species. 5084. Winter barley, late barley, or square barley (b), Orge carrée d'hiner, Escourgeon, Fr., has the grains disposed in four or in six rows, large and thick skinned. It is chiefly cultivated in the north of England and in Scotland, on account of its hardiness; but from the thickness of its rind it is ill adapted for malting, and is some out of use. and is going out of use

5085. Bigg, bug, or barley big, is a variety of winter barley known by always having six rows of grains by the grains being smaller and the rind thicker, and by its being earlier than the parent variety. Prolessor Martyn says, he has frequently counted forty-two grains on one ear of bigg, when common or long-

fessor Martyn says, he has frequently counted forty-two grains on one ear of bigg, when common or long-eared barley had only twenty-two.

5086. Common or long-eared barley (c), is known by its very long spike or ear, flatted transversely, greater in breadth than thickness, with chaff ending in an awn sixteen times the length of the grain. This sort is cultivated in many parts of England and Scotland; though some object to it because the ears being long and heavy they think it apt to lodge.

5087. Naked barley, or wheat barley, Orge nue à deux rangs, Fr., is known by the grain separating easily from the chaff, and is by some considered as nothing else than spelt wheat, which it greatly resembles. It does not appear to be cultivated at present in any part of Britain.

5088. Sprat, or battledore barley (d), Orge eventail, Orge-riz, Fr., is known by its low stature, coarse straw, short broad ears, and long awns. The long awns and closeness of the ears protect it better from birds than most other sorts, but as the straw is scanty and of little use it is not much cultivated.

5089. Besides these sorts there are some local varieties, as Thanet barley, Putney barley, &c. which are merely names given to the varieties common in those places. The Thanet is the winter, and the Putney the sprat barley.

the sprat barley.

5090. New varieties may be procured by selection or crossing, as in the case of wheat. (5009.)

5091. In choosing a sort of barley for cultivation, regard must be had to the soil and The hardiest may be considered the winter barley, and the earliest, and perhaps the best, is the spring barley. The long-eared is also a much esteemed variety.

5092. In choosing from any particular variety, the best grain for sowing is that which is free from blackness at the tail, and is of a pale lively yellow colour, intermixed with a bright whitish cast; and if the rind be a little shrivelled, it is so much the better, as it shows that it has sweated in the mow, and is a sure indication that its coat is thin. The husk of thick-rinded barley being too stiff to shrink, will lie smooth and hollow, even when the flour has shrunk from it within. The necessity of a change of seed from time to time, by sowing that of the growth of a different soil, as it has been observed, is in no instance more evident than in the culture of this grain, which otherwise becomes coarser and coarser every year. But in this, as well in all other grain, the utmost care should be taken that the seed is full bodied.

5093. The best soil for barley is a light rich loam, finely pulverised. It will neither grow well on a sandy or soft soil, nor on strong clays, such as are suitable for wheat.

5094. The preparation of the soil is sometimes by a naked fallow, but generally by a turnip fallow; sometimes it is taken after peas and beans, but rarely by good farmers either after wheat or oats, unless under special circumstances.

5095. When sown after turnips it is generally taken with one furrow, which is given as fast as the turnips are consumed, the ground thus receiving much benefit from spring frosts. But often two or more furrows are necessary for the fields last consumed; because, when a spring drought sets in, the surface, from being poached by the removal or consumption of the crop, gets so hardened as to render a greater quantity of ploughing, harrowing, and rolling necessary than would otherwise be called for. When sown after beans and peas, one winter and one spring ploughing are usually bestowed; but, when after wheat or oats, three ploughings are necessary, so that the ground may be put in proper condition. These operations are very ticklish in a wet and backward season, and rarely in that case is the grower paid for the expense of his labour. Where land is in such a situation as to require three ploughings before it can be seeded with barley, it is better to summer fallow it at once, than to run the risks which seldom fail to accompany a quantity of spring labour. If the weather be dry, moisture is lost during the different processes, and an imperfect germination necessarily follows: if it be wet, the benefit of ploughing lost, and all the evils of a wet seed-time are sustained by the future crop. (Grown.)

5096. To whatever crop barley succeeds, the harrow and roller, when the plough alone is insufficient, should be employed in reducing the soil to a considerable degree of fineness. In most cases more than one earth is given; though, after a winter furrow, the grubber may be used in spring instead of the plough. After turnips, eaten on the ground by sheep, the land, being consolidated by their treading, sometimes receives two ploughings; but, if only one, it should be well harrowed and rolled; and it is often finished by harrowing after the roller, especially if grass-seeds be sown, which are covered by this last barrowing. Barley is sometimes sown on the first ploughing, and covered by a second shallow ploughing. As it

5097. Manure can seldom be given with advantage to a crop that occupies the soil so short a period as barley, and therefore it generally is sown on land which has been enriched for a preceding crop.

5098. The climate in which barley delights is warm and dry. There are instances of a crop being sown and ripened without having enjoyed a single shower of rain; but gentle showers from the time it is sown till it begins to shoot into the ear, are favourable; while heavy rains at any period, and especially immediately after sowing, or during the

blossoming, ripening, and reaping seasons, are highly injurious.

5099. The best season for sowing barley is considered to be from the beginning of April to the middle of May; but bigg may be sown either in autumn to stand the winter, or as late as the first week of June. In England, the winter or four-rowed barley is frequently sown in autumn, and stands the most severe winters. With respect to the lateness at which bigg and summer barley may be sown, much depends on the sort of weather which occurs during the first three weeks after sowing.

5100. When barley is sown late it is sometimes steeped in common water to promote its germination; but 5100. When barley is sown late it is sometimes steeped in common water to promote its germination; but it is seldom pickled or otherwise prepared. The advantages of steeping are, procuring an equal germination, and consequently ripening, and getting the start of weeds. The following directions are given for performing the operation:— First, take out about one-third of the contents of the sacks of seed barley or bear to allow for the swelling of the grain; lay the sacks with the grain to steep in clean water; let it be covered with it for at least twenty-four hours; when the ground is very dry, and no likelihood of rain for two or three days, it is better to lie thirty-six hours. Sow the grain wet from steeping without any addition. The seed will scatter well as clean water has no tenacity; only the sower must put in a fourth or a third more seed in bulk than is usual of dry grain, as the grain is swelled in that proportion. Harrow it in as quickly as possible after it is sown; and, though not necessary, give it the benefit of a fresh furrow if convenient. You may expect it up in a fortnight at farthest. (Brown.)

5101. The quantity of seed is different in different cases, according to the quality of the soil and other circumstances. Upon very rich lands, eight pecks per acre are sometimes sown; twelve is very common; and upon poor land, more is sometimes given.

5102. Whether the practice of giving so small a quantity of seed to the best lands is advantageous or the reverse, seems a disputed point among the best farmers. That there is a saving of grain there can be no doubt; and that the bulk may be as great as if more seed had been sown, there can be as little question. Little argument, however, is necessary to prove that thin sowing of barley must be attended with considerable disadvantage; for if the early part of the season be dry, the plants will not only be stinted in their growth, but will not send out offsets; and if rain afterwards fall, an occurrence that must take place some time during the summer, often at a later period of it, the plants begin to stool, and send out a number of young shoots. These young shoots, unless under very favourable circumstances, cannot be expected to arrive at maturity; or if their ripening be waited for, there will be a great risk of losing the early part of the crop, a circumstance that frequently happens. In almost every instance an unequal sample is produced, and the grain is for the most part of an inferior quality. By good judges, it is thought preferable to sow a quantity of seed sufficient to ensure a full crop, without depending on its sending out offsets; indeed, where that is done, few offsets are produced, the crop grows and ripens equally, and the grain is unifornly good. (Brown on Rural Ajjūirs.)

5103. The modes of sowing barley are either broad-cast, or in rows by the drill or The broad-cast mode is almost universally adopted; unless in lands much infested with annual weeds, where drilling and hand-hoeing, and in particular cases

horse-hoeing, may be employed with advantage.

5104. The only culture which barley requires while in a growing state, is hoeing and weeding if in rows, and weeding alone if broad-cast. Sometimes barley is rolled to compress a soft soil and exclude the drought, and when very thick it may be first harrowed Grass seeds and clover are sown with the grain before the last harrowing, when the broad-cast mode is adopted; and immediately before hoeing, when the barley is in rows. The former is much the best mode for insuring a strong plant of clover.

5105. Eating down barley, which from winter or very early sowing is over-luxuriant, is practised in some districts, but it is alleged that mowing is much better than feeding it; because the scythe takes off only the rank tops, but the sheep feed upon all indifferently; nor should they even, in any case, be left

upon it too long, because, being particularly fond of the sweet end of the stalk next the root, they bite so close as to injure the future growth of the plant.

5106. Barley is ripe when the red roan, as the farmers term it, meaning a reddish colour on the ear, is gone off; or when the cars droop, and fall, as it were, double against the straw, and the stalks have lost their verdure; but in the latter case it is too ripe.

5107. In the harvesting of barley more care is requisite than in taking any of the other white crops, even in the best of seasons; and in bad years it is often found very difficult to save it. Owing to the brittleness of the straw, after it has reached a certain period it must be cut down; as, when it is suffered to stand longer, much loss is sustained by the breaking of the heads. On that account it is cut at a time when the grain is soft, and the straw retains a great proportion of its natural juices, consequently requires a long time in the field before either the grain is hardened or the straw sufficiently dry. put into the stack sooner it is apt to heat, and much loss is frequently sustained.

5108. Barley is generally cut down in England with the cradle scythe, and either tied up or carted home loose after lying in the swath some days to dry It is not apt to shed; but in wet weather it will be likely to spout or grow musty; and therefore every fair day after rain it should be shaken up and turned: and when it is tolerably dry, let it be made up into shocks; but be careful never to house it till thoroughly dry, lest it mow-burn, which will make it malt worse than if it had spired in the field. It is remarked by Lisle, that poor thin barley should be cut a little sooner than if the same plants were strong and vigorous; as the straw, when the plants are full ripe, in such cases will not stand against the scythe. In this situation, barley in particular should lie in swath till it is thoroughly dry. Some of his barley, which lay out in swath five or six days in very fine weather, though both blighted and edge-grown, grew plump, and acquired very near as good a colour as the best. He reckons short scythes the best for mowing lodged or crumpled corn, because they miss the fewest plants; and observes, that a bow upon the scythe, which carries away the swath before it, is preferable to a cradle, the fingers of which would be pulled to pieces by the entangled corn, in drawing back the scythe. In Scotland and Ireland it is generally reaped with the sickle, bound in sheaves, and set up in shocks.

5109. In stacking barley many farmers make an opening in the stack from top to bottom. This opening is generally made by placing a large bundle of straw in the centre of the stack, when the building commences, and in proportion as it rises the straw is drawn upwards, leaving a hollow behind; which, if one or two openings are left in the side of the stack near the bottom, insures so complete a circulation of air, as not only to

prevent heating, but to preserve the grain from becoming musty.

5110. The threshing and dressing of barley require more labour than those of any other grain, on account of the difficulty of separating the awns from the ears. For this purpose some threshing machines are furnished with what is called a hummelling machine, already described (2799.): and where this is wanting, it is customary to put the grain, accompanied with a portion of threshed straw, a second time through the machine. Where barley has been mown, the whole of the straw requires to be twice threshed, independently of the necessity of getting rid of the awns.

5111. The produce of barley, taking the average of England and the south of Scotland, Donaldson considers, might be rated at thirty-two bushels; but when Wales and the north of Scotland are included, where, owing to the imperfect modes of culture still practised, the crops are very indifferent, the general average over the whole will not probably exceed twenty-eight bushels the acre. Middleton states it as varying in England from fifteen to seventy-five bushels per acre. The average produce of the county of Middle-

sex, he says, is about four quarters of corn and two loads of straw per acre.

5112. The uses of barley are various. In Wales, Westmorland, Cumberland, and in the north, as well as in several parts of the west of Scotland, the bread used by the great body of the inhabitants is made chiefly from barley. Large quantities of the barley cultivated in England are converted into beer, ale, porter, and what is called British spirits, as English gin, English brandy, &c. The remainder, beyond what is necessary for seed, is made into meal, and partly consumed in bread by the inhabitants of the above-mentioned districts, and partly employed for the purpose of fattening black cattle, hogs, and poultry. There is a much greater share of the Scotch barley consumed in distillation, in proportion to the quantity cultivated, than of the English. Exclusive of what is used for seed, the Scotch barley is either converted into beer or ale; or made into potbarley, or into meal, for the use of the inhabitants in the more remote and less cultivated parts of the kingdom; or, lastly, into whisky. In The Report of Middlesex it is stated, that much of the most ordinary barley is given to poultry: the rest is sold to the maltsters, except so much as is reserved for seed.

5113. But malt is the great purpose to which barley is applied in Britain. To understand the process of malting, it may be necessary to observe that the cotyledons of a seed, before a young plant is produced, are changed by the heat and moisture of the earth into sugar and mucilage. Malting grain is only an artificial mode of effecting this by steeping the grain in water and fermenting it in heaps, and the arresting of its progress towards forming a plant by kiln drying, in order to take advantage of the sugar in distillation for spirit or fermentation for beer. The grain of barley contains starch and sugar; and the chemical constituents of both these ingredients are very nearly alike. In the process of malting, a portion of the starch is converted into sugar, so that the total quantity of sugar, and consequently the source of spirit, is increased by the transformation. by the transformation.

5114. To choose a proper sample of barley for malting, observe the directions given for choosing seed

5115. Of pot-barley there are two sorts, pearl and Scotch; both are produced by grinding off the husk, and the pearl barley is produced by carrying the operation so far as to produce roundness in the kernel. It is used in soups, gruels, and medicinal drinks, 5116. Barley meal is ground like oatmeal or flour; the coarser sort, with the bran, is used for fattening live stock, especially pigs and poultry; but fine bolted barley flour, made into a thin pottage or pudding, and spread out in thick cakes, and toasted on a hot plate of metal, forms a light breakfast bread, much esteemed in some parts of Scotland. It is served in a recent state, hot, and spread with butter and honey, and eaten in several folds. Two parts of barley flour, one of wheat flour, and one of rye, are said to make a light and very agreeable loaf of bread.

5117. The produce of barley in flour is 12lbs. to 14lbs. of grain. Sir H. Davy found 1000 parts of barley meal to afford 920 parts of soluble or nutritious matter; viz. 790 of mucilage or starch, 70 of sugar, and 60 of gluten.

5118. Barley straw is chiefly used for litter and packing; it is unfit for thatch or rope-

making, and of little value as fodder.

5119. The diseases of barley are few, and chiefly smut, but of quite a different species from that which affects the wheat, and one which it is found cannot be prevented by pickling and liming.

The Oat. — Avèna sativa L.; Triándria Digýnia L., and Gramíneæ J. L'Avoine, Fr.; Haber, Ger.; Vena, Ital.; and Avena, Span.

5120. The oat is a very useful grain, and more peculiarly adapted for northern climates than either wheat, rye, or barley. Its native country is unknown, unless the wild oat be considered as the parent species, which is highly probable. The culture of the oat in France is chiefly confined to latitudes north of Paris. It is scarcely known in the south of France, Spain, or Italy; and in tropical countries its culture is not attended to. Britain it has long been very generally cultivated, formerly as a bread corn, but now chiefly as horse-food. Of all the grain this is the easiest of culture, growing in any soil that admits of ploughing and harrowing.

5121. The varieties of oats are more numerous than those of the other grains, and some of them are very distinctly marked. The principal are as follows: -

727

5122. The white oat or common oat (fig. 727. a), Avoine blanche, Fr., in most general cultivation both in England and Scotland, and known by its white husk and kernel.

5123. The black oat, Avoine à grappe noir, Fr., known by its black husk; cultivated on poor soils, in the north of

England and Scotland. Enigiand and Scotland.

5124. The red oat, known by its brownish red husk, thinner and more flexible stem, and firmly attached grains. It is early, suffers little from winds, meals well, and suits windy situations and late climates. It is understood to have originated in Peebleshire, on the estate of Magbie-bill, by which name it is sometimes known.

which name it is sometimes known.

5125. The Poland odt, known by its thick white husk, awnless chaff, solitary grains, short white kernel, and short stiff straw. It requires a dry warm soil, but is very prollife, The black Poland oat is one of the best varieties; it sometimes weighs 50lbs. per bushel. It is, however, very liable to be shed by the wind after it begins to ripen; it requires a fine dry tilth.

5196. The Friezland or Dutch oat, has plump, thin-skinned, white grains, mostly double, and the large one sometimes awned. It has longer straw than the Poland, but in other respects resembles it.

respects resembles it.

5127. The potato oat has large, plump, rather thick-skinned, white grains, double and treble, with longer straw than either of the last two sorts. It is almost the only oat now raised on land in a good state of cultivation in the north of England and south of Scotland, and usually brings

a higher price in the London market than any other variety. It was discovered growing in a field of potatoes in Cumberland, in 1788; and from the produce of the single stalk which there sprung up by accident, probably from the manure, has been produced the stock now in general cultivation. 5128. The Georgian ont, is a large, grained, remarkably prolific variety introduced from Georgia, by R. Barclay, Esq. of Bury Hill, to Britain and the north of Europe. On rich soil in good tilth, Mr. Barclay finds it yield more grain per acre than the potato oat or any variety whatever.

5129. The Siberian or Tatarian oat (b), is considered by some as a distinct species. The grains are black or brown, thin and small, and turned mostly to one side of the paniele; and the straw is coarse and reedy. It is little cultivated in England, but found very suitable for the poor soils and exposed situations on the sides of the Dublin and Wicklow hills.

on the sides of the Dubin and Wicklow fills.

5130. A variety called the winter out, Avoine d'hiver, Fr., has lately come into notice in some parts of England, but we have not been able to ascertain its origin. Mr. Bennett of Chaxhill, near Gloucester, sows two bushels per acre in October; finds the plants very luxuriant at Christmas, tillering like wheat: he depastures them with ewes and lambs all the spring, and then shuts them up, and reaps an ample crop early in August. The grain is rather longer than that of the white oat, and the colour rather lighter than that of the black oat; Mr. Bennett received the seed from a friend in Momouthshire, who he conjectures received it from Bristol, so that it is probably a recent importation. (Country Times, Feb. 8th, and Cor.

with Mr. Bennett.)
5131. There are other varieties, as Church's oat, the Angus oat, the dun oat, &c., but they are either too local or obsolete to require particular notice. In the oat, as in other plants extensively cultivated, new varieties will always be taking the place of old ones.

5132. To procure new varieties adopt the mode by selection, by which, as it appears above, the potato and red oat were brought forward; or proceed systematically by cross impregnation, as directed for raising new varieties of wheat. Degeneracy, Brown

observes, has taken place to a certain extent in the potato oat; but it is presumed that the consequences might be removed with ease, were first principles returned to. To make a selection of the strongest ears, which carried the purest grain, is not a difficult business; and were this selection attended to by half a dozen farmers in a district, it is obvious, that the breed, or variety, might be preserved pure and uncontaminated. If slovenly farmers were not provided with good seed, it would be their own fault; since, if they would not take the trouble to select and breed for their own use, they might always be provided by those who were either better qualified for making the selection, or were more attentive to the interests of agriculture. (Brown.) Some of the Northumberland farmers have been at the pains to select the grains, instead of the ears, after being threshed. The best seeds are picked out by hand by women.

5133. In choosing a sort from among the varieties described, the potato and Poland are the best for lowlands, and the red oat for uplands and late climates in a state of good cultivation. For inferior soils the white or common oat, and for the poorest of all

the black oat, may be adopted.

5134. The soil for oats may be any kind whatever, from the stiffest clays to moss or bog, provided it be laid sufficiently dry. The most tenacious clays, and meagre gravels and sands, where scarcely any useful seed-bearing plant, except buck-wheat, could be grown, will produce a crop of oats if ploughed at a proper season, and the seed judi-

ciously sown and covered.

5135. The preparation of the soil for oats is less than for any other grain. It is almost always the first crop on newly broke-up lands; and as it prospers best on a soil not too finely pulverised, it is commonly sown on one earth. In regular rotations, oats are chiefly sown after grass; sometimes upon land not rich enough for wheat, that had been previously summer-fallowed, or had carried turnips; after barley, and rarely after wheat, unless cross-cropping, from particular circumstances, becomes a necessary evil. One ploughing is generally given to the grass-lands, usually in the month of January, so that the benefit of frost may be gained, and the land sufficiently mellowed for receiving the harrow. In some cases a spring furrow is given when oats succeed wheat or barley, especially when grass-seeds are to accompany the crop. The best oats, both in quantity and quality, are always those which succeed grass; indeed, no kind of grain seems better qualified by nature for foraging upon grass-land than oats; as a full crop is usually obtained in the first instance, and the land left in good order for succeeding ones. (Tr. on Rural Affairs.)

5136. The climate for oats should be cool and moist; when dry and warm, the panicles are so dried and contracted that they cease to convey sufficient nourishment to the ears, which thus never become plump, but thick husked, long awned, and unproductive in meal. This is very often the case with the oats in Scotland in a very dry year, and very

common in the south of England in most years.

5137. The season of sowing oats is from the last week in February to the end of April. About the middle of March is preferred by the best farmers. No preparation is ever given to the seed; but it should be plump, fresh, and free from the seeds of weeds. Common oats sown in autumn are generally killed during winter, the plant being in this respect more tender than wheat, rye, or barley bigg. In some parts of Ireland, and especially in the county of Dublin, the Friezland oat is sown in autumn; and the advantage is they ripen nearly a month sooner than those sown in spring, an important object in a moist climate.

5138. The quantity of seed, where oats are sown broad-cast, is usually from four to six bushels to the acre. Land sown with potato oats requires less seed, in point of measure, than when any of the other sorts is used: first, because this variety tillers better than any other; and next, because having no awn, a greater number of grains are contained in a

bushel.

5139. The mode of sowing oats is almost universally broad-cast; but where they are sown after turnips, or on other well pulverised soils, some adopt the row culture.

5140. The after-culture depends on the mode of sowing, but seldom consists of more

than weeding before the flower-stalks begin to shoot up.

5141. In harvesting oats in England, they are generally cut down with the scythe, and carried loose to the barn or stack; but in the northern districts, and where threshing machines are used, whether mown, or, what is most usual, reaped with the sickle, they are tied in sheaves to facilitate the process of threshing. Oats are ready for the scythe or sickle when the grain becomes hard, and the straw yellowish. They should generally be cut before they are dead ripe, to prevent the shedding of the grain, and to increase the value of the straw as fodder. They rarely get much damage when under the harvest process, except from high winds, or from shedding, when opened out after being thoroughly wetted. The early varieties are much more liable to these losses than the late ones; because the grain parts more easily from the straw,—an evil to which the best of grain is at all times subject. Early oats, however, may be cut a little before

dead ripe, which, to a certain extent, lessens the danger to which they are exposed from high winds; and if the sheaves are made small, the danger from shedding after rains is considerably lessened, because they are thus sooner ready for the stack. Under every management, however, a greater quantity of early oats will be lost during the harvest process than of the late ones; because the latter adhere firmly to the straw, and consequently do not drop so easily as the former. (Brown.) In harvesting oats in wet seasons, the practice of gaiting the sheaves (3176.) is generally adopted. In Sweden, in most seasons, the oat crop is dried on frames or poles (704.); and in Russia, not only oats, but barley and rye, are kiln-dried in the straw.

5142. Kiln-drying oats and other corns in the straw has been found necessary, and is very generally practised through the north of Russia, Livonia, Courland, and Lithuania, being the last operation of harvest for preserving all kinds of corns, peas, beans, and buck-wheat. They are dried in the fields as much as can be; but, when brought home, they are kiln-dried, and are then ready to be either threshed out immediately, or put up in barns, without any danger of either corn or straw becoming musty or rotting. The common practice of the boors is, during winter, to thresh out by degrees, as in this country, their oats and barley, in order to have straw fresh for their cattle, such straw being their only provender. The process of kiln-drying by no means prevents the germination of the grain when used for seed, while it not only preserves the grain and straw but improves their taste and salubrity. It enables Russia to export large quantities of rye and wheat, with less risk of damage to the grain than is incurred by other nations of the north of Europe.

5143. The kiln (fig. 728.) in general and established use throughout Rus-

and the corn or grain ends up: the walls then rise above the ribs about five or six feet more, the kiln being closed by a simple ceiling of cross joists at this height, covered with thin turf. Any cheap and ordinary reof answers to cover the whole. The fire-place is constructed so as to throw back the ascending spark; a small porch (c), directly opposite to the fire-place losed. At one end of the kiln there is put on in the evening, and left on the kiln through the night, after the wood has been burned into charcal, and the door above the fire-place closed. At one end of the kiln there is frequently an open shed or barn (d), for convenience in bringing corn to, or taking it from, the kiln.

5144. The produce of oats is generally considered greater and of better quality in the northern than in the southern counties; and the reasons are obviously that, in the former, more attention is paid to their culture, and the climate is more favourable for the maturation of the grain. Ten quarters an acre is reckoned a good crop in the north, but the produce is often twelve and thirteen quarters, and the straw from two to three and a half loads per acre.

5145. The produce of oats in meal amounts to 8 lbs. for 14 lbs. of corn. Sir H. Davy found 100 parts of oats afford 59 parts of starch, six of gluten, and two of saccharine matter.

5146. The use of oats in the north, in Ireland, and in some parts of Yorkshire and Derbyshire, is partly for meal and partly for horse-food. In the south it is almost entirely for horse-food, poultry, and groats for gruel. It is occasionally malted and used The fine powder which is produced by husking the corn, or making grist, forms the sowens of the Scotch (the flummery of the Irish), an agreeable light and wholesome supper dish.

5147. The diseases of the oat are few. Sometimes it is found attacked by the smut; but the more common injury sustained by oats is from wire worms, or larvæ of insects which generally abound in lands newly broken-up from turf. One of the most certain modes of avoiding these is, by not ploughing the ground, especially if old turf, till immediately before sowing. By this means the insect is turned down, and before it can work its way to the surface (if ever it does) the corn is beyond its reach. gardeners destroy and retard the progress of the gooseberry caterpillar by digging under the bushes; for it is found that the eggs and larvæ of insects, like seeds and bulbs, when buried too deep in the ground, have their progress retarded, or their vital principle In late harvests, more especially in the northern parts of the island, the oat is liable to be frosted and rendered unfit for seed before being harvested. There is no remedy for such an accident; but we have shown (4997.) how it may be detected, so as not to disappoint the sower of such grain. (Encyc. of Gard. 4663.)

Sect. V. Cereal Grasses cultivated in Europe, some of which might be tried in Britain.

5148. The cereal grasses which the climate of Britain does not readily admit of cultivating, are the maize, Canary corn, millet, and rice.

Subsect. 1. Maize, or Indian Corn. - Zèa Màys L.; Monæcia Triándria L., and Gramineæ J. Le Mais, or Blé de Turquie, Fr.; der Mays, Germ.; Gran turco, Ital.; and Maiz, Span.

5149. The maize is the noblest looking of the cereal grasses. It is considered to be a native of South America, to have been cultivated in Mexico and Peru from time immemorial, to have been introduced to Europe about the beginning of the 16th century, and to England in 1562. It is at present cultivated in almost every part of the universe where the summer temperature equals or exceeds that common to latitude 45°, and even to 48°. In France, in Arthur Young's time (1787), the principal country of the maize was to the south of a line drawn from Bordeaux to Strasbourg, in lat. 48° 35'; but it is at present cultivated as far north as Nancy, which is in latitude 49°, — a fact which shows that this grain is taking a wider range of temperature. "It flourishes on the western continent from about the 40th degree of southern to higher than the 45th degree of northern latitude. It is extensively produced in Africa and in Asia; on all the shores of the Mediterranean, in Spain, Italy, part of France, and the countries of the Levant, it is the food in most common use. Of the cultivated Cereàlia, indeed, it is that which, next to the rice, supplies food to the greatest number of the human race; and it may be held to be the most valuable gift of the new world to the old." (Quar. Jour. Ag. i. 485.) In England it has been cultivated for upwards of a century, in nursery gardens in the neighbourhood of the metropolis, for the curious purpose of supplying seedsmen in all parts of the island with ears of the corn to ornament their shop windows: it has also been grown in the kitchen gardens of some individuals who have lived in America, for the purpose of using the ears in a green state: it has been tried also in the fields, and more especially in 1828 and 1829, in consequence of the public attention being called to the subject by Mr. Cobbett.

5150. As a bread corn it cannot be greatly commended; the ear is highly productive of flour, but that flour is deficient in gluten, and cannot be made into bread without a large admixture of the flour of wheat. For fattening cattle and poultry of every description it is found excellent, and its culture in Europe can only be recommended with a view to this object.

5151. Varieties. Like other plants which have been long in cultivation in various countries, there are

numerous varie-ties of the maize. According to La gasca, there are 130 varieties known in Spain. That grown in the warmer parts of America called large yellow, Mais jaune, grand, Fr. (fig. 729.) There is a large red, which differs from the other only in the colour of the skin of the grain: both have very large and hand-some ears (fig. 730.) There is the large yellow flint. the large white flint, the sweet corn, the pearl corn, the maize quarantine, ripening in forty days, and the Egyptian or chicken corn, Maïs à poulet, le plus petit et le plus plus petit et le plus morin's catalogue. There is also what is called Cobbett's corn (fig. 731.), which seems to be nothing more than . S the Maïs quaran-taine. The two

last varieties have small handsome cars (figs. 732, and 733.), and can hardly be distinguished from each other. All these sorts have been tried together in the same field, and the Egyptian or chicken corn found decidedly the most early, and the Maize quarantaine, forty days' corn, or Cobbett's corn, next. These two sorts, therefore, alone deserve culture in this country. The Zèa Curagùa, the Valparaiso corn, is a distinct species, to which a sort of religious reputation is attached, on account of the craits, when records edition records this the grains, when roasted, splitting regularly into the form of a cross,

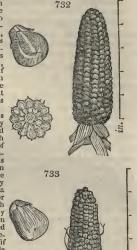

ir.

5152. Soil and climate. A rich loamy soil, which will grow good wheat, tobacco, or potatoes, will grow the strongest plants; but the corn 731 plants; but the corn 732

on such plants will be much less likely to ripen than that produced on a dry, warm, sandy, or calcareous soil. It must be obvious, from what has been before advanced, that there are few, if any, parts of Britain north of York where the climate will be at all suitable to this

grain. 5153. Culture. This grain is almost every where sown or planted in rows, placed at such a width as to admit of horse-hocing the in-tervals. When this is practised, as the grain contains very little gluten, the crop may be considered as a be considered as a good preparation for wheat in very rich soils; it accordingly precedes that grain in the best cultivated parts of North America; but we question if it would be advisable to follow this practice in old cultivated countries, notwithstanding that maize and wheat differ so much in regard to gluten.

5154. The preparation of the soil may be the same as for a crop of barley, according to Cobbett; but we should say, the same as for a crop of turnips on the raised ridglet or Northumberland system.

5155. Soving. The quantity of seed required is from one bushel to three bushels per acre. In Long Island, near New York, the time of sowing is from the 10th to the 20th of May; in France, from the 15th of April to the 20th of the same month, according to Cobbett; but we have no doubt that, in situations where the earliest varieties will succeed at all, they will succeed if sown a week or ten days later. The grain will retain its vegetative powers for at least six years. (Gard. Mag. vol. via. via.)

doubt that, in situations where the corn in the grain will retain its vegetative powers for at least six years. (Cara. 2020, vol. vi. p. 444.)
5156. The mode of planting the corn in America is by drawing shallow drills, commonly three or four feet distant from each other, and dropping the seeds by hand, at eight inches apart, in the row. This distance is evidently too great for the early dwarf varieties; and we think three furrows, or twenty-seven inches, the advantage of the early dwarf varieties; and we think three furrows, or twenty-seven inches, the advantage of the early dwarf varieties; and we think three furrows, or twenty-seven inches, the advantage of the early dwarf varieties; and we think three furrows, or twenty-seven inches, the advantage of the early dwarf varieties; and we think three furrows, or twenty-seven inches, the distant from each other, and dropping the seeds by hand, at eight inches apart, in the row. This distance is evidently too great for the early dwarf varieties; and we think three furrows, or twenty-seven inches, the ordinary width between rows of potatoes and turnips, much more suitable. We should decidedly prefer dibbling, either by hand or by a machine, to opening a drill and depositing the seeds. In several places in France the seeds are sown broad-cast and harrowed in, and the after-culture consists in hand-hoeing between them. By sowing on raised drills the horse-hoeing system may be applied as effectually as in the culture of turnips or beans. Cobbett recommends intervals between the rows of five feet, and the plants at six inches' distance in the row, with a view to admit a superior degree of tillage between, with a view to the wheat crop. He also describes the mode of planting in hills. The situations of these hills having been marked out by a light plough, or even by trailing a log of wood, first in lines five feet apart in one direction, and next in lines in the opposite direction at right angles to the former, so as to leave the surface in squares, the planter takes a hoc, and at every intersection of the lines makes a little hole about an inch and a half deep, and about six inches in diameter, and in this hole five or six cested are regularly distributed, and covered over with fine earth to the depth of an inch and a half. It is evident that by this mode of planting the growth may be very thoroughly worked during the growth of the crop; but it is evident also that it could only be adopted in this country on dry soils, that would admit of being kept during spring and autumn without water furrows.

5151. Transplanting maize may be adopted on a small scale, the advantages of which are that the ground may be better prepared before planting, and that the crop may be made to come in in succession with one which has stood in the ground during winter. The plants may be raised in a hothed, and protected by m

ground."

5159. Topping the plants. The male and female blossoms being on different parts of the plant, have given rise to this operation. The male flowers are always situated on the top or summit of the stem, and the female flowers below, near the bottom. "The flowers at the top having performed their function, and deposited the pollen on the stigma beneath, become no longer necessary to the plant; and they, accordingly, with all the elevated part of the stem which supports them, may be wholly removed. This process is termed topping by the Americans, and is delayed until the blades or leaves may be also stripped off

without injury. The period for performing this is denoted by the state of forwardness of the vegetation. 'The time for topping is, when you, upon stripping the husks, open a little at the tops of the ears, find the grains of the corn to be hard, — not hard enough to grind, nor dry, — but hard enough to resist the strong pressure of the thumb nail. A second criterion is, all the farian having completely quiet telt the tasset being completely dead and dry. A third is, the perfect deadness of the ends of the silk; where, instead of the bright green that appeared before, hanging gracefully down, like the beard of an extraordinarily cunning and blaspheming Jew, you will perceive it to be a little contemptible bunch of withered, up and brown-looking stuff. When all these signs appear, the top and the blades have performed their office, and the sooner they are taken away the better; because, after this, they do no good, and only serve to retard the ripening of the ears by the exclusion which they cause to the sun and the wind.' The tops and leaves being removed, they are laid in bunches in the intervals, suffered to try, and then carried away and stacked. This part of the produce, we are told, is now a precious deposit for the winter: 'it is liable to no inconvenience to which hay is not liable; and weight for weight, and weather for weather, an acre of corn tops and blades will give more nutriment to cattle.' They are reserved by the American farmers as food for their horses and oven in spring; they are given to race horses and other delicate and highly prized animals. They are cut into chaff, and then mixed with barley and rye. Mr. Cobbett has stated this part of the produce to be more valuable than a crop of hay; but he has not given us data, either as regards the weight of the crop, or the quantity of the animals it will feed, to enable us to judge of the correctness of his opinion. In France and southern Europe, these parts of the plant are, in like manner, used for fodder; but we are not aware that they are held

ears are slipped or broken from the stem by the hand, and are carried directly to the Dath-noof to undergo the process of husking. The huskers, who are generally women and children, are seated around or along-side of a large heap of ears; they have baskets placed before them; they strip off the husks, fing them behind them, and throw the ears into a basket. These baskets as filled, are carried to the granary, or corn-crib, as it is called in America. It may be two feet wide at the bottom, five feet high up the sides to the eaves, and five feet across at the top. It is open or grated at the bottom, with spars at the sides, has a weather-tight roof, and is raised from the ground by posts surrounded with this as a protection against rats and mice. The husks form an excellent material for stuffing mattresses, and are used for this purpose in America and on the continent of Europe. The now almost leafless stalks which remain in the fields in America are frequently burnt, but on the continent are used as litter for cattle running loose in the farmyard. The ears remain in the granary till they are wanted for shelling, or separating the grains from the receptacle. On the continent the ears are cut or broken from the stems as in America, and on a large scale are preserved in small open granaries, such as have been described; but more frequently they are hung up unbusked under the projecting eaves of all manner of buildings, and remain there till wanted for husking and shelling.

This, Cobbett tells us, is done in America by scraping or rasping the ears
upon a piece of iron, fixed across a tub, into
which the grains fall. The iron is commonly a upon a piece of iron, fixed across a tub, into which the grains fall. The iron is commonly a bayonet. In this country there are machines of different kinds (fig. 734, and § 2550.), which perform the operation of shelling with great rapidity; but whoever has a threshing machine might, by setting the rollers and drum somewhat wider than usual, dispense with manual labour, both in the operations of husking and shelling; and indeed we see no reason why the crop should not be harvested like a crop of drilded beans, with Gladstone's bean reaper (2740.), and sheaved, shocked, stacked, and threshed, like any other grain.

5162, Produce. In America and Australia, the produce in corn is from fifty to seventy bushels to the acre; on the continent it is gene

bushels to the acre; on the continent it is generally between fifty and sixty; and the produce in this country, as it appears by some experiments recorded in the Gard. Mag. vol. vi. p. 60 to 67., would probably be similar, notwithstanding the circumstance of Mr. Cobbett, Mr. Moore of Sandy, in Bedfordshire, notwithstanding the circumstance of Mr. Cobbett, Mr. Moore of Sandy, in Bedfordshire, and some others, having raised on small spots at the rate of 100 bushels per acre and upwards. The produce in straw in America and warm countries, where the tallest with success, it would not equal that of a crop of oats or barley.

5163. The application of this crop, according to Cobbett, is various and important: "pig-feeding, sheepfeeding, sox and cow-feeding, poultry-feeding, forse-feeding, and man-feeding;" to which we may add fish, carp being fed with maize in France. For "man-feeding" it is only made use of in America till the larmer can afford to grow wheat; and on the continent it is only used as a bread corn by the poorest of the people. The wretched inhabitants of the southern part of the Neapolitan territory live chiefly on maize; as those of some mountainous districts in the north of Italy ive on bread made from chestnuts, or buck-wheat. The most important purpose to which the corn uncrushed can be applied in Europe, appears to us to be the feeding of poultry. All the fat geese noted for heir large livers in the north-west of France and south-cast of Germany are fed with maize, the grains unbroken; and the smaller poultry in the tenure, the pour war war of the laws of the product of the pour war of the pour and the smaller poultry in the security was the sample of the laws of poultry. All the fat geese noted for their large livers in the north-west of France and south-cast of Germany are fed with maize, the grains unbroken; and the smaller poultry in the tenure, the poultry was the sample of the laws a put the fat general to comments.

smaller poultry in these countries are also chiefly fee hany purposes to which the corn may be applied in this countries. We killed, last spring, one single pullet, not of a large and the second of the many purposes to which the corn may be applied in this countries. We killed, last spring, one single pullet, not of a large a post of the second of th

with this corn, broken or ground into meal.

In order to have a fat turkey, or even a really fat fowl, we are compelled to resort to cromming. If the farmer's wife have a compelled to resort to cromming. If the farmer's wife have a tip, with a leathers the statement of the control of the co

and prove, that I could save them all this trouble, they would say, '(iod bless you, Sir; you are the best friend (the inventor of toe and sugar excepted) that ever administered to the comfort of womankind.' Well, then, this I do for them now; let their of womankind with the confort with the work of the work of

converted into a porringer for a boy to eat porridge out of, the coops, well broken up by the pole of the axe, may go to light the fire, and the four hours'saved morning and evening may be employed in spinning and preparing the stuff to make shirts and shifts, and sheets, or, which makes less noise, in knitting stockings for the whole family." (Quar. Jour. Agr. vol. i. p. 507.)

5165. In common with other grain, maize may be fermented, so as to produce beer; or distilled from, so as to produce spirits; the straw containing a good deal of saccharine matter that also might be extracted.

as to produce spirits; the straw containing a good deal of saccharine matter that also might be extracted.

5166. The green ears of maize are applied to various purposes. In the neighbourhood of Paris, before the male blossom has expanded, the female is gathered and pickled, in the manner of cucumbers; and this is practised to some extent by the French and Germans. When the grain has arrived at its milky state, the ears are then gathered for the purpose of boiling or roasting. In America they are roasted on or before hot embers, and eaten with salt and butter. Boiled, they are not quite so delicate; but are still very good, especially if boiled with fat pork. The ears are generally ift for these purposes during the month of September, and a large field may afford soft ears for six weeks.

5167. The meal of maize, besides being given to the smaller poultry, is also used for fattening swine, old sheep which have lost part of their teeth, and for feeding old horses which cannot grind the ears whole. Of a finer quality it is given to negroes, and eaten by various persons in America, in the form of porridge, puddings, and cakes. In this country, the Rev. Henry Berry of Pensham House, Worcestershire, has found maize meal, purchased from Liverpool, superior to oatmeal in maintaining the condition of his hounds. (Country Times, March 22d, 1830). The meal of maize, made into paste, and fried with fat bacon, is the ordinary food of the peasants of great part of the Brabant. It serves them likewise for fattening their fowl, of which they feed great quantities for the markets of the rest of Brabant and of Holland. (Comm. Board of Agr.)

5168. Diseases and enemies. The Phalæ ha forfieldis Lin. is said to deposit its eggs in the stems of the plant, and the larvæ which these produce eat out its interior, so as to weaken the strength of the spikes. There are also three species of smut, Uredo Pers., which are parasitic on the maize, and destroy the grain by reducing it to a black powder. One species is peculiar to the flower, a

be troublesome in this country.

Canary Corn. — Phálaris canariénsis L.; Triándria Digýnia L., and Gramineæ J. Alpiste de Canaire, Fr.; Kanariengras, Ger.; Falari, Ital; and Alpiste, Span. (fig. 735.)

5169. The Canary grass is an annual, with a culm from a foot to eighteen inches in height, and lively green leaves almost half an inch in width. The seeds are thickly set in a subovate panicle or spike. It is a native of the Canary Islands; but now naturalised in several parts of England, and on the Continent. It flowers from June to

August, and ripens its seeds from September to October. It has long been cultivated in the Isle of Thanet, and a few other places in Kent and Essex: it is there considered an uncertain crop, both on account of the seasons, it being the latest of all the grasses in ripening its seeds, and of the fluctuation of prices.

5170. The culture of the Canary grass consists in pulverising a loamy soil in good heart, or manuring it if worn out; though every judicious farmer tries to avoid giving manure to a corn crop unless after a naked fallow. The seeds are sown in rows at about a foot apart, generally by the ribbing process: the season the month of February, and the quantity of seed four or five gallons per acre. The after-culture consists in repeated hoeings and weedings.

5171. The reaping process seldom commences before the end of September. The culm being leafy, and the seed difficult to separate from the chaff, it requires to lie in handfuls for a week or more, and to remain more than that time in the field after being tied up in sheaves. In the Isle of Thanet it is cut with a hook, provincially called a twibil and a hink; by which it is laid in lumps, or wads, of about a sheaf each. The seed clings remarkably to the husk; and, in order to detach it, the crop is left a long time on the ground, to receive moisture sufficient to loosen the enveloping chaff, otherwise it would be hardly possible to thresh out the seed. The wads are turned from time to time, to have the full benefit of the rains and sun.

5172. The common produce of Canary grass is from thirty to thirty-four bushels per acre; but under the best management in the Isle of Thanet it is often fifty bushels per acre.

5173. The use of the seed is chiefly as food for Canary and other cage and aviary birds. The chaff is superior to that of every other culmiferous plant for horse-food, and the straw, though short, is also very nutritive.

Subsect. 3. The Millets. - Pánicum and Sórghum L.; Triándria Digýnia and Polygàmia Monæcia L. and Gramíneæ J. Panis and Sorgho, Fr.; Panick and Hirse, Ger.; Panico and Sageno or Sorgo, Ital.; and Alcandia, Span.

5174. Of the millet there are three distinct genera: the Polish millet (Digitària), cultivated in Poland; the common millet (Panicum), or panic grass, cultivated in Germany,

and sometimes in this country; and the great or Indian millet (Hólcus), cultivated in India, Italy, and America.

5175. Of the common millet there are three species: Setaria germanica (fig. 736. a), a native of the south of Europe; the P. miliaceum (b), a native of the East Indies; and the Setaria itálica (c), also of

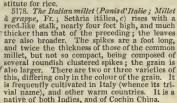

East Indies; and the Setària itálica (e), also of Indian origin.

5176. The German millet (Moha de Hongrie, Fr.; S. germánica, a) rises with a jointed reed-like stalk, shout three feet high, and about the size of the common reed, with a leaf at each joint a foot and a half long, and about an inch broad at the base where broadest, ending in an acute point, rough to the touch, embracing the stalk at the base, and turning downwards about half the length. The stalks are terminated by compact spikes, about the thickness of a man's finger at bottom, growing taper towards the top, eight or nine inches long, and closely set with small roundish grain. It is annual, and perishes soon after the seeds are ripe. There are three varieties of it, the yellow, white, and purple grained. It was formerly cultivated for bread in some of the northern countries. northern countries,

northern countries.

5177. The common or cultivated millet (Millet commun, Fr.; Panicum miliaceum, b) rises with a read-like channelled stalk, from three to four feet high; at every joint there is one reed-like leaf, joined on with soft hairs; the leaf has none, but has several small longitudinal furrows running parallel to the midrib. The stalk is terminated by a large loose panicle hanging on one side. Of this species there are two varieties, the brown and the yellow; the latter of which was formerly in cultivation, and is now sometimes sown for feeding poultry, and as a sub-

5179. The Polish millet, or manna grass of the Germans (Digitària sanguinàlis, formerly Pánicum sanguinàlis, jūg. 737.), is a low decumbent, annual plant, seldom rising above nine inches or a foot high, with hairy leaves and slender panicles. It tillers much, and forms a close tuft, spreading and rooting at the joints. It is a native of England but not common. It grows in abundance in Poland, and is sometimes cultivated, the seeds being used like those of the other millets as a substitute for rice or sago.

or sago.

crosago.

Sorghum L., Sorghum vulgare, W. em. fig. 738. Sorgho, gros millet d'Italie, Fr.; Sorgsamen, Ger.; Sagina, Ital.; and Melea, Span.) has a stem which rises five or six feet high, is strong, reedy, and like those of the maize, but smaller. The leaves are long and broad, having a deep furrow through the centre, where the midrib is depressed in the upper surface, and is very prominent below. The leaves are two feet and a half long, and two inches broad in the middle, embracing the stalks with their base. The flowers come out in large panicles at the top of the stalks, resembling, at first appearance, the male spikes of the Turkey wheat; these are succeeded by large roundish seeds, which are wrapped round with the chaff. This grain is a native of India, where it is much used to feed poultry, and is frequently sent to Europe for the same purpose. It is much cultivated in Arabia, and most parts of Asia Minor; and has been introduced into Italy, Spain, Switzerland, and some parts of Germany, also into China, Cochin China, and the West Indies, where it grows commonly five or six feet high, or more, and being esteemed a hearty food for labourers, is called negro Guinea corn. Its long awns or bristles defend it from the birds. In England, the antumns are seldom dry and warm enough to ripen the seed well in the field. In Arabia it is called dora or durra; the flour is very white, and they make good bread of it, or rather cakes, about two inches in thickness. The bread which they make of it in some parts of Italy is dark and coarse. In Tuscany it is used chiefly for feeding poultry and pigeons; sometimes for swine, kine, and horses. Cassalpinus says, that cattle fed on the green herb are apt to swell and die, but thrive on it when dried. They make brushes and brooms of its stalks in Italy, which Ray observed in the shops at Venice, and which are sent to this country. Of this species there are two distinct varieties; one distinguished by black, and the other by red, husked seeds, besides subvaricties.

5181. The only sorts of millet which can be cultivated with success in this country are the German, cultivated, and the Polish sorts. According to Professor Thaer, the cultivated is to be preferred, as having the largest grain.

5182. The soil for the millet should be warm, sandy, rich, and well pulverised to a good pth. The seed is sown in May, very thin, and not deeply covered. In the course of its growth no plant, Professor Thaer observes, is more improved by stirring the soil, after which it grows astonishingly fast, and smothers all weeds.

5185. In harvesting the millet, great care is requisite not to shed the seed; and as it ripens rather unequally, it would be an advantage to cut off the spikes as they ripen, as

in reaping maize. No grain is easier to thresh, or to free from its husk by the mill. It is used instead of rice, and in Germany bears about the same price. It produces a great bulk of straw, which is much esteemed as fodder.

5184. The great Indian millet will grow in this country to the height of five or six feet; but will not ripen its seeds, or even flower, if the season is not dry and warm. If its culture is attempted, it should be raised in a hotbed and transplanted.

Subsect. 4. Rice, and some other Cereal Grámina.

739 The rice (Oryza sativa, fig. 739.) has been tried in this country, and, if sown very early, would probably ripen its seeds. The hill variety, which does not require watering, would probably succeed best. But there is no inducement to cultivate this and other grains or seeds when they can be imported at so low a rate. We merely introduce them to record the resources of British agriculture in case of necessity.

5186. The Zizània aquática (fig. 740.) might be cultivated on the margin of ponds for its seeds, which much resemble those of Polish millet. It is exceedingly prolific, grows in great luxuriance, and produces abundance of bland farinaceous seeds, in all the shallow streams of the dreary wilderness in northwest America, between the Canadian lakes and the hilly range which divides Canada from the country on the Northern Pacific Ocean. Its seeds contribute essentially to the support of the wandering tribes of Indians, and feed immense flocks of wild swans, geese, and other water fowl, which resort there for the purpose of breeding. Productive as is this excellent plant, and habituated to an ungenial climate, and to

situatious which refuse all culture, it is surprising, says Pinkerton (Geog. vol. iii. p. 330.), that the European settlers in the more northern parts of America

European settlers in the more normern parts of America, have as yet taken no pains to cultivate and improve a vegetable production which seems intended by nature to become, at some future period, the bread corn of the north.

5187. The Glycèria fluitans resembles the Zizania, and the seeds are used in Germany like those of Polish millet. Various species of Panicum, Hordeum, and Bromus afford tolerable supplies of edible seeds.

5188. The buck-wheat (Polýgonum Fagopỳrum; Riz, Fr.; Reiss, Ger.; Riso, Ital.; Arroz, Span.) is vulgarly considered as a grain; but not being a bread-corn grass, we have classed it among manufactorial plants. (Chap. VIII. Sect. IV.)

CHAP. III.

Culture of Leguminous Field-Plants, the Seeds of which are used as Food for Man or Cattle.

5189. The seeds of the cultivated legumes are considered to be the most nutritive of vegetable substances grown in temperate climates. They contain a large proportion of matter analogous to animal substances, having when dry the appearance of glue, and being as nourishing as gluten. To the healthy workman this substance supplies the place of animal food; and Von Thaer states, that in Germany neither sailors nor land labourers are content unless they receive a meal of legumes at least twice a week. The straw or haulm, he says, cut before it is dead ripe, is more nourishing than that of any of the cereal grasses. But leguminous plants are not only more than all others nourishing to man and animals, but even to vegetables they may be said to supply food; since they are not only known to be less exhausting to the soil than most other plants, but some of them, and more especially the lupine, have been ploughed in green as manure from the earliest Many scientific agriculturists consider a luxuriant crop of peas or tares as nourishing the soil by stagnating carbonic acid gas on its surface; which corresponds with the universal opinion of their being equal to a fallow, and with the value set on them in rotation, as already explained. (4939.) Two reasons may be given for the circumstance of peas and tares not exhausting the land so much as other crops: first, because they form a complete shade for the ground; and next, because they drop so many of the

leaves upon the surface. The legumes cultivated in British farming are, the pea, bean, tare, and vetch, to which might be added the lentil, kidneybean, and chick pea.

5190. The nutritive products of these plants are thus given by Sir H. Davy, Einhoff, and Thaer: -

	English Name.	In 100 Parts.						
Systematic Name.		Whole quantity of soluble or nutritive matter.	Mucilage or starch.	Saccharine matter, or sugar.	Gluten or albumen.	Extract, or matter rendered insoluble during evaporation.

The Pea. — Pisum sativum L.; Diadélphia Decándria L., and Leguminòsæ J. Les Pois, Fr.; Erbse, Ger.; Piscello, Ital.; and Pesoles, Span. (fig. 741.)

5191. The pea is the most esteemed legume in field cultivation, both for its seed and haulm. It is supposed to be a native of the south of Europe, and was cultivated by the Greeks and Romans. In this country it has been grown from time immemorial: but its culture appears to have diminished since the more general introduction of herbage, plants, and roots; and the pea, except near large towns for gathering green, and in a few places for boiling, has given way to the bean, or to a mixture of peas and beans. There are various inducements, however, to the cultivation of peas in dry warm soils near large towns. When the crop is good and gathered green, few pay better: the payment is always in cash, and comes into the pocket of the farmer in time to meet the exigencies of the hay, and sometimes even of the corn, harvest. The ground, after the peas have been removed, is readily prepared for turnips, which also pay well as a retail crop near towns; and the haulm is good fodder.

5192. The varieties of the pea are numerous; but they

may be divided into two classes: those grown for the ripened seed, and those grown for gathering in a green state. The culture of the latter is chiefly near large towns, and may be considered as in part belonging to gardening rather than agriculture. lately a new sort of pea been brought into notice about Banbury in Oxfordshire. It is. called the "nimble hog pea." It appears to be a grey variety of the early frame, as it has single flowers, and is fit to cut about the end of June, notwithstanding it must not be sown earlier than the middle of April. On the excellent land about Banbury the produce is four quarters to the acre, and turnips sowed on the stubble are up and sometimes hoed out before the regular turnip crop!

5193. The grey varieties (Pois gris, Pois-agneau, Bisaille, Fr.) are, the early grey, the late grey, and the purple grey; to which some add the Marlborough grey, and horn grey.

5194. The white varieties (Pois blanc, Fr.) grown in fields are the pearl, early Charlton, golden hotspur, the common white or Suffolk, and other Suffolk varieties.

5195. New varieties of the pea are readily procured by selection or impregnation, of which a striking example given by Knight has been already referred to. (1632.)

5196. In the choice of sorts, where it is desired to grow grey peas for the sake of the seeds or corn, the early variety is to be preferred in late situations, and the late variety in early ones; but when it is intended to grow them chiefly for covering the ground and for the haulm, then the late varieties claim the preference, and especially the purple grey. Of white peas, to be grown for gathering green, the Charlton is the earliest, and the pearl or common Suffolk the most prolific. When white peas are grown for boilers, that is for or common Suffolk the most prolific. splitting, the pearl and Suffolk are also the best sorts.

5197. To have recourse to early sorts is supposed by some to be of considerable importance in the economy of a farm, when the nature of the soil is suitable, as by such means the crops may in many cases be cut and secured while there is leisure, before the commencement of the wheat harvest; and that where the nature of the soil is dry and warm, and the pea crop of a sufficiently forward kind, it may be easy to obtain a crop of turnips from the same land in the same year, as has been suggested above. But in this view it is the best practice to put in the crops in the row method, and keep them perfectly clean hy means of attentive hand and horse hoeing; as in that way the land will be in such a state of preparation for the turnips, as only to require a slight ploughing, which may be done as fast as the pea crop is removed, and the turnips seed may be drilled in as quickly as possible upon the newly turned up earth. In some particular districts a third crop is even put into the same land, the turnips being sold off in the autumn, and coleworts substituted for the purpose of greens in the following spring. This, according to Middleton, is the practice in

some places in Middlesex. But it is obviously a method of cultivation that can only be attempted on the warm and fertile kinds of turnip soil, and where the pea crops are early; on the cold heavy and wet descriptions of land it is obviously impracticable, and wholly improper.

5198. The soil best suited for peas is a dry calcareous sand; it should be in good tilth, not too rich nor dunged along with the crop. In Norfolk and Suffolk peas are often sown on clover leys after one furrow, or after corn crops on two furrows, one given in autumn, and the other early in spring.

5199. The climate required by the pea is dry and not over warm, for which reason, as the seasons in this country are very often moist and sometimes exceedingly dry and hot in June and July, the pea is one of the most uncertain of field crops.

5200. The season of sowing must differ considerably according to the intentions of the cultivator.

5201. For podding early to be sold green, they should be sown at different times, from January to the end of March, beginning with the driest and most reduced sorts of land; and with this intention in some southern counties they are sown in the autumn. For the general crops from February to April, as soon as the lands can be brought into proper order, is the proper season; the grey sorts being employed in the early sowings, and the white sorts in the later. Young says, that where these crops cannot be sown in February, they should always be completed in the following month. It is observed by the same writer, that, in sowing after a single furrow, the white boiling pea, of many sorts and under various names, is more tender than the greys and various kinds of hog peas; but he has many times put them into the ground in February, and, though very smart frosts followed, they received no injury. He suniformly found, that the earlier they were sown the better. There is also a particular motive for being as early as possible; that is, to get them off in time for turnips. This is most profitable husbandry, and should never be neglected in dry and warm soils and situations. If they are sown in this month, and a right sort chosen, they will be off the land in June, so that turnips may follow at the common time of sowing that crops.

5202. Steeping the seed in water is sometimes practised in late sowings.

5203. The quantity of seed must be different in different cases and circumstances, and according to the time and manner in which the crop is put into the ground; but, in general, it may be from two and a half to three bushels, the early sowings having the largest proportion of seed. In planting every furrow slice, Young says, two bushels and a half constitute the usual proportion; but, when drilled at greater distances, six or seven pecks will answer.

5204. The most common mode of sowing peas is broad-cast; but the advantages of the row culture in the case of a crop so early committed to the soil must be obvious.

5205. The best farmers always sow peas in drills either after the plough, the seed being deposited commonly in every second or third furrow; or, if the land is in a pulverised state, by drawing drills with a machine or by ribbing. In Norfolk and Suffolk peas are generally dibbled on the back of the furrow, sometimes one and sometimes two rows on each; but dibbling in no manner appears to us so well suited for a farmer's purpose as the drill. In Kent, where immense quantities of peas are grown, both for gathering green and for selling ripe to the seedsmen, they are generally sown in rows from eighteen inches to three feet asunder, according to the kind, and well cultivated between. Peas laid a foot below the surface will vegetate; but the most approved depth is six inches in light soil, and four inches in clay soil, for which reason they ought to be sown under furrow when the ploughing is delayed till spring. Of all grain, beans excepted, they are the least in danger of heins buried. beans excepted, they are the least in danger of being buried.

5206. The after culture given to peas is that of hoeing, either by hand or horse. Where the method of hand-culture prevails, it is the general custom to have recourse to two hoeings; the first when the plants are about two or three inches in height, and again just before the period in which they come into blossom. In this way the vigorous vegetation of the young crop is secured, and a fresh supply of nourishment afforded for the setting of the pods and the filling of the peas. At the latter of these operations the rows should be laid down, and the earth well placed up to them, the weeds being previously extirpated by hand labour. It has been stated, that in some parts of Kent, where this sort of crop is much grown, it is the practice, when the distance of the rows will permit, to prevent the vegetation of weeds, and forward the growth of pea crops, by occasionally horse-hoeing, and the use of the brake-harrow, the mould being laid up to the roots of the plants at the last operation by fixing a piece of wood to the harrow. This should, however, only be laid up on one side, the peas being always placed up to that which is the most fully exposed to the effects of the sun.

5207. In harvesting the ripened pea considerable care is requisite, both on account of the seed and haulm.

the seed and haulm.

5208. When pea crops become ripe they wither and turn brown in the haulm or straw, and the pods begin to open. In this state they should be cut immediately, in order that the loss sustained by their shedding may be as little as possible. It is observed that in the late or general crops, after they are reaped or rather cut up by means of a hook, it is the usual practice to put them up into small heaps, termed wads, which are formed by setting small parcels against each other, in order that they may be more perfectly dried both in the seed and stem, and be kept from being injured by the moisture of the ground. But, in the early crops, the haulm is hooked up into loose open heaps, which, as soon as they are perfectly dry, are removed from the ground and put into stacks for the feeding of animals, which are said to thrive nearly as well on it as on hay. When intended for horses, the best method would seem to be that of having them cut into chaff and mixed with their other food. Young says, that forward white peas will be fit to cut early in July; if the crop is very great they must be hooked; but if small, or only middling, mowing will be sufficient. The stalks and leaves of peas being very succulent, they should be taken good care of in wet weather: the tufts, called wads or heaps, should be turned, or they will receive damage. White peas should always be perfectly dry before they are housed, or they will sell but indifferently; as the brightness and plumpness of the grain are considered more in them than in hog peas at market. The straw also, if well harvested, is very good fodder for all sorts of cattle and for sheep; but if it receives much wet, or if the heaps are not turned, it can be used only to litter the farmyard with. It is the practice in some districts to remove the haulm, as soon as it has been cut up by hooks constructed

with sharp edges for the purpose, to every fifth ridge, or even into an adjoining grass field, in order that it may be the better cured for use as cattle-food, and at the same time allow of the land being immediately prepared for the succeeding crop. When wet weather happens whilst the peas lie in wads, it occasions a considerable loss, many of them being shed in the field, and of those that remain agreat part will be so considerably injured as to render the sample of little value. This inability in peas to resist a wet harvest, together with the great uncertainty throughout their growth, and the frequently inadequate return in proportion to the length of haulm, has discouraged many farmers from sowing so large a portion of this pulse as of other grain; though on light lands which are in tolerable heart, the profit, in a good year, is far from inconsiderable. far from inconsiderable.

5209. In gathering green peas for the market, it is frequently a practice with the large cultivators of early green-pea crops in the neighbourhood of London to dispose of them, by the acre, to inferior persons, who procure the podders; but the smaller farmers, for the most part, provide this description of people themselves, who generally apply at the proper season.

5210. The business of picking or podding the peas is usually performed by the labourers at a fixed price for the sack of four heaped bushels. The number of these labourers is generally in the proportion of about four to the acre, the labour proceeding on the Sundays as well as other days. It is sometimes the custom to pick the crops over twice, after which the rest are suffered to stand till they become ripe, for the purpose of seed. This, however, mostly arises from the want of pickers, as it is considered a loss, from the peas being less profitable in their ripe state than when green. Besides, they are often improper for the purpose of seed, as being the worst part of the crop. It is therefore better to have them clear picked when hands can be procured. After this they are loaded into carts, and sent off at suitable times, according to the distance of the situation, so as to be delivered to the salesmen in the different markets from about three to five releafs, in the morning. In many cases in other parts, the early statherings are however sent to the distance of the situation, so as to be derivered to the satisfine in the different markets from about three to five o'clock in the morning. In many cases in other parts, the early gatherings are, however, sent to the markets in half-bushel sieves, and are frequently disposed of at the high price of five shillings the sieve; but at the after periods they are usually conveyed in sacks of a narrow form, made for the purpose, which contain about three bushels each, which, in the more early parts of the season, often fetch twelve or fourteen shillings the sack, but afterwards mostly decline considerably; in some seasons so much as scarcely to repay the expenses. This sort of crop affords the most profit in such pea seasons as are inclined to be cool, as under such circumstances the peas are most retarded in their maturation or ripening, and of course the markets kept from being overabundantly supplied.

5211. The threshing of peas requires less labour than that of any other crop. Where the haulm is to be preserved entire it is best done by hand; as the threshing machine is apt to reduce it to chaff. But where the fodder of peas is to be given immediately to

horses on the spot, the breaking of it is no disadvantage.

5212. The produce of the pea in ripened seeds is supposed by some to be from three and a half to four quarters the acre; others, however, as Donaldson, imagine the average of any two crops together not more than about twelve bushels; and that on the whole, if the value of the produce be merely attended to, it may be considered as a less profitable crop than most others. But as a means of ameliorating and improving the soil at the same time, it is esteemed of great value.

5213. With respect to the produce in green peas in the husk, the average of the early crops in Middlesex is supposed to be from about twenty-five to thirty sacks the acre, which, selling at from eight to eighteen shillings the sack, afford about eighteen pounds the acre. The author of The Symposis of Husbandry, however, states the produce about Dartford, in the county of Kent, at about forty sacks the acre, though, he says, fifty have sometimes been gathered from that space of land.

5214. The produce of peas in straw is very uncertain, depending so much on the sort and the season: in general it is much more bulky than that of the cereal grasses; but may be compressed into very little

5215. The produce of peas in flour is as 3 to 2 of the bulk in grain, and husked and split for soups as 4 to 2. A thousand parts of pea flour afforded Sir H. Davy 574 parts of nutritive or soluble matter; viz. 501 of mucilage or vegetable animal matter, 22 of sugar, 35 of gluten, and 16 of extract or matter rendered insoluble during the operation.

5216. The use of peas for soups, puddings, and other culinary purposes, is well known.

5216. The use of peas for soups, puddings, and other culinary purposes, is well known.

5217. In some places porridge, brose, and bread are made of pea-flour, and reckoned very wholesome and substantial. In Stirlingshire it is customary to give pea or bean biscuits to horses, as a refreshment, while in the yoke. The portion of peas not consumed as human food is mostly appropriated to the fattening of hogs and other domestic animals; and, in particular instances, supplies the place of beans, as the provender of labouring horses; but care should be taken, when used in this way, that they are sufficiently dry, as, when given in the green state, they are said to produce the gripes, and other bowel complaints, in those animals. Bannister, after observing that the halm is a very wholesome food for cattle of every kind, says, there is generally a considerable demand for peas of every denomination in the market, the uses to which they may be applied being so many and so various. The boilers, or yellow peas, always go off briskly; and the hog-peas usually self for 6d. or 1s. per quarter more than beans. For feeding swine the pea is much better adapted than the bean, it having been demonstrated by experience, that hogs fat more kindly when fed with this grain than with beans; and, what is not easy to be accounted for, the flesh of swine which have been fed on peas, it is said, will swell in boiling, and be well tasted; whilst the flesh of the bean-fed hog will shrink in the pot, the fat will boil out, and the meat be less delicate in flavour. It has, therefore, now become a practice with those farmers who are curious in their pork, to feed their hogs on peas and barley-meal; and if they have no peas of their own growth, they rather choose to be at the expense of buying them, than suffer their hogs to eat beans. Nay, so far, says he, do some of them carry their prejudice in this particular, as to reject the grey peas for this use, as bearing too near an affinity to the bean, and therefore reserve their growths of white pe

5219. Pea straw cut green and dried is reckoned as nourishing as hay, and is considered excellent for sheep.

5220. In the saving of any particular sorts of peas for seed, they should be carefully looked over while in flower, in order to draw out all such plants as are not of the right kind; as there will always be, in every sort, some roguish plants, which, if left to mix, will cause degeneration. As many rows as may be thought sufficient to furnish the desired quantity of seed should then be marked out, and left till their pods turn brown, and begin to split, when they should immediately be gathered up, with the haulm; and if the farmer has not room to stack them till winter, they may be threshed out as soon as they are dry, and put up in sacks for use: but particular care should be taken not to let them remain too long abroad after they are ripe; as wet would rot them; and heat, after a shower of rain, makes their pods burst in such a manner that the greater part of their seeds would be lost.

5221. The diseases of peas are few, and chiefly the worm in the pod and the fly on the leaves and flower. They are also liable to be mildewed or blighted. None of these evils, however, are very common; and there is no known way of preventing them but by judicious culture. Late sown peas are particularly liable to be injured by the mildew and A'phis; and should either of these attack the plant before the pods are filled, they invariably fail. In 1826 almost all the crops of peas were destroyed by the A'phides, so that they were mown for the haulm only.

Sect. II. The Bean. — Vícia Fàba L.; Diadélphia Decándria L., and Leguminòsæ J. Féverole, Fr.; Bohn, Ger.; Fava, Ital.; and Alverjanas, Span.

5222. The bean is a valuable field plant, as affording food for live stock, and in part for man. It is said to be a native of Egypt; but, like other long domesticated plants, its origin is very uncertain. It has been cultivated in Europe and Asia time out of mind. Beans have been long known in Britain; but it is only of late years that they were extensively cultivated upon general soils, being formerly considered as adapted only to rich and moist clays. At that time they were all sown according to the broad-cast system; in which way, instead of benefiting the ground, they were of incalculable detriment. Weeds got away at the outset, and in dry seasons often ruined the crop; whilst in every season the grass or perennial weeds which happened to be in the ground increased in strength and in quantity, the openness of the bean crop at bottom allowing them to thrive without interruption.

5223. The drilling of beans with a small mixture of peas is now become a general practice in every well cultivated district of the north, more particularly in those where soil and climate permit the practice to be successfully executed. In this way not only heavy crops are raised, but, what is of great importance, the ground is kept constantly in good order, provided suitable attention is bestowed upon the cleaning process. This is generally carried on by horse-hoeing the crop at different times, so long as the hoe can be used without doing damage; and in this way an able auxiliary is brought forward to the assistance of summer fallow, whereby less stress need be laid upon that radical process

than otherwise would be indispensably necessary. (Brown.)

5224. The varieties of the bean may be included under two general heads, - the white

or garden beans, and the grey or field beans.

5225. Of the white or garden beans (Fève de marais, Fr.) sown in the fields, the mazagan and long-pod are almost the only sorts. Of the grey beans, that known as the horse bean, the small or ticks, and the prolific or Heligoland, are the chief sorts. New varieties are procured in the same manner as in other plants. A variety is in use in some parts of Lincolnshire, called the winter bean (Féverole d'hiver, Fr.). It is planted in October in the usual manner, and is ready to harvest in the last week in July or the first week in August. They are said to have been introduced from the Continent in 1825. We have lately seen a field of this bean at the Oaks Farm, near Woking, in Surrey, which was planted in October 1829, and in full bloom May 12th following. This circumstance, after so severe a winter, is a proof to us that this is a most valuable variety. (Gard. Mag. vol. vi.)

5226. In the choice of sorts, tick beans are supposed by some farmers to be more productive than horse-beans; but the latter grow higher in the stem, and produce a more stagnated state of the air, or smother the land more, consequently are the most suitable for the stronger sorts of soil; and Young remarks, that "the common little horse-bean has the advantage of all others in being more generally marketable; for in certain situations it is not always easy to dispose of ticks, Windsors, long-pods, and various other large sorts. They also grow higher, shade the ground in summer more from the sun, and yield a larger quantity of straw, which makes excellent manure. But some of the other sorts are generally supposed to yield larger products. In purchasing beans for seed, care should be taken to choose such as are hard and bright, without being shrivelled in their appearance."

5227. The best soils for beans are clays and strong loams. On such soils they generally succeed wheat or oats, but sometimes also clover leys. Turnip soils or sands are by no

means proper for them.

5228. In the preparation of the soil much depends on the nature of the land and the state of the weather; for as beans must be sown early in the spring, it is sometimes inpossible to give it all the labour which a careful farmer would wish to bestow. It must also be regulated in some measure by the manner of

In all cases it ought to be ploughed with a deep furrow after harvest or early in winter; and as

sowing. In all cases it ought to be ploughed with a deep furrow after harvest or early in winter; and as two ploughings in spring are highly advantageous, the winter furrow may be given in the direction of the former ridges, in which way the land is sooner dry in spring than if it had been ploughed across. The second ploughing is to be given across the ridges, as early in spring as the ground is sufficiently dry; and the third furrow either forms the drills or receives the seed. (Supp. E. Brit. art. Agr.)

5299. Brown, one of the best bean-growers in Britain, gives the following directions: — The furrow ought to be given early in winter, and as deep as possible, that the earth may be sufficiently loosened and room afforded for the roots of the plant to search for the requisite nourishment. This first furrow is usually given across the field, which is the best method when only one spring furrow is intended; but as it is now ascertained that two spring furrows are highly advantageous, perhaps the one in winter ought to be given in length, which lays the ground in a better situation for resisting the rains, and renders it sooner dry in spring, than can be the case when ploughed across. On the supposition that three furrows are to be given; one in winter and two in spring, the following is the most eligible preparation: — The land being ploughed in length as early in winter as is practicable, and the cross gutter and headland furrows sufficiently dug out, take the second furrow across the first as soon as the ground is dry enough in spring to undergo the operation; water-furrow it immediately, and dig again the cross gutter and headland furrows, otherwise the benefit of the second furrow may be lost. This being done, leave the field for some days till it is sufficiently dry, when a cast of the harrows becomes necessary, so that the surface may be levelled; then enter with the ploughs and form the drills. (Treatise on Rural Affairs.)

520. Manure is frequently applied to the bean crop, especially if it succeeds whea

5232. The climate most favourable to the bean is one neither very dry nor very moist; the first brings on the fly, and the last prevents the setting of the blossoms. In general, however, a dry summer is most favourable to the production of seed, and moist weather

to the growth of the haulm.

5233. The time of sowing beans is as early as possible after the severity of winter is over; in the south, sometimes in January, but never later than the end of March, as the ripening of the crop and its safe harvesting would otherwise be very precarious in this Bannister thinks that the proper time for planting beans in Kent is towards the latter end of January or early in the following month; though this business may be continued with advantage till the middle or latter end of March, if the weather should prevent their being got in at an earlier season: but in general it is best to embrace the first opportunity of sowing them after Candlemas, as they often miscarry when the season is procrastinated beyond that time, especially if a dry summer should succeed.

5234. The mode of sowing is almost always in rows. Though still sown broad-cast in several places, and sometimes dibbled, they are for the most part drilled by judicious cultivators, or deposited after the plough in every furrow, or only in every second or third furrow. In the latter method the crop rises in rows, at regular intervals of nine, eighteen, or twenty-seven inches, and the hand-hoe ought invariably to be employed; but it is only where the widest interval is adopted that the horse-hoe can be used with much

effect in their subsequent culture.

effect in their subsequent culture.

5235. There are two modes of drilling beans. In one of these the lands or ridges are divided by the plough into ridgelets or one bout stitches, at intervals of about twenty-seven inches. If dung is to be applied, the seed ought to be first deposited, as it is found inconvenient to run the drill-machine afterwards. The dung may then be drawn out from the carts in small heaps, one row of heaps serving for three or five ridgelets, and it is evenly spread and equally divided among them in a way that will be more minutely described when treating of the culture of turnips. The ridgelets are next split out or reversed, either by means of the common plough or one with two mould-boards, by which means both the seed and the manure are perfectly covered. When beans are sown by the other method, in the bottom of a common furrow, the dung must be previously spread over the surface of the winter or spring ploughing. Three ploughs then start in succession, one immediately behind another; and a drill harrow either follows the third plough or is attached to it, by which the beans are sown in every third furnw, or at from twenty-four to twenty-seven inches asunder, according to the breadth of the furrow, or increase in the state of the dung and to plough it down with a strong furrow; after this shallow furrows are drawn, into which the seed is deposited by the drill-machine. Whichever of these modes of sowing is followed, the whole field must be carefully laid dry, by means of channels formed by the plough, and when necessary by the shovel; for neither then nor at any former period should water be allowed to stagnate on the land.

5237. The dibbling of beans is considered by Arthur Young as an excellent method when well performed; but the grand objection to it is the difficulty of getting it well done.

5238. When dibbling becomes the common husbandry of a district, the workmen find that great earnings are to be made by it, and this is much too apt to make them careless and eager to earn still more; and if a very minute attention is not paid to them by the constant attendance of the farmer, they strike the holes so shallow that the first peck of a rook's bill takes the seed, and acres may be destroyed if the breed of those birds be encouraged. Boys are employed for weeks together to keep the fields, but all works that depend on boys are borribly neglected, and thus the farmer suffers materially; however, if the seed is deposited two and a half or (better) three inches deep, it is not so easily eradicated. In some districts, as Middlesex, Surrey, &c., the method is to plant this pulse in rows struck out by a line, by which a great saving is made in the article of seed, a circumstance which is thought to compensate for the extraordinary charge of this mode of husbandry; and thus far it may be fairly acknowledged that the method of planting, beans by the dibber is greatly to be preferred to that of sowing the seed at random. The economy of this agricultural process is thus explained; — The rows are marked out one foot asunder, 3 H 4.

and the seed planted in holes made two inches apart: the lines are stretched across the lands, which are formed about six feet over; so that when one row is planted, the sticks to which the line is fastened are formed about six feet over; so that when one row is planted, the sticks to which the line is fastened are moved by a regular measurement to the distance required, and the same method pursued till the field is completed. The usual price for this work is ninepence per peck, and the allowance two bushels per acre. Great confidence must necessarily be reposed in the people who transact the business of planting beans by the dibber; for, if inclined to fraud, they have it in their power to deceive their employer, by throwing a great part of the seed into the hedge; by which means their daily profits are considerably enhanced, their own labour spared, and every discovery effectually precluded till the appearance of the crop. Then, indeed, the frequent chasms in the rows will give sufficient indications of the fraud; but by this time perhaps the villainous authors of the mischief may have escaped all possibility of detection, by having conveyed themselves from the scene of their injunity. themselves from the scene of their iniquity.

5239. The quantity of seed allowed is very different in the southern and northern parts of Britain: in the former, even when the rows are narrow, only two bushels or two bushels and a half; but in Scotland, seldom less than four bushels to the English statute acre, even when sown in ridgelets twenty-seven inches distant, and a bushel more when sown broad-cast. When beans are sown or planted thick, the top pods only fill to the number of three, and four, and half a dozen; when thin, the plants will pod and fill to the bottom. Both in the broad-cast and drill husbandry, it is common to mix a small quantity of peas along with beans. This mixture improves both the quantity and quality of the straw for fodder, and the pea straw is useful for binding up the sheaves in harvest.

The after culture of the bean crop commences with harrowing just before the When sown in rows, in either of the modes already young plants reach the surface. mentioned, the harrows are employed about ten or twelve days after; and, being driven across the ridgelets, the land is laid completely level for the subsequent operations, and the annual weeds destroyed.

the annual weeds destroyed.

5241. After the beans have made some growth, sooner or later, according to the state of the soil with regard to weeds, the horse-hoe is employed in the intervals between the rows; and followed by the handhoe for the purpose of cutting down such weeds as the horse-hoe cannot reach; all the weeds, that grow among the beans beyond the reach of either hoe, should be pulled up with the hand. The same operations are repeated as often as the condition of the land, in regard to cleanness, may require.

5242. Before the introduction of the horse-hoe, which merely stirs the soil, and cuts up the weeds, a common small plough, drawn by one horse, was used in working between the rows, and is still necessary where root-weeds abound. This plough goes one bout, or up and down in each interval, turning the earth from the beans, and forming a ridgelet in the middle; then hand-hoes are immediately employed; and, after some time, a second hand-hoeing succeeds, to destroy any fresh growth of weeds. The same plough, with an additional mould-board, finally splits open the intermediate ridgelet, and lays up the earth to the roots of the beans on each side. The benefit of laying up the earth in this manner, however, is alleged to be counterbalanced by the trouble which it occasions in harvest, when it is difficult to get the reapers to cut low enough; and it may be properly dispensed with, unless the soil is very wet and level.

5243. In moist warm seasons, this grain hardly ever ripens effectually; and it is exceedingly difficult to get the straw into a proper condition for the stack. In such cases, it has been found of advantage to switch off the succulent tops with an old scythe blade set in a wooden handle, with which one man can easily top dress two acres a day. This operation, it is said, will occasion the crop to be ready for reaping a fortnight earlier, and also, perhaps, a week sooner ready for the stack-yard after being reaped.

5244. Before reaping beans the grain ought to be tolerably well ripened, otherwise the quality is impaired, whilst a long time is required to put the straw in such a condition as to be preserved in the stack. In an early harvest, or where the crop is not weighty, it is an easy matter to get beans sufficiently ripened; but, in a late harvest, and in every one where the crop takes on a second growth, it is scarcely practicable to get them thoroughly ripened for the sickle. Under these circumstances, it is unnecessary to let beans stand uncut after the end of September, or the first of October; because any benefit that can be gained afterwards, is not to be compared with the disadvantages that accompany a late wheat seed-time.

5245. Beans are usually cut with the sickle, and tied in sheaves, either with straw ropes, or with ropes made from peas sown along with them. It is proper to let the sheaves lie untied several days, so that the winning process may be hastened, and, when tied, to set them up on end, in order that full benefit from the air may be obtained, and the grain kept off the ground. (Brown.) 5246. Beans are sometimes mown, and, in a few instances, even pulled up by the roots. They should in every case be cut as near the ground as possible, for the sake of the straw, which is of considerable value as folder, and because the best pods are often placed on the stems near the roots. They are then left for a few days to wither, and afterwards bound and set up in shocks to dry, but without any head sheaves. (Supp. &c.)

5247. Beans are stacked either in the round or oblong manner; and it is always proper, in the northern counties at least, if the stack is large, to construct one funnel or

more to allow a free circulation of air.

5248. The threshing of beans is nearly as easy as that of peas. Threshing them by a machine may be considered advantageous as breaking the coarser ends of the straw, and separating the earth from their root-ends, or roots, if they have been reaped by pulling.

5249. The produce of beans, when proper management is exercised, and where diseases have not occurred, is generally from twenty-five to thirty-five bushels per acre. says, that a crop of beans, taking the island at large, may be supposed to vary from sixteen to forty bushels, but that a good average crop cannot be reckoned to exceed twenty. In Middlesex, Middleton tells us, that bean-crops vary from ten to eighty bushels per acre. They are rendered a very precarious crop by the ravages of myriads of small black insects of the A'phis kind. The lady-birds (Coccinélla) are supposed to feed on them, as they are observed to be much among them. Foot says, the average produce is from

three and a half to four quarters per acre. In Kent, A. Young thinks, they probably exceed four quarters; but in Suffolk, he should not estimate them at more than three; yet five or six are not uncommon.

5250. The produce in haulm, in moist seasons, is very bulky.

5251. In the application of beans, the grain in Scotland is sometimes made into meal, the finer for bread, and the coarser for swine; but beans are for the most part applied to the purpose of feeding horses, hogs, and other domestic animals. In the county of Middlesex, all are given to horses, except what are preserved for seed, and such as are poddcd while green, and sent to the London markets. When pigs are fed with beans, it is observed that the meat becomes so hard as to make very ordinary pork, but good bacon. It is also supposed that the mealmen grind many horse-beans among wheat to be manufactured into bread.

be manufactured into bread.

5252. The flour of beans is more nutritive than that of oats, as it appears in the fattening of hogs; whence, according to the respective prices of these two articles, Dr. Darwin suspects that peas and beans generally supply a cheaper provender for horses than oats, as well as for other domestic animals. But as the flour of peas and beans is more oily, he believes, than that of oats, it may in general be somewhat more difficult of digestion; hence, when a horse has taken a stomachful of peas and beans alone, he may be less active for an hour or two, as his strength will be more employed in the digestion of them than when he has taken a stomachful of oats. A German physician gave to two dogs, which had been kept a day fasting, a large quantity of flesh food; and then taking one of them into the fields, hunted him with great activity for three or four hours, and left the other by the fire. An emetic was then given to each of them; and the food of the sleeping dog was found perfectly digested, whilst that of the hunted one had undergone but little alteration. Hence it may, he says, be found advisable to mix bran of wheat with the peas and beans, a food of less nutriment, but of easier digestion; or to let the horses eat before or after them the coarse tussocks of sour grass, which remain in moist pastures in the winter; or, lastly, to mix finely cut straw with them. It is observed in the fifth volume of The Bath Papers, that it has been found by repeated experience, that beans are a much more hearty and profitable food for horses than oats. Being out of old oats the two last springs, the writer substituted horse-beans in their stead. In the room of a sack of oats with chaff, he ordered them a bushel of beans with chaff, to serve the same time. It very soon appeared the beans were superior to the oats, from the life, spirit, and sleekness of the horses. 5253. Bean straw, when mixed with peas, Brown considers as affording almost as much nourishment when properly harvested as is gained fr

quality.

5254. The produce of beans in meal is, like that of peas, more in proportion to the grain than in any of the cereal grasses. A bushel of beans is supposed to yield fourteen pounds more of flour than a bushel of oats, and a bushel of peas eighteen pounds more, or, according to some, twenty pounds. A thousand parts of bean flour were found, by Sir H. Davy, to yield 570 parts of nutritive matter, of which 426 were mucilage or starch, 103 gluten, and 41 extract, or matter rendered insoluble during the process.

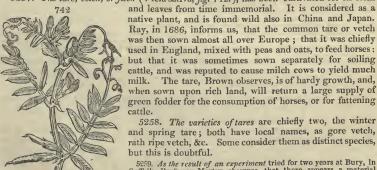

5255. The diseases of beans are, the rust, mildew, black fly or A'phides, and in conse-

quence the honey dews.

See A-phides, when they live on beans, are of a dirty bluish-black colour, similar to those on the elder and cherry. The larvæ of the Coccinella septempunctata, as well as the perfect insects, devour the A'phis. Several of the small summer birds, viz. largest willow-wren, middle, and smallest wren, white-throat, lesser white-throat, black-cap, and Dartford warbler, also live on them. The A'phides of beans are brought on byvery dry weather: they are most prevalent on the summits of the plants; and some have attempted to mitigate the evil by cutting off the tops. In general, however, the disease is without remedy, either preventive or positive. In extreme cases they destroy the leaves, stalks, and fruit; and when this is foreseen, the best thing the farmer can do is to mow the crop or plough it down, and prepare the land for wheat or otherwise, according to the rotation.

The Tare. — Vícia sativa L.; Diadélphia Decándria L., and Leguminosæ J. Vesce commun de printemps et d'hiver, Fr.; Wicke, Ger.; Loglio, Ital.; and Arveja, Sp.

5257. The tare, vetch, or fitch (Vicia sativa, fig. 742.), has been cultivated for its stem

5258. The varieties of tares are chiefly two, the winter and spring tare; both have local names, as gore vetch, rath ripe vetch, &c. Some consider them as distinct species,

5259. As the result of an experiment tried for two years at Bury, In Suffolk, Professor Martyn observes, that there appears a material difference in the constitution, if we may so call it, of the two tares in question. Not to say any thing of a triding difference in the colour and size of their seeds, the only visible mark of distinction seems to be a disparity in the first leaves of the upright stalks, which in the spring

tare are elliptic, and rounded or notched at the end, but in the winter tare linear and drawn to a point. The leaves on the branches which afterwards issue below, and in time form the bulk of the plants, are the same in both vetches. But, whatever the difference may be, it is evident that the seeds of the two sorts ought to be kept separate; since each sown out of its proper season is found not to prosper. 5270. New varieties of tare may be obtained by the usual means; and it is thought that some of the numerous species of this plant, which are natives of Europe, might be cultivated with advantage. The French cultivate a variety which they call Vesce blanche, or Lentille du Canada, Vicia sativa álba. They include also among their forage vetches Vicia angustifolia, Crácca, Pseddo-Crácca, biennis, sépium, and latea. The Vicia narbonénsis and serratifolia are cultivated in Germany. Dr. Anderson has recommended the V. sépium; and a writer in The Bath Agriculturul Transactions, the V. Crácca. Some species of Láthyrus, Orobus, and E ryum might probably also be tried with success.

5261. In choosing between the spring and winter tare, every thing must depend on the intention of the crop. If the object is to have early feed, the winter variety is undoubtedly to be preferred; but where the land is foul and requires to be two or three times ploughed in spring, or where a late crop is desired, or a crop for seed, then the spring variety will generally deserve the preference.

5262. The soil preferred by the tare is a clay, but they will grow in any rich soil not In a moist climate, the haulm grows so luxuriant as to rot at bottom; and in one over dry it is deficient in length. A dry season, however, is on the whole more favourable than a moist one, as this crop soon covers the surface.

5263. The preparation of the soil seldom consists of more than one ploughing, if for autumn sowing; and of a winter and spring ploughing, when to be sown in spring. If in the latter case the land is very foul, several ploughings are given, or one ploughing and several stirrings with the cultivator In general, tares succeed some of the corn crops. In England manure is sometimes given either with a view to eating them off early, and following with a crop of turnips, or to enriching the soil for a crop of wheat.

5264. The time of sowing depends on the kind of tare, and the purpose in view.

5265. The winter variety is sown in September and October; and the first sowing in spring ought to be as early as the season will permit. If they are to be cut green for soiling throughout the summer and autumn, which is the most advantageous method of consuming them, successive sowings should follow till the end of May. Summer tares, when meant for seed, Brown observes, ought to be sown early, "otherwise the return will be imperfect; but when for green food, any time betwixt the first of April and the latter end of May will answer well, provided crops in succession, from the first to the last-mentioned period, be regularly cultivated. Instances are not wanting of a full crop being obtained even when the seed was sown so late as the middle of June, though sowing so late is a practice not to be recommended. In Middlesex, the winter sowings are commenced about the beginning of August: in the northern counties no winter-sowings are made, as the tare there will not endure the severity of that season. that season.

5266. The mode of sowing tares is mostly broad-cast, which should be performed as evenly as possible over the surface of well-prepared land; the seeds being afterwards covered in by proper harrowing, in order to prevent their being picked up by birds, and ensure their perfect vegetation and growth. It has been suggested, however, that, in rich clean soil, it is probable the row-method would succeed well with this sort of crop, which, as Marshal states, is the practice in some of the southern districts of the island. After the seed is sown, and the land carefully harrowed, a light roller ought to be drawn across, so that the surface may be smoothed, and the scythe permitted to work without interruption. It is proper also to guard the field for several days against the depredations of pigeons, who are remarkably fond of tares, and will pick up a great part of the seed, unless constantly watched.

5267. The quantity of seed to an acre is from two and a half to three and a half bushels, according to the time of sowing, and to whether they are to be consumed green or left to

stand for a crop.

5268. When tares are intended for seed, less seed is required than when they are grown for soiling or for drying the haulm. A writer in The Farmer's Magazine (vol. i.) has suggested, that the most productive method of sowing this crop, when intended for seed, is to mix them amongst beans when drilled, at the rate of one firlot of tares to one boll of beans. From trials made it is ascertained, it is said, that the quality of the tares is vastly improved by being blended with beans, as, by clinging to the latter, they are kept from the ground, and enjoy the full benefit of the sun for ripening them in a perfect manner; and they are in this way much easier harvested than when sown by themselves. They answer, at the same time, for bands to tie the principal crop; and the produce may, on an average of seasons, be considered as at least double. A little rye sown with winter tares, and a few oats with the spring sort, not only serve to support the weak creeping stems of the tares, but add to the bulk of the crop by growing up through the interstices.

5239. In the choice of the seed it is hardly possible to distinguish the grain of the winter from that of the spring variety: the former is alleged to be rather smaller and lighter coloured; but the only reliance must be on the honesty of the vendor. Plump seed, and a sample free from the seeds of weeds, will of course be selected, whatever be the variety.

5270. The after culture given to tares consists merely in pulling out the larger weeds, unless they are in rows, in which case the horse or hand hoe is applied; or intended for seed, in which case weeding must be more particularly executed.

5271. In reaping tares for soiling they ought always to be cut with the scythe, as the sickle, by breaking asunder the stalks, and tearing up a number by the roots, renders the second crop of little value. When mown early, they will in a moist season produce three mowings, but generally two. In reaping tares for seed, they may be either mown or taken with the sickle, and treated like peas in drying, stacking, and threshing.

5272. Tares are eaten off the ground in some places by different kinds of live stock, particularly by sheep; and as the winter-sown variety comes early in spring, the value of this rich food is then very considerable. The waste, however, in this way, even though the sheep are confined in hurdles, must be great; and still greater when consumed

by horses or cattle.

5273. Tare crops are sometimes made into hay, in which case more attention is found necessary than in those of most of the artificial grasses, as wet is more injurious to them, and they require more sun and air; but in other respects they demand the same cautious management, in order to preserve the foliage from being lost. The time for cutting for this purpose is, according to the author of The Synopsis of Husbandry, when the blossoms have declined and they begin to fall and lie flat. When well made, the hay is of the best and most nutritious quality.

5274. The produce of tares cut green is, according to Middleton, ten or twelve tons per acre, which is a large crop; and when made into hay about three tons per acre, which shows the disadvantage of making these crops into hay. It is found that the spring tare-

crops are lighter, and most liable to be injured by a dry season.

5275. The produce in seed is likewise found to be considerable, being by some stated at from three to six sacks; but in other instances forty bushels, or more, have been obtained from the acre.

5276. In the application of tares they are found to be a hearty and most nourishing food

for all sorts of cattle.

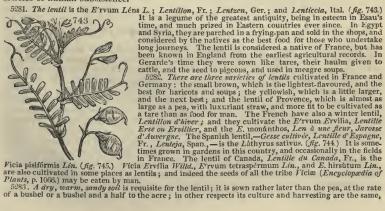

5277. Cows give more butter when fed with this plant than with any other food whatsoever. Horses thrive better upon tares than they do upon clover and rye-grass; and the same remark is applicable to the fattening of cattle, which feed faster upon this article of green fodder than upon any kind of grass or esculent with which we are acquainted. Danger often arises from their eating too much, especially when esculent with which we are acquainted. Danger often arises from their eating too much, especially when podded; as colics, and other stomach disorders, are apt to be produced by the excessive loads which they devour. Perhaps a great quantity of fixed air is contained in this vegetable; and as heavy crops are rarely dry at the root when cut, it is not to be wondered that accidents often happen, when the animal is indulged with the unrestrained consumption of them. Were out straw mixed with the tares in the racks or stalls in which they are deposited, it is probable that fewer accidents would follow, though this assistant is only required when the tares are wet, foul, or over succulent. If the plants are cut green, and given to live stock, either on the field or in the fold-yards, there is, perhaps, no green crop of greater value, nor any better calculated to give a succession of herbage from May to November. The winter-sown tare, in a favourable climate, is ready for cutting before clover. The first spring-crop comes in after the clover must be all consumed or made into hay; and the successive spring sowings give a produce more nourishing for the larger animals than the aftermath of clover, and may afford green food at least a month longer. In the county of Sussex, Young observes, "tare crops are of such use and importance that not one tenth of the stock could be maintained without them; horses, cows, sheep, hogs, all feed upon them; hogs are soiled upon them without any other food. This plant maintains more stock than any other plant whatsoever. Upon one acre Davis maintained four horses in much better condition than upon five acres of grass. Upon eight acres he has kept twelve horses and five cows for three months without any other food; no artificial food whatever is equal to this excellent plant." This statement must be coupled with the usual produce of turnips in Sussex, 10 or 15 tons per acre: hence the suppose superiority of tares to every other green crop. Tares cut green, Professor Thaer observes, draw n than hay or any other herbage.

5578, The use of the grain of tares is generally for reproduction; but they are also given to pigeons, by which they are highly relished, and it is thought they would form a very good food for poultry. In Germany they are given to horses, cows, sheep, and swine.

5279. The diseases of tares are so few as to be of no consequence. A crop is sometimes, but rarely, lost by mildew.

Sect. IV. Various Legumes which might be cultivated in British Farming.

5280. The lentil, kidneybean, and chick pea are grown both in France and Germany, as field plants, for their seeds, which are used as food. They are by no means likely to become articles of general culture in Britain; but it is worth while to know that they may be cultivated here instead of being imported, and also that they form very excellent articles of human subsistence.

and it ripens sooner. The lentil, Young observes, is a crop not uncommon about Chesterford in Essex, where they sow a bushel an acre on one ploughing in the beginning or middle of March. It is there the custom to make hay of them, or seed them for cutting into chaff for trough-meat for sheep and horses, and they sow them on both heavy and dry soils. It is, however, added, that the whole country is of a calcareous nature. It is likewise stated, that attention should be paid not to water horses soon after eating this sort of food, as they are apt to hove them. They are asserted to be cultivated for the same purpose in Oxfordshire, and probably in other districts.

5283. The produce of the lentil in grain is about a fourth less than that of the tare; and in straw it is not a third as much, the plants seldom growing above one foot and a half high. The straw is, however, very delicate and nourishing, and preferred for lambs and calves; and the grain on the Continent sells at nearly doubt the price of peas. Ein.

744

double the price of peas. Ein-hoff obtained from 3840 parts of lentils, 1260 parts of starch, and 1433 of a matter analogous to animal matter.

5285. The use of the lentil on the Continent is very general, both in soups and dressed with a butter sauce as haricot. They are imported from Hamburgh, and sold in London for the same purpose.

5286. The chick pea (Poischiche Gauance, Fr.; Cicer ariethum, fig. 52.), grows naturally in the south of Europe, and is cultivated there for the same purposes as the lentil, but it is too delicate for field culture in this coun-

try.

15287. The kidneybean (Phasebous vulgàris L.; Haricot, Fr.; Schminkbohne, Ger.; and Fagiuolo, Ital.) is a native of India, but ripens readily in dry summers in most parts of Britain. Its culture has been hitherto confined to gardens; but it might be grown equally well in dry, warm, rich, and sheltered soils, being grown in the fields of Germany, Switzerland, and in similar climates. The sort generally used for this purpose is the small dwarf white; the ground is prepared by several stirrings, and the seed is dibbled in rows eighteen inches or two feet asunder in the beginning of May. The ground is hoed and weeded during the summer, and the crop is ripe in August. It is usually harvested by pulling up the plants, which, being dried, are stacked or threshed. The haulm is of little bulk or use, but the seed is used in making the excemed French dish called harict, which it is desirable the cottagers of this country should be made acquainted with. There is, perhaps, no other vegetable dish so cheap and easily cooked, and at the same time so agreeable and nourishing. The beans are boiled and then mixed with a little sail butter or other fat, and a little milk or water and flour. From 3840 parts of kidneybean, Einhoff obtained 1805 parts of mucilage. Haricots and lentils are much used in all Catholic countries during Lent and maigre days, as they, from their peculiar constituents, form so excellent a substitute for animal food. During the prevalence of the Roman religion in this country, they were probably much more generally used than at present; as reformations are often carried farther than is necessary, possibly lentils may have been left off by Protestants, lest the use of them should be considered a symptom of popery.

5288. The white lumine (Lumin blanc, Fr.; Luphnus âlbus L., £g. 746.) a symptom of popery.

a symptom of popery.

5288. The white lupine (Lupin blanc, Fr.; Lupinus âlbus L., fig. 746.)
was cultivated by the Romans as a legume, and is still occasionally
grown in Italy and France. The seeds were formerly, and are sometimes
now, used as food; but more generally the whole plant is mown and
given as herbage to cattle, and sometimes the crop is ploughed down as manure.

CHAP. IV.

Plants cultivated for their Roots or Leaves in a recent State as Food for Man or Cattle.

5289. Plants cultivated for their roots or leaves are various, and most of them are adapted both for human food and that of domestic animals; but some are chiefly or entirely grown for the nurture of live stock. The plants which we include under this head, are the potato, turnip, carrot, parsnep, beet, cabbage tribe, lettuce, and chiccory. The culture of roots may be considered a branch of farming almost entirely of modern origin, and more peculiarly British than any other department. Turnips were cultivated by the Romans, and in modern times brought into notice as objects of field culture in the last century; but they were most imperfectly managed, and of very little utility in agriculture till their culture was undertaken by the British farmer. potato, carrot, and parsnep were also first cultivated in the fields of this country. Friable or light soil, superior pulverisation and manuring, the row-method, and careful after-culture, are essential to the maturation of the plants to be treated of in this Chapter; and hence the importance of such crops as preparations for those of the bread corns.

5290. The nutritive products of these plants are thus given by Sir H. Davy: -

		In 1000 Parts.					
Systematic Name.	English Name.	Whole quantity of soluble or nutritive matter.	Mucilage or starch.	Saccharine matter or sugar.	Gluten or albumen.	Extract, or matter ren- dered inso- luble during evaporation.

Sect. I. The Potato. - Solanum tuberosum L.; Pentandria Monogýnia L., and Soldnea J. Pomme de Terre, Fr.; Cartoffel, Ger.; Tartufflo or Pomo di Terra, Ital.; and Batata, Span.

5291. The potato is ascertained to be a native of South America, having been found wild both in Buenos Ayres and in Chili; though Humboldt was very doubtful if that could be proved: he admits, however, that it is naturalised there in some situations. Sir J. Banks (Hort. Trans. vol. i. p. 8.) considers that the potato was first brought into Europe from the mountainous parts of South America, in the neighbourhood of Quito, where they were called papas, to Spain, in the early part of the sixteenth century. From Spain, where they were called battatas, they appear to have found their way first to Italy, where they received the same name with the truffle, taratoufli. The potato was received by Clusius, at Vienna, in 1588, from the governor of Mons, in Hainault, who had procured it the year before from one of the attendants of the Pope's legate, under the name of taratouflo, and learned from him that it was then in use in Italy. In Germany it received the name of cartoffel, and spread rapidly even in Clusius's time.

of taratouffo, and learned from him that it was then in use in Italy. In Germany it received the name of cartoffel, and spread rapidly even in Clusius's time.

5292. To England the potato was brought from Virginia by the colonists sent out by Sir Walter Raleigh in 1584, who returned in July 1586, and "probably," according to Sir Joseph Banks, "brought with them the potato." Thomas Herrici, in a report on the country, published in De Bry's Collection of Vogages, (vol. i. p. 17.), describes a plant called openank (not openank), as in the Hort. Trans.), with "roots as large as a walnut, and others much larger; they grow in damp soil, many hanging together, as if fixed on ropes; they are good food, either boiled or roasted." Gerarde, in his Herbal, published in 1597, gives a figure of the potato, under the name of the potato of Virginia, whence, he says, he received the roots; and this appellation it appears to have retained, in order to distinguish it from the battatas, or sweet potato (Convôlvulus Batàtas), till the year 1640, if not longer. "The sweet potato," Sir Joseph Banks observes, "was used in England as a delicacy long before the introduction of our potatoes: it was imported in considerable quantities from Spain and the Canaries, and was supposed to possess the power of restoring decayed vigour. The kissing comfits of Falstaff, and other confections of similar imaginary qualities, with which our ancestors were duped, were principally made of these and of eringo roots."

5293. The potato was first planted by Sir Walter Raleigh, on his estate of Youghall, near Cork, and, Gough says, was "cherished and cultivated for food" in that country before its value was known in England; for, though they were soon carried over from Ireland into Lancashire, Gerarde, who had this plant in his garden in 1597, under the name of Battòta virginiàna, recommends the roots to be eaten as a delicate dish, not as common food. Parkinson mentions, that the country of Galway, that the potato was introduced there previous to its bein

5295. Potatoes, as an article of human food, are, next to wheat, of the greatest importance in the eye of the political economist.

5296. From no other crop that can be cultivated will the public derive so much food as from this valuable esculent; and it admits of demonstration, that an acre of potatoes will feed double the number of people that can be fed from an acre of wheat. Potatoes are also a nourishing and healthy food, relished by almost every palate; and it is believed there is hardly a dinner served up for six months in the year without them, in any part of the kingdom. Notwithstanding all these things, and they are of great importance in one point of view, we are doubtful whether potatoes can be placed so high in the scale as

They require a great deal of manure, while, generally speaking, little is returned by them; they are a bulky unhandy article, troublesome in the lifting and carrying processes, and interfering with the seed season of wheat, the most important one to him; and, from particular circumstances, they cannot be vended unless when raised in the vicinity of large towns: hence they are in most respects an unprofitable article. To the farmer, the real criterion is the profit which potatoes will return in feeding beasts; and here, we apprehend, the result will altogether be in favour of turnips, and rutabága, as the most profitable articles for the turners.

articles for that purpose.

5227. What is called the yam, or Surinam potato, was formerly considered of importance to the farmer, as an assistant to his turnip crop, or rather a succedaneum, which is of material benefit when turnips are consumed; but as this variety cannot be used as human food, the extension of its culture cannot be recommended. By cultivating any of the good eating sorts for the use of cattle, a succedaneum may be had for the human species in years of scarcity.

5298. The value of potatoes as a fallow crop, and as an article of food for cattle compared with turnips and cabbages for the same purposes, Marshal observes, may be considered thus:

5299. Potators are more nutritious; and, in the opinion of those who have used them, fatten cattle much quicker than either turnips or cabbages. Potatoes, too, being secured from the severities of winter, are a more certain article of fatting than turnips or cabbages; both of which are liable to perish under an alternation of frost and thaw; and the turnip, more particularly, is locked up, or rendered more difficult to be come at, during a continuance of snow or frost. Turnips and cabbages, if they out weather the severities of winter, occupy the soil in the spring when it should be prepared for the succeeding crop; while potatoes, if properly laid up, are a food which may be continued without inconveniency until the cattle be finished, or the grass has acquired the requisite bite for finishing them in the field. On the other hand, notices are allowed proposed to the property of coultivate. the planting is a todious dirty business: and taking hand, potatoes are a disagreeable crop to cultivate: the planting is a tedious dirty business; and taking them up may be called the filthiest work of husbandry, especially in a wet autumn. A powerful argument for the extensive culture of potatoes as food for live stock is, that in seasons of searcity they can be adopted as human food. Here, as in many other points, the opinion of Marshal and other English agriculturists is rather at variance with that of the Northumberland and Berwickshire cultivators. In Berwickshire and Roxburghshire, a crop of potatoes is often taken before turnips, by means of which the land is restored to a fertile state,

5300. The varieties of the potato are innumerable: they differ in their leaves and bulk of haulm; in the colour of the skin of the tubers; in the colour of the interior compared with that of the skin; in the time of ripening; in being farinaceous, glutinous, or watery; in tasting agreeably or disagreeably; in cooking readily or tediously; in the length of the subterraneous stolones to which the tubers are attached; in blossoming or not blossoming; and, finally, in the soil which they prefer.

5301. The earliest varieties of the potato are chiefly cultivated in gardens, and therefore we shall only notice such early sorts as are grown in the fields. These are —

The early kidney, The nonsuch, The early shaw, and The early champion. The last is the most generally cultivated round London; it is very prolific, hardy, and mealy. Early varieties, with local names, are cultivated near most large towns, especially Manchester, Liverpool, Glasgow, Edinburgh, and the metropolis.

5302. The late field varieties in most repute are -The red-nosed kidney.

The recursors.

Large kidney.

Bread fruit, raised in 1810, from seed, and esteemed one of
the best field potatoes, being white, mealy, well tasted,

and prolific. Lancashire pink eye, good.

Black skin, white interior, and good. Purple, very mealy, productive, and keeps well. Red apple, mealy, keeps the longest of any. Tartan, or purple and white skinned, an esteemed Scotch potato, prolific, mealy, exceedingly well tasted, and keeps well.

5303. The varieties grown exclusively as food for live stock are -

The yam or Surinam potato; large, red and white skinned, and the interior veined with red; flavour disagreeable, and not such as to admit of its being used as human food. It succeeds best on heavy lands.

The ox noble; large, yellow without and within, very prolific, not fit to eat.
The late champion; large and prolific, white skinned, and may be used as human food.

not such as to admit of its being used as human food. It The late champion; large and prolific, white skinned, and may succeeds best on heavy lands.

5304. New varieties of potatoes are procured with the greatest case. The following directions are given in a useful work on this plant: — Pluck off the apples when the stalk has ceased to vegetate and is drying up. The seed being then fully ripe, break the apple in a hair sleve, wash the pulp clean from the seeds, and dry them in the sun; then sow the seed in beds in March, and take the potatoes up in October. They will attain the size of nutmegs, or at most be no larger than walnuts. Select the fairest and best, and keep them secure from frost by thoroughly drying, and intermixing, and covering them with sifted wood or coal-ashes. Plant them in April following, at the distance of fifteen inches asunder; and when the plant is two inches high, hill them with fresh earth. This may be done several times, constantly taking care to keep them clean from weeds. Observe when the stalks decay; some will be found decaying much sooner than others; these are the early kinds, but those that decay last are the sorts which come late. Take them up in rotation as they ripen, and let the produce of each potato be kept scarate till the next year. Such as come early may be tried as soon as they are taken up, by dressing one or two: should they be approved, the remainder may be preserved; but those which are late should not be fried before January or February, for it will be found that the late kind of potatoes, newly raised, are very soft, and cut like soap, until they have been locardees; those planted the third year may, perhaps, produce two sacks; and their increase afterwards will be very considerably greater. Thus it takes full three years to form an adequate judgment of potatoes raised from seed; and, after all, if one in ten succeed so as to be worth preserving, it is as much as can be reasonably expected. In general, the produce of the seed will resemble the parent stock; but

These he cultivated in his fields, deeming them preferable to all other sorts as admitting of later planting and earlier removal; and this practice he justly considered as highly favourable to the succeeding crop

of wheat.

5306. In choosing a sort or sorts of potatoes from the numerous varieties which are to be found every where, perhaps the best way is, for the selector to procure samples and taste them, and to fix on what best pleases his palate. The shaw is one of the best early potatoes for general field culture; and the kidney and bread-fruit are good sorts to come in in succession. The Lancashire pink is also an excellent potato; and we have never in any part of the British Isles tasted a potato equal in mealiness and flavour to this variety, as cultivated round Prescot, near Liverpool. The red apple and tartan are of undoubted preference as late or long keeping potatoes. The yam is decidedly the best potato for stock, and will produce from twelve to fifteen tons per acre.

5307. The soil in which the potato thrives best is a light loam, neither too dry nor too moist, but if rich, it is so much the better. They may, however, be grown well on many other sorts of lands, especially those of the mossy, moory, and similar kinds, where they are free from stagnant moisture, and have had their parts well broken down by culture, and a reasonable portion of manure added. The best-flavoured table potatoes are almost always produced from a newly broken up pasture ground not manured; or from any new soil, as the site of a grubbed up copse or hedge, or the site of old buildings or roads. Repeated on the same soil they very generally lose their flavour. The yam produces the largest crops on a loamy and rather strong soil, though it will grow well on any that is deeply ploughed and well manured.

deeply ploughed and well manured.

5308. In preparing the soil for potatoes, it is of much importance to free it as completely as possible from root weeds, which cannot be so well extirpated afterwards, as in the culture of turnips, and some other drilled crops, both because the horse-hoe must be excluded altogether at a time when vegetation is still vigorous, and because at no period of their growth is it safe to work so near the plants, especially after they have made some progress in growth. It is the earlier time of planting, and of finishing the after-culture, that renders potatoes a very indifferent substitute for fallow, and in this respect in no degree comparable to turnips. For this reason, as well as on account of the great quantity of manure required, their small value at a distance from large towns, and the great expense of transporting so bulky a commodity, the culture of potatoes is by no means extensive in the best managed districts. Unless in the immediate vicinity of such towns, or in very populous manufacturing counties, potatoes do not constitute a regular rotation crop, though they are raised almost every where to the extent required for the consumption of the farmer and his servants, and, in some cases, for occasionally feeding horses and cattle, particularly late in spring. The first ploughing is given soon after harvest, and a second, and commonly a third, early in spring; the land is then laid up into ridgelets, from twenty-seven to thirty inches broad, as for turnips, and manured in the same manner. and manured in the same manner.

and manured in the same manner.

5309. The best manure for the potato appears to be littery farmyard dung; and the best mode of applying it, immediately under the potato sets. Any manure, however, may be applied, and no plant will bear a larger dose of it, or thrive in coarser or less prepared manure: even dry straw, rushes, or spray of trees, may be made use of with success. It is alleged, however, that recent horse manure, salt, and soapers' ashes, have a tendency to give potatoes a rank taste, and to render them scabby.

5310. The best climate for the potato is one rather moist than dry, and temperate or cool, rather than hot. Hence the excellence of the Irish potatoes, which grow in a dry, loamy, calcareous soil, and moist and temperate climate: and hence, also, the inferiority of the potatoes of France, Spain, and Italy, and even Germany. In short, the potato is grown nowhere in the world to the same degree of perfection as in Ireland and Lancashire, and not even in the south of England so well as in Scotland, and the north and western counties: all which is, in our opinion, clearly attributable to the climate.

5311. The season for planting potatoes in the fields, depends much on the soil and climate. Where these are very dry, as they always ought to be for an early crop, the sets are usually put in the ground in March or earlier; but for a full crop of potatoes, April is the best time for planting. Potatoes, indeed, are often planted in the end of May, and sometimes even in June; but the crops, although often as abundant, are neither so mellow nor mature as when the sets are planted in April, or in the first eight or ten

days of May. For seed, however, they are preferable.

5312. In preparing the sets of potatoes, some cultivators recommend large sets, others small potatoes entire, and some large potatoes entire. Others, on the ground of experience, are equally strenuous in support of small cuttings, sprouts, shoots, or even only the eyes or buds. With all these different sorts of sets, good crops are stated to have been raised, though tolerable-sized cuttings of pretty large potatoes, with two or three good eyes or buds in each, are probably to be preferred.

or buds in each, are probably to be preferred.

5313. Independently of the increased expense of the seed, it is never a good practice to make use of whole potatoes as sets. The best cultivators in Ireland and Scotland invariably cut the largest and best potatoes into sets, rejecting, in the case of kidney potatoes, the root or mealy end as having no bud, and the top or watery end as having too many. No objection is made to two or even three buds on each set, though one is considered sufficient. A very slight exercise of common sense might have saved the advocates for shoots, scooped out eyes, &c., their experiments and arguments, it being evident, as Brown has observed, to every one with any practical knowledge of the nature of vegetables, that the strength of the stem at the outset depends in direct proportion upon the vigour and power of the set. The set, therefore, ought to be large, rarely smaller than the fourth part of the potato; and if the potato is of small size, one half of it may be profitably used: at all events, rather err in giving over-large sets, than in making them too small; because by the first error no great loss can be sustained; whereas, by the other, a feeble and late crop may be the consequence. It is ascertained beyond doubt in Lancashire, Cheshire, and other counties in the north and west of England, that sets taken from the top or watery end of the potato, planted at the same time with sets taken at the root or mealy end, will ripen their tubers a fortnight sooner. It is ascertained also, and accounted for on the same general principle, that the plants raised from unripe tubers are both vigorous and more early than such as are raised from tubers perfectly ripe. (See Gard.Mag.vol.ii.) 5314. Sets should always be cut some days before planting, that the wounds may dry up; but no harm will result from performing this operation several weeks or months beforehand, provided the sets are not exposed too much to the drought so as to deprive them of their natural moisture.

5315. The quantity of sets depends on the size of the potatoes; in general, where the sets are sufficiently large, from eight to ten cwt, will be required for an acre: more than ten for yams, and fewer than eight cwt. for the early nonsuch and ash-leaved.

The modes of planting the potato are various.

5316. The modes of planting the potato are various.

5317. Where spade culture is employed, they are very frequently planted on beds (provincially lazy-beds), of four or six feet wide, with a trench or gutter of a foot or eighteen inches in width between, which supplies soil for earthing up the potatoes. This is the rudest mode of planting and cultivating potatoes, and unworthy of being imitated either on a farm or in a garden. The next mode is planting on a plain surface, either with or without manure, according to the state of the soil. Here the sets are placed in rows, with a distance of from eighteen inches to two feet and a half between the rows according to the kind of potato, and from four to nine inches in the rows. In planting, a hole for each set is made by a man with a spade, while a woman or boy drops the set, and the earth is replaced; or the potato dibber is used, and the ground afterwards slightly harrowed. Another mode of planting on a plain surface, when the soil is inclined to be dry, is in some cases practised, which is, after the land has been brought into a proper condition by ploughing over twice or oftener and well harrowed, to spread the manure regularly over the whole surface, the sets being planted in every third furrow, and the dung with the fine earth turned upon them by the next furrow of the plough. In this way the manure is however placed upon the sets, which has on experiment been fully shown to be injurious to the produce. Besides, from the whole, of the surface of the ground being covered with dung, a considerably larger proportion must be requisite than when deposited only in the drills, and of course the crop cannot be cultivated to advantage in that respect.

of the surface of the ground being covered with dung, a considerably larger proportion must be requisite than when deposited only in the drills, and of course the crop cannot be cultivated to advantage in that respect.

5318. In planting the potato on sward land, after it has been prepared by the use of a plough that just pares off the surface and deposits it in the furrow, it is advised by Somerville to place the sets upon the inverted sod, and cover them with the loose mculd from below by means of a common plough; or the trench plough may be used with perhaps more advantage; but a better method is that of paring and burning. In some cases the practice is, however, to turn down the turf with or without manure, and then to put in the sets by a dibble; though the former is probably the better practice, as the turfy material on which the sets are put soon begins to decay, and the purpose of a manure is in some measure answered by it. It is a plan that may be adopted with advantage where manure is carce, as in bringing waste and other coarse grass lands into the state of preparation for grain crops.

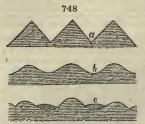

5319. A mode of planting potatoes and at the same time trenching the land, is practised in Lancashire, and in some districts in the north-east of Scotland. The farmer having carried the dung, and laid it on the field in heaps, at proper distances, the operation is performed by the manufacturers and people who rent the field, and in the following manner:— Across the end of the ridge a trench is formed, about three feet wide, and from ten to fourteen inches deep, according to the depth and quality of the subsoil. That being done, a second trench of the same breadth is marked off, and the surface-soil, to the depth of six or eight inches, is thrown into the bottom of the former trench, over which a sufficient quantity of dung being laid, the potatoes are planted at the distance of eight or ten inches from each other, and then as much earth is taken from the bottom of the former trench, over which a sufficient quantity of wards sown.

5320. The mode of planting potatoes practised by the best farmers of the northern districts, is in drills formed by the plough in the same manner as in preparing the land for turnips. The soil is laid up into ridgelets from twenty-seven to thirty inches broad, the manure is distributed between them, and on this manure the sets are placed from four to eight inches asunder; they are then covered by reversing

drills formed by the plough in the same manner as in preparing our minor of such that into ridgelets from twenty-seven to thirty inches broad, the manure is distributed between them, and on this manure the sets are placed from four to eight inches assunder; they are then covered by reversing the ridgelets.

5321. The planting of early potatoes is carried to a very high degree of perfection in Lancashire. It is stated in The Lancashire Agricultural Report, in respect to the raising of seed potatoes, that upon the same ground from which a crop has already been taken, the early seed-potatoes are in some places afterwards planted; which, after being got up about November, are immediately cut up into sets, and preserved in oat busks or saw-dust, where they remain till March, when they are planted, after having had one sprout taken off, which is also planted. The sprouts are of a length sufficient to appear above ground in the space of a week. But the most approved method is, to cut the sets, and put them on a room-floor, where a strong current of air can be introduced at pleasure, the sets laid thinner, as about two layers in depth, and covered with the like materials (chaff or saw-dust) about two inches thick: this screens them from the winter frosts, and keeps them moderately warm, causing them to vegetate; but at the same time admits air to strengthen them, and harden their shoots, which the cultivators improve by opening the doors and windows on every opportunity afforded by mild soft weather. They frequently examine them; and when the shoots are sprung an inch and a half, or two inches, they carefully remove one half of their covering, with a wooden rake, or with the hands, taking care not to disturb or break the shoots. Light is requisite, as well as air, to strengthen and establish the shoots; on which account a green-house has the advantage of a room, but a room answers very well with a good window or two in it, and if to the sun still better. In this manner they suffer them to remain till the planting seaso

Some lay the potatoes intended for plants early in the year, before they are wanted to be cut, loose and separate in straw, or on warm boarded floors; and others put them on flakes or frames, in warm situations near the fire, for the same purpose, in order that they may sprout; and when so sprouted to the length of balf an inch or an inch, they are then carefully cut as described, assorted, and planted. (Card. Mag.

sprouted to the length of half an inch or an inch, they are then carefully cut as described, assorted, and planted. (Gard. Mag. vol. i. p. 407.)

5323. In the north of Lancashire the potatoes are removed from their winter quarters in the last week of January, and spread out on a floor or placed on shewe in a room where a fire is kept, or in an upper room of a warm house. On the 2d of February they are covered with a blanket or woollen cloth for about four weeks, which is then taken off in order to harden the sprouts. Towards the latter end of March the sprouts will be found about two inches long, and, if they are carefully set, the potatoes will be ready in seven or eight weeks afterwards. Some bring the sets forward by spreading them, out and slightly covering them with light mould under the stage or on the shelves of a greenhouse, or in a cucumber frame, or in a loft over a stable or cow-house. (Gard. Mag. vol. ii, p. 48.)

5324. In Denbighshire the early potatoes cultivated are the Foxley, the Nelson, and the Rufford kidney. Potatoes intended for sets the following year are taken up before they are ripe, just when the outer skin peels off, and before the stalk or stem begins to wither; they are then laid upon a gravel walk, or any dry surface fully exposed to the sun: they remain in that situation for a month or six weeks, when they become quite green and soft, as if roasted, and often much shrivelled; they are then put away in a cellar or pit, where they will remain dry, and often much shrivelled; they are fit to be planted. The tubers are therefore cut, seldom into more than two sets, viz. the eye or top part, which is planted by itself, and found to come a fortnight earlier; and the root or bottom part, which succeed them. (Gard. Mag. vol. ii, p. 172.)

tubers are therefore cut, seldom into more than two sets, viz. the eye or top part, which is planted by itself, and found to come a fortnight earlier; and the root or bottom part, which is planted by itself, and found to come a fortnight earlier; and the root or bottom part, which succeed them. (Gard. Mag. vol. ii, p. 172.)

5325. In gardens in the south of England potatoes are planted in a warm border from the first week of October, till the latter end of November. They are placed nine or ten inches under the surface, and well covered with dung. About the latter end of March they begin to appear above the surface, when the ground is deeply hacked with a mattock, and made very loose about the plants; then in a fortnight or three, weeks move the surface again, but the plants need not be earthed up unless they are very much exposed to the wind, when a little may be drawn about them to keep them steady. By this method fine ash-leaved kidney potatoes may be gathered by the 12th or 15th of May, even in situations not very favourable for early crops, and nearly three weeks earlier than they can be gathered from scts planted in the same situation in the latter end of February; and if ordinary care is taken in planting, no danger need be apprehended from the frost. (Gard. Mag. vol. vi. p.59.) Every farmer knows that, among the corn raised after a crop of potatoes, potato plants will be found which can only have sprung from tubers preserved there all the winter, in consequence of having been buried by the plough deeper than the frost could reach. It is evident, therefore, that this garden mode of raising a crop of early potatoes might be douded in the field, more especially where the soil was dry; but the success would depend entirely on the deep pronging or grubbing of the soil between the rows early in spring. This might be done to the same degree of perfection as in the garden by the excellent implements of Wilkie or Kirkwood. (2656, and 5326. In Cornwall early potatoes are planted in October, spring up a few males o

4955.)
5336. In Cornwall early potatoes are planted in October, spring up a few weeks afterwards, are ready before the autumnal frost stops their growth, and the soil being covered with litter to exclude the frost, they are begun to be used about the end of December, and continue in use till May, when they are succeeded by the spring planted crops. Of late years Covent Garden market has received supplies of early potatoes from Cornwall, treated in the above manner. (Gard. Mag. vols. ii. v. vi.) Farly potatoes, when they first come through the ground, are liable to be injured by spring frosts; but there is an easy and effectual remedy to every cultivator who will take the trouble—and that is to water them, so as to thaw off the frost before sunrise. In Ayrshire, where even late potatoes are liable to this injury, acres are sometimes so watered on a single farm; all the hands being called to business by the break of day, and the water being sprinkled on the young sprouts, from vessels of any sort, by means of a handful of straw. A garden-pot and rose would of course answer better.

5327. The after culture of potatoes consists in harrowing, hoeing, weeding, and earthing up.

5938. All potatoes require to be earthed up, that is, to have at least one inch in depth of earth heaped on their roots, and extending six or eight inches round their stem. The reason of this is, that the tubers do not, properly speaking, grow under the soil, but rather on, or just partially bedded in, its surface. A coating of earth, therefore, is found, by preserving a congenial moisture, greatly to promote their growth and magnitude, as well as to improve their quality, by preventing the potatoes from becoming green on the side next the light. The earth may be thrown up from the trenches between the beds by the spade; or, where the potatoes are planted in rows, the operation may be performed with a small plough, drawn by one horse, or by the hoe. In Scotland, where the potato is extensively cultivated by the farmer, as food for cattle as well as man, the plough is universally used. In Ireland, where the bed, or lazy-bed, manner is adopted, the earth is thrown up from the intervening trenches. The hoe is generally used by market_argleers

manner is adopted, the earth is thrown up from the intervening trenches. The noe's generally dead by market-gardeners.

5329. The after-culture, where potatoes are planted in ridgelets, as above described (5319.), commences when the plants begin to rise above the surface. They are then harrowed across, and afterwards the horse-hoe, or small hoeing plough, and the hand-hoe are repeatedly employed in the intervals, and between the plants, as long as the progress of the crop will permit, or the state of the soil may require. The earth is then gathered once, or oftener, from the middle of the intervals towards the roots of the plants, after which any weeds that may be left must be drawn out by hand; for when the radicles have extended far in search of food, and the young roots begin to form, neither the horse nor hand-hoe can be admitted without injury.

without injury.

without injury.

5330. The after-culture adopted in some parts of Devonshire is somewhat singular, and deserves to be noticed. The sets are there generally cut with three eyes, and deposited at the depth of three inches with the spade or dibber: when the first shoot is three inches high, prepare a harrow with thorns interwoven between the tines, and harrow the ground over till all the weeds are destroyed, and not a shoot of the potatoes left. It may seem strange that such an apparent destruction of a crop should cause an increase; but it may be affirmed as an incontestable fact, that by this means the produce becomes more abundant. The reason appears to be this: although three eyes are left to a piece of potato, one always vegetates before the others, and the first shoot is always single; that being broken off, there is for the present a cessation of vegetation. The other eyes then begin to vegetate, and there appear fresh shoots from the broken eye; so that the vegetation is trebled, the earth made loose, and the lateral shoots more freely expanded. If these hints are observed, the produce of potatoes, it is said, will exceed a fifth of the crop obtained by the usual mode of cultivation.

3 I

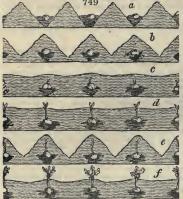

5331. The culture of potatoes in the district of Kintyre is thus given by an intelligent writer in the Transactions of the Highland Society.

5332. The land is generally ploughed as early in spring as possible, and that at least twice. In cases where the two ploughings do not sufficiently pulverise the ground, it receives a third, and after every ploughing is well harrowed. The greatest attention ought always to be given to these preparatory operations.

properations.

5333. The ground being now prepared, and the season for planting arrived, drills are made for receiving the seed with the common plough; these are drawn about two feet asunder, and three inches in depth. The first seven of them are all drawn from one end of the field, the plough returning out of work from the other end, in order to affort time and room for the operation of putting in the seed, and also the dung, where this last operation is rendered necessary. By the time the ploughman has drawn three of these shallow drills or furrows, the persons in charge of the seed begin to plant the first of them, laying each plant at a distance of from nine to ten inches; these are followed by others who put the dung on the top of it, in the case already mentioned, where the manure is to be put into the drill. The ploughman, having completed seven of these drills, may now proceed to return, by ploughing to the depth of seven inches between the first and second drills, so as to cover the seed in the first. He then opens another of the shallow drills of three inches, at the distance of two feet, as before mentioned, from the last which he had made, being the seventh; and returning back, he makes another of the seven inche deep furrows between the second and third rows of seed, which covers the second: returning, he opens another seed-drill; and back again a deep one, between the third and fourth rows of seed, which covers the third row; and so on from each end of the field. In this manner the drilling and planting will proceed, without any interruption or interference the one with the other, the plough having at first attained a sufficient distance from the planters to have always a drill open before they can overtake it. The great advantage of placing the seven for much nearer the surface than the deeper furrow alongside of it is, that it is more effectually preserved from the bad effects of wet or damp, consequently less liable to be injured by frost, and it springs sooner. sooner.

sooner.
5334. In this state the field is allowed to remain from a fortnight to three weeks, when it is cross harrowed to a perfect level. Afterwards, as soon as the drills can be distinguished by the potatoes shooting above the ground, the plough is again applied, and the drills are formed as before; but in doing so, the plough is taken as close as possible to the plant upon both sides; on one side the plough is lightly put in, but on the other it is inserted as deep as possible, throwing the soil over on its neighbouring row of seed, filling up the vacuum which the plough had previously left at it, and forming at the same time a ridge, as it was originally, on the top of the plant. What is thus ploughed in the forenoon is cross harrowed completely level during the same afternoon. The great advantage which I apprehend to be derived from this process is the loosening of the soil, destroying the weeds, and the saving of hand-hoeing. I am satisfied, from my own particular experience and observation, that this mode of treating the young growth of the potato is far preferable to any other I have seen practised, either here or elsewhere, however forbidding the rough usage thus given to the young plant may appear to one inexperienced in this particular mode of cultivating it.

process is the loosening of the soil, destroying the weeds, and the saving of hand-hocing. I am satisfied from my own particular experience and observation, that this mode of treating the young growth of the potato is far preferable to any other I have seen practised, either here or elsewhere, however forbiding the rough usage thus given to the young plant may appear to one inexperienced in this particular mode of cultivating it.

5335. As soon as the vecets begin to appear, the plough is again introduced, which, in the idium of this country, is called "taking from the potatoes," which is done by running pretty close to the plant of this country, is called "taking from the potatoes," which is done by running pretty close to the plant of this country, is called "taking from the potatoes," which is done by running pretty close to the plant of this country, is called "taking from the potatoes," which is done by running pretty close to the plant of the certain the composing the may say the plant of the plough between the rows, and esperating the earth composing the middle ridge above mentioned, towards the plant on each side, but without covering it. After this, the process of "putting to" of earth is continued as the plant grows, and takes place at least twice, until the stems are so high that a single horse going among them may seriously injure them. The "putting to" will now be understood as a deeper insertion of the plough is received by an experienced cultivator in the putting to "will now be understood as a deeper insertion of the plough in the middle of the drill. The whole of the labour of ploughing, drilling, "taking from," and "putting to" the potatoes, a showed escribed, is performed with the common plough." (Hight, Soc. Trans. vol. viii, p.63)

5336. The field culture of the potato in Argyleshire is thus given by an experienced cultivator in the field with the sent way as for turnings, and place the field, which is then planted, the plough going one bout along the furrows of the potatoe, the plant have

per acre of additional tubers will be produced. The experiments are related in the second volume of *The Horticultural Transactions*, and the practice is similar to one common among the growers of bulbous roots in Holland, as alluded to by Dr. Darwin, who also recommends its application to the potato. A woman or boy will crop the blossoms from an acre of potatoes in a day, or even in less time, when the crop is not excessively luxuriant.

5338. The taking of the crop of potatoes on a small scale is generally performed with the spade or three-pronged fork; but under judicious farm management, and the row culture, by the common plough.

5339. The coulter is removed and the plough goes first along one side of all the ridgelets of a ridge, or any convenient breadth, and then, when the potatoes so brought to view are gathered by women placed at proper distances, it returns and goes along the other side. When the land is somewhat moist, or of a tenacious quality, the furrow-slice does not give out the roots freely, and a harrow which follows the plough is commonly employed to break it and separate them from the mould. Various contrivances have been resorted to for this purpose. A circular harrow or break, of very recent invention, to be attached to the plough, has been found to answer the purpose well, and to effect a considerable saving of labour. A machine for taking up and collecting potatoes is said to have been invented by Mr. Michael Barry of Swords near Dublin; but though we have written to that gentleman, we have been unable to procure a description or drawing of his invention.

Swords near Dublin; but though we have written to that gentleman, we have been unable to procure a description or drawing of his invention.

5340. A mode of taking part of a crop suited to cottagers and others, especially in years of scarcity, deserves to be mentioned. Having ascertained that some of the tubers have attained an eatable size, go along the rows and loosen the earth about each plant with a blunt sitek, taking two or three of the largest tubers from each and returning the earth carefully. By keeping the edge of the blunt spatula or spade perpendicular to the main stem of the plant, the flat side will be parallel to the radiating roots, by which means they will be comparatively little injured. By this means both an early supply, and the advantage of two crops, may be obtained; for the tubers which remain will increase in size, having now the nourishment destined to complete the growth of those removed.

5341. Potatoes intended for seed should be taken up a fortnight or three weeks before being fully ripe, for reasons that have been given in treating of early potatoes, and will be recurred to in treating of the diseases of this plant. The ill shaped, small, bruised, or diseased tubers should be laid aside, and the fairest and best dried in the sun, spread on a cellar or loft floor, and covered with ashes, or chaff of sufficient thickness to keep out the frost. In this state they may remain till wanted for cutting. Some persons in Ireland plant potatoes from which they intend to procure sets extremely late, namely, the first week in July. The produce consequently never attains the same degree of size or ripeness as that of an earlier planted crop. earlier planted crop.

5342. Potatoes are stored and preserved in houses, cellars, pits, pies, and camps. ever mode is adopted, it is essential that the tubers be perfectly dry, otherwise they are certain of rotting, and a few rotten potatoes will contaminate a whole mass.

5343. The most effectual mode, and that which is generally adopted, consists in putting them into close houses, and covering them well up with dry straw. In some parts of Scotland it is a common practice to dig pits in the potato-field, when the soil is dry and light, and, putting in potatoes to the depth of three or four feet, to lay a little dry straw over them, and then cover them up with earth, so deep that no frosts can affect them. Another method, which is practised in England as well as Scotland, is to put them together in heaps, and cover them up with straw, in the manner of preserving turnips, with this addition, that the heaps are afterwards well covered with earth, and so closely packed together as to exclude frost. The farmers in Lancashire in the course of taking them up sort and separate their potatoes according to their sizes, and are particularly careful to throw aside all those that are spoiled before asing, or that are cut in the taking up. This is a very necessary and proper precaution (although by no means generally attended to), as the crop must have a much better chance for keeping, than when diseased or cut potatoes are stored up with it. It is also of great advantage to have the work performed in a dry season, as the potatoes seldom keep well when taken up wet, or when placed in any sort of repository for keeping while in that state.

up with it. It is also of great advantage to have the work performed in a dry season, as the potatoes seldom keep well when taken up wet, or when placed in any sort of repository for keeping while in that state.

5344. Potato pies, as they are called, are recommended by Young as the best mode in which potatoes can be stored. A trench, one foot deep and six wide, is dug, and the earth cleanly shovelled out, and laid on one side, and on the bottom of the trench is laid over them a bedding of straw. One horse carts shoot down the potatoes into the trench; and women pile them up about three feet high, in the shape of a house roof. Straw is then carefully laid over them six or eight inches thick, and covered with earth a foot thick, neatly smoothed by flat strokes of the spade. In this method he never lost any by the severest frosts; but in cases of its freezing with uncommon severity, another coat of straw over all gives absolute security. These pies when opened should each be quite cleared, or they are liable to depredation. To receive one at a time, besides also being at first filled for immediate use, he has a house that holds about 700 bushels, formed of posts from fir plantations with wattled sides, against which is laid a layer of straw, and against the sides exteriorly earth six feet thick at the bottom and eighteen inches at top; the roof flat, with a stack of beans upon it. This he has found frost tight. The beans keep out the weather, he says, and yet admit any steam which rises from the roots, which, if it did not escape, would rot them.

5345. Several other modes of preserving potatoes are in use in different places. In Rutlandshire, Marshal says, the method of laying up potatoes is universally that of camping them; a method somewhat similar to the above, but which requires to be described. Camps are shallow pits, filled and ridged up as a roof with potatoes; which are covered up with the excavated mould of the pit. This is a happy mean, lee thinks, between burying them in deep pits and laying them upon

5346. In Canada and Russia the potato is preserved in boxes in houses or cellars, heated when necessary to a temperature one or two degrees above the freezing point by stoves. (Farm. Mag. vol. xx. p. 449.)

3 I 2

5347. To keep potatoes any length of time, the most effectual way is to place them in thin layers on a platform suspended in an ice cellar. There the temperature being always below that of active vegetation, they will not sprout; while not being above one or two degrees below the freezing point, the tubers will not be frost bitten. Another mode is to scoop out the eyes with a very small scoop, and keep the roots buried in earth. A third mode is to destroy the vital principle by kiln-drying, steaming, or scalding. A fourth mode is to bury them so deep in dry soil that no change of temperature will reach them, and consequently, being without air, they will remain upwards of a year without vegetating.

5348. The produce of the potato varies from five to eight, and sometimes ten or twelve tons per acre; the greatest produce is from the yam, which has been known to produce twelve tons or 480 bushels per acre. The haulm is of no use but as manure, and is sometimes burned for that purpose, being slow of rotting.

5349. The most important application of the potato crop is as human food; on this it is unnecessary to enlarge.

unnecessary to enlarge.

550. Einhaff found mealy potatoes to contain twenty-four per cent. of their weight of nutritive matter, and rye seventy parts: consequently, sixty-four and a half measures of potatoes afford the same nourishment as twenty-four measures of rye. A thousand parts of potato yielded to Sir H. Davy from 200 to 260 parts of nutritive matter, of which from 155 to 200 were mucilage or staro, fifteen to twenty sugar, and thirty to forty gluten. Now, supposing an acre of potatoes to weigh nine tons, and one of wheat one ton, which is about the usual proportion; then as 1000 parts of wheat afford 950 nutritive parts, and 1000 of potato say 220, the quantity of nutritive matter afforded by an acre of wheat and potatoes will be nearly as nine to four; so that an acre of potatoes will supply more than double the quantity of human food afforded by an acre of wheat. The potato is perhaps the only root grown in Britain which may be eaten every day in the year without satiating the palate, and the same thing can only be said of the West India yam and bread fruit. They are, therefore, the only substitute that can be used for bread with any degree of success; and indeed they often enter largely into the composition of the best loaf bread with any degree of success; and indeed they often enter largely into the composition of the best loaf bread without at all injuring either its nutritive qualities or flavour. (Edin. Encyc. art. Baking.) In the answer by Dr. Tissot to M. Linquet, the former objects to the constant use of potatoes as food, not because they are pernicious to the body, but because they hurt the faculties of the mind. He owns that those who eat maize potatoes, or even millet, may grow tall and acquire a large size; but doubts if any such ever produced a literary work of merit. It does not, however, by any means appear that the very general use of potatoes in our own country has at all impaired either the health of body or vigour of mind of its inhabitants.

5551. The manufacture of potato flour

5352. The quantity of farina which potatoes produce varies not only according to the species, but according to the period when the extraction takes place. The variations produced by this last cause are nearly as follows:—Two hundred and forty pounds of potatoes produce of farina, or potato flour, in

August, from 23 to 25 pounds.

March from 45 to 38 pounds. April....... 38 ... 28 May....... 28 ... 20

5358. A large circular pan is now procured, and set upon the fire. The farina is gradually put into the pan, till what is conceived to be sufficient for one cooking be supplied. As the natural tendency of the farina, in a warm state, is to adhere to the pan, great care is requisite in constantly turning and stirring it. This is effectually done with a broad flat piece of wood, having a long handle to prevent inconvenience from the heat. A temperature of 1509 Fahrenheit suits best for perfecting the tapica. When the farina becomes quite hard, dry, and gritty, it is then ready, and may be taken off the fire. (Quar. Journ. Agr.

becomes quite hard, dry, and gritty, it is then ready; and may be taken off the fire. (Quar. Journ. Agr. vol. ii. p. 68.)

7339. The ordinary economical applications of the potato, next to those of the culinary and baking arts, are in starch-making and the distillery. Starch is readily made from the scraped and washed tubers cut into small pieces and steeped in water; and a spirit is distilled from mashed potatoes, fermented so as to change a portion of the starch into sugar. In general it is found that three and a half bushels of potatoes afford the same quantity of spirit as one of malt.

7330. Potash may be extracted from potato leaves and stalks by the following process:— Cut off the stalks when the flowers begin to fall, as that is the period of their greatest vigour; leave them on the ground eight or ten days to dry, cart them to a hole dug in the earth about five feet square and two feet deep, and then burn them, keeping the ashes red-hot as long as possible. Afterwards take out the ashes, pour boiling water on them, and then evaporate the water. "There remains after the evaporation a dry saline reddish substance, known in commerce under the name of salin; the more the ashes are boiled, the greyer, and the more valuable the salin becomes. The salin must be calcined in a very hot oven, until the whole mass presents a uniform reddish brown. In cooling it remains dry, and in fragments bluish within, and white on the surface; in which state it takes the name of potash." (Smith's Mechanic, vol. ii. p. 381.)

5361. Among extraordinary applications of the potato, may be mentioned cleaning woollens, and making wine and ardent spirit.

woollens, and making wine and ardent spirit.

5382. Cleaning woollens. The refuse of potatoes used in making starch when taken from the sieve, possesses the property of cleansing woollen toths, without hurting their colour; and the water decanted from the starch powder is excellent for cleaning silks, without the smallest injury to the colour.

5383. Wine, of a good quality, may be made from frosted potatoes, if not so much frosted as to have become soft and watery. The potatoes must be crushed or bruised with a mallet, or put into a cider press. A bushel must have ten gallons of water, prepared by boiling it, mixed with half a pound of hops, and half a pound of common white ginger. This water, after having boiled for about half an hour, must be poured upon the bruised potatoes, into a tub or vessel suited to the quantity to be made. After standing in this mixed state for three days, yest must be added to ferment the liquor. When the fermentation has subsided, the liquor must be drawn off, as fine as possible, into a cask, adding half a pound of raw sugar for every gallon. After it has remained in the cask for three months, it will be ready for use.

5364. Ardent spirit. Potatoes that have been injured by the frost produce a much greater quantity of spirit, and of a much finer quality, than those that are fresh; they require a proprotion of malt-wash to promote the fermentation. About one fourth part of malt-worts, or wash, ought to be fermented at least six hours before the potato-wash is joined to it; otherwise the potato-wash, having an aptitude to ferment, will be ripe for the still before the malt-wash is ready; hence the effect will be, to generate an acid which renders the spirit carse, and, when diluted with water, of a milky or bluish colour. When the spirit is strong, the acid is held in solution; but appears as above, when diluted with water. (Farmer's Mag. vol. xvii. p. 325.)

In the application of potatoes as food for live stock, they are often joined with hay, straw, chaff, and other similar matters, and have been found useful in many cases, especially in the later winter months, as food for horses, cows, and other sorts of live stock. With these substances, and in combination with others, as bean or barley-meal and pollard, they are used in the fattening of neat cattle, sheep, and hogs.

Side. Potatoes are much more nutritive when boiled; they were formerly cooked in this way, but are now very generally steamed, especially in the north. The practice has been carried to the greatest extent by Curwen in feeding horses. He gives to each horse, daily, a stone and a half of potatoes mixed with a tenth of cut straw. One hundred and twenty stones of potatoes require two and a quarter bushels of coals to steam them. An acre of potatoes, he considers, goes as far in this way as four of hay. Von Thaer found them, when given to live stock, produce more manure than any other food: 100 lbs. of potatoes producing 66 lbs. of manure of the very best description. The baking of potatoes in an oven has also been tried with success. (Comm. Board of Agriculture, vol. iv.); but the process seems too expensive. Potatoes should not be given raw to animals of any description, except, perhaps, when hogs are let in to root and pick up what may have escaped notice in the field. Washing was formerly a disagreeable and tedious business, but is now rendered an easy matter, whether on a large or small scale, by the use of the washing machine.

is prevented. After the water is come nearly to boil, pour it off, and replace the hot by cold water, into which throw a good portion of salt. The cold water sends the heat from the surface to the heart of the potato, and makes it mealy. Like all other vegetables, they are improved by being boiled with salt, which ought not, therefore, to be spared. (Mech. Mag. i. 13.)

5369. Frosted potatoes may be applied to various useful purposes, for food by thawing in cold water, or being pared, then thawed, and boiled with a little salt. Salt, or saltpetre, chaff, or bruised oats, boiled with them, will render them fit food for cattle, swine, poultry, &c. Starch, and paste for weavers, bookbinders, and shoemakers, may be made from them when too sweet to be rendered palatable, and also an ardent spirit, from hydrometer proof to 10 per cent over proof.

5370. The diseases of the potato are chiefly the scab, the worm, and curl.

5370. The diseases of the potato are chiefly the scab, the worm, and curl.

5371. The scab, or ulcerated surface of the tubers, has never been satisfactorily accounted for; some attributing it to the ammonia of horse-dung, others to alkali, and some to the use of coal ashes. Change of seed, and of ground, are the only resources known at present for this malady. The worm and grub both attack the tuber, and the same preventive is recommended. The only serious disease of the potato is the curl, and this is now ascertained to be produced by the too great concentration of the sap in the tuber; and this concentration, or thickening, is prevented by early taking up. This discovery was first made by the farmers near Edinburgh, who observed that seed potatoes procured from the curl, and it consequently became a practice, every three or four years, to procure a change of seed from these districts. On enquiry, it was found, that the potatoes in these upland grounds continued in a growing state till the haulm was blackened by the first forsts of October. They were then taken up, when, of course, they could not be ripe. Subsequent experiments, which will be found detailed in The Farmer's Magazine, and Caledonian and London Horticultural Transactions, have firmly established the fact, that the curl is prevented by using unripe seed; therefore the farmer ought to select his seed stock a fortnight or three weeks before he takes up the general crop, as already recommended. It is also a safe practice frequently to change the seed, and also to change the variety.

5372. Shirreff, an ingenious speculator and practical agriculturist, is of opinion that there are only two causes for the curled disorder in potatoes. The first is excessive seed-bearing, that is, carrying great quantities of plums or apples; from the effects of which, if the plant be not too far advanced in life, it may recover for a time, by removing it to a shady or upland situation. The sond cause is time or old age, which never fails ultimately to bring the curled

quantities of plums or apples.

The Turnip. - Brássica Ràpa L.; Tetradynàmia Siliquòsa L., and Crucíferæ J. Rave, Fr.; Rübe, Ger.; Rapa, Ital.; and Nabo, Span.

5373. The turnip is a native of Britain, but in its wild state it is not to be recognised by ordinary observers from wild mustard. It was cultivated as food for cattle by the Romans; and has been sown for the same purpose in the fields of Germany and the Low Countries from time immemorial.

Countries from time immemorial.

5374. When they were introduced in this country, as a field plant, is unknown: but it is probable turnips would be found in some gardens of convents from the time of the Romans; and it is certain that they were in field culture before the middle of the seventeenth century, though then, and for a long time afterwards, in a very inferior and ineffectual manner. It has been stated that turnips were introduced from Hanover in George I.'s time; but so far from this having been the case, George II. caused an abstract of the Norfolk system of turnip husbandry to be drawn up for the use of his subjects in Hanover. (Campbell's Politi. Survey, &c. vol. iii. p. 80.) The introduction of improved turnip culture into the husbandry of Britain, Brown observes, "occasioned one of those revolutions in rural art which are constantly occurring among husbandmen; and, though the revolution came on with slow and gradual steps, yet it may now be viewed as completely and thoroughly established. Before the introduction of this root, it was impossible to cultivate light soils successfully, or to devies suitable rotations for cropping them with advantage. It was likewise a difficult task to support live-stock through the winter and spring months; and as for feeding and preparing cattle and sheep for market during these inclement seasons, the practice was hardly thought of, and still more rarely attempted, unless where a full stock of hay was provided, which only happened in very few instances. The benefits derived from turnip husbandry are, therefore, of great magnitude. Light soils are now cultivated with profit and facility; abundance of food is provided for man and beast; the earth is turned to the uses for which it is physically calculated; and, by being suitably cleaned with this preparatory crop, a bed is provided for grass seeds, wherein they flourish and prosper with greater vigour than after any other preparation." (Treatise on Rural Affairs.)

5375. Turnips and clover, it is elsewhere observed, " are the two main pillars of the best courses of British husbandry; they have contributed more to preserve and augment the fertility of the soil for producing grain, to enlarge and improve our breeds of cattle and sheep, and to afford a regular supply of butcher's meat all the year, than any other crops; and they will probably be long found vastly superior, for extensive cultivation, to any of the rivals which have often been opposed to them in particular situations. Though turnips were long cultivated in Norfolk before they were known in the northern counties, yet it is an undoubted fact that their culture was first brought to perfection in Roxburghshire, Berwickshire, and Northumberland, and chiefly through the exertions of Dawson, of Frogden, in the first named county, and of Culley, in the latter.

5376. Drilling turnips, as well as other crops, evidently originated with Tull, whose first work, Specimen of a Work on Horse-hoeing Husbandry, appeared in 1731. It appears that Craig, of Arbigland, in Dumfrieshire, began to drill turnips about 1745; and next we find Philip Howard, of Corby, drilling in 1755; and Pringle, drilling "from hints taken from Tull's book," in 1756 or 1757. William Dawson, who was well acquainted with the turnip culture in England, having been purposely sent to reside in those districts

for six or seven years, where the best cultivation was pursued, with an intention not only of seeing, but of making himself master of, the manual operations, and of the minutiæ in the practice, was convinced of the superiority of Pringle's mode over every other he had seen, either in Norfolk or elsewhere; and in 1762, when he entered on Frogmore Farm, near Kelso, in Roxburghire, he immediately adopted the practice upon a large scale, to the amount of 100 acres yearly. Though none of Pringle's neighbours followed the example, yet no sooner did Dawson, an actual or rent-paying farmer, adopt the same system, than it was immediately followed, not only by several farmers in his vicinity, but by those very farmers adjoining Pringle, whose crops they had seen, for ten or twelve years, so much superior to their own: the practice in a few years became general. Drilling turnips was first introduced to the county of Northumberland, about the year 1780.

5377. The varieties of turnip grown by farmers may be arranged as whites and yellows.

5378. Of white turnips, by far the best and most generally cultivated is the globe; but there are also the green-topped, having the bulb tinged greenish; and purple-topped, with the bulb reddish: which, though they do not produce so large a crop as the globe or oval, stand the winter better, and the red-topped, it is said, will keep till February. The pudding, or tankard turnip, has a white bulb which rises from eight to twelve inches high, standing almost wholly above ground. It is less prolific than any of the others, and more liable to be attacked by frost.

5379. Of yellow turnips, there are the field or Aberdeen yellow, which is more hardy than the globe, and answers well for succeeding that variety in spring; and the rutabaga, or Swedish turnip, which may be preserved for consumption till June. The Siberian turnip has a bulb and a branchy top, but both of inferior quality. It is a hybrid between a white rutabaga and field cabbage, or between rape and cabbage.

5380. New varieties are obtained by selection and by counter impregnation; but in either case the greatest care is requisite to keep the plants at least a furlong from any others of the brassica tribe likely to flower at the same time, otherwise the progeny will certainly be hybridised.

5381. The choice of sorts may be considered as limited to the white, globe, yellow, and Swedish, according as early, middling, or late supplies are wanted. No other varieties are grown by the best farmers.

5382. In the choice of seed the farmer must rely on the integrity of the seed-dealer, as it is impossible to discover from the grains whether they will turn out true to their

5383. Turnip-seed requires to be frequently changed; and the best is generally procured from Norfolk and Northumberland. The Norfolk seed, Forsyth observes, is sent to most parts of the kingdom, and even to Ireland: but after two years it degenerates; so that those who wish to have turnips in perfection should procure it fresh every year from Norwich, and they will find their account is odoing; for, from its known reputation, many of the London seedsmen sell, under that character, seed raised in the vicinity of the metropolis, which is much inferior in quality.

5384. Turnip-seed of any age will grow, if it has been carefully preserved; that which is new, comes up first, and therefore it is not a bad plan to mix new and old together, as a means of securing a braird against drought or the fly. Whether plants from new or old seed are most secure from the depredations of the fly, is perhaps a question which cannot be easily determined, even by experiments; for concomitant circumstances are frequently so much more operative and powerful as to render the difference between them, if there be any, imperceptible. It is, however, known to every practical man, that new seed vegetates several days before the old, and more vigorously; and it is equally well known that the healthy and vigorously plants escape the fly, when the stinted and sickly seldom or never escape it. Hence it would seem, that new seed, cateris paribus, is more secure from the fly than old.

5385. The soil for turnips should always be of a light description. In favourable seasons very good crops may be raised on any soil; but from the difficulty of removing them, and the injury which the soil must sustain either in that operation, or in eating them on the spot with sheep, they never on such soils can be considered as beneficial to Turnips cannot be advantageously cultivated on wet tenacious soils, but the farmer. are grown on all comparatively dry soils under all the variations of our climate. On dry loams, and all soils of a looser texture, managed according to the best courses of cropping, they enter into the rotation to the extent of a fourth, a sixth, or an eighth part of the land in tillage; and even on clayey soils they are frequently cultivated, though on a smaller scale, to be eaten by cattle, for the purpose of augmenting and enriching the manure, into which the straw of corn is converted.

5386. The climate most desirable for the turnip is cool and temperate. This was long ago noticed by Pliny, and it is so obvious on the Continent that it admits of no dispute. Von Thaer observes that the turnips grown on the fields of Germany seldom exceed half a pound in weight, and that all his care could not raise one beyond fourteen pounds. In France and Italy they are still less. A rapid climate is equally disadvantageous to the turnip; and they are accordingly found of no size in Russia, Sweden, and many parts of North America. Even turnips grown in the southern counties of England, in the same excellent manner as in Northumberland, never equal the size of those grown in the

latter county, or further north, or in Ireland.

5387. The field culture of turnips is effected either by sowing the seed of the plant from the hand on a flat surface, or by depositing it on the tops of little ridges. best cultivated districts, the latter method is universally practised and approved of, chiefly for these reasons: -1. By this method the land may be more easily and perfectly cleaned during the growth of the plants; the width of the rows affording the means of better tilling the intervals. 2. The plants can be more cheaply and quickly hand-hoed, the process being so simple as to be taught to young persons in a few hours; whereas when the plants are not regularly disposed in rows, a considerable degree of experience and time are requisite. S. The manure may be more perfectly covered, and by being applied in a more effectual manner to the roots of the plants, a smaller quantity will suffice. And lastly, the turnips may be kept drier, and crops of them in consequence raised on land so wet as otherwise to be incapable of yielding a return of any We shall give their culture from an excellent paper in the Quarterly Journal of Agriculture, vol. i., from which also this paragraph is quoted.

5388. Preparation of the land. The land intended for the turnip crop is ploughed in autumn, after the preceding crop of grain has been reaped. If the soil be not of a very dry nature, the land is formed into ridges of fifteen feet or more, and care is taken that no water shall stagnate on the ground. In this condition the land remains during the winter; and it is ploughed again in spring as soon as the ground is sufficiently dry for that purpose, and as soon as the other labour of the farm will allow: this second ploughing is generally made in a direction to cross the previous one. The land is then repeatedly grubbed and harrowed in various directions, for the purpose of pulverising it, and of dragging to the surface, and disengaging all weeds and roots; to assist in which process the aid of the roller is frequently requisite; the roots and weeds disengaged are then gathered with care, and either burnt in little heaps on the ground, or removed away to a larger heap, to be mixed with quick lime and other substances, to form a compost for the roots and weeds disengaged are then gathered with care, and either burnt in little heaps on the ground, or removed away to a larger heap, to be mixed with quick-lime and other substances, to form a compost for the succeeding year; at the same time such stones as impede the tillage may be removed: after this the land is again ploughed, and generally, as before, in a direction crossing the last furrows; and the same process of harrowing, rolling, and collecting the disengaged weeds, is repeated. The earth is once more ploughed, and again the same operations are resorted to; after which the land is usually in a fit state to be formed into ridges or drills. Should this not be so, the operations of ploughing, harrowing, and gathering of weeds must be repeated, and that until the land is cleared of all injurious roots, and reduced to a loose or friable state. The perfect preparation of the ground in this stage of its culture, is of very great importance to the future crop. importance to the future crop.

5389. Forming the ridges. After the preparation described, the land is formed into little ridges or ridgelets, either by the common plough, or by a plough with two mould-boards, formed for that purpose. The first of these is to be preferred when the method of performing the work is once pointed out in the fields. The ridges are formed with a sharp top, as a transverse section (fig. 751.) will show. The distance

of these ridgelets may be from twenty-seven to thirty inches, measuring from top to top. This interval is necessary to allow of the horse-hoe tilling the intervals, in the manner to be afterwards described, and to admit a sufficient circulation of air between the rows of the plants.

5390. Manner of applying the manure. The chief manure applied to this crop is farmyard dung, or that which is produced by the consumption of the straw and other produce of the farm. This manure ought to be well rotted, and to that end either turned over in the court-yard some weeks previously to its ought to be well rotted, and to that end either turned over in the court-yard some weeks previously to its being used, or carried out in winter to the fields intended for the turnips, and there id in one or more large heaps. If the carts are not suffered to go upon these heaps, the putrefactive process will proceed with greater quickness. When the ridgelets are formed in the manner described, the dung is filled into carts drawn by one horse, and transported quickly to the land. The manner of applying it is this:—The horse with the loaded cart walks in the interval of the ridges, so that a wheel of the cart shall go in each of the horse of the two ridges adjoining. The person why

these passing down the middle of each ridgelet split it into two, so that a new ridgelet is formed, whose top is immediately above the former hollow of the old ridgelet, (fig. 755.) The dung is now completely covered, and a new ridge for the reception of the seed is at once formed. The double mould-board plough performs this 754

operation at once, the common plough by going and returning up the middle of each ridge,

5392. Broad-cast dunging. Instead of depositing the manure in the manner described, it is sometimes laid upon the stubble after harvest, and then ploughed in. This is only practicable where there is a supply of manure remaining from the preceding year, or where it can be elsewhere procured; and is only advisable when the land is so clean as to require little preparation in the succeeding spring. As liberal an expenditure as can be afforded of manure is always expedient in the case of this crop, the goodness of which will much depend upon the fertility we are able to communicate to the soil. Ten or twelve tons per acre may be considered the regular manuring on a turnip-farm, where a proper rotation of crops is followed.

5393 Lines sea used askes. Sometimes line is applied to the turnin crop together with dung. This

5333. Lime, sea-weed, askes. Sometimes lime is applied to the turnip crop, together with dung. This may be done by laying the lime upon the stubble after harvest, or better still, by spreading it upon the ground, and harrowing it well immediately, before the forming of the ridgelets for the reception of the dung. Putrescent manures, however, are considered superior to the calcareous for the production of this plant; and all of the former kind may be used with effect. Street dung is an exceedingly good manure; sea-weed will also be useful: this last, however, is not applied in the manner of the farmyard dung, but is carried off as it is cast on shore, laid on the surface, and suffered to remain so till the land is

ploughed. Ashes generally produce a good effect in causing the seeds to vegetate quickly, but the fertilising powers of some of these do not appear to be of a permanent nature. Bruised bones and various other substances have been used with much benefit; but it is to be observed, that putrescent manures form the main support of the turnip cultivator, and that the others are only to be regarded as subsidiary.

5394. Sowing the turnips. The land being formed into ridgelets in the manner described, is ready for the reception of the seed. This is sown on the tops of the ridgelets by machines of various forms.

5395. The most simple of these consists of a hollow cylinder of tin, fixed upon an axle, and moving round with two light wheels, distant from each other twenty-seven or thirty inches, which are made to run in the hollows of the ridges. (2688.) The seed is put into the cylinder through an aperture which opens and shuts for that purpose: this cylinder turning round with the axle, the seed drops, through small equidistant holes made in it, into a tin tube, by which it is conveyed to the ground. Immediately before this tube is a hollow coulter of iron, sharp before, which incloses the forepart of the tin tube, and makes a track in the ground from one to two inches deep, into which the seed drops. This simple apparatus is mounted upon a light wooden frame-work, having two shafts behind, by which the workman holds and keeps it steady in its course. It is then attached by a rope to a light wooden roller, in the shafts of which the animal of draught is yoked. More perfect machines, however, may be employed where turnips are cultivated upon a large scale, and we may refer to that of French (2688.) as one of the best.

5396. The preparation of turnip-seed for sowing, by steeping in the drainings of dunghills and other similar matters, has been recommended as a likely mode to prevent the fly; but it is not found to have this effect, and is never followed.

5397 The following mode of preparation is sometimes adopted:—Half new and half old seed are mixed together; then half is taken and steeped in water for three or four hours; afterwards both steeped and unsteeped seed are mixed and immediately sown. The object of this preparation is to obtain four different brairds or risings of the seed, which are supposed to give four chances of escaping the fly that attacks the infant plants, instead of one. Another mode is to join radish-seed to the above, new and, old, steeped in the foregoing manner, it being found that the fly prefers the radish to the turnip. Some recommend the mixing of an equal quantity of rape-seed with the turnip-seed, alleging, that if a fly cuts off the turnips, the rape may be left for a crop; and that if the turnips escape, the rape may be treated as weeds. The most common precaution, however, as to the fly, is to sow thick, or to mix the seed with soot, lime, or ashes.

5398. The quantity of seed used may be from two pounds to two and a half pounds avoirdupoise per acre. It is necessary to give a sufficient quantity of seed, to provide against the loss of plants from the ravages of insects, and other contingencies. But the quantity should not be excessive; because the plants, when too thick, get interwoven together, and thence become difficult to be thinned in a proper manner.

5399. The sowing process being completed, the ridgelets remain flattened and compressed. (fig. 756.)

5400. The several operations of forming the ridgelets, spreading the dung, covering it by the plough, and sowing the seed, ought to be carried on in close succession. The dung must be immediately covered, that none of its powers may be lost by evaporation; and the seed, to ensure its early vegetation, ought to be sown as soon as possible upon the moist earth turned up. The various works of the turnip culture, thus carried on at the same time, furnish the best specimen which the culture of the fields affords of the beneficial effects of a proper division of labour. The process has all the appearance and effects of garden culture, with the difference of its being conducted with incomparably greater economy and despatch.

5401. The period of sowing in the north of England and Scotland is from the 1st to the end of June, though it is often continued to the middle of July. The turnips, however, sown after the latter of these periods seldom attain to a proper size; and, when sown earlier than the 1st of June, they are apt to shoot forth the seed-stem before winter, by which not only the soil is deteriorated, but the nutritive juices of the root exhausted. In the south of England they may be sown somewhat later than in the north.

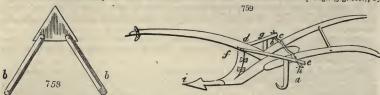

5402. The time of sowing in other countries must be varied by the nature of the climate and soil. It is to be inferred, that in warmer countries, where vegetation is more rapid, the sowing should be deferred till a later period. At Roville, in the north of France, M. de Dombasle sometimes sows in August, and yet obtains a medium crop.

5403. Hoeing. When the plants are an inch or more in height, or when weeds appear amongst them, the process of hoeing commences. This is done either by a small plough drawn by one horse, going and returning along the hollow of each ridgelet, and cutting of a slice of earth from the sides, as near to the turnips as possible (fig. 757.)

or by the horse-hoe, of which there are various kinds. The most simple of these consists of a flat triangular share (fig. 758. a), with two lateral arms (b, b), formed to set wider or narrower, and fixed to a beam and handles by three upright coulters of iron; or, which is better, the lateral arms are omitted, the triangular share fixed to the beam, and two moveable upright coulters attached by a cross bar.

5404. One of the best turnip horse-hoes is formed from the skeleton of a common plough (fig. 759.), by

two coulters of iron curved inwards (a, b), and fixed to wooden bars (c, f), and (c, d), which last again are hooked to the beam of the implement, and made, by means of a cross iron bar (g, h), to be set at a greater or smaller distance from each other as it may be required. A broad iron share (i) moves in the middle of the hollow of the ridges, while the two coulters on each side go as near to the rows of turnips as can be done with safety; and in this manner the intervals of the ridges are tilled, and the weeds within them, and as near to the plants as the coulters can go, cut up and destroyed. By removing the wooden bar and coulters of this machine, and hooking to it, on each side, a small cast-iron mould-board, it is converted to the double mould-board plough also, as we have seen.

5405. The brakes or horse-hoes of Wilkie (2666,), Finlayson (2667,), or of Kirkwood (4955.), may easily be set and arranged for this or any other description of culture; so that it requires no new implements.

5406. The hand-hoers go to work, each having a little iron hoe, fixed upon a wooden handle about three feet in length (fig. 760.). The breadth of the blade (a) of this hoe is eight inches; and the workers, standing in the hollow with their faces to the ridges, hoe the turnip plants, leaving them standing singly, at the distance from each other of from the turnips are cleaned of all weeds; the superfluous plants cut up and pushed into the intervals, where they die; and the plants to be preserved left standing singly at the distance required. A transverse section of the ridges will then appear thus (fig. 761.), and

761

The plants should not be nearer to each other than ten inches, that a longitudinal section thus: (fig. 762.) they may increase to a proper size. 762

5407. Second horse-hocing. Soon after the operation in question, weeds will again sprout up in the intervals of the ridges and amongst the plants. In the course, therefore, of twelve days or more the horse-hoe again passes through the intervals of the ridges, cutting up all the weeds that may have sprung up; and soon after the hand-hoers again go to work with the same instrument as before, cutting up all weeds which may have grown amongst the turnips, and carefully singling any plants that may by chance have been omitted in the first hoeing. After this process, a section of the ridges will appear thus: (fig. 763.)

5408. Third horse-hoeing. Sometimes the horse-hoe passes once more down the intervals after a short period; but more generally the previous hand-hoeing concludes the process upon all the drier lands, the weeds being now kept down by the rapid growth of the plant, and the overshadowing of the interval of its leaves. Very commonly, however, at an interval of eight or ten days after the last hand or horse-hoeing, the earth which had been taken from the roots of the plants by these several hoeings is again laid back, either by the little one-horse plough already mentioned, or by the double mould-board plough, passing down the intervals of the rows and ridging up the earth thus: (fig. 764.) The design in this ope-

ration is, that any weeds remaining in the intervals after the former hoeings may be destroyed, and that the land and turnips may be kept more dry during wet weather and the months of winter. This concludes the culture of the turnip, which now grows rapidly without further care; and by the beginning of September the leaves of a good crop will have covered the entire surface, making a transverse section of the ridges appear thus: (fig. 765.)

5409. The Swedish turnip is cultivated, used, and stored precisely in the same manner as the common turnip; but it is generally sown several weeks earlier. It does not attain to the same weight by the acre; and, as it is more difficult to raise, it ought to receive a greater quantity of manure, and to be always upon good land. has a property which the common turnip has not, that of bearing to be transplanted

when young; so that, where blanks appear in a field, the spaces may be filled up by transplanting. Analogous to the Swedish turnip, in hardiness and nutritive qualities, is the large yellow or Aberdeen turnip. This root is perhaps superior to the Swedish turnip, in so far as it may be raised with less difficulty. It serves the same purpose of a succedaneum to the common turnip in spring.

5410. Consumption of the turnips. By the end of October or beginning of November,

when the pastures have decayed, the turnips begin to be used for food.

when the pastures have decayed, the turnips begin to be used for food.

5411. When sheep are to be fed, the turnips are either pulled up by the hand, and carried away, as wanted, into the fields, in which the sheep are kept, and there spread regularly upon the ground; or more frequently and economically the sheep are at once driven into the fields of turnips, and suffered to consume the roots as they stand. In this case the animals are not suffered to range over the whole field at first, but are confined to a space of an acre or more, by means of nets, or a series of moveable rails or hurdles. When the sheep have eaten the roots very nearly, the remnant in the ground may be picked up by a little hoe (fig. 763) or by the turnip chopper already described (2372); and when the whole are consumed, the nets or rails, or hurdles, are moved to another division, and so on throughout the field, leaving the spaces before cleared open to the sheep to move upon. This manner of consuming the turnips affords an admirable rack with a cover, containing a small quantity of hay, which seems to be relished by the animals amid their moister food.

5412. In the feeding of ozen, the turnips may be laid down on a dry field, as in the case first mentioned; but the proper and regular manner of feeding these animals is to supply them with the turnip in the house or open yard, littering them at the same time plentifully and regularly with straw, and giving them what they choose to consume of it as provender, with their turnip-lood. Cattle are fed cither by being given the better mode of feeding, the turnips being supplied from troughs or otherwise, and a shed for shelter being always at hand and open to the cattle to repose in. It is well, however, that too many animals, of different strength and size, be not put together, lest they disturb each other in feeding. Sometimes courts are made and divided into separate compartments, holding only two cattle in each, and this is found to be an exceedingly good practice. When cattle are of value,

cut off the leaves and tails of the turnip, giving the leaves to the younger and less valuable stock, and the bulb only to that which is to be fed.

5413. Young cattle, not intended to be immediately fattened, receive only a limited portion of turnips, their principal provender being straw. By receiving a portion of turnips with their drier provender, these animals are kept in a much more healthy condition than if confined to the latter food, and continue to grow throughout the whole season, instead of pining away at the time when green herbage can no longer be found for them. With the design, too, of keeping them in a good condition, turnips are supplied in a limited quantity to milch cows, and in particular at the time of calving. The turnip, however, though it adds to the quantity of milk, gives it a strong and disagreeable flavour.

5414. When both sheep and cattle are fed upon a farm, it is usual to pull up every alternate four or five rows of turnips for the cattle, leaving the remainder on the ground for the sheep, so that the land on which the turnips had grown may receive its proportion of the manure produced. (Quar. Jour. Ag. vol. i. p. 286.)

1541. When both succeptant caute are just to provide the sheep, so that the land on which the turnips had grown may receive its proportion of the manure produced. (Quar. Jour. Ag. vol. i. p. 286.)

5415. The advantages of eating turnips on the place of their growth by sheep, both in manuring and consolidating the ground, are sufficiently well known to every farmer. One great defect of the interior sort of turnip soil is the want of tenacity; and it is found that valuable crops of wheat may be obtained upon very light porous soils, after turnips so consumed. It is not uncommon to let turnips at an agreed price, for each sheep or beast, weekly. This varies according to age and size, and the state of the demand, from four-pence or less, to eight-pence or more, for each sheep weekly, and from two shillings to five for each beast. An acre of good turnips, say thirty tons, with straw, will fatten an ox of sixty stone, or ten Leicester sheep. Supposing the turnips worth six guineas, this may bring the weekly keep of the ox to six shillings and three-pence halfpenny, and of the sheep to about seven-pence halfpenny and evek. In this way of letting, however, disputes may arise, as the taker may not be careful to have then eaten up clean. The person who lets the turnips has to maintain a herd for the taker; and when let for cattle, and consequently to be carried off, the taker finds a man and horse, and the letter maintains both. The taker has to provide hurdles or nets for fencing the allotments to sleep; but the letter must fence his own hedges if necessary. The period at which the taker is to consume the whole is usually fixed in the agreement, that the seller may be enabled to plough and sow his land in proper season. (Suppl. to Enege. Brit.) The rule for selling turnips in Norfolk is calculated from the fact, that one acre of good turnips is sufficiently for 100 sheep for one week. Then, whether turnips be dear or cheap, the price per week may be easily found—at 5t, per acre, 1s, per week per head, and soy of all oth

5418. Near large towns the most profitable mode of disposing of turnips is to the

cow-keepers and green-grocers.

The application of turnips in domestic economy is well known. They may also be used in the distillery; and a wine is said to be made from them by the London manufacturers of imitations of foreign wine.

5420. The storing of turnips is attended with too much labour and risk to be of much advantage in the greater part of the kingdom. Common turnips are never stored in any great quantity, though sometimes a portion is drawn and formed into heaps, like

potato camps, and lightly covered with straw, or preserved for some time under a shed. On these occasions, before storing up, the shaws or leaves and the tap-roots must be cut off and removed, to prevent heating and rotting. The heaps must not be covered with earth-like potatoes, for in this case their complete destruction is inevitable. contains too much water to be preserved for any length of time in a fresh and palatable state, after being removed from the ground; and though the loss in seasons unusually severe, particularly in the white globe variety, is commonly very great, it is probable that a regular system of storing the whole, or the greater part, of the crop every season would, upon an average of years, be attended with still greater loss; besides the labour and expense, where turnips are cultivated extensively, would be intolerable. (Supp. &c.)

5421. Taking up and replacing is a mode by which turnips have been preserved, by Blaikie of Holkham, and some others. The mode is to cart the turnips from the field where they grow, to a piece of ground near the farm-offices, before the winter rains set in, when, the tap-root being cut off, the plants are set on the surface of the ground, in an upright position, as close to each other as they can stand, where they keep much better than in a store during the whole season. The advantages of having them quite close to the homestead, in place of bringing them most probably from a distant part of the farm in wet or stormy weather, are so obvious, as fully to justify a recommendation of the practice.

5422. Replacing and carthing have also been tried with success, especially with the Swedish turnip. Being pulled and freed from their roots and leaves, they are carted to a piece of well worked dry soil near the farmery, and there deposited in rows, so close as nearly to touch each other in the bottom of shallow furrows, the plough covering one row as another furrow is opened. In this way many tons are quickly earthed in, and on a very small space, and they can be turned out when wanted with equal facility. (Farmer's Magazine, vol. xxiii. p. 282.)

5423. The produce of turnins cultivated in the bread_cost_manner in England residents.

5423. The produce of turnips cultivated in the broad-cast manner in England varies from five to fifteen tons per acre: the latter is reckoned a very heavy crop. In Northumberland and Berwickshire, a good crop of white globe turnips drilled usually weighs from twenty-five to thirty tons per acre, the yellow and Swedish commonly a few tons less. Of late there have been instances of much heavier crops, and in Ayrshire it would appear that above sixty tons have been raised on an English acre, the leaves not included. (Farmer's Magazine, vols. xv. and xvi.) But such an extraordinary produce must have been obtained by the application of more manure than can be provided, without injustice to other crops, from the home resources of a farm; and where turnips form a regular crop in the rotation, no such produce is to be expected under any mode of culture.

5424. The produce of the turnip in nutritive matter, as proved by Sir H. Davy, was forty-two parts in a thousand; of which seven were mucilage, thirty-four sugar, and one Swedish turnips afforded sixty-four parts in a thousand of nutritive matter, of which nine were starch, fifty-one sugar, two gluten, and two extract. According to Von Thaer, 100 lbs. of turnips are equal to twenty-two of hay; and an ox to get fat on

turnips ought to have one third of its weight daily.

5425. To raise turnip seed, the usual mode is to select the most approved specimens of the variety to be raised at the season when they are full grown; and either to remove all others from the field and leave them to shoot into flower stems next year, or to transplant them to a place by themselves, where they will be secure from the farina of other plants of their genus. In either case they must be protected by earthing up from the winter's frost and rains, and in the ripening season from the birds.

5426. The true sort of Swedish turnip can very easily be kept by only attending to the plants when in ower. All the degenerated ones bear bright yellow flowers, which should be pulled out before the seed pens. The true sort have a brownish yellow flower. This saves the expense of transplanting if a corner

ripens. The true sort have a brownish yellow flower. This saves the expense of transplanting if a corner or one ridge of a field can be found convenient for saving.

5427. The Norfolk seed-growers have a sort of theory on the subject of transplanting turnips for seed which it may be worth while to attend to. According to that theory, where turnip seed is collected from such turnips as have been sown three or four years in succession, the roots are liable to be numerous and long, and the necks or parts between the bulbs and leaves coarse and thick; and when taken from such as have been transplanted every year, these parts are liable to become too fine, and the tap-roots to be diminished in too great a proportion. Of course the most certain plan is to procure seed from turnips that are transplanted oney ear and sown the next; or, if they be transplanted once in they years, it is supposed, that the stock may be preserved in a proper state of perfection. It is stated, that the method of performing this business in the best way, is to select such turnips as are of the best kinds and of the most perfect forms from the field crops, and after cutting their tops off, to transplant them, about the month of November, or following month, into a piece of ground that has been put into a fine state of tillage by repeated ploughing or digging over, and which should be situated as near the house as it can be, in order that the birds may be better kept from it. The seed will mostly be ready for gathering in the end of July, or in the following month.

that the birds may be better kept from it. The seed will mostly be ready for gathering in the end of July, or in the following month.

5428. Others cultivators, however, advise that the seed collected from a few turnips thus transplanted should be preserved and sown in drills, in order to raise plants for seed for the general crop, drawing out all such as are weak and improper, leaving only those that are strong and which take the lead; and that when these have formed bulbs, such as do not appear good and perfect should be taken out, as by this means turnip seed may be procured, not only of a more vigorous nature, but capable of vegetating with less moisture, and of producing stronger and more hardy plants. The practice of transplanting the whole of the turnips for seed for the main crops, they contend, is not only highly expensive, but injurious, by diminishing the strength of the plants from the destruction of their tap-roots. Very good seed may, however, be raised in either of the methods that have been here described.

diminishing the strength of the plants from the destruction of their tap-roots. Very good seed may, however, be raised in either of the methods that have been here described.

5429. The best Norfolk turnip-seed growers are of opinion that unless the seed be always saved from transplanted roots, the stock will infallibly degenerate in the manner here described. The statement that transplanting once in three years is sufficient, was a mere pretence with some of the growers to enable them to save two thirds of the heavy expense which attends transplanting turnips, and to get the same price for their seed as if it had been properly saved. The only exception to this is in what the Norfolk farmers calls the "pudding" or "long pudding" turnip, which is too tender to bear the winter. For a stock, a few sorts are taken up and protected from cold like mangold wurzel; and for a general crop the

seed is sown broadcast and not hoed, but suffered to grow like rape. So treated the plants form very small woody sorts, which are capable of enduring frosts. (J. L.)

5430. After the seed has become fully ripened, it is mostly reaped by cutting off part of the stems, and afterwards tying them up into sheaves, which, when sufficiently dry, are put into long stacks, and kept through the winter, in order to be threshed out about the time when it is wanted. But as in this way much seed is liable to be lost, by its readiness to escape from the pods in which it is contained, it is advised, as a much better practice, to have it immediately threshed out, either upon a cloth in the field where it grew, or in some other convenient place, being then put into bags proper for the purpose and placed in a situation which is perfectly dry. From seed crops of this sort being subject to much injury, and loss in different ways, the quantity of produce must be very different under different circumstances; but it may in general be stated at not less than from twenty to twenty-four bushels he acre. The price of turnip seed being seldom less than seven or eight shillings the bushel, on account of the great demand for it, it may at first appear to be a very advantageous sort of culture; but from the exhausting nature of the crop, the loss sustained in grain, and the quantity of manure afterwards necessary, it is probable that turnip seed can only be grown to advantage in particular circumstances of solar, it is probable that turnip seed can only be grown to advantage in particular circumstances of solar, it is probable that turnip seed can only be grown to advantage in particular circumstances of solar his is probable that turnip seed can only be grown to advantage in particular circumstances of solar his is probable that turnip seed can only be grown to advantage in particular circumstances of solar his is probable that turnip seed can only be grown to advantage in particular circumstances of solar his is probable that turnip seed ca

5431. The diseases and injuries to which turnips are liable are various. At their first appearance their leaves are liable to the attacks of the fly (A'phis and Háltica,) the caterpillar, the slug, and the mildew. Their bulbs and roots are attacked by worms of different kinds; by a singular tendency to monstrosity, known provincially by the name of fingers and toes; by the anbury; by canker, and by wasting or gangrene from water or frost. Of all or most of these injurious diseases it may be observed, that they neither admit of prevention or cure by art. Under favourable circumstances of soil, climate, culture, and weather, they seldom occur; therefore all that the cultivator can do is to prepare and manure his land properly, and in the sowing season supply water when the weather is deficient in showers or the soil in humidity.

5432. The fly attacks the turnip when in the seed-leaf, and either totally devours it, or partially eats the leaves and centre-bud, so as to impede the progress of the plants to the second or rough leaves. Whether the eggs of these flies are deposited on the plants or in the soil, does not appear to be ascertained;

5432. The fly attacks the turnip when in the seed.leaf, and either totally devours it, or partially eats the leaves and centre-bud, so as to impede the progress of the plants to the second or rough leaves. Whether the eggs of these flies are deposited on the plants or in the soil, does not appear to be accretained; in all probability they are attached to the former, as in the goodeberg caterpillar, and most case of flies in the life of the seed, as already treated of, are all that have yet been done in the way of preventive to this evil.

5433. The caterpillar makes its appearance after the plants have produced three or more rough leaves, these they cat through, and either destroy or greatly impede the progress of the plants. There can be little doubt that the eggs of these caterpillars are deposited on the leaves of the plants by a species on onth, as the caterpillar may be detected when not larger in diameter than a hair. As preventives to the moths from fixing on the turnips for a depository for their eggs, it has been proposed to place vessely with tar in different parts of the field, the smell of which is known to be very offensive to moths and all the supposed the norths or parent flies were about to commence their operations. To destroy the awns, &c. have been proposed.

5434. The stag and snaid attack the plants both above and under ground, and eat both the leaves and roots. Rolling, soot, quicklime, awns, &c. have been proposed to annoy them; but the only effectual mode is, immediately after the turnips are sown, to strew the ground with cabbage leaves, of leaves of any of the Britssica tribe. On these, especially if sweet from incipient decay, the slugs will pasture, and may be gathered off by women or children every morning. If as many ending the leave of the past to the past principle decay, the slugs and removing the leave once in twenty-four hours. This mode we have found most effectual, and it is extensively practical by market and other gardeners. (Energy. of Gard. 2275.)

5435. The milder and b

can be placed upon fresh mould, as this disease has been known to prevall upon lands that had scarcely ever before borne a crop of turnips (Farmer's Magazine, vol. xiii.). The only effectual preventive would be to hinder the insect from laying its eggs.

5441. The canker attacks the roots, and partly the bulbs, of turnips, and is known by the ulccrated appearance it produces. Some consider it owing to the presence of too much iron in the soil, and recommend liming as a preventive.

5442. Wasting and putterfaction, from excess of water or frost, are to be prevented by earthing up the bulbs, or taking up and storing.

The Carrot. - Daúcus Carota L.; Pentándria Digýnia L., and Umbelli-Carotte, Fr.; Gelbe Rübe, Ger.; Carota, Ital.; and Chirivia, Span.

5443. The carrot is a biennial plant, a native of Britain; but though long known as a garden plant, it is comparatively but of recent introduction in agriculture. It appears to have been cultivated from an early period in Germany and Flanders, and introduced from the latter country to Kent and Suffolk early in the 16th century. As the carrot, requires a deep soil, inclining to sand, it can never enter so generally into cultivation as the potato or turnip; but, as observed by a judicious writer, it has been too much neglected on lands where it would have yielded a more valuable product, perhaps, than any bulbous or tap-rooted plant whatever. Several contradictory experiments in its culture have been detailed in a number of publications, from which the practical husbandman will be at a loss to draw any definite conclusion: but, in a recent communication to the Board of Agriculture, from Robert Burrows, an intelligent Norfolk farmer, who has cultivated carrots on a large scale, and with great success, for several years, so accurate an account is presented of the culture, application, and extraordinary value of this root, that carrots will probably soon enter more largely into the rotation of crops on suitable soils. (Supp. &c.) This person had more experience than any one; but he, after a few years, discontinued to cultivate carrots so extensively as he did at the time the communication to the Board of Agriculture was made. The consumption of carrot seed in Norfolk had, in 1821, diminished from three or four tons a year to as many cwts.

5444. The varieties of carrot cultivated in gardens are numerous, and readily increased by the usual means; but the only sort adapted for the field is the long red or field carrot. New seed is most essential, as it will not vegetate in the second year. Old seed, or a mixture of old and new, and also the mixture of the horn carrot, the seed of which is sent over in large quantities from Holland, ought to be carefully avoided.

5445. The best soil for the carrot is a deep rich sandy loam; such a soil ought at least to be a foot deep, and all equally good from top to bottom. On any other the field culture of the carrot will not answer.

5446. In preparing the soil for the carrot, it is essential to plough it before winter, that it may be pulverised by frost; and to work it well by the plough and cultivator in spring, to at least the depth of a foot. This deep tillage may be perfectly accomplished either by means of the trench-plough following the common one, or by the common one alone, with a good strength of team; but the former method is to be preferred, wherever the lands are inclined to be stiff or heavy. Three ploughings are mostly found sufficient, where the land has been previously in a state of tillage; but more may in other cases be necessary. The first ploughing should be made to the depth of ten, twelve, or fourteen inches, and be performed when the soil is tolerably dry, about the beginning of October. It may remain in this condition till towards the middle of February, when it should be turned over a second time, but in a cross direction, to nearly the same depths. In March a third ploughing may be given, in order to the putting in of the seed. This may be somewhat lighter than the preceding ones. As soon as the last ploughing has been given in March, the land should be harrowed, and the surface made as fine as possible.

5447. In Suffolk the farmers sow carrots after turnips, barley, and peas set upon a ryegrass ley; the crops upon the first have generally been most productive; next to that they prefer the latter. In the first place, they feed off the turnips by the beginning of February, and then lay the land up in small balks or furrows, in which state it remains till the second week in March, when it is harrowed down, double furrowed to the depth of about twelve inches, and the seed sown.

5448. The climate most suitable to the carrot is the same as for the turnip; but, from the depth to which their roots penetrate, they will thrive better than the turnip in a dry and warm climate.

5449. Manure, according to some, should not be given to carrots the year they are sown, as it is alleged that when the roots meet with it they become forked, scabbed, and wormy. This, however, is chiefly applicable to cases in which recent unfermented manure has been given, or where other manure has not been properly broken in pieces and spread over the soil or in the drills. The Suffolk and Norfolk farmers, who are the best carrot-growers, always use dung; a suitable proportion of well rotted farmyard dung being constantly turned into the soil at the last ploughing in March. for it has been fully shown, by various trials detailed in The Annals of Agriculture and other books on husbandry, that though good crops of carrots may be occasionally grown without the use of manure, it is only by the liberal application of that substance that the greatest produce possible can be obtained; as they are in general found to bear a relative proportion to the quantity that may have been employed.

5450. Burrows prepares the land with a good dressing of about sixteen cart-loads per acre of rotten farmyard manure or cottager's ashes: the load is about as much as three able horses can draw; and, if bought, costs about four shillings and sixpence per load, besides the carting on the land. He usually sows

wheat stubbles after clover, ploughing the first time in autumn, and once more in the early part of the month of February, if the weather permits; setting on the manure at the time of sowing, which is about the last week in March, or sometimes as late as the second week in April.

5451. In Suffolk, when carrots are intended to be sown after peas, they usually plough the stubble as soon as the harvest is over, in order that the land may clear itself of weeds; in December it is laid up in small balks, to receive the benefit of the frosts; in February it is harrowed down, and manured at the rate of fifteen loads per acre; the manure is ploughed in to the depth of about four inches; and in the month of March the land is double furrowed, and the seed sown. By pursuing this method, they say, the manure lies in the centre of the soil, and not only affords nourishment and support to the carrot in its perpendicular progress, but renders it easy to be turned up by a single ploughing, and greatly promotes the growth of the succeeding crop of barley. In Norfolk it is the practice to sow carrots after a crop of turnips. The manure, after being put on the land in the beginning of March, is first ploughed in with a common plough, and afterwards trench-ploughed about fourteen or fifteen inches deep; it is then harrowed very fine, and the seed sown about the middle of March.

5452. The segment and the seed sown about the middle of March.

5452. The season preferred by Burrows for sowing the carrot is the last week in March or first in April; but he prefers the first period, having generally found early-sown crops

the most productive.

5453. The usual preparation of the seed for sowing, is mixing it with earth or sand, to cause it to separate more freely; but Burrows adds water, turns over the mixture of seeds and moist earth several times, and thus brings it to the point of vegetating before "Having weighed the quantity of seed to be sown, and collected sand or fine mould, in the proportion of about two bushels to an acre, I mix the seed with the sand or mould, eight or ten pounds to every two bushels, and this is done about a fortnight or three weeks before the time I intend sowing; taking care to have the heaps turned over every day, sprinkling the outside of them with water each time of turning over, that every part of the sand heaps may be equally moist, and that vegetation may take place alike throughout. I have great advantage in preparing the seed so long beforehand; it is by this means in a state of forward vegetation, therefore lies but a short time in the ground, and, by quickly appearing above ground, is more able to contend with those numerous tribes of weeds in the soil, whose seeds are of quicker vegetation."

5454. Crude, the French translator of Von Thaer's work, describes in a note (tom. iv. 237.) a practice nearly similar to that of Burrows. Crude uses sciure (night soil) instead of earth, and waters with the drainings of dunghills. He keeps the mixture in a warm but shady situation for eight days; by that time the seed is nearly ready to vegetate, and he sows it immediately.

5455. The quantity of seed when carrots are sown in rows is two pounds per acre, and for broad-cast sowing five pounds. Burrows sows ten pounds per acre in the broad-cast manner.

5456. The usual mode of sowing the carrot is broad-cast; but a much better mode in our opinion would be to sow them in rows at twelve or fourteen inches' distance; drawing the drills, and hoeing the intervals with any suitable drill and hoe.

5457. The most common practice, when carrots are best cultivated, is the hand or broad-cast method, the seed being dispersed as evenly as possible over the land, after the surface has been reduced to a very fine state of pulverisation by harrowing, in order to provide a suitable bed for it to vegetate in; being then covered in by means of a light harrow. As the seed of the carrot is not of a nature to be deposited with much regularity by the drill, and as the young plants can be easily set out to proper distances in the operation of hoeing, this is probably the most appropriate method of putting such sort of seed into the ground; and an additional proof of it is indeed found in its being that which is almost universally adopted in those districts where carrot-husbandry is practised to the greatest extent. But with the view of having the after-culture of the crops more perfectly performed, and at the same time to save the great expense of hand-labour in hoeing the crop, the drill method has been attempted by some cultivators, but we believe without complete success. The work is finished in equidistant rows at the distance of from twelve to fitteen or eighteen inches from each other, according to the mode of hoeing that is practised. In this business some cultivators do not make use of drill-machines, but strike the land into small furrows by hoes or other implements contrived for the purpose, and then cast the seed over the ground by the hand, covering it in either by slight harrowing, or hoeing in the tops of the ridgelets. It is added, that "in this method, where a drill-machine is used, it has been advised by an intelligent cultivator to deposit the seed to the depth of one inch in the rows, leaving the spaces of fourteen inches between them as intervals; the seed in these cases being previously steeped in rain-water for twenty-four hours, and left to sprout, after which it is mixed with saw-dust and dry mould, in the proportion of one peck and a half of each to a pound of the seed. The land is afterwards lig 5457. The most common practice, when carrots are best cultivated, is the hand or broad-cast method,

5458. The after-culture given the carrot consists entirely of hoeing and weeding.

5459. The after-culture given the carrot consists entirely of hoeing and weeding.
5459. In Suffolk they are hoed generally three times in the season. The first time, as soon as the plants can be distinguished from the weeds which surround them. The operation should be performed with three-inch hoes, having handles not above two feet in length; and it requires great attention, as it is extremely difficult to distinguish and separate the young carrots from the weeds. The second hoeing should be given in three or four weeks afterwards, according to the forwardness of the crop; it may be performed with common hoes, care being taken to set out the plants at proper distances. From eight to fifteen or eighteen inches, each way, are the common distances at which they are allowed to stand; and it has been proved, from many years' experience in districts where they are most cultivated, that carrots which grow at such distances always proves a more abundant crop than when the plants are allowed to stand closer together. The third hoeing is commonly given about the middle or end of June; and in this, besides destroying the weeds, another material circumstance to be attended to is, to set out the carrots at proper distances, and also, wherever any have been left double at the former hoeings, to take the worse of the two plants away.

5460. Carrots sown according to the plan of Burrows are ready to hoe within about five or six weeks. He hoes three and sometimes four times, or until the crop is perfectly clean: the first hoeing is with hoes four inches long, and two and a quarter inches wide. The second hoeing invariably takes place as soon as the first is completed, and is performed with six-inch hoes, by two and a quarter inches wide. By this time the plants are set; the first time of hoeing nothing was cut but the weeds. He leaves the plants nine inches apart from each other; sometimes they will be a foot, or even farther asunder.

5461. Carrots are taken up generally in the last week of October. Burrows's practice is to let the work to a man who engages women and children to assist him. work is performed with three-pronged forks; the children cut off the tops, laying them and the roots in separate heaps, ready for the teams to take away.

5462. "I take up in autumn a sufficient quantity to have a store to last me out any considerable frost or snow that may happen in the winter months; the rest of the crop I leave in the ground, preferring them fresh out of the earth for both horses and bullocks. The carrots keep best in the ground, nor can the severest frosts do them any material injury; the first week in March it is necessary to have the remaining part of the crop taken up, and the land cleared for barley. The carrots can either be laid in a heap with a small quantity of straw over them, or they may be laid into some empty outhouse or barn, in heaps of many hundred bushels, provided they are put together dry. This latter circumstance it is indispensably necessary to attend to; for if laid together in large heaps when wet, they will certainly sustain much injury. When selecting such as I want to keep for the use of my horses until the months of May and June, in drawing over the heaps (which should be done in the latter end of April, when the carrots begin to sprout at the crown very fast) I throw aside the healthy and most perfect roots, and have their crowns cut completely off and laid by themselves; by this means, carrots may be kept the month of June out in a high state of perfection." (Communications to the Board of Agriculture, vol. vii. p. 72.)

5463. Storing a whole crop of carrots may be a desirable practice when winter wheat is to follow them, in which case the same mode may be adopted as for turnips or potatoes, but with fewer precautions against the frost, as the carrot, if perfectly dry, is very little injured by that description of weather.

5464. The produce of an acre of carrots in Suffolk, according to Arthur Young, is at an average 350 bushels; but Burrows's crops averaged upwards of 800 bushels per

acre, which considerably exceeds the largest crop of potatoes.

5465. The uses to which the carrot is applied in Suffolk are various. Large quantities are sent to the London markets, and also given as food to different kinds of live Horses are remarkably fond of carrots; and it is even said, that when oats and carrots are given together, the horses leave the oats and eat the carrots. The ordinary allowance is about forty or fifty pounds a day to each horse. Carrots when mixed with chaff, that is, cut straw, and a little hay, without corn, keep horses in excellent condition for performing all kinds of ordinary labour. The farmers begin to feed their horses with carrots in December, and continue to give them chiefly that kind of provender till the beginning or middle of May; to which period, with proper care, carrots may be preserved. As many of the farmers in that country are of opinion that carrots are not so good for horses in winter as in spring, they give only half the above allowance of carrots at first, and add a little corn for a few weeks after they begin to use carrots.

at first, and add a little corn for a few weeks after they begin to use carrots.

5466. The application of the carrot to the feeding of working cattle and hogs is thus detailed by Burrows:—"I begin to take up the carrot crop in the last week of October, as at that time I generally finish soiling my horses with lucern, and now solely depend upon my carrots; with a proper allowance of hay, as winter food for my horses, until about the first week of June following, when the lucern is again ready for soiling. By reducing this practice to a system, I have been enabled to feed ten cart-horses throughout the winter months for these last six years, without giving them any corn whatever, and have at the same time effected a considerable saving of hay, from what I found necessary to give to the same number of horses, when, according to the usual custom of the country, I fed my horses with corn and hay. I give them to my cart-horses in the proportion of seventy points weight of carrots a horse per day, upon an average; not allowing them quite so many in the very short days, and sometimes more than that quantity in the spring months, or to the amount of what I withheld in the short winter days. The men who tend the horses slice some of the carrots in the cut chaff or hay, and barn-door refuse; the rest of the carrots they give whole to the horses at night, with a small quantity of hay in their racks; and with this food my horses generally enjoy uninterrupted health. I mention this, as I believe that some persons think that carrots only, given as food to horses, are injurious to their constitutions; but most of the prejudices of mankind have no better foundation, and are taken up at random, or inherited from their grandfathers. So successful have I been with carrots, as a winter food for, horses, that with the assistance of lucern for soiling in summer, I have been enabled to prove by experiments conducted under my own personal inspection, that an able Norfolk team-horse, felly worked two journeys d day, winter and summer,

potato. These and other circumstances considered, it appears to be the most valuable of all roots for working horses.

5468. The use of the carrot in domestic economy is well known. Their produce of nutritive matter, as ascertained by Sir H. Davy, amounts to ninety-eight parts in one thousand, of which three are starch, and ninety-five sugar. They are used in the dairy in winter and spring to give colour and flavour to butter. In the distillery, owing to the great proportion of sugar in their composition, they yield more spirit than the potato: the usual quantity is twelve gallons per ton. They are excellent in soups, stews, and haricots, and boiled whole with salt beef.

5469. To save carrot seed, select annually some of the most perfect and best-shaped roots in the taking-up season, and either preserve them in sand in a cellar till spring, or plant them immediately in an open airy part of the garden, protecting them with litter during severe frosts, or earthing them over, and uncovering them in March follow-The seed is in no danger of being contaminated by any other plant, as the wild carrot, even should it happen to grow in the neighbourhood, flowers later. In August it will be fit to gather, and is best preserved on the stalks till wanted. This is the most

certain mode of procuring genuine and new seed, but still it will be found advisable to change it occasionally.

5470. The diseases of carrots are only those which are common to most plants, such as mildew, insects, &c. The mildew and worms at the root frequently injure crops, and are to be guarded against as far as practicable by a proper choice of soil, season of sowing, and after-culture.

Sect. IV. The Parsnep. — Pastinàca sativa L.; Pentándria Digýnia L., and Umbellíferæ J. Le Panais, Fr.; Pastinake, Ger.; Pastinaca, Ital.; and Zanahoria, Span.

5471. The parsnep is a biennial plant with a fusiform root like the carrot, and nearly equal in its products of nutritive and saccharine matter. It is a native of most parts of Europe and generally cultivated in gardens, but is only of late and very partial introduction as a field plant. Its culture has been chiefly confined to the Island of Jersey, where it attains a large size, and is much esteemed for fattening cattle and pigs. It is considered rather more hardy than the carrot, and its produce is said to be greater. It may be sown either in autumn or spring, and its seed admits of drilling by machinery. The plants when they come up are more easily recognised than carrots, and consequently their culture is on the whole more simple, less dependent on manual labour, and, therefore, more suited to farming. For the rest, their culture is the same as that of the carrot.

5472. The variety best suited for the field is the large Jersey, the seed of which should be procured from the island, as that of the garden parsnep sold by the seedsmen never attains the same size.

5473. The soil, preparation, and manure for this plant are the same as for the carrot.

5474. The quantity of seed for sowing in drills is from four to five pounds per acre, and for broad-cast six or eight pounds. It must always be new, as two years' seed does not come up freely. It may or may not be prepared by steeping; but it requires no earth or sand, or rubbing, like carrot seed, as it passes freely through the same drill that will sow tares or peas.

5475. The time of sowing is generally about the middle of February; but some sow in September, in which case the seed does not vegetate till early in spring. The latter method, however, is obviously against the culture of the soil, which must thus remain a year in a consolidated state.

5476. The manner of sowing is generally in drills at fifteen or eighteen inches' distance; but some sow broad-cast, and harrow in the seed; and in Jersey parsneps and beans are generally cultivated together. The beans are first dibbled in, and afterwards the parsnep seed scattered over the surface and harrowed. It is acknowledged that a good crop of both plants is never obtained; and therefore, though this mode may be found to answer in the mild climate of Jersey, it is not to be imitated in other places. Drills and broadcast without any intermixture of plants are the only advisable modes.

5477. The after-culture and taking up are the same as for the carrot, with this difference, that the parsnep when sown broad-cast is generally thinned out to twelve inches, at an average, plant from plant; and, when in rows eighteen inches apart, to nine inches in the row.

5478. The produce is said to be greater than that of carrots; and the economical application the same. In the fattening of cattle it is found equal if not superior, performing the business with as much expedition, and affording meat of exquisite flavour and a highly juicy quality. The animals eat it with much greediness. It is reckoned that thirty perches, where the crop is good, will be sufficient to fatten a perfectly lean ox of three or four years old, in the course of three months. They are given in the proportion of about thirty pounds' weight morning, noon, and night; the large ones being split in three or four pieces, and a little hay supplied in the intervals of those periods. the result of experiment has shown that not only neat cattle, but hogs and poultry, become fat much sooner, and are more bulky, than when fed with any other root or vegetable; and that the meat is more sweet and delicate. The parsnep is excellent food for cows; and, with hay during winter, the cows of Jersey and Guernsey yield butter of a fine yellow hue, of a saffron tinge, as excellent as if they had been in the most luxuriant pasture. In these islands beans are cultivated along with parsneps, in double rows, twelve feet asunder, and the beans eighteen inches apart every way. The beans are planted first, and the ground afterwards harrowed, and the parsneps sown broad-cast. (Com. to B. of Agr. vol. i. p. 215.)

5479. Parsnep leaves, being more bulky than those of carrots, may be mown off before taking up the roots, and given to cows, oxen, or horses, by which they will be greedily

eaten.

5480. The use of the parsnep in domestic economy is nearly the same as that of the carrot. They are much esteemed to salt fish, and are sometimes roasted for that purpose.

Their produce in nutritive matter is 99 parts in 1000, of which 9 are mucilage and 90 sugar. Gerarde says, that a very good bread was made from them in his time. They afford as much spirit as the carrot, and make an excellent wine.

5481. To save parsnep seed, proceed as with the carrot. The parsnep, being more hardy and luxuriant than the carrot, is less liable to the mildew and worms, but equally so to become forked if the soil be not deep and well pulverised, and the manure minutely divided and equally distributed.

The Field Beet. - Bèta L.; Pentándria Digýnia L., and Chenopodeæ J. Betterave Champêtre, Fr.; Mangold-würzel, Ger.; Biettola, Ital.; and Betarraga, Span.

5482. The field-beet, commonly called the mangold-würzel, and sometimes erroneously the root of scarcity (in German mangel würzel), is supposed by Professor Thaer to be a mongrel between the red and white beet. It has a much larger bulb than either, and that bulb, in some varieties, grows in great part above ground. It has been a good deal cultivated in Germany and Switzerland, both for its leaves and roots; the leaves are either used as spinach or given to cattle; and the roots are either given to cattle, used in distillation, or in the manufacture of sugar. The culture of the field-beet in Britain is very recent, and it may be questioned whether it has any advantages over the turnip for general agricultural purposes. It admits, however, of being cultivated on ridgelets and with as little manual labour as the turnip, while it will prosper on a stronger soil, and near large towns it is not liable to the depredations usually committed on turnips or carrots, as the root is unpalatable either raw or boiled.

5483. The variety preferred in Germany is one slightly tinged with red for cattle, and the pale yellow variety for the distillery and sugar manufacture. The seed must not exceed a year old, and great care should be taken that the seed of the common red and white beet are not mixed with it. The seed of every variety of beet is very apt to dege-

5484. Any soil will suit this plant provided it is rich; immense crops have been raised on strong clays; but such soils are not easily prepared for this sort of crop, and are also ill adapted for after-culture.

5485. The preparation should be exactly the same as for turnips; and the seed should be sown on the ridgelets in the same manner. Some, however, dibble in the seed in order to save the expense of thinning. The season of sowing is the same as for the parsnep, and should not be deferred later than the middle of April. The after culture consists in horse-hoeing, hand-hoeing, and weeding, as in the culture of the turnip, and the plants are thinned out to about the same distance in the rows. Blanks may be filled up by transplanting, or, as in the case of the Swedish turnip, whole crops may be reard in this way, but the produce is never so large. As the transplanting, however, takes place in May, more time is afforded, and drier weather obtained for cleaning the soil. The plants are set by the dibbler along the centre of the ridgelets, which are previously consolidated by rolling.

5486. The produce is, cæteris paribus, about the same as that of the Swedish turnip; but the nutritive matter afforded by the beet is 136 parts in 1000, of which 13 are mucilage, 119 sugar, and 4 gluten. According to Von Thaer, they afford ten per cent. of nutritive matter, and are in that respect to hay as 10 to 46, and to potatoes as 20 to 46. An acre would thus appear to afford more nourishment than turnips, carrots, or parsneps.

5487. Practical men are not agreed as to the value of this root, compared with the Swedish turnip; but the majority seem to think, that as a food for milk cows, the mangold is to be preferred, more especially as it gives no unpleasant taste to the milk and butter. It has this advantage over turnips, that it thrives better than they do in a dry warm season, being a plant that naturally requires more light and heat than the turnip.

5488. The application of the field-beet is almost confined to the fattening of stock, and feeding of milch cows. Near London they are in repute for the latter purpose; and, according to Von Thaer, they cause a great increase of milk, as well as improve its flavour. The tops are first taken off, and given by themselves; and then the roots are taken up, washed, and given raw. The roots are much more easily injured by frost than the turnip, carrot, or parsnep, and are stored with difficulty. The leaves make a very good spinach, but the roots cannot be used in cooking like those of the red beet. In the distillery it is nearly half as productive as the potato; but, according to Von Thaer, it is not likely to yield much profit in the manufacture of sugar.

5489. The manufacture of sugar from mangold wirzed is still, however, carried on in France, and, although we think it can never ultimately compete with that from the cane, it seems of late years to be on the increase. We shall therefore give a short account of the process, premising that the greatest quantity of sugar is not obtained from the greatest bulk of root, but rather from small roots produced from dry calcareous soils, at the rate of from fifteen to twenty-five tons an acre. One cwt. of sugar is the general produce obtained by the most perfect apparatus from one ton of root. As soon as the leaves begin to turn yellow, the root may be said to have arrived at maturity; and it is time to take up the crop, and to begin the process of sugar-making, an operation which continues from October to February in the larger manufactories. Take the roots up dry, and keep them so; the smaller the heap the better, because the least fermentation will effectually prevent the formation of sugar. The difference in amount and quality of sugar is always in favour of that made at the beginning of the season. The root, in keeping, undergoes a chemical change, often amounting to a total loss of its saccharine matter; although its outward appearance indicates no such change.

5490. Process of sugar-making. The roots should first be washed, and then rasped, to reduce them to

5490. Process of sugar-making. The roots should first be washed, and then rasped, to reduce them to a state of pulp. Of course, in large manufactories, they are provided with rasping machines; and it is

somewhat difficult to find a substitute on a small scale. I should imagine, though, that a stout iron plate, punched with triangular holes, the rough edges of which are left standing, somewhat after the manner of a mutneggrater, might answer the purpose, only that I would have it somewhat concave instead a cider-mill and press within a reasonable distance, it might inswer to take the roots titheor, slice them, and pass them through the mill. When by these or any other means they are reduced them, and pass them through the mill. When by these or any other means they are reduced them, and pass them through the mill. When by these or any other means they are reduced pulp, the juice should be pressed from the pulp, which is thus done: — It is put into carvass bags, not too fine, so as to impede the running of the juice, nor yet so coarse as to let the pulp through the meshes. The bags should be so fitted as, when pressed, to occupy about an inch in depth. Most manufactories use about twenty-five of these bags at one pressing, but this depends on the power of the press into the juice-cistern below. The operation of pressing should immediately follow that of rasping. This point should be particularly attended to.

5491. Defecation. The juice being expressed from the pulp, the next process is the defecation of the price, and here, too, no time should be lost. This is effected by boiling: a copper boiler should be used, inice, and here, too, no time should be lost. This is effected by boiling: a copper boiler should be used, including the properties of the pression of the pulp, the next process is the defectation of the press. The proper quantity is assertained by carefully examining the juice every time the acid is added, with a drop of syrup of violets in a spoon, which ought to turn of a green colour. About thirty ounces of the acid to every 100 gallons of juice will be necessary. This done, the fire is quenched, and the boiler left to settle for half an hour; at the end of which time, the liquor is drawn off: by so

5495. To save seed, select the finest specimens, preserve them in sand during winter, and plant them in an airy part of the garden in March. The rest is easy.

5496. To diseases no plant is less liable than the beet.

The Cabbage Tribe. — Brássica L.; Tetradynàmia Siliquòsa L., and Cruciferæ J. Chou, Fr.; Kohl, Ger.; Cavolo, Ital.; and Col, Span.

5497. The cabbage tribe is of the greatest antiquity in gardens, and most of the species may be cultivated in the fields with success. For the common purposes of farming, however, there can be little doubt that they will afford less profit than any of the plants hitherto treated of in this chapter; but near large towns or sca-ports they may answer the purpose of the farm-gardener. Cabbage culture, Brown observes, is much more hazardous, far less profitable, and attended with infinitely more trouble, than that of turnips; while the advantages to be derived are not, in our opinion, of a description to compensate the extra hazard and trouble thereby incurred.

5498. The culture of cabbage has been strongly recommended by several speculative agriculturists, and examples adduced of extraordinary produce and profits; but any plant treated in an extraordinary manner will give extraordinary results; and thus an inferior production may be made to appear more valuable than it really is. One reason why so much has been said in their favour, by Arthur Young and other southern farmers, is, that they compare them with the produce of turnips, which, in the south of England, is

averaged at only fifteen tons per acre.

5499. The variety of cabbage, cultivated in the fields for cattle, is almost exclusively the large field cabbage, called also the Scotch, Strasburg, drumhead, &c. For the purposes of domestic economy, other varieties of early and late cabbage, as the York, Battersea, sugar-loaf, imperial, &c. are grown; and also German greens, Savoy cabbage, and even Brussels sprouts and broccoli.

5500. The cow cabbage, Casarean cole, or tree cabbage (Brassica oleràcea L. var. acéphala Dec.; Chou cavalier, Chou à vaches, Chou branchu, Chou en arbre, Chou mille têtes, Fr.; Caulet, Flem.), is much cul-

tivated for milch cows in French Flanders, the Netherlands, and in Jersey and Guernsey; and it has been introduced, at different periods, into this country, without having ever come into general cultivation. The Chow cautet de Flandre differs from the French variety in having red leaves; and the Chow nert branchu, the Chow mille têles du Poiteau, differs from the first in not growing quite so high, and in forming a somewhat tufted head. No variety among these, and the many that might be named, appears so suitable for field culture in the climate of Britain as the Scotch or drumhead cabbage.

suitable for field culture in the climate of Britain as the Scotch or drumhead cabbage. 5501. In Jersey, the cow cabbage is sown from about the 20th of August to list of September, in a good soil, and planted out from November to January and February in succession, at from twenty to thirty inches' distance, in a good, substantial, well manured soil; as no plant is more exhausting, or requires a better soil; but perhaps no one plant produces so large a quantity of nutriment during its period of vegetation. About the month of April they begin (from the first crop) to strip the under leaves; cut them in small pieces; mix them with sour milk and bran, or other farinaceous substances; and give them as food to ducks, geese, hogs, &c. During the whole summer they continue stripping the plant as above stated, until it attains the height of from six to twelve feet; and if a scarcity of brage prevails, the green leaves form excellent food for cows and oxen, with alternate feeds of hay and straw. The tops and side shoots are excellent at table during winter and spring. The longest of the stalks are frequently used to support scarlet runners and other French beans, and as cross rafters for farm buildings, under thatch, and have been known to last more than half a century, when kept dry, for the latter purpose. (Gard. Mag. vol. v.)

5502. Any soil that is rich will suit the cabbage, but a strong loam is preferred. best mode of preparation for field cabbage is that for potatoes or turnips, the plants being dibbled along the centre of each ridgelet. For early cabbage no ridgelets are required,

as the plants are inserted in rows, by a line, at much narrower distances.

5503. The season for planting, for a full crop of field cabbages, is usually March; but cabbages may be planted as late as June, and produce a tolerable crop by November; and in this way they may sometimes be made to succeed an unsuccessful sowing of turnips. The plants used in March should be the produce of seed sown, in an open loamy part of the garden, in the preceding August; but those planted in May or June may be the produce of seed sown in the February or March of the

same year.

5504. The preparation given to the plants consists in pinching off the extremity of their tap-root, and any tubercles which appear on the root or stem, and in immersing the root and stem in a puddle, or mixture of earth and water, to protect the fibres and pores of the root and stem from the drought. The plants may then be inserted by the dibber, taking care not to plant them too deep, and to press the earth firmly to the lower extremity of the root. If this last point is not attended to in planting by the dibber, the plants will either die, or, if kept alive by the moisture of the soil or rain, their process will be very slow. When the distance between the ridgelets is twenty-seven inches, the plants are set about two feet asunder in the rows; and the quantity required for an acre is about 6000 plants. Some recommend sowing as for turnips; but, by this mode, one of the advantages of a green crop is infringed on, viz, the time given to clean the land. Where cabbages are sown, that operation must be performed at least a month soner than if they were planted; consequently, the best month of the cleaning season is lost. To plant or sow a green crop on land in good heart, that does not require cleaning, will seldom be found good husbandry. It may succeed near large towns, where roots and other green produce sell high, but it can never enter into any general system of farming.

5505. The after-culture consists in horse and hand-hoeing and weeding; and the crop is taken by chopping off the heads with a spade, leaving an inch or two of stalk to each. They may be preserved by housing, but only for a short time. The produce is said to be from thirty-five to forty tons per acre. Sir H. Davy found that 1000 parts of cabbage gave seventy-three of nutritive matter, of which forty-one are mucilage, twenty-four

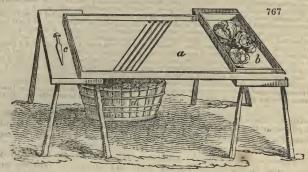

saccharine matter, and eight gluten.

5506. The application of the field cabbage is generally to the feeding of milch cows, and sometimes to the fattening of oxen and sheep. For the former purpose, great care must be taken to remove the outside decaying leaves; otherwise they are apt to give an unpleasant flavour to the milk and butter. Cabbages are also eaten by swine and horses, and are reckoned excellent food for sheep that have newly dropped their lambs, and for calves. A cow will eat from 100 to 150lbs. of cabbage per day, and a sheep ten or twelve pounds, besides a moderate allowance of hay. Some farmers consider that ewes fatten faster on cabbages than on turnips, and that ewes having lambs are much more prolific in milk when so fed. (Country Times, Feb. 8. p. 47.) Early or garden cabbages are sold to green-grocers, or to the consumers, or to ships' victuallers for the purpose of being pickled or made into sour crout.

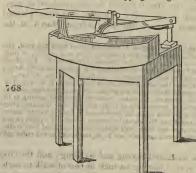

being pickled or made into sour crout.

5507. Satted cabbage, or sawerkraut, is thus prepared in Germany:— Any sort of cabbage or kail, or even turnips and kidneybeans, may be prepared in this way; but white, compact-headed, large cabbages are preferred, and next compact-headed red cabbages. The first process of preparing them is to scoop out the interior part of the stalk, with an iron instrument or scoop; they are then cut into small shreds by a wooden machine, composed of a flat board or tray, which has a ledge on two sides, to steady a box or frame into which the cabbages are put. In the middle of the board are four flat pieces of steel, similar to the steel part of a spokeshave, placed in an oblique direction; and the near edge of each being a little raised up, with small spaces between each, to let the shreds fall down into a tub placed underneath to receive them. The cabbages are then put into the box before described, which is pushed backwards and forwards, when the cabbages are then put into the box before described, which is pushed backwards and forwards, when the cabbages, being cut by the steel, fall in small shreds into a tub placed place. A barrel stands by ready to receive them when cut, the sides of which are first washed with usegar. A man stands on a chair by the barrel, with clean wooden shoes on, whose business it is to salt and prepare them, which is done in the following manner: the man first takes as much of the cut cabbage as covers about four inches above the bottom; he next strews upon it two handfuls of salt, one handful of unground pepper, and a small quantity of salad oil; he then gets into the barrel, and treads it down with his wooden shoes till it is well mixed and compact. He next takes another layer of cabbage, and puts salt and pepper on it as before, and treads it daym and as ogoes on till the barrel is filled. A board is then placed on it, and upon the board some very heavy weights are put; and it remains so ten or fifteen days, when it partially ferments, and a great deal o

who prepare sauerkraut are Tyrolese, and carry their machine (fg. 767.), which has not been invented more than ten or twelve years, on their backs from house to house. This machine contains a cutting tray (a), box into which the cabbages are placed (b), scoop (c), and tub into which the shreds fall (d). (Gard. Mag. vol. iii, p. 343.)

5508. Newton's machine for chopping cabbage or other vegetables, roots, or meat (fig. 768.), consists of five knives let into an iron plate, and the latter is screwed to the working bar. The knives are

five knives let into an iron plate, and the latter is screwed to the working bar. The knives are fastened, by bolts passing through them, close under and above the iron plate. The sliding plate is for the purpose of preventing the meat from being scattered; and to this plate are added scrapers, which are screwed underneath, for the purpose of cleaning the knives at every stroke. A spring raises the knives, and enables any person to chop at least twenty times as much meat, in the same time, as can be done by the common mode. The length of the knives being equal to the breadth of the trough, no meat can possibly escape the knives; nor will the meat require so much turning as is usually wanted. When it does require turning, it is easily done by alternately pressing the knives at either end of the trough, sliding them towards the middle. The machine is also applicable for cutting fat, suet, &c. previously to rendering them into tallow; likewise to chopping madder and other roots for calico printers, or as used in their recent state for dyers; and for dividing potatoes, carrots, and other esculent roots, cabbage for sauer kraut, and

roots used in feeding cattle. (Smith's Mechanic, vol. ii. p. 860.)

5509. To save cabbage seed, select a few fine specimens, and plant them by themselves where they will be in no danger of being contaminated by others of the Brássica tribe when in flower. The seed will keep many years.

of the diseases of cabbages are the same as those of the turnip, with the exception of the forked excrescence. On the roots of the plants are frequently found knobs, which, in the preparation for transplanting, should, as we have already observed, be carefully removed.

Sect. VII. Other Plants which might be cultivated in the Fields for their Roots or Leaves, as Food for Man or Cuttle, in a recent State.

5511. Every hardy garden plant may be cultivated in the fields, and with very little manual labour. Accordingly we find onions, spinach, cress, radishes, and even cucumbers, grown by farmers, or farm gardeners in the neighbourhood of the metropolis, and also in other places. None of these plants, however, can be considered as belonging to agriculture; nor should we notice those which follow, but because they have been tried and recommended by zealous cultivators, and are treated of in some works on farming. No plant can be considered as belonging to agriculture that is not in sufficient demand, or of sufficient general use in feeding stock, as to admit of its frequent occurrence in rotations; and such certainly cannot be said to be the case with the Jerusalem artichoke and lettuce, now about to be noticed.

5512. The Jerusalem artichoke (Helianthus tuberosus L.; Topinambour, Fr.) is a tuberous-rooted plant, with leafy stems from four to six feet high. It thrives well on soft moist soils, and even, it is said, on moist peat soils; and it is alleged that its tops will afford as much fodder per acre as crop of ostators more; and its roots half as many tubers as an ordinary crop of potatoes. (Agricultural Magazine, 1807-8.) The soil may be cultivated in all respects like the potato. The tubers, being abundant in the market by maceration, and manufactured into cordage or cloth; and this is said to be done in some parts of the north and west of France, as about Hagenau, where this plant, on the poor sandy soils, is an object of field culture.

PRACTICE OF AGRICULTURE.

PART III.

5513. The common Cos lettuce (Lacthea sativa L.) has been grown for feeding pigs, and other purposes. Arthur Young informs us, in his Calendar of Husbandry, that he first observed the sowing of lettuces for hogs practised, on a precty regular system on the common control of the party of the common control of the c

Grant, a nurseryman Lewisham, and tried by number of cultivators. Ca the of every kind are said to be fond of this plant; and so great is its produce on good soil, that Mr. Grant thinks an acre might be made to produce thirty tons of green fodder in one year. He has fodder in one year. He has grown it to the height of seven feet as thick as it could stand on the ground. plant is of easy propagation by seed or division of the roots; the better way would probably be to sow in a gar-den, and transplant when the

den, and transplant when the plants were a year old. All the symphytums are plants of bably continue to produce crops for many years; and, in that point of view, it would seem to be a valuable plant for the cottager who keeps a cow. (Gard. Mag. vol. v. and Country Times, May 10th, 1850.)

5517. The day lify (Hemerocállis fúlva L., fig. 771.) was brought into notice by Mr. Elles, late of Longleat. In the years 1826-7, he observed, accidentally, how extremely fond cattle were of this plant, even eating it down to the roots when an opportunity occurred; and as he knew, from long experience, that it would, even in dry ground, produce herbage in the middle and latter end of

April, equal in quantity to any water meadow, the extreme facility with which it may be propagated and grown in almost any soil and situation, and also its apparently nutritious nature, he was induced to give it a trial in a plot of ground of about twenty rods, attached to the cottage in which he lived. He did so, and after two years' trial found the day lily produce a supply of green food in April and towards the middle of May, when there is little or no pasture grass, and never could detect any unpleasant flavour in the milk or butter, though given in considerable quantities. The day lily, of which there are two species, differing very little in appearance, H. flava and fulva, is a perennial of great duration, rapid increase, and of easy propagation by division. It certainly well deserves trial as a permanent herbage plant, especially for the cottager and small farmer. (Gard. Mag. vol. v. p. 441.)

CHAP. V.

Culture of Herbage Plants.

5518. The cultivation of clovers and other herbage plants, used exclusively as food for live stock, is comparatively a modern improvement. They were known, as we have seen, to the Greeks and Romans, and cultivated from a very early period in the low countries; but do not appear to have attracted much notice in Britain till the sixteenth century, when our frequent intercourse with Holland led to the introduction of some of our best field plants and agricultural practices. At present clovers enter largely into the succession of crops, on all soils, and in every productive course of management. Before they were introduced into cultivation, it was necessary, when land was exhausted by grain crops, to leave it in a state of comparative sterility for several years, before it became either valuable as pasture or again fit for carrying corn: but at present clovers are not only indispensable in the cultivation of white and green crops alternately, upon very rich soils, but are the foundation of convertible husbandry on land that is not so rich as to permit of a constant aration, and which therefore requires two or more years' pasturage at certain intervals. Lucern and saintfoin, though of much less value as general crops, are valuable plants in particular situations; more especially the latter, which will produce good crops on dry chalky and limestone soils, where most other agricultural plants, and even grasses, would barely maintain their existence.

5519. The characteristic points of culture of this class of plants are broad-cast sowing, mowing, soiling, and hay-making; and that when cut for the two last purposes, two or

more crops may be had in a season from the same roots.

5520. The nutritive products of the principal herbage plants are thus given by Sir H. Davy: —

1		7-7-	In 1000 Parts.						
	Systematic Name.	English Name.	Whole quantity of soluble or nutritive matter.	Mucilage, or starch.	Saccharine matter, or sugar.	Gluten, or albumen.	Extract, or matter rendered insoluble during evaporation.

Sect. I. The Clover Family. — Trifòlium L.; Diadélphia Decándria L., and Leguminòsæ J. Tréfle, Fr.; Klee, Ger.; Trifoglio, Ital.; and Trebol, Span.

5521. The clovers (fig. 772.) are a numerous family, chiefly natives of Europe: those selected by the agriculturist are natives of Britain; and one species, the white or creeping clover, is often found in great luxuriance in native pastures. As rye-grass is very generally sown with clovers, it will be necessary to treat of its culture in connection with these plants, reserving, however, the more particular consideration of rye-grass till we treat of the hay grasses. (Chap. VI.) Many intelligent cultivators consider rye-grass as a very severe crop for the soil; and it is alleged that wheat does not succeed well after the herbage with which rye grass is intermixed in any considerable quantity. Other plants have accordingly been recommended as a substitute for rye-grass, and cock's-foot (Dáctylis glomeràta) has been tried, apparently with great success, by Coke of Holkham in Norfolk, and others; but this is a very coarse grass when allowed to rise to any height, and the use of it for hay has not yet been ascertained. Donaldson considers the general introduction of clovers, and the cultivated grasses, as one of the greatest improvements in modern husbandry. The commencement of improvements in the different species of live-stock, in the modes of cultivation, and in the superior quality, as well as quantity, of the crops of grain, may all, he thinks, be dated from the period when the sowing of clovers and grass-seeds was first introduced into the different districts of the kingdom.

5522. The species of clover in cultivation are: -

5523. The red clover (Trifolium praténse, fig. 772. a), a biennial, and sometimes, especially on chalky soils, a triennial plant, known from the other species by its broad leaves, luxuriant growth, and reddish purple flowers. In its wild state a perennial.

5524. The white, or creeping, or Dutch clover (T. repens, b), a perennial plant, known by its creeping stems and white flowers.

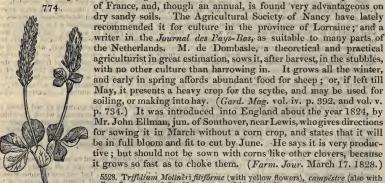

5525. The yellow clover, hop-trefoil, or shamrock clover, the black nonsuch of the Norfolk farmers
(T. procumbens, c), an annual, known by its procumbent shoots
and yellow flowers. This species is seldom cultivated; the yel-

and yellow flowers. This species is seldom cultivated; the yellow clover of the seed shops being the Medicago lupulina, the lupuline, or minette dorée of the French. (Fig. 773.)

5556. The meadow clover, cow-clover, cow-grass, or marliagrass, the first the best name (T. mèdium, d), a perennial; resembling the red clover, but of a paler hue, dwarfer habit, with pale red or whitish flowers, and long roots very sweet to the taste. This species is but partially cultivated, and it is extremely difficult to procure the seeds genuine. It comes into flower from twelve to fifteen days later than the common red clover, has a solid stalk, a narrower leaf, and both leaves and flowers have a paler hue. A poor sandy soil, it is said, will produce a good crop of cow-clover that would not produce half a crop of the common red clover; it is also as good the second year as the first. Some farmers sow it because the crop comes in between the first and second cutting of the red clover as green food. green food.

5527. The flesh-coloured clover (Trifolium incarnatum Lin.; Farouche or Trefle de Roussillon, Fr. fig. 774.) has long been cultivated in some of the southern departments of France, and, though an annual, is found very advantageous on

5528. Trifolium Molineri filiforme (with yellow flowers), campistre (also with yellow flowers), and fragiferum, are cultivated in France; but we believe chiefly ou the poorer soils. Seeds of them and of all the other species may be correctly obtained from Vilmorin Andrieux and Co., seed merchants in Paris.

5529. In the choice of sorts the red or broad clover is the kind most generally cultivated on land that carries corn and herbage crops alternately, as it yields the largest produce for one crop of all the sorts. White and yellow clover are seldom sown with it, unless when several years' pasturage is intended.

The soil best adapted for clover is a deep sandy loam, which is favourable to its long tap-roots: but it will grow in any soil, provided it be dry. So congenial is calcareous matters to clovers, that the mere strewing of lime on some soils will call into action clover-seeds, which it would appear have lain dormant for ages. At least this appears the most obvious way of accounting for the well known appearance of white clover in such cases.

5531. The climate most suitable for the clovers is one neither very hot nor very dry and cold. Most leguminous plants delight both in a dry soil and climate, and warm temperature, and the clover will be found to produce most seed under such circumstances; but as the production of seed is only in some situations an object of the farmer's attention, a season rather moist, provided it be warm, is always attended by the most

bulky crops of clover herbage.

5532. The preparation of the soil and the manures, which clover receives in ordinary farm culture, are those destined also for another crop; clover mixed with a certain proportion of rye-grass being generally sown along with or among corn crops, and especially with spring-sown wheat, barley, and the early varieties of oats. Unless, however, the soils on which these crops are sown are well pulverised, and have been some years under tillage, clovers will not succeed in them, it being ascertained that newly broken-up levs or pasture grounds cannot be sown down or restored to clover and grasses till the soil is thoroughly comminuted, and the roots of the former grasses and herbage plants completely destroyed.

5533. The time of sowing clover-seeds is generally the spring, during the corn seed time, or from February to May; but they may also be sown from August to October, and when they are sown by themselves, that is, unaccompanied by any corn crop, this will be found the best season, as the young plants are less liable to be dried up and impeded in their progress by the sun, than when sown alone in spring and remaining tender

and unshaded during the hot and dry weather of July.

5534. Some prepare the seed for sowing by steeping in water or in oil as in Switzerland, and then mixing it with powdered gypsum, as a preventive from the attacks of insects.
5535. The manner of sowing is almost always broad-cast. When sown with spring corn, clover and grass-seeds are usually put in immediately water the land has been pulverised by harrowing in the corn-seed, and are themselves covered by one course more of the harrows; or, if the corn is drilled, the small seeds are sown immediately before or after hand-hoeing; and the land is then finished by a course of the harrows. Clover is generally sown by hand, though of late years the broad-cast drill (fig. 722.) has been used, both in the case of the clovers and the grasses. A lighter harrow is generally employed in covering such seeds, than that used for corn. When the land is under an autumn-sown crop of wheat or other grain, though the clovers and ryc-grass are still sown in spring, the proper period must depend both upon the state of the land and the progress of the crops; and it may be often advisable to break the crust formed on the surface of tenacious soils, by using the harrow before the clovers are sown, as well as afterwards to cover them. Sometimes the roller only is employed at this time, and there are instances of clover and rye-grass succeeding when sown, without either harrowing or rolling. But it is commonly of advantage to the wheat crop itself, to use the harrows in spring, and the roller alone cannot be depended on, unless the season be very favourable. In some cases grass-seeds are sown by themselves, either in autumn tage to the wheat crop itself, to use the harrows in spring, and the roller alone cannot be depended on, unless the seasou be very favourable. In some cases grass-seeds are sown by themselves, either in autumn or spring, but rarely on tillage land. Nature has not determined any precise depth for the seed of red clover more than other seed. It will grow vigorously from two inches deep, and it will grow when barely covered. Half an inch may be reckoned the most advantageous position in clay soil; a whole inch in what is light or loose. It is a vulgar error, that small seed ought to be sparingly covered. Misled by that error, farmers commonly cover their clover seed with a bushy branch of thorn; which not only covers it unequally, but leaves part on the surface to wither in the air.

5536. In the operation of souing some consider it best to sow the clover and rye-grass separately, alleging that the weight of the one seed, and lightness of the other, are unfavourable to an equal distribution of both.

bution of both.

bution of both.

5537. The quantity of seed sown on an acre is exceedingly various; not only when more or less white or yellow clover is sown along with grass-seeds and red clover, or when pasturage is intended; but, even when they are the only kinds sown, the quantity is varied by the quality of the soils, and the different purposes of hay, soiling, or one year's pasture, to which the crop is to be applied. When pasture is the object, more seed ought to be allowed than is necessary when the crop is to be cut green for soiling; and for hay, less may suffice than for either of the former. Finely pulverised soils do not require so much seed as clays, on which clover and rye-grass are very frequently sown among autumn or winter-sown wheat, when there is more danger of a part of it perishing from being imperfectly covered. In general, eight or ten pounds may be taken as the minimum quantity, though there have been instances of good crops from less; and from that to fourteen points or more per English statute acre. Rye-grass, commonly at the rate of a bushel per acre, but in many cases only half, or two thirds of a bushel, is mixed with this weight of clover, and both are sown at the same time. The rye-grass may be either of the perennial or annual variety, as it is understood that the herbage is to be continued for only one year; and the annual is sometimes sown in preference, as producing a bulkler crop than the perennial.

and both are sown at the same time. The rye-grass may be either of the perennial or annual variety, as it is understood that the herbage is to be continued for only one year; and the annual is sometimes sown in preference, as producing a bulkier crop than the perennial.

5538. When it is intended to retain the land in pasture for several years, the quantity of red clover is diminished, and several kinds of more permanent herbage are added, the most common of which are white and yellow clover, and ribwort. No general rule can be laid down as to the proper quantity of each of these kinds; in some cases red and white clover are sown in equal proportions, and in others the latter is made greatly to predominate. The yellow clover and ribwort are not often sown at the rate of more than two or three pounds per acre. It is scarcely necessary to add, that, in this case, the rye-grass should always be of the perennial sort.

5539. In the selection of clover and rye-grass seeds particular attention should be paid to their quality and cleanness; the purple colour of the clover seed denotes that it has been ripe and well saved; and the seeds of weeds may be detected in it by narrow inspection, if there are any; bursiness on the seeds are frequently mixed up with the seeds of the rye-grass, which it is difficult either to discover or to separate from them. Between the seeds of the annual and perennial rye-grass the difference is hardly discernible; and therefore, unless it is of his own growth, the cultivator must depend in a great measure on the character of the person from whom he purchases it. Red clover from Holland or France has been found to die out in the season immediately after it has been cut or pastured; while the English seed produces plants which stand over the second, many of them the third, year (General Report of Scottand, vol. i. p. 537.); thus remaining in the latter case four summers in the ground from the time of sowing.

5540. The after-culture of clover and rye-grass consists chiefly of picking off any stones or other hard bodies which may appear on the surface in the spring succeeding that in which it was sown, and cutting out by the roots any thistles, docks, or other large grown weeds. After this the surface should be rolled once to smooth it for the scythe. This operation is best performed in the first dry weather of March. Some give a topdressing of soot, gypsum, common lime, peat, or wood-ashes, at this time or earlier:

gypsum has been particularly recommended as a top-dressing for clovers, and the other herbage legumes; because as their ashes afford that substance in considerable quantities, it appears to be a necessary ingredient of their food. Dutch ashes (427.) have been strongly recommended as a top-dressing for red clover, and they also contain gypsum; but where the soil is in good heart, and contains calcareous matter, any description of topdressing, though it may be of advantage when it does not interfere with the general

economy of the farm, cannot be considered necessary. (Supp. E. Brit. art. Agr.)

5541. The taking of the clover, or clover and rye-grass crop, is either by cutting green for soiling, by making into hay, or by pasturing. It is observed in The Code of Agriculture, that it is a most important point to ascertain in what cases cutting, or feeding, is more beneficial. If fed, the land has the advantage of the dung and urine of the pasturing stock; but the dung being dropped in irregular quantities, and in the heat of summer, when it is devoured by insects, loses much of its utility. If the dung arising from the herbage, whether consumed in soiling, or as hay, were applied to the land, in one body, and at the proper season, the operation would be more effectual. The smother of a thick crop, continued for any time upon the ground, greatly tends to promote its fertility; and it has been pretty uniformly found, after repeated trials, upon soils of almost every description, that oats or any other crop taken after clover that has been cut, either for soiling or hay, is superior to the crop taken after clover pastured by sheep.

5542. Soiling is a term applied to the practice of cutting herbage crops green for feeding or fattening live stock. On all farms, under correct management, a part of this crop is cut green, for the working horses, often for milch cows, and, in some instances, both for growing and fattening cattle. There can be no doubt of the advantages of this practice, in regard to horses and cows; but for young and for fattening beasts, a sufficient number of experiments are not known to have been yet made with any great degree of accuracy. Young animals require exercise in the open air, and, probably, will not be found to thrive so well in houses or fold-yards, during summer, as on pastures; and though in every case there is a great saving of food, the long, woody, and comparatively naked stems of the plants, with leaves always more or less withered, are perhaps not so valuable in the production of beef on fattening stock as a much smaller weight of herbage taken in by pasturage. Milch cows, however, are so impatient of heat and insects, that this way of feeding them, at least for a part of the day, in warm weather, ought to be more generally adopted; and the convenience of having working horses always at hand, besides that they fill their stomachs speedily, is of not less importance than economy. (See Communications to the Board of Agriculture, vol. vii. Brown's Treatise on Rural Affairs, vol. ii. General Report of Scotland, vols. ii. and iii.)

5543. In feeding cattle with green clover, attention must be paid to prevent swelling, or hoving, which is very apt to take place when they are first put on this food, especially if it is wet with rain or dew; and cattle are exposed to this danger, whether they are sent to depasture the clover, have it cut and brought home to them; though, if the plants are somewhat luxuriant, the danger is greater in the former case. After being accustomed to this rich food for a few days, during which it should be given rather sparingly, the danger is much diminished; but it is never safe to allow milch cows, in particular, to cat large quan-

tities of wet clover.

5544. The making herbage plants into hay is a process somewhat different from that of making hay from atural grasses. All the herbage tribe ought to be mown before the seed is formed, and indeed before the natural grasses. plants have fully blossomed, that the full juice and nourishment of the herb may be retained in the hay. By the adoption of this system, the hay is cut in a better season, it can be more easily secured, and it is much more valuable. Nor is the strength of the plant lodged in the seed, which is often lost. The great advantage of converting under-ripe herbage and grass into hay is now beginning to be known. There is

much more valuable. Nor is the strength of the plant lodged in the seed, which is often lost. The great advantage of converting under-ripe herbage and grass into hay is now beginning to be known. There is much more saccharine matter in it, and it is consequently greatly more nutritious. A crop of clover or saintfoin, when cut in the early part of the season, may be ten per cent. lighter than when it is fully ripe; but the loss is amply counterbalanced, by obtaining an earlier, a more valuable, and more nutritious article; while the next crop will be proportionably more heavy. The hay made from old herbage which has ripened its seed will carry on stock, but it is only hay from herbage cut when young, and soon after it has come into flower, that will fatten them. When the stems of clover become hard and sapless, by being allowed to bring their seeds towards maturity, they are of little more value as provender than an equal quantity of the finer sort of straw of corn.

5545. The mode of making clover-hay, and that of all herbage plants, as practised by the best farmers, is as follows: — The herbage is cut as close to the ground and in as uniform and perfect a manner as mossible with a sharp scythe. The surface having been in the preceding spring freed from stones and well rolled, the stubble after the mower ought to be as short and smooth as a well shavon grass-lawn. The part of the stems left by the scythe is not only lost, but the after-growth is neither so vigorous nor so weighty, as when the first cutting is taken as low as possible.

5546. Soom as the swath or yow of cut herbage is thoroughly dry above, it is gently turned over (not tedded or scattered) without breaking it. Sometimes this is done with the hand, or with a small fork; and some farmers are so anxious to prevent the swath from being broken, that they only permit the use of the rake shaft. The grass, when turned over, in the morning of a dry day, is put into cocks in the afternoon. The mode of performing this is very simple and expeditious; and no

5518. The best managers disapprove of spreading out the swaths of clover and ryg-grass, though this is often necessary with natural grasses, which are cut and harvested later in the season. The more the swath is kept unbroken, the hay is greener, and the more fragrant.

5519. Another mode of hay making, said to have been originally practised in Lancashire, has been found to answer well in the moist atmosphere of the west of Scotland. This is called tippling or rippling; and if the grass is dry, the operation begins as soon as it is mown. "In making a tipple, a person with his right hand rolls the swath inwards, until he has a little bundle; then the same is done by the left, until both meet and form eight to twelve pounds, or nearly so. This bundle is then set up against the legs, or tetween the feet; a rope is twisted of the grass, while the bundle is supported in this manner, and the other hands are the tipple taper to a point, and give it as much a conical shape as possible. If the crop is strong, threats row of tipples placed on each swath; if light, two of these are put into one row. After standing a few hours, they become so smooth on the outside, that the heaviest rains seldom wet them through; and when wet, they are soon dried again in good weather. As soon as ready, they are put into the summer-rick, or, if very dry, even into the winter stack, but are never opened out or tedded, to make them dry, as they never require it. By this method, not a blade is lost, and the hay is nearly as green as a leaf dried in a book. In a moderate crop, one woman will tipple to one mower, and a woman will rake to two tipples: we weather for a considerable length of time." (General Report of Scotland, vol. ii. p. 11).

5559. The making of clover hay, as practised in Courland, and adopted from that country in Silesia, is said to save not only a number of hands, but the hay is better and more nourishing. The hay is prepared by self-fermentation, whereby it retains its nutritious juices and only loses its watery particles;

must be attended to:—
5553. Hue, first. If the cock has only fermented in the middle, and on that side where the cold wind did not act upon it, the whole heap must nevertheless be opened on the following morning. That which has already fermented must be separated and spread to dry; it must be turned towards noon, and may be carted into the barn in the evening; but that part of the cock which has not fermented must be again put together into large cocks, and fermented in the same manner as the preceding part, after which it

carted into the barn in the evening; but that part of the cock which has not fermented must be again put together into large cocks, and fermented in the same manner as the preceding part, after which it may be spread to dry, and brought into the barn.

5554. **Rule second.** In such cases where a small portion of the cock has fermented thoroughly, but not the greater part, the heap must be spread abroad in the morning, but must be again made into a close cock in the evening, in such a manner that the part which has fermented be placed at the top or outside of the cock, and that which has not fermented be inclosed within it; then on the ensuing morning, or, if the weather be cold and rainy, on the morning afterwards, the clover-heap may be again spread abroad, and the clover treated as in the case first mentioned.

5555. **Rule third.** If, in spreading the heap abroad, it be found that nearly the whole of the clover has fermented; if will not be necessary to delay the housing of the whole on account of some small portion; but the clover may be dried and carted into the barn. The small portion which remained unfermented will not occasion any disaster to the other which has fermented; for there is a material difference betwixth hay thus managed, and the meadow-grass which is brought whilst damp, or wet with rain, into the barn, which will grow musty and putrid.

5556. **Rule fourth.** In such instances, where some of the cocks of clover have thoroughly fermented, and it rains on the morning, they ought to be spread abroad, for the clover must be opened and spread, even if it rains violently; since, if it were suffered to remain longer in the heap, it would take fire, or its juices would be injured by too much fermentation; the leaves and stalks would become black, and the clover which has fermented clover must be turned from time to time, but not carted into the barn till dry. This drying takes place, if the rain discontinues for a few hours, much more expeditiously with the clover which has been for so long a ti

very gentle warmth, is usually perceptible, both in the field-ricks and in the stacks, for a few days after they are built. But this is a quite different thing from that intentional heating, carried so far, in many instances, as to terminate in conflagration.

very gentle warmth, is usually perceptible, both in the field-ricks and in the stacks, for a few days after they are built. But this is a quite different thing from that intentional heating, carried so far, in many instances, as to terminate in conflagration.

5558. The after-growth or second crop of clover is vigorous or weak, according to the proportion of clover clauts to rye-grass, to the time when the first crop was cut, and to the moisture and warmth of the season. When the first cutting has been made early for soiling, there will sometimes be three cuttings in one season. The first of these after-cuttings may be made into hay, and sometimes the second; but in general both are consumed by soiling or pasturing, unless in some dry warm districts, as Norfolk, and parts of Suffolk, Kent, &c., where the second growth is left to ripen its seed. In the northern counties the second crop is seldom made into hay, owing to the difficulty of getting it thoroughly dried at a late period of summer, when other more urgent operations usually employ all the labourers of a farm. If it is cut for this purpose, the best method of saving it is to mix it up with straw, which will absorb a part of its jutices. It is often cut green, as a part of the soiling system; or, where a sheep stock is kept, pastures by the old ewes, or other sorts, that are to be fattened the ensuing winter on turnips.

5550. Techering may be considered a rude practice, and is chiefly confined to the north of Scotland and Ireland. In The Agricultural Report of Aberdeenshire it is stated, that there are some cases where the plan of tethering can be practiced with more profit than even soiling. In the neighbourhood of Peter-head, for instance, they tether milch cows on their grass fields, in a regular and systematic method; moving each tether forward in a straight line, not above one foot at a time, so as to prevent the cows from treading on the grass that is to be eaten; care being always taken to move the tether forward, like a person cutting clover with

5563. The produce of clover-hay, without any mixture of rye-grass, on the best soils is from two to three tons per acre, and in this state in the London market it generally sells 20 per cent. higher than meadow-hay, or clover and rye-grass mixed. The weight of hay from clover and rye-grass varies, according to the soil and the season, from one ton to three tons per English acre, as it is taken from the tramp-ricks; but after being stacked, and kept till spring, the weight is found to be diminished twenty-five or thirty

per cent. 157 18 9 fl

5564. The value of clover and rye-grass hay, in comparison with the straw of beans or peas, may be in the proportion of three to two; and with the finest straw of corn crops, in the proportion of two to one. One acre of red or broad clover will go as far in feeding horses or black cattle as three of ordinary pasture; and when it is cut occasionally, and given to them fresh, it will, probably, go still much farther, as no part of it is lost by being trodden down. With the exception of licern, and the herbage of rich marshes, there is no crop by which so much stock can be supported as by clover. It may be profitably employed in fattening sheep in spring, and with this food they will soon be ready for the butcher. Afterwards, a crop of hay may be got, and two or three weeks after the hay has been taken off, sheep intended to be fattened on turnips may be turned in, and kept there, until the turnips are ready for them.

5565. The nutritive products of clovers will be found in the table. (5520.)

5566. The saving of clover seed is attended with considerable labour and difficulty. Clover will not perfect its seeds, if saved for that purpose early in the year; therefore it is necessary to take off the first growth either by feeding or with the scythe, and to depend for the seed on those heads that are produced in the autumn. Seed clover turns out to good account in those years when the crops are not injured by the blight, which is often fatal to them, or by the rains in the autumn, which sometimes prove their destruction; for the time of harvesting this seed falling out late when rainy weather may be expected, renders it, on that account, very tedious.

25567. When the first crop is fed off, it is eaten till about the end of May, frequently by ewes and lambs; and this is understood to be an advantageous practice, because the land is less exhausted, and the green food is of great value for stock in the spring months. It is not uncommon, however, to cut the first growth for a hay crop, and this should be done earlier than usual. The growth thus reserved for seed must be suffered to remain till the husks become perfectly brown, when it is cut and harvested in the usual mainter, feaving it on the field till it is very dry and crisp, that the seeds may become more fully hardened; it may then be laid up dry, to be threshed out at the farmer's convenience. Much labour and expense are necessary in separating the seed from the cipsule or seed-coat; especially when it is effected by threshing, which seldom costs less than from five to six or seven shillings per bushel. By the use of mills the work may be done much cheaper. may be done much cheaper,

5563. The management of a crop of clover with a view to saving seed is thus given by a cultivator in Buckinghamshire. A moderate bulk of haulm is generally found most productive of seed, and a moderately rich, sharp, dry soil is the best for having moderate haulm. The field may be pastured till the middle of May, and then shut up till the ripening is completed. August is generally the ripening month, and the maturity of the seed may be known by the leaves becoming brown and dropping off. Observe the seed from time to time, and when it has changed from a bright yellow to a deep purple, it is then ready for the seythe. After the crop is cut down, disturb it as little as possible by fork or rake. Form it into small cocks not larger than muck heaps. Should favourable weather ensue, nothing more is necessary than to turn these cocks once over, shortly before carting home. And, should the weather prove fickle, these small heaps of withered straw are very soon dried, perhaps in one good day, by turning up the bottom, after the top has become a little dried. After remaining some time in the field, the cocks subside considerably and become caked, by which the flowers adhere together and repel the rain; of course, no loss of top can be sustained by gently turning them to dry. It thus appears, that cover for seed is not so liable to be injured as clover for hay. In general six or ten days of favourable weather render it fit to carry to the rick-yard and stack. It may either be threshed by a light flail, or by threshing machines, having a particular additional cover introduced below the drum or beater for that purpose.

5560. In threshing, whether by the flail or machine, the first operation is to sparate the heads or spikes of seeds from the haulm. This operation separates none of the seed, which remains firm in the withered florets, and requires to be separated by a course of light thrashing, similar to that used for hummelling barley. When on examination it is found that the seed is all separated, the operations of sitt

5572. The produce in seed may generally be from three to four or five bushels per acre, when perfectly clean, weighing from two to three hundred weight. But there is great uncertainty in the produce of clover seed, from the lateness of the season at which it becomes ripe; and the fertility of the soil is considerably impaired by such a crop. Yet the high value of the seed is a great inducement to the saving of it, in favourable (Dickson's Practical Agriculture, vol. ii. p. 863.)

5573. The diseases of clover are the blight or mildew, and suffocation or consumption, from insects, slugs, and worms. It often happens that clover, after being repeated at

short intervals on the same soil, either fails or does no good; whether that is owing to a disease, or to a defect of some peculiar substance which enters into the food of the plant, does not appear to be clearly ascertained. A top-dressing with ashes or lime is said to be unfavourable to the slug; but where vermin of this sort are very numerous, the most certain remedy is a naked fallow well worked in the hottest months.

Sect. II. Lucern. — Medicago sativa L.; Diadélphia Decándria L., and Leguminosæ J. La Lucerne, Fr.; Futterklee, Ger.; Medica, Ital.; and Mielga Span. (fig. 775.)

5574. Lucern is a deep-rooting perennial plant, sending up numerous small and tall clover-like shoots, with blue or violet spikes of flowers. It is a native of the south of Europe, and appears to be acclimated in the warmer parts of England. Lucern or medic is highly extolled by the Roman writers, and also the cytisus, the latter a low evergreen shrub. Lucern is much grown in Persia and Lima, and mown in both countries all the year round; it is also of unknown antiquity in old Spain, Italy, and the south of France. It was introduced to England from the latter country, according to Miller, in 1657. It is mentioned by Hartlib, Blythe, and other early writers, and was tried by Lisle; but it excited little attention till after the publication of Harte's Essays, in 1757. It is now only cultivated in a few places, and chiefly in Kent. Columella estimated lucern as the choicest of all fodder, because it lasted many years, and bore being cut down four, five, or six times a year. It enriches, he says, the land on which it grows, fattens the cattle fed with it, and is often

a remedy for sick cattle. About three quarters of an acre of it is, he thinks, abundantly sufficient to feed three horses during the whole year. The good in autors Loop of the

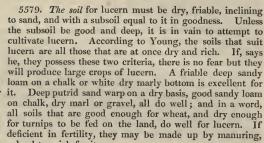

5575. Clover has found no great reception in this country, though it was so much esteemed by the ancients, and has been long cultivated to advantage in France and Switzerland. It any good reason can be given for this, it is, that lucern is a less hardy plant than red clover, requires three or four years before it comes to its full growth, and is for these and other reasons ill adapted to entire into general rotations. Where the climate and soil suit, perhaps a field of it may be advantageously sown, adjoining the homestall, to afford early cutting or food for young or sick animals, for which it is said to be well adapted; but though it will produce good crops for eight or ten years, yet from the time the farmer must wait till this crop attains its perfection, and from the care requisite to keep it from grass and weeds, we do not think it is ever likely to come into general culture. The Highland Society have lately offered premiums for the culture of this plant in Scotland, and crops have been produced in dry sandy soils in the neighbourhood of Edinburgh; the climate, however, and the alternate and convertible system of culture generally pursued in the northern parts of the island, and which seems so well adapted to its agricultural circumstances, forbid the hope that it can ever become general.

5576. There are no varieties of the lucern deserving the notice of a cultivator.

5577. What is called the yellow lucern is the Medicago falcata (Lucerne en famille, or Luzerne de Suède, Fr. fig. 776.), a much hardier and coarser plant, common in several parts of England, but not cultivated any where except in some poor soils in France and Switzerland.

5578. Medicago maculita and muricata are cultivated in France, but to a very limited extent on poor soils. M. lupülina (lupuline, or Minette dorée, Fr.) resembles our well known hop trefoil, black (from its seeds) nonsuch, or yellow clover; but it is seldom cultivated in

Britain,

but he never yet met with any land too rich for it.

5580. The preparation of the soil consists in deep ploughing and minute pulverisation; and, in our opinion, the shortest way to effect this, is to trench it over by the spade to two or three feet in depth, burying a good coat of manure in the middle or at least one foot from the surface. This is the practice in Guernsey, where lucern is highly prized.

5581. The climate for lucern, as we have already hinted, must be warm and dry; it has been grown in Scotland and Ireland, and might probably do well in the southern counties of the latter country, but in the former it has not been found to answer the commendations of its admirers.

5582. The season most proper for sowing lucern is as early as practicable in the spring months, as in this way the plants may be fully established before the season becomes too hot. The latter end of March, for the more southern districts, may be the most proper period; and the beginning of the following month for those of the north. When sown late, there is more danger of the plants being destroyed by the fly, as it has been observed by Tull. If the plants are intended to be transplanted out in the garden method, it will also be the best practice to sow the seed-bed as early in the spring as the frosts will admit, in order that they may be strong, and fit to set out about the beginning of August.

5583. The manner of sowing lucern is either broad-cast or in drills, and either with or without an accompanying crop of corn for the first year. Broad-cast, with a very thin crop of barley or other spring corn, is generally, and in our opinion very properly, preferred. Arthur Young, who has treated largely on this plant, observes, that "the greatest success by far that has been known is by the broad-cast method, which is nearly universal among the best lucern farmers, even among men who practise and admire the drill husbandry in many other articles. But as they mostly (not all) depend on severe harrowing for keeping their crops clean, which is a troublesome and expensive operation, he still ventures to recommend drilling; but very different drilling from that which has been almost universally practised, viz. at distances of eighteen inches or two feet. Objections to these wide intervals are numerous. If kept clean hoed, the lucern licks up so much dirt, being beaten to the earth by rain, &c., that it is unwholesome, and the plants spread so into these spaces, that it must be reaped with a hook, which is a great and useless expense. For those reasons, as well as for superiority of crop, he recommends drilling at nine inches, which in point of produce, mowing, and freedom from dirt, is the same as broad-cast; and another advantage is, that it admits scarifying once a year, which is much more powerful and effective than any harrowing. These facts are sufficient to weigh so much with any reasonable man, as to induce him to adopt this mode of drilling, as nearer to broad-cast by far than it is to drills at eighteen to twenty-four inches, which open to a quite different system, and as et of very different evils. Nine-inch rows might practically, but not literally, be considered as broad-cast, but with the power of scarifying. And in regard to the material point, of with or without corn, two considerations, he says, present themselves. One is the extreme liability of lucern to be eaten by the fly, which does great mis

5584. The quantity of seed, when the broad-cast method is adopted, is said to be from fifteen to twenty pounds per acre, and from eight to twelve if drilled. The seed is paler, larger, and dearer than that of clover: it is generally imported from Holland, and great care should be had to procure it plump and perfectly new, as two-years-

old seed does not come up freely. The same depth of covering as for clover will

5585. Lucern may be transplanted, and when the soil is very rich and deep, it is said to produce very large plants; but such plants, from the bulk of their stools, are not likely to be so durable as those of a less size; and on the whole, for this reason and others relative to expense, the plan of transplanting does not seem advisable unless for filling up blanks.

5586. The after-culture of lucern, sown broad-cast, consists in harrowing to destroy grass and other weeds; rolling, after the harrowing, to smooth the soil for the scythe; and such occasional top-dressings of manure as the state of the plants may seem to require.

5587. When lucern is drilled, horse-hoeing may be substituted for harrowing, which, as already observed, is the only advantage of that mode of sowing. The harrowing may commence the second year, and the weeds collected should always be carefully removed: light harrows may be used at first, and in two or three years such as are heavier. In succeeding years two harrowings may be required, one early in the spring, and the other at the close of the summer. For these, and especially the last, Arthur Young recommends the use of a harrow of weight sufficient for four horses, and which does not cover a breadth of more than four feet. The mode of hoeing, either by the hand or horse-hoe, or of stirring by the drill harrow, requires no description.

5588. The top-dressings given to lucern may be either of the saline or mixed manures. Ashes are greatly esteemed, and also gypsum and liquid manure of any kind. Arthur Young advises to apply dung, in the quantity of about twenty tons to the acre, every five or six years. Kent, however, thinks it a better practice to put a slight coat on annually in the spring season. Some recommend a slight top-dressing sown by hand every spring. The farmer will in this, as in every case, exercise his own judgment, and be guided by the wants of the plants, the return they yield for the expense bestowed on

them, and the equable distribution of manure among his other crops.

5589. The taking of lucern by mowing for soiling, or hay, or by tethering, hurdling, or pasturing, may be considered the same as for clover. Lucern frequently attains a sufficient growth for the scythe, towards the end of April, or beginning of the following month; and, in soils that are favourable for its culture, will be in a state of readiness for a second cutting in the course of a month or six weeks longer, being capable of undergoing the same operation, at nearly similar distances of time, during the whole of the summer season. In this last sort of soil, with proper management, in the drill method, it has been found to rise to the height of a foot and a half in about thirty or forty days, affording five full cuttings in the summer. But in the broad-cast crops, in the opinion of some, there are seldom so many cuttings afforded in the season, three or four being more common, as the growth is supposed to be less rapid than by either of the other modes.

5590. The application of lucern is also the same as that of clover. The principal and most advantageous practice is that of soiling horses, neat cattle, and hogs: but as a dry fodder, it is also capable of affording much assistance; and, as an early food for ewes and lambs, may be of great value in particular cases. All agree in extolling it as food for cows, whether in a green or dried state. It is said to be much superior to clover, both in increasing the milk and butter, and improving its flavour. In its use in a green state, care is necessary not to give the animals too much at a time, especially when it is moist, as they may be hoven or blown with it, in the same way as with clover, and other green food of luxuriant growth.

5591. The produce of lucern, cut three times in a season, has been stated at from three to five and even eight tons per acre. In soiling, one acre is sufficient for three or four cows during the soiling season; and a quarter of an acre, if the soil be good, or half an acre on a moderate soil, for all sorts of large stock, for the same period. Say, however, that the produce is equal in bulk and value to a full crop of red clover, then, if continued yearly for nine or ten years (its ordinary duration in a productive state), at an annual expense of harrowing and rolling; and a triennial expense of top-dressing, it will be of sufficient value to induce farmers, who have suitable soils and climates, to lay down a few acres under this crop near their homestalls.

5592. The nutritive product of lucern, according to Sir H. Davy, is $2\frac{3}{10}$ per cent., and is to that of the clovers and saintfoin as 23 to 39. This result does not very well agree

with the superior nutritive powers attributed to lucern.

5593. To save seed, the lucern may be treated precisely as the red clover, and it is much more easily threshed, the grains being contained in small pods, which easily separate under the flail, or a threshing machine, or clover mill.

5594. The diseases of lucern appear to be the same as those of clover. In Kent, blight and the slug are its greatest enemies.

Sect. III. Saintfoin. — Hedýsarum Onobrýchis L.; Diadélphia Decándria I., and Leguminòsæ J. Bourgogne, or Esparcette, Fr.; Esparzette, Gcr.; Cedrangola, Ital.; and Esparsita, Span. (fig. 777.)

Esparsita, Span. (fig. 777.)

5595. Saintfoin is a deep-rooting perennial with branching spreading stems, compound
leaves, and showy red flowers. It is a notine of England

leaves, and showy red flowers. It is a native of England and many parts of Europe, but never found except on dry, warm, chalky soils, where it is of great duration. It has been long cultivated in France and other parts of the Continent, and as an agricultural plant was introduced from France to England about the middle of the seventeenth century. It has since been a good deal cultivated in the chalky districts; and its peculiar value is, that it may be grown on soils unfit for being constantly under tillage, and which would yield little under grass. This is owing to the long and descending roots of the saintfoin, which will penetrate and thrive in the fissures of rocky and chalky understrata. Its herbage is said to be equally suited for pasturage and for hay, and that eaten green it is not apt to swell or hove cattle like the clovers or lucern. Arthur Young says, that upon soils proper for this grass no farmer can sow too much of it; and in The Code of Agriculture it is said to be "one of the most valuable herbage,

plants we owe to the bounty of Providence."

5596. There are no varieties of the saintfoin in England, but many other species of the same numerous family might be cultivated, such, for example, as the French honey-suckle, a biennial that might be substituted for red clover on rich soils. The French have a variety which they call Sainfoin à deux coupes, and they also cultivated the Sain-

foin d'Espagne or Sulla.

5597. The best soil for this plant is that which is dry, deep, and calcareous; but it will grow on any soil that has a dry subsoil. Kent thinks that the soils most suited to the culture of this sort of grass are of the chalky loam, and light sandy or gravelly kinds, or almost any of those of a mixed quality, provided they are sufficiently dry, and have a rocky or hard calcareous bottom to check the roots at the depth of a foot or fifteen inches below the surface, which he conceives necessary, as the plants are apt to exhaust themselves in running down; and for this reason he considers it improper for being sown where there is great depth of mould or soil. It is a plant that is asserted by Marshal to afford a large produce even on those soils which are of the poorest quality, and on such as are of a more rich and friable nature to frequently produce abundant crops. Still, he conceives, that it is only in the calcareous soils, as the dry chalk and limestone, or such as have been well impregnated with that sort of matter, that it succeeds in a perfect manner or becomes durable. The advantages resulting from growing this plant on sandy soils in Norfolk have been already stated. (4744.)

5598. The best preparation which any soil fit for this plant can undergo is, unquestionably, trenching; and we have little doubt that in most cases, all things considered, it would be found the cheapest. The usual preparatory culture, however, is the same as for clover, ploughing more deeply than ordinary, either by means of the trench plough, or, what is better because more simple, by the common plough going twice, in the same track. Boys (Communications to the Board of Agriculture, vol. iii) recommends as a preparation for saintfoin: Ist year, pare and burn for turnips, to be eaten on the lad by sheep, with the aid of some fodder; 2d, barley, to be sown very early with clover seed; 3d, clover eaten off by sheep; 4th, wheat; 5th, turnips with manure; and, 6th, barley with saintfoin. The corn crops must be carefully weeded, and in particular cleared of charlock. Under this system, the produce has been great, and the ground has been laid down in the highest order with saintfoin, or any other grass calculated for this species of soil.

5599. With respect to the season of sowing saintfoin, it may be observed, that the earlier it can be put into the soil in the spring the better, as from the greater moisture of such soils there will be a greater probability of its vegetating in a perfect manner. Where the sowing is executed at a late period, and dry weather succeeds, Bannister thinks that much of the seed is prevented from growing, and that the young plants are more exposed to destruction from the fly; therefore, according to this writer, the sowing of saintfoin seed ought never to be deferred longer than the beginning of March, and it is still better to complete this work in February. Some, however, suppose it may be deferred to the middle of March without injury, and this is soon enough if it is to be sown with barley.

5600. The manner of sowing is generally broad-cast; but it may be sown in drills and even transplanted, though neither of these modes can be recommended. Some advise its being sown with about half the quantity of barley usually sown for a full crop, which may shade and keep it moist during the first summer, and at the same time not injure it from the crop being lighter, which is sometimes the case. Where the barley is drilled, the saintfoin may afterwards be put in, in the same manner, but in a contrary direction. If sown over the wheat, it should be harrowed in, and afterwards rolled. In whatever method it is sown, as the seeds are larger than those of many other herbage plants, they should be covered in with more care, and to a somewhat greater depth. By some the ploughing of the seed in with a very thin or shallow

furrow is recommended. In most cases, especially in all the more light sorts of land in which this sort of crop is grown, the use of the roller may be necessary immediately after the seed is put into the ground. It is the practice in some districts to sow a small portion of clover seed with saintfoin, with the idea of increasing the first year's produce; but as plants of different kinds seldom answer well when grown together, from there being a continual contest in their growth for an ascendancy, it is perhaps a better method to increase the proportion of the seed, without mixing it with that of other sorts. It is, however, supposed by Marshal that such a practice is beneficial in ultimately procuring a fine clean crop of saintfoin upon the land. It is a sort of crop that grows in so perfect a manner in the broad-cast method, that there can seldom be any necessity for having recourse to the drill. It may, however, be cultivated in the latter mode with much success; and, in Norfolk, it is the practice with some cultivators to have it drilled at nine inches across the barley crops which have been sown in the same way.

5601. The quantity of seed in the broad-cast method, which is that mostly employed, is about four bushels the acre, though less is frequently given; but on such soils as are proper for this plant it is always necessary to have a full proportion of seed. By some, however, a much smaller quantity is made use of; and where the drill system is had recourse to, a still smaller proportion is used, as from two to two and a half or three bushels. It has been observed, that in Lincolnshire, where this plant is much grown, "the common allowance of seed is five bushels to an acre, and that a gentleman south of Lincoln advises the sowing a small quantity of trefoil with it (about four pounds on an acre)." The reson for this is, that in that exposed country, the young plants suffer more by the sun in summer than by the frost in winter. Of course the trefoil coming to perfection the first year, and living only t bushel

5603. The after-culture and management of saintfoin consists in occasional dressings. with manure, and, in the judicious intervention of mowing and pasturing.

with manure, and, in the judicious intervention of mowing and pasturing.

5604. Some farmers do not mow in the first, year, while others do; but in the second year, and in the succeeding summers, a crop of hay may be taken, and the after-grass fed down with any sorts of stock but sheep, till towards December. These should not be permitted to eat it too close, as, from the largeness of the roots, they might by so doing injure the crowns of the plants. In the following autumn there will, however, be less risk in this respect, and sheep as well as cattle stock may be turned in and kept upon the pastures till they are well eaten down, being always careful to shut them up as early as possible in the beginning of the year. This is the opinion of Kent. As this sort of herbage is thought to be improved in its taste by being nipped by the frost, it may be a proper practice not to turn stock upon these leys too early in the autumnal season; perhaps not before the latter end of September, when this sort of rouen or after-grass will be found to have much effect in promoting the flow of milk in cows, as well as in forwarding the condition of fattening beast; great store of feed being still left for sheep. But with this set of stock they should not be too closely fed down, nor should the sheep remain too long upon them. It has been suggested that all sorts of cattle stock should be removed by the beginning of the year from these rouens, as much harm might be done by their continuing longer.

5605. In top-dressing saintfoin peat-ashes are the best material that can be made use of where they can be procured in sufficient quantity; and other sorts of ashes are likewise found beneficial where these cannot be bad. They should be applied so as to form a thin, even, regular dressing over the whole surface of the crop. In this view soot has also been found of great utility when spread evenly over such leys about the beginning of January, in the proportion of about twenty-five or thirty bushels to the statute acre; and malt-dust has

5606. In taking and using the saintfoin crop, the same practices may be followed as in taking clover: it may be mown for soiling, hay, or seed; and eaten on the spot by tethering, hurdling, or common pasturing.

507. In making it into hay, it is cut immediately on its coming into full blossom, and as it remains but a short time in this state, as much expedition as possible should be employed both in mowing and making the produce into hay. It is remarked by the author of The Synopsis of Husbandry, who resides in a district where the culture of saintfoin is frequent, that of all other hay plants, it requires the least pains in making. When the season is favourable, the hay-makers may follow the scythe, and having turned over the swaths, throw them into wind-rows the succeeding day after the crop is mown, when it may be immediately formed into cocks, and the whole crop be fit for carting in a week, sometimes in three days after it is mown. Though it may appear very green, and the stack when made take on or acquire a considerable degree of heat, there is no danger to be apprehended, provided the weather has been fair during the hay-making; as it is so far from taking harm by heating in the stack, that the contrary state is the most to be feared. For this reason great care is necessary not to suffer the folder to continue fong either in the swath or in cocks, lest the sun and wind should dry it up too fast, and by exhaling its judes prevent the heating in the stack, and thereby render it of little value. In order to preserve its succlience, in some places they finish the stacks out of the cocks. It is likewise a practice with many farmers, where the crop is slight, to turn the swaths, and then run them into cocks with a three pronged barley fork, following with a wooden dew rake, the head of which is of sufficient width to cover the ground occupied by three or four swaths, in this manner proceeding with the utmost despatch, and saving a deal of labour and expense in the business.

5608. In regard to the frequency of cutting saintfoin, it is probable that on the thinner sorts of soils it can seldom be done more than once; but on those of the deeper sorts two crops may sometimes be taken, in the same manner as with clover, care being taken in these cases that the future growth of the plants be

not injured by this means.

5609. The usual duration of saintfoin, in a profitable state, is from eight to ten years. It attains its perfect growth in about three years, and begins to decline towards the eighth or tenth on calcareous soils, and about the seventh and eighth on gravels. There are instances, however, of fields of saintfoin, which had been neglected and left to run into pasture, in which plants have been found upwards of fifty years from the time of sowing. It has been cultivated upwards of a century on the Cotswold Hills, and there roots of it have been traced down into stone quarries from ten to twenty feet in length, and in Germany Von Thaer found them attain the length of sixteen feet. In general the great enemy to the endurance of saintfoin is the grass, which accumulates and forms a close turf on the surface, and thus chokes up the plant.

5610. The quantity of produce in the state of hay, on a medium of soils and cultivation, may probably be estimated at from about one and a half to two tons the acre; and on the poorer and thinner staple sorts of land it will, perhaps, seldom afford less than from a ton

to a ton and a half on the acre.

5611. The nutritive products of saintfoin are the same as clover; viz. $3\frac{3}{10}$, being $1\frac{6}{10}$ per

cent more than those of lucern.

5612. In saving seed from saintfoin, it should remain on the land till the husks become of a somewhat brownish colour, and the seeds are perfectly plump and firm; as by these means they will not only be better in their quality, but be in less danger of being injured in the field, from the very short time that it will be necessary for them to remain, and also less in danger of being hurt by heating when laid up for future use. It has been stated, that it requires some experience to know of what degree of ripeness it is best to cut the seeded saintfoin, because all its seeds do not ripen at the same time. Some ears blossom before others; and every ear begins to blossom at its lower part, and continues to blow gradually upwards for many days; so that before the flower is gone off at the top, the seeds are almost mature at the bottom. From this cause, if the cutting be deferred till the top-seeds are quite ripe, the lower, which are the best, would shed and be lost.

5613. The best time to cut it is when the greater part of the seed is well filled, the first blown ripe, and the last blown beginning to be full. The unripe seeds will ripen after cutting, and be in all respects as good as those that were ripe before. Some, for want of observing this, have suffered their saintfoin seed to stand till all of it has shed, and been lost in cutting. Saintfoin should never be cut in the heat of the day, while the sun shines out; for then much, even of the unripe seed, will shed in mowing. The right time for this work is the morning or evening, when the dew has rendered the plants supple. When the weather is fine and clear, the saintfoin will soon dry sufficiently in the swaths, without turning them; but if any rain has fallen, and there is a necessity for turning them, it should be done very gently while they are moist, and not with two swaths together, as in hay made of saintfoin hefore it has seeded. If the swaths are turned with the handle of the rake, it is best to raise up the ear-sides first, and let the stub-side rest on the ground in turning; but if it is done with the teeth of the rake, let the stub-side be lifted up, and the ears rested on the earth. If it be cocked at all, the sooner it is done the better; because, if the swaths are dry, much of the seed will be lost in separating them, the ears being entangled together. When moist, the seeds stick fast in the ear; but when dry, they drop out with the least touch or shaking. It is, however, the best practice, as soon as the proper degree of maturity has been attained by the crop, to movi it nas short a time as possible, and let it remain exposed in the swath until the upper surface is fully dried, when it must be wholly turned over, but in a very careful manner, so as to prevent the seeds from shedding and being lost. When this side has been rendered perfectly dry and crisp in the same way as the other, the crop should either be threshed ont upon cloths in the field where it is grown, or laid up in stacks to be afterwards

5614. The work of threshing out the seeds in this kind of crop is much less troublesome and expensive than in the clover kind. In cases where threshing-machines are in use, the business may be executed by them with great ease and facility. It has, however, been observed by a late writer, that "when the season is favourable, the practice of threshing it out in the field is probably the most beneficial, as the stems or haulm may be laid up for the purpose of fodder in the stack."

5615. As the threshing in the field cannot be done but in very fine weather, and while the sun shines in the middle of the day, the best manner of performing it is to have a large sheet pegged down to the ground, for two men to thresh on with their flails, while two others bring them fresh supplies in a smaller sheet, and two more clear away the hay that has been threshed. The seed is emptied out of the larger sheet, and riddled through a large sieve, to separate it from the chaff and broken stalks; after which it is put into sacks, and carried into the barn to be winnowed. Care should be taken not to let the hay get wet, as in that case it would be spoiled. It is a very important, but difficult matter, to keep the seed that has been threshed in the field from becoming wet. If it be winnowed immediately, and laid in a heap or put into a sack, it will ferment to such a degree in a few days that the greater part of it will lose its vegetative quality. During that fermentation it will be very hot, and smell sour. Spreading it upon a barn-floor, though but seven or eight inches thick, will answer no end, unless it be frequently and regularly turned until the heating is over: but even this will not make its colour keep so bright as if it were well housed, well dried, and threshed in the winter. Laid up unthreshed it will keep without any danger of spoiling, because it does not lie close enough to heat. The best way to preserve the seed threshed in the field is to place a layer of straw upon a barn-floor, and upon that a thin layer of seed; then another layer of straw, and another layer of seed; and so on. By this means the seed, mixing with the straw, will be kept well, and come out in the spring in as fresh colour as when it was put in.

5616. In respect to the produce in seed, it is said to be usually "from about four to five sacks in some districts, but in others it will probably be much less, especially on the shallower sorts of saintfoin soils." But this must obviously be liable to great variation from seasons, &c.

5617. The diseases of saintfoin are few, there being little danger of failure after it has escaped the fly, which attacks the clover tribe in germinating.

Various Plants (not Gramíneæ) which are or may be cultivated as Herbage SECT. IV. and for Hay.

5618. Among the inferior herbage plants which are occasionally cultivated, are burnet. Those which might be cultivated are very numerous, and inribwort, furze, and spurry. cludes several species of Vícia, Láthyrus, Galèga, Lòtus, Trifòlium, Medicàgo, and others of the native Leguminosæ, or pea-like flowering plants; and Achillèa, Alchemilla Cheiránthus, Spártium, Apium, and a variety of others of different families. exception of the chiccory and furze, there are none of these plants that deserve the attention of the professional farmer; ribwort and burnet are occasionally sown; but they are of little value as hay plants, and in most pastures their place might be more advantageously occupied by one or other of the natural grasses. With respect to the other plants enumerated, they have never been tried but by way of experiment, and are only mentioned as resources under peculiar circumstances, and as a field of enquiry and exertion for the amateur cultivator.

5619. The burnet (Pimprenelle grande, Fr.; Potèrium Sanguisórba L. fig. 778.) is a native plant, a hardy perennial with compound leaves, blood-coloured flowers, and a long tap-root. It was originally brought into notice by Roque, a commer.

778 eial gardener, at Wallbam green, near London, who found means to procure the patronage of the Dublin and other societies to this plant, which, being a novelty, attracted the attention and called forth the eulogies of Arthur Young, and other leading agriculturists of the day. Miller, however, at the time observed, that whoever will give them selves the trouble to examine the grounds where it naturally grows, will find the plants left uneaten by the cattle, when the grass about them has been cropped to the roots; besides, in wet winters and on strong land, the plants are of short duration, and therefore very unfit

strong land, the plants are of short duration, and therefore very unfit for the purpose of pasture or hay, nor is the produce sufficient to tempt any persons of skill to engage in its culture.

5690. Curtis says of burnet, that it is one of those plants which it has for some years past been attempted to introduce into agriculture; but not answering the farmer's expectation, it is now in a great degree laid aside. Cattle are said not to be fond of it; nor is its produce sufficient to answer the expense attending its culture. It is to be lamented that persons do not pay a little attention to the nature of plants before they so warmly recommend them. A small plant, scarcely ever met with but on hilly and chalky ground, and to which cattle in such situations do not show any particular attachment, is not likely to afford better or more conjous nourishment than the clovers and other plants better or more copious nourishment than the clovers and other plants already in use

5621. According to Boys, in The Agricultural Survey of Kent, it affords herbage in the winter and spring months, but is not much liked

affords herbage in the winter and spring months, but is not much liked either by cattle or sheep.

5622. Dr. Anderson reports, that burnet retains its verdure pretty well during the winter months, but affords such scanty crops as hardly to be worth the attention of the farmer.

5623. A correspondent in the Museum Rissicum, a work very favourable to burnet, confesses with reluctance that it is not deserving of any exalted character, but rather the contrary; and that it is in no degree to be compared to the common clover, which is cultivated at half the expense. It appears from some accounts there that horses will not cat it at all, and that kine frequently will not take it without great reluctance. Its slow growth is also made a great objection: being only about five inches high, and having scarcely one head in flower; whilst lucern, on the same soil, sown the same day and much thicker, was eighteen or twenty inches in height. It is not meant by this, however, to discourage that laudable spirit of improvement which so happily prevails at present; but to caution such as introduce any new plant to make themselves well acquainted with its natural history.

5624. Those who wish to cultivate burnet, as an herbage and hay plant, may treat it exactly as directed for saintfoin: as a pasture plant it is sown among the grasses in the same way as white or yellow clover. A bushel of seed is commonly sown to an acre.

5625. The ribwort plantatain (Plantain des Près, Fr.; Plantago lanceoldta L., fig. 779.) is a hardy native

hushel of seed is commonly sown to an acre.

5625. The ribwort plantain (Plantain des Près, Fr.; Plantago lanceolàta L., fig. 779.) is a hardy native with a tuft of long ribbed leaves springing from the crown of the root, long naked flower-stems, and a long moniliform tap-root. It abounds in dry soils, as do several other species of plantain, especially the P. mèdia. On dry soils it affords little herbage, and is often left untouched by cattle. Curtis, Withering, and other British botanists, speak unfavourably of the ribwort as a pasture herb; but Haller attributes the richness of the milk in the Swiss dairies to the flavour of this plant, and that of the Alchemilla, in the mountain pastures. In rich moist or watered lands its herbage is more abundant, and its flavour altered,—a circumstance not uncommon in the vegetable kingdom, but from which it does not always follow that the plant so altered is deserving of culture. In conformity with this observation, though navour atered,—a circumstance not uncommon in the vegetable kingdom, but from which it does not always follow that the plant so altered
is deserving of culture. In conformity with this observation, though
the ribwort is a scanty and rejected herbage, on poor dry soils, it is said
by Zappa of Milan to grow spontaneously in every meadow of Lombardy, especially in those which are irrigated. It vegetates early,
flowers at the beginning of May, ripens in five weeks, and is cut with
the Poa trivialis; the height of the leaves is about one foot, and of
the stalk a foot and a half; it multiplies itself much by the seed, and
a little by the roots, which it continues for some time to reproduce.
Ribwort, more especially in a cultivated state, is eaten heartily by
every sort of cattle, and in particular by cows, who like it most in
May, when it has great influence on the milk, as the hay has on the
flesh. In Scotland it is a useful addition to the proper grasses on lands
to be pastured by sheep, at the rate of two or three head to the acre.
Where kept well fed down by stock, there can be no doubt of its being
a very good and nourishing pasturage plant for both cattle and sheep;
but it is by no means adapted for hay or soiling.

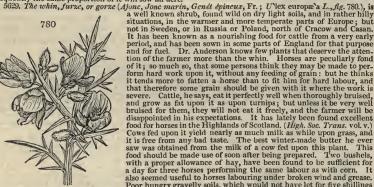

5626. Young says, that he had long before recommended this plant for laying land to grass, and sowed
on his own farm. At the same time, he thinks it extravagant to propose dandclion and sorrel as plants

3 L 2

proper for a cow pasture, and conjectures that those plants, being found among good ones, have qualities given them which do not properly belong to them: he is likewise inclined to make the same conjecture in respect to narrow-leaved plantain, ribwort, or rib-grass, and should even have preferred dandelion and sorrel to it; but he is cautious of opposing theory to practice.

5627. Dr. Anderson states, that narrow-leaved plantain or ribgrass is well liked by horses and cattle, and yields a very good crop upon rich ground tending to dampness, if it is at the same time soft and spongy; but that upon any soil which has a tendency to bind, or upon dry ground, it furnishes a very scanty crop. It has been made use of in some parts of Yorkshire as a summer grass. As an article of pasturage for cattle and sheep, it is there in high esteem: it is not, however, well eaten by horses. As an article of hay, it is held to be detrimental to the crop; retaining its sap an unusual length of time, and when fully dry falling into a small compass, or being broken into fragments and left behind in the field.

5628. The culture of the plantain is the same as that of clover; its seed is about the same size, and consequently the same proportion of it will sow an acre.

form hard work upon it, without any feeding of grain: but he thinks it tends more to fatten a borse than to fit him for hard labour, and that therefore some grain should be given with it where the work is severe. Cattle, he says, eat it perfectly well when thoroughly bruised, and grow as fat upon it as upon turnips; but unless it be very well bruised for them, they will not eat it freely, and the farmer will be disappointed in his expectations. It has lately been found excellent to disappointed in his expectations. It has lately been found excellent food for horses in the Highlands of Scotland. (High. Soc. Trans. vol. v.) Cows fed upon it; yield nearly as much milk as while upon grass, and it is free from any bad taste. The best winter-made butter he ever saw was obtained from the milk of a cow fed upon this plant. This food should be made use of soon after being prepared. Two bushels, with a proper allowance of hay, have been found to be sufficient for a day for three horses performing the same labour as with corn. It also seemed useful to horses labouring under broken wind and grease. Poor hungry gravelly soils, which would not have let for five shillings by sowing them with furze-sc, in places where fuel has been scarce; the furze being frequently used for heating ovens, burning lime and bricks, and also for drying malt: but it is not worth cultivating in countries where fuel of any kind is cheap, or upon such lands as will produce good grass, corn, or other crops employed as the food of animals.

5630. The culture of the whin is thus given by the same author:—A field of a good dry loamy land, being well prepared, he sowed, along with a crop of barley, the seeds of the whin in the same way as clover is usually sown, allowing at the rate of from fifteen to thirty pounds of seed to the acre. The seeds, if harrowed in and rolled with the barley, quickly spring up, and advance under the shelter of the barley quiring the summer, and keep alive during the winter. Next season, if the field has not a great tendency

taste them; but a few that have been used to the food will, he observes, soon teach all the rest how to use it.

5631. Another very economical way of rearing whins, but which he has seen practised rather than experienced himself, is this:—Let a farm be enclosed by means of a ditch all round, with a bank thrown up on one side, and if stones can be had, let the face of that bank be lined with the stones, from bottom to near the top, this lining to slope backwards with an angle of about sixty or seventy degrees from the horizon. Any kind of stones, even round ones gathered from the land, will away the purpose very well; upon the top of the bank sow whin-seeds pretty thick, and throw a few of them along the face of the bank. Young plants will quickly appear. Let them grow for two years, and then cut them down by means of a hedge-bill, sloping down by the face of the bank. This mode of cutting is very easy, and as the seeds soon insinuate themselves among the crannics of the stones, the whole face of the bank seeds soon insinuate themselves among the crannics of the stones, the whole face of the bank becomes a close hedge, whose shoots spring up with great luxuriance. If another ditch be made on the other side of the bank, and if this be managed in the same way, and the hedge cut down only once every second year (and in this way it affords very good food for beasts), the inside and outside being cut down alternately, the fence will at all times continue good, as the hedge at the top will at all times be complete. This mode of rearing whins is, he remarks, both convenient and economical. But where stones cannot be obtained for making the facing, the bank very soon moulders down, and becomes until for the purposes of a fence. Circumstances have prevented him from ascertaining what is the weight of the crop that may be thus attained, but he thinks he may safely venture to say, that it is at least equal to that of a crop of green clover; and if it be considered, that this affords a green succulent food during winter, on

order to guard against its being destroyed: as, during the beginning of the season, nature seems to be solely employed about the great work of fructification, and it is not till near Midsummer that the whin begins to push forth its wood-bearing branches, which advance with great luxuriance during the latter part of the season only, it may happen, that if care be not taken to have the grass that springs up on the field, before the whin begins to send out its shoots, eaten close down, that grass will acquire such a luxuriance before the young branches of the whin begin to advance, as to overtop them, and choke them entirely. Whoever, therefore, has a field under this particular crop, must be careful to advert to this circumstance, or, if the field be in good heart, he will infalliby lose it. The field therefore should be kept as

781

d heart, he will infallibly lose it. The field therefore should be kept as a pasture, bare as possible during the beginning of the season, and the cattle should only be taken from it when the shoots of the whin begin to advance with vigour. Under this management, he presumes, it may be kept for many years, and yield full crops; but, unless the mowers be particularly attentive at the beginning, to cut it as low as possible, it will very soon become impossible to cut the field with a scythe, as the stumps will acquire so much strength as to break the scythe when it happens to touch them.

5632. The spurry (Spergule, Fr.; Spérgula arvénsis L., fig. 781.) is a diminutive annual weed, on dry sandy corn-lands, in most parts of Europe. In Germany and the Netherlands, it is sown on the corn stubbles, and in the intervals of time that occur between some crops is fed with sheep. It may be sown and according to the specific of the spurry of the spurry and stored in the specific strength and the specific strength and the specific strength as the specific strength as

stubiles, and in the intervals of time that occur between some crops is fed with sheep. If Ir may be sown and reaped in eight weeks, either in autumn or spring. It is said to enrich the milk of cows, so as to make it afford excellent butter; and the mutton fed on it is preferable to that fed on turnips. Hens eat spurry greedily, and it is supposed to make them lay a great number of eggs. Whether in hay, or cut green, or in pasture, Von Thaer observes, it is the most nourishing, in proportion to its bulk, of all forage, and gives the best flavoured milk and butter. It has been recommended to be cultivated in England; but it over next the avenue of seed and labour in this country even on the

is not likely that such a plant can ever pay the expense of seed and labour in this country, even on the poorest soil, or at all events, as Pro essor Martyn observes, we have many better plants for such soils.

5633. The common broom (Genet commun, Fr.; Spártium scoparium L, fig. 782.) is cultivated in the southern parts of France, on the poorer sorts of soil, in the same way as henp,

6783.

for the purpose of stripping the bark from it, and converting it into a kind from t, and converting it unto a kind of thread. It is likewise cultivated in these places as a winter-food for sheep, and it is said they eat it with great avidity, preferring it to many other plants. It is, however, liable to produce disease of the urinary passages, by its diuretic qualities. It has been recommended by Young to be cultirecommended by Young to be culti-vated in England as food for sheep and horses, who are said to eat it after they get accustomed to it; also for thatch, ropes, besoms, food for bees, fuel, and burning on the spot to improve the soil. Its culture is the same as that of the whin; but very peculiar, indeed, must be that situ-ation, where its culture is attempted attempted. It is

ation, where its culture is attempted for any of the above purposes. It is useful protection of game in plantations, from which source abundance may be had for besoms. The Spanish broom (S. júnceum L., fig. 783), might broom (S. júnceum L., fig. 783), might with a large sweet tap-root. It is a native of Sicily, but endures the British winter like a native plant. It is sown along with clover and serventive of the rot in sheep. Fleet, of Hampshire, famous for curing the rot in sheep, cultivates it largely with success: he sows half a bushel to the acre, with a bushel of rye-grass with spring corn; and he finds that it lasts in the ground till it is permitted to seed. He feeds it constantly; it being excellent for sheep, and, when suffered to get bushel to the acre, with a bushel of rye-grass with spring corn; and he finds that it lasts in the ground till it is permitted to seed. He feeds it constantly; it being excellent for sheep, and, when suffered to get a head, wonderfully fed upon by pigs in the autumn. After September, it will not, he says, run to seed. When it was ploughed up he obtained good oats. The land was poor, and in the next round of the course, the clover was much the better for the parsley having been sown or the clover omitted; for in a field half parsley, half clover, when the clover came again to be sown, it was excellent on the parsley half, but bad on the clover part. In laying down land to grass, Hoyte, in the fourth volume of Communications to the Board of Agriculture, advises the sowing with twelve pounds of white clover, two pecks of rye-grass, and two pounds of parsley to the acre, as the parsley stands two years, and by its diuretic qualities prevents the sheep from dying of the red-water, which too luxuriant clovers are apt to produce. In Scotland, also, it has been sown with success, and greedly eaten by horses, cows, and bogs. The secting a longer period to germinate than that of any other agricultural plant, and might probably be advantageously prepared by steeping and turning. It must be fresh, as two-year-old seed will not grow. It is easily procured by the pound or bushel, from the seedsman, to as easily raised by letting a few drills in a garden shoot into flower-stems.

5635. The Spira'a Ulmāria L.; queen of the meadows, Reine des Près Fr.; the Scabiòsa arvénsis; the Hesperis matronalis; the Centaurèa Jacea, are sown in France along with the perennial grasses, and their seeds may be had in the French seed shops, but they cannot be recommended in soils and climates where any of the clovers or true grasses will thrive so as to form an abundant herbage.

5635. The wallfouréer (Chetrámbus Chelri L.) is a well known garden flower, and at the same time a native, and very hardy on dry soils. Like the parsley it is an antis

afforded by Lotus corniculatus; its nutritive powers compared with that plant are as nine to eight; but on the whole, he says, both species are greatly inferior to white clover. (Gram. Wob. 2d ed. p. 311.) Lotus villosus and tetragonolobus, the Lotier cultivé of the French (fig. 786.), are a good deal cultivated in France on light soils The latter is an annual sown in our The latter is an annual sown in our

The latter is an annual sown in order gardens.

5638. The fenugreek (Sennegrain, Fr.; Trigonella Feenumgrae cum L., Fg. 787.), Greek hay, was formerly cultivated in Italy, and still holds a prominent place in the agriculture of Egypt. In France it is cultivated to a limited extent near Paris for its code which are used in medicine. seeds, which are used in medicine.

seeds, which are used in medicine.

5639. The serradilla (Ornithopus sativus of Personon's Synopsis) was introduced for purposes of field culture about the year 1818, from Portugal, and sown upon the light barren downs of Thetford in Norfolk, and Ampthill and other places in Bedfordshire. It is said to have produced abundant crops, two feet high, of excellent fodder, where scarcely any thing else would grow. Its culture, however, is no longer in use in England, and it does not enter into the agriculture of France.

France.

France.
5640. Galèga officinàlis; Láthyrus Cicera, latifòlius, sylvéstris, praténsis, hirsùtus, heterophýllus, and tingitànus;
E'rvum Ervília, and monanthos; Lotus villosus, and tetragonólobus; Vícia angusti-folia, Crácca, Pseudo-Crácca, iona, tracca, rseudo-tracca, biénnis, sèpium, and lùtea; Anthyllis vulnerària; and Astrágalus glyciphyllos and galegifórmis, are all used as herbage plants in the agriculture of France.

ture of France.

5641. The oriental bunias
(Bunias orientalis L., fig. 783.
a) is a perennial plant, with
leaves, branches, and its general habit of herbage, not
unlike the wild chiccory. It is a native of the Levant, and
has been cultivated by way of experiment in the grass
garden at Woburn. It is less productive than chiccory,
bears mowing well, and affords the same nutriment, in
proportion to its bulk, as red clover. (Agricultural Chem.
p. 374.)

proportion to its bulk, as red clover. (Agricultural Chem. p. 374.)
5642. The yarrow (Millefeuille, Fr.; Achillèa Millefolium L. sig. 788. b), the common and alpine ladies'
mantle (Alchemilla vulgàris and alpina L.), and others, have been tried among perennial grasses, sown
in parks, with a view to give flavour to milk, butter, mutton, and venison. Sinclair considers yarrow as
an essential ingredient of the most fattening and healthy pastures. In all the pastures most celebrated
for fattening or dairy produce, which he examined in Devonshire, Lincolnshire, and in the vale of
Aylesbury, yarrow was present more or less in every part of the surface. (Hort. Gram. Wob. 2d
edit. p. 412.)

CHAP. VI.

Cultivated Grasses.

5643. The forage or hay and pasture grasses, of which we are now about to treat, are found clothing the surface of the earth in every zone, attaining generally a greater height, with less closeness at the root in the warm climates; and producing a low, close, thick, dark green nutritive herbage, in the cooler latitudes. The best grass pastures, those which are most productive and nutritive, are such as are found in countries that have least cold in winter, and no excess of heat in summer. Ireland, Britain, and part of Holland and Denmark, may equal or surpass any countries of the world in this respect; but in every zone where there are high mountains, there are certain positions between the base and summit, where, from the equability of the temperature, turf may be found equal to that in marine islands. It is a singular circumstance with regard to grasses,

that in the greater part of North America, the sorts that grow naturally on the plains are almost all annuals, and consequently with the first frost they die, and the ground remains naked till a fresh crop rises from the self-sown seeds next spring. same thing may be said of Poland and Russia, with the exception of the banks of rivers and the mountains.

5644. The universal presence of the forage grasses, and the rapidity with which all soils become covered with them when left uncultivated, are the obvious reasons why their systematic selection and culture are but of recent date. Though the Romans cultivated clovers, and were careful of their meadows, it does not appear that the seeds of the proper grasses were collected and sown by them. None of the agricultural writers, from Peter of Bologna to Parkinson in 1640, say a word about sowing grasses, though they all mention clover and lucern. This branch of culture appears to have originated in England about the middle of the seventeenth century, and the grass made choice of was the rye-grass. The first mention made of it for cultivation is in Dr. Plot's Oxfordshire, printed in 1677. "They have lately sown," says he, "ray-grass, or the Gràmen Ioliàceum, by which they improve any cold, sour, clay-weeping ground, for which it is best, but good also for drier upland grounds, especially light stony or sandy land, which is unfit for saintfoin. It was first sown in the Chiltern parts of Oxfordshire, and since brought nearer Oxford by one Eustace, an ingenious husbandman of Islip, who, though at first laughed at, has since been followed even by those very persons that scorned his experiment." The first grass tried after rye-grass appears to have been the Phleum pratense, by Rocque of Walham Green, about 1760. Soon afterwards the seed of cock's-foot grass was introduced from Virginia, under the name of orchard-grass, by the Society of Arts. (Ann. Reg. 1765, 141.); fox-tail was tried at a later period, on the suggestions of Stillingfleet and Curtis. Curtis.

5645. Stillingflect, about 1759, drew the attention of the reading agriculturist to the selection of different species of grasses; as did Dr. Anderson about the same time, and Swayne (Grámina Poiscaua) and Curtis (Observations on British Grasses) soon afterwards. The origin of this attention to grasses and native plants may be traced to the practice of forming local floras by botanists, and especially to the Flora Succiea of Linnaus; and the British Floras of Hudson, Withering, Lightfoot, Smith, &c. in which the medical and economical properties of the plants were mentioned; and, in imitation of Linnaus, particular notice taken of the surface which fed upon them

taken of the animals which fed upon them.

5646. John Duke of Bedford made the latest and most laborious efforts towards attaining a knowledge of the comparative value of all the British and some foreign grasses worth cultivating. The result is given in an appendix to Sir H. Davy's Agricultural Chemistry, and more at large in Sinclair's Hórtus Gramineus Woburnensis, 8vo. 2d edit. 1825, a work which may truly be said to form an epoch in this department of agriculture, and which will probably long continue to be the ground-work of all that shall continue to be done in this branch of the subject.

5647. With respect to the general culture of grasses, though no department of agriculture is more simple in the execution, yet, from their nature, considerable judgment is required in the design. Though grasses abound in every soil and situation, yet, all the species do not abound in every soil and situation indifferently. On the contrary, no class of perfect plants is so absolute and unalterable in its choice in this respect. The creeping-rooted and stoloniferous grasses will grow readily on most soils; but the fibrous-rooted species, and especially the more delicate upland grasses, require particular attention as to the soil in which they are sown; for in many soils they will either not come up at all, or die away in a few years, and give way to the grasses which would naturally spring up in such a soil when left to a state of nature. Hence, in sowing down lands for permanent pasture, it is a good method to make choice of those grasses which thrive best in adjoining and similarly-circumstanced pastures for a part of the seed; and to mix with these what are considered the very best kinds.

5648. The most important feature in the culture of pasture grasses is mixture of sorts. The husbandman, observes one of the most scientific agriculturists in Scotland, who clothes his fields only with ryegrass and clover, employs a limited machinery, the former being unproductive in summer, the latter moderately so in spring; but when he, for this purpose, uses a variety of plants differing in their habits of growth, and periods of luxuriance, a numerous and powerful machinery is kept successively in full operation. (Quar. Jour. Ag. vol. ii. p. 247.)
5649. The effect of a mixture of grasses may be accounted for from some species putting forth their foliage, and reaching a maximum of produce at different periods from other kinds. From some being gregarious or social, and others solitary and never producing a close turf; by sowing seeds of several species together, which are dissimilar in their habits of growth, and arrive at a maximum of produce at different periods of summer and autumn, there is secured throughout the season a succession of fresh berbage, rendered, by the erect and creeping foliage of the different species, so dense and abundant as greatly to surpass in quantity that obtained from the cultivation of two or three kinds only. (Ibid. p. 246.)

5650. New and excellent varieties of many of the grasses, especially those used or fit to be used in the convertible husbandry, might no doubt be obtained by selection and cross-breeding, and it is much to be wished that this were attempted by cultivators.

5651. The grasses to be here treated of may be classed as tall sorts, or those best fitted for hay; and dwarf grasses, or those fit only for pasturage: those experimented on at Woburn will next be noticed.

Sect. I. Tall-growing or Hay Grasses.

5652. The hay grasses for the purposes of agriculture may be advantageously divided into those of temporary, and those of permanent duration.

Subsect. 1. Tall or Hay Grasses of temporary Duration.

5653. The most valuable of this division are the biennial, or, as it is commonly but erroneously called, the annual, perennial, and subperennial rye-grass (fig. 789. a), the 3 L 4

cock's-foot grass(b), and woolly soft grass(c). Where a crop of hay is desired within the year, it is necessary to resort to such grasses as are annuals in the strict sense of the word: and none can be better for this purpose than the common oat (Avena sativa), cut and made into hay when it comes into flower. Next in order may be mentioned the other cereal grasses and the annual varieties of Bròmus: the latter, however, are very coarse grasses, though prolific in culm.

5654. The biennial rye-grass (Lòlium perénne var. biénne L.) is well known, as being universally sown, either with or without clover, among corn crops, with a view to one crop of hay in the succeeding season.

It attains a greater height, and produces a longer broader spike of flowers, than the perennial rye-grass, and the produce in hay is considered greater than that of any other annual grass, equally palatable to cattle. It prefers a rich loamy soil, but will grow on any surface whatever, not rock or undecayed bog.

5655. The perennial rye-grass (Lòlium perénne L. Ivraie vivace, Fr.; Daurende Lolche, Ger.; and Loglio vivace, Ital.) differs from the other in being of somewhat smaller growth, and in abiding for several years, according to the variety and the soil

and culture.

5656. Many consider this grass coarse, benty, and very exhausting to the soil; but, after all the experiments that have been made on the other grasses, none have been found to equal it for a course of mowing and pasturing for two, three, or seven years. It is sown in Italy, and especially in Lombardy, and also in France and Germany, along with clover, for the same purposes as in this country; and, as Von Thaer has remarked, though some have tried other species, both in these countries and in England, they have in the end returned to rye-grass. When intended as a pasture-grass, if stocked hard, and when for hay, if mown early, the objections to it are removed. (Code of Agriculture.) G. Sinclair says the circumstance of its producing abundance of seed, which is easily collected, and vegetates freely on any soil, its early perfection and abundant herbage the first year, which is much relished by cattle, are the merits which have upheld it to the present day, and will probably for some time to come continue it a favourite grass among farmers. But the lattermath is inconsiderable, the plant impoverishes the soil in a high deeper if not cut before the seed ripens. When this is neglected, the field after midsummer exhibits only a brown surface of withered straws. Let the produce and nutritive powers of rye-grass be compared with those of the cock's-foot grass, and it will be found inferior nearly in the proportion of 5 to 18; to meadow fox-tail of 5 to 12; and to meadow fescue of 5 to 17. (Hort. Gram. Wob. 2d edit. 215. and see § 5662.) In a subsequent page he observes, "The new varieties, however, of this species of grass, which have been discovered of late years, remove in a considerable degree the serious objections which applied to the common rye-grass." (Ib. 412.) The varieties alluded to are all perennial, and as under:

Slender rye-grass, common in dry impoverished pasture land. Compound or broad spiked rye-grass, found in rich solls, long under grass, and chiefly in beaten perts, as cart-ways, &c. It has a short broad spike, crowded with spikelets at the top. Pacey's rye-grass, found in rich meadow lands, and introduced by Facey, a cultivator in the uplands of Staffordshire; spike nearly upright, spikelets shorter than in the compound rye-grass, the stem furnished with long leaves, and the root leaves large and numerous. Sinclair considers this the most value and the content of the rye-grass.

of Acre House, Lincolnshire, an eminent cultivator of the pasture grasses, who, in 1825, had 60 varieties of Lölium perenne under experiment.

Stickney's rye-grass, introduced by Stickney of Holderness. Russell's rye-grass, first cultivated by the late B. Holdich, Esq., editor of The Farmer's Journal, from seed obtained of a plant in a rich fen pasture, pointed out to Holditch by the Duke of Bedford.

Church bennet, or Church bent-grass, an excellent variety of rye-grass, cultivated in some parts of Herkshire.

All the above, except the first two, are excellent varieties. Pacey's and Russell's are considered the best.

the best.

5657. The proportional value which the grass at the time of flowering bears to the grass at the time the seed is ripe, is as 10 to 11. The proportional value which the grass of the lattermath bears to the grass at the time of flowering, is as 4 to 10; and to grass at the time the seed is ripe, as 4 to 11.

5658. The seed of perennial rye-grass is not to be distinguished from that of the annual variety. It may be collected by hand, in most parts of Britain, from old pastures, and a considerable quantity is annually so procured in Kent and Sussex. It is also grown purposely for seed in England and Scotland. Formerly it was the practice for farmers to collect the seed which dropped from the hay used by their horses; but rye-grass, grown for hay, is now cut, by all judicious farmers, when it is just coming into flower; and therefore to collect the glumes or empty husks can be of no use as seed. It has also been a common practice, in regard to rye-grass, to let the mixed crop of that and clover stand till the seeds of the former have attained a considerable degree of ripeness, when it is cut down and made into hay, in the usual manner; and the seeds of the rye-grass are separated by the use of the fiall, commonly before the hay is put into the field-ricks. Sometimes, when lut a small quantity is wanted, the hay is merely shaken well upon a cloth, when it is building in the stack-yard; or afterwards in the stable-loft, before it is put into the horse's racks. But in all of these methods, in order to obtain good seed, the clover must remain uncut beyond the proper season; and it is thus materially injured in quality, while the value of the rye-grass seed, in such a crop, is merely a secondary consideration.

5659. When seed is the principal object of the culture of rye-grass, it ought not to be mixed with clover at all, though it may be sown along with any of the kinds of corn, and treated the year after in every respect as a crop of corn; bound up in sheaves, built in stacks, threshed with the fiail, and d

5661. The cock's-foot grass (Dáctylis glomeràta L., fig. 788. b) is an imperfect perennial, and grows naturally on dry sandy soils. This grass may be known by its coarse appearance, both of the leaf and spike, and also by its whitish green hue.

and grows naturally on dry sandy soils. This grass may be known by its coarse appearance, both of the leaf and spike, and also by its whitish green hue.

5662. One writer says, he has cultivated it largely, and to his satisfaction, on wet loams on a clay marl bottom, upon which the finer grasses are apt to give way in a few years to the indigenous produce. If suffered to rise high, it is very coarse; but, fed close, is a very valuable sheep pasture. He has sown two bushels an acre, and 10lbs. common red clover; and when the clover wears out, the grass fills the lands and abides well in it. It grows well in winter. It has been found highly useful as an early sheep feed. It is early, hardy, and productive, but is a coarser plant than rye-grass, and requires even greater attention in regard to being cut soon, or fed close. It does best by itself, and the time of its ripening being different from that of clover, it does not suit well to be mixed with that plant. The pasturage it affords is luxuriant, and particularly agreeable to sheep. It is cultivated to a great extent, and with astonishing success, at Holkham. The quantity of sheep kept upon it, summer and winter, is quite surprising; and the land becomes renovated by lying two or three years under this grass, and enriched by the manure derived from the sheep. A field, in the park at Woburn, was laid down in two equal parts, one part with re-grass and white clover, and the other part with cock's-foot and red clover: from the spring till midsummer, the sheep kept almost constantly on the rye-grass; but after that time they left it, and adhered with equal constancy to the cock's-foot during the remainder of the season. In The Code of Agriculture (p. 497. 3d edit), it is stated, that Sinclair of Woburn considers "no grass so well surproses as cock's-foot, and in the second edition of the Hortus Gramineus Woburneus's, it is observed, that if one species only is thought preferable to another in the alternate husbandry, that species is the Dáctylis than Festica durins

benefit of its merits.

5664. The woolly soft grass (Hólcus lanàtus L., fig. 580. c) is an imperfect perennial, and rather late flowering grass, of a short unsubstantial appearance, and found chiefly in poor dry soils. It is, however, a very common grass, and grows on all soils, from the richest to the poorest. It affords abundance of seed, which is light, and easily dispersed by the wind.

5665. It was cultivated at Woburn on a strong clayey loam, and the proportional value which the grass at the time the seed is ripe, bears to the grass at the time of flowering, is as 11 to 12. Young of Essex observes of this grass, that it flourishes well on any moist soil, and should be sown chiefly with a view to sheep, for it is not so good for other stock: many acres of it have been cultivated on his farm for sheep, and it has answered well when kept close fed. Marshal, in his Midland Counties, mentions it as a good grass for cows and other cattle, but bad for horses. In his Rural Economy of

Yorkshire, he, however, condemns it altogether.

5666. According to Sinclair, of Woburn, "it appears to be generally disliked by all sorts of cattle. The produce is not so great as a view of it in the fields would indicate; but being left almost entirely untouched by cattle, it appears the most productive part of The hay which is made of it, from the number of downy hairs which the herbage. cover the surface of the leaves, is soft and spongy, and disliked by cattle in general." The Woburn experiments lead to the conclusion that the Hólcus móllis is a better hay plant than the species here noticed; but as that is a more durable perennial it is less fitted for the temporary purposes of this section.

5667. The culture of these grasses may be considered the same as that of rye-grass, which was discussed when treating of clover and rye-grass. (5540.) The seeds of all of them are sold by the principal seedsmen, or may be gathered on grass-fields, or hedge

wastes, by women or children at an easy rate.

Subsect. 2. Tall or Hay Grasses of permanent Duration.

5668. No permanent grass has been found equal to the rye-grass for the purposes of convertible husbandry, but others have been selected which are considered superior for The principal of these are the fescue, fox-tail, and meadow-grass. culturists, indeed, are not all agreed on the comparative merits of these grasses with ryegrass; but there are none who do not consider it advisable to introduce a portion of each, or most of these species along with rye-grass, in laying down lands to permanent pasture. The nutritive products of these grasses, of perennial rye-grass, and of that singular grass fiorin, are thus given by Sir H. Davy : -

					In 100 Parts.					
Systema:ic Name.	English Name.	Whole quantity of soluble or nutritive matter.	Mucilage or starch.	Saccha- rine mat- ter or sugar.	Gluten or albumen.	Extract or matter rendered insoluble during eva- poration.				
Festica Ioliàcea (fig. 790. c) Hólcus odorátus Anthoxánthum vérnum Alopecàrus pratéusis (d) Poa fértilis (e) triviális (f) Cynosàrus cristátus Lòlium perénne Agróstis stolonífera	Spiked fescue grass Sweet-scented soft grass Sweet-scented vernal grass Meadow fox-tail grass Fertile meadow grass Roughish meadow grass Crested dog's-tail grass Perennial rye-grass Fiorin Fiorin cut in winter	19 82 50 33 78 39 35 39 54 76	15 72 43 24 65 29 28 26 46 64	2443653458	1 1	2636764523				

5669. Of the fescue grass there are three species in the highest estimation as meadow hay grasses, viz. the meadow, tall, and spiked fescue. (fig. 790. a, b, c.)

hay grasses, viz. the meadow, tall, and spiked fescue. (fig. 790. a, b, c.)

5670. The F. pratinis (a), or the meadow or fertile fescue grass, is found in most rich meadows and pastures in England, and is highly grateful to every description of stock. It is more in demand for laying down meadows than any other species except the rye-grass. By the Woburn experiments, the value of this grass at the time the seed is ripe, is to that of the grass at the time of flowering, as 6 to 18. The loss which is sustained by leaving the crop of this grass till the seed be ripe is very great. That it loses more of its weight in drying at this stage of growth, than at the time of flowering, perfectly agrees with the deficiency of nutritive matter in the seed crop, in proportion to that in the flowering crop: the straws being succulent in the former, they constitute the greatest part of the weight; but in the latter they are comparatively withered and dry, consequently the leaves constitute the greatest part of the weight. It may be observed here, that there is a great difference between straws or leaves that have been dried after they were cut in a succulent state, and those which are dried by nature while growing. The former retain all their nutritive powers; but the latter, if completely dry, very little, if any the Festica pratensis, from which it differs in little, except that it is larger in every respect. The produce is nearly three times that of the F. pratensis, and the nutritive powers of the grass are superior, in direct proportion, as 6 to 8. The proportional value which the grass of the lattermath bears to that of the crop, is as 16 to 20; and to the grass at the time the seed is ripe, as 12 to 16 inverse. Curtic observes, that as the seeds of this plant, when cultivated, are not fertile, it can only be introduced by parting its roots and planting them out; in this there would, says he, be no great difficulty, provided it were likely to answer the expense, which he is strongly of opinion it would in certain eases; i

5672. The spiked fescue grass, or darnel fescue grass (Festica loliàcea L. c), resembles the rye-grass in appearance, and the tall fescue grass in the infertility of its seeds. It is considered superior to rye-grass either for hay or permanent pasture, and improves in proportion to its age, which is the reverse of what takes place with the rye-grass.

5673. The meadow fox-tail grass (Alopecurus praténsis, d) is found in most meadows; and when the soil is neither very moist nor very dry, but in good heart, it is very productive. It also does well on water meadows. Sheep and horses seem to have a greater relish than oxen for this grass.

5674. In the Woburn experiments, it was tried both on a sandy loam and a clayey loam, and the result gave nearly three fourths of produce greater from a clayey loam than from a sandy soil, and the grass from the latter is comparatively of less value, in proportion as 4 to 6. The straws produced by the sandy soil are deficient in number, and in every respect less than those from the clayey loam; which will account for the unequal quantities of the nutritive matter afforded by them; but the proportional value in which the grass of the lattermath exceeds that of the crop at the time of flowering, is as 4 to 3: a difference which appears extraordinary, when the quantity of flower-stalks which are in the grass at the time of flowering is considered. In the Anthoxanthum odoratum the proportional difference between the grass of these crops is still greater, nearly as 4 to 9; in the Poa praténsis they are equal; but in all the

latter flowering grasses experimented upon, the flowering straws of which resemble those of the Alopechrus praténsis, or Anthoxánthum odorátum, the greater proportional value is always, on the contrary, found in the grass of the flowering crop. Whatever the cause may be, it is evident, that the loss sustained by taking the crops of these grasses at the time of flowering is considerable. The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe, is as 6 to 9. The proportional value which the whole of the lattermath crop bears to that at the time the seed is ripe, is as 5 to 9; and to that at the time of flowering, proportionably as 13 to 24. Next to the fescue, this grass is in the greatest reputation for laying down mowing grounds; but it is unfortunately subject to the rust in some situations. situations

5675. Of the meadow grass there are two species in esteem as hay plants, the smooth-stalked, and roughish.

These plants compose the greater part of the celebrated Orcheston meadows near Salisbury, and also of

the meadows near Edinburgh.

the meadows near Edinburgh.

5676. The great or smooth stalked meadow grass, the spear grass of America (Pòa praténsis, e), is distinguished by its height, smooth stem, and creeping roots. According to Sole it is the best of all the grasses: its foliage begins to shoot and put on a fine verdure early in the spring, but not so soon as some other grasses. Every animal that eats grass is fond of it; while it makes the best hay, and affords the richest pasture. It abounds in the best meadows about Laycock and Chippenham, and has the valuable property of abiding in the same land, while most other grasses are continually changing. According to some it delights in rather a dry than a moist soil and situation, on which account it keeps its verdure better than most others in dry seasons; but it thrives most luxuriantly in rich meadows.

5677. By the Woburn experiments, the proportional value in which the grass of the lattermath are of equal value. This grass is, therefore, of least value at the time the seed is ripe; a loss of more than one fourth of the value of the whole crop is sustained if it is not cut till that period; the straws are then dry, and the root-leaves in a sickly decaying state: those of the lattermath, one four the plant of the plant for the purpose of hay, it will, from this circumstance, and the superior value of the grass of the lattermath, compared to that of the seed-crop, appear well adapted for permanent pasture. It was of this grass that the American prize bonnet, in initiation of Leghorn, was manufactured by Miss Woodhouse. Woodhouse

Woodhouse, 5678. The roughish meadow grass (Poa triviàlis L., f) delights in moist, rich, and sheltered situations, when it grows two feet high, and is very productive. By the Woburn experiments it appears that the proportional value in which the grass of the seed crop exceeds that at the time of flowering, is as 8 to 12; and that of the seed crop, as 11 to 12. Here, then, is a satisfactory proof of the superior value of the crop at the time the seed is ripe, and of the consequent loss sustained by taking it when in flower; the produce of each crop being nearly equal. The deficiency of hay in the flowering crop, in proportion to that of the seed crop, is very striking. Its superior produce, the highly nutritive powers which the grass seems to possess, and the season in which it arrives at perfection, are merits which distinguish it as one of the most valuable of those grasses which affect moist rich soils and sheltered situations; but on dry exposed situations, it is altogether inconsiderable; it yearly diminishes, and ultimately dies off, not unfrequently in the space of four or five years. quently in the space of four or five years.

5679. The above are six of the best British grasses, for either dry or watered meadows. The seeds of the meadow fescue, fox-tail, and smooth and rough meadow grasses may be had from the seedsmen, and they are sown in various proportions with the clovers and The seeds of the two sorts of meadow grass are apt to stick together, and rye-grass. require to be well mixed with the others before being sown. The tall and spiked fescue grasses, having a number of barren flowers, are not prolific in seeds, and they are therefore seldom to be got at the seed-shops; though they may occasionally be had there gathered from plants in a wild state.

5680. As hay grasses, adapted for particular soils and situations, the cat's tail or Timothy, floating fescue, and fiorin grass, have been recommended; but it cannot be said that the opinions of cultivators are unanimous in their favour. Timothy has certainly been found to answer well on moist, peaty soils, and in several cases fiorin also. 5681. The cat's tail or Timothy grass (Phlèum praténse L., fig. 791. a) is a native plant,

It was first brought into notice by Timothy and found both in dry and moist soils. Hudson, about 1780, who introduced it from Carolina, where it was in great repute. On moist rich soils it is a prolific grass, but late; on dry soils it is good for little, and for cultivation in any way is disapproved of by Withering, Swaine, Curtis, and others, as having no properties in which it is not greatly surpassed by the Alopecurus praténsis.

5682. The Woburn experiments, however, present this grass as one of the most prolific for hay. Sixtyfour drachms of the straws afforded seven drachms of nutritive matter. The nutritive powers of the

straws simply, therefore, exceed those of the leaves, in the proportion of 28 to 8; the nutritive powers of the grass, at the time of flowering, exceed those of the grass at the time the seed is ripe, in the proportion of 10 to 23; and the nutritive powers of the lattermath, those of the grass of the flowering crop, in the proportion of 8 to 10. The comparative merits of this grass will, from the above particulars, appear to be very great; to which may be added the abundance of fine foliage that it produces early in the spring. In this respect it is inferior to Poā fértilis and Pōā angustifolia only. The value of the straws at the time the seed is ripe, exceeds that of the grass at the time of flowering, in the proportion of 28 to 10, a circumstance which raises it above many others; for from this property its valuable early foliage may be depastured to an advanced period of the season, without injury to the crop of hay, treatment which in grasses that send forth their flowering straws early in the season would cause a loss of nearly one half in the value of the crop, as clearly proved by former examples; and this property of the straws makes the plant peculiarly desirable for hay. In moist and peaty soils it has in various instances been found highly productive.

5683. The floating fescue grass, Festuca fluitans (b), is found in rich swamps, especially in Cambridgeshire, where it is said to give the peculiar flavour to Cottenham and Cheddar cheese. It is also found in ditches and ponds in most parts of the country.

5684. It is greedily devoured by every description of stock, not excepting hogs and ducks, and geese eagerly devour the seeds, which are small, but very sweet and nourishing. They are collected in several parts of Germany and Poland, under the name of manna-seeds (schwiden), and are esteemed a delicacy in soups and gruels. When ground to meal, they make bread very little inferior to that from wheat. The bran is given to horses that have the worms; but they must be kept from water for some hours afterwards. Geese, and other water-fowl, are very fond of the seeds. So also are fish; trout, in particular, thrive in those rivers where this grass grows in plenty. It has been recommended to be sowed on meadows that admit flooding; but Curtis justly remarks, that the flote-fescue will not flourish except in land that is constantly under water, or converted into a bog or swamp.

5685. The water meadow grass (Poa aquática, c) is found chiefly in marshes, but will grow on strong clays, and yield, as the Woburn experiments prove, a prodigious produce, flowering from June to September. It is one of the largest of our grasses.

5686. In the fens of Cambridgeshire, Lincolnshire, &c., immense tracts, that used to be overflowed and to produce useless aquatic plants, and which, though drained by mills, still retain much moisture, are covered with this grass, which not only affords rich pasturage in summer, but forms the chief part of the winter fodder. It has a powerfully creeping root; and bears frequent mowing well. It is sometimes cut thrice in one season near the Thames. It grows not only in very moist ground, but in the water itself; and with cards-tail, burr-reed, &c., soon fills up ditches; and occasions them to require frequent cleansing. In this respect it is a formidable plant, even in slow rivers. In the Isle of Ely they cleanse these by an instrument called a bear, which is an iron roller, with a number of pieces of iron, like small spades, fixed to it; this is drawn up and down the river by horses walking along the bank, and tears up the plants by the roots, which float, and are carried down the stream. The grass was, however, cultivated at Woburn on a strong tenacious clay, and yielded considerable produce. on a strong tenacious clay, and yielded considerable produce.

5687. The florin grass (Agrostis stolonifera, d) is a very common grass both in wet and dry, rich and poor situations. Few plants appear to be more under the influence of local circumstances than this grass. On dry soils it is worth nothing; but on rich marl soils, and in a moist soil, if we may put confidence in the accounts given of its produce in Ireland, it is the most valuable of all herbage plants.

soils, and in a moist soil, if we may put confidence in the accounts given of its produce in Ireland, it is the most valuable of all herbage plants.

5688. It was first brought into notice by Dr. Richardson in 1809, and subsequently extelled, and its culture detailed in various pamphlets by the same gentleman. It appears to be exclusively adapted for moist peat soils or bogs. In The Cade of Agriculture it is said, "On mere bogs, the fiorin yields a great weight of herbage, and is, perhaps, the most useful plant that bogs can produce." According to Sir H. Davy, the fiorin grass, to be in perfection, requires a moist climate or a wet soil; and it grows luxyriably in cold clays unfitted for other grasses. In light sands, and in dry situations, its produce is much inferior as to quantity and quality. He saw four square vards of floring rass cut in the end of January, in a meadow exclusively appropriated to the cultivation of florin by the Countess of Hardwicke, the soil of which is a damp stiff clay. They afforded twenty-eight pounds of fodder, of which one thousand parts afforded sixty-four parts of nutritive matter, one sisting nearly of one sixth of sugar, and five sixth of mucilage, with little extractive matter." In another experiment, four square yards gave twenty-seven pounds of grass. Lady Hardwicke has given an account of a trial of this grass; wherein twenty-three milch cows, and one young horse, besides a number of pigs, were kept a fortnight on the produce of one acre. On the Dukcof Bedford's farm, at Maulden, fiorin hay was placed in the racks before horses, in small distinct quantities, alternately with common hay; but no decladed preference for either was manifested by the horses in this strail. Florin has been tried in the highlands of Soctland, and a premium awarded in 1821 for a field of three acres planted on land previoudly worth very little, at Appin, in Argyleshire. (Highl. Soc. Trans. Vol. vi p. 229.) Hay-tea has also been made from fiorlin, and found useful in rearing calves, being mixed wit

5691. A number of other species of tall grasses, well adapted for meadows and haymaking, might be here enumerated; but we have deemed it better to treat only of the most popular sorts, of which seeds may be purchased; all the others of any consequence will be found in a tabular view (Sect. III.), accompanied by a summary statement of their products in hay and aftermath, nutritive matter, and general character.

5692. The preparation of the soil, and the sowing of the usual meadow grasses, differ in nothing from those of clover and rye-grass already given. The after-treatment of dry meadows, including the making of natural hay, will be found in the succeeding Chapter on the management of grass-lands; that of watered meadows was naturally given when

treating of their formation. (4431.)

SECT. II. Grasses chiefly adapted for Pasturage.

5693. In treating of pasturage grasses we shall make a selection of such as have been tried to some extent, and of which the seeds are in the course of commerce. On soils in good condition, and naturally well constituted, no better grasses can be sown for pasturage than those we have described as tall grasses for hay-meadows; but for early and late pasturage, and secondary soils, there are others much more suitable.

5594. The pasture grasses for early pasturage on all soils are the Anthoxanthum odoratum, Hólcus odoratus, Avena pubescens, and Poa annua.
5995. The pasture grasses for late herbage on all soils are chiefly the different species of Agróstis and

Phlèum. 5596. The pasture grasses for poor or secondary soils are the Cynosùrus cristàtus, Festùca duriúscula and ovìna, Pòa comprèssa, cristàta, and angustifòlia.

5697. The grasses that afford most nutritive matter in early spring, are the fox-tail grass and the vernal grass; the former has been already mentioned as one of the best

5698. The sweet-scented vernal grass (Anthoxánthum odorátum, fig. 792. a) is common in almost all

pastures, and is that which gives the fragrance to natural or meadow-hay. It is chicfly valuable as an early grass; for, though it is eaten by stock, it does not appear to be much relished by them. From the Woburn experiments, it appears that the smallness of the produce of this grass renders it improper for the purpose of hay; but its early growth, and the superior quantity of nutritive matter which the lattermath affords, compared with the quantity afforded by the grass at the time of flowering, cause it to rank high as a pasture grass, on such soils as are well fitted for its growth; such are peat-bogs, and lands that are deep and moist.

as a pasture grass, on such soils as are well fitted for its growth; such are peat-logs, and lands that are deep and moist.

5699. The downy oat grass (Avèna pubéscens, b), according to the Woburn experiments, possesses several good qualities, which recommend it to particular notice; it is hardy, early, and more productive than many others which affect similar soils and situations. Its growth after being cropped is tolerably rapid, although it does not attain to a great length if left growing; like the Pòa prateins it sends forth flower-stalks but once in a season, and it appears well calculated for permanent pasture on rich light soils.

5700. The annual meadous grass (Pòa annua, c) is the most common of all grasses, and the least absolute in its habits. It is almost the only grass that will grow in towns and near works where the smoke of coal abounds. Though an annual grass, it is found in most meadows and pastures perpetually flowering, and affording an early sweet herbage, relished by all stock, and of as great importance to birds as wheat is to man. It hardly requires to be sown, as it springs up every where of itself. However, it may not be amiss to sow a few pounds of it per acre wherever perpetual pasture (not hay) is the object.

5701. The fine bent grass (Agrostis vulgàris, d) is one of the most common grasses, and, according to the Woburn experiments, one of the earliest. The A, pallostris is nearly as early in producing its foliage, though both flower late, and neither is very prolific either in bulk or nutritive matter.

5702. The narrow-leaved meadou grass (Pòa angustifòlia, e), though it flowers late, yet is remarkable for the early growth of the leaves. According to the Woburn experiments the leaves attain to the length of more than twelve inches before the middle of April, and are soft and succulent; in May, however, when the flower-stalks make their appearance, it is subject to the disease termed rust, which affects the whole plant; the consequence of which is manifest in the great deficiency

5703. The best natural pastures of England, examined carefully during various periods of the season, were found by Sinclair of Woburn to consist of the following plants:—

Alopecurus praténsis. Dáctylis glomerata. Festuca praténsis.

Phlèum praténse. Anthroxánthum odorátum. Hólcus avenàceus.

Vícia sèpium. Lòlium perénne. Bròmus arvénsis (frequent). Pòa ánnua. Avèna praténsis.

These afford the principal grass in the spring, and also a great part of the summer produce : -Avéna flavéscens. Hórdeum praténse. Cynosùrus cristàtus. Hólcus lanàtus. Trifòlium praténse Trifòlium rèpens. Festùca duriúscula.

Pòa triviàlis.

Pòa praténsis. Láthyrus praténsis.

These yield produce principally in summer and autumn: -

Achillèa Millefolium. Agróstis stolonífera and palústris. These vegetate with most vigour in autumn : -

Tríticum rèpens.

Ranúnculus àcris. Plantàgo lanceolàta.

Rùmex Acetòsa.

Ramfuculus àcris. Plantàgo lanceolàta. Rùmex Acetòsa.

The first and last of these plants are to be considered injurious; and the other is of little value as herbage. (Hort. Gram. Wob. 2d edit. 133.)

5704. The above mixture sown at the rate of four or five bushels to the acre, on well prepared soil without corn or other crop of any kind, could hardly fail of producing excellent pasture in the following year, and for an indefinite period. The best time for sowing is July or August, as spring-sown seeds are apt to suffer with the droughts of June and July. Fifteen of the above sorts are to be had from the seed.shops; and all of them may be gathered from natural pastures, or bespoke from collectors. Sinclair of Woburn, having entered into the seed and nursery business, and having expressed his intention to devote his particular attention to supplying the public with grass and other agricultural seeds, will probably render such seeds more common in commerce. (Advt. by Cormack, Son, and Sinclair.)

5705. Of late pasture grasses the different species of cat's-tail (Phlèum) and bent-grass (Agróstis) are the chief, and especially the Timothy and fiorin grass. The grasses, Sir H. Davy observes, that propagate themselves by stolones, the different species of Agròstis, supply pasture throughout the year; and the concrete sap, stored up in their joints, renders them a good food even in winter.

5706. Of pasture grasses for inferior soils one of the most durable is the dog's-tail grass (Cynosurus cristatus, fig. 793. a). This is a very common grass on dry, clayey, or firm

surfaces. It is one of the best grasses for parks, being highly relished by the South Down sheep and deer.

5707. The hard fescue grass (Festiva duriúscula, b) is one of the best of the dwarf sorts of grasses. It is grateful to all kinds of cattle; hares are very fond of it; at Woburn they crop it close to the roots, and neglect the Festiva ovina and Festiva rubra, which grow contiguous to it. It is present in most good meadows and pastures, and, with F. ovina, is the best for lawns.

5708. The Festiva glubra (c), and hordeiformis (d), greatly resemble the hard fescue, and may be considered enally described as restrict and lawn grasses.

500. The results galora (c), and noraeiforms (a), greatly resemble the nard rescue, and may be considered equally desirable as pasture and lawn grasses.

5700. The yellow oat grass (Avena flavéscens) is very generally cultivated, and appears, from the Woburn experiments, to be a very valuable grass for pasture on a clayey soil.

5710. Of pasture grasses for inferior soils and upland situations, one of the principal is the Festica

ovina, or sheep's fescue grass (fig. 794. a). This grass is peculiarly grass is peculiarly adapted for hilly sheep dwarf grass, but re-lished by all kinds of cattle. According to Sinclair's experience, "on dry soils that are incapable of producing the larger sorts, this should form the principal crop, or rather the whole; for it is seldom or never, in its natural state, found

5712. On the culture of these grasses it is unnecessary to enlarge, as it must obviously be the same as that of rye-grass or any of the others.

5713. The chief difficulty is to get the seed in sufficient quantity, for which a good mode is to contract with a seedsman, a year beforehand, for the quantity wanted. With all the pasture grasses, except the last class, we should recommend at least half the seed to be that of the perennial rye-grass; and we think it should also form a considerable part of the seeds used in laying down all meadows, except those for the aquatic or stoloniferous grasses. These, if they thrive, are sure to choak and destroy it, and therefore neither rye-grass, nor any other grass, should ever be sown with Timothy grass or fiorin.

5714. The formation of grassy surfaces by distributing pieces of turf over them has long been practised in gardening, in levelling down raised, or filling up hollow, fences, and in other cases of partially altering a grassy surface.

in other cases of partially altering a grassy surface.

5715. It is said to have been first used in agriculture by Whitworth, of Acre-house, Lincolnshire; and in 1812 it was brought forward on a large scale by John Blomfield, of Warham, in Norfolk, a tenant of Coke's. Blomfield planted eleven acres in this way. An account of the process, which is styled transplanting turf, or inoculating land with grass, has been published by Francis Blaikie, Coke's steward. (On the Cowersion of Arable Land into Pasture, 12mo, 1817.)

5716. An abstract of the process of transplanting turf, and an opinion on it, are thus given in The Code of Agriculture. A piece of good clean, sweet old turf, which ought principally to consist of fibrous-rooted plants, is cut into small pieces of about three inches square, and placed about six inches apart on the surface of ground prepared for that purpose. In this way one acre of turf will plant nine acres of arable land. The pieces of turf should be carefully placed with the grass side uppermost, and the plants pressed well into the ground. No more turf should be cut, carried, and spread in any one day than is likely to be planted before night. If the transplanted turf is found deficient in any particular species of favourite plants, as white clover, permanent red clover, &c. the seeds of those plants should be sown upon the young pasture in April. When the ground is in proper temper (between wet and dry) the pasture should be frequently well pressed down by heavy rollers, which will cause the plants to extend themselves along the ground rather than rise into turts, which otherwise they would be apt to do. No stock should be permitted to feed upon the transplanted pasture in the first spring or summer, nor until the grasses have perfected and shed their seeds. Indeed the pasturing should be very moderate until the mother grass-plants and their young progeny have united and formed a compact turf. The exper's rent, poor's rates, and taxes for that year; nor for restoring the land whence the turf

SECT. III. General View of the Produce, Uses, Character, and Value of the principal British Grasses, according to the Result of John Duke of Bedford's Experiments at Woburn.

5717. In all permanent pastures, Sir H. Davy observes, nature has provided a mixture of various grasses, the produce of which differs at different seasons. are to be made artificially, such a mixture ought to be imitated; and, perhaps, pastures superior to the natural ones may be formed by selecting due proportions of those species of grasses fitted for the soil, which afford respectively the greatest quantities of spring, summer, lattermath, and winter produce; a reference to the results of the Woburn experiments, he adds, will show that such a plan of cultivation is very practicable.

experiments, he adds, will show that such a plan of cultivation is very practicable.

5718. The manner in which these experiments were conducted is thus described:—"Spots of ground, each containing four square feet, in the garden at Woburn Abbey, were enclosed by boards in such a manner that there was no lateral communication between the earth included by the boards, and that of the garden. The soil was removed in these euclosures, and new soils supplied; or mixtures of soils were made in them, to furnish as far as possible to the different grasses those soils which seem; most favourable to their growth; a few varieties being adopted for the purpose of ascertaining the effect of different soils on the same plant. The grasses were either planted or sown, and their produce cut and collected, and dried at the proper seasons, in summer and autumn, by Sinclair, His Grace's gardener. For the purpose of determining, as far as possible, the nutritive powers of the different species, equal weights of the dry grasses or vegetable substances were acted upon by hot water till all their soluble parts were dissolved; the solution was then evaporated to dryness by a gentle heat in a proper stove, and the matter obtained carefully weighed. This part of the process was likewise conducted with much address and intelligence by Sinclair, by whom all the following details and calculations are furnished. The dry extracts supposed to contain the nutritive matter of the grasses, were sent to me for chemical examination. The composition of some of them is stated minutely; but it will be found from the general conclusions, that the mode of determining the nutritive power of the grasses, by the quantity of matter they contain soluble in water, is sufficiently accurate for all the purposes of agricultural investigation." (Agr. Chem. app.)

5719. The leading results of these experiments we have endeavoured to present in a tabular view; farther details will be found in the paragraphs (antecedent and posterior) referred to in the first colum

5722. On the nutritive products, Sir H. Davy has the following valuable remarks, some of which, concerning the mode in which the animal economy is operated on by the different substances composing the nutritive matter, the agriculturist will find useful, as applied to the tables before given (5000. 5190. &c.) of the nutritive products of the corns, legumes, and roots. The only substances which Sir H. Davy detected in the soluble matters procured from the grasses, are mucilage, sugar, bitter extract, a substance analogous to albumen, and different saline matters. Some of the products from the aftermath crops gave feeble indications of the tanning principle. In the experiments made on the quantity of nutritive matter in the grasses, cut at the time the seed was ripe, the seeds were always separated; and the calculations of nutritive matter made from grass and not hay.

grass and not hay.

5723. The order in which these substances are nutritive is thus given:—" The albumen, sugar, and mucilage, probably when cattle feed on grass or hay, are for the most part retained in the body of the animal; and the bitter principle, extract, saline matter, and tannin, when any exist, probably for the most part are voided in the excrement, with the woody fibre. The extractive matter obtained by boiling the fresh dung of cows, is extremely similar in chemical characters to that existing in the soluble products from the grasses. And some extract, obtained by Sinclair from the dung of sheep and of deer, which had been feeding upon the Lölium perenne, Dáctylis glomeràta, and Trifolium rèpens, had qualities so analogous to those of the extractive matters obtained from the leaves of the grasses, that they might be mistaken for each other. The extract of the dung, after being kept for some weeks, had still the odour of hay. Suspecting that some undigested grass might have remained in the dung, which might have furnished mucilage and sugar, as well as bitter extract, I examined the soluble matter very carefully for these substances. It did not yield an atom of sugar, and scarcely a sensible quantity of mucilage." Sinclair, in comparing the quantities of soluble matter efforded by the mixed leaves of the Lölium perénne, Dáctylis glomeràta, and Trifolium rèpens, and that obtained from the dung of cattle fed upon them, found their relative proportions as 50 to 13.

5722. From these facts it appears probable that the bitter extract, though soluble in a large quantity of water, is very little nutritive; but probably it serves the purpose of preventing, to a certain extent, the fermentation of the other vegetable matters, or in modifying or assisting the function of digestion, and may thus be of considerable use in forming a constituent part of the food of animals. A small quantity of bitter extract and saline matter is probably all that is useded; and beyond this quantity the soluble matters must be more

5725. In comparing the composition of the soluble products afforded by different crops from the same grass, Sir H. Davy found, in all the trials, the largest quantity of truly nutritive matter in the crop cut when the seed was ripe, and least bitter extract and saline matter; most extract and saline matter in the autumnal crop; and most saccharine matter, in proportion to the other ingredients, in the crop cut at the

autumnal crop; and most saccharine matter, in proportion to the other ingredients, in the crop cut at the time of flowering.

5726. The greater proportion of leaves in the spring, and particularly in the late autumnal crop, accounts for the difference in the quantity of extract; and the inferiority of the comparative quantity of sugar in the summer crop probably depends upon the agency of light, which tends always in plants to convert saccharine matter into mucilage or starch. Amongst the soluble matters afforded by the different grasses, that of the Flynmus arenarius (fig. 711. a) was remarkable for the quantity of saccharine matter it contained, amounting to more than one third of its weight. The soluble matters from the different species of Festica, in general, afforded more bitter extractive matter, than those from the different species of Festica, in general, afforded more bitter extractive matter, than those from the different species of Pos. The nutritive matter from the seed crop of the Poa compréssa was almost pure mucilage. The soluble matter of the seed crop of Phleum praténse, or meadow cat's-tail, afforded more sugar than any of the Poa or Festica species. The soluble parts of the seed crop of the Hólcus fanatus, contained no bitter extract, and consisted entirely of mucilage and sugar. Those of the Hólcus dorðrtus afforded bitter extract, and a peculiar substance having an acrid taste, more soluble in alcohol than in water. All the soluble extracts of those grasses, that are most liked by cattle, have either a saline or subacid taste; that of the Hólcus lanatus is similar in taste to gum arabic. Probably the Hólcus lanatus, which is so common a grass in meadows, might be made palatable to cattle by being sprinkled over with salt.

which is so common a grass in meadows, might be made parazole to cattle by being spinisted over with sail.

5727. No difference was found in the nutritive produce of the crops of the different grasses cut at the same season, which would render it possible to establish a scale of their nutritive powers; but probably the soluble matters of the aftermath crop are always from one sixth to one third less nutritive, than those from the flower or seed crop. In the aftermath the extractive and saline matters are certainly usually in excess; but the aftermath hay mixed with summer hay, particularly that in which the fox-tail and soft grasses are abundant, would produce an excellent food.

5728. Anthroxinthum odoratum E. B.—The proportional value which the grass, at the time of flowering, bears to that at the time the seed is ripe, is as 4 to 13. The proportional value which the grass, at the time of flowering, bears to that at the time the seed is ripe, is nearly as 9 to 13.

5729. Holicus odoratus Host, G. A.—The proportional value which the grass, at the time of flowering, bears to that at the time the seed is ripe, is as 17 to 21. The grass of the lattermath crop, and that of the crop at the time of flowering, taking the whole quantity, and their relative proportions of nutritive matter, are in value nearly as 6 to 10: the value of the grass, at the time the seed is ripe, exceeds that of the lattermath in proportion as 21 to 17. Though this is one of the earliest of the flowering grasses, it is tender, and the produce in the spring is inconsiderable. If, however, the quantity of nutritive matter which it affords be compared with that of any of these species which flower nearly at the same time, it will be found greatly superior. It sends forth but a small number of flower-stalks, which are of a slender structure compared to the size of the leaves. This will account, in a great measure, for the equal quantities of nutritive matter afforded by the grass at the time of flowering, and the lattermath.

5730. Cynosiurus ce

lattermath. Style Cymosurus ceruleus E. B. (Sestèria cerulea E. of P. 1070.)—The produce of this grass is greater than its appearance would denote; the leaves seldom attain to more than four or five inches in length, and the flower-stalks seldom arise to more. Its growth is not rapid after being copped, nor does it seem to withstand the effects of frost, which, if it happens to be severe and early in the spring, checks it so much as to prevent it from flowering for that season; otherwise, the quantity of nutritive matter which the grass affords (for the straws are very inconsiderable) would rank it as a valuable grass for permanent

pasture.

5731. Avènq pubéscens E. B. (Trisètum pubéscens E. of P. 1062.) — The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe, is as 6 to 8. The proportional value which the grass at the time of flowering bears to that of the lattermath, is as 6 to 8. The grass of the seed-crop, and that of the lattermath, are of equal value. The downy hairs which cover the surface of the leaves of this grass, when growing on poor light soils, almost entirely disappear when it is cultivated on a riplex soil.

5732. Pòa carùlea var. praténsis E. B. - If the produce of this variety be compared with that of

Poa praténsis, it will be found less; nor does it seem to possess any superior excellence. The superior nutritive power does not make up for the deficiency of produce by 80 lbs. of nutritive matter per acre. 5733. Festica hordeifórmis H. Cant. — This is rather an early grass, though later than any of the preceding species: its foliage is very fine, resembling the E. duriviscula, to which it seems nearly allied, differing only in the length of the awns, and the glaucous colour of the whole plant. The considerable produce it affords, and the nutritive powers it appears to possess, joined to its early growth, are qualities which strongly recommend it to further trial.

5734. Festica glatica Curtis. — The proportional value by which the grass at the time of flowering exceeds that at the time the seed is ripe is as 6 to 12. The proportional difference in the value of the flowering and seed crops of this grass is directly the reverse of that of the preceding species, and affords another strong proof of the value of the straws in grass which is intended for hay. The straws at the time of flowering are of a very succulent nature; but, from that period till the seed be perfected, they gradually become dry and wiry. Nor do the root-leaves sensibly increase in numer or in size, but a total suspension of increase appears in every part of the plant, the roots and seed-vessels excepted. The straws of the Poa trivialis are, on the contrary, at the time of flowering, weak and tend; but as they advance towards the period of ripening the seed, they become firm and succulent; after that period, however, they rapidly dry up, and appear little better than a mere dead substance.

5735. Festica glabra Wither. B. — The proportional value which the grass at the time the seed is ripe, is as 2 to 8. The proportional value which the grass of the leatermath bears to that of the crop at the time of flowering, is as 2 to 8; and to that of the crop, at the time of flowering, is as 2 to 8; and to that of the crop at the time of flowering their

attended to.

attended to.

5736. Festbca rhbra Wither, B. — The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe is as 6 to 8. This species is smaller in every respect than the preceding. The leaves are seldom more than from three to four inches in length; it affects a soil similar to that favourable to the growth of the Festbca ovina, for which it would be a profitable substitute, as it will clearly appear on a comparison of their produce with each other. The proportional value which the grass of the lattermath bears to that at the time the seed is ripe is as 6 to 8, and is of equal value with the grass

of the lattermath bears to that at the time the seed is ripe is as 6 to 8, and is of equal value with the grass at the time of flowering.

5737. Festbac available. B. — The dry weight of this species was not ascertained, because the smallness of the produce renders it entirely unfit for hay.

5738. Festbac admirea Hud. — This species is nearly allied to the Festbac ovina, from which it differs little, except that it is larger in every respect. The produce, and the nutritive matter which it affords, will be found superior to those given by the F. ovina, if they are brought into comparison.

5739. Bròmus diándrus Curt. Lond. (B. madritlenis E. of P. 1140.) — This species, like the Festbac cambrica, is strictly annual; the above is therefore the produce for one year; which, if compared with that of the least productive of the perennial grasses, will be found inferior, and it must consequently be regarded as unworthy of culture.

5740. Poa angustifolia With. 2. — In the early growth of the leaves of this species of Poa, there is a striking proof that early flowering in grasses is not always connected with the most abundant early produce of leaves. In this respect, all the species which have already come under examination are greatly inferior to that now spoken of. The culms are most valuable for the manufacture of the finest straw plait.

5741. Avèna elàtior Curt. (Hólcus avenàceus E. of P. 14227.) — This grass sends forth flower-straws during the whole season; and the lattermath contains nearly an equal number with the flowering crop. It is subject to the rust, but the disease does not make its appearance till after the priod of flowering; it affects the whole plant, and at the time the seed is ripe the leaves and straws are withered and dry. This

It is subject to the rust, but the disease does not make its appearance till after the period of flowering; it affects the whole plant, and at the time the seed is ripe the leaves and straws are withered and dry. This accounts for the superior value of the lattermath over the seed crop, and points out the propriety of taking the crop when the grass is in flower.

5742. Poa clatior Curt.—The botanical characters of this grass are almost the same as those of the Avena elatior, differing in the want of the awns only. It has the essential character of the Holci (florets, male and hermaphrodite; calyx husks two-valved, with two florets); and since the Avena elatior is now referred to that genus, this may with certainty be considered a variety of it.

5743. Festbea duritiescula E. B.—The proportional value which the grass at the time the seed is ripe bears to that at the time of flowering, is as 6 to 14 nearly. The proportional value which the grass of the lattermath bears to that at the time of flowering, is as 5 to 14; and to that at the time the seed is ripe as 5 to 6. The above particulars will confirm the favourable opinion which was given of this grass when speaking of the P. Avorieiformis, and F. glabra. (5733, and 5735.) Its produce in the spring is not very great, but of the finest quality, and at the time of flowering is considerable. If it be compared with those affecting similar soils, such as POa prateriosis, Festica ovina, &c. either considered as a grass for hay or permanent pasture, it will be found of greater value.

5744. Millium effisiam.— This species in its natural state seems confined to woods as its place of growth; but the trial that is here mentioned confirms the opinion that it will grow and thrive in open exposed situations. It is remarkable for the lightness of the produce in proportion to its bulk. It produces foliage early in the spring in considerable abundance; but its nutritive powers appear comparatively little.

5745. Poa maritima E. B.—The proportional value which the grass of the

a fine early foliage in the spring. The produce is very great, and its nutritive powers are considerable. It appears, from the above particulars, to be best adapted for hay. A very singular disease attacks, and sometimes nearly destroys, the seed of this grass: the cause of this disease seems to be unknown; it is denominated clauss by some; it appears by the seed swelling to three times its usual size, in length and thickness, and the want of the corcle. Dr. Willdenow describes two distinct species of it; first, the simple clavus, which is neither a successful to the seed of the corcle. The will denow describes two distinct species of it; first, the simple clavus, which is violet blue, or blackish, and internally too has a bluish colour, with a fetid smell, and a sharp pungent taste. Bread made from grain affected with this last species, is of a bluish colour; and when caten, produces cramps and giddiness.

5752. Bromus littloreus Host. G. A.—The proportional value which the grass, at the time of flowering, bears to that at the time the seed is ripe, is as 6 to 14. This species greatly resembles the preceding, in habit and manner of growth; but is inferior to it in value, which is evident from the deficiency of its produce, and of the nutritive matter afforded by it.—The whole plant is likewise coarser, and of greater bulk in proportion to its weight. The seed is affected with the same disease which destroys that of the former species.

former species.

5753. Festiva fluitans Curt. Lond. (Glycèria fluitans E. of P. 1090.)—The above produce was taken from grass that had occupied the ground for four years; during which time it had increased every year. It appears, therefore, contrary to what some have supposed, to be capable of being cultivated in perennial

pastures.

5754. Poa fértilis Host, G. A.—If the nutritive powers and produce of this species be compared with any other of the same family, or such as resemble it in habit and the soil which it affects, a superiority will be found, which ranks this as one of the most valuable grasses. Next to the part angustifolia, it produces the greatest abundance of early foliage, of the best quality, which fully compensates for the compa-

rative lateness of flowering.

5755. Arindo colorida Hort. Kew. — The strong nutritive powers which this grass possesses recommend it to the notice of occupiers of strong clayey lands which cannot be drained. .1ts produce is great, and the foliage will not be denominated coarse, if compared with grasses which afford a produce equal in

5756. Hordeum pratense E. B — The specific characters of this species are much the same as those of the Poa fértilis, differing in the compressed figure of the straws and creeping root only. If the produce were of magnitude, it would be one of the most valuable grasses; for it produces foliage early in the spring,

and possesses strong nutritive powers.

5751. Avena flavescens Curt. Lond. (Trisètum flavescens E. of P. 1060) — The proportional value which the grass, at the time the seed is ripe, bears to that at the time of flowering, is as 9 to 15. The proportional value which the grass of the lattermath bears to that at the time of flowering, is as 5 to 15; and to

tional value which the grass of the lattermath bears to that at the time of flowering, is as 5 to 15; and to that at the time the seed is ripe, as 5 to 9.

5758, Bromus stérvits E. B.—64 dr. of the flowers afford of nutritive matter 2.2 dr. The nutritive powers of the straws and leaves are, therefore, more than twice as great as those of the flowers. This species, being strictly annual, is of comparatively little value. The above particulars show that it has very considerable nutritive powers, more than its name would imply, if taken at the time of flowering; but if left till the seed be ripe, it is, like all other annuals, comparatively of no value.

5759, Holcus mollis.—64 dr. of the roots afford of nutritive matter 5.2 dr. The proportional value which the grass, at the time the seed is ripe, bears to that at the time of flowering, is as 14 to 18. The above details prove this grass to have merits, which, if compared with those of other species, rank it with some of the best grasses. The small loss of weight which it sustains in drying might be expected from the nature of the substance of the grass; and the loss of weight at each period is equal. The grass affords the greatest quantity of nutritive matter when in flower, which makes it rank as one of those best adapted for hay.

5760, Pha fertilis var. B. Host, G. A.—The proportional value which the grass, at the time of flowering, bears to that at the time the seed is ripe, is as 6 to 20.

as 6 to 20.

5761. Philium nodbsum Wither. —This grass is inferior in many respects to the Philium pratense. It is sparingly found in meadows. From the number of bulbs which grow out of the straws, a greater portion of nutritive matter might have been expected. This seems to prove that these bulbs do not form so valuable a part of the plant as the joints, which are so conspicuous in the Philium pratense, the nutritive powers of which exceed those of the P. nodbsum as 8 to 28.

5762. Agrástis vulgaris Wither. —This is one of the most common of the bents, and likewise the earliest; in these respects it is superior to all others of the same family, but inferior to several of them in produce, and the quantity of nutritive matter it affords. As the species of this family are generally rejected by the cultivator, on account of the lateness of their flowering; and this circumstance, as has already been observed, does not always imply a proportional lateness of foliage, their comparative merits in this respect may be better seen, by bringing them into one view, as to the value of their carly foliage. This restricts

all Te	The apparent Difference Their nutritive of Time. Powers.	The apparent Difference of Time.	Their nutritive Powers.
Agróstis vulgàris paiústris stolonífera canina strícta	- Middle of April - 1-23.	Agróstis nívea - Three weeks later littoralis rèpens - Ditto ditto rexischaa - Ditto ditto fascicularis - Ditto ditto -	- · 2 - 3 - 3 - 2

5763. Pánicum sanguinàle E. B.—This species is strictly annual; and from the results of this trial, its nutritive powers appear to be very inconsiderable.

5764. The grasses which afford the best culms for straw plait are, according to Sinclair, as follow:—

For heath or moor coil. Petituca orna, duriuscula, and hordelforms, Narius stricts.

Dry soil. Cynosirus cristatus, Poa angustifolia, Hórdeum pratense, Anthoxanthum odoralum, Agróstis lohata, splear venti, flaréscens, and vulgàris mútica, Avena pubéscens, Feeder sorn on poor soils, and usgreen and bleached; but are found inferior to the above grasses for the finest plait.

5765. The period for cutting the culms is when they are in blossom. They are bleached by pouring boiling water over them, in which they remain ten minutes, and are afterwards spread on a grass-plot for seven or eight days. Sinclair found that by letting the culms remain in hot water from one to two hours, only two or three days' bleaching was required. When bleached, they are taken up, washed clean, and put in a moist state in a close vessel, where they are subjected to the finnes of burning sulphur for two hours. Green culms, immersed for ten minutes in a strong solution of acetic acid, and then subjected to the sulphureous acid gas, are bleached perfectly white in half an hour. Green culms, immersed for fifteen minutes in muriatic acid, diluted with twenty times its measure of water, and then spread on the grass, became in four days as perfectly bleached as those culms which were scalded and bleached eight days on the grass. The texture of the straw was not in the least injured by these processes. The application of the sulphureous acid gas to the moistened culms, even after scalding and bleaching on the grass, had, in every instance, the effect of greatly improving the colour, and that without being productive of the smallest injury to the texture of the straw. (Hort. Gram. Wob. 2d edit. 427.)

5766. To imitate the Leghorn plait in the most perfect manner, the straws should be plaited the reverse way of the common English split-straw plait. In the English plait, the straws are flattened by a small hand-mill made for the purpose; but the Leghorn plait has the straws worked without flattening, and pressure is applied after the plait is made. It is essential that these two points should be observed by those who wish to rival the finest Leghorn manufacture. By reversing the common mode of platting, the fingers have a much greater power in firmly and intimately knitting the straws; and the round or unflattened state of the straws allows of their being more closely knitted,—a circumstance that gives an appearance similar to the real Leghorn plait. (Ibid.) The varieties of wheat or rye already mentioned (5002, and 5057.) are now generally considered far preferable to any of the forage grasses for the purposes of straw plait. of straw plait.

CHAP. VII.

Management of Lands permanently under Grass.

5767. In every country by far the greater proportion of perennial grass lands is the work of nature: and it is not till an advanced period in the progress of agriculture that much attention is paid to their management. But as the extension of tillage, planting, and the formation of parks and gardens, limit the range of the domestic animals, their focd becomes more valuable; and it then becomes an object to increase it by the culture of roots and artificial herbage on some lands, and by the improved management of the spontaneous productious of others. In a highly cultivated country like Britain, therefore, those lands retained in grass either are, or ought to be, such as are more valuable to the owners in that state than they would be in any other. Such lands naturally divide themselves into two classes: those which are fit either for mowing or pasture; and those which are fit for pasture only.

Sect. I. Perennial Grass Lands fit for mowing, or Meadow Lands.

5768. Under the term meadow, we include all such land as is kept under grass chiefly for the sake of a hay crop, though occasionally, and at particular seasons of the year, it may be depastured by the domestic animals; and we usually include under this term the notion of a greater degree of moisture in the soil, than would be thought desirable either for permanent pasture or lands in tillage. Where hay is in great demand, as near large towns, and especially if a good system of cropping is but little understood, a great deal of arable land may be seen appropriated to hay-crops; but the most valuable meadows are such as are either naturally rather moist, or are rendered so by means of irrigation. There are three descriptions of these meadows: those on the banks of streams and rivers; those on the uplands, or more elevated grounds; and bog-meadows; and each of these kinds may be stocked with grasses, either naturally or by art, and may be irrigated by one or other of the different watering processes already described.

5769. River-meadows, or those which are situated in the bottoms of valleys, are in general by far the most valuable. They are the most productive of grass and hay, yielding sustenance for cattle through the summer and the winter, and producing an everlasting source of manure for the improvement of the adjoining lands.

Source of manure for the improvement of the adjoining lands.

5770. The soil is deep, and commonly alluvial, having been deposited by water, or washed down from the adjoining eminenes; the surface is even, from the same cause; and, what is of considerable importance, it has a gradual declivity or surface-drainage to the river or stream which almost invariably flows in the lowest part of every valley, and which is essential to this description of meadow. The principal defects to which such lands are liable are, the oozing out of springs towards their junction with the rising lands, and the inundations of the river or stream. The former evil is to be remedied by under-draining, and the latter by embanking. Such meadows are generally stocked with the best grasses; and their culture consists of little more than forming and keeping open a sufficient number of surface gutters or furrows to carry off the rain-water; rooting out such tuits of rushes, or bad grasses and herbage, as may occasionally appear; destroying moles, and spreading the earth they throw up; removing heavy stock whenever their reet poach the surface; shutting up, bush-harrowing, and rolling at the commencement of the growing season; and finally so adjusting the mowing and pasturing as to keep the land in good heart without laying on manure.

5771. The most suitable meadows for irrigation are of this description; the necessary drains and other works are executed with greater care, and with less expense; and the management, as we have seen (4390.), is also comparatively easier than in watering sloping surfaces.

Upland meadows, or mowing lands, are next in value to those of valleys.

5772. Upland meadous, or mowing lands, are next in value to those of valleys.

5773. The soil is either naturally good, and well adapted for grass, or, if inferior by nature, it is so situated as to admit of enrichment by ample supplies of manure. Of this last description are the upland meadows or hay lands of Middlesex; which, though on the most tenacious, and often stony clays, are yet, by the abundance of manure obtained from the metropolis, rendered as productive as the best upland soils employed as hay lands. The roots of perennial grasses, whether fibrous or creeping, never strike deep into the soil; and thus, deriving their nourishment chiefly from the surface, top-dersings, of well-rotted manure, repeated on the same field for centuries, form at last a thin black stratum among the roots of the grass, which produces the most luxuriant crops.

5774. The culture of upland meadows requires more attention and expense than that of valleys; being more difficult to drain, and requiring regular supplies of manure. The irregular surface of uplands is apt either to contain springs or to stagnate the surface water; the first produce marsh plants and coarse herbage, and the latter destroys or weakens whatever is growing on the surface, and encourages the growth of moss. Both evils are to be remedied by the obvious resources of drainage, Moss is a very common enemy to grass lands, and is only to be effectually destroyed by rich dressings of manure. Rolling, and top-dressings of lime and salt, have been recommended for destroying it; but there is no mode by

which it can be subdued and kept under, but by adding strength to the grass plants, and thereby enabling them to suffocate their enemy. Moss is never found on rich lands unless they are completely shaded by trees. Besides mole-hills, upland meadows, when neglected, are frequently troubled with ants, which form heaps or hillocks of grass and earth, more injurious and more difficult to get quit of than those of moles. The mode of taking moles is a simple operation, and will be described in the proper place; that of destroying ants is more complicated and tedious, and, being peculiar to grass lands, shall here be described.

be described.

5775. Ant-hills, or habitations, are injurious to meadow lands, by depriving the farmer of a crop in proportion to the surface they occupy, and by interfering with the operations of rolling and mowing. They consist of little eminences, composed of small particles of sand or earth, lightly and artfully laid together, which may often be computed at a tenth part, or more, of old grass-lands. In some places, where negligence has suffered them to multiply, almost half the land has been rendered useless; the hills standing as thick together as grass-cocks in a hay-field: and what is very surprising, this indolence is defended by some, who affirm, that the area or superficies of their land is thereby increased; whereas it is well known that very little or no grass ever grows thereon, and, therefore, if the surface is increased, the produce is

proportionably decreased. proportionably decreased.

5776. In order to remove ant-hills, and destroy the insects, it has been a custom in some places, at the beginning of winter, and often when the weather was not very cold, to dig up the ant-hills three or four inches below the surface of the ground, and then to cut them in pieces, and scatter the fragments about; but this practice only disseminates the ants, instead of destroying them, as they hide themselves among the roots of the grass for a little time, and then collect themselves together again upon any little eminence, but this practice only disseminates the ants, instead of destroying them, as they hide themselves among the roots of the grass for a little time, and then collect themselves together again upon any little eminence, of which there are great numbers ready for their purpose, such as the circular ridges round the hollows where the hills stood before. It is, therefore, a much better method to cut the hills entirely off, rather lower than the surface of the land, and to let them lie whole at a little distance, with their bottom upwards; by this means the ants, which are known to be very tenacious of their abodes, continue in their habitations until the rains, by running into their holes of communication, and sagnating in the hollows formed by the removal of the hills, and the frosts, which now readily penetrate, destroy them. If a little soot were thrown on the places, and washed in with the rains, it would probably contribute greatly to the intended effect. The hills, when rendered mellow by the frosts, may be broken and dispersed about the land. By this method of cutting the hills, one other advantage is gained; the land soon becomes even and fit for mowing, and the little eminences being removed, the insects are exposed to the wet, which is very disagreeable and destructive to them. It would, perhaps, be a better practice than that of suffering the hills to remain on the ground, to collect the parts of them which have been pared off into a heap, in some convenient place, and then form them into a compost, by mixing a portion dquick-lime with them. In wet weather these insects are apt to accumulate heaps of sandy particles among the grass, called by labourers sprout-hills, which quickly take off the cede of the scythe. These hills, which are very light and compressible, may be conveniently removed by frequent heavy rolling.

5777. In the Norfolk mode of cutting and burning ant-hills, the process is, to cut them up with the anapade sharp spade or shovel, in irregular lumps of from ten to fifteen inches in diameter,

5779. Where grass lands are sufficiently rolled with a heavy roller once or oftener every year, no ant-hills will ever be formed greater than the roller can compress, and consequently no injury will be sustained. In this, as in most other cases of disease, proper regimen is the best cure. In domestic economy, various directions are given for destroying bugs, lice, and other vermin; but who ever had any to destroy, who

directions are given for destroying bugs, lice, and other vermin; but who ever had any to destroy, who attended properly to cleanliness?

5780. The surface of some grass lands that have been long rolled is apt to get into that tenacious state denominated hide bound. When this is the case, scarifying the turf with a plough, consisting only of coulters, or harrow-teeth, or, in preference to all other implements, with Wilde or Kirkwood's brakes, so that the whole surface may be cut or torn, is to be recommended. That tenacious state, rolling tends to increase; whereas, by scarifying, the surface is loosened, and the roots acquire new means of improved vegetation. This operation seems particularly useful, when it precedes the manuring. When hay land of a retentive quality is depastured by cattle or horses in wet seasons, it receives much injury from their feet, and becomes what is technically called poached. Every step they take leaves an impression, which fills with rain water, and then the hole stands full like a cup. This wetness destroys the herbage, not only in the hole, but that also which surrounds it, while at the same time the roots of the grasses, as well as the ground, are chilled and injured. No good farmer, therefore, will permit any cattle to set a foot on such land in wet weather, and few during the winter months, on any consideration. Sheep are generally allowed to pasture on young grasses in dry weather, from the end of autumn to the beginning of March; they are then removed, and it rarely happens that any animal is admitted till the weather be dry, and the surface so firm as to bear their pressure without being poached or injured.

5781. In manuring upland meadows, the season, the sort, the quantity, and the frequency of application are to be considered.

are to be considered

are to be considered.

5782. With regard to the season at which manure should be applied, a great difference of opinion prevails among the farmers of England. In the county of Middlesex, where almost all the grass lands are preserved for hay, the manure is invariably laid on in October (Middlesex Report, p. 224.), while the land is sufficiently dry to bear the driving of loaded earts without injury, and when the heat of the day is so moderated as not to exhale the volatile parts of the dung. Others prefer applying it immediately after the hay-time, from about the middle of July to the end of August, which is said to the the "good old time" (Com. to Bourd of Agriculture, vol. iv. p. 138.); and if that season is inconvenient, any time from the beginning of February to the beginning of April. (Dickson's Practical Agriculture, vol. iv. p. 915.) It is, however, too common a practice to carry out the manure during frosty weather, when, though the ground is not cut up by the earts, the fertilising parts of the dung are dissipated, and washed away by the snow and rains before they can penetrate the soil.

is not cut up by the carts, the termising parts of the dung are dissipated, and washed away by the snow and rains before they can penetrate the soil.

5783. There is scarcely any sort of manure that will not be useful when laid on the surface of grass grounds; but, in general, those of the more rich dung kinds are the most suitable for the older sort of sward lands; and dung, in composition with fresh vegetable earthy substances, the most useful in the new leys or grass lands. In Middlesex it is the practice of the best farmers to prefer the richest dung they can procure, and seldom to mix it with any sort of earthy material, as they find it to anwer the best with regard to the quantity of produce, which is the principal object in view; the cultivators depending chiefly for the

sale of their hay in the London markets. It is the practice to turn over the dung that is brought from London in a tolerable state of rottenness, once chopping it well down in the operation, so as to be in a middling state of fineness when put upon the land. It is necessary, however, that it should be in a more rotten and reduced state when applied in the spring, than when the autumn is chosen for that purpose. (Dickson's Practical Agriculture, vol. ii. p. 915.) 5784. Some interesting experiments have been made with different kinds of manure, for the purpose of ascertaining their effects, with regard to the quantity and quality of the produce on different kinds of land. Fourteen lots, of half an acre each, were thus manured, and the grass was made in bay, all as nearly alike as possible. The greatest weight of hay was taken from the lot manured with horse, cow, and slaughterhouse dung, all mixed together, of each about an equal quantity. It lay in that state about two months; and was then turned over, and allowed to lie eight or ten days more, after which it was put on the land before it had done fermenting, and spread immediately. To ascertain the quality of the produce of the different lots, a small handful from each was laid down on a dry clean place, where there was little or no grass, and six horses were turned out to them one after another. In selecting the lots, there seems to have been little difference of tasts among the horses; and all of them agreed in rejecting two lots, one of which had been manured with blubber mixed with soil, and the other with soot, in both instances laid on in the month of April preceding. (Lancashire Report, p. 150. et seq.)

manured with blubber mixed with soil, and the other with soot, in both instances laid on in the month of April preceding. (Lancashire Report, p. 130. et seq.)

5785. The proportion of manure that is necessary must, in a great measure, depend upon the circumstances of the land, and the facility of procuring it. In the district of London, where the manure is of a very good and enriching quality, from its being produced in stables and other places where animals are highly fed, the quantity is usually from four or five to six or seven loads on the acre, such as are drawn by three or four horses, in their return from taking up the hay to town. (Dickson's Pract. Agr. vol. ii. p. 916.

5786. Manure is laid on at intervals of time wave as when the product of the same and the place of the same and the place.

5786, Manure is laid on at intervals of time more or less distant, according to the same circumstances that determine the quantity of it. Though there are some instances of hay grounds bearing fair crops that determine the quantity of it. Inough there are some instances of nay grounds bearing tair crops every year during a length of years, without any manure or any advantage from pasturage, except what the after-grass has afforded (Marshal's Review of Reports to the Board of Agriculture, p. 183. Western Department; yet, in general, manure must either be allowed every third or fourth year, in the land depastured one year, and mown the other; "or, what is better, depasture two years, and mow the third." (Northumberland Report, p. 111.) A succession of hay crops without manure, or pasturage, on mead own not irrigated, is justly condemned by all judicious farmers, as a sure means of impoverishing

5787. Bog meadows are the least valuable of any; they are of two kinds; peat bogs. and earthy bogs.

and earthy bogs.

5788. Peat bogs are situated in hollows or basins, which, from having no natural outlet for water, and not being so deep or so plentifully supplied with that element as to constitute lakes, becomes filled up with aquatic plants and mosses. By the decay of these after a certain time, and the drainage and culture of art, a surface of mossy soil is formed on which some of the inferior grasses may be sown or will spring up naturally. In warm moist climates, and where the mould of the bog is rich, fiorin or Timothy grass may be found to answer; but in general the woolly soft grass and cock's foot are resorted to, unless indeed lime be applied, or a coating of sand or earth, in which cases the clovers and better grasses will sometimes answer. These bogs are in general too soft for pasturing any other animals than sheep.

5789. Earthy bog meadows are situated either in hollows or on slopes. They are formed by an accumulation of water in the subsoil, which not finding a free passage in any one point, spreads under and filtrates upwards through a considerable extent of surface. The grasses on such meadows before they are drained are chiefly of the sprot or Júncus kind; but by draining the quality of these is improved, and better kinds appear. Such meadows yield a considerable produce of coarse hay; they abound chiefly in cold hilly districts devoted to breeding.

5790. The culture and management of bog meadows differ in nothing essential from those of the river kinds. A lighter roller is used in spring, the greatest care is taken in eating down the latter grass, whether with small cattle or sheep; and in some cases, in very dry weather in summer, the main drains are dammed up for a few weeks in order to stagnate the water, and supply the soil with moisture. No manure is ever given unless in the case of some cultivated peat bogs, which are dressed with earthy or saline mixtures.

saline mixtures

5791. As branches of culture common to every description of hay lands may be mentioned, the hay-making, the application of the after-grass, and pasturage.

5792. The making of natural or meadow hay has been carried to greater perfection in the neighbourhood of London than any where else; and it may therefore, with great propriety, be recommended as an example to the rest of the kingdom. The following account of it is drawn from Middleton's Agricultural Survey of Middlesex :

5793. When the grass is nearly fit for mowing, the Middlesex farmer endeavours to select the best mowers, in number proportioned to the quantity of his grass and the length of time it would be advisable to have it in hand; which having done, he lets it out, either as piece-work, or to he mown by the acre. In the latter way, each man mows from one acre and a half to an acre and three quarters per day; some there are who do two acres per day during the whole season. About the same time he provides five hay-makers (men and women, including loaders, pitchers, stackers, and all others) to each mower. These last are paid by the day, the men attending from six till six, but the women only from eight till six. For an extra hour or two in the evening, when the business requires despatch, they receive a proportionate

allowance.

5794. The mowers usually begin their work at three, four, or five o'clock in the morning, and continue to labour till seven or eight at night; resting an hour or two in the middle of the day. Every hay-maker is expected to come provided with a fork and a rake of his own; nevertheless, when the grass is ready, and labourers scarce, the farmer is frequently obliged to provide both, but for the most part only the rake. Every part of the operation is carried on with forks, except clearing the ground, which is done with rakes; and loading the carts, which is done by hand.

rakes; and loading the carts, which is done by hand 5795. First day. All the grass mown before nine o'clock in the morning is teided, in which great care is taken thoroughly flower than the state of the control of th

into what are called single wind rows; and the last operation of this day is to put it into grass-cocks. 5796. Second day. The thusiness of this day commences with tedding all the grass that was mown the first day after nine o'clock, and all that was mown this day before nine o'clock. Next, the grass-cocks are to be well shaken out into staddles (or separate plots) of five or six yards' diameter. If the crop should be so thin and light as to leave the spaces between these staddles rather large, such spaces must be immediately raked clean, and the rakings mixed with the other hay, in order to its the staddles, and after that, to turn the grass that was teided in the first part of the morning, once or twice, in the manner described for the first day. This should all be done before twelve or one o'clock, so that the whole may lie to dry while the work-people are at dinner. After dimner, the first thing to be done is to rake the staddles into double wind-rows; next, to

rake the grass into single wind-rows; then the double wind-rows are put into bastard-cocks; and lastly, the wind-rows are put into grass-cocks. This completes the work of the second

rows are put into passacrocks. This completes the work of the second day, and also that movement and not spread on the second day, and also that movement he early pure of this day, is first to be tedded in the morning, and then but no cocks into staddless of less extent. These smaller staddles, though last spread, are first turned, then those which were in grass-cocks; and next the grass is turned once or twice before twelve or one oclock, when the projet go to dimer as usual. If the weather has proved sunny and fine, the hay which was last night in field; but if the venture should be a proper state to be carfield; but if the venture should be a proper state to be carfied; but if the venture should, on the contrary, have been

cool and cloudy, no part of it prohably will be fit to carry. In that case, the first thing set about after dinner, is to rake that which was in grass-cooks last night into double wind-rows; then the grass which was this morning spread from the swaths into single wind-rows. After this, the hay which was last night in bastard-cocks, is made up into full-sized cocks, and care taken to rake the hay up clean, and also to put the rakings upon the top of each cock. Next, the double wind-rows and put into bastard-cocks, and the single wind-rows into grass cocy. The control of the standard cocks and the single wind-rows into grass cocy. The control of the standard cocks and the single wind-rows into grass cocy. The control of the standard cocks and the single wind-rows into grass cocy. The standard cocks in the standard cocks, just mentioned, are usually carried before dinner. The other operations of the day are such, and in the same order, as before described, and are continued daily until the hay harvest is completed.

ried; but if the weather should, on the contrary, have been completed.

5799. As general indes, the grass should, as much as possible, be protected both day and night, against rain and dew, by cocking. Care should also be taken to proportion the number of hay-makers to that of the theoretical that there may not be more grass in hand at any one time than can be managed according to the foregoing process. This proportion is about twenty hay-makers (of which number twelve may be women) to four mowers; the latter are sometimes taken half a day to assist the former. But in hot, windy, or very drying weather, a greater proportion of hay-makers will be required than when the weather is cloudy and cool. It is particularly necessary to guard against spreading more hay than the number of hands can get into cocks the same day, or before rain. In showery and uncertain weather, the grass may sometimes be suffered to lie three, four, or even five days in swath. But before it has lain long enough for the under side of the swath to become yellow (which, if suffered to lie long, would be the case), particular care should be taken to turn the swaths with the heads of the rakes. In this state, it will cure so much in about two days, as only to require being tedded a few hours when the weather is fine, previously to its being put together and carried. In this manner hay may be made and put into the stack at a small expense, and of a moderately good colour; but the tops and bottoms of the grass are insufficiently separated by it. by it.

by it.

5800. The hay-te-ding machine has been invented since Middleton described the hand process as above,
This machine (fig. 372.) is found to be a most important saving of manual labour. It is computed that a
boy and horse with the machine will ted as much in an hour as twelve or fifteen women. The hay-rake,
which may be added to the same axle when the tedder is removed, is also an equal saving, and a requisite
accompaniment to it; as where few or no women are kept for tedding, there must encessarily be a deficiency of rakers. These machines are coming into general use near London, where the price of manual
labour is high and hands sometimes scarce. They are also finding their way among the proprietors
of extensive parks in all parts of the country, as saving much labour in making hay from natural
nasture.

intour is high and hands sometimes scarce. They are also finding their way among the proprietors of extensive parks in all parts of the country, as saving much labour in making hay from natural pasture.

5801. There are no hay-stacks more neatly formed, nor better secured, than those made in Middlesex. At every vacant time, while the stack is carrying up, the men are employed in pulling it, with their hands, into a proper shape; and, about a week after it is finished, the whole roof is properly thatched, and then surved room receiving any damage from the wind, by means of a straw rope, extended along the eaves, are surved room receiving any damage from the wind, by means of a straw rope, extended along the eaves, are selected to receive the stack, just of sufficient length for the rain when the stack appears to be placed in a situation which may be suspected of being too damp in the where, a trench, of about six or eight inches deep, is dug round and nearly close to it, which serves to convey all the water from the spot, and renders it perfectly dry and secure.

5802. During the hay harvest it is of great advantage to the farmer, to give constant personal attendance on every party, directing each operation as it goes on. The man who would cure his hay in the best manner, and at a moderate expense, must not only urge the persons who make the hay, the men who load the waggons, and those who make the stack, but the should be on the alert, to contrive and point out the manner in which every person may do his labour to the most advantage. Unless he does this, one moiety of the people in his hay-field will be of no material use to him; and if he should be absent for an hour or more, during that time little or nothing will be done. The farmers of Middlesex engage many hay-makers some of them have been known to employ two or three hundred; such men did it necessary to be on horseback, and the work-people find them sufficient employment. A man of energy will make the most of every hour, and secure his hay while the sun

be proportionally better dried. The stolones of this grass being remarkably vivacious, cannot easily be so dried as to admit of stacking in large bodies.

5808. The salting of hay, at the time of stacking, has been practised in Derbyshire and in the North Ridding of Yorkshire. The salt, particularly when applied to the crop of rouen, or when the first crop has received much rain, checks the fermentation, and prevents moulding. It straw is mixed with the hay, the heating of the stack is still further prevented, by the straw imbiling the moisture. Cattle will eat, not only such salted hay but even the straw mixed with it, more eagerly than better hay not salted, and

will also thrive as well upon it. The quantity recommended is, a peck of salt to a ton of hay. By this application, hay that had been flooded was preferred by cattle to the best hay that had not been salted. 5809. To make hay-tea. Boil at the rate of a handful of hay to three gallons of water, or, if the water be poured boiling hot on the hay, it will answer nearly as well. Give it to the cattle and horses are anywiseill, and under cover, give it to them blood-warm. This drink is so extremely nutritive, that it nourishes the cattle astonishingly, replenishes the udders of the cow with a prodicious quantity of milk, makes the horse stale plentifully, and keeps him healthy and strong; and by this method one truss or hundred of hay will go as far as eight or ten would otherwise do. The cattle and horses do not seem to like it at first; but if they are kept till very thirsty, they will drink freely of it ever alterwards. The hay, after being used as before mentioned and dried, may be used as litter for horses and cattle; it will make very good manure, and save straw, which is a considerable advantage, especially where there is a scarcity of that article. (Davis's Rep. of Wilts.)

5810. The after-grass on all meadows is generally fed off; on firm lands, and in the dry season, by either sheep or heavy cattle; but in the winter only by sheep, unless the soil is so dry as not to be injured by the feet of cows or horses. The feet of the latter are much less injurious than those of the former; but their bite being closer is more apt to tear up the plants, than the bite of the horned tribe.

5811. Cattle are generally removed from meadow.lands in Middlesex in November; horses in the month following, and sheep allowed to remain till February. In Lincolnshire, Leicestershire, and on many river.meadows, every description of stock is allowed to remain till April, and sheep till May. In some districts, the whole of the after-growth is preserved from every species of stock till the following May, when it is fed off with sheep: but this greatly retards the hay crop for that year. It is evident that a good deal must depend on the farmer's other resources for keep for his stock.

5812. The after-grass, where manure is very abundant, is sometimes mown and made into hay or rouen, a soft and not very nutritive food, given to cows or sheep; but this is reckoned a bad practice, even in the neighbourhood of London, where manure may be had in abundance. It is also the usage of some to leave the after-grass on the ground without being eaten till spring, when it is asid to be preferable, for ewes and lambs, to turnips, cabbages, or any other species whatever of what is termed spring-feed. This mode of management, which is strongly recommended by Young, and in some cases by Marshal also, is unknown in the north; where, though it is, in many instances, found beneficial, with a view to an early spring growth, not to eat the pasture too close before winter, it would be attended with a much greater loss of herbage, than any advantage in spring could compensate, to leave the after-growth of mown grounds untouched till that season.

5813. A system of alternate moving and feeding is practised on some hay lands, partly to save labour and manure, and partly to subdue mosses and coarse grasses. On some soils even rich grass lands, when annually mown, become subject to weeds; for it tends to encourage moss, and gives advantage to the stronger-rooted grasses, which gradually change, and deteriorate the nature and quality of the herbage. The bottom becomes thin, the white clover disappears, and coarser plants occupy the ground. When this takes place, the pasture should be fed, instead of being mown, for the space of two or three years, until the weeds have been subdued, and the finer grasses re-appear.

5814. By adopting the plan of mowing and freeding alternately, a farmer, it is said, may go on longer without the application of manure, but his fields, in the end, will be ruined by it. It is contended, that to maintain a proper quantity of stock, the land must be accustomed to keep it, particularly in the case of sheep: that where land has been used to the sycthe, if manured for pastures, it will often produce more grass; but that grass will not (cateris paribus) support so much stock, nor fatten them nearly so well: and that old pasture will not produce so much hay as land that has been constantly mowed; for each will grow best as it has been accustomed to grow, and will not readily alter its former habits. On the other hand, it is asserted, that many experienced farmers prefer the system of feeding and mowing alternately, as they find that, under that system, the quality and quantity of the hay have been improved; and the pasturage, in the alternate year, has been equally sweet and productive.

Sect. II. Permanent Pastures.

5815. Permanent pastures may be divided into two kinds: rich or feeding lands; and hilly or rearing pastures. Under the former, we may comprehend all old rich pastures capable of fattening cattle; and under the second, such as are only adapted to rearing them, or are more advantageously depastured with sheep.

Subsect. 1. Rich or feeding Pastures.

5816. Feeding pastures may include such as are equally fit for hay-lands, or for being converted to arable husbandry; their characteristic being, that they are used for feeding stock, and keeping working animals and milch cows in good condition. We mentioned in a former chapter, that pasturage for one year, or for two, or more, is frequently interposed in the course of cropping arable land, to prevent that exhaustion of the soil which is commonly the consequence of incessant tillage crops. The same culture and manage-ment recommended here for rich grass lands are equally applicable to them; there being no difference, except that the latter are generally considered less suitable than rich old turf for fatting heavy stock, such as large oxen.

5817. The culture and management of feeding pastures, whether of a few years, or of perpetual duration, may be considered in regard to those necessary operations already noticed under the former section: such as the extirpation of weeds and noxious shrubs, clearing away ant and mole-hills, the application of manure, the time of stocking, the number of the animals and whether all should be of one or of different species, &c., the extent of the enclosures, and the propriety of eating the herbage close or leaving it always in a rather abundant state; all these are questions which it is scarcely possible to decide in a satisfactory manner, by the application of general rules. They can only be solved,

with any pretentions to utility, by a reference to the particular circumstances of each case; for the practice of one district, in regard to these and other points, will be found quite inapplicable to others where the soil and climate, and the purposes to which the pastures are applied, are materially different.

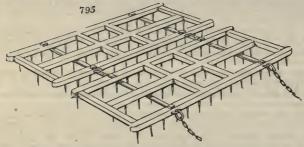

5818. The weeding of pastures should be regularly attended to. Weeds in pastures injure the farmer by the ground they occupy, the seeds they disperse, and sometimes, by

influencing the quality of milk, or the health of the cattle.

influencing the quality of milk, or the health of the cattle.

5819. On the large scale of a farm small creeping weeds cannot be removed: but large perennial plants, such as the dock, item, nettle; and biennials, such as the thistle, and ragweed; together with rushes and coarse tuits or tussocks of tail oat-grass, should never be permitted to shoot up into flower. The dock ought to be taken out by the root with the dock-weeder, and the others cut over with spadlets or spuds. Nettles may be mown over, as may some other weeds, and some descriptions of rushes; fern is most effectually killed by bruising or twisting asunder the stem, when the frond or herb is nearly fully expanded. Smaller weeds may be mown, and this operation should never be deferred later than the appearance of the flowers. Where the sloe-thorn forms part of the enclosure hedges, or the English elm, hoary poplar, and some other trees, grow in or around the field, they are apt to send up suckers; these should be pulled up, otherwise they will soon become a serious nuisance. In some parts of England, especially in the central districts, the hedge wastes, from the spread of the sloe-thorn and creeping rose (Rosa arvehaiss), are sometimes six or ten vards in width.

5830. To prevent the growth of mosses is one of the greatest difficulties in the management of old pasture land; by these the finer species of grasses are apt to be overwhelmed, and the coarse sorts only remain. Drainage, and the use of rich composts, are in this case necessary. Harrowing and cross harrowing with a common harrow, or with what are called grass harrows (\$Ex.795.), which go from one to two inches

deep, with a sprinkling of grass-seeds afterwards, and some lime or well prepared compost, are the most likely means of destroying the moss, and improving the pasture. Feeding sheep with oil-cake, and allowing them to pasture on the land, has also been found effectual for the destruction of moss, and bringing up abundance of grass. But the radical remedy is to plough up such grass lands upon the first appearance of moss, or before it has made any considerable progress, and sow them with corn.

5821. The removal of ant and mole hills should be attended to during the whole summer. The manner of destroying ants has already been described; mole-hills spread on grass lands may be considered as of service rather than otherwise. These operations, together with weeding, and spreading the manure dropped by the larger stock, should go on together at intervals during the whole summer.

5822. The application of manures to grazing lands, which not being used as hay grounds afford no means of supply, may certainly be considered a preposterous practice, and one

that must be ruinous to the other parts of a farm.

that must be ruinous to the other parts of a farm.

5823. In the Code of Agriculture it is nevertheless stated, that "to keep grass in good condition, a dressing of from thirty to forty cubic yards or cart-loads of compost is required every four years. The application of unmixed putrescent manure will thus be rendered unnecessary, which ought at least to be avoided, in meadows appropriated for the feeding of dairy cows, from its affecting the quality of the milk." (p. 476.) Grass lands kept at an expense of this kind will seldom, it is believed, be found to remunerate a farmer sufficiently. The same thing is recommended (probably from inadvertence or mere following the track of preceding writers) in Dickson's Practical Agriculture, vol. ii, p. 935. But, except the dung dropped by the pasturing animals, which should always be regularly spread from time to time, it may be laid down as a rule of pretty extensive application, that if grass lands do not preserve their fertility under pasturage, it would be much better to bring them under tillage for a time, than to enrich them at the expense of land carrying crops of corn. (Sup. &c. art. Aer.)

5894. Trathing or stacking on the field, or carrying to be consumed there during winter, the provender that ought to have furnished disposable manure for the use of the farm at large, is another practice not less objectionable. It is to no purpose that such a wasteful practice is defended on dry light soils, which are alleged to be thus benefited by the treading of the cattle. (Marshal's Rural Economy of Yorkshire, vol. ii. p. 131.) During the frequent and heavy falls of rain and snow in winter, there is scarcely any land so dry as not to be injured by the treading of heavy cattle; and were there any thing gained in this respect by this management, it would be much more than counterbalanced by the loss of a great part of the manure, from the same cause. The able writer to whom we have just now referred very properly disapproves of carting on manure in winter; and for the same

5825. The time of stocking pastures in spring must evidently be earlier or later, according to the climate, and in the same climate according to the season; and the state of growth, which it is desirable that the grass should attain before being stocked, must in some degree be determined by the condition and description of the animals to be employed in consuming it; whether they are only in a growing state or approaching to fatness; whether milch cows or sheep, or a mixture of animals of different species. conveys no very precise idea respecting these points, though the remark itself is just, to say that the herbage should not be allowed to rise so high as to permit the coarser plants to run to seed; and that it is bad management to suffer store stock to be turned upon a full (Marshal's Yorkshire, vol. ii. p. 129.)

bite. (Marshal's Yorkshire, vol. ii. p. 129.)

5826. The great objects to be aimed at are, that the stock, of whatever animals it may consist, should be carried forward faster or slower, according to the purposes of their owner; and that no part of the herbage should be allowed to run to waste, or be unprofitably consumed. But nothing but carreful inspection of the land and of the stock, from time to time, can enable any grazier to judge with certainty what are the best measures for attaining these objects. "Fatting cattle," says Marshal, "which are forward in flesh, and are intended to be finished with grass, may require a full bite at first turning out; but for cows, working oxen, and rearing cattle, and lean cattle intended to be fatted on grass, a full hite at the first turning out is not requisite. Old Lady-day to the middle of April, according to the progress of spring, appears to me, at present, as the best time for shutting up mowing grounds and opening pastures." (Marshal's Yorkshire, vol. ii, pp. 152, 153.)

5827. In regard to the state of the growth of pastures when first stocked, some distinction should be made between new leys and old close swards. To prevent the destruction of the young plants, whether of clover or other herbage, on the former description of pasture, which would be the consequence of stocking them too early, especially with sheep, they should be allowed to rise higher than would be necessary in the case of old turf; and to secure their roots from the further injury of a hot summer, it is advisable not to feed them close in the early part of the season, and probably not at any time throughout the whole of the first or second season, if the land is to be continued in pasture. The roots of old and firm sward, on the other hand, are not in so much danger, either from close feeding or from the heats of summer; and they are in much less danger from the frests and thass of winter.

5828. With regard to the stock which should be emoloued. all soils rather moist and of

5828. With regard to the stock which should be employed, all soils rather moist and of such a quality, as is the case with rich clays, as to produce herbage suited to the fattening of cattle, will, in general, be more advantageously stocked with them than with sheep: but there can be no other rule for the total exclusion of sheep, than the danger of the rot; nor any other general rule for preferring one kind of stock to another, than their comparative profits. (Sup. art. Agr.)

5829. Whether the stock should be all of one or of different kinds is another question to

be discussed.

5830. With regard to a mixed stock, the sentiments and practice of the best graziers seem to be in its favour. It is generally understood that horses and cattle intermixed will eat grass cleaner than any species will alone, not so much from their separately affecting different grasses, as from the circumstance of both species disliking to feed near their own dung." (Marshal's Yorkshire, vol. in p. 154.) "Some few graziers follow the old custom of keeping only one kind of stock upon the same ground, whilst others, we think, with more propriety, intermix with oxen and cows a few sheep, and two or three colts in each pasture, which both turn to good account, and do little injury to the grazing cattle. In some cases sheep are a real benefit, by eating down and destroying the ragwort (Senècio Jacobæ'a), which disgraces some of the best pastures of the county, where oxen only are grazed." (Northumberland Report, p. 196.) In Lincolnshire, where grazing is followed to a great extent, and with uncommon success, as well as in most other districts, the practice seems to be almost invariably, to keep a mixed stock of sheep and cattle on the same pasture (Lincolnshire Report, p. 174.), in proportion varying with the nature of the soil and the quality of the herbage.

5831. To estimate the number of animals that may be depastured on any given extent of ground is obviously impossible, without reference to the particular spot in question; and the same difference exists with regard to the propriety of feeding close, or leaving the pastures rough, that prevails in most other parts of this subject. Though there is loss in stocking too sparingly, the more common and dangerous error is in overstocking, by which the summer's grass is not unfrequently entirely lost. On rich pasture lands in the neighbourhood of Banbury, in Oxfordshire, one ox and two sheep are calculated as stock sufficient for one acre.

5832. With respect to the size of enclosures, small fields are much to be preferred to large ones, for heavy stock.

large ones, for heavy stock.

5833. Besides the advantages of shelter, both to the animals and the herbage, small fields enable the grazier either to separate his stock into small parcels, by which means they feed more at their ease, or to give the best pastures to that portion of them which he wishes to come earliest to market. The advantages of moderate-sized enclosures are well known in the best grazing counts; but the subdivisions are in some instances much more minute than is consistent with the value of the ground occupied with fences, or necessary to the improvement of the stock. In all cases, says Marsha, where fatting cattle or dairy cows make a part of the stock, and where situation, soil, and water will permit, every suit of grazing grounds ought, in my idea, to consist of three compartments: one for head stock, as cows or latting cattle; one for followers, as rearing and other lean stock; and the third to be shut up to freshen for the leading stock. (Marshal's Yorkshire, vol. ii. p. 158.)

5834. Large enclosures are in general best adapted for sheep. These animals are not only impatient of heat and liable to be much injured by flies, in small pastures often surrounded by trees and high hedges, but they are naturally, with the exception perhaps of the Leicester variety, much more restless and easily disturbed than the other species of live stock. "Sheep," says Lord Kaimes, "love a wider range, and ought to have it; because they delight in short grass: give them eighty or ninety acres, and any fence will keep them in; confine them to a field of seven or eight acres, and it must be a very strong fence that keeps them in; "Gentleman Farmer, p. 203." Though fields so large as eighty or nivety acres can be advisable only in hilly districts, yet the general rule is nevertheless consistent with experience, in regard to all our least domesticated varieties.

5835. With respect to the promriety of cating the herbage close, or leaving it rather in an

5835. With respect to the propriety of cating the herbage close, or leaving it rather in an abundant state, an eminent agriculturist observes, that there seems to be a season, some time during the year, when grass lands, particularly old turf, should be eaten very close, not merely for the sake of preventing waste, but also for the purpose of keeping down the coarser kinds of plants, and giving to the pastures as equal and fine a sward as possible.

coarser kinds of plants, and giving to the pastures as equal and fine a sward as possible.

5836. The most proper period must partly depend upon the convenience of the grazier; but it can hardly be either immediately before the drought of summer or the frost of winter. Some time in autumn, when the ardent heat of the season is over, and when there is still time for a new growth before winter, may be most suitable for the land itself, and generally also for the grazier, his fat stock being then mostly disposed of, or carried to the after grass of mown grounds. The sweeping of pastures with the scythe may be employed as a substitute for this close feeding; the waste and labour of which, however, though but trifling, it does not seem necessary to incur on rich grazing lands, under correct management. (Sup. E. Brit. art. Agr.)

58:77. Rogging pasture lands is a practice which is sometimes adopted in districts where there is a scarcity of winter food. Under that system, fields in pasture are shut up early in May, and continued in that state till November or December, when the farmer's stock is turned in, and continue to pasture till the May succeeding. Such management, however, can only be advisable on a soil of the driest nature, which will not be injured by poaching in the wettest seasons. It is practised in a few places in Cardiganshire; but is considered by the late Thos, Johnes, Ego, of Hafod, as the result of necessity, the farmers not being able to bring sufficient stock to eat it down in season, when its nutritive powers are in their best state.

are in their best state,

5838. Water should be provided for every field under pasture; and also shelter and shade, either by a few trees, or by a portable shed, which may be moved with the stock from one enclosure to another. Where there are no trees,

rubbing posts are also found a desirable addition. In Germany they have portable sheds which are employed both in summer and winter, and generally with a piece of rock-salt fixed to a post for the cattle to suck at. (fig. 796.)

Hilly and Mountainous Pastures. Subsect. 2.

5839. Hilly pastures include such low hills as produce fine short herbage, and are with much advantage kept constantly in pasture, though they are not altogether inaccessible to the plough; as well as such tracts as, from their acclivity and elevation, must necessarily be exclusively appropriated to live stock. The former description of grass lands, though different from the feeding pastures, of which we have just treated, in respect to their being less convenient for tillage management, are nevertheless in other circumstances so nearly similar, as not to require any separate discussion. These low hills are for the most part occupied with sheep, a very few cattle being sometimes pastured towards their bases; and they frequently comprise herbage sufficiently rich for fattening sheep, together with coarser pastures for breeding and rearing them.

5840. In regard to the management of upland pastures, of the rules which judicious farmers practise, the following deserve to be selected;

ote 5842. Mountainous pastures, from which the plough is altogether excluded, have been commonly classed among waste lands; even such of them as bear herbage by no means of inconsiderable value; as well as heaths and moors with patches of which the green pastures are often chequered The general term wastes is therefore a very indefinite expression; and, indeed, is not unfrequently made to comprehend all that extensive division of our territory that neither produces corn nor rich herbage. Yet it is on such tracts that by far the greater part of our butcher's meat and wool is grown, and not a little of the former fully prepared for the market. Foreigners and superficial readers at home must accordingly be greatly mistaken, if they imagine that what are called wastes by the Board of Agriculture, and other writers on grural seconomy, are really altogether unproductive y and it would be a still grosser error to believe that all those wastes owe their continuance to neglect or mismanagement; and that any exertions of human industry can even render the greater part of them, including all the mountainous tract of Great Britain, more valuable than they are at present, without a much greater

expenditure of capital than, under almost any circumstances, they could possibly return (Sup. art. Agr.)

(Sup. art. Agr.)

5843. Menteath of Closeburn, in Dumfriesshire, has regenerated old pasture by paring up the turf with a paring plough or spade, laying it to one side for a week or two, and again replacing it where it was before, after the subsoil had been stirred by ploughing and harrowing, and a little lime, ashes, or other manure added. A field so treated was found, in four years, to keep fifteen head of cathe fully better than it did ten in its former state. The improvement is considered to give of annual profit one third of the prime cost, so that in little more than four years it will clear itself. (Gard. Mag. vol. vi.)

5844. Improving pasture without taking a crop of corn. The same gentleman having had a considerable extent of the poorest moorland in Scotland in his estate of Closeburn, Dumfriesshire, entertained the opinion that it might pay for improving the pasture without taking a crop of corn this poor soil, which in general was a peat earth upon a gravel or sand or red freestone, and which he considered too poor to produce a remunerating crop of corn. He accordingly set to work to improve about a thousand acres of this poor soil from four hundred to eight hundred feet above the sea, and sometimes pared and burned nearly two hundred acres in one summer, which he ploughed in the autumn and allowed to lie in that state till the next spring, when he laid on about one hundred and seventy bushels of quicklime, or lime shells, as they are there called from their shelling or falling to pieces when watered, per English acre, and in the month of July harrowed in between five and six bushels of Hilcus landtus grass seed. The greatest part of this land has now been improved about twenty years, and is continuing to yield abundance of grass, and is worth from 12s. to 1st, per acre, while in its natural state it was scarcely worth 2s.; and Mr. M. is convinced it would pay amply for another dressing of lime, which a Scotch farmer, he says, would not think of, as the plough is upon all occasions the implement in

restored without dung or great quantities of earth. (C. G. Stuarr Menteath, March 1850), in Gard.
Mag. vol. vi.) for improvements of which mountainous pastures are susceptible are, draining and sheltering by plantations. Some parts might probably be enclosed by strips of plantation between stone walls, or by stone walls alone; but as the stock on mountain pastures are generally under the care of a herdsman, the advantages of change of pasture and alternate eating down and saving or sparing the grass, by keeping out the cattle, are obtainable without the use of fields.

SECT. III. Improvement of Grass Lands, by a temporary Conversion to Tillage.

5846. The practice of breaking up grass lands, either with a view to their being soon after restored, or to their permanent retention in aration, has occasioned much discussion, and even attracted the attention of the Legislature, and the Board of Agriculture. In The Code of Agriculture it is stated, that a "much larger proportion of the united kingdom, than is at present so cultivated, might be subjected to the alternate system of husbandry, or transferred from grass to tillage, and then restored to grass." Much of the middling sorts of grass lands, from 200 to 400 feet above the level of the sea, is of this description; and many husbandmen, and most indiscriminate friends of the corn laws and the landed monopoly, regret that such lands are left in a state of unproductive pasturage, and excluded from tillage. Were the trade in corn free, the idea of tilling such lands would be at least problematical.

lands would be at least problematical.

5847. A very extensive enguiry was made, in consequence of a requisition from the House of Lords to the Board of Agriculture, in December 1860, "into the best means of converting certain portions of grass lands into tillage, without exhausting the soil, and of returning the same to grass, after a certain period, in an improved state, or at least without injury;" and the information collected by the Board, upon that subject, is in the highest degree satisfactory and important.

5818. On this subject the opinion of one of our first writers is, "that though it is impossible to deny that much grass land in England would be more productive, both to the proprietor and occupier, under a good course of cropping, than under pasture; yet it is no less certain, that there are large tracts of rich grazing land, which, in the present state of the demand for the produce of grass lands, and of the law of England, with regard to tithes, cannot be employed more profitably for the parties concerned, than in pasture. The interest which the Board of Agriculture has taken in this question, with a view on a bundant supply of corn for the wants of a rapidly increasing population, seems, therefore, not to have been well directed. Instead of devoting a large pertion of their volumes to the instruction of farrers, regarding the best method of bringing grass lands into tillage, and restoring them again to meadow or pasture, without deterioration; the first thing required was, to attempt removing the almost insuperable obstruction of tithes, by proposing to the legislature an equitable plan of commutation. If some beneficial arrangement were adopted on this head, there is no reason to doubt, that individual interest would soon operate the wished-for change; and that all grass lands capable of yielding more rent and profit under tillage than under pasture would be subjected to the plough, as fast as the demands of the population might require. (Sup. E. B. art. Agr.) In giving the essence of the infor

5849. In giving the essence of the information collected by the Board, we shall first state the opinions as to such grass lands as should not be broken up, and next the directions for breaking up and laying down the others, that at lan a man have , showed the grant range steen with a co-

Subsect 1. | Grass Lands that ought not to be broken up by the Plough.

5850. There are various sorts of grass lands that ought not to be broken up; as water meadows; salt marshes; lands apt to be overflowed; lands near large populous towns, where the produce of grass land is always in demand, and consequently dear; and lowlying tracts, in the valleys of mountainous countries, particularly in chalky districts, where old meadow land is scarce, and where a portion of it, to raise early and late food for stock, gives a great additional value to the adjoining upland. But whether rich lands, which have long remained in grass, and continue productive, should ever be converted into tillage, is a question respecting which a great diversity of opinion has that terrary more valuable has the s

5851. The lands considered as best adapted for permanent pasture are of three kinds: strong tenacious clays, unfit for turnips or barley, which are said to improve the more the longer they are kept under a judicious system in grass; soft clayey loams, with a clayey or marly bottom or substratum; and rich, sound, deep-soiled land, or vale land, enriched by nature at the expense of the higher grounds, generally lying in a situation favourable with respect to climate.

favourable with respect to climate.

5852. The advantages of such pastures are represented in the strongest light. It is affirmed, that they feed cattle to a greater weight; that they are not so easily scorched by the summer's drought; that they feed cattle to a greater weight; that they are not so easily scorched by the summer's drought; that they greater weight; that they are not so easily scorched by the summer's drought; that they greater wariety of prasses; that the high considering them are much better preserved; that they produce a greater variety of grasses; that, when properly laid down, they yield a succession of pasture throughout the whole season; that the herbage is sweeter, and more easily digested; and that they return an immense produce at a trifling expense.

5853. To break up lands possessing these advantages, it is said, can only be justified by the most urgent public necessity, and to prevent the horrors of famine. The real value of such lands will appear by considering their rent and produce. The grass lands in Lincolnshire are accounted the richest in the kingdom. The rents are various; from It. 18s. to 3l, per acre; and the value of the produce from 3l, per acre to 10l. This produce arises from beef, mutton, and wool; and is obtained subject to little variation from the nature of the seasons, and at a trifling expense. The stock maintained per acre on the best grazing lands surpasses what could be fed by any arable produce. It is not at all uncommon to feed at the rate of from six to seven sheep in summer, and about two sheep in winter. The sheep, when put on the grass, may weigh from 18 lbs. to 20 lbs. per quarter, and the increase of weight would be at the rate of 4 lbs. per quarter, or 16 lbs. per sheep. But suppose in all only 100 lbs. at 8d. per pound, that would amount to 3l. 17s. 10d. The wool would be worth about two guineas more, besides the value of the winter keep; and the total may be stated at about 7l. per acre, got at little expense. Such lands, it is evident, cannot be bet

5854. Grass land on tenacious clays and heavy loams, when brought in a succession of years, or perhaps of ages, into a state of great productiveness, cannot be ploughed without the risk of great injury, and are more profitable in the production of herbage than they

could be in the production of grain.

5855. Grass on deep-soiled sound vale lands would be productive of corn if ploughed; but would be probably injured by cultivation: from their texture being altered, and rendered unduly loose and open by tillage; from the native plants being more or less destroyed or enfeebled; and from the great decomposition and waste of the principles of

fertility resident in the soil.

5856. The extent of these descriptions of land, however, is not so great that the advantages of breaking them up could probably ever be a national object, or worth the risk of injuring their future productiveness in grass. But there are pasture lands of an inferior sort, which are too apt to be confounded with those already described; and respecting the propriety of occasionally appropriating them to arable culture, there can hardly be a Such lands do not depend upon their intrinsic fertility, but upon annual supplies of manure derived from the arable land in their neighbourhood.

Subsect. 2. Advantages and Disadvantages of breaking up Grass Lands.

5857. The advantages of breaking up grass lands, not of the richest quality, will appear by a comparison of their produce with that of arable lands.

5838. From the enquiry of the Board of Agriculture, it appears that an acre of clover, tares, rape, potatoes, turnips, cole, or cabbages, will furnish at least thrice as much food as the same acre would have done, had it remained in pasture of a medium quality; and, consequently, that the same extent of land would maintain at least as much stock as when in grass, besides producing every other year a valuable crop of corn; and this, independently of the value of the straw, which, whether consumed as litter, or as food for cattle, will add considerably to the stock of manure. It follows that, with the exception of rich pastures, arable land is, on an average, superior to grass land, with respect to furnishing articles of human food, in the proportion of three to one; and consequently every piece of land unnecessarily kept in grass, the produce of which will only maintain one person, is depriving the community of food capable of maintaining two additional members

of which will only maintain one person, is depriving the community of food capable of maintaining two additional members.

5859. The principal objection to the conversion of old turf into arable land arises from an alleged inferiority, both in bulk and nutritive properties, in the new when compared to the old herbage. It is certain, that by no art can we at once produce a surface of grasses which can be at all compared to some of the richest pastures in Buckinghamshire, Lincolnshire, and Leicestershire; but these are not the pastures which any prudent agriculturist would recommend to be broken up, whatever might be the price of corn; and more especially in Britain, and with a prospect of the trade in corn being at no distant period free. Still, in by far the greater number of cases where the soil will admit of the convertible husbandry, and where that husbandry is as well understood and practised as it is in the north of England and south of Scotland, we should have no hesistation in leaving it to the farmer to break up whatever pastures he thought be could do with profit during a fourteen or twenty-one years' lease. A gentleman who had a large farm, principally consisting of strong rich clay (every field of which, with hardly any exception, he occasionally broke up), was accustomed to lay them down with a crop of barley, and to sow fourteen pounds of white clover, a peck of rib-grass, and three quarters of hay seeds, per acre. By this liberal allowance of seed, he always secured a thick coat of herbage the first year, which differed from old pasture in being more luxuriant. Such lands, therefore, under judicious management, will rarely be injured by the plough. When laid down from tillage into grass, they may not carry for the first year or two such heavy cattle as they would afterwards; but they will support more in number, though of a smaller size, and bring a greater weight of butcher meat to market. It is often desirable to keep one or two moderate-sized enclosures, of from ten to twenty acres, according t

5860. There are many cases where this doctrine, though in general to be recommended, ought not to be carried to its full extent. In Norfolk, where the land is commonly light, and where the sheep are both bred and fed upon the same farm, a proportion of permanent pasture is essential. Much injury, in particular, has been sustained by breaking up permanent pastures on such soils, more secially when subject to rectorial tithes. Many lands of an inferior soil, which kept two sheep on an acre, paying only vicarial tithes, and rented at ten shillings per acre, since they have been broken up cannot pay, even without rent, the tithe of corn and the expense of cultivation. A farm in general lets best with a fair proportion of grass land upon it, which admits of a mixed management; in consequence of which, if one object fails another may be successful. another may be successful.

5861. With respect to the disadvantages of breaking up pastures, it is alleged in The Code of Agriculture, that there is a risk of tenants breaking through their engagements (p. 473. 3d edit.); by which we suppose is to be understood, the chance of their taking a few good crops from the newly broke-up lands, and then leaving the farm. Tenants who would do this must certainly be as wicked as the landlords who would put in their power would be imbecile. No other disadvantage is stated, and this may safely be left to work its own cure.

Breaking up Grass Lands, and afterwards restoring them to Grass. SUBSECT. 3.

5862. On the subject of breaking up and laying down grass lands, the following particulars are discussed in the Code of Agriculture, as the result of the information communicated to the Board: - Whether any previous steps are necessary before lands in grass are broken up? the proper mode of effecting that object; the course of crops; the manure necessary; the system of management during the rotation; the mode of laying down the land again to grass; that of sowing the grass-seeds; and the subsequent management.

5863. If the land be wet, it is advisable to drain it completely, previously to its being broken up; for it is not improbable that its being kept in pasture was partly on account

of its wetness.

5863. Land that has been long in pasture does not require dung during the first course of crops that is taken after being broken up; but the application of calcareous manure is always, in such cases, expedient, Sometimes lime is spread on the ground before it is ploughed; at other times when it is either under summer-fallow, or a drilled crop of turnips. Marl and chalk also have been used for the same purpose with great advantage. The land thence derives additional strength and vigour; the succeeding crops are much improved; the soil is commonly so softened in its texture, that it may be ploughed with half the strength that would otherwise be necessary; and whenever it is restored to grass, the herbage is abundant.

5865. Wherever the soil is not too shallow, nor of a friable nature, or when the turf cannot soon be rotted, if land is to be broken up from old pasture, the system of paring and burning is proper. In this way, good tilth is speedily procured; the damage that might otherwise be sustained by the grub, the wire-worm, and other insects, is avoided, while the soil receives a stimulus which ensures an abundant crop.

5866. Where paring and burning cannot take place, the land may be trenched or double-ploughed. This is effected by means of two ploughs following each other, the first plough taking off a thin surface of about three inches, and the second going deeper in the same place, covering the surface sod with fine mould; both furrows not exceeding the thickness of the vegetable mould or other good soil. If the land is ploughed with one furrow, the operation ought to be performed before winter, that it may receive the benefit of the succeeding frosts, by which the success of the future operations will not only be promoted, but most of the insects lodged in the soil will be destroyed. When one furrow alone is taken, the best size is four inches and a half deep by eight or nine broad. The strain on horses in ploughing ley land is mostly from the death depth.

5867. The rotation of crops to be adopted, when grass lands are broken up, must partly depend upon the soil, and partly on the manner in which it is prepared for cultivation. As a general principle, however, it may be laid down, that unless by the course of cropping to be pursued the bad grasses and other plants indigenous to the soil are extirpated, they will, when the land is again laid down to grass, increase and prevail with more rapidity and effect than seeds chosen by the farmer; and the consequence must be, a heavy disappointment in the future crops of grass, perhaps solely, or at least principally, attributable to a previous defective management. It is necessary, therefore, to enter into details upon this subject as applicable to clay, chalk, peat, loam, and sand.

into details upon this subject as applicable to clay, chalk, peat, loam, and sand.

5868. Clay. The process of conversion in clayey soils should be commenced with paring and burning, especially where the grub is suspected. The following course may then be adopted:—1. Rape, fed with sheep; 2. beans; 3. wheat; 4. beans; 5. wheat; 6. fallow; 7. wheat, sown with grass-seeds. This may seem severe cropping, but it is justified by experience when old grass clay-land is broken up. If the land has not been pared and burnt, the first crop ought to be either oats or dibbled beans. To do justice to the plan of restoring the land to grass, there ought to be, in all cases, according to the soil, either a naked or turnip fallow, before the sowing of grass-seeds is attempted. But on mellow loamy clay land, consisting of fine old grass pasture, where it is thought necessary or advisable to break up such land, it should be done in detached pieces, so as to suit the convenience of the occupier, and the following course should be adopted:—1. Autumnal ploughing for oats in spring; 2. fallow for rape, to be eartially eaten, and hoed in spring, and to stand for seed; and 9. wheat with grass-seeds. This is a very profitable rotation, and applicable to the best grazing land in Lincolnshire.

5869. Chalk. Paring and burning are considered in this case to be indispensable as a preparation for turnips, which ought, where manure can be got, to be raised two years in succession; then, barley, clover, wheat; and, after one or two additional crops of turnips, the land may be laid down with saintfoin to great advantage.

wheat; and, after one or two additional crops of turnips, the land may be laid down with saintfoin to great advantage.

5870. Peat. On this soil paring and burning are essentially necessary. Under a judicious system, the greatest and quickest profit is thus secured to the farmer, with advantage to the public, and without injury to the landlord. Draining also must not be neglected. The crops to be grown on pet soils are, I rape or potatoes; 2. oats; 3. turnips; 4. oats or wheat; and 5. clover or grass-seeds. A liberal application

of lime, where it can be obtained, is of the greatest service in enabling such soils to bring corn to its full perfection." In the fens of Thorney, the following course was recommended: — I. Paring and burning for rape; 2. oats; and 3. wheat with grass-seeds; if the land were safe from water, the Lammas sort, if not, spring wheat. This short course, it is contended, preserves the land in heart; and it afterwards produces abundant crops of grass. But long courses; in such a soil, run the lands to weeds and straw, without matter in the grain

without quality in the grain,

5871. Loam. The courses of crops applicable to this soil are too numerous to be here inserted. If the
sward is friable, the following rotation may be adopted:—1. Oats; 2. turnips; 3. wheat or barley;
4. beans; 5. wheat; 6. fallow or turnips; 7. wheat or barley, and grass-seeds. If the sward is very tough
and coarse, instead of taking oats, it may be pared and burnt for turnips.

5872. Sand. On rich and deep sandy soils, the most valuable that can be raised is a crop of carrots. For
inferior sands, turnips, to be eaten on the ground; which should then be laid down with barley and grass-

5873. According to the improved system of laying down lands to grass, land-ought to be previously made as clean and fertile as possible. With that view, all the green crops raised ought to be consumed upon the ground; fallow or fallow crops ought not to be neglected; and the whole straw of the corn crops should be converted into manure, and applied to the soil that produced it. Above all, the mixing of calcareous matter with the soil, either previously to, or during the course of, cropping, is essential. Nothing generally improves meadows or pastures more than lime or marl: they sweeten the herbage, render it more palatable to stock, and give it more nourishing properties.

the more palatable to stock, and give it more nourishing properties.

5874. When turnips are raised upon light land, sheep should be folded on them; whereas, if the land is strong or wet, the crop should be drawn, and fed in some adjoining grass-field, or in sheefs. If the land is in high condition, it is customary to cart off half the turnips, and eat the other on the ground. But this is not a plan to be recommended on poor soils.

5875. It has been disputed whether grass-seeds should be sown with or without corn. In favour of the first practice, that of uniting the two crops, it is maintained, that where equal pains are taken, the future crop of grass will succeed as well as if they had been sown separately, while the same tilth answers for both. On the other hand, it is observed, that as the land must, in that case, be put into the best possible order, there is a risk that the corn-crop will grow so luxurinatly as to overpower the grass-seeds, and, at any rate, will exclude them from the benefit of the air and the dews. If the season also be wet, a corn crop is aptitude, and the grass will, in a great measure, be destroyed. On soils moderately fertile, the grasses have a better chance of succeeding; but then, it is said, that the land is so much exhausted by producing the corn-crops, that it seldom proves good grass land afterwards. In answer to these objections, it has been urged, that where, from the richness of the soil, there is any risk of sowing a full crop of corn, less seed is used, even as low as one third of the usual quantity; and that a moderate crop of grain nurses the young plants of grass, and protects them from the rays of a hot sun, without producing any material injury. Where the two crops are united, barley is the preferable grain, except on peat. Barley has a tenidency to loosen the texture of the ground in which it grows, which is favourable to the vegetation of grass-seeds. In the choice of barley, that sort should be preferred which runs least to straw, and which is the soonest ripe. O

5877. When the corn is carried off, the young crop of grass should be but little fed during autumn, and that only in dry weather; but heavily rolled in the following spring, in order to press the soil home to the roots. It is then to be treated as permanent pasture. By attention to these particulars, the far greater proportion of the meadows and pastures in the kingdom, of an inferior, or even medium quality, may be broken up, not only with safety, but with great profit to all concerned.

for the description of the descr CHAP, "VIII, " THE STATE OF ST

Plants cultivated on a limited Scale for various Arts and Manufactures.

5878. The plants used as food for men and animals are by far the most generally cultivated in every country; and, next, those of clothing, building, and other arts of convenience or luxury. The former are often called agricultural, and the latter commercial or manufactorial plants. Of manufactorial plants, only a few are at present cultivated. in Britain; the national policy rendering it preferable to import them, or substitutes, from other countries. Some, however, are still grown in nearly sufficient quantities for home consumption, as the hop, mustard, rape, and a considerable quantity of flax, anise, and carraway; some hemp, teazle, and woad are also raised. These and other plants may be classed as grown for the clothing, distilling, brewing, oil-making, estermet the best time, and accurangly within these presta kailem bus pittermed bus

Flax. — Linum usitatissimum L.; Pentindria Pentaginia L., and Lineæ Dec. Lin, Fr.; Flacks, Ger.; and Line, Ital. and Span. (fig. 797. a.)

5880. The flax has been cultivated from the earliest ages, and for an unknown length

of time in Britain, of which it is now considered a naturalised inhabitant. It is cultivated both for its fibre for making thread, and its seed for being crushed for oil; but never has been grown in sufficient quantity for either purpose. The legislature of the country, as Brown observes, has paid more attention to framing laws regarding the husbandry of flax than to any other branch of rural economy; but it need not excite surprise that these laws, even though accompanied by preminins, have failed to induce men to act in a manner contrary to their own interest. The fact is, the culture of flax is found on the whole less profitable than the culture of corn. It is one of the most severe crops when allowed to ripen its seed; but by no means so when pulled green.

5881. The varieties of the common flax are few, and scarcely deserving of notice. Marshal mentions the blue or lead-coloured flax as being

cultivated in Yorkshire, and Professor Thaer mentions a finer and coarser variety; he also, as well as some other agriculturists, has tried the Linum perenne (b), but though it affords a strong fibre, it is coarse and difficult to separate from the woody matter.

5882. The soils most proper for flax, besides the alluvial kinds, are deep and friable loams, and such as contain a large proportion of vegetable matter in their composition. Strong clays do not answer well, nor soils of a gravelly or dry sandy nature. But whatever is the kind of soil, it ought neither to be in too poor nor in too rich a condition: because, in the latter case, the flax is apt to grow too luxuriantly, and to produce a coarse sort; and, in the former case, the plant, from growing weakly, affords only a small produce. (Tr. on Rural Affairs.)

583. If there is water at a small depth below the surface of the ground, it is thought by some still better; as in Zealand, which is remarkable for the finences of its flax, and where the soll is deep and rather stiff, with water almost every where, at the depth of a foot and a half or two feet. It is said to be owing to the want of this advantage; that the other provinces of Holland do not succeed equally well in the culture of this useful plant; not but that fine flax is also raised on high-lands, if they have been well tilled and manured, and if the seasons are not very duy. It is remarked, in the letters of the Dublin Agricultural Society, that moist stiff soils yield much larger quantities of flax, and far better seed, than can be obtained from light lands; and that the seed secured from the former may, with proper care, be rendered full as good as any that is imported from Riga or Zealand. M, Du Hamel, however, thinks that strong land can hardly yield such fine flax as lighter ground.

5884. The place of flax in a rotation of crops is various, but in general it is considered as a corn or exhausting crop, when the seed is allowed to ripen; and as a green, or pea, or bean crop, when the plant is pulled green.

5885. Flax, Donaldson observes, is sown after all sorts of crops, but is found to succeed best on lands lately broken up from grass. In Scotland, the most skilful cultivators of flax generally prefer lands from which one crop of grain only has been taken, after having been several years in pasture. When such lands have been limed or marled, immediately before being laid down to grass, the crop of flax seldom or never misgives, unless the season prove remarkably adverse. In the north of Ireland flax is generally sown by the small farmers after potatoes. In Belgium, it is supposed not to do well after peas or beans; nor to succeed if sown oftener on the same soil than twice in nine years. (Von Thaer.)

5886. The preparation of the soil, when grass land is intended for flax, consists in breaking it up as early in the season as possible, so that the soil may be duly mellowed by the winter frosts, and in good order for being reduced by the harrows, when the seed by the harrows, when the seed is distributed to procure the aid of frost, without which the surface cannot be rendered fine enough for receiving the seed. Less frost, however, will do in the latter than in the former case; therefore, the grass land ought always to be earliest ploughed. At seed-time, harrow the land well before the seed is distributed, then cover the seed to a sufficient depth, by giving a close double harrowing with the harrows. Water-furrow the land, and remove any stones and roots that may remain on the surface, which finishes the seed process.

giving a close double harrowing with the harrows. Water-furrow the land, and remove any stones and roots that may remain on the surface, which finishes the seed process.

5887. The ordinary season of sowing flax-seed is from the middle of March to the middle or end of April, but the last week of March and the first ten days of April are esteemed the best time; and accordingly within these periods the greatest quantity of flax-seed is sown in this country. In France and Italy it is often sown in the autumn, by which a larger crop is produced, especially when seed is desired.

5888. The quantity of seed depends on the intention of the crop. When a crop of seed is intended to be taken, thin sowing is preferable, in order that the plants may have room to throw out lateral shoots, and to obtain air in the blossoming and filling seasons.

But it is a mistake to sow thin when flax is intended to be taken; for the crop then becomes coarse, and often unproductive. From eight to ten pecks per acre is the proper quantity in the last case, but when seed is the object, six pecks will do very well. (Rrown.) Thick-sown flax runs up in height, and produces fine soft flax; if sown thin, it does not rise so high, but spreads more and puts forth many side branches, which produce abundance of seed, and such seed is much better filled, plumper and heavier, than the seed produced from thick-sown flax. (Donaldson.)

5889. In the choice of seed, that which is of a bright brownish colour, oily to the feel,

and at the same time weighty, is considered the best.

and at the same time weighty, is considered the best.

5890. Linseed, imported from various countries, is employed. That brought from Holland is, however, in the highest estimation; as it not only ripens sooner than any other that is imported, but also produces greater crops, and flax of that quality which best suits the chief manufactures of the country. American seed produces, in common, fine flax; but neither the quantity of flax nor of the pods, provincially the "bolls," which contain the seeds, is so large as the produce from Dutch linseed. Riga seed yields a very coarse sort of flax, but a greater quantity of seeds than any other. It is common in some parts of Scotland to sow seeds saved from the crop of the preceding year, especially when that crop was raised from seed imported from Holland. The success of this practice is found to depend greatly on changing the seed from one sort of soil to another of an opposite nature; but the saving in the expense of purchasing that sort of seed, in place of what is newly imported from Holland, is so inconsiderable, and the risk of the crop misgiving so much greater in the one case than in the other, that those only who are ignorant of the consequences, or who are compelled from necessity, are chargeable with this act of ill-judged parsimony. Flax-seed is by some farmers changed every three years, but many have sown the same seed ten years in succession without perceiving any degeneracy. When any degeneracy takes place, the seed of flax grown on a different soil, as moss, moor, sand, &c. without any view to the produce in fibre, will, its said, answer as well as foreign seed.

5891. The manner of sowing is almost always the same; but when seed is the main object, drilling may be adopted, by which seed will be saved in sowing, cleaning conducted at less expense, and the plants rendered more vigorous and branchy by the stirring of the soil and the admission of air between the rows. The fibres of flax grown in this way, however, will be shorter, and less equal in thickness throughout their length,

than flax grown by the broad-cast mode, and tolerably thick.

5892 The after-culture of flar consists chiefly in weeding, but sometimes it commences with rolling the surface, which is a very proper operation when the soil is very dry, the season advanced, or the earth very porous. By this process the earth is pressed firmly to the seeds, and they are thereby stimulated to vegetate sooner, and the drought is kept out. On some soils, and in wet or stormy seasons, flax is apt to be laid, to guard against which some cultivators run across their flax field slender poles fixed to stakes: but a better method is to run small ropes across the field, both lengthwise and breadthwise, where necessary; for these being fastened where they intersect one another, and supported by stakes at due distances, form a kind of network, which is proof against almost every accident that can happen from tempestuous weather.

5893. In Scotland a crop of flax, it is said, has been sometimes weeded by turning a flock of sheep at large at the field. They will not taste the young flax plants, but they carefully search for the weeds, which

they devour.

5894. The flax crop is taken by pulling, on which there is a considerable difference of opinion. None, however, think of pulling it before it comes into flower, when fibre is the sole object; or before the seed in the capsules acquires a brownish colour, when fibre and seed jointly are required, or when seed alone is the object.

fibre and seed jointly are required, or when seed alone is the object.

5895. Some argue for it pulling while green, in order that its fibres may be softer and finer; others, with the same view, pull it up before its seeds are quite formed; and others again think that it should not be pulled till some of the capsules which contain the seeds have begun to open, being of opinion that the fibres of green flax are too tender, and that they fall into tow. On the other hand, it is certain the fibres of flax which has stood till it is very ripe are always stiff and harsh, that they are not easily separated from the reed, and that they do not bleach well. Here, therefore, as in most other cases, both extremes should be avoided; and it consequently seems most reasonable to think that the properest time for pulling flax, is when its stalks begin to turn from a green to a yellow, when its leaves begin to fall, and when its seeds begin to be brown. Donaldson observes, that a crop of flax frequently grows short, and runs out a great number of seed-bearing branches. When that is the case, the seeds, not the flax, ought to be the farmer's chief object, and the crop should be allowed to stand till the seeds are in a great measure perfected. But that when the crop thrives, and is likely to become more valuable for the flax than the seeds, it should be pulled soon after the bloom drops off, and before the peds turn hard and sharp in the points. When flax is grown for its fibre, Brown considers it the safest course to take it a little early, any thing wanting in quantity being, in this way, made up by the superiority of quality.

5896. The operation of pulling flax differs according to the intention of the crop. When it is grown for the fibre it is pulled and tited into sheaves like corn, and carried off immediately to be watered. But when the seed it so be taken from the plant, it is pulled and laid in handfuls.

when the sect is to be taken from the plant, it is put he seeds, to lay it in handfuls, partly across eich other; the reason for which is, that the bisiness of rippling is, thereby facilitated, as the ripplers, in place of having to separate each handful from the bundle, find it by this simple precaution already done to their hand. Although it is of much importance, yet it very seldom happens that much atten ion is bestowed to separate the different sorts of flax from each other, in pulling the crop. In most fields, there are varieties of soils; of course some parts of a field will produce fine flax other coarse; some long, and some short: in a word, crops of others coarse; some long, and some short: in a word, crops of these sorts of flax a fill undergo an equal degree of watering, grassing, breaking, and heckling, without sustaining great injury.

5893. As the flax is pulled, it is lald together by handfuls, with the seed end turned to the south. These handfuls should

meither lie quite in a line with each other, nor directly across, but a little stanting upwards, so that the air may easily pass through them. Some, instead of this method, tie the hancfuls of flax loosely at the top, then spread out their roots, and thus set several of them together upright upon their roots. In either of these ways, the flax is g.n.rally left twelve or fourteen days in the field to dry it. This drying is certainly not necessary for the rippling, because the tipple will separate the capsules from the flax as effectually before it has been dried as it will afterwards; and if it is done with a view to rippen the seed, longer time of steeping, which wil become necessary in consequence of this drying, than the seed can be benefit of; because, the more the membrane which connects the nbres to the reed is dried, the greater must be the degree of putrefaction necessary to loosen and destroy the cohesion of this connecting membrane; the finer parts of the flax itself must necessarily be

destroyed by this degree of putrefaction; and if the putrefaction does not arise to such a degree as to destroy the cohesion of this membrane, the fibres of the flax will adhere so strongly to the reed, that the force necessary in scutching will prove

equally detrimental to the flax. The practice adopted in some parts of Britany seems therefore much more rational, which is, to ripple the flax after it has lain in the air two or three days; but even one day will be sufficient, if the weather is dry.

915

5899. In the process of rippling, which is the next operation, a large cloth should be spread on a convenient spot of ground, with the ripple placed in the middle of it.

5900. In performing this business, the pods containing the seeds are forced from the stalks by means of the iron comb called a ripple, fixed on a beam of wood, on the ends of which two persons sit, who, by pulling the seed end of the flax repeatedly through this comb, execute the operation in a very complete manner. It is remarked by the author of The Present State of Husbandry in Great Britain, that "those who bestow much attention on the cultivation of flax in Scotland generally ripple off the seed, even when there is no intention of saving it; as it is found, when flax is put into water without taking off the pods, the water soon becomes putrid, in consequence of which the flax is greatly injured."

5901. The management of the capsules, and the separation of the seed, form the next operation.

5902. The capsules obtained should be spread in the sun to dry, and those which separate from the pods of their own accord, being the fullest and ripest, should be set apart for sowing, in case the precaution of raising some flax purposely for seed has not been attended to. The capsules are then broken, either by treading or by threshing, in order to get out the remaining seeds, the whole of which, as well as the others, should be carefully sifted, winnowed, and cleaned. When the seed is laid up, it must be frequently stirred, or ventilated, to prevent its heating. Even this second seed affords a considerable profit, by the oil which it rights each also by the purposed when broken keep for the seed also by the burner seed when broken keep for the seed also by the burner seed when broken keep for the seed also be burner seed when broken keep for the seed also be burner seed when broken keep for the seed also be burner seed when the seed also be the seed also be businessed when the seed also be the seed also be seed as the seed also be businessed when the seed also be seed as the seed also be seed as the seed also be seed as the s it yields, and also by being used when broken for fattening of cattle.

5903. To facilitate the separation of the fibre from the bark, it is necessary to accelerate the process of decay or putrefaction. This may be done in different ways; but the chief are bleaching alone, and steeping and bleaching.

5904. Bleaching is a tedious and laborious operation when it is intended as a substitute for steeping, but it is less likely to injure the fibre, and may be adopted on a small scale when steeping places are not at hand. In Dorsetshire, and some other places, flax, instead of being steeped, is what is called dewretted; that is, the stalks are allowed to arrive at that state in which the harl or woody parts separate most easily from the boon, reed, or fibre, by a more gradual process, that of ripening by the action and influence of the dew. This is nothing more than exposing the flax to the influence of the weather for a longer period than is necessary, when the operation of watering has been previously performed. Steeping, we watering, however, is the most universal practice both in Britain and on the Continent. 5905 Steeping or watering, however, is and will be the general practice till flax-dressing machines come into universal use. In performing this operation, the flax, whether it has been dried and rippled, or pulled green, is loosely tied into small bundles, the smaller the better, because it is then most equally watered; and these bundles are built in the pool in a reclining upright posture, so that the weight placed above may keep the whole firmly down. The weights made use of are commonly stones placed on planks, or directly on the flax.

and these bundles are built in the pocl in a reclining upright posture, so that the weight placed above may keep the whole firmly down. The weights made use of are commonly stones placed on planks, or directly on the flax.

5906. The Flemish mode of steeping flax, as described by Radcliff, is said to improve the quality of the flax; and greatly increase its whiteness. This mode differs from the common practice, in placing the bundles in the steep vertically, instead of horizontally; in immersing the flax by means of transverse sticks, with that degree of weight annexed which shall not push it down to the bottom, but leave it the power to descend spontaneously towards the conclusion of the steepage; and in leaving at first a space of at least half a foot between the bottom and the roots of the flax. The spontaneous descent of the flax is an indication of its being sufficiently steeped; and the strength and quality of the fibre are said to be much better preserved by this mode, in which the temperature of the atmosphere acts with most force on the upper part of the plant, which needs it most.

5907. The water most proper for steeping flax should be clear, soft, and in standing pools. Compared with running water, pools occasion the flax to have a better colour, to be sooner ready for the grass, and even to be of superior quality in every respect. When soft, clear, stagnating water cannot be obtained without art, a pit or canal is filled with water for some time (a week or two) before it is proposed to pull the flax; by this means the water acquires a greater degree of warmth than river-water possesses, which contributes greatly to facilitate the object farmers have in view in immersing green flax in water, namely, to make the harl or flaxy substance part easily and completely from the boon or reed.

5908. The period that flax ought to remain in the water, depends on various circumstances; as the state of ripeness in which it was pulled, the quality and temperature of the water, &c. The most certain rule by which t

(Brown.)
5909. Grassing or bleaching flax is the next operation, the intention of which is to rectify any defect in the watering process, and carry on the putrefactive process to that point when the fibre will separate from the bark, boon, reed, or harl (as the woody part of the stem is called), with the greatest ease. In performing this operation, the flax is spread very thin on the ground, and in regular rows; the one being made to overlap the other a few inches, with a view of preventing, as much as possible, its being torn up and scattered by gales of wind. Old grass-ground, where the herbage does not grow to any great height, is the best for the purpose; as when the flax is covered by the grass or weeds, it is frequently rotted, or at least greatly injured thereby.

5910. The time allowed for grassing is regulated by the state of the flax, and seldom exceeds ten or twelve days. During this time it is repeatedly examined; and when it is found that the boon has become very brittle, so that, on being broken, and rubbed between the hands, it easily and freely parts from the harl, it is taken up, a dry day being chosen for the purpose, and, being bound in sheaves, is either sent directly to the mill, which is the usual practice in the northern districts, or broken and scutched by a machine or implement for the purpose.

5911. Steeping flax in hot water and soft soap (said to be the invention of Lee, and for which he was granted by parliament a secret or unenrolled patent) is said to separate the fibre from the woody matter better than steeping in water simply; and this in the short space of two or three hours, and either with green flax, or such as has been dried and stacked for months or years. When flax is to be separated by this new mode, the cultivator has only to pull it in handfuls, dry it, bind it into sheaves or faggots, and put it up in stacks like corn, till wanted by the manufacturer.

or breaking, by which the woody part is broken; and heckling or combing, by which the fibre is separated from the woody part, and sorted into lengths. These operations are often all performed by the cottager, or small farmer, who grows flax for the purpose of spinning the fibre in his own family. But there are also public flax mills, impelled by water or other powers, by which flax is scutched, and it is then heckled by professed hecklers, a circuit trace which has some its last

-5913. A method of preparing flax in such a manner as to resemble cotton in whiteness and softness, as well as in coherence, is given in The Succisis Transactions for the year 1747. For this purpose a little sea water is to be put into an iron pot or an untimed copper kettle, and a mixture of equal parts of birch ashes and quicklime strewed upon it; a small bundle of flax is to be opened and spread upon the birch-ashes and quicklime strewed upon it; a small fluinds of flax is to be opened and spread upon the surface, and covered with more of the mixture, and the stratification continued till the vessel is sufficiently filled. The whole is then to be boiled with sea-water for ten hours, fresh quantities of water being oceasionally supplied in proportion to the evaporation, that the matter may never become dry. The boiled flax is to be immediately washed in the sea by a little at a time, in a basket, with a smooth stick at first, while hot; and when grown cold enough to be borne by the hands, it must be well rubbed, washed with soap, laid to bleach, and turned and watered every day. Rejectitions of the washing with scap expedite the bleaching; after which the flax is to be beat, and again well washed; when dry, it is to be worked and boiling them in the description of the same manner as common cotton and makes the trivial to the description of the property of the same manner as common cotton and measured the property of the same manner as common cotton and measured the private washers for forty.

The best to this rip are,

chand ble mile list

its quality.

5914. Lee's method of breaking flast and hemp, without dew-retting, was invented in 1810, and was the first step towards a great improvement, brought nearer perfection by the new patent machines of Messrs. Hill and

Bundy.
5915: Hill and Bundy's machines (fig. 789.) are portable, and may be worked in barns or any kind of out-house; they are also well calculated for parish workhouses and charicalculated for parish worklouses and chari-table institutions; a great part of the work being so light that it may be done by chil-dren and infirm persons; and such is the construction and simplicity of the machines, that no previous instruction or practice is required; their introduction, therefore, into those asylums would be the means of effect ing a considerable reduction of the poor's rate. The woody part is removed by a very simple machine; and, by passing through a machine equally simple, the flax may be brought to any degree of fineness, equal to the best used in France and the Netherlands, for the finest lace and cambric. The original length of the fibre, as well as its

strength, remains unimpaired; and the difference of the produce is immense, being produced from four tons of stem. The expense of working each ton obtained by one ton of flax being produced from four tons of stem. The expense of working each ton obtained by this method is only five pounds. The glutinous matter may be removed by soap and water only, which will bring the flax to such perfect whiteness, that no further bleaching is necessary, even after the linen is woven; and the whole process of preparing flax may be completed in six days.

5916. The produce of flax in seed is generally from six to eight, sometimes as high as ten or twelve, bushels per acre; and the price depends in a great measure on that of foreign seed imported; as, when sold to oil-makers, it is generally about one half of that of Dutch seed sold for the purpose of sowing.

5917. The price of home-cultivated linseed is considerably advanced of late in some of the southern and western counties of the kingdom, in proportion to what it is in the northern, owing to the circumstance of its being much used as food for fattening cattle. The average price of the linseed cultivated in the kingdom at large cannot, it is supposed, be rated higher than from three to four shillings the bushel. The seed is separated into three qualities; the best for sowing, the second best for crushing for oil, and the interior for beliling a rescaled. inferior for boiling or steaming for cattle,

5918. The produce of flax in fibre varies exceedingly. Before being sorted, the gross product of fibre varies from three cwt. to half a ton per acre.

'5919. The use of flax in the linen manufacture is well known. The seed is crushed for oil, which is that in common use by painters; the cake or husk, which remains after the expression of the oil, is sold for fattening cattle, and in some places as a manure; and the inferior seed, not fit to crush, is boiled and made into flax-seed jelly, which is esteemed excellent nutriment for stock.

5920. As the making of flax-seed jelly is an agricultural operation, we shall here describe it. The proportion of water to seed is about seven to one. The seed having been steeped in part of the water for eight-and-forty hours previously to the boiling, the remainder of the water is added cold, and the whole boiled gently about two hours, being kept in motion during the operation, to prevent its burning to the boiler. Thus the whole is reduced to a jelly-like, or rather a gluey or ropy, consistence. After being cooled in tubs, it is given, with a mixture of barley-meal, bran, and cut chaff; a bullock being allowed about two quarts of the jelly per day, or somewhat more than one quart of seed in four days: that is, about one sixteenth of the medium allowance of oil-cake.

by v.5921. The diseases of flux are few, and are chiefly the fly, which sometimes attacks the plants when young, the midew, and the rust.

Subsect. 2. Hemp. - Cunnabis sativa L.; Diw'cia Pentandria L., and Urticea J. Chanvre, Fr.; Hanf, Ger.; Canapa, Ital.; and Canomo, Span. 92

5922. The hemp is a plant of equal antiquity with the flax. It is supposed to be a native of India, or of some other Asiatic country, being too tender to be even naturalised in Europe. It is one of the few plants employed in British agriculture in which the male and female flowers are in different plants, a circumstance which has some influence on its culture and management. It grows to a great height on good soils; sometimes to six or seven feet in this country, but in Italy generally higher; and Crud states, that in the Bolognese territory he has seen it fifteen feet eight inches high, and a friend of his eighteen feet six inches: in both cases the fibre being of remarkable beauty. This luxuriance of the hemp in warm countries may be one reason why it has never been much cultivated in England. In the Isle of Axholme, in Lincolnshire, it has been cultivated from time immemorial, and also for some centuries in Suffolk, but chiefly for local manufacture. The culture, management, and uses of hemp are nearly the same as those of flax. When grown for seed, it is a very exhausting crop; but when pulled green, it is considered a cleaner of the ground, and is said to have the property of preserving from insects any crop which it may surround. The objections to this crop are, that its coming in the midst of harvest is embarrassing; and that the attention it demands in every state of its progress is too great, where it is only a secondary consideration.

5923. The soils most suitable for hemp are those of the deep black putrid vegetable kind, which have a situation low and somewhat inclined to moisture, as well as the deep mellow loamy or sandy sorts. But the quantity of produce is in general much greater on the former than the latter; though, according to some, of an inferior quality. Mellow

rich clayey loams do well; and nothing better than old meadow land.

5924. The preparation of the soil, and the place in the rotation, are the same as for flax. 5925. The season of sowing is towards the end of April, when there is no longer any danger of frost injuring the rising plants. The quantity of seed is from two to three bushels, according to the quality of the land. In quality the seed must be fresh, heavy, and bright in colour. Broad-cast is the universal mode of sowing; and the only afterculture consists in keeping off birds when it is coming up; in weeding; and sometimes in supporting the crop by cross rods or lines, as in the case of flax.

5926. In taking the hemp crop, two methods are in use, according to the object in view. When the crop is grown entirely for the fibre, it is pulled when in flower, and no distinction made between the male and female plants. But as it is most commonly grown both with a view to fibre and seed, the usual practice is to pull the male plants as soon as the setting of the seed in the females shows that they have effected their purpose. the female plants require four or five weeks to ripen their seeds, the males are thus pulled

so long before them.

5927. In the operation of pulling the males, the pullers walk in the furrows between the ridges, and reach across to the crown of the ridge, pulling one or two stalks at a time, and carefully avoiding to tread down the female plants. The male stalks are easily known by their yellowish hue and faded flowers. They are tied in small bundles, and immediately carried to the watering pool, in the manner of flax.

5928. The operation of pulling the females commences when the seed is ripe, which is known by the brownish or grevish hue of the capsules and the fading of the leaves. The stalks are then pulled and bound up into bundles, being set up in the same manner as grain, until the seed becomes so dry and firm as to shed freely; great care should be taken in pulling not to shake the stalks rashly, otherwise much of the seed may be lost. It is advised that, after pulling the seed, hemp may be set to stand in shocks of five sheaves, to dry the seed; but, in order to prevent any delay in watering, the seed-pods may be cut off with a chopping-knife, and dried on canvass exposed to the air under some shed or cover. This last method of drying the seed will prove of great advantage to the hemp, as the seed and pods, when green, are of such a gummy nature that the stems might suffer much by sun-burning or rain, which will discolour and injure the hemp before the seed can be sufficiently dried upon the stalks. Besides, the threshing out the seed would damage the hemp in a considerable degree.

5929. Hemp is watered (provin. water-retted), bleached (provin. dew-retted), and grassed in the same manner as flax. Grassing is omitted in some places, and drying substituted; and in other districts watering is omitted with the female crop, which is dried and stacked, and dewed or bleached the following spring. On the Continent hot water and green soap have been tried; and here, as in the case of flax, it is found that steeping for two hours in this mixture is as effectual in separating the fibre from the woody matter, as watering and grassing for weeks.

5930. Although hemp, in the process of manufacturing, passes through the hands of the breaker, heckler, spinner, whitester, weaver, and bleacher, yet many of these operations are frequently carried on by the same person. Some weavers bleach their own yarn and cloth; others their cloth only: some heckle their tow, and put it out to spinning; others buy the tow, and put it out to spinning; others buy the tow, and put it out; and some carry on the whole of the trade themselves.

5931. The produce of hemp in fibre varies from three to six cwt. per acre; in seed from eleven to twelve bushels.

5932. The uses of hemp are well known, as well as its great importance to the navy for sails and cordage.

15933 Exceedingly good inchaback is made from it, for towels and common table cloths. The low priced hempen cloths are a general wear for husbandmen, servants, and labouring manufacturers, the letter sorts for working farmers and tradesmen in the country; and the finer ones, seven-eighths wide, are pre-

ferred by some gentlemen for strength and warmth. They possess this advantage over Irish and other linens, that their colour improves in wearing, while that of linen declines. English hemp, properly manufactured, stands unrivalled in its strength, and is superior in this respect to the Russian. Considerable quantities of cloth are imported from Russia for sheeting, merely on account of its strength; for it is coarser at the price than linen: our hempen cloth, however, is preferable; being stronger, from the superior quality of the thread, and at the same time lighter in washing. The hemp raised in England is not of so dry and spongy a nature as what we have from Russia and India, and therefore it requires a smaller proportion of tar to manufacture it into cordage. Tar being cheaper than hemp, the rope-makers prefer foreign hemp to ours; because they can make a greater profit in working it: but cordage must certainly be stronger in proportion as there is more hemp and less tar in it, provided there is a sufficient quantity of the latter to unite the fibres. An oil extracted from the seeds of hemp is used in cookery in Russia, and by painters in this country. The seeds themselves are reckoned a good food for poultry, and are supposed to occasion hens to lay a greater quantity of eggs. Small birds in general are very fond of them; but they should be given to caged birds with caution, and mixed with other seeds. A very singular effect is recorded, on very good authority, to have been sometimes produced by feeding bullfinches and goldfinches on hempseed alone, or in too great quantity, — that of changing the red and yellow on those birds to a total blackness.

5934. The hemp has few or no diseases.

Subsect. 3. The Fuller's Thistle, or Teasel. - Dipsacus fullonum L.; Tetrándria Monogýnia L., and Dipsaceæ J. Chardon à foullon, Fr.; Kardendistel, Ger.; Dissaco, Ital.; and Cardencha, Span. (fig. 799.)

5935. The fuller's thistle is an herbaceous biennial, growing from four to six feet high; prickly or rough in the stem and leaves, and terminated by rough burr-like heads of flowers. It is a native of Britain, flowers in July, and ripens its seed in September. It is cultivated in Essex and the west of England, for raising the nap upon woollen cloths by means of the crooked awns or chaffs upon the heads; which, in the wild sort, are said to be less hooked. For this purpose they are fixed round the circumference of a cylinder, which is made to turn round, and the cloth is held against them. In the Journal of a Naturalist we are informed, that the teasel forms an article of culture in cottage gardens in the clothing districts of Gloucestershire.

5936. There are no varieties of the cultivated teasel, and the wild species is not materially different from it, and may be used in its stead, though its chaff is not quite so rigid.

> 5937. The soils on which the teasel grows strongest are deep loamy clays, not over-rich. The situation should be rather elevated, airy, and exposed to the south. In a rotation it may occupy the place of a green and corn crop, as in the first year the plants are treated like turnips, and in the second the crop is ripened. The soil should be ploughed deep, and well comminuted by cross-ploughings, or stirrings with pronged implements, as the cultivator.

> 5938. The sowing season is the beginning of April: the quantity of seed is from one peck to two pecks per acre, and in quality it should be fresh and plump.

> 5939. The mode of sowing is almost always broad-cast, but no crop is better adapted for being grown in drills, as the plants require hoeing and thinning. The drills may be either sown on ridgelets or a flat surface, in the manner of turnips, or by ribbing. The distance between the rows may be from eighteen inches to two feet. In Essex, caraway is commonly sown with the teasel-crop; but this is reckoned a bad plan.

> 5940. The after-culture of this crop consists the first year in hoeing and stirring the soil, and in thinning out the

plants to the distance of one foot every way, if sown broad-cast, or to the distance of six Vacancies may be filled up by transplanting; and a separate inches if sown in rows. plantation may be made with the thinnings, but these never attain the same vigour as the seedlings. The culture in the second year consists also of hoeing, stirring, and weeding, till the plants begin to shoot.

5941. When the teasel is grown broad-cast, the intervals between the plants are dug by means of spades which have long narrow blades, not more than about four inches in breadth, having the length of sixteen or eighteen inches. With these the land is usually worked over in the intervals of the plants three or four or eighteen inches. With these the land is usually worked over in the intervals of the plants three or four times during the summer months; and in the course of the following winter, as about the latter end of February, the land between the plants is to be again worked over by the narrow spades, care being taken that none of the mould falls into the hearts of the plants. Again about the middle of May, when they begin to spindle, another digging over is given, the earth being raised round the root-stems of the plants, in order to support and prevent them from being blown down by the wind. Some cultivators perform more frequent diggings, that the ground may be rendered cleaner and more mellow; consequently the growth of the plants will be the more effectually promoted. This business, in Essex, has usually the name of spaddling, and is executed with great despatch by labourers accustomed to perform it.

The taking of the teasel crop, when no regard is had for seed, commences about the middle of July, when the blossoms begin to fall from the top, or terminating heads of flowers.

5943. It is the best method to have the heads cut as they become ripe; but the work is mostly executed at three times, at the distance of about ten days or a fortnight from each other. It is performed by means of a knife, contrived for the purpose, with a short blade and a string attached to halt. This last is done in order that it may be hung over the hand. A pair of strong gloves is likewise necessary. Thus prepared,

the labourer cuts off the ripe heads along the rows or lines with about nine inches of stem, and ties them up in handfuls with the stem of one that is more perfectly ripened. On the evening of the day on which they are cut, they should be put into a dry shed; and when the weather is fine and the air clear, they should be taken out and exposed to the sun daily till they become perfectly dry. Much care must, however, be taken that no rain falls upon them. In doing this, some make use of long small stakes or poles, on which these handfuls are hung during the time of their preparation.

5944. As soon as they are completely dried, they should be laid up in a dry room, in a close manner, till they become tough and of a bright colour, and ready for use. They should then be sorted or separated into three kinsks, by opening each of the small bundles. These are distinguished into kings, middlings, and scrubs, according to their different qualities. They are afterwards, the author of The Somerset Report says, made into packs, which, of the first sort, contain nine thousand heads, but when of the second, twenty thousand; the third is a sort of very inferior value. By some, before forming them into packs, they are done up into what are termed staves, by means of split sticks, when they are ready for sale,

1945. The produce of teasel varies from ten to fifteen packs on the acre; nine packs of kings, nineteen of middlings, and two of scrubs, are reckoned a large crop, with a

great bulk of haulm. Often, however, the crop fails.

5946. The use of the heads of the teasel has been already mentioned. The haulm is of no use but for burning as manure. Parkinson observes, that this is a sort of crop that may be grown to advantage on many lands, in a rotation, as a fallow to prepare for wheat; and by burning the straw and refuse stuff after the crop is reaped, it will be found not to impoverish, but rather to improve the land. In their young state, the teasel plants stand the winter without danger; and are a good crop for clearing land of all weeds, from their lateness in the process of hoeing, their being few weeds that vegetate at so On all these accounts they become an advantageous crop for the advanced a season.

5947. To save seed, leave a few of the very best plants uncropped, and then, when the seed is ripe, cut off only the largest and terminating heads, from which the seed is easily separated by beating with flails, and cleaned by the winnowing machine, or a sieve.

5948. The chief injuries to which the teasel is liable are those inflicted on it while young, by the fly and slug.

Madder. — Rùbia tinctòrum L.; Tetrándria Monogýnia L., and Rubiàceæ J. Garance, Fr.; Färberröthe, Ger.; Robia, Ital.; and Rubia, Span. (fig. 800.)

5949. The dyer's madder has a perennial root, and an annual stalk. The root is com-

posed of many long, thick, succulent fibres, almost as large as a man's little finger; these are joined at the top in a head, like the roots of asparagus, and strike very deep into the ground, being sometimes more than three feet in length. From the upper part (or head of the root) come out many side roots, which extend just under the surface of the ground to a great distance, whereby it propagates very fast; for these send up a great number of shoots, which, if carefully taken off in the spring soon after they are above ground, become so many plants. It is a native of the south of Europe, flowers in June, and seeds soon afterwards; but by them it is never propagated. Madder is mentioned by the Greeks as a medical plant, but when it was first used in dyeing is uncertain. It has been cultivated in Holland and Flanders, and other parts of the Continent, for the latter purpose for many centuries, and has been tried in this country; but unless the importation of the root from the Continent be entirely prevented, it will not answer. culture has been attempted at different times when our

commerce with the Dutch was interrupted, or when they raised the price of the article exorbitantly high. At present it may be imported not only from Holland, but from

France, Italy, and Turkey.

5950. The soils most suited to the cultivation of madder are deep, fertile, sandy loams, not retentive of moisture, and having a considerable portion of vegetable matter in their It may also be grown on the more light descriptions of soil, of sufficient composition. depth, and in a proper state of fertility.

5951. The preparation of the soil may either consist in trench ploughings, lengthwise and across, with pronged stirrings, so as to bring it to a fine tilth; or, what will often be

found preferable, by one trenching two feet deep by manual labour.

5952. The sets or plants are best obtained from the runners, or surface-roots of the old These being taken up, are to be cut into lengths of from six to twelve inches, according to the scarcity or abundance of runners. Sets of one inch will grow if they have an eye or bud, and some fibres; but their progress will be injuriously slow for want of maternal nourishment. Sets may also be procured by sowing the seeds in fine light earth a year before they are wanted, and then transplanting them; or sets of an inch may be planted one year in a garden, and then removed to the field plantation.

in rows nine or ten inches asunder, and five or six inches apart in the rows. Some plant promiscuously in beds with intervals between, out of which earth is thrown in the lazybed manner of growing potatoes; but this is unnecessary, as it is not the surface, but the

descending, roots which are used by the dyer.

5954. The operation of planting is generally performed by the dibber, but some leveral plant them by the aid of the plough. By this mode the ground is ploughed over with a shallow furrow, and in the course of the operation the sets are deposited in each furrow, leaning on and pressed against the furrow-slice. This, however, is a bad mode, as there is no opportunity of firming the plants at the roots, and as some of the sets are apt to be buried, and others not sufficiently covered of the set of the sets are apt to be buried, and others not sufficiently covered.

5955. The after-culture consists in hoeing and weeding with stirring by pronged hoes, either of the horse or hand kind. Some earth up, but this is unnecessary, and even in-

jurious, as tearing the surface-roots, and than the surface worth worth a view of

ho5956. The madder-crop is taken at the end of the third autumn after planting, and generally in the month of October. By far the best mode is that of trenching over the ground, which not only clears it effectually, but fits it at once for another crop. Where madder, however, has been grown on land prepared by the plough, that implement may be used in removing it. Previously to trenching, the haulm may be cleared off with an old scythe, and carted to the farmery to be used as litter to spread in the straw-yards.

105957... Drying the roots is the next process, and, in very fine seasons, may sometimes be effected on the soil, by simply spreading the plants as they are taken up; but in most seasons, they require to be dried on a kiln, like that used for malt or hops. They are dried till they become brittle, and then packed up in bags for sale to the dyer.

5958. The produce from the root of this plant is different according to the difference of the soil, but mostly from ten to fifteen or twenty hundred weight where they are suit-

able to its cultivation, no re befred read more

5959. In judging of the quality of madder-roots, the best is that which, on being broken in two, has a brightish red or purplish appearance, without any yellow cast being exhibited.

5960. The use of madder-roots is chiefly in dyeing and calico-printing. The haulm which accumulates on the surface of the field, in the course of three years, may be carted to the farm-yard, and fermented along with horse-dung. It has the singular property of dyeing the horns of the animals who eat it of a red colour.

5961. Madder-seed in abundance may be collected from the plants in the September

of the second and third years; but it is never so propagated,

5962. Madder is sometimes blighted; but in general it has few diseases.

Subsect. 5. Wood. — Isatis tinctoria L.; Tetradynamia Siliquosa L., and Cruciferæ J. Pastel or Guede, Fr.; Waid, Ger.; Guade, Ital.; and Gualda, Span. (fig. 801.)

England, flowers from May to July, and its seeds are ripe 80125 of vertom July to September. It has been cultivated in France 19 to 19 for an unknown length of time; and was introduced to much England in 1582, and grown with success. 18 It is now 19 for the purpose of growing it for two or four years, at a high price, 19 for the purpose of growing it for two or four years, 19 for the purpose of growing it for two or four years, 19 for the purpose of growing it for two or four years, 19 for the colony, and move from place to place as they complete their engagements. 11 It is sometimes, however, grown by 19 stationary farmers, 19 The leaves are the parts of the plant used, and it is considered a severe crop.

J 5964. There is a variety of wood called the Dalmatian, described by Miller, and also a wild sort; but only the

common is cultivated in this country.

fresh, such as those of the rich, mellow, loamy, and deep, vegetable kind. Where this culture is carried to a considerable degree of perfection, as in Lincolnshire, the deep,

rich, putrid, alluvial soils on the flat tracts extending upon the borders of the large rivers, are chiefly employed for the growth of this sort of crop; and it has been shown by repeated trials that it answers most perfectly when they are broken up for it immediately from a state of sward.

5966. The preparation of the soil, when woad is to be grown on grass land, may either be effected by deep ploughings, with the aid of the winter's frost, cross ploughing and

harrowing in spring; by deep ploughing and harrowing in spring; by paring and burning; or by trench-ploughing, or spade trenching;

5967. The first mode appears the worst, as it is next to impossible to reduce old turf in one year, and, even if this is done, the danger from the grub and wire worm is a sufficient argument against at. By ploughing deep in February, and soon afterwards sowing, the plants may germinate before the grub is able to rise to the surface; by trench-ploughing, the same purpose will be better attained; and, best of all, by spade trenching. But a method equally effectual with the first, more expeditions, and more destructive to grubs, insects, and other vermin, which are apt to feed on the plants in their early growth, is that of paring and burning. This is, however, chiefly practised where the sward is rough and abounds with rushes, sedge, and other plants of the coarse kind, but it might be had recourse to on others, with benefit.

9.5968. The time of sowing may be extended from February to July. Early sowing, however, is to be preferred, as in that case the plants come up stronger and afford more produce the first season.

5969. The mode of sowing is generally broad-cast, but the plant might be most advantageously grown in rows and cultivated with the horse-hoe. The rows may be nine inches or a foot apart, and the seed deposited two inches deep. The quantity of seed for the broad-cast method is five or six pounds to the acre; for the drill mode, two pounds are more than sufficient, the seed being smaller than that of the turnip. New seed, where it can be procured, should always be sown in preference to old; but, when of the latter kind, it should be steeped for some time before it is put into the ground.

5970. The after-culture of the woad consists in hoeing, thinning, prong-stirring, and weeding, which operations may be practised by hand or horse tools, as in the culture of

5971. Gathering the crops. The leaves of the spring-sown plants will generally be ready towards the latter end of June or beginning of July, according to the nature of the soil, season, and climate; the leaves of those put in at a later period in the summer are often fit to be gathered earlier. This business should, however, constantly be executed as soon as the leaves are fully grown, while they retain their perfect green colour and are highly succulent; as when they are let remain till they begin to turn pale, much of their goodness is said to be expended, and they become less in quantity, and of an inferior quality for the purposes of the dyer.

5979. In the execution of this sort of business, a number of baskets are usually provided in proportion to the extent of the crop, and into these the leaves are thrown as they are taken from the plants. The leaves are detached from the plants, by grasping them firmly with the hand, and giving them a sort of a sudden twist. In favourable seasons, where the soils are rich, the plants will often rise to the height of eight or ten inches; but in other circumstances, they seldom attain more than four or five; and where the lands are well managed they will often afford two or three gatherings, but the best cultivators seldom take more than two, which are sometimes mixed together in the manufacturing. It is necessary that the after-croppings, when they are taken, should be constantly kept separate from the others, as they would injure the whole if blended, and considerably diminish the value of the produce. It is said that the best method, where a third cropping is either wholly or partially made, is to keep it separate, forming it into an inferior kind of woad.

5973. The produce is mostly from about a ton to a ton and a half of green leaves. The price varies considerably; but for woad of the prime quality, it is often from twenty-five to thirty pounds the ton, and for that of an inferior quality six or seven, and sometimes much more.

5974. To prepare it for the dyer, it is bruised by machinery to express the watery part; it is afterwards formed into balls and fermented, re-ground, and fermented in vats, where it is evaporated into cakes in the manner of indigo. The haulm is burned for manure or spread over the straw-yard, to be fermented along with straw-dung.

.95975. The use of woad in dyeing is as a basis for the black and other colours.

.. 5976. To save seed, leave some of the plants undenuded of their leaves the second year, and when it is ripe, in July or August, treat it like turnip-seed.

5577. The only diseases to which the woad is liable are the mildew and rust. When young it is often attacked by the fly, and the ground obliged to be re-sown, and this more than once even on winter-ploughed grass lands.

Subsect, 6. Weid, or Dyer's Weed. — Reseda Luteola L.; Dodecandria Trigima L., and and Resedacea Lindl. Gaude, Fr.; Waud, Ger. (fig. 802.)

5978. Weld is an imperfect biennial, with small fusiform roots, and a leafy stem from one to three feet in height. It is a native of Britain, flowers in June and July, and ripens its seeds in August and September. It is cultivated in a few places in England, and chiefly in Essex, for its spike of flowers, and sometimes also for its leaves, both of which are used in dyeing. Its culture may be considered the same as that of woad, only being a smaller plant it is not thinned out to so great a distance... It has this advantage for the farmer over all other colouring plants, that it only requires to be taken up and dried, when it is fit for the dyer. It is, however, an exhausting crop.

5979. Weld will grow on any soil, but fertile loams produce the best crops. In Essex,

it is grown on a stiff loam, moderately moist.

5980. The soil being brought to a fine tilth, the seed is sown in April or the beginning of May, generally broad-cast. The quantity of seed is from two quarts to a gallon per acre, and it should either be fresh, or, if two or three years old, steeped a few days in water previously to being sown. Being a biennial, and no advantage obtained from it the first year, it is sometimes sown with one advantage obtained from it the first year, it is sometimes sown with the prince of the property of the transparence of the property
5981. The crop is taken by pulling up the entire plant: and the proper period for this purpose is when the bloom has been produced the whole length of the stems, and the plants are just beginning to turn of a light or yellowish colour; as in the beginning or middle of July in the second year. The plants are usually from one foot to two feet and a half in height. It is thought by some advantageous to pull it rather early, without waiting for the ripening of the seeds; as by this means there will not only be the

greatest proportion of dye, but the land will be left at liberty for the reception of a crop of wheat or turnips; in this case, a small part must be left solely for the purpose of

5982. In the execution of the work, the plants are drawn up by the roots in small handfuls; and, after each handful had been tied up with one of the stalks, they are set up in fours in an erect position, and left to dry. Sometimes, however, they become sufficiently dry by turning without being set up. After they have remained till fully dry, which is mostly effected in the course of a week or two, they are bound up into larger bundles, each containing sixty handfuls, and weighing fifty-six pounds. Sixty of these bundles constitute a load, and, in places where this kind of crop is much grown, are tied up by a string made for the purpose, which is sold under the title of weld cord.

5983. The produce of weld depends much on the nature of the season; but from half a load to a load and a half per acre is the quantity most commonly afforded. It is usually sold to the dyers at from five or six to ten or twelve pounds the load, and sometimes at considerably more. It is mostly bought by persons who afterwards dispose of it to the dyers. The demand for it is sometimes very little, while at others it is so great as to raise the price to a high degree. It is sometimes gathered green and treated like woad or indigo; but in general the dried herb is used by the dyers in a state of decoction.

5984. The use of weld in dyeing is for giving a yellow colour to cotton, woollen, mohair, silk, and linen. Blue cloths are dipped in a decoction of it, which renders them green; and the yellow colour of the paint called Dutch pink is obtained from weld.

5985. To save seed, select a few of the largest and healthiest plants, and leave them to

The seed is easily separated.

5986. The chief disease of weld is the mildew, to which it is very liable when young, and this is one reason that it is often sown with other crops.

Subsect. 7. Bastard Saffron. - Carthamus tinctòrius L.; Syngenèsia Polygàmia Æqualis L., and Cynarocephalæ J. Carthame, Fr.; Wilder Safran, Ger. (fig. 140. p 174.)

5987. The bastard saffron is an annual plant, which rises with a stiff ligneous stalk, two feet and a half or three feet high, dividing upwards into many branches, with ovate pointed sessile leaves. The flowers grow singly at the extremity of each branch; the heads are large, enclosed in a scaly calyx; each scale is broad at the base, flat, and formed like a leaf of the plant, terminating in a sharp spine. The lower part of the calyx spreads open, but the scales above closely embrace the florets, which stand out nearly an inch above the calyx; these are of a fine saffron colour, and this is the part which is gathered for the use of the dyer.

5988. It grows naturally in Egypt and some of the warm parts of Asia; but, being an annual, our summers admit of its going through a course of existence in this country. Sown in April, it flowers in July and August, and the seeds ripen in autumn; but if the season proves cold and moist, when the plants are in flower, there will be no good seeds produced; so that there are few seasons wherein the seeds of this plant come to perfection in England.

5989. It is cultivated in great plenty in Germany, and was formerly grown in England. In Houghton's Collections, it is related by a gentleman, in 1683, that twenty-five acres in the Vale of Evesham, in Gloucestershire, were sown with this seed; the soil a mixed sand of about fifteen shillings an acre in value; it bore a crop of wheat the year before, was dressed for barley, and had a harrowing extraordinary. This piece of ground was taken for two years by an adventurer in this seed, at the rate of twenty-five pounds per acre, in consideration that this plant is said to be a great impoverisher of land. He sold the flowers in London for 10t per pound; a price, he said, much below his expectation. He gained above thirty shillings an acre clear profit, except the price of the seed; but of this there was a plentiful return about one hundred and forty bushels), which, had it been well managed, would have amounted to a considerable value. Like

most other manufactorial plants it is considered an impoverisher of the ground; both by exhausting it, and by affording but little haulm as manure.

5990. The soil it requires is light, and the preparation and culture, according to Von Thaer, equal to that of the garden. The seed is sown in rows, or deposited in patches two feet apart every way, and when the plants come up, they are thinned out, so as to leave only two or three together. The soil is stirred and weeded during summer. In August the flowers begin to expand: the petals of the florets are then to be cut off with a blunt knife, and dried in the shade, or on a kiln, like the true saffron. This operation is performed in the early part of the day, and continued daily till October. The plants are then pulled up, sheaved and shocked, and threshed for their seed.

5991. The use of the flower of bastard saffron is chiefly in dyeing. It is also put in soups, pies, and puddings, like the leaves of the marigold or the common saffron. The oil produced from the seed is used both in medicine and painting. The stalks of the plants

are commonly burnt for manure.

Subsect. 8. Various Plants which have been proposed as Substitutes for the Thread and dyeing Plants grown in Britain.

5992. Though few of these are likely to come into cultivation, yet it may be useful to notice them, with a view to indicating our resources for extraordinary occasions; to leading the young cultivator to reflect on the richness of that immense store-house, the vegetable kingdom; and to pointing out sources of experiment and research for the amateur agriculturist. Every kind of limitation has a tendency to degrade the mind, and lessen enterprise. The plants to be here enumerated, naturally arrange themselves as thread plants and colouring plants.

thread plants and colouring plants.

5993. The thread plants that have been tried are the Asclèpias syrlaca, Urtlca diofca (or nettle), Urtlca canadeuse (or Canadian nettle), the Spàrtium júnceum, and Cytisus scopàrius (brooms), Epilibium angustifolium, Eric'phorum polystachyon, &c. The Asclèpias syrlaca, Syrian swallow-wort, or Virginian silk, is a creeping rooted perennial, with strong erect stems from four to six feet high. It is a native of Virginia, and flowers in July. The flowers are succeeded by pods, containing a down or cotton, which the poor people in Virginia collect and fill their beds with. In Germany, and especially at Leignitz, attempts were made, in 1750 and 1800, Von Thaer informs us, to cultivate the plant as a substitute for cotton. It was found to grow readily on a poor soil; but the growers could not undersell the importers, nor produce so good an article. The Erichorum polystachyon, or cotton grass, grows abundantly in our bogs, and its seeds are furnished with a cottony substance, gathered by the country people to stuff pillows, &c. This substance has been spun and woven into very good cloth. The common nettle affords a fibre which has also been spun and manufactured. The fibre of the Spártium júnceum, rush like, or Spenish broom, a native of the south of Europe, but quite hardy in Britain, is made into very good cloth both in the south of France and in Spain. The fibre of the common broom makes an inferior description of cordage in the former country. The Epilöbium angustifolium, and other species of willow herb, common by the sides of brooks, afford a very good fibre, as do a great variety of plants; and in Sweden a strong cloth is made from the stems of the wild hop (Hamulus Lòpulus), and the same thing has been done in England. (Trans. Soc. Arts. 1791.) Indeed there are few plants the fibres of which might not be separated and rendered available for the purpose of spinning threads for weaving into cloth, or of mashing for making paper. The fibres and bark of several plants, for the l

5994. Broom flax is prepared by steeping the twigs or most vigorous shoots of the former year, for two or three weeks, more or by boiling them for about an hour in water. This dome, the flax comes treely from the twigs; and, where there is not machinery for the purpose, may be easily peeled or stripled off; by children or others, at any time when not quite dry, in the same way as hemp is peeled from the stalks. Being cleared of the

flax, and steeped for some time in boiling water, the twig, or wood, becomes tough and beautifully white, and is worth, at a making early browns, &c. When stripped from the twigs, the flax requires only to be well washed in cold water, then wrung and shaken well, and hung out to dry, previously to its being sent off to the paper manufacturers. (Smith's Mechanic, vol. ii.)

5995. Of colouring plants, the number that may be, and even are employed, is almost endless. The reader has only to look into any botanical catalogue, and observe the number of plants whose specific names are formed from the adjective tinetbrius; and these, though numerous, are still only a small part. On looking into the Flòra Británnica, or Flòra Suécica, he will there find a number of plants, trees, and even mosses and ferns used for dyeing. A number have been tried in this country and given up; as an instance, we mention Gàlium vèrum, which, in 1789, when the price of made er was high, was tried under the authority of the privy council for trade. The Cròton tinctòrium, Genista tinctòria, Ithámnus cathárticus and infectòrius, and Plantàgo Psyllium, are cultivated in France as dyeing plants.

SECT. II. Plants cultivated for the Brewery and Distillery.

5996. Of plants grown expressly for their use in the brewery, the only one of consequence is the hop; the anise and caraway are grown on a very limited scale for the distillery.

Subsect 1. The Hop. - Humulus, Lupulus L.; Diacia Pentandria L., and Urticea J. s be Houblon, Fr.; Hoppen, Ger.; Lupolo, Ital.; and Lupulo, Span. (fig. 803.)

5997. The hop is a perennial-rooted plant, with an annual twining stem, which, on poles or in hedges, will reach the height of from twelve to twenty feet or more. It is a native of Britain, and most parts of Europe, in hedges, flowering in June, and ripening its seeds in September, The female blossom is the part used; and as the male and female flowers are on different plants, the female only is cultivated.

the female only is cultivated.

5998. When the hop was first used for preserving beer, or cultivated for that purpose, is unknown; but its culture was introduced to this country from Flanders in the reign of Henry VIII. Water Blith, in his English Improver. Improved, 1699, the third edition, 1653, p. 240, has a chapter upon improvement by plantations of hops, &c. He observes, that "hops were then grown to be a national commodity: but that it was not many years since the famous eity of London petitioned the parliament of England against two anusancies; and these were Newcastle coals, in regard to their stench, &c. and hops, in regard they would spoyl the taste of drink, and endanger the people; and had the parliament heen no wiser than they, we had been in a measure pined, and in a great measure starved, which is just answerable to the principles of those men who ery down all devices or ingenious discoveries as projects, and thereby stifle and choke improvements."

choke improvements."

choke improvements,"
5999. The hop has long been cultivated extensively in many parts of England, but not much in Scotland or Ireland. According to Brown, hops are not advantageous in an agricultural point of view, because much manure is abstracted by them, while little or none is returned. They are an uncertain article of growth, often yielding large profits to the cultivator, and as often making an imperfect return, barely sufficient to defray the expenses of labour. In fact, hops are exposed to more diseases than any other plant with which we are acquainted; and the trade affords a greater room for speciation, than any other exercised within the British dominions. (Brown.) Parkinson in a paper on the culture of the hop in Nottinghamshire, published in the Farm. Mag. vol. xvi., observes that, "the hop is said to be a plant very properly named, as there is never any certainty in cultivating it."

6000, There are several varieties of the hop. The writer of The Synopsis of Husbandry distinguishes them under the titles of the Flemish, the Canterbury, the Goldings, the Farnham, &c., and says that the Flemish is held in the lowest estimation of any.

9 6001: The Flemish hop, he says, is of a smaller size, of a much closer contexture, and of a darker green colour, that may of the rest, and grows on a red bind; and has so near an affinity, the wild or hedge, lop, that it would never answer for cultivation, did it not possess the property of resisting the blast with greater vigour than the other kinds; so that, in vears when these last are covered with flies and liee; the Flenish hop appears strong and healthy. At picking time, likewise, this kind of hop, he says, takes less damage, either by the sun or rain, than any other; and upon these accounts, it may answer the wiews of the planter to have a few acres of it, which will secure him a crop in a blasting season, when those of the more valuable class are destroyed, so as to be worth nothing.

6002. The soils most favourable to the growth of hops are clays and strong deep loams: but it is also of great importance that the subsoil should be dry and friable; a cold, wet, tenaceous, clayey understratum being found extremely injurious to the roots of the plants, as, when they penetrate below the good soil, they soon become unproductive, and ultimately decay.

15 food. A chalky soil, Bannister says, is, of all others, the most inimical to the growth of this vegetable; the reason of which he takes to be the dry and parching quality of the chalk, by which the roots are prevented from absorbing a quantity of moisture, equal to the stipply to the vine or bind with say during its growth; for though a dripping summer is by no means kindly to the welfare of the hop, yet since the vine in a healthy state is very luxuriant, and furnished with a large abundance of branches, leaves, fruit, &c., it follows that the demand of moisture from the soil must be proportionably great to preserve the plant in health and vigour; and for this reason the ground ought not to be deficient in natural humidity. Hence we generally find the most luxuriant vine growing on deep and rich land, as moulds, &c.; and in these grounds it is common, he says, to grow a load on an acre. But it is to be observed, however, that the abundance of fruit is not always in proportion to the length of the vines; since those soils which, from their fertility, cause a large growth of vine are more frequently attacked by the blast, than land of a shallower staple, where the vine is weaker and less tuxuriant.

6004. But though rich, moulds generally produce a larger growth of hops than other soils, there is one

stable, where the vine is weaker and less luxuriant; and the content of the plant, than other soils, there is one stable, where the vine is weaker and less luxuriant; and the stable produce a larger growth of hops than other soils, there is one exception to this rule, where the growth is frequently eighteen or twenty hundred per acre. This is on the rocks in the neighbourhood of Maidstone, in Kent, a kind of slaty ground, with an understratum of stone. On these rocks there is a large extent of hop-garden, where the vines run up to the tops of the longest poles, and the increase is equal to that on the most fertile soil of any kind.

6005. The most desirable situation for a hop plantation is ground sloping gently towards the south of south-west, and screened, by means of high grounds or forest-trees, from the north and north-east. At the same time it ought not to be so confined as to prevent that free circulation of air which is indispensably necessary where plants grow so close together, and to such a height. A free circulation of air, in a hop-ground, not only conduces to the health and vigour of the plants, but also prevents the crops from being blighted, or what the hop-farmers call fire-blasted, which often happens towards the middle of a large close-planted hop-ground; while the outsides, in consequence of the more free circulation of air that there takes place, receive no injury whatever. It is a strong the mids of the sea, or in the neighbourhood of marshy or fenny levels, are seldom favourable to the growth of hops, as such grounds generally miscarry in a blasting year; and though, from the fertility of the soil, they may perhaps bring a plentfull crop; in those seasons when the growth is generally grown between the rows of fruit trees in due or ploughed orchards-old to gain and the definition of the plants of the provided or plants of the plants of the plants of the plants.

et this either by the paring or clearbrador, One going and remrit river

6007. In preparing the soil previously to planting, considerable attention is necessary, by fallowing, or otherwise, to destroy the weeds, and to reduce the soil to as pulverised a state as possible. The ridges should also be made level, and dung applied with a liberal The most effectual preparation is trenching either by the plough or by manual labour.

6008. The mode of planting is generally in rows, making the hills six feet distant from each other; though there are some people who, from avaricious motives, prefer a five-feet plant." But as this vegetable, when advanced in growth, produces a large redundancy of bind or vine, and leaves, it should seem that six feet cannot be too wide a distance; and that those which are planted closer will, from too confined a situation, be prevented from enjoying a free circulation of the air; from which much injury may proceed, as blasts, mildews, moulds, and other accidents, not to mention the disposition of the vine to house or grow together at the tops of the poles, whereby the hops are so overshadowed as to be debarred the influence of the sun, and prevented from arriving at half their growth.

6009. As the planters differ in the number of hills to be made on the same given quantity of land, so are they no less capricious as to the manner of placing them; some choosing to set them out with the most cautious regularity in rows of equal distances, whilst others prefer planting in quincumx. The former method has this advantage; that the intervals may, in the carly part of the summer, be kept clean by means of the cultivator and harrow; but, in the latter method, these implements are rendered inadmissible by the irregular station of the plants; and the ground must be tilled with the hoe at a greatly increased expense, as the same labour might be performed to as much advantage with one horse; a man, and a boy, who will do more work in a day than half a dozen labourers can with a hoe.

6010. The ordinary season for planting is spring, in February or March; but if bedded plants, or such as have been nursed for one summer in a garden, are used, then by planting in autumn some produce may be had in the succeeding year. But, according to the author of The New Farmer's Calendar, "the time for planting is commonly that of dressing and pruning the old vines when cuttings may be had, which is in March or April; but when root-sets are used, as on the occasion of grubbing up an old plantation, October to the beginning of November. But at whatever period they are planted, great care should be taken that the same sorts be planted together, as by this means there are advantages derived in their after-culture."

6011. The plants or cuttings are procured from the old stools, and each should have two joints or eyes; from the one which is placed in the ground springs the root; and from the other the stalk, provincially the bind. They should be made from the most healthy and strong binds, each being cut to the length of five or six inches. Those to be nursed are planted in rows a foot apart, and six inches asunder, in a garden; and the others at once where they are to remain.

6012. The mode of performing the operation of planting in Kent is as follows: -

6013. The land having been previously cleaned and prepared, dung is laid on the field in small heaps near the places where it is proposed to plant the hop slips or sets. These places are commonly marked off, by infixing a number of stakes at proper and regular distances; that done, small pits are formed by taking out a spit, or spade's depth of earth; and the earth below being gently loosened, certain quantity, about half a bushel, of dung is laid, thereon; then the earth that was formerly taken out is again replaced, and so much added as to form a small hillock. On this hillock, five, six, or seven sets, procured from the roots or shoots of the old stock, are dibbled in. The plants are placed in a circular form towards the top of the hillock, and at the distance of five or six inches from each other. They are made to incline towards the centre of the hillock, where another plant is commonly valeed.

hillock, and at the distance of five or six inches from each other. They are made to incline towards the cepatre of the hillock, where another plant is geommonly placed.

6014. Another mode of planting is as follows:—Strike furrows with the plough at equal distances of eight feet; when finished, repeat the same across in the opposite direction, which will divide the piece into eight-feet squares. The hills are to be made where the furrows cross each other, and the horse-hoe may be admitted between the rows both ways. According to the Suffolk husbandry, the plantations are formed into beds sixteen feet wide, by digging trenches about three feet wide, and two or three feet deep; the earth that comes out being spread upon the beds, and the whole dug and levelled. Upon this they, in March, form the holes six feet asunder every way, twelve inches diameter, and a spit deep, by which three rows are formed on each bed. Into each hole they put about half a peck of very rotten dung, or rich compost, and scatter earth upon it; and in each they plant a set, drawing earth enough to it afterwards to form something of a billock

form something of a hillock

6015. An interval crop is generally taken in the first summer of a hop plantation. Beans are very generally grown; and Bannister is of opinion that two rows of beans may be planted in each interval without any damage to the hops, whether bedded sets or cuttings. In the latter case, this method may be pursued in the second year, at the end of which the vine from the cuttings will not be in a more forward state than that from the bedded sets in the first autumn after planting. Others, however, think that neither beans, cabbages, nor any other plants, except onions, should be put in.

6016. The after-culture of the hop, besides the usual processes of hoeing, weeding,

stirring, and manuring, includes earthing-up, staking, and winter dressing.

6017. Hoeing in hop plantations may always be performed by a horse implement; and one in use for this purpose in the hop counties, and of which the expanding horse-hoe (fig. 335.) is an improvement, is known by the name of hop-nidget. When the hop-stools are formed in the angles of squares, the intervals may be hoed both lengthwise and across, and thus nothing is left to be performed by manual labour but pulling out any weeds which may rise in the hills.

6018. Sirring, in the hop districts, is chiefly performed in winter with a three-pronged fork (provincially spud); but it might be equally well effected then or at any season of the year with the common plough, and the expanding horse-hoe set with coulters or prongs. With the latter implement the soil might be stirred to any desirable depth, either in summer or winter; and, with the plough, the surface could be changed at discretion. Once going and returning would effect this, either by the paring or clearing out;

that is, forming either a ridglet, or gutter between the rows, both lengthwise and across. Twice or thrice going in the same direction would also succeed, and would be the preferable mode of covering in manure. 6019. In the application of manure, various modes are adopted. Some always use well rotted stable dung; others, composts of earth and dung; and a few, littery dung. In laying it on, many prefer the autumn to the spring, and heap it on the hills without putting any between the rows. Others put it all between the rows, alleging that laying it on the hills encourages insects, exposes the dung to evaporation and loss, and sonetimes, when mixed with earth, hinders the plants from coming up. A great deal will be found in favour of, and against each of these modes, in the numerous works on the culture of the hop, which have been written during the last three centuries; but it must be obvious to any person generally conversant with vegetable culture, that well rotted stable dung must be the best kind for use; and early in spring the best season for laying it on; that little benefit can be derived by the roots when it is laid on the hills, and, consequently, that it ought to be turned into the soil between the rows by the plough. Fitty cart-loads of dung and earth, or thirty of dung, once in three years, is reckoned a good dressing; but some give ten or twelve loads every year. Too much dung renders the hops what is called mouldy, and too little causes the crop to be poor and more liable to be eaten by insects.

6020. Earthing-up commences the first May after planting, whether that operation be performed in spring or autumn. By the end of the spring season, the young shoots have made some progress, and the earth is then drawn up to their roots from the surrounding Intervals, in order to strengthen them. The noxt earthing-up is in autumn, when the hills are by some covered with compost or manure; but by such as prefer ploughing in the manure between the rows, this earthing-up is not given. Some give an earthing-up

earthings-up. Gold. In dressing the hop plants, the operations of the first year are confined to twisting and removing the haulm, to which some and cuping or earthing-up in autumn.

the haulm, to which some add cuping or earthing-up 6022. The operation of triisting is confined to such plants have been planted in apring, and are not expected to produce any crop that season. It is performed in the end of June or in knot; so that, by thus discouraging their growth, the roots are enabled to spread out more vigorously, and to acquire strength previously to the approach of the whiter season.

6023. Removing he haulm takes place soon after Michaelmas, and consists simply in cutting it over with a sickle, and carrying it off the field for litter or burning. After this operation, some add cuping, or covering the hill with a compost; but this some add cuping, or covering the hill with a compost; but this flowers, such as those planted from bedded sets in the preceding autumn, consists in supplying three or four half poles, that is, poles of four or five feet in length to each hill, and on removing the haulm in autumn, as in the other case.

6025. The yearly divising of established hop plantations consists of what is pro includy called picking. This operation is gene6026. The yearly divising of statiching or statching or setting

6034. Tying the shoots or vines to the poles is the last operation in the after or summer culture of the hop. This requires the labour of a number of persons, generally women, who tie them in several different places with withered rushes, but so loosely as not to prevent the vines from advancing in their progress towards the tops of the poles. When the vines have got out of reach from the ground, proper persons go round, with standing ladders, and tie all such as appear inclined to stray.

go round, with standing ladders, and the all such as 6035. The seaton for this operation varies from the middle of May to the end of June, and one important part of the operation consists in selecting the shoots. The forwardest vine should always be extirpated, as it is well known that the branches arising from these early shoots will produce little, if any, fruit. The se cond shoots, where the hills are not overloaded with plents, and where the ground is not of a nature to send forth a very luxuriant vune, may with safety be tied up: but he re the land is apit to push forwar al a great redundancy of shoots, where the vine is always strong and vicrous, and where the failure in the crop chiefly arises from this cause, the greatest of a proper vine; especially in years which may be supposed to for a proper vine; especially in years which may be supposed to be a 'tend d with a blast; such as those wherein an easierly wind has prevailed throughout the month of March, whence one may fairly conclude that the same weather will happen during the course of the month of May, which never falls to

ppear inclined to stray,

bring the long-wined fly.

In such a season it would be well
worth while to tradicate all the vine which first appears, and
trust to a later shoot, so as to protract the tying till the last week
in May. This intut was taken from the observ-tions made in
such blasting years on the poor and thin lands where the vine
such blasting years on the poor and thin lands where the vine
towards the latter end of May, when thot on the forward ground
will have advanced nearly to the tops of the poles, and to an inattentive observer seems to promise fal for a crop; whereas, to
those who have been conversant in the se matters, the loss of the
crop, tho gh the vine at that time be green and flourishing,
may be easily fore-een; whilst on the poorer soils there is generally a saving crop even in years when the blast is most prevalent. These conside ations have suggested the protracting of
the growth of the wine in the manner above mentioned, which
seems conformable to reason and experience.

Taking the crop is a most important operation in the hop economy 6036

6087. Hops are known to be ready for pulling when they acquire a strong scent, and the seeds become firm and of a brown colour, which, in ordinary seasons, happens in the first or second week of September. When the pulling season arrives, the utmost assiduity is requisite on the part of the planter, in order that the different operations may be carried on with regularity and despatch; as the least neglect, in any department of the business, proves in a great degree ruinous to the most abundant crop, especially in precarious seasons. Gales of wind at that season, by breaking the lateral branches, and bruising the hops, prove nearly as injurious as a long continuance of rainy weather, which never fails to spoil the colour of the crop, and thereby render it less saleable.

prove nearly as injurious as a long continuance of r the crop, and thereby render it less saleable.

60:38. As a preparation for pulling the hops, frames of wood, in number proportion do to the size of the ground, and the pickers to be employed, are placed in the tyart of the field which, by alwing be, most exposed to the influence of the sun, is somest ready. These frames, which are called hins or cribs, are v. rs simple in the construction, being only four pieces of boards seven or eight feet long to the same the training of the construction height of the property of the same height. A man always attends the pickers, whose business it is to cut over the vines near the ground, and to lay the poles on the frames to be picked. Commonly two, but stidom more than three, poles are laid on at a time. Six, seven, or eight pickers, worner, girls, and boys, are employed at the same pickers, worner, girls, and boys, are employed at the same than any or stakes, are dropped by the pickers into a large cloth, hung all round within-side the frame on tenter-hooks. When the cloth is full, the hops are emplied into a large sack, which is carried home, and the hops laid on a kin to be dried. This is always home, the poles of the control of the dried of the control of the picking season, that the coasts or kins may never 6041. The operation of draying hops is not to

be unsupplied with hops; and if it is found that the hops rise faster than could have been expected, and that there are more gathered in a day than can be conveniently dried off, some of the worst pickers may be discharged; I being v-ty prejudicial for the green hops to continue long in the sacks before they are put on the oasy, as they will in a few hours begin to heat, and acquire an unsight colour, which will not be taken off in the put of the oasy, as they will in a few hours begin to heat, and acquire an unsight colour, which will not be taken off in the hopping, it is no easy matter to prevent the kilns from being overrun, supposing that there were pickers enough to supply them f the weather h doen dry, be cause in a wet cold time the hops require to lie a considerable while longer on the kiln, norder that the superabundant moisture may be dred up. It is therefore expedient in this case that each m assuring be divided into a number of green pockets or pokes. The number of num

6041. The operation of drying hops is not materially different from that of drying malt;

and the kilns, or oasts, are of the same construction.

6042. The hops are spread on a hair-cloth, and from eight to ten, sometimes twelve, inches deep, according to the dryness or wetness of the season and the ripeness of the bops. A thorough knowledge of the best method of drying hops can only be acquired by long practice. The general rules are, to begin with a slow fire, and to increase it gradually, till, by the heat on the kiln, and the warmth of the hops, it is known to have arrived at a proper height. An even steady fire is then continued for eight or ten hours, according to the state or circumstances of the hops, by which time the ends of the hop-stalks become quite shrivelled and dry, which is the chief sign by which to ascertain that the hops are properly and sufficiently dried. They are then taken off the kiln, and laid in a large room or lot till they become quite cool. They are now in condition to be put into bags, which is the last operation the planter has to perform previously to sending his crop to market.

are now in condition to be put into bags, which is the last operation the planter has to perform previously to sending his crop to market.

6083. When hops are dried on a cockle-oast, sea-coal is the usual fuel, and a chaldron is generally esteemed the proper allowance to a load of hops. On the hair kilns, charcoal is commonly used for this purpose. Fifty sacks of charcoal are termed a load, which usually sells for about fifty shillings. The price for burning is three shillings per load, or twelve shillings for each cord of wood. The process of drying having been completed, the hops are to be taken off the kiln, and shovelled into an adjoining chamber called the stowage-room; and in this place they are continually to be laid as they are taken off the kiln, till it may be thought convenient to put them into bags, which is rarely done till they have lain some time in the heap; for the hops, when first taken off the kiln, being very dry, would (if put into the bags at that time) break to pieces, and not draw so good a sample as when they have lain some time in the heap; whereby they acquire a considerable portion of toughness, and an increase of weight.

6044. The bagging of hops is thus performed:

6045. The bagging of hops is thus performed:—

6045. In the floor of the room, where the hops are laid to cool, there is a round hole or trap, equal in size to the mouth of a hop bag. After tying a handful of hops in each of the lower corners of a large bag, which serve afterwards for handles, the mouth of the bag is fixed securely to a strong hoop, which is made to rest on the edges of the hole or trap; and the bag itself being then dropped through the trap, the packer goes into it, when a person who attends for the purpose puts in the hops in small quantities, in order to give the packer an opportunity of packing and trampling them as hard as possible. When the bag is filled, and the hops trampled in so hard as that it will hold no more, it is drawn up, unloosed from the hoop, and the end sewed up, other two handles having been previously formed in the corners in the manner mentioned above. The brightest and finest coloured hops are put into pockets or fine bagging, and the brown into coarse or heavy bagging. The firmer are chiefly used for brewing fine ales, and the latter by the porter brewers. But it is to be observed, that where hops are intended to be kept for any length of time, it is most proper to put them into coarse cloth. The proper length of a bag is two ells and a quarter, and of a pocket nearly the same, being one ell in width. The former, if the hops are good in quality, well cured, and tight trodden, will weigh about two hundred and a half; and the latter, if of the Canterbury pocketing, about one hundred and a half. If the weight either exceeds or falls much

short of this medium, it induces a surmise, that the hops are either in themselves of an inferior quality, or have been injudiciously manufactured in some respect or other.

67 have been injuniciously manufactured in some respect or other.

6046. Fallance's apparatus for packing and preserving hops, is an hexagonal case of wood, eighteen feet long and two feet in diameter, with a piston or rammer, to be worked by a screw or other means so as to compress the hops more closely than has hitherto been done. When the case is full, a lid is fastened down by iron plates and nails, and any crack or joint that may appear is filled with coment, so as to exclude the air. With this precaution, Mr. Fallance states, hops may be kept perfectly good for half a century. (Newton's Journal, vol. vii. p. 12.)

6047. The stripping and stacking of the poles succeed to the operation of picking. It is of some consequence that this business be executed as soon as possible after the crop is removed; not only because the poles are, when set up in stacks, much safer from thieves, but because they are far less damaged by the weather than when dispersed about the ground with the vine on them. The usual price for stripping and stacking is five shillings per acre. At this time, such poles as may be deemed unfit for further service should be flung by, that the planter may have an early knowledge of the number of new poles which will be wanted; and thus the business of bringing on the poles may be completed in the winter time, when the horses are not required about other labour; and these new poles may be drawn from the wood on the ground, and adjusted to the separate stacks, as the state of the different parts of the ground may require, and the whole business finished before the poling season: whereas, when this method of flinging out the old poles is neglected at the stacking, the planter, being ignorant of the number of new poles that will be required for the ensuing year, often finds at the poling season that he has not laid in a sufficient stock.

6048. In performing the operation of stacking the poles are set up in somewhat conical piles, or congeries of from two hundred to five hundred each. The method of proceeding is this: — Three stout poles of equal length are bound together, a few feet from their tops, and their feet spread out, as those already mentioned for pointing the poles. These serve as a stay to the embryo pile; the poles being dropped in on each side, between the points of the first three, cautiously keeping an equal weight on every side; for on this even balance the stability of the stack depends. The degree of inclination or slope, and the diameter of the base of the pile, vary with the length and the number of poles set up together. A stack of three or four hundred of the long poles of the environs of Maidstone, occupy a circle of near twenty feet in diameter. It is observable, however, that the feet of the poles do not form one entire ring; but are collected in bundles or distinct divisions, generally from three to six or eight in number; each fasciculus being bound tightly together, a few feet from the ground, with a large rough rope made of twisted vines, to prevent the wind from tearing away the poles. The openings between the divisions give passage to violent blasts, and tend to prevent the piles from being thrown down in a body; a circumstance which does not often take place in screened grounds; but, on the high exposure of Cox Heath, where great quantities of new poles brought out of the Weald are piled for sale among the Maidstone planters, it is not uncommon for the piles to be blown down, and to crush in their fall the sheep or other animals that may have taken shelter under them. A caution this to the inexperienced in the business of stacking; and an apology, if one is wanted, for the minuteness of the detail.

6049. The operation of stripping is generally performed by women; being nothing more than tearing off the bind or vines. Many people burn it on the ground; others suffer it to be carried off by their workmen for firing; and there are some who tie it up into small bundles, which they bring home and form into a stack, to answer the purpose of bavins in heating their ovens or coppers.

6050. The produce of the hop crop is liable to very considerable variation, according to soil and season, from two or three to so much as twenty hundred-weight; but from nine to ten, on middling soils, in tolerable seasons, are considered as average crops, and twelve or fourteen as good ones. Bannister asserts that sixty bushels of fresh-gathered hops, if fully ripe, and not injured by the fly or other accident, will, when dried and bagged, produce a hundred-weight. Where the hops are much eaten by the flea, a disaster which often befalls them, the sample is not only reduced in value, but the weight diminished; so that, when this misfortune occurs, the planter experiences a two-fold loss.

6051. To judge of the quality of hops, as the chief virtue resides in the yellow powder contained in them, which is termed the condition, and is of an unctuous and clammy nature, the more or less clammy the sample appears to be, the value will be increased or diminished in the opinion of the buyer. To this may be added the colour, which it is of very material consequence for the planter to preserve as bright as possible, since the purchaser will always insist much on this article; though, perhaps, the brightest-coloured hops are not always the strongest flavoured.

6052. The duration of the hop plantation on good soil may be from fifteen to thirty years; but in general they begin to decline about the tenth year. Some advise that the plantation should then be destroyed, and a fresh one made elsewhere; others consider it the best plan to break up and plant a portion of new ground every two years, letting an equal quantity of the old be destroyed, as in this way a regular succession of good plantation will be kept up at a trifling charge.

6053. The expense of forming new hop-plantations is in general very great, being estimated, in many districts, at from not less than seventy to a hundred pounds the acre. The produce is very uncertain; often very considerable; but in some seasons nothing, after all the labour of culture, except picking, has been incurred. Where the lands are of proper sort for them, and there are hop-poles on the farm, and the farmer has a sufficient capital, it is probably a sort of husbandry that may be had recourse to with advantage; but under the contrary circumstances, hops will seldom answer. In growing them in connection with a farm, regard should be had to the extent that can be manured without detriment to the other tillage lands. On the whole, the hop is an expensive and precarious crop, the culture of which should be well considered before it is entered upon.

6054. The use of the hop in brewing is to prevent the beer from becoming sour.

6055. In domestic economy the young shoots are eaten early in the spring as asparagus, and are sold under the name of hop-tops. They are said to be diuretic; and taken in an infusion, to be good against the scurry. The herb will dye wool yellow. From the stalks a strong cloth is made in Sweden: for this purpose they must be gathered in autumn, soaked in water all winter; and in March, after being drted in a stove, they are dressed like flax. They require a longer time to rot than flax, and, if not completely macerated, the woody part will not separate, nor the cloth prove white or fine. Hence a farmer who has a hop plantation need neither grow asparagus nor flax, and may, when the flowers fail from disease, separate the fibre from the vine, and employ the poor, or machinery, in spinning and weaving it. A decoction of the roots of hops is considered as good a sudorific as sarsaparilla; and the smell of the flowers is found to be soporific. A pillow filled with hops was prescribed for the use of George III. in his illness

6056. The hop is peculiarly liable to diseases. There is scarcely any sort of plant cultivated as a field-crop that is more liable to become diseased than the hop. in the very early stage of its growth, to be devoured, as it rises above the surface of the ground, by the ravages of an insect of the flea kind. At a more advanced stage, it is subject to the still more injurious effects of the green or long-winged fly, red spider, and otter moth: the first, by the depositing of their ova, afford the means of producing lice in great abundance, by which the plants are often very greatly, if not wholly, destroyed; and the larvæ of the last prey upon the roots, and thus render the plants weak and subject to disease. The honey-dew is another disease to which the hop is exposed about the same time, and by which it is often much in-The mould occurs in general at a somewhat later period, and is equally injurious. Hop-crops are also exposed to other injuries, as the blight and fire-blast; but which take place at different times, though mostly towards the latter periods of the growth of the plants.

growth of the plants.

6057. The flea, which is said to be an insect of the same kind as that which is so prejudicial to the young turnip, is observed to make the greatest havoe in seasons when the nights are cold and frosty, and the days hot and inclined to be dry; eating off the sweet tender tops of the young plants, which, though not wholly destroyed, shoot forth afterwards in a far less vigorous manner, and of course become more exposed to diseases. It has been found to commit its depredations most freently on the plants in grounds that have been dunged the same year: on which account it has been suggested that the manure employed for the purpose of covering the hills should be previously well mixed and incorporated, as directed above (6019.); and that it should be applied either over the whole of the land, or only the hills, as soon as possible after the plants have been cut over; but the former practice is probably the best. It makes its greatest depredations in the more early, cold, spring months, as the latter end of April and beginning of the succeding month, disappearing as the season becomes more mild and warm. In these cases, the principal remedy is that of having the land in a sufficient state of fertility, to enable the young plants to shoot up with such vigour and rapidity as to become quickly incapable of being fed upon and devoured by the insect. The frequent stirring of the mould about the roots of the plants with the hoe may be of utility in the same view.

6058. The green or long-winged fly is highly destructive to the young leaves of the plants, and mostly makes its appearance about the latter end of May, and in the two succeeding months; being ignorantly supposed to be produced by the prevalence of north-easterly winds about that period. Under such a state of the wind, they are said to scarcely ever fail of covering the leaves; and by dropping their ova, of producing abundance of lice, which often much injure the crops; as when they have once obtained complete possession of the plants, the

course much injured in their produce. Stirring the earth well about the roots of the plants may probably sometimes be serviceable in cases of this kind.

6060. The honey-deumostly occurs after the crops have been attacked by some of these kinds of insects, and when the weather is close, moist, and foggy. In these cases, a sweet clammy substance, which has the taste of honey, is produced upon the leaves of the plants, and they have at first a shining appearance, but soon afterwards become black. It is a disease that mostly happens in the more forward crops; and the chief dependence of the planter for its removal, according to Bannister, is that of heavy thunder showers taking place; as by this means, when the destruction of the hops has not proceeded too far, they are often much restored, the insects that devour the leaves and vines being greatly destroyed, the growth of fresh shoots promoted, and a favourable bloom brought on the plants.

6061. The fen, mould, or mildew, is a disease to which the crop is exposed at a later period of its growth, and which chiefly attacks the part where the hop is attached to the stem. It is said that its production is greatly promoted by moist damp weather, and a low situation; those crops that grow on low, close, rich grounds being most liable to be attacked by it; and it is found to soon spread itself over the whole crop, after it has once seized upon any part of it. The nature of this vegetable disease has not been yet sufficiently investigated. It has been suggested by Darwin and Willdenow to be a plant of the fungus kind, capable of growing without light or change of air, attaching itself to plants already in a morbid condition, and by its roots penetrating their vessels: and on this supposition, the best remedy is believed to be thiming the plants, in order to afford a more free circulation of air, and admit the light more extensively, by which the viging or of the hop-plants may be restored, and the disease he of course removed. In this view, it is probable, by planting t

and in a very sudden manner: and besides the most forward and luxuriant vines aree most subject to be affected. It has been suggested, that in exposures where the crops are particularly liable to injury, it may be advisable to plant thinner, to keep back the growth of the plants as much apossible, by extirpating all the most forward shoots, and to employ a less proportion of the earthy compost in their culture.

In respect to the duty on hops, it is best for the planter to have the acts before But every grower of hops in Britain is legally obliged to give notice to the excise, on or before the first day of September, of the number of acres he has in cultivation, the situation and number of his oasts, and the place or places of bagging, which, with the store-rooms, or warehouses, in which the packages are intended to be lodged, are entered by the revenue officer. No hops can be removed from the rooms thus entered, before they have been weighed and marked by a revenue officer; who marks, or ought to mark, not only the weight, but the name and residence of the grower, upon each package.

Culture of the Coriander and Caraway. (fig. 804. a, b.)

6065. The coriander (Coriándrum sativum L., fig. 804. a) is a small-rooted annual,

with branchy stems rising from one foot to one foot and a half in height. It is a native of the south of Europe, and appears to be naturalised in some parts of Essex, where it has been long cultivated. It flowers in June and July, and the seeds ripen in July and August.

seeds ripen in July and August.

6066. The culture and management of coriander consist in sowing it on a light rich soil in September, with seeds ripened the same year. Twenty pounds of seed will sow an acre. When the plants come up, thin them to six or eight inches' distance every way, and, next spring, stir the soil with a pronged hoe. In August the seed will be ripe, and if great care be not used, the largest and best part of it will be lost. To prevent this, women and children are employed to cut plant by plant, and to put them immediately into cloths, in which they are carried to some convenient part of the field, and there threshed upon a sail-cloth. A few strokes of the flail get the seeds clean out, and the threshers are ready for another bundle in a few minutes. In Essex it is sometimes cultivated with caraway and teazle. (See Caraway.)

6067. The produce of coriander is from ten to fourteen evt on an acre. It is used by the distillers for flavouring spirits, by the confectioners for encrusting with sugar, and

spirits, by the confectioners for encrusting with sugar, and

by the druggists for various purposes; for all of which it is said to have a ready sale.

6068. The caraway (Càrum Cárui, b) is a biennial plant with a taper root, like a parsnep, but much smaller, running deep into the ground. The stems rise from eighteen inches to two feet, with spreading branches and finely cut deep green leaves. It is a native of England, in rich meadows in Lincolnshire and other places, and has been long cultivated in Essex. It flowers in May and June, and the seeds ripen in autumn

6099. The culture and management are the same as those of coriander. In all probability both plants would answer if sown like clover among a crop of corn; and hoed and thinned when the crop was removed, and again in the following spring. The method of culture in Essex is, about the beginning of March to plough some old pasture land; if it has been pasture for a century the better; and the soil should be a very strong clayey loam. Twelve pounds of craway seed are mixed with ten pounds of criander, and twelve pounds of teasel seed; this is sufficient for one acre; and is sowed directly after the plough, harrowing the land well. When the plants appear of sufficient strength to bear the hoe, which will not be until about ten weeks after sowing, it must not be omitted; and in the course of the summer, the crop will require three hoeings, besides one at Michaelmas. The coriander being annual, will be fit to cut about the beginning of July. It is left in the field after cutting, and threshed on a cloth in the same manner as rape seed. About April following the caraway and teasel will want a good hoeing done deep and well; and another about the beginning of June. The caraway will be fit to cut in the beginning of July, and must be threshed in the same manner as the coriander. This compound crop is mostly sown on land, so strong as to require being a little exhausted to make it fit for corn. Caraway and coriander are oftener sown without teasel; the latter being a troublesome and uncertain crop, and the produce of caraway much greater without it. 6069. The culture and management are the same as those of coriander. In all probability both plants

out teaser: the latter being a frontiesome and uncertaint rop, and the produce of caraway, on the very rich old leys in the hundreds or low lands of Essex, has often amounted to twenty cwt. an acre. There is always a demand for the seed in the London market.

6071. The uses of the caraway are the same as those of coriander, and its oil and other preparations are more used in medicine. Dr. Anderson says, both the roots and tops may be given to cattle in

spring.

Subsect. 3. Plants which may be substituted for Brewery and Distillery Plants.

6072. As substitutes for hops, we may mention the common box (Búxus sempervirens), the leaves and twigs of which are said to be extensively used in all the beer brewed in The marsh trefoil (Menyánthes trifoliàta) is much employed in Germany, and on the Continent generally; and, it is said, was formerly used in this country. ounce of the dried leaves is considered equivalent to half a pound of hops. The plant is of easy culture in moist soil: all the plants of the same natural order, Gentianea, and especially the different species of Gentiana, might be used in the same manner, more particularly the G. lùtea, rùbra, and purpùrea. In Switzerland, a spirit is distilled from the roots of G. lùtea. The dried roots of Geum urbanum, common in hedges, are sliced,

enclosed in a thin linen bag, and suspended in the beer cask, by the brewers of Germany, to prevent, it is said, the beer from turning sour, and to give it the odour of cloves. (Gard. Mag. vol. vi. p. 148.) In Sweden, Norway, and the north of Scotland, the heath (Erica L.) and common broom were, and still are, occasionally used as substitutes for In some parts of France and Germany nothing else is used but broom tops. In Guernsey the Teucrium Scorodònia is used, and found to answer perfectly. In England, the different species of mugwort and wormwood have been used for that purpose; and the foreign bitter, quassia, a tree of Guiana, is still used by the porter brewers. Whoever has good malt, therefore, or roots, or sugar, and understands how to make them into beer, need be at no loss for bitters to make it keep.

931

6073. Carminative seeds, equal in strength to those of the caraway and coriander, are furnished by a very considerable number of native or hardy plants, and of flavours to which the drinkers of cordials and liqueurs are attached. Such are the fennels (Fænículum) cultivated in Germany, parsley, myrrh, angelica, celery, carrot, parsnep, cow parsnep, and many other umbelliferous plants; avoiding, however, the hemlock, fool's parsley, æthusa, and some others which are poisonous. In Dantzic, where perhaps more seeds are used for flavouring spirits than any where else, several of the above and other plants are employed. Kümmel, their favourite flavour, is that of the cumin (Cuminum Cyminum), an annual plant, a native of Egypt, and cultivated in the south of Europe; but too tender for field culture in this country. But caraway or fennel seeds are very generally mixed with cumin, or even substituted for it in distilling kümmel-wasser.

SECT. III. Oil Plants.

6074. In Britain there are few plants grown solely for the production of oil; though oil is expressed from the seeds of several plants, grown for other purposes, as the flax,

Our chief oil plant is the rape.

6075. Rape is the Brássica Nàpus L.; Navette, Fr.; Rübsamen, Ger.; Rapa silvatica, Ital.; and Naba silvestre, Span. It is a biennial plant of the turnip kind, but with a caulescent or woody fusiform root scarcely fit to be eaten. Von Thaer considers the French and Flemish colza (Kohlsaat, Ger.) a different plant from our rape: colza is more of the cabbage kind, and distinguished by its cylindrical root, cut leaves, and greater Decandolle seems to be of the same opinion.

6076. Brássica campéstris oleífera, according to these writers, is the colsat or colza, or rape of the Continent, the most valuable plant to cultivate for oil; its produce being to that of the Brássica Napus, or British colsat or rape, as 955 to 700. It is distinguished from the B. Napus by the hispidity of its leaves. It would be desirable for agriculture, Decandolle observes, that, in all countries, cultivators would examine whether the plant they rear is the B. campéstris oleífera or the B. Napus oleífera, which can easily be ascertained by observing whether the young plant is rough or smooth; if hispid, it is the B. campéstris; if glabrous, the B. Napus. Experiments made by Gaujuc show the produce of the first, compared with that of the second, to be as 955 to 700. (Hort. Trans. v. 23.)

6077. For its leaves as food for sheep, and its seed for the oil-manufacturer, rape, or coleseed, has been cultivated from time immemorial. It is considered a native, flowers in May, and ripens its seeds in July. It may be sown broad-cast, or in rows, like the common turnip, or it may be transplanted like the Swedish turnip. The culture of rape for seed has been much objected to by some, on account of its supposed great exhaustion of the land; but where the soil and preparation are suitable, the after-culture properly attended to, and the straw and offal, instead of being burnt, as is the common practice, converted to the purposes of feeding and littering cattle, it may, in many instances, be the most proper and advantageous crop, that can be employed by the farmer.

6078. The Culleys in Northumberland used to cultivate rape on thin clays, as a preparation for wheat, of which they had valuable crops afterwards. The land, in the early part of the season, was prepared as for fallow, and the rape sown in June or July, and eaten off by sheep in September or October; after which the soil was once ploughed for wheat. The rape may also be sown among a crop of drilled winter beans in May.

6079. The soils best suited for rape are the deep, rich, dry, and kindly sorts; but, with plenty of manure and deep ploughing, it may be grown in others.

plenty of manure and deep ploughing, it may be grown in others.

6080, Young says, that upon fen and peat soils and bogs, and black peaty low grounds, it thrives greatly, and especially on pared and burnt land, which is best suited to it; but it may be grown with perfect success on fenny, marshy, and other coarse waste lands, that have been long under grass, when broken up and properly prepared. As a first crop on such descriptions of land, it is often the best that can be employed. The author of The New Farmer's Calendar thinks that this plant is not perhaps worth attention on any but rich and deep soils; for instance, those luxuriant slips that are found by the sea-side, fens, or newly broken up grounds, where vast crops of it may be raised.

6081. The preparation of old grass lands, if not pared and burned, need be nothing more than a deep ploughing and sufficient harrowing to bring the surface to a fine mould; and this operation should not be commenced in winter, because the grub and wire-worm would have time to rise to the surface; but in February or March, immediately before sowing, or in July, or after the hay crop is removed, if the sowing is deferred till that season. When sown on old tillage lands, the preparation is pretty much the same as that usually given for the common turnip: the land being ploughed over four or five times, according to its condition, as a fine state of pulverisation or tilth is requisite for the perfect growth of the crop. In this view, the first ploughing is mostly given in the autumn, that the soil may be exposed to the influence of the atmosphere till the early part of the spring, when it should be again turned over twice, at proper intervals of time; and towards the beginning and middle of June one or two additional ploughings should be performed upon it, in order that it may be in a fine mellow condition for the reception of the seed.

6082. In a rotation of crops, the place which rape occupies is commonly between two of the culmiferous kind. On rich soils it may be succeeded to the greatest advantage by wheat, as it is found to be an excellent preparation for that sort of grain; and by its being taken off early, there is sufficient time allowed for getting the land in order for sowing wheat.

6083. The season for sowing rape is the same as that for the common turnip, and the

manner, whether in broad-cast or rows, the same.

6084. The row method on the flat surface seems the best for newly broken up lands; and the rows on ridglets, with or without manure, the best for lands that have been under the plough. Where the object is the keep of sheep in autumn or winter by eating it down, the broad-cast method and thick sowing are evidently the best, and are generally resorted to in Lincolnshire and the fenny districts. The quantity of seed when sown thick may be a peck an acre; but when drilled or sown thin, two or three pounds will suffice. The seed should be fresh, black, and plump. Yacancies may always be filled up by transplanting.

6085. The season of transplanting begins as soon after the corn harvest as possible, being generally performed on the stubble of some description of corn crop.

60%. One deep ploughing, and a degree of harrowing sufficient to pulverise the surface, are given; and the plants may be dibbled in in rows a foot apart, and six inches in the row or narrower, according to the lateness of the season of planting, and the quality of the soil; for it must be considered that plants transplanted so late as September or October will be far from being go strong in the succeeding spring, as those sown in June and left where they are to run. The seed-bed from which the plants are obtained should have been sown in the June or July preceding the transplanting season, and may be merely a ridge or two in the same or in an adjoining field. We have already noticed (464) the Flemish mode of transplanting, by laying the plants in the furrow in the course of ploughing; but as the plants cannot be properly firmed at the lower part of the root, we cannot recommend it.

6087. The after-culture of rape is the same as that of the turnip, and consists in hoeing

6088. The plants on the poorer soils may be left at six or eight inches apart or narrower, but on the rich they may be thinned to twelve or fifteen inches with advantage to the seed. Few are likely to grow the plant on ridglets with manure; but, if this were done, the same distance as for turnips will ensure a better crop of seed than if the plants were closer together. In close crops the seed is only found on the summits of the plants; in wide ones on rich soils, it also covers their sides. When rape seed is grown purposely for sheep keep, no hoeing, thinning, or weeding, are necessary. Rape grown for seed will not be much injured by a very slight cropping from sheep early in the autumn, but considerably so by being eaten down in winter, or in the succeeding spring. The seed begins to ripen in the last week in June, and must then be protected as much as possible from birds.

6089. In harvesting rape great care is requisite not to lose the seed by shaking, chaffing, or exposure to high winds or rains.

6090. It is reaped with the hook, and the principal point is to make good use of fine weather; for, as it must be threshed as fast as reaped, or at least without being housed or stacked like other crops, it requires a greater number of hands in proportion to the land, than any other plant. The reaping is very delicate work; for if the men are not careful, they will shed much of the seed. Moving it to the threshing floor is another work requiring attention. One way is to make little waggons on four wheels with poles, and cloths strained over them; the diameter of the wheels being about two feet, and the cloth body five feet wide, six long, and two deep; these are drawn by one horse, and the whole expense is not more than 30s. or 40s. In large farms, several of these may be seen at work at a time in one field. The rape is lifted from the ground gently dropped at once into these machines without any loss, and carried the threshers, who keen In large farms, several of these may be seen at work at a time in one field. The rape is lifted from the ground gently, dropped at once into these machines without any loss, and carried to the threshers, who keep hard at work, being supplied from the waggons as fast as they come, by one set of men, and their straw moved off the floor by another set. Many hands of all sorts being employed, a great breadth of land is finished in a day. Some use sledges prepared in the same way. All is liable to be stopped by rain, and the crop much damaged; it is, therefore, of very great consequence to employ as many people as possible men, women, and boys, to make the greatest use of fine weather. The seed is likewise sometimes cleaned in the field, and put into sacks for the market. But when large quantities of seed are brought quickly together, as they are liable to heat and become mouldy, it may be a better method to spread them out thinly over a barn, granary, or other floor, and turn them as often as may be necessary.

6091. The produce where the plant succeeds well, and the season is favourable for securing the seed, amounts to forty or fifty bushels or more on the acre. Marshal thinks, indeed, that on the whole it may be considered as one of the most profitable crops in husbandry. There have been, says he, instances, on cold, unproductive, old pasture-lands, in which the produce of the rape crop has been equal to the purchase value of the land. seed is sold by the last of ten quarters, for the purpose of having oil expressed from it in mills constructed for that purpose. The price, like that of all crops of uncertain and irregular demand, is continually varying.

6092. The uses to which the rape is applied are the following: -

6093. The use of the seed for crushing for oil is well known; it is also employed as food for tame birds,

6093. The use of the seed for crushing for oil is well known; it is also employed as food for tame birds, and sometimes it is sown by gardeners, in the same way as mustard and cress, for early salading.
6094. The rape-cake and rape-dust, the former adhering masses of seed husks, after the oil has been expressed, and the latter loose dry husks, are used as a top-dressing for crops of different kinds. They are reduced to powder by a malt mill or other grinding machine, and sometimes sown broad-cast over young clovers, wheats, &c., and at other times drilled along with turnip seed. Four hundred weight of powder sown with turnip seed will go over one acre in drills, but three times the quantity is required for an acre sown broad-cast. Experience has proved, that the success of this manure depends in a great measure on the following season. If rain happens to fall soon after the rape-dust is applied, the crop is generally abundant; but if no rain falls for a considerable period the effects of this manure are little discernible, either on the immediate crop or on those which succeed it. There are turnip drills contrived so as to deposit the manure along with the seed.
6095. The use of the haulm to cattlesin winter is very considerable. The stover (pods and points broken off in threshing) is as acceptable as hay, and the tops are eaten nearly as greedily as cut straw, and are at least better than wheat straw. When well got, the smaller stalks will be caten up clean. The offal makes excellent litter for the farm-yard, and is useful for the bottoms of mows, stacks, &c. The haulm of this plant is frequently burned; and, in some places, the ashes, which are equal to potash, are sold; by which practice, if no manure is substituted, the soil must be greatly deteriorated. It is a custom in Lincolnshire,

sometimes to lay lands down with cole, under which the grass seeds are found to grow well. But this sort of crop, as already observed, is most suited to freshly broken-up or burned lands, or to succeed early peas, or such other green crops as are mowed for soiling cattle.

6096. The leaves as a green food for sheep are scarcely surpassed by any other vegetable, in nutritious properties, and in being agreeable to the taste of the animals; but in quantity of produce, it is inferior to both turnips and cabbages. The crops are fed off occasionally from the beginning of November to the middle of April: being found of great value, in the first period, for fattening dry ewes, and all sorts of old sheep; and, in the latter, for supporting ewes and lambs. The sheep are folded upon them in the manner practised for turnips, in which way they are found to pay frcm 50s. to 60s. the acre; that quantity being sufficient for the support of ten sheep, for ten or twelve weeks, or longer, according to circumstances. Rape has been found, by experience, to be superior to turnips in fattening sheep, and in some cases, even to be apt to destroy them by its fattening quality. In The Corrected Report of Lincolnshire it is likewise observed, that rape grown on fresh land has the stem as brittle as glass, and is superior to every other kind of food in fattening sheep; while that produced on old tillage land has the stem tough and wiry, and containing comparatively little nourishment.

6097. The Sésamum orientàle (Sésame, Fr.; Sesamo, Ital.), Bignoniàceæ, is cultivated in Italy for its seeds, which are eaten roasted like those of maize, boiled like those of the millet, made into a coarse flour like those of the beech or buck wheat, but principally

bruised for an oil used as a substitute for butter.

6098. Among other plants which may be cultivated by the British farmer as oil plants, may be mentioned all the species of the Brássica family, the Sinàpis or mustard family, and the Ráphanus or radish family, with many others of the natural order of Crucíferæ. The seeds of these plants, when they remain too long on the seedsman's hands for growing, are sold either for crushing for oil, or grinding with mustard seed. This includes a good deal of wild charlock and wild mustard seed, which is separated in the process of cleaning grain by the farmers among whose corn these plants abound, and sold to the seed agents, who dispose of it to the oil or mustard millers. Various other Crucíferæ, as the Myagrum sativum, Ráphanus chinénsis var. olèifer, both cultivated in Germany, the Erýsimum, Sisýmbrium officinale, Turritis, &c., might also be cultivated for both purposes.

6099. The small or field poppy (Papaver Rhae'as; Oilette, Fr.), and also the Maw seed (P. somniferum, var. Pavot, Fr.), a variety of the garden poppy, are, as we have seen (467.), cultivated on the Continent as oil plants; the oil being esteemed in domestic economy next to that of the olive. Other species might be grown for the same purpose. of them being annual plants require only to be sown on fine rich land in April; thinned out to six or eight inches' distance when they come up, according to the species; kept clear of weeds till they begin to run; and to have their capsules as they ripen gathered

by hand and dried in the sun.

6100. The sunflower (Heliánthus ánnuus; Turnesol, Fr.; and Girasole, Ital.) has been cultivated in Germany for its seeds, which are found to yield a good table oil; its husks are nourishing food for cattle.

6101. The A'rachis hypogæ'a, Myagrum sativum, Hésperis matronàlis, Ráphanus sativus

olèifer, and Rícinus communis are cultivated in France as oil plants.

SECT. IV. Plants used in Domestic Economy.

6102. Among agricultural plants used in domestic economy, we include the Mustard, Buck-wheat or Beech-wheat, Cress, Tobacco, Chiccory, and a few others; with the exception of the first, they are grown to a very small extent in Britain, and therefore our account of them shall be proportionately concise.

Subsect. 1. Mustard. — Sinàpis L.; Tetradynàmia Siliquòsa L., and Crucíferæ J. Moutarde or Sénevé, Fr.; Senf, Ger.; Senapa, Ital.; and Mostaza, Span.

6103. There are two species of mustard in cultivation in the fields, the white mustard (Sinàpis álba, fig. 805. a), and the black or common (Sinàpis Both are annuals, natives of Britain and most parts of Europe, and cultivated there and in China, for an unknown period. White mustard flowers in June, and ripens its seeds in July. Black mustard is rather earlier. Mustard is an exhausting crop, but profitable when the soil answers, and especially in breaking up rich loamy lands, as it comes off earlier, and allows time for preparing the soil for wheat. In breaking up very rich grass lands, three or four crops are sometimes taken in succession. cannot, however, be considered as a good general crop for the farmer, even if there were a demand for it, as, like most of the commercial plants, it yields little or no manure. The culture of black or common mustard is by far the most extensive, and is chiefly carried on in the county of Durham. The seed of the black mustard, like that of the wild sort and also of the wild radish, if below the depth of three or four inches, will remain in the ground for ages without germinating: hence, when once introduced it is

difficult to extirpate. Whenever they throw the earth out of their ditches in the Isle of Ely, the bank comes up thick with mustard; and the seed, falling into the water and sinking to the bottom, will remain embalmed in the mud for ages without vegetation.

6104. No such luxury as mustard, in its present form, was known at our tables previously to 1720. At that time the seed was only coarsely pounded in a mortar, as coarsely separated from the integuments, and in that rough state prepared for use. In the year I have mentioned, it occurred to an old woman of the name of Clements, resident at Durham, to grind the seed in a mill, and to pass the meal through the several processes which are resorted to in making flour from wheat. The secret she keep for many years to herself, and, in the period of her exclusive possession of it, supplied the principal parts of the kingdom, and in particular the metropolis, with this article; and George I. stamped it with fashion by his approval. Mrs. Clements as regularly twice a year travelled to London, and to the principal towns throughout England, for orders, as any tradesman's rider of the present day; and the old lady contrived to pick up not only a decent pittance, but what was then thought a tolerable competence. From this woman's residing at Durham, it acquired the name of Durham mustard. (Mech. Mag. vol. iv. p. 87.)

6105. Any rich loamy soil will raise a crop of mustard, and no other preparation is required than that of a good deep ploughing and harrowing sufficient to raise a mould on the surface. The seeds may be sown broad-cast at the rate of one lippie per acre; harrowed in and guarded from birds till it comes up, and hoed and weeded before it begins In Kent, according to the survey of Boys, white mustard is cultivated for the use of the seedsmen in London. In the tillage for it, the ploughed land is, he says, harrowed over, and then furrows are stricken about eleven or twelve inches apart, sowing the seed in the proportion of two or three gallons per acre in March. The crop is after-

wards hoed and kept free from weeds. 6106. Mustard is reaped in the beginning of September, being tied in sheaves, and left three or four days on the stubble. It is then stacked in the field. It is remarked that rain damages it. A good crop is three or four quarters an acre; the price from 7s. to Three or four crops are sometimes taken running, but this must in most 20s. a bushel.

cases be bad husbandry.

6107. The use of the white mustard is or should be chiefly for medical and horticultural purposes, though it is often ground into flour, and mixed with the black, which is much stronger, and far more difficult to free from its black husks. The black or common mustard is exclusively used for grinding into flour of mustard, and the black husk is separated by very delicate machinery.

6108. The French either do not attempt to separate the husk, or do not succeed in it, as their mustard when brought to table is always black. It is, however, more pungent than ours, because that quality resides chiefly in the husk. The constituents of mustard seed appear to be chiefly starch, mucus, a bland fixed oil, an acrid volatile oil, and an ammoniacal sait. The fresh powder, Dr. Cullen observes, shows little pungency; but when it has been moistened with vinegar and kept for a day, the essential oil is evolved, and it is then much more acrid.
6109. The leaves of the mustard family, like those of all the radish and Brassica tribe, are eaten green by cattle and sheep, and may be used as pot-herbs. The haulm is commonly burned; but is better employed as litter for the straw-yard, or for covering underdrains, if any happen to be forming at the time.

6110. As substitutes for either the black or common mustard, most of the Cruciferæ enumerated when treating of oil plants (6098.) may be used, especially the Sinapis arvénsis, or charlock, S. orientàlis, chinénsis, and brassicata, the latter commonly cultivated The Raphanus Raphanistrum, common in corn fields, and known as the wild mustard, is so complete a substitute, that it is often separated from the refuse corn and sold as Durham mustard seed.

Subsect. 2. Buck-wheat. — Polygonum Fagopyrum L.; Octándria Trigýnia L., and Polygoneæ J. Blé noir or Blé Sarrazin, Fr. (corrupted from Had-razin, i. e. red corn, Celtic); Buchweitzen, Ger.; Miglio, Ital.; and Trigo negro, Span. (fig. 806.)

6111. The buck-wheat, or more properly beech-wheat (from the resemblance of the seeds to beech mast, as its Latin and German names import), is an annual fibrous-rooted plant, with upright flexuous leafy stems, generally tinged with red, and rising from a foot to three feet in height. The flowers are either white or tinged with red, and make a handsome appearance in July, and the seeds ripen in August and September. Its native country is unknown; though it is attributed to Asia. It is cultivated in China and other countries of the East as a bread corn, and has been grown from time immemorial in Britain, and most parts of Europe, as food for poultry and horses, and also to be ground into meal for domestic purposes. The universality of its culture is evidently owing to the little labour it requires: it will grow on the poorest soil, and produce a crop in the course of three or four months. It was cultivated as early as Gerard's time (1597), to be ploughed in as manure: but at present, from its inferior value as a grain, and its yielding very little haulm for fodder or manure, it is seldom grown but by gentlemen in their plantations to encourage game. Arthur Young, however, "recommends farmers in general to try this crop. Nineteen parishes out of twenty, through the kingdom, know it only by name. It has

numerous excellencies, perhaps as many to good farmers, as any other grain or pulse in use. It is of an enriching nature, having the quality of preparing for wheat, or any other crop. One bushel sows an acre of land well, which is but a fourth of the expense of seed-barley." Its principal value is not so much in the crop as in the great good it does the land by shading it from the heat of the sun. When the wheat fallow can be perfectly cleaned before the middle of June, it is far better to sow the ground with buckwheat than let it be bare; the wheat crop, whether the dung be laid on before or after the buck-wheat, will be one third better than without it. (J. M.)

6113. In the culture of the buckwheat the soil may be prepared in different ways, according to the intention

of the future crop; and for this there is time till the end of May, if seed is the object, and till June if it is to be ploughed in. It will grow on any soil, but will only produce a good crop on one that is tolerably rich. It is considered one of the best crops to sow along with grass seed; and yet (however inconsistent) Arthur Young endeavours to prove that buck-wheat, from the closeness of its growth at the top, smothers and destroys weeds, whilst clover and grass-seeds receive considerable benefit by the shade it affords them from the piercing heat of the sun!!

6114. The season of sowing cannot be considered earlier than the last week of April or first of May, as the young plants are very apt to be destroyed by frost. The mode is always broad-cast, and the quantity of seed a bushel per acre; it is harrowed in, and requires no other culture than pulling out the larger weeds, and guarding from birds

till the reaping season.

6115. Buck-wheat is harvested by mowing in the manner of barley. mown, it must lie several days, till the stalks are withered, before it is housed. It is in no danger of the seeds falling, nor does it suffer much by wet. From its great succulency it is liable to heat, on which account it is better to put it in small stacks of five or six loads each, than in either a large one or a barn.

6116. The produce of the grain of this plant, though it has been known to yield seven quarters an acre, may be stated upon the average at between three and four; it would be considerably more did all the grains ripen together, but that never appears to be the case, as some parts of the same plant will be in flower, whilst others have perfected

their seed.

6117. The use of the grain of buck-wheat in this country is almost entirely for feeding poultry, pigeons, and swine. It may also be given to horses, which are said to thrive well on it; but the author of The New Farmer's Calendar says, he thinks he has seen it produce a stupefying effect.

6118. It has been used in the distillery in England; and it is a good deal used in that way, and also as horse-corn, on the Continent. Young says, a bushel goes farther than two bushels of oats; and mixed with at least four times as much bran, will be full feed for any horse for a week. Four bushels of the meal, put up at 4 cwt. will fatten a hog of sixteen or twenty stone in three weeks, giving him afterwards three bushels of Indian corn or hog-peas broken in a mill, with plenty of water. Eight bushels of buck-wheat meal will go as far as twelve bushels of barley meal.

6119. The meal of buck-wheat is made into thin cakes called crumpits in Italy, and even in some parts of England; and it is supposed to be nutritious, and not apt to turn acid upon the stomach. (Withering.)

6120. The biossoms of this plant afford a rich repast to bees, both from the quantity of honey they contain, and from their long duration. On this account it is much prized in France and Germany, and Du Hamel advises bee farmers to carry their hives to fields of this crop in the autumn, as well as to heath lands.

lands.

6121. The haulm of buck-wheat is said to be more nourishing than clover when cut while in flower. Banister says, it has a peculiar inebriating quality. He has seen hogs, after having fed heartily on it, come home in such a state of intoxication as to be unable to walk without recling. The dried haulm is not eaten readily by any description of animal, and affords but very little manure. On the whole, the crop is of most value when ploughed in green for the latter purpose.

6122. As a seed crop, the author of The New Farmer's Calendar seems justified in saying, it is only valuable on land that will grow nothing else.

Subsect. 3. Tobacco. - Nicotiàna I.; Pentándria Monogýnia L., and Solaneæ J. Le Tabaco, Fr.; der Tabak, Ger.; Tabacco, Ital.; Tabaco, Span.; and Petum or Petume,

6123. The species cultivated are annuals, natives of Mexico, or other parts of America, and, according to some, of both hemispheres. It was brought to Europe early in the sixteenth century, after the discovery of America by Columbus, probably about 1519; from Portugal to France about 1560, by John Nicot, after whom the plant is named; and to England, according to Lobel, about 1570; according to Hume by Ralph Lane, in 1586, from the island of Tobacco in the Gulf of Mexico, whence the popular name.

In 1586, from the Island of Tobacco in the Gulf of Mexico, whence the popular name. 6124. The custom of smoking is of unknown antiquity in Asia, Persia, and other eastern countries; but whether the plant used was tobacco is very doubtful. The natives of Mexico, in the present day, not only use it as an article of luxury, but as a remedy for all diseases, and, when provisions fail them, for allaying the pains of hunger and thirst. The use of smoking was introduced to England by Capt. Lane, who had learned the custom in Virginia, in 1586. He brought home with him several pipes and taught the custom to Sir Walter Ralegh, who soon acquired a taste for it, and began to teach it to his friends. He gave, we are told, "smoking parties" at his house at Islington, when the guests were treated with nothing but a pipe and a mug of ale and nutmer. (Biog. Bit.) Down to the time of Elizabeth, it was not uncommon for ladies to smoke. During the reign of James her successor, most of the princes of Europe violently opposed its use. James of England wrote a book against it; the Grand Duke of Moscow forbade its entrance into his territory under pain of the knowt for the first offence, and death for the next. The emperor of the Turks, the king of Persia, and pope Urban VIII., issued similar prohibitions, all of which were as ridiculous as those which attended the introduction of coffee, or Jesuit's bark. At present, all the sovereigns of Europe, and most of those of other parts of the world, derive a considerable part of their revenue from tobacco. revenue from tobacco.

6125. The cultivation of tobacco on the Continent was not attempted, except in gardens, till the beginning of the seventeenth century. Under Louis XIII. and XIV., its cultivation was allowed in certain provinces of France; and about the same time it was introduced as an article of cottage or spade culture, in Holland, Germany, and part of Sweden. It also spread into Switzerland and Italy, and to various countries of the East. It is at present cultivated in almost every country of the world, but for commercial purposes chiefly on the Continent and islands of North America, and more especially in Virginia, Cuba, and St. Domingo. In no other parts of the world is it so well manufactured for the purpose of smoking as in Havanna

as in Havanna.
6126. In England the practice of planting and growing tobacco began to creep in in the time of Charles II.; and an act was passed fixing a penalty of 101. for every rood of land so cultivated, but making it lawful, however, to grow small quantities, not exceeding half a pole, "in a physic or university garden, or in any private garden for physic or chirurgery." This act and others were confirmed by different acts during the reign of Geo. III. Notwithstanding this act, however, tobacco was much cultivated a few years prior to 1782, in the vales of York and Ryedale. In the latter district it did not excite the notice of regal authority; and was cured and manufactured by a man who had formerly been employed upon the tobacco plantations in America; who not only cured it properly, but gave it the proper cut, and finally prepared it for the pipe. But in the vale of York the cultivators of it met with less favourable circumstances. Their tobacco was publicly burnt, and themselves severely fined and imprisoned. Penalties, it was said, were paid to the amonnt of 30,000. This was enough to put a stop to the illegal cultivation of tobacco. But, perhaps rather unfortunately, it has likewise put a stop to the cultivation of that limited quantity of half a rood, which the law allows to be planted for the purpose of physic and chirurgery, or destroying insects.

quantity of half a rood, which the law allows to the particle of half a rood, which the law allows to the particle of half a rood destroying insects.

6127. In Scotland, about the same time, tobacco was cultivated in various parts, more especially in the neighbourhood of Kelso and Jedburgh. Its produce was so great, that thirteen acres at Crailing fetched 1041, at the low rate of 4d. per lb. (being 480 lbs. per acre), and would have brought more than three times as much, had not an act of parliament obliged the cultivator to dispose of it to government at that price. (County Reports.)

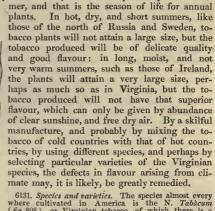

6128. In Ireland, tobacco was introduced into the county of Cork, with the potato, by Sir Walter Palech: but the culture of the former does not appear to have made much progress, though, according

(County Reports.)
6128. In Ireland, tobacco was introduced into the county of Cork, with the potato, by Sir Walter Ralegh; but the culture of the former does not appear to have made much progress, though, according to Humboldt, it preceded that of the potato in Europe more than one hundred and twenty years, having been extensively cultivated in Portugal at the time that Sir Walter Ralegh brought it from Virginia to England in 1586. A writer in 1725, quoted by Brodigan, says, I have not heard that a rood of tobacco was ever planted in this kingdom. An act of George III. repealed several preceding acts, that prohibited the growth and produce of tobacco in Ireland; and this is the foundation on which Ireland now rests her claim to that branch of culture. Until the year 1828, Brodigan obscress, the culture was limited; but in that year there were one hundred and thirty acres under tobacco; and in 1829, one thousand acres in Wexford alone. "It has been partially cultivated in the adjoining counties of Carlow, Waterford, and Kilkenny, and in other places. In the province of Connaught an experiment was made in the vicinity of Westport. It has been grown in one or two instances near Dublin; in the northern section of the kingdom two or three trials have taken place on a small scale;" and Mr. Brodigan, the author of the treatise from which we quote, has cultivated several acres in the neighbourhood of Drogheda, preparing the soil by horse labour as for turnips.

6129. The restrictive system will probably, at no distant time, be removed from tobacco, and from every other crop; but that tobacco ever will enter into the general course of crops of the British farmer, we do not think likely; because, when trade in this, as in every thing else, is once made free, the tobacco of warmer climates will unquestionably be preferred to that of the British isles. At present there is a number of gentlemen in the House of Commons who use tobacco; but should its use become unfashionable among the higher classes, we should not be surpris

6130. The annual species of tobacco, like the annual species of almost all dicotyledonous plants, may be grown in every country and climate; because every country has a sum-

mate may, it is likely, be greatly remedied.

6131. Species and varieties. The species almost every where cultivated in America is the N. Tablacum (fig. 808.), or Virginian tobacco, of which there is a variety or sub-species known as N. macrophylla, but of which we have never seen any plants. N. ristica is very generally cultivated almost to the exclusion of the other species in the north of Germany, Russia, and Sweden, where almost every cottager grows his own tobacco for smoking. It also seems to be the principal sort grown in Ireland. There is a variety of it cultivated in Wexford, erroneously denominated Oronooko, and another commonly called negro-head. Both are very hardy and very productive, but the produce is not of a very good flavour. There are other species grown in America; the best Havannah cigars are said to be made from the leaves of N. repinda (fig. 810.a), a species introduced to this country from Havannah so late as 1823. The Indians of the Rocky Mountains of North America are said to prepare their tobacco from N. quadriválvis (fig. 810.b), introduced in 1813, and N. mana (fig. 810.c) introduced in 1823. These species are all annuals, and the last requires the protection of a green-house to make it ripen its seeds. There are everal very distinct varieties, if not species, cultivated in the Caraccas, of which some account by Mr. Fanning, proprietor of the Botanic Garden of the Caraccas, will be found in the Gardener's Magazine, vol. vi. p. 327. There are also some other annual species, and some species of the genus Petthia which is nearly allied to the Nicotiána, the leaves of which may be purchased in every good tobacco. There can be little doubt that the N. Tabbacum, the seeds of which may be purchased in every good tobacco. There can be little doubt that the N. Tabbacum, the seeds of which may be purchased in every good tobacco. experiment.

In a strict sense, the native soil of the tobacco is unknown in this 6132. Soil. country; by which we mean the primitive earths or rocks to which it belongs. are inclined to attribute it to alluvium and sand-stone rather than to clay or lime.

Virginia the best tobacco is grown in a rich loamy, but rather light soil, which has been newly taken into cultivation. In Alsace, where we have seen stronger tobacco of the Virginian kind than in any other part of France or in Germany, the soil is a brown loam, rather light than heavy, such as would grow excellent potatoes and turnips, and which has been for an unknown period under the plough. Wherever potatoes or turnips may be cultivated, there we think tobacco may be grown.

6133. Climate. As it is beyond a doubt that the best tobacco is produced in countries within the tropics, it is evident that it cannot be worth culture in Britain in situations not naturally mild or warm. Tobacco can never be worth growing in situations much

above the level of the sea, nor on wet springy soils or northern exposures.

6134. Culture. We shall notice in succession the practice in the West Indies, Virginia, and Maryland, in Alsatia, in Holland, in the South of France, and in Ireland, as lately practised by Mr. Brodigan, and suggest what we think the best mode. shall draw our information chiefly from a valuable article in the Nouveau Cours Complet d'Agriculture, edition 1823, and from the treatise of T. Brodigan, Esq., 1830; looking into Carver's Treatise on the Tobacco Plant, 1779; Tatham's Historical and Practical Essay, 1800; Jennings's Practical Treatise, 1830; and our own notes of 1813-15, 18, 19, and 1828, on Sweden, Germany, and France.

[Carver's Treatise on the Tobacco Plant, 1779; Tatham's Historical and Practical Essay, 1830; and our own notes of 1813–15, 18, 19, and 1828, on Sweden, Germany, and France.

6135. Culture in the West Indies. In the island of Tortuga, the tobacco seeds are sown in beds twelve feet square, and transplanted into the fields when about the size of young lettuces, in rows three feet always and transplanted into the fields when about the size of young lettuces, in rows three feet apprays and the plants three feet distant in the row. The soil is hood and kept clear of weets, and the plant of the plants three feet distant in the row. The soil is hood and kept clear of weets, and the plant of the plants of the plants of the clear of the plants of the plants of the plants of the clear of the plants are plants of the plants are

The surface is laid out into beds or ridglets two feet and a half wide, with alleys between of nine inches or a foot. The beds are raised two feet above the alleys, and are composed of alternate layers of rich soil and dung rotten almost to mould. The direction of the bed is north and south, and on each two rows of plants are inserted at eighteen inches' distance between the rows, and at the same between plant and plant; the plants of one row alternating with the interstices of the others. The summer culture is the same as in Virginia, but the gathering of the crop is differently performed. When the leaves have shown the usual symptoms of maturity, the lowest, or those of the third quality, and the middle leaves, or those of the second quality, are stripped off and kept separate, and from four to six at top left on for some time longer. The leaves stripped off are separately dried, and in the mean time the plants watched, and every sucker or bud which makes its appearance pinched off. The top leaves, or those of the first quality, are gathered when ready; and all the remaining parts of the process with the three qualities is exactly the same as in Virginia. (Did.)

6138, Culture in Alsatia, and generally in the north and west of France and south of Gormanus.

usual symptoms of maturity, the lowest, of those of the Gund quanty, and the mindue leaves, of those of longer. The leaves stripped off are separately dried, and in the mean time the plants watched, and every sucker or bud which makes its appearance pinched off. The top leaves, or those of the first quality, are gathered when ready; and all the remaining parts of the process with the three qualities is exactly the same and the plant of the process with the same and the plant of the

6142. The curing process, by Mr. Brodigan, is as follows:—About the middle of August, the plants having gttained their full size, four or five of the bottom leaves of each plant are taken off, "suffered to lie on the around for some time; and when they lose their brittleness, and can be safely andled, they are carried home to a barn, and there put in a heap for fermentation. The heap is turned, placing that in the centre which was before in the bottom or exterior, and the temperature is not allowed to exceed 100° or 110°. After remaining two or three days in this heap, the leaves are spread out and cooled, and strung by the midrib on lines of packthread; they are then hung up in an airy shady place, roofed in. When the leaves thus suspended have acquired an auburn colour, they are fit for a second fermentation. "A quantity of hay must be placed between the tobacco and the ground, and the heap may be made of an oblong or comic figure, the end of the stems being placed inwards. The heap being made, it is to be surrounded with hay, blankets, or other close covering. The period for this fermentation will depend upon the state of the weather, and the dryness and size of the leaves. In four or five days I generally found the heat sufficiently high to penetrate and reduce the stems, and when that is accomplished the heap is to be cooled by spreading it out to dry. In reducing very strong tobacco, I found in 72 hours, 126°; but the general range of the second fermentation was from 120° to 125° Fahrenheit. In some cases I had to resort to a third fermentation of the same tobacco, but the heat did not rise beyond 90°. Upon this important point of fermentation, or sweating the tobacco, but the heat did not rise beyond 90°. Upon this important point of fermentation, or sweating the tobacco, I have given the result of my practice. For greater accuracy, and the benefit of the inexperienced, I have given the result of my practice. For greater accuracy, and the benefit of the inexperienced, I have given the result of my practi it will possess more or less of crudeness until the month of March following. To correct this crudity, or any acrimony that may exist, different preparations are used in different countries. In Brazil the leaves are steeped in a decoction of tobacco and gum copal. In Virginia, I understood, they sprinkle the tobacco, in the packing process, with a decoction of the green tobacco stems, or a decoction of hay, with a small portion of molasses: the effect of this innocent application is to soften and improve the flavour, darken the colour of the tobacco, and render it, in appearance, a more merchantable commodity. The next and last operation is to tie the leaves in hands, and pack them in bales or portable packages." (p. 166.) [6143. Improvements in the carring process. Some of Mr. Brodigan's tobacco, he informs us, only wanted age to be as good as Virginia. Tobacco improves by a sea voyage, as it undergoes a certain degree of fermentation in the hogsheads in the spring or summer months. Drying houses heated by flues or steam, as now erected in America, he thinks would be an improvement in Ireland. Captain Basil Hall visited a tobacco plantation on James River, and found the house in which the hands were hung up with fires of wood made upon the earthen floor. The flavour of the wood unrut in this way, Mr. Brodigan states, is now strongly perceptible in the tobacco of late years imported from America.

6144. As suggestions derived from considering what we have read and observed on the subject of cultivating and curing tobacco, we submit the following.

subject of cultivating and curing tobacco, we submit the following.

6145. Where a farmer, who thoroughly understands and successfully practises the Northumberland mode of cultivating turnips, intends growing tobacco as a field crop, we would recommend him to prepare the soil exactly as for Swedish turnips, give a double dose of well rotted manure, mix the seed with fifty times its bulk of sand or bone dust, and sow with Common's turnip drill, usually called French's, about the middle of May. When the plants come up, they may be thinned out as turnips are, to sixteen or eighteen inches apart, and topped in the beginning of August. The rest of the process may be conducted as in Alsace, drying, however, in a barn or house heated by an iron stove. A cottager, or spade cultivator, may find it worth his while to sow in a hotbed or in a flower pot, and transplant: he may dry his leaves the first time under the eaves of his cottage, and the second time in his garret; or if the quantity is small for home use, in his kitchen. For his tobacco liquor, or sauce, he may grow a score or two of poppy plants, collect the opium from them, and mix this with whisky or spirit of any kind, in which abundance of peach leaves, or a few leaves of Laurus nobilis, or one or two of the common laurel, have been infused, addling water and salt as directed above. A gardener, where there are hothouse sheds, may dry and ferment in them; and indeed with such opportunities, and seeds of N. repándum, he ought to grow better tobacco than any person whatever not in Virginia or the West Indies.

6146. Produce. A Ccording to Morse (American Geography). "An industrious person

in Maryland can manage 6000 plants, which, at a yard to each plant, cover considerably more than an English acre of ground: - the produce of these 6000 plants is 1000 lbs. of tobacco. 'A hogshead,' says Warden, 'weighing 1350 lbs., is considered a good crop, and sufficient employment for one labourer. In general four plants will yield a pound, though very rich land will yield double the quantity. On the fresh, rich lands of Kentucky, from 1000 to 1500 lbs. are raised per acre." (Brodigan, p. 189.) The leaves of four plants in Virginia make one pound of tobacco. According to Brodigan, the average produce in the county of Wexford is 1200 lbs. per English acre. In Meath, he has had 1680 lbs. per English acre. The money cost of production he estimates at 181. where the land is prepared by horse labour, and 30% where it is prepared by manual labour, per English acre. The produce, at 161.8s. per hogshead of 1350 lbs., barely pays the expense.

6147. To save seed. Allow a few of the strongest plants to produce their flowers; they will have a fine appearance in July and August, and in a favourable season each plant will ripen as much seed in September as will sow a quarter of an acre by the drill system of culture, or stock half a dozen acres by transplanting.

6148. The value of tobacco as an agricultural crop is much diminished, from the circumstance of its producing no manure.

6149. "The arguments of the immortal Jefferson against the culture of tobacco, and in favour of wheat, have their weight in Virginia, where manure is not to be procured in proportion to the demand, and where the produce of that state has to enter into competition with that of the fresh lands of the western country. It is perfectly true, that where tobacco is generally cultivated, his picture of wretchedness is realised. It is the same in France, in the wine districts, where the people, from the want of corn, and the hogs, poultry, and other essential comforts it produces, are the most wretched of any in that country. It is with tobacco in America as with sugar in the West Indies, both are cultivated from their relative advantages over other crops. Sugar is more profitable than tobacco in the West Indies, although the tobacco grown there is of superior quality, and tobacco is preferred in America to wheat, where the soil and climate admit its cultivation. In some situations its grown as a matter of necessity: such is the richness of their alluvial and fresh lands, that wheat cannot be produced until that excess of fertility is reduced by a course of

941

tobacco, maize, or hemp." (Brodigan, p. 84.) The farmers of Virginia, as the immortal Jefferson predicted (Hist. of Virginia), have now ascertained that it is better to raise wheat at one dollar a bushel than tobacco at eight dollars per hundred weight. (Ibid. p. 127.) As a source of labour, Mr. Brodigan thinks the culture and cure of tobacco a desirable employment for the rural population of Ireland. Its great advantage is that it affords employment for those intervals when the labouring poor are at present destitute of occupation. "The cultivation of a potato crop is of vital importance to the Iris peasant; but as soon as that crop is planted, there is a long interval of idleness and distress. The stock of potatoes is then generally exhausted or unfit for use, and the summer months are the most pineting times with the poor. The planting of tobacco may be may be said to commence when the other is furnished; and the field management occupies the interval of idleness, and that is occupied in the curing of the tobacco. (Brodigan, p. 178.) As a cleaning crop and a preparation for wheat, it must be at least equal to the potato.

6150. The analysis of the tobacco stalk is given by Mr. Brodigan on the authority of Mr. Davy of Dublin. The object was to ascertain whether the stalks contained any quantity of the tannin principle, of alkali, or of any useful vegetable substance.

6151. The presence of the tannin principle could not be detected; and the alkali afforded was not very considerable. One thousand parts of the stalks yielded fifty-eight of ashes, which afforded three parts and a quarter of alkali, mostly potash. The stalks contain nearly one tenth of their weight of tobacco; and where tobacco is employed either in fumigating or in making decoctions for the destruction of insects, it may be useful to know, that ten parts of the stalk will always produce effects equal to one part of the leaves.

6152. Diseases and enemies. "In Virginia, the diseases and injuries to which tobacco is liable, are, in the language of the planter, worm-holes, ripe-shot or sun-burnt, moon-burnt, house-burnt, stunted by growth, torn by storms of hail or wind, injured or killed by frost. In Ireland we are exempt from those damages, except what may arise from heavy gales, which, in exposed situations, lacerate and break off the leaves; or an early frost, which is seldom injurious before Michaelmas, at which time, if the planter be careful, he can have his tobacco off the ground." (Brodigan, p. 197.)

ful, he can have his tobacco off the ground." (Brodigan, p. 197.)

6153. The same writer, however, enumerates the enemies of the tobacco in Ireland, as "the red or ring worm, which is so destructive in some situations to wheat and corn crops, the grub, slug, caterpillar, and the tobacco-worm. Where the first two predominate in the soil, it is better not to plant tobacco; for there is no effectual mode of arresting their ravages. A correspondent in the county of Wexford has informed me, that two gentlemen in his neighbourhood attempted the planting of six acres of tobacco this last season, and the plants were no sooner put down than they were cut off by the red worm; they planted again, and the same fate attended them; they planted a third time, and they were a third time destroyed. Thus all their labour and expense were lost; and in the month of July, they sowed the ground with turnips. The grub, or rook-worm as it is called, marches from plant to plant beneath the soil, sccure from observation; he attacks the roots of the plants when grown to a considerable height, and thus prostrates a whole field. Where numerous, it is in vain that you seek for the enemy; but as soon as the plant appears isiekly, it is advisable to pull it up, and you are likely to meet a pair of grubs, as they are companionable travellers. The other enemies are visible, and not so destructive. The slug attacks the young plants in the seed-bed and in the field, and devours the young leaves: he will also cut the leaves of the tobacco in every stage of its growth, which is a proof that its caustic or poisonous property does not attach to it in the green state. The caterpillar generally appears in the warm month of July; it is large and of a voracious aspect. As soon as the leaves appear perforated, this enemy must be sought for, and he will be found in the day-time in the shaded parts of the plants. The caterpillar appears to exist only in close and warm situations."

(Brodigan, p. 161.) Limewater or cow urine effectually destroys slugs, snail

6154. The manufacture of tobacco we have slightly described in the Encyclopædia of Plants. We have since had an opportunity of witnessing the progress of all the different operations carried on in preparing shag and other kinds of smoking tobacco, pig-tail and other chewing tobacco, various snuffs, and different kinds of cigars, in one of the most extensive manufactories in London; and the conviction on our mind is, that very little in the way of manufacturing can be attempted by the gardener or cottager. That little we shall shortly describe.

That little we shall shortly describe.

6155. The tobacco, being properly fermented and cured, may be kept closely pressed and excluded from air, in casks, till wanted; or when the curing process is completed, macking tobacco and snuff may be made from it as follows: — Open out the leaves singly, and from each tear out the midrib. The midribs are better adapted for rasping into snuff than for cutting into shag for smoking; and being scented by any essence, such as that of thyme, anise, lemon, or more especially by that of the root of Ir is forentina, the orris root of the druggists, may be tied up in what are called carrots, or rolls, about eighteen or twenty inches long, two or three inches in diameter in the middle, and half an inch at each end. They are tied with packthread drawn as tight as possible, and the threads quite close, so as to compress the tobacco into one solid substance, and completely to exclude the air. When snuff is wanted, unroll a part of the packthread at one end, and rasp the tobacco into snuff with a file or grater. The carrot may then be laid in a dry place till wanted for a fresh supply. The soft parts of the leaves may be treaded in the same manner, and a snuff produced which some prefer to the other. Gardeners may dry leaves of any odoriferous plant, such as thyme, mint, Alogsia citriodbra, &c., and tie them up in the tobacco carrot as substitutes for liquid scents; and, if thought necessary, they may add a leaf or two of Feratrum álbum to add pungency. For cottagers, there are agrimony, wild thyme, and various other plants, which may be added. The soft parts of the leaves, from which the midribs have been removed, may be slightly sprinkled with water, without any admixture whatever, and twisted into a rope, about the thickness of a common straw rope. The rope may then be coiled up in a ball, as firmly and compactly as possible, tied round in two or three places with packthread, wrapped in paper, and placed in a dry situation, excluded from the air, till wanted for use. When to be u

ture, may consult Cours d'Agriculture Complet, Paris, 8vo, edit. 1823, art. Tabac; Carver's Treatise, London, 8vo, 1779; Tatham's Essay, London, 8vo, 1800; the Experienced Bremen Cigar Maker, or fundamental and practical instructions for making twenty-five sorts of cigars according to the latest experience, Chemnitz, Kretschmar, 1824, 8vo; Schmidt's Tobacco Culture of the French and Dutch combined, with the Mode of preparing the Plant for Use. Dresden, 8vo, 1824. Arndd. The two latter works are in German.

Subsect. 4. Other Plants used in Domestic Economy, which are or may be cultivated in

6157. Many garden plants might be cultivated in the fields, especially near large towns, where manure is easily procured, and a demand for the produce exists. Among such plants may be mentioned the cress, parsley, onion, leek, lettuce, radish, &c. There are also some plants that enter into the agriculture of foreign countries where the climate is not dissimilar to our own, which might be very effectually cultivated in this country were it desirable. Among these is the chiccory, the roots of which are used as a substitute for coffee. The lettuce might be grown for its milky juice, as a substitute for, or rather a variety of opium. Of dwarf fruits, as the strawberry, currant, gooseberry, raspberry, &c., we add nothing here, having already alluded to them in treating of orchards.

6158. The agriculturist who attempts to grow any of the above plants can hardly expect to succeed unless his knowledge extends beyond the mere routine of country husbandry, either by reading and the study of the nature of vegetables, or by some experience in the practice of gardening. No farmer on a moderately extensive scale will find it worth while to attempt such productions, whatever may be his knowledge or resources; and for the garden-farmer, or the curious or speculative amateur, we would recommend observation and enquiry round the metropolis, and the reading of books on horticulture. All that we shall do here, will be to give some explanation of the culture and management of cress and echicary. chiccory.

6159. The garden cress (Lepídium sativum L.), too well known to require any description, is grown in the fields in Essex, the seed being in some demand in the

6160. It is sown on any sort of soil, but strong loam is the most productive. After being well pulverised on the surface, the seed is sown broad-cast and lightly harrowed in. The season of sowing for the largest produce is March, but it will ripen if sown the first week in May. The quantity of seed to an acre varies from two to four pecks, according to the richness of the land; the seed will not grow the second year. No after-culture is required but weeling. The crop is reaped and left in handfuls to dry for a few days, and then threshed out like rapeseed or mustard in the field.

6161. The use of the cress seed is chiefly for sowing to cut for young turkeys; and for forcing salads by the London cooks on hot moist fiannels and porous earthenware vessels. A very considerable quantity is also used in horticulture, it being one of the chief early salads, and cut when in the seed leaf. The hallm is of yery little use as litter, and on the whole, the crop is exhausting.

is of very little use as litter, and, on the whole, the crop is exhausting.

6162. The culture of the chiccory as an herbage plant has already been given (5514.); when grown for the root to be used as a substitute for coffee, it may be sown on the same soil as the carrot, and thinned out to the same distance as that plant.

6163. These roots are taken up in the first autumn after sowing in the same manner as those of the carrot. When they are to be manufactured on a large scale, they are partially dried, and in that state sold to the manufacturers of the article, who wash them, cut them in pieces, roast them on a kilh, and grind

to the manufacturers of the article, who wash them, cut them in pieces, roast from two ounces to three or four pounds. In that state it is sold either as a substitute for coffee, or for mixing with it. But when a private family cultivates this plant for home manufacture, the roots are laid in a cellar among sand, and a few taken out as wanted, washed, cut into slices, roasted in the coffee roaster till they become of a brown colour, and then passed as wanted through the coffee mill.

6164. The value of the chiccory as a coffee plant, Von Thaer observes in 1810, is proved by its having been cultivated for that purpose for thirty years. Dr. Howison has written some curious papers on the subject in The Calcdonian Horticultural Memoirs (vol. iv.), and both that gentleman and Dr. Duncan approve of taste, as some prefer the flavour of the powdered roots of dandelion to that of either coffee or chiccory. Dr. Duncan is of opinion that chiccory might be cultivated with great national advantages as a substitute for the exotic berry. (Disco. to Calcd. Hort. Soc. 1820.) Bosc says the decoction of chiccory roots is wholesome, but that it has nothing more belonging to it of coffee than the colour. He sees no objection to its use as a substitute, but deprecates as fraudulent its mixture with the powder of real coffee.

6165. The value of the chiccory as a salad plant appears to us not to be sufficiently appreciated in this country. Great quantities of the blanched leaves of chiccory are sold in the markets of the Netherlands very early in the spring, and supply a grateful salad long before lettuces are to be had. The roots are taken up on the approach of winter, and packed in cellars in alternate layers of sand, so as to form ridges with the crowns of the plants on the surface of the ridge. Here, if the frost be excluded, they soon send out leaves in such abundance as to

(fig. 812.), an annual distinguished by its triangular pods, a native of the south of Europe, is cultivated in Hungary (§ 630.), and in some parts of Germany, for the seeds as a substitute for The culture is the same coffee. as that of the common pea or tare.

811

6167. In a former section (6055.) we have hinted that no farmer who cultivates the hop need be without a vegetable equal to asparagus, or fibre similar to that of flax to employ his servants in spinning; and from the foregoing observations it would seem that whoever has a garden may grow his own coffee and tobacco.

Sect. V. Plants which are or may be grown in the Fields for Medicinal Purposes.

6168. A number of medicinal plants were formerly grown in the fields; but vegetable drugs are now much less the fashion; a few powerful sorts are retained, which are either collected wild or are natives of other countries, and the rest of the pharmacopæia is chiefly made up of minerals. It may safely be affirmed that there are no plants belonging to this section which deserve the notice of the general farmer; but we have thought it desirable to notice a few sometimes grown by farming gardeners, and which may be considered as belonging almost equally to horticulture and agriculture, or as points of connection between the two arts. These are the saffron, liquorice, rhubarb, lavender, mints, chamomile, and thyme.

6169. The saffron, or autumn crocus (Crocus salivus L., fig. 813. a), is a bulbous-rooted

perennial, which has been long cultivated in the south of Europe, and since Edward III.'s time in England, and chiefly at Saffron Walden in Essex. It was abundantly cultivated there, and in Cambridgeshire, Suffolk, and Herefordshire, in the beginning of the seventeenth century; but the quantity of land under this crop has been gradually lessening for the last century, and especially within the last fifty years, so that its culture ss now almost entirely confined to a few parishes round Saffron Walden. (Young's Essex.) This is owing partly to the material being less in use than formerly, and partly to the large importations from the East, often, as Professor Martyn observes, adulterated with bastard saffron (Cárthamus tinctòrius) and marigolds (Caléndula officinàlis).

6170. The bulbs of the saffron are planted on a prepared soil, not poor nor a very stiff clay, but, if possible, a hazel mould on chalk. They are planted in July, in rows six inches apart across the ridges, and at three

a hazel mould on chalk. They are planted in July, in rows six inches apart across the ringes, and at the inches' distance in the rows.

6171. The flowers, which are purple, and appear in September, are gathered, carried home, and the stigmas picked out, together with a portion of the style; these are dried on a kiln between layers of paper, and under the pressure of a thick board, to form the mass into cakes.

6172. The crop of an acre averages two pounds of dried cake after the first planting, and tenty-four pounds for the next two years. After the third crop the roots are taken up, divided, and replanted.

6173. The uses of saffron in medicine, domestic economy, and the arts, are various. It is detersive, resolvent, anodyne, cephalic, ophthalmic, &c.; but its use is not without danger: in large doses it promotes drowsiness, lethargy, vomiting, and delirium; even its smell is injurious, and has been known to produce syncope. It is used in sauces by the Spaniards and Poles; here and in France it enters into creams, biscuits, conserves, liquors, &c., and is used for colouring butter and cheese, and also by painters and dyers.

6174. The liquorice (Glycyrrhiza glàbra L., fig. 813. b.; Liquoritia officinàlis H.B. 10493.) is a deep-rooting perennial, of the Leguminosæ, with herbaceous stems rising four or five feet high. It has long been much cultivated in Spain; and since Elizabeth's time has been grown in different parts of England.

has been grown in different parts of England.

6175. The soil for the liquorice should be a deep sandy loam, trenched by the spade or plough, or the aid of both, to two and a half or three feet in depth, and manured if necessary. The plants are procured from old plantations, and consist of the side roots, which have eyes or buds. In autumn, when a crop of liquorice is taken up for use, these may be taken off and laid in earth till spring, or they may be taken from a growing plantation as wanted for planting. The planting season may be either October or February and March. In general the latter months are preferred. The plants are dibbled in rows three feet apart, and from eighteen inches to two feet in the row, according to the richness of the soil. The after-culture consists in horse-hoeing and deep stirring, in weeding, and in cutting over and carrying away the haulm every autumn after it is completely withered. As the plants do not rise above a foot he first season, a crop of onions or beans is sometimes taken in the intervals. The plants must have three summers' growth, at the end of which the roots may be taken up by trenching over the ground. These are either immediately sold to the brewers' druggists, or to common druggists, or preserved in sand, like carrots or potatoes, till wanted for use. They are used in medicine and porter-brewing.

6176. The rhubarb (Rhèum palmàtum L., fig. 813. c) is a perennial, with thick oval roots which strike deep into the ground, large palmate leaves, and flower-stems six or eight feet high. Its leaves are the best of all the kinds of rhubarb for tarts. The Society of Arts exerted itself for many years to promote the culture of this plant, as did Dr. Hope of Edinburgh. It has accordingly been cultivated with success both in England and Scotland; though the quality of the root produced is considered by the faculty inferior to that of the Russia or Turkey rhubarb, as Professor Martyn thinks, an inferiority probably owing to the moisture of our climate, and the imperfect mode of drying.

to that of the Russia or Turkey rhubarb, as Professor Martyn thinks, an inferiority probably owing to the moisture of our climate, and the imperfect mode of drying.

6177. In the culture of this plant, if bulk of produce be the object, then a deep, rich, loamy sand should be chosen; but if flavour, then a dry, warm, somewhat calcareous sand. Prepare as for liquorice, and sow in patches of two or three seeds, in rows four feet apart, and the same distance in the rows. Transplanting from seed-beds may be adopted; but the roots are never so handsome and entire. As soon as the plants appear, leave only one in a place. The plants will now stand in the angles of squares of for feet to the side. The after-culture consists in horse-hoeing and deep stirring, both lengthwise and across; in ploughing in the same directions; in mever letting the flower-stems rise higher than two feet, or show flowers or seed unless some is wanted for propagation; and in removing the decayed haulm every autumn. The plants, having stood three or four summers, may be taken up, and their main roots dried in a very slow manner by any of the following modes:—The common British mode of curing or drying the rhubarb, after cleaning the roots, is to cut them into sections, an inch or more in thickness, string them, and dry them in airy lofts, laundries, or kitchens, in a gradual manner. This has long been the practice of private gardeners who grow the root for their own use, and has also been adopted by cultivators for the druggists. The rhubarb is cured in Tartary by being thoroughly cleaned, the smaller branches cut off, and then cut transversely into pieces of a moderate size; these are placed on long tables or boards, and turned three or four times a day, that the yellow viscid juice may increporate with the substance of the root. If this juice be suffered to run out, the roots become light and unserviceable; and if they be not cut within five or six days after they are dug up, they become soft and ecay very specially. Four or five days after th

quantities of the roots are annually collected for exportation in the Chinese provinces, within the lofty range of the Himalaya. The best is that which comes by way of Russia, as greater care is taken in the selection; and on its arrival at Kiachta, within the Russian frontiers, the roots are carefully examined, and the damaged pieces removed. Mr. Sweet has been informed that the stems of the leaves have the same effect as the root; only, of course, a greater portion of them will require to be used. They may be made up in a small tart, like the stems of the common rhubarb. (Gard. Mag. vol. v. p. 161.)

6179. The lavender (Lavandula Spica L. fig. 813. d) is a dwarf odoriferous shrub of three or four years' duration, grown in the fields in a few places round London, and chiefly in Surrey, for the spikes of flowers used by the druggists, perfumers, and distillers. The soil should be a poor dry calcareous gravel. The seeds should be sown in a garden in spring, and the plants may be transplanted in September or March following, in rows two feet apart, and kept free from weeds. The second season they will yield a few flowers, and a full crop the fourth, after which the plants will continue productive for five or six years. The spikes are gathered in June, dried in the shade, and sold in bundles to the herbalists, druggists, &c.

6180. Thyme, wormwood, marjoram, savory, and some other aromatics, are cultivated in the same manner, and for similar purposes. Being usually smaller plants, they should be planted closer; but to have much flavour the soil must be dry and calcareous.

6181. Chamomile (Anthemis nóbilis) is a creeping perennial, grown for its flowers. It only requires to be planted on a poor soil, in rows a foot apart, and hoed between. It will produce abundance of flowers annually from June to September, which are gathered, and dried in the shade. They are sold by weight to the druggists and apothe-The double-flowered variety is, from its beauty, that commonly cultivated; but the single possesses more of the virtues of the plant according to its weight.

6182. The mints (Mentha), and especially the peppermint (Mentha piperita), are creeping-rooted perennials, cultivated on rich marshy or soft black moist soils for dis-The plants are grown in beds with trenches of a foot or more in width and depth between, so as to admit of irrigation. The sets are obtained from old plantations, and planted in rows across the beds at six inches' distance every way, in March or April. No produce worth notice is obtained in the first year, but a full crop in the third, and the shoots will continue to produce for five or six years. The spikes of flowers, and in some cases the entire herbage, are cut over in June, as soon as the flowers expand, and carried immediately to the druggist's still. Some growers distil it themselves.

6183. The common valerian (Valeriàna officinàlis L.) is sometimes cultivated for its roots for the druggists. It is a native plant, and prefers a loamy soil. In Derbyshire the plants, which are either procured from the offsets of former plantations, or from wild plants found in wet places in the neighbouring woods, are planted six inches asunder, in rows twelve inches apart. Soon after it comes up in the spring the tops are cut off, to prevent its running to seed, which would spoil it. At Michaelmas, the leaves are pulled and given to cattle, and the roots dug up carefully, and clean washed; the remaining top is then cut close off, and the thickest part slit down to facilitate their drying, which is effected on a kiln, after which they must be packed tight, and kept very dry, or they will The usual produce is about 18 cwt. per acre. This crop receives manure in the winter, and requires a great deal.

6184. The orchis or salep plant (O'rchis mascula L.) is a tuberous perennial, which grows plentifully in moist meadows in Gloucestershire, and other parts of the country. It flowers in May and ripens seeds in July. It has been proposed to cultivate it for its tubers to be used as salep; but the plant is very difficult of propagation from seed, and can hardly be multiplied at all by the root; and, though it may answer to collect the tubers and prepare them, it is not likely their culture will ever pay. As the plant is very abundant in some situations, it may be useful to know its preparation, which is thus

described in Phil. Trans. vol. lix.

described in *Phil. Trans.* vol. IIX.

6185. The bulb is to be washed in water, and the fine brown skin which covers it is to be separated by means of a small brush, or by dipping the root in hot water, and rubbing it with a coarse linen cloth. When a sufficient number of bulbs are thus cleansed, they are to be spread on a tin plate, and placed in an oven heated to the usual degree, where they are to remain six or ten minutes, in which time they will have lost their milky whiteness, and acquired a transparency like horn, without any diminution of bulk. Being arrived at this state, they are to be removed, in order to dry and harden in the air, which it will require several days to effect; or, by using a gentle heat, they may be finished in a few hours. By another process, the bulb is boiled in water, freed from the skin, and afterwards suspended in the air to dry; it thus gains the same appearance as the foreign salep, and does not grow moist or mouldy in wet weather, which those that have been barely dried by heat are liable to do. Reduced into powder, they soften and dissolve in boiling water into a kind of mucilage, which may be diluted for use with a lage quantity of water or milk. Thus prepared, they possess very nutritious qualities; and if not of the very same species as those brought from Turkey and used for making salep, they so nearly resemble them as to be little inferior. In Turkey the different species of the O'rchis are said to be taken indifferently; but in England, the O'rchis mascula is the most common. (Gloucestershire Report, 377.)

CHAP. IX.

Marine Plants used in Agriculture.

6186. All marine plants may be used as manure with great advantage, either in a recent state or mixed with earth. It is used in this way more or less in all agricultural countries bordering on the sea, and in Britain in all those friths and estuaries, where, from the water not being at the maximum of saltness, the plants which grow in it are not sufficiently charged with soda to render it worth while to burn them for the sake of the salt.

fil87. The use of sea-weed, as an article from which kelp might be manufactured, seems to have been practically recognised in Scotland about the beginning of the eighteenth century. The great demand for kelp in the manufacture of glass and soap at Newcastle, and of alum at Whitby, seems to have introduced the making of this commodity upon the shores of the Forth, so early as about the year 1720. It began to be manufactured in the Orkney Islands in the year 1723, but in the western shires of Scotland the making of kelp was not known for many years after this date. The great progress of the bleaching of linen cloth in Ireland, first gave rise to the manufacture of kelp in that kingdom; and from Ireland it was transferred to the Hebrides about the middle of the eighteenth century. On the shores of England the kelp plants are not abundant.

6188. All marine plants may be used for the manufacture of kelp, but the principal species in use on the British shores belong to the Linnean genus Fucus. Fucus vesiculòsus (fig. 815. a) is considered by kelp-makers as the most productive; and the kelp obtained is, in general, supposed to be of the best quality. Fucus nodosus (b) is considered to afford a kelp of equal value to that of the above species, though perhaps it is not quite so productive. Fucus serratus (c), or black-weed, as it is commonly called, is neither so productive as the preceding, nor is the kelp procured from it so valuable. This weed is seldom employed alone for the manufacture of kelp; it is in general mixed with some of the other kinds. Fucus digitatus (Laminaria digitata H. B. 15, 343.) (d) is said to afford a kelp inferior in quality to that obtained from any of the others; it forms the principal part of the drift-weed.

6189. The plants are cut in May, June, and July, and exposed to the air on the ground till nearly dried, care being taken to prevent them, as much as possible, from being exposed to the rain. They are then 3 P

burned in a rude sort of kiln, formed by digging a pit in the sand, or by enclosing a portion of the surface with loose stones. On the bottom of this kiln a peat fire is kindled, and the weed is gradually added, till

the fire extends over the whole floor; the weed is then spread lightly on the top, and added in successive portions. As it burns it leaves ashes, which accumulating towards evening, become semifused, and are then well stirred. Another day's burning increases the mass; and this is continued till the kiln is nearly filled. On some occasions the kiln consists of a cavity in the ground, over which bars of iron are placed; and on this the ware is burned, the ashes falling into the cavity, where they are well worked by the proper instruments.

the proper instruments.
6190. Kelp is generally divided into two kinds; the cut-weed kelp, and the drift-weed kelp; the former made from the weed which has been recently cut from the rocks, the latter from that which has been drifted ashore. The latter is supposed to yield a kelp of inferior quality. Some specimens of kelp, however, made from sea-weed which had been drifted ashore, tend to prove that this is not always the case. Weed which has been exposed to rain during the process of drying, affords a kelp of inferior quality. It is of the utmost importance to the manufacturer of kelp, to keep his weed as much as possible free from rain. For this purpose many employ sheds; when these are not at hand, the weed which has been laid out to dry should be collected into one heap during the rain; when this ceases, it should again be immediately spread out. It has often been matter of dispute, how old the plants should be before they are cut. In general, three years is considered sufficient: this, however, from some trials which have been made to ascertain this point, seems to be too long. From experiments, it appears, that the produce of kelp, from one ton of three years' old weed, is only eight pounds more than that from the same quantity of two years' old; from this we would conclude, that the weed ought to be cut every two year. Though perhaps less weed may be procured from the same extent of ground occupied by weed of two, than of three years' growth, yet the difference may not be so great as to render it worth while to allow the weed to remain for three years.

three years.

6191. In order to increase the quantity of kelp, it has been suggested to the Highland Society, that the seed of the Salsola Sòda might be imported and cultivated at a small distance from the shore, with the design of mixing the plant with the sea-ware, for the improvement of the kelp. It was formerly imagined, that the barilla plant would not produce any quantity of alkali, worth its cultivation, if planted in France; but in the year 1782, some spirited individuals procured a quantity of barilla seed, and made a plantation of it near the coast of the Mediterranean, in the province of Languedoc, and had the satisfaction for several years to find, that the barilla which they produced from these plants was of a quality equal to that which they usually procured from Alicant. Why, then, may not a similar attempt in our own country be equally successful?

6192. Other plants. If the growers of kelp could contrive to make some considerable plantations of the most productive of the kali, or of furnitory, wormwood, and other inland plants, which yield large quantities of potash, and collect the crop to burn with the other materials, the carbonate of potash resulting from their incineration would decompose the sea salt, and a great accumulation of carbonate of soda would be produced. It was proved long ago by Du Hamel, that the marine plants produced soda merely in consequence of their situation, for when they have been cultivated for some years in an inland spot they yield only potash.

6193. There are immense tracts of shore on the mainland and islands of Scotland which may be easily cultivated for the production of kelp, from which at present not one penny is derived. All the cultivation requisite is, to place whin or other hard stones, not under the size of the crown of a hat, upon such vacant spaces. Contracts have been made to plant shore lands in the Highlands with such stones, at the rate of 200. per Scots acre. Such stones are generally to be found at high-water mark, on all the shores of the lochs of the Highlands. They are put into a boat at high water, then carried to the ground to be planted, and thrown overboard; on the ebb of the tide they are distributed regularly over the shore, preserving a clear space of one foot round every stone, which distance, after very minute examination, appears to be the most eligible for producing the greatest crop of ware. It it evident these stones should be of a round shape; as the more surface that is exposed to the alternate action of the air and water, so much more kelp ware will be produced from a given space of ground. In four years the first crop may be cut, which, on the above data will yield about four per cent on the original expense. But the crop may be manufactured into kelp in every third year thereafter, which, on the same data, is equal to about five per cent. In this improvement there is no hazard of bad crops; and if the manufacture is begun early enough in the season, there is little danger to be apprehended from bad weather; it being understood that the operation of kelp-making can be carried on, should there be no more than two dry days in eight. (Highland Society's Trans. vols. v. and vi.)

6194. The cultivation of barilla (Salsòla Sòda, Chenopòdeæ, a native of Spain), on a small scale, was tried in the gardens of Tynningham, the seat of the Earl of Haddington, in 1789, but without success, although planted under a south wall, in a most sheltered part of the garden. (J. M. in Gard. Mag.) The culture of this and other species is practised to some extent in the neighbourhood of Alicant in Spain, and the details given

in the Cours Complet, &c. art. Soude. The ground is brought into good tilth, and manured; and the seed sown broadcast in October or November; in the following spring the plants will be found an inch high, and must be kept clear of weeds till the month of August, when, being at its full growth, it may be mown or pulled up (for it has scarcely any roots), dried, and afterwards burnt in holes in the ground like kelp.

6195. The sea-wrack grass (Zostèra marina; Fluviàles) is found in abundance on different parts of our own shores, as at Yarmouth, the bays of the Orkney Islands, and

other bays not exposed to the immediate fury of the ocean.

other bays not exposed to the immediate fury of the ocean.

6196. It grows in banks of sand and mud, which banks appear to be held together principally by the roots of this plant, which are strong and succulent, and throw out numerous lateral fibres. It grows at such depths as to be left nearly dry by the ebbing of spring tides. During the autumn, and beginning of winter these leaves are thrown on shore in large quantities. They are of a very imperishable nature, and may be kept for any length of time in fresh or salt water, without any apparent decay. In the Orkney Islands this grass is thrown ashore during winter in large quantities, and collected by the inhabitants with other marine plants into heaps, for manure. In these heaps it is allowed to ferment, and sometimes, before heing applied, it is mixed with earth or other matters. It is also used as thatch, and forms a more durable defence against the violent winds and heavy rains of that climate than straw. A few years ago, in consequence of premiums offered by the Highland Society, this grass was applied as a substitute for horse-hair, and stuffing mattresses and furniture: for this purpose it is carefully washed twice in fresh water, then dried quickly; and afterwards, any sea-weed that had got mixed with it picked out. In the Orkneys it is steeped in fresh-water lakes for a week, then taken out and spread wet on the ground, and picked, while in this state, from extraneous matters. Exposure to drought for one day will make it sufficiently dry for packing. When dry, care must be taken, if the weather is windy, to gather it into heaps or cocks, otherwise it may be blown away, being then extremely light. It is sent to market in large bags of sacking, or twisted into ropes of the thickness of a man's waist, and then compactly made up in nets, formed of ropes made of bent grass. It is sold at the Asylum for the Industrious Blind at Edinburgh, who employ it in stuffing mattresses. (Highl. Soc. Trans. vol. vi. p. 592.)

CHAP. X.

Weeds or Plants injurious to those cultivated in Agriculture.

6197. Every plant which appears where it is not wanted may be considered injurious, though some are much more so than others. A stalk of barley in a field of oats is a weed, relatively to the latter crop, but a thistle is a weed in any crop; weeds, therefore, may be classed as relative and absolute.

6198. Relative weeds, or such cultivated plants as spring up where they are not wanted, give comparatively little trouble in extirpating them. The most numerous are the grasses when they spring up in fields of saintfoin or lucern, or among corn crops in newly broken up grass lands. The roots of chiccory, in fields that have been broken up after bearing that crop for some years, those of madder, liquorice, &c., are of difficult extirpation. When the potato crop has not been carefully gathered, or mustard has been allowed to shed its seed, they also occasion trouble. Other cases will readily occur to the practical man, and need not be mentioned.

and need not be mentioned.

6199. Absolute weeds, or such native plants as are considered injurious to all crops, are very numerous, and may be variously arranged. Some affect in a more peculiar manner corn-fields and tillage lands, and these are chiefly annuals, as wild mustard, wild radish, poppy, blue-bottle, cockle, darnel, &c.; or biennials, as the thistle; or perennials, as couch-grass, knot-grass, black-couch, polygonum, &c.; on lands laid down to grass for a few years, dock, ox-eye daisy, ragweed, &c. Others infest grass lands, and these are chiefly perennials, such as crowfoot, one of the most difficult of weeds to extippate; thistlest, docks, rushes, sedges, moss, and an endless variety of others. Some are more particularly abundant in hedges; of which the reedy and coarse grasses, as couch-grass, brome-grass; the climbing and twining lants, as goose-grass (Galium Aparine); and the twiners, as bind-weed (Convólvulus), are the most injurious.

6200. With regard to the destruction of weeds, they may be classed first according to

their duration.

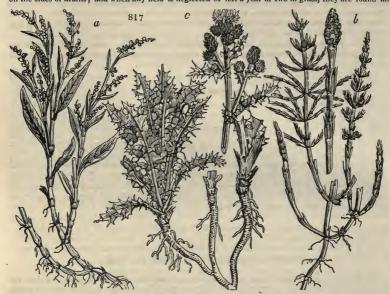

6201. All annuals and biennials, as said-wort (fig. 816. a), and sorrel (b), are effectually destroyed by cutting over the plant at anypoint below that whence the seed leaves originated, as this prevents them from ever springing again from the roots. Perennials of the fibrous-rooted kind may be destroyed of in the same manner, as the crowfoot, ragweed, the fibrous-rooted grasses, and many others. Some weed, the fibrous-rooted grasses, and many others. Some manns; but almost all the thick-rooted perennials require to be whole gradients.

nusiform-rooted perennials may also be destroyed by similar means; but almost all the thick-rooted perennials require to be wholly eradicated.

6202. The perennial weeds, which require their roots to be wholly eradicated, may be classed according to the kind of roots. The first we shall mention are the stoloniferous roots or surface shoots of plants, by which they propagate themselves. Of this kind are the creeping crowfoot, goosefoot or wild tansy, potentillas, mints, strawberries, black couch-grass, and most of the Agrosticlea and other grasses. The next are the under-ground creeping roots, as the couch-grass, Convólvulus arvénsis, and other species of bind-weed, coltsfoot (fig. 816. c), sowthistle, several tetradynamous plants, as toadflax, Scrophularia, nettle, hedge-nettle (Stachys), Lamium, Ballota, &c. Some of these, as the bindweed and corn-mint, are extremely difficult to eradicate; a single inch of stolone, if left in the ground, sending up a shoot and becoming a plant. The creeping and descending vivacious roots are the most difficult of all to eradicate. Of this class are the Polfgonum amphibium (fig. 817. a), the reed (Arûndo Phragmites), the horse-tail (Equisètum, fig. 817. b), and some others. These plants abound in deep clays, which have been deposited by water, as in the carses and clay-vales of Scotland. In the Carse of Falkirk for example, the roots of the Polygonum amphibium are found example, the roots of the Polygonum amphibium are found 3 P 2

every where in the subsoil alive and vigorous. They send up a few leaves every year in the furrows and on the sides of drains; and when any field is neglected or left a year or two in grass, they are found all

over its surface. Were this tract left to nature for a few years, it would soon be as completely covered with the Polygonum as it must have been at a former age, when it was one entire marsh partially covered by the Frith of Forth. The horse tail is equally abundant in many soils, even of a dier desceiption; and the corn-thistle (Serrátula arvénsis, fig. 817. c) even in dry rocky grounds. Lightoot (Flòra Scotica) mentions plants of this species dug out of a quarry, the roots of which were nineteen feet in length; it would be useless to attempt eradicating the roots of such plants. The only means of keeping them under, is to cut off their tops or shoots as soon as they appear; for which purpose, lands subject to them are best kept in tillage. In grass lands, though they may be kept from rising high, yet they will, after being repeatedly mown, form a stool or stock of leaves on the surface, which will suffice to strengthen their roots, and greatly to injure the useful herbage plants and grasses.

6203. Tuberous and bulbous-rooted veceds, are not very numerous; wild garlic, arum, and bryony are examples; and these are only to be destroyed by complete eradication.

6204. Ramose, Jusignorm, and similarly rooted perennials, of which rest-harrow, fern, and scabious are

examples; and ness are only to be destroyed by complete standards.

6204. Ramose, fusiform, and similarly rooted perennials, of which rest-harrow, fern, and scabious are examples, may in general be destroyed by cutting over below the collar or point whence the seed-leaves have issued. Below that point the great majority of plants, ligneous as well as herbaceous, have no power of sending up shoots; though there are many exceptions, such as the dock, burdock, &c., among herbs, and the thorn, elm, poplar, cherry, crab, &c., among trees.

6205. Holdich has taken a different view of the subject of weeds, and classed them, not according to the modes by which they may be destroyed, but according to the injuries which they do to the soil or the crop. He has divided them into two classes, weeds of agriculture, or arable lands, and pasture weeds.

6206. Arable weeds are arranged as, i. those which infest samples of corn; 2 root or fallow weeds, and such others as are hard to destroy; 3, those which are principally objectionable as they incumber the soil; 4, underling weeds, such as never rise with the crop, nor come into the sickle. Under these heads, each weed in its respective division is treated of as to its deteriorating qualities and mode of destruction.

weed in his respective division is treated of as to it of a foot o

Rhœ'as); 3. Blue-bottle (Centaurèa Cyanus); 4. Mayweed (A'nthemis Cótula); and 5. Corn marigoid (Chrysánthemum

(A'nthemis Cótula); and o. Corn mangote (m.).

6209. The weeds called underlings, or such as never rise in the crops, are, 1. Groundsel (Senecio rulgaris); 2. Annual meadow grass (Peà ánnua); 3. Chickweed (Stellaria média); 4. Shepherd's purse (Thiáṣab biras pastòris and erécta); 5. Spurry (Spérgula arvénsis); 6. Chamomile (Matricària Chamomilla); 7. Fat-hen (Chenopòdium ábum); 8. Common corn saled (Fèdia olitòria), 9. Flix-weed (Sisymbrium Sophia); 10. Common fumitory (Fumària officinàlis); 11. Sand mustard (Sinàpis muràlis).

6210. Pasture weeds are, 1. Dwarf-thistle (Cárduus acaúlis); 2. Common chamomile (A'nthemis nóbilis); 3. Star-thistle (Centaurèa Calcitrapa); 4. Ox.-eye daisy (Chrysánthemum leucánthemum); 5. Great fleabane (Conỳza squarròsa); 6. Cheese-rennet (Gàlium vèrum); 7. Long-rooted hawkweed (Apárgia autumnàlis); 8. Wild thyme (Thỳmus Serpfilum); 9. Sheep's sorrel (Ròmex Acctosélla); 10. Knot-grass (Polýgonum aviculàre); 11. Yellow rattle (Rhinánthus Crista gálli); 12. Common carline thistle (Carlina vulgàris).

6211. Pasture weeds which generally prevail in loamy soils, and such also as are prevalent in clayer and damp soils, are principally as follows:—1. Yellow goats-beard (Tragopolon praténsis); 2. Marsh thistle (Carduus paldstris); 5. Melancholy thistle (Cárduus bercophyllus); 4. Meadow thistle (Carduus praténsis); 5. Common butter-bur (Tussilàgo Petasltes);

6. Common ragwort (Senècio Jacobe'e); 7. Common daisy (Bellis perénnis); 8. Common black knapweed (Centaurea nigra); 9. Broad-leaved dock (Rômex obusifolius); 10. Orchis (O'rchis máscula, maculata, latifolia, mòrto, and pyramidàlis); 11. Common cow-parsney (Heraclèum Sphondylium); 12. Sedge (Carex), various species.

6212. A catalogue of weeds could be of little use to the agriculturist, as the mere names could never instruct him as to their qualities as weeds, even if he knew them by

their proper names. Besides, weeds which abound most, and are most injurious in one district, are often rare in another. Thus, the poppy abounds in gravelly districts, the charlocks on clays, the chickweed, groundsel, nettle, &c., only on rich soils. Flora, or any of the national Floras, as Lightfoot's Flora Scotica, and Smith's British Flora, and, we may be allowed to add, our own Encyclopædia of Plants and Hortus Británnicus, by pointing out the habits of indigenous plants, may be of considerable use to the agriculturist who has acquired a slight degree of the science of botany.

BOOK VII.

THE ECONOMY OF LIVE STOCK AND THE DAIRY.

6213. The grand characteristic of modern British farming, and that which constitutes its greatest excellence, is the union of the cultivation of live stock with that of vegetables. Formerly in this country, and in most other countries, the growing of corn and the rearing of cattle and sheep constituted two distinct branches of farming; and it was a question among writers, as, according to Von Thaer, it still is in Germany, which was the most desirable branch to follow. The culture of roots and herbage crops at last led gradually to the soiling or stall-feeding husbandry, in imitation of the Flemings; and afterwards, about the middle of the last century, to the alternate husbandry, which is entirely of British invention, and has been more effectually than any thing else the means of improving the agriculture of the districts where it is practised.

of improving the agriculture of the districts where it is practised.

6214. It is observed by Brown, that "though horses, neat cattle, sheep, and swine are of equal importance to the British farmer with corn crops, yet we have few treatises concerning the animals, compared with the immense number that have been written on the management of arable land, or the crops produced uponit. But though so little has been written, the improvement of those animals has not been neglected; on the contrary; it has been studied like a science, and carried into execution with the most sedulous attention and dexterity. We wish it could be stated, that one half of the care had been applied to the selecting and breeding of wheat and other grains, which has been displayed in selecting and breeding the best proportioned and most kindly feeding sheep. A comparison cannot, however, be made with the slightest degree of success; the exertions of the sheep-farmers having, in every point of view, far exceeded what has been done by the renters of arable land. Even with cattle considerable improvement is and as to swine, an animal of great benefit to the farmer, in consuming offal which would otherwise be of no value, it is to be regretted that very much remains to be done."

6215. The first important effort in the improvement of inte stock was made by Robert Bakewell, who was born on his father's estate of Dishley, in 1726. Mr. Bakewell wrote nothing himself; so the first scientific work on the subject was written by George Culley, in 1782, who had formed himself on Bakewell's model. The systematic improvements of Mr. Bakewell were developed in various agricultural reports, and consisted in attempts to lessen such parts of the animal frame of cattle and sheep as were least useful to man, as bone, cellular substance, and appendages; at the same time increasing such other parts, as flesh or muscle, and fat, as become more important in the furnishing man with food. These ends he endeavoured to accomplish by a judicious selection of individual vermin

CHAP. I.

The cultivated Horse. - E'quus Cabállus L.; Mammàlia Bélluæ L., and Pachydérmes Solipedes Cuvier. Cheval, Fr.; Pferde, Ger.; Cavallo, Ital.; and Caballo, Span.

6216. The horse family, by far the most important among the brute creation as a servant to man, includes several species both in a wild and cultivated state, as the E'quus Hemionus, or wild mule, a native of Arabia and China, and which it is supposed would form an excellent race of small horses, could they be reduced to a state of domestication; the E. Asinus, or ass, well known; the E. Zèbra, or striped ass; the E. Quágga, by some considered a variety of the zebra; and the E. bisúlcus, or cloven-footed horse, a native of Chile, and by many supposed to belong to a distinct genus.

3 P 3

6217. The common horse, justly considered as the noblest of quadrupeds, is found in a wild state in the deserts of Great Tartary, in the southern parts of Siberia, and in other parts of Asia, and in the interior of Africa. He has long been domesticated and cultivated in most parts of the earth, for the various purposes of war, hunting, parade, the saddle, and draught; and in some places, partly for his flesh and the milk of the female. The parts of a horse, when no longer endued with life, are applied to various useful purposes. The blood is used as manure. The bones are broken and boiled, to produce oil, and are afterwards ground into an excellent manure; some of the bones are also employed in the mechanical arts. The flesh supplies food for the domestic carnivorous animals, the cat and dog; for carnivorous birds, kept for amusement or curiosity; for fish, &c. We shall consider the horse in regard to its varieties, organology, anatomy, physiology, diseases, breeding, rearing, training, feeding, and working

SECT. I. Varieties of the Horse.

6218. The varieties of the domestic horse are numerous. The indigenous horse of every country, operated on by climate, assumes that form best adapted to its locality. would soon, however, be led to mix with the native breeds that variety which presented in its aboriginal state the finest form and most valuable qualifications. This being found centred in the horses of Arabia, Persia, and Barbary, the inhabitants of Europe generally sought an amelioration of their own breeds by an admixture of oriental blood.

6219. The Arabian horses (fig. 818. is a portrait of one brought by Buonaparte from Egypt, and now living in the royal garden of Paris,) are reckoned the best, and the solicitude with which the Arabs preserve these horses pure and unmixed is remarkable. The care with which they are nutured, and the skill disclosed in their equisition management are no lose. care with which they are nurtured, and the skill displayed in their questrian management, are no less admirable. None but stallions of the finest form and purest blood are allowed access to their mares, which is in ever permitted but in the prosence of a professional witness or public officer, who attests the fact, records the mame, and signs the pedigree of each. The Persian horses are considered next in value; and after them the horses of Andalusia in Spain. The Barbary horses are descended from the Arabians, and nuch esteemed. Jackson (Empire of Morocco, p. 42.) mentions one very fleet variety, used for hunting the ostrich, and fed entirely on camel's milk. The horses of India, though active and oil flormed, are small and vicious, the climate being unfavourable to their greater developement. Those of Turtary are of a moderate size; but strong, muscular, full of spirit, and active. The Tartars are considered skilful riders. Like the Kalmucks, they eat the flesh of horses as we do that of oxen, and use their milk either in curd or fernented.

or fermented.

6220. Of the European varieties of the horse, those of Italy were formerly in greater esteem than at present; but still those of the Neapolitans shine both under the saddle and in traces. Great numbers are bred in Sicily; those of Sardinia and Corsica are small, but active and spirited. The Swiss horses partake of the same qualities.

small, but active and spirited. The Swiss horses partake of the same qualities.

6221. The Spanish horses have long been highly esteemed. The invasion of the Moors, in 710, brought a vast influx of oriental blood into Spain; and the continuance of the Moorish yoke during several centuries produced altogether so improved a race there, that the best Spanish horses are preferred by some to the Barbs. The Spanish Genette has long been celebrated for its elegance, sprightliness, and durability. The best breeds of Spain are generally finely carcased, and well limbed, active, ready, and easy in their paces, docile and affectionate to their owners, full of spirit and courage, but tempered with mildness and good-nature; they are, for the most part, of a moderate size. Those which are bred in Upper Andalusia are deemed the most valuable. The Portuguese horses, or rather marces, were famous of old for being very fleet and long-winded; but of late, it is said, they are much degenerated.

6222. France abounds in horses of all kinds, whose origin may be traced to a mixture of their native breeds with the Asiatic introduced by the irruption of the Goths, and originally received from the Scythians, and the true eastern blood received from Spain, Barbary, and Arabia. With these admixtures, however, the horses of France have not yet borne a high character throughout Europe; and although under the dominion of Napoleon more than two hundred pure Arabian stallions were imported, and the northern states plundered of their choicest specimens, by which the breeds have been much improved; still France imports yearly vast numbers from this country, particularly hunters and high bred carriage horses. Of their own breeds, Limousin furnishes some good saddle horses, and hunters also. Next to those, Normandy claims precedence for a well-formed and useful breed. There are also very good bidets, or ponics, in Auvergne, Poitou, and Burgundy. Lower Normandy and the district of Cotentin furnish some very tolerable coach horses, and which are mor

swellings.
6224. Holland furnishes a race of horses which are principally serviceable in light draught work: the best come from Friesland.

6225. Germany is not destitute of good horses. The native breeds, heavy and ill-formed, received their first improvement from admixture with the Asiatic horses. In after-times the Germans obtained still

finer breeds from the Arabs, Turks, and the Barbary states, which they still preserve with some care as stallions; some good specimens are also obtained from Spain. In a general point of view, however, the German horses are more fitted for the manege than for racing or hunting; in which qualities they are inferior to the Hungarian and Transylvanian horses. The horses of Bohemia are not distinguished by any eminent qualities. The Hussars and Transylvanians are accustomed to slit the nostrils of their horses under a notion of civing their breath a free passage and improving their wind, as well as to render any eminent quanties. The russars and transpirations are accusioning their wind, as well as to render them incapable of neighing, which, in the field, would be often inconvenient. The Croatian horses are nearly allied in qualities and character to the Hungarian and Bohemian: these, as well as the Poles, are remarkable for being, as the French term it, $b \dot{e} g u t$, or keeping the mark in their teeth as long as they

remarkable for being, as the French term it, begul, or keeping the mark in their teeth as long as they live.
6226. The Polish horses are hardy, strong, and useful, but they are generally of a middling size. In the marshy parts of Prussia, and towards the mouth of the Vistula, there is a breed of tall strong horses, resembling those of Friesland, but of inferior value.
6227. The horses of Russia are not much regarded by other nations. They are small but hardy, and capable of enduring great fatigue. Great attention is, however, paid to such as are very fast in their trot; and such a breed is much encouraged for trotting matches on the snow and ice. Those of the Turkish breed are handsome and finely shaped, but too slight and weak for heavy cavalry. The Kalmuck horses are somewhat higher than the Russian common horses, and are so lasting and constitutionally strong as to be able to run three or four hundred. English miles in three days. They subsist, summer and winter, solely upon grass in the great deserts which are between the rivers Don, Volga, and Yaik, where they are collected in great herds of four hundred, five hundred, or even a thousand. They are excellent swimmers, and pass the river Volga, where it is from one mile to two miles broad, with great ease.
6228. The horses of Sweden are low and small, and the Norway breed may be comprehended under the same description, but they are strong, hardy, and active. Denmark, and also Holstein and Oldenburg, boast a large variety of horses, which has long been esteemed as peculiarly adapted for heavy cavalry and carriage uses, though they are apt to fail with respect to elegance of limb and symmetry of parts; their heads being large, their sitoulders heavy, their backs long, with croups too narrow to correspond with their force parts. In the Islands of Perce there is a race of horses of small growth, but strong, speedy, and very sure-footed. They are never shod, and feed abroad without shelter both summer and winter. In Suderoe, one of these islands, they have a pecu

6229. The British varieties of saddle horse may be reduced to the racer, the hunter, the improved hack, the old English road horse, the galloway, and the pony; the two latter of which we shall consider in another place.

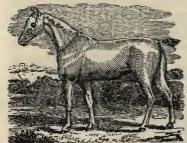

6230. The race horse (fig. 819.) is descended nearly in a direct line from the Arabian, the Persian, and the Barb. In an agricultural point Persian, and the Barb. In an agricultural point of view, this celebrated breed might at first sight appear of little importance; but it is probable, that to the amusement afforded by it to the rich and powerful, we are indebted for the principal improvements in every other variety of this most valuable animal. Races or courses were very early a part of British sports; and it is natural to suppose that, on this account, endeavours would be made to improve and enlarge the breeds of the native horses. Roger de Bellesme, Earl of Shrewshay, is the first on record who imported a Snanish

breeding of horses, which would tend still further to extend the search after better specimens. There is reason, however, to believe, that the courses of those times were little more than ordinary trials of speed between the indigence, or these slightly improved breeds; and it was not until the days of Henry VII. and VIII., that the true eastern blood was collected in any considerable quantities. During these reigns, however, it becoming very general to import stallions from Arabia, Barbary, and Persia, a new and highly improved race rapidly extended itself. This improvement was carried subsequently to its acmé by an equally careful selection of mares as of horses; and thus we find king James importing a set of mares of the purest blood, significantly called the royal mares. From these periods, the breeding of the race horse was pursued with the utmost care, as well in regard to purity of blood, as in the increase of his bodily powers, by the most nutritious food and duly apportioned exercise, during his training for the courses, then becoming so fashionable in England. Thus has been produced a breed unrivalled throughout the world for symmetry of form, switness of progression, and durability under exercition. The accounts on record of feats performed by some of our horses on the turf are truly astionishing. Bay Malton ran at York four miles in seven minutes and forty-three seconds. Childers, known by the name of the flying Childers, moved through a space equal to eighty-two feet and a half in a second. After these Eclipse, Highflyer, Matchem, Hambletonian, and others, have contributed to keep up the reputation of the English racer.

Briglish racer.

6231. Climate has a great influence over the form of animals, and that form is found indigenous to each which best fits it for the purposes required of it. In the arid plains of the east, where herbage is scarce, a form is given which east fits it for the purposes required of it. In the arid plains of the east, where herbage is scarce, a form is given which enables its brute inhabitants to readily transport themselves from one spot to another; and as in every situation the flesh of the horse is greedily sought after by the predatory tribes, so here, where those are peculiarly strong and active, the horse is formed peculiarly agile and swift to escape their attack, as well as peculiarly light, that his weight might not sink him in the sandy plains, nor his bulk retard him in his flight. Removed, however, to more temperate climes, where vegetation affords by its luxuriance more nutriment, and where the restrictions of danger have ceased to operate, we no longer see him equally small and slender; but, with equal capacity for swift progression, we find him expanded into a form capable of keeping up that progression with a durability unknown to the original breeds from which he sprang. Symmetrically formed as we now see him, he at once evinces his claim to great speed. His bony skeleton exhibits a base founded on the justest geometrical principles, presenting a series of lengthened levers acting by means of a condensed muscular and tendinous organization of great power, on angles capable of great flexion and extension; while his pointed form fits him to cleave that atmosphere, from which his deep cheet enables him to draw by extensive inspirations wind and vigour to continue his exertions. Purity of blood, by which is meant the result of confining to particular races or English racer.

breeds the means of continuing their species, is observed with equal care and jealousy by the breeders of the English race, as by the Arabians; and turf jockeys assert they can discover a taint or departure from this

The heights varied from fifteen hands to filteen hands two inches; and the colours were frequently mixed.

6235. The objection, however, to English horses, both of the original and of the more early improved breeds, and which is even still seen among them, is, that they want grace or expression in their figure and carriage; that they are somewhat obstinate and sullen; and that a certain stifnes in their shoulders, and want of suppleness and elasticity in their limbs, render them unift for the manege. As this is an important charge against the excellence of our breeds, it may be worth consideration how far it is founded in truth. Commerce requires despatch, and England as a great commercial country makes every thing subservient to an economical use of time. Conformably to these principles, many of the qualities of our horses, but principally those of flexibility and safety in progression, are certainly sacrificed to speed, in which they undoubtedly excel all horses in the world. It is well known that all animals intended by nature for quick progression, are formed low in their fore parts, and have usually narrow upright shoulders; which defects are too common in English horses in general. On the contrary, in most of the improved breeds of continental horses, the fore hands are elevated, and the shoulders wide and oblique; by which, flexibility and safety in progression are gained at some expense of celerity; for the strong lumbar muscles of horses so formed, operating on the lengthened spinous processes of the dorsal vertebre with increased advantage, elevate the fore parts higher; and even in default of this form in the fore parts, yet a corresponding effect is produced in foreign horses by the great strength and expansion of their haunches and croups, and by the greater inclination in their hinder extremities towards the common centre of gravity of the body: for as speed depends first on the extent to which he angles of the limbs can be opened, and secondly, on the efforts of the body in its transit to counter

purity to the sixteenth remove. 6232. The hunter (fig. 820.) is derived from horses of entire blood, or such as are but little removed from it, uniting with mares of substance, correct form, and good action. In some instances hunters are derived from large mares of the pure breed, propagating with powerful stallions of the old English road horse. This favourite and valuable breed is a happy combination of the speed of the Arabian, with the durability of the native horse. More extended in form, but framed on the same principles, he is able to carry a considerable weight through heavy grounds, with a swiftness equalled only by the animal he pursues, and with a perseverance astonishing to the natives of every other country. Hence the extreme demand for this breed of horses in every European country; our racing stallions being now sent to propagate in the eastern climes, whence they were some of them origin. good action. In some instances hunters are derived eastern climes, whence they were some of them origi-

eastern climes, whence they were some of them originally brought.

6233. The improved hackney (fig. 821.) is derived, like the former, from a judicious mixture of the blood breed with the native horse, but exhibiting a greater proportion of the latter. Hackneys are now, however, mostly bred from stallions possessing nearly the same proportion of blood with the hunter; but with a form and qualities somewhat different. In the hackney, as safety is as requisite as speed, we look particularly to the fore parts to see that they are high and well placed; that the head is not heavy, nor the neck disproportionately long or short; that the legs stand straight (that is, that a perpendicular line drawn from the point of the shoulder should meet the toe); and that the elbows turn out: and although a perfect conformation in the hinder parts is necessary to the hackney, it is in some measure subordinate to the same perfection in the fore parts; whereas in the racer and hunter, but particularly in the former, the form of the hinder is even of more consequence than that of the fore parts.

ticularly in the former, the form of the hinder is even of more consequence than that of the fore parts.

6234. The old English road horse. This most useful breed is now nearly extinct, although some northern agriculturists appear to be making efforts to revive the race. It has so long been known in this country that it although it is probable that it originally sprang from a judicious culture from horses of Norman, German, or Flemish extraction, which horses were very early imported to enlarge our small breeds, and to render them equal to the heavy loads they were accustomed to carry as pack-horses; and of which kind the old English road horse unquestionably is, (fig. 882.) Neither is it at all impossible, that, in the more fertile parts of the island, an original breed (fig.822.) Neither is it at all impossible, that, in the more fertile parts of the island, an original breed existed of considerable power and bulk. Athelstan expressly prohibited the exportation of English horses, and the "scythed chariots drawn by fiery steeds" of the ancient Britions struck terror even into Casar's legions. These accounts of the antiquity of the English horse, receive additional strength from the notices we obtain of the fossil between the brees taxing the nor own according to strength from the notices we obtain or the Iossail bone of horses having been found, according to Parkinson, in various parts of the island. The old English road horse possessed great power, with short joints, a moderate shoulder, elevated crest, with legs and feet almost invariably good. The heights varied from fifteen hands to fitteen hands two inches; and the colours were frequently mixed.

go through any ground, and activity sufficient to accomplish the most extraordinary leaps. As roadsters, these horses have ever proved valuable, uniting durability, ease, and safety with extreme docility.
In form they may be considered as affording a happy mixture of an improved hack with our old
English roadster.

6237. The British varieties of saddle horse of more inferior description are very numerous, as cobs,
galloways, and ponies. Cobs are a thick, compact, hackney breed, from fourteen hands to fourteen hands two inches high, in great request for elderly and heavy persons to ride, or to drive in low phaetons, &c.
Galloways and ponies are lately in much request also for low chaises; a demand which will lead to a
cultivation of their form; the number bred requires little increase, as several waste districts or moors
throughout England are already appropriated principally to the purpose of rearing ponies.

6238. The British varieties of year or cavarly horse, and of carriage and cart horse, are considered to
have been derived from the German and Flemish breeds, meliorated by judicious culture. Most of the
superior varieties contain a mixture of Arabian or Spanish blood. Cavarly horses are found amongst the
larger sort of backneys; and the observations made in the late wars sufficiently show the justice of the
selection. Except in a few unhappy instances, where a mistaken admiration of the Hulans had led to
selecting them too light, the English cavalry horse possessed a decided superiority over the best French
horses in strength and activity, as well as over the Germans, whose horses on the other hand, by their
bulk and heavy make, were incapable of seconding the efforts of the British dragons. The coach, chariot, and stage horses are derived many of them from the Cleveland bays, further improved by a mixture
of blood. Others are bred from a judicious union of blood and bone, made by the breeders in Yorkshire,
Lineolnshire, and other midland counties.

of blood. Others are bred from a judicious union of blood and bone, made by the breeders in Yorkshire, Lincolnshire, and other midland counties.

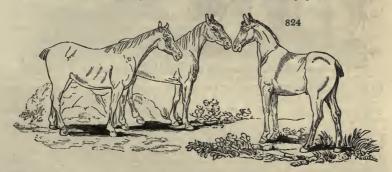

6239. The varieties of draught horse were originally as numerous as the districts in which they were bred, each having its favourite breed; but since the intercourse among farmers and breeders has been greater, those in common use are so mixed as to render it difficult to determine of what variety they partake the most. At present the principally esteemed draught horses are the Suffolk punch, the Cleve-laud bay, the black, and the Lanark or Clydesdale. The native breeds of draught horses of England, Scotland, Wales, and Ireland, are much too small for the purposes of agricultural draught as now conducted; but by cultivation, the improved breeds pointed out have furnished such animals as are equal to every thing required of them.

6240. The black horse (fig. 823.), bred in the midland counties of England, is a noble and useful animal; and furnishes those grand towns we see in the cool.

and furnishes those grand teams we see in the coal flour, and other heavy carts and waggons about London and furnishes those grand teams we see in the coal, flour, and other heavy carts and waggons about London; where the immense weight of the animal's body assists his accompanying strength to move the heaviest loads. But the present system of farming requires horses of less bulk and more activity for the usual agricultural purposes, better adapted for travelling, and more capable of enduring fatigue; consequently this breed is seldom seen in the improved farms. The black cart horse is understood to have been formed, or at least to have been brought to its present state, by means of stallions and mares imported from the Low Countries; though there appears to be some difference in the accounts that have been preserved, in regard to the places whence they were originally brought, and to the persons who introduced them. (Culley on Live Stock, p. 32., and Marshal's shal, under too confined a view, and probably prejudiced as well as for the alleged tendency to become flat and pommiced in the feet, is most unreasonably severe on it, when he says, "the breed of grey rats, with which this island has of late years been overrun, are not a greater pest in it than the breed of black fen horses; at least while cattle remain scarce as they are at present, and while the flesh of horses remains to be rejected as an article of human food." (Marshal's Yorkshire, vol. ii, p. 164.) The present improved sub-variety of this breed is said to have taken its rise in six Zealand mares, sent over from the Hague by the late Lord Chesterfield, during his embassy at that court.

6241. The Cleveland bays (fig. 824.), which owe some of their most valuable properties to crosses with

the race-horse, have been long celebrated as one of the best breeds in the island; but they are said to have degenerated of late. They are reared to a great extent in Yorkshire, the farmers of which county are remarkable for their knowledge in every thing that relates to this species of live stock. In activity and hardiness, these horses, perhaps, have no superior. Some capital hunters have been produced by putting full-bred stallions to mares of this sort; but the chief object latterly has been to breed coach-horses, and such as have sufficient strength for a two-horse plough. Three of these horses draw a ton and a half of coals, travelling sixty miles in twenty-four hours, without any other rest but two or three baits upon the road; and frequently perform this labour four times a week.

6242. The Suffolk punch (fig. 825.) is a very useful animal for rural labour, and is particularly esteemed by the farmers of Nortolk, Suffolk, and Essex, but the merit of this breed seems to consist more in constitutional hardiness than in any apparent superiority of shape. "Their colour is mostly yellowish or sorrel, with a white ratch or blaze on their faces; the head large, ears wide, muzzle coarse,

fore-end low, back long sometimes, but always very straight, sides flat, shoulders too far forward, hind-

estraight, sides hat, shoulders too far forward, hind-quarters middling, but rather high about the hips, legs round and short in the pasterns, deep-bellied, and full in the flank. Here, perhaps, lies much of the merit of these horses; for we know, from ob-servation and experience, that all deep-bellied horses carry their food long, and consequently are enabled to stand longer and harder days' works. enabled to stand longer and harder days' works. However, certain it is, that these horses do perform surprising days' works. It is well known, that the Suffolk and Norfolk farmers plough more land in a day than any other people in the island; and these are the kind of horses every where used in those districts." (Culley on Live Stock, p. 27.) Since Culley's time much pains have been taken to improve this useful breed, and to render them, by cultivation, fitted not only for heavy but for light work. It is no uncommon thing for a Suffolk stallion to fetch from 2001. to 3001. The hest show of these stallions in England is at Woodbridge Lady-day fair, where Suffolk cart mares have brought from 1001. to where Suffolk cart mares have brought from 1001, to 150L, and one mare and her offspring a few years ago at this fair brought 1000l. The figure (825.) hardly does justice to the animal. (M.)

6243. The Clydesdale horse (fig. 826.) has been long in high repute in Scotland and the north of England; and, for the purposes of the farmer, is probably equal to any other breed in Britain. Of the origin of this race, various accounts have been given, but none of them so clear, or so well authenticated, as to merit any notice. They have got this name, not because they are bred only in Clydesdale or Lanarkshire, for the same description of horses are reared in the other western countries of Sustand and June 11 the Lanarkshire, for the same description of horses are reared in the other western counties of Scotland, and over all that tract which lies between the Clyde and the Forth, but because the principal markets at which they are sold, Lanark, Carnwath, Rutherglen, and Glasgow, are situated in that district, where they are also preserved in a state of greater purity than in most other parts. They are rather larger than purity than in most other parts. They are rather larger than the Suffolk punches, and the neck is somewhat longer; their

the Suffolk punches, and the neck is somewhat longer; their colour is black, brown, or grey, and a white spot on the face is esteemed a mark of beauty. The breast is broad; the shoulder thick, with the reaching cartilaginous portion of the blade-bone nearly as high as the withers, and not so much thrown backwards as in road horses; the hoof round, but not to long; the hucks visible, but not prominent, and the space between them and the ribs short; the tail heavy, and well haired; the thighs meeting each other so near as to leave only a small groove for the tail to rest on. One most valuable property of this breed is, that they are remarkably true pullers, a restive horse being rarely found among them.

among them.
6244. The Welsh horse (fig. 827. a) bears a near resemblance, in point of size and hardiness, to the best of

the native breed of the highlands of Scotland, and other hilly countries in the north of Europe. It is too small for the present two-horse ploughs; but few horses are equal to them for enduring fatigue on the road. "I well remember," says Culley, "one that I rode for many years, which, to the last, would have gone upon a pavement by choice, in preference to a softer road." (Observations on Live

the road. "I well remember," says curiey, one that I would have gone upon a pavement by choice, in preference to a softer road." (Observations on Live Stock, p. 35.)

6245. The galloway (b), properly so called as being found chiefly in that province of Scotland, has now become very rare, the breed having been neglected from its unfitness for agricultural purposes. Galloway is, however, used as a term for any horse between the pony size and the hack; and in this point of view is sufficiently numerous, and very commonly bred by small farmers on commons and wastes. The true galloway is somewhat larger than the Welsh horse, and is said to resemble the Spanish horses; there is also a tradition, that some of the latter, that had escaped from one of the vessels of the Armada, wrecked on the coast of Galloway, were allowed to intermix with the native race. Such of this breed as have been preserved in any degree of purity are of a light bay or brown colour, with black legs, and are easily distinguished by the smallness of their head and neck, and the cleanness of their bone.

6246. The still smaller horses of the Highlands and isles of Scotland, (c) are distinguished from larger breeds by the several appellations of ponies, shelties, and in Gaelic of garrons or gearrons. They are reared in great numbers in the Hebrides, or western isles, where they are found in the greatest purity. Different varieties of the same race are spread over all the Highland districts, and the northern isles. This ancient breed is supposed to have been introduced into Scotland from Scandinavia, when the Norwegians and Danes first obtained a footing in these parts. "It is precisely the same breed that subsists at present in Norway, the Ferce Isles, and Iceland, and is totally distinct from every thing of horse kind on the continent of Europe, south of the Baltic. In confirmation of this, there is one peculiar variety of the horse in the Highlands, that deserves to be noticed: it is there called the eel-backed horse. He is of different colours, l

resemblance to an eel stretched out. This very singular character subsists also in many of the horses of Norway, and is nowhere else known." (Walker's Hebrides, vol. ii. p. 158.) "The Highland horse is sometimes only nine, and seldom twelve hands high, except in some of the southern of the Hebrides, where the size has been raised to thirteen or fourteen hands by selection and better feeding. The best of this breed are handsomely shaped, have small legs, large manes, little neat heads, and are extremely active and hardy. The common colours are grey, bay, and black; the last is the favourite one." (General Report of Scotland, vol. iii. p. 176.)

SECT. II. Organology or exterior Anatomy of the Horse.

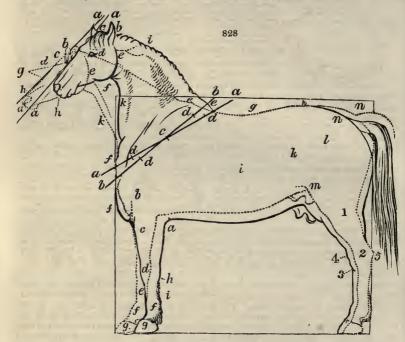

6247. A just knowledge of the exterior conformation of the horse, to be able to form a correct judgment on the relative qualities of the animal, forms the ne plus ultra of a scientific horseman's aim; but it is a branch of knowledge not to be obtained without much study and experience. In considering a horse exteriorly, his age, his condition, and other circumstances should be taken into the account; without which attention it is not possible to determine, with precision, the present or future state of a horse when he is seen under various peculiarities. A horse of five years old, though considered as full grown, yet experiences very considerable alterations of form after that period. He then becomes what is termed furnished; and all his points (i. e. his adult form), before hidden in the plumpness of youth, or disguised by extreme obesity, now show themselves. From the effects of muscular exertion promoting absorption, he becomes more angular, and to the painter's eye, would prove more picturesque, but less beautiful. A horse likewise low in flesh and condition, is hardly the same animal as one in full flesh and condition; and again, the sleekness acquired from relaxed labour, with full and gross feeding, is very unlike the robust form acquired from generous diet with correspondent exertion.

6248. The examination of the subject of organology is conveniently pursued by dividing it into head, neck, trunk, or body, and extremities or legs. The greater number of well proportioned horses, with the exception of the head and neck, come within a quadrangle; not one strictly equilateral as depicted by Lawrence (Richard) and Clark, but one whose horizontal dimensions are usually between a twenty-fourth and twenty-eighth greater than their perpendiculars. It must, however, be kept in mind, that with some considerable deviations from this quadrangular form, many horses have proved superiorly gifted in their powers; and that a deviation from these proportions appears in some instances, as in that of the race horse, not only favourable, but necessary also to his Nature will not be limited, and the perfection of her operations is not alone dependent on the arbitrary arrangement of parts, but on a harmony and accordance of the whole, internal as well as external. To the artist, however, such admeasurement is useful, inasmuch as it prevents any singular departure from a symmetrical appearance, which is but too common among our animal draughtsmen. To the amateur it also offers a convenient, though not an unerring guide. Our exemplification of the organology appears by placing a blood and a cart horse within the same square (fig. 828.), by which the differences between the various parts of the one and the other are readily contrasted.

6249. The organs of the head. The head of the horse is remarkable for its dimensions, formed by an elongation of the jaws; yet in him, as in most of the grazing tribes, its bulk is in an inverse proportion to the length of the neck, otherwise the muscles would It is an important part considered as relative to beauty alone, it not be able to lift it. being in the inferior heavy breeds but little marked by grace or expression; but in the improved varieties it presents lines worthy the painter's pencil and the poet's fancy. Neither is it too much to say, that in no part of the body is this amelioration of breed so soon detected as in the head. Can any thing be conceived more dissimilar than the small inexpressive features of the cart horse, and the bold striking ones that grace the head of the blood horse? The quick succession of movements in his pointed ears, the dilatations of his expanded nostrils, or his retroverted eyes, which give fire and animation to the character of his head when under the influence of any excitement. more worthy of remark, when it is considered that some of the principal aids to expression in the human countenance are wanting in the horse. Man borrows much of his facial expression from his eyebrows, and when to these the varied action of the mouth is added, it amounts to more than a half of the total expression. A great accession of beauty is gained in the improved breeds by the increase of the facial angle, which in them is about 25°, but in the heavy breeds is usually only 23° (a a a a).

6250. The ears $(b\ b)$ in the improved breeds are small and pointed; in the heavy they are not only large and ill shaped, but they frequently separate from each other; these defects gave rise to the barbarous custom of cropping, now happily in a great measure abolished. The ears are criterio of the spirit, as well as of the temper; we have seldom seen a horse which earried one ear forward and the other backward during his work that was not hardy and lasting. Being not subject to early fatigue, he is attentive to every thing around him, and directs his ears different ways to collect sound from every quarter. The ears are also indications of temper, and a horse is seldom either playful or vicious but his ears are laid flat on the neck. It is fortunate that we are provided with such a warning, by an animal that does not want craft to surprise us, nor strength to render his resentment terrible.

6251. The forehead next presents itself (c c), straight, and of a proper width in the improved bree.ls, adorned by nature with an elegant portion of hair, which, detaching itself from the rest of the mane, flows down the face to protect both that and the ears from the attacks of insects.

62.52. The eyes (dd) deserve particular attention, not only for their utility, but as objects of beauty and expession. In the blood horse the orbitary fosse, or eye-sockets, are more prominent and more inclined, by which the axes of his eyes diverge more from each other than those of the heavy breed; by which not only which the axes of his eyes diverge more from each other than those of the neary breeq; by which not only he is enabled to see further behind him, but the prominence of his eyes gives great beauty and expression to the blood head. The further consideration of the eyes, and their criteria of soundness, will be postponed to the anatomical detail. In old horses most of the fat of the body, which is more superficially placed in the young, becomes absorbed; in this way the eye, which is usually embedded in a vast quantity of this matter, losing its assistance, sinks within its orbits, and thus the cavities above, called eye-pits, shows themselves deeply in a good horse.

deeply in an aged hore. 6253. From the ears to the angle of the jaws (e e) large vessels and extensive glands are situated. Within these branches of the posterior jaw is lodged the throat, and it will be observed how necessary it is that these branches should expand sufficiently to admit of the motions of the head, particularly of those influenced by the reining-in of the bridle; otherwise the blood-vessels and other parts must be injuriously

fluenced by the reining-in of the bridge; chiefwise the pressed upon.

6254. The hollow between the jaws is called the channel, and at the under part of it (f) a considerable branch of an artery proceeds from the inner side over and around the outer, which branch forms the most convenient situation for feeling the pulse of the horse.

6255. The face (g) of the improved breed of horses presents either a straight line, or one slightly curved inward towards the lower part; whereas, in the heavy breeds, it is very commonly found to be curved outward. This part comprises, as with man, from the forehead to the lips. When the face is covered with white, it is considered a blemish; but when a white spot only exists in the forehead, it is considered a beauty.

considered a beauty.
6256. The markings in the face are useful to describe a horse by, and frequently lead to the recovery of a strayed or stolen one. In regimental accounts these marks are carefully noted. When a spot extends down the face, it is termed a blaze; and when further continued into the muzzle, it is called blaze and snip. When a star is distinct, but with it there are white markings which begin some distance below it, and are continued downwards, it is called a race, 6257. The muzzle (h h) includes the lips, mouth, and nostrils; the darker the colour of this part the more is the horse esteemed: very dark brown horses are an exception, for in them it is usually of a tan colour, and is praised both as a beauty and indicative of excellence. It is both a beauty and an excellence that the nostrils be thin, angular, and large.
6258. The lips should be thin, firm, and by no means 100se and pendulous, as is the case in the old and sluggish. The lips in the horse are the principal organs of touch and discrimination, and hence are exquisitely esnsible.

sluggish. The lips in the horse are the principal organs of touch and discrimination, and hence are exquisitely sensible.

6259. The form of the mouth, as receiving the bit, is important. It is also of more consequence than is usually supposed, that its commissure or opening be sufficiently deep; when shallow, it is not only inclegant, but it will not admit a bridle favourably into its proper resting place upon the bars. Within the mouth are situated the teeth, which are so placed as to have interrupted portions of jaw above and below of considerable extent. These vacancies are called bars, and are parts of extreme importance to the horse-man, as it is by means of agents called bits resting on these parts, and operating on their sensibility by means of a lever, the long arm of which is in the hand of the rider, that he ensures obedience. In aid of this mechanism, to one-portion of this lever is attached a chain, called a curb, which acting on the outer part of the chin, increases the pressure. This latter part has been called the barb or beard, but its situation is evidently above that.

6260. The teeth (fig. 829.), which present themselves on the lower parts of the jaws, are the incisive and canine. The two front incisives are popularly called nippers or gatherers (a); the two next adjoining, separators or middle teeth (b); and the outer, the corners (c); but it would be more definite to say the first, second, and third incisives, beginning at the corner. The tusks or tushes (dd) occupy part of the intermediate space between the incisive and grinding teeth. The teeth, as criteria of age, will be considered in the anatomical detail.

in the anatomical detail.

6261. The organs of the neck. The exterior parts which compose the neck are first the upper surface, which is furnished throughout its whole extent with an elegant assemblage of hair called mane (fig. 828. e e). In some instances, as in stallions, it is of enormous length and thickness. In dark-coloured horses it is commonly black, but in horses of colours approaching to a light hue the reverse is frequently seen, and the mane and tail is smooth is an object with most horsemen, but the pulling the hair out in tufts by wrapping it round the fingers is a most erroneous practice, and not only at the time frustrates the end intended, but a mane so pulled will seldom hang well after. The writer of this has always made use of a three-pronged angular mane-puller, which, if used two or three times a week, will bring both mane and tail into perfect order, and will keep them so. This iron is manufactured and sold by Long, veterinary instrument maker in Holborn, London.

6263. The upper surface of the neck (i) should form a moderate but elegant curve, which is greatly favourable to beauty: this curve is, however, not so considerable in the pure eastern variety as in the better sort of northern horse.

sort of northern horse.

6264. The under surface of the neck (k k) should be nearly straight; in the cock-throttled horse it arches outwards, and the upper surface in these instances is sometimes hollowed inwards in equal proportions, when such horse is called ewe-necked. When this deformity is considerable, it prevents the head from being carried in its true angle, and particularly so under the action of the bridle; in which case the nose being projected forwards, carries the axis of the eyes upwards: such horses are called stargazers; and it is to be observed that they are seldom safe-goers. In mares and geldings a very just criterion of a sluggish disposition, may be formed from the presence of a considerable quantity of flesh on the upper surface of the neck: when the crest is very thick and heavy, it is almost an unerring prognostic of a decided sluggard. In stallions it, however, forms a distinctive sexual mark, and therefore is less to be depended upon in them. In a well-proportioned horse, the length of the neck, the length of the head, and of the angle uniting the two, should give the height of the withers from the ground. When the neck is too long, the head must of course gravitate by the increased length of the arm of the balance; it likewise seldom presents a firm or proper resistance to the bridle. When, on the contrary, the neck is too short, the head is frequently ill placed, and the lever in the hand of the rider will be too short also.

6265. The organs of the trunk or carcase are various. Considered as a whole, Clark has not unaptly likened it, when separated from the limbs, to a boat; within which are disposed various important viscera. The bony ribs he likens to the wooden ones encompassing the vessel, and the sternum or breast-bone, being perpendicularly deep and thin, carries the resemblance further, and fits the machine to cleave the air as the boat does the water. Within this animal vessel, according with the justest mechanical principles, the weightiest of the viscera, the liver, is placed in the centre, and the others follow nearly in the relative order of their gravity; so that the lungs, the lightest of the whole, are stowed in front, where great weight would have been most disad-

Vantageous.

6266. The shoulders (a a, b b) are commonly considered as extending from the withers above to the point in front, and to the line behind formed from the elbow upwards: but a correct description considers them as those parts immediately concerned in motion; that is, the scapula or blade-bone, and its attachments. The shoulders are too apt to be confounded with the withers above, and with the arm below, erroneously called the point of the shoulders. From this confusion, great error is committed in appreciating their nature and action; but this is removed by recourse to the skeleton (fig. 880.i, k, l). The withers (e) may be justly proportioned at the same time that the shoulders may be narrow, straight, and altogether badly formed, and vice versā. The shoulders should be muscular and narrow, but not heavy; and to determine between these essential points, requires the eye of experience in the viewer, and the presence of condition in the viewed. A muscular shoulder is essentially necessary, when we consider that the fore extremities are wholly connected by muscle, and not as in man, by the intervention of the bony union of the clavicle or collar bone. In the horse, therefore, we find that large muscular masses unite the shoulder blade, by its upper and inner surfaces, to the chest; while other powerful muscles for the shoulder shoulders is propelled forwards, its wight and force being received by the fore extremities, painful and hurtful shocks would have been experienced at every step. Powerful muscles for the shoulders are also as necessary for progression as for stachment. It is not therefore with judgment that a very thin meagre shoulder is commonly preferred. It is by the union of strength with just proportions, and a proper situation of the parts, that the value of the animal is determined.

determined.

6267. The centre of action in the shoulders (c) is in their common centre, and the extent of action of any part moving on its centre, is dependent on the length of such part; the motion the shoulder enjoys is confined to the perpendicular backwards, and to as great an elevation of the muscles as they will admit of forwards. It will be therefore evident that the more oblique is the situation of the shoulder blade, the greater number of degrees it can go through; it must be as evident also that when the shoulder blade is long and deep, as well as oblique, that this advantage is increased. It is commonly observed, although it is not invariably the case, that when the shoulder is short, it is also upright (b b). Obliquity and length in the shoulder favour the safety of the progression also; for as the angles formed between the shoulder, the arm, and fore-arm, are consentaneous, and make, when in action, a bony arch; so the obliquity and length of the shoulders is favourable to a due elevation of the limb, on which, in a great degree, depends the safety of progression. Thus mares are, ceteris partibus, more unsafe than horses, their shoulders being short to correspond with the low mare-like forehand; and their decreased obliquity usually regulates an increased obliquity in the whole limb downwards, or as is familiarly expressed, they stand with their legs under them. Unfavourable as is this form of the mare, both or the speed and safety of their action, it was given for advantageous purposes: for, by such a position in the fore extremities, the hinder are raised higher to afford additional security against the evils of gravitation and dislodgement of the foal from the pelvis. Few rules can be laid down in the exterior conformation that are more important, or of such general application, as that a short and upright shoulder, particularly when united with an

inclined direction of the whole limb backwards, is a sure mark of an unsafe goer, and commonly, though not invariably, of a slow one also. It now and then happens indeed, that horses having defective shoulders prove speedy and good movers, which would appear to contravene these principles; but it will be found, that, wherever horses having these defects in their fore legs yet prove quick and safe in progression, they invariably have hinder parts of great strength and proportion to make up the deficiency. Indeed, it appears probable, that the hind and fore parts do not bear the same relative proportion in all horses alike; in blood horses, the withers are not always high, and although their shoulders are commonly deep and oblique, yet the fore limbs are altogether short in proportion to the hinder, in a great number of the fleetest racers: for, as speed appears to be a principal end in their formation, and as comparative anatomy furnishes us with abundant proof that all animals destined to make considerable caps (and the full gallop is nothing more than a succession of leaps) are low before, the end of their formation is really best answered by this arrangement of parts; it is also more than probable that, altough speed in the gallop may be found with a defective forehand, yet, in the slower paces of the canter, trot, and walk, a justly formed shoulder is more immediately requisite. This subject will be still further elucidated when we treat on the mechanical properties of the skeleton.

6268. The withers (e) are formed by the long transverse processes of the dorsal vertebree (fig. 830.9), and as their use is to serve as levers to muscles, so their length characterised by the height of the withers must be of great advantage, alevate horses going above their ground; for the muscles of the back, acting to greater advantage, elevate the fore parts more forcibly. From this we may also learn that the elevation of the fore parts, or the horse's going above his ground, as elevated action is expressed, is not altogether

horse.

6270. The back. Where the withers end the back commences (g); the length should be moderate only, for a long cylinder cannot be so strong as one of less length; long-backed horses are easy because the action and the reaction are considerable; but what is gained in elasticity is lost in strength. When the back is too short, the extremities are so much approximated that they frequently overreach each other, and the hind foot strikes that before it, in progression: the back should be nearly straight, it has naturally an inclination in the line of its gravity; but this exists in very different degrees in different horses. When the incurvation inwards is considerable, such horses are called saddle-backed, and are usually considered weak; but, to keep up the counterpoise, the crest in such horses is generally good; they also ride pleasantly, and commonly carry much apparent careas; sometimes indeed too much. When the back is curved upwards, it is called roach-backed; when considerably so, it is unfavourable to the liberty of action, as well as to the elasticity of motion: in these cases, to counteract the curve outward, the head is also usually carried low. A short-backed horse is in considerable request with many persons, who do not consider that when it is too much so there is seldom great speed; for the hinder extremities cannot be brought sufficiently under the body to propel the mass forwards.

usually carried low. A short-backed norse is in considerable request with many persons, who do not consider that when it is too much so there is seldom great speed; for the hinder extremities cannot be brought sufficiently under the body to propel the mass forwards.

6271. The loins (h) may be considered as the part which extends from immediately behind the hinder edge of the saddle, when properly placed, to the rump. Anatomically it begins at the sacrum (fig. 830, z), whose processes being sometimes defective or interrupted, leave an indentation, as though the union between the back and loins were incomplete; and such horses are said to be badly loined; but although it may in some measure deprive the muscles of some slight attachments, yet the evil is not so considerable as is imagined. The width of the loins is of considerable import to the strength of the animal, as it affords a greater surface for the attachment of the powerful muscles of the back and loins; and the muscles themselves should be so prominent, as to seem to swallow the back-bone amongst them. When the protuberances of the ilium or haunch bone are very prominent, the horse is said to be ragged hipped; but it operates to his disadvantage only in appearance, as extent in these parts, being favourable to muscular attachment, is always beneficial.

6270. The croup extends from the loins to the setting on of the tail (n n). It should be long and only slightly rounded, which is another characteristic of the blood or improved breed. In the cart horse, on the contrary, it is seen short and much more considerably rounded (n n). A long croup is in every point of view the most perfect, for it affords a very increased surface for muscular attachment, and although the large buttocks of the cart horse would at first sight convey an idea of great strength and extent, yet, attentively viewed, it will be found that the early rounding of the sacral line, the low setting on of the tail, and the small space which necessarily exists between the hips and buttocks,

surface of muscular attachment, compared with the broad croup, wide haunches, and deep spread thighs of the blood horse.

6273. The flank (k), is the space contained between the ribs and haunches; when too extensive it indicates weakness, because it is the consequence of too long a back; and such a horse is said not to be well ribbed up. When the transverse processes of the lumbar vertebre are short, as in badly loined horses, this part is hollow. The flank is usually looked to also as indicative of the state of respiration: thus, when it rises and falls quicker than ordinary, unless violent exertion has just been used, it betokens present fever, or otherwise, chronic disease of the lungs.

6274. The belly (i). Having taken a tour round the upper parts of the carcase, we will carry the survey downwards and forwards. Anteriorly, the ribs should be wide upwards, and as much deepened below as possible, which affords what is termed great depth in the girth. This form greatly increases the surface of attachment of the motive organs, the muscles, and also allows room for the free expansion of the lungs, and consequently is favourable to the wind. Posteriorly, the ribs should form the body as much as possible into a circular figure, that being of all others the most extended, and affording the best surface for the absorption of nutriment; thus barrelled horses, as they are termed, are greatly esteemed, and found to be lasting in work and readily brought into condition, and more easily kepts on. When the chest is too flat and straight, the belly is also small: hence, neither can the blood absorb its vital principle from the air, nor the lacteals the chyllierous juices from the intestines; these horses are therefore seldom durable. As less nutriment is taken up by the constitution, so less is eaten, thus also they are seldom good feeders; As less nutriment is taken up by the constitution, so less is eaten, thus also they are seldom good feeders;

and as the pressure on the intestines must be considerable from the small containing surface, so they are usually likewise what is termed washy; that is, easily purged, whereby an additional cause of weakness exists, from the too early passing off of the food. Such horses are, nowever, very commonly spirited and lively, although not lasting. A knowledge of the advantages gained by a circular form of careass or belly, as affording the greatest capacity, is what constituted Bakewell's grand secret in the breeding of cattle: he always bred from such animals as would be most likely to produce this form, well knowing that no other would fatten so advantageously.

6275. The whirtbone (I), among the jockeys and grooms, is the articulation of the thigh bone, with the pelvis, or basin, and forms the hip joint. The ligaments of this powerful joint are sometimes forcibly distended by violence, and a very obstinate lameness is usually the consequence. The situation of the thigh (I, m) is in the horse, as in most quadrupeds, enveloped within the range of the trunk.

6276. The stifle (m) corresponds with the knee of the human figure, and is the point at the lower portion of the flank. It is evident that the part below this, which is generally called the thigh or gascoin, is erroneously so named. It should be very muscular and extended; it should also make a considerable angle with the femur or thigh, and form a direct line under the hip or haunch. Its length in all animals destined for speed is considerable. and as the pressure on the intestines must be considerable from the small containing surface, so they are

6277. The fore extremities or legs. In treating of the mechanical properties of the skeleton, we shall have to point out the essential differences between the geometrical structure and functions of the fore and hinder extremities. We shall here content ourselves with a simple examination of the individual parts.

6278. The arm of the horse (b) is apt to be overlooked, nor, without some consideration, does it strike the observer, that the arm covered with muscles, and enveloped within the common skin of the chest, extends from the elbow (a) to the point of the shoulder, as it is termed, but correctly to its own point below and before the shoulder blade. (fig. 830.) The same reasons which render a muscular, oblique, and deep shoulder advantageous, also make it desirable that this part should be muscular and extensive in length and breadth, and that its obliquity should be proportionate to that of the shoulder: whence it results, that the more acute the angle between them, the greater will be the extent of the motion gained by the

that the more acute the angle between them, the greater will be the extent of the motion gained by the flexion and extension of the parts.

6279. The fore arm (c), which horsemen consider and call the arm, is placed upright to counteract the angular position of the real arm and shoulder bones. As it is always found long in animals destined for great speed, as we witness in the hare and greyhound, it should therefore be also of considerable length in the horse, when speed is a requisite quality; but for the cadences of the manege, where the elasticity is required to be distributed equally through all parts of the limb, it is chosen short. The fore-arm is broad and large, particularly upwards, for here the powerful muscless that operate the motions of the parts below, are almost all of them situated. To prevent incumbrance, and to give solidity, these muscles degenerate into tendons and ligaments below the fore-arm; but above, it is essentially necessary to strength that they should be large and well marked.

6280. The knee (d), so called, is properly, with reference to human anatomy, the carpus or wrist. It is composed of many bones to enable it to resist the jar arising from the action of the perpendicular parts above and below it. All the joints of the extremities, but particularly those of the knee and hock, should be broad, that the surface of contact may be increased, and the stability augmented; by this means, likewise, a more extensive attachment is afforded to muscles and ligaments; their insertions are also thereby removed farther from the centre of motion.

6281. As criteria of safe going, the knees should be particularly examined when it is contemplated to

be broad, that the surface of contact may be increased, and the stability augmented; by this means, likewise, a more extensive attachment is afforded to muscles and ligaments; their insertions are also thereby rese, a more extensive attachment is afforded to muscles and ligaments; their insertions are also thereby rese, to see whether the skin has been broken by falls; and in this, very minute attention is required; force, to see whether the skin has been broken by falls; and in this, very minute attention is required; force, to see whether the skin has been broken by falls; and in this, very minute attention is required; force, to see whether the skin has been broken by falls; and in this, very minute attention is required; force and the stability of the white or staring hairs, &c., that more than common nicety is required rubbing it down picking out the white or staring hairs, &c., that more than common nicety is required rubbing it down picking out the white or staring hairs, &c., that more than common nicety is required to require the stability of the stability of the stability of the stability of a very common the control of the dark. It is not every horse whose knees betray a sear, that is a stumbler's, he were, prudent to remember, that it is not every horse whose knees betray a sear, that is a stumbler's, he were proven the stability of the stability large to prevent the free bending of the knee, he is not at all more liable to fall than another of the stability large to prevent the free bending of the knee, he is not at all more liable to fall than another ones. It, therefore, a horse with a sear on his knee have the forchand good, and if his action correspond thereto, he ought not to be refused on this ground; but with a different conformation he ought to be steadily rejected, let the tale told be ever so plausible. In gross heavy horses a scabby eruption often seats itself around the inner bend of the knee (h), which is called mallenders.

6282. The casson or shaw (c) carries the limb down elegant, l

6234. The pastern and fetlock (ff). General usage has applied the term fetlock to the joint itself, and pastern to the part extending from the fetlock to the oot; properly speaking, the fetlock or footlock is only the posterior part of the joint, whence grows the lock or portion of hair, which, in many horses, flows over and around the hinder part of the foot; a short and upright pastern is inelastic, and such horses are uneasy goers; they are unsafe also, for the pastern being already in so upright a position, requires but little resistance, or only a slight shock, to bring it forwards beyond the perpendicular; and the weight of the machine then forces the animal over. Nor are these the only evils arising from this formation, for the ends of the bones being opposed to each other in nearly a perpendicular direction, receive at each movement a jar or shock, which leads to an early derangement of the joint, and to the appearance called overshot. On the contrary, when the pasterns are too long they are frequently too oblique also; and although their elasticity may be pleasant to the rider, such formation detracts from the strength of the limb. These joints both before and behind are very subject to what is called windgalls, which are swellings formerly supposed full of air, whence their name; but they are now known to contain an increased quantity of the mucus destined to lubricate the parts in their motions. These puffy elastic tumours are originally small and hidden between the lower end of the canon and the flexor tendon, or back sinew; but when hard work has inflamed all the parts, the secretion within increases, and then they become visible to the eye; but unless they are so considerable as to obstruct the due action of the parts, they are no otherwise objectionable than as they tell a tale of inordinate wear of the limbs generally.

the parts, they are no otherwise objectionable than as they tell a tale or mordinate wear of the image generally.

6285. The form of the pasterns influences the defect called cutting, which arises from a blow given to either the fore or hind fetlocks by one leg to the other during its elevation. Horses narrow in the chest, or which turn their toes out, or have other peculiarities of form, cut permanently, and are then very objectionable; but others only cut when fatigued, or when very low in flesh. Horses often cut when young, who leave it off when furnished, and of mature growth.

6286. The feet (gg). These essential and complex organs will be more fully examined in the anatomical detail, but much also presents itself to the consideration in an exterior examination. Horses might be presumed to be naturally born with perfect feet; but experience shows that defects in these organs are hereditary. In some, the peculiarities of climate operate; and in others, a constitutional predisposition exists; dependent on some cause with which we are unacquainted.

6287. Climate influences the form of the horse's fool. In the arid plains of the east, where every impediment to an extensive search for food is removed, the feet are hard, dry, and small; this form, notwithstanding the alterations of breed and culture, in some degree still adheres to the blood or aboriginal eastern horse: artificial habits have extended the evil, and now small and contracted feet are to be seen in every variety, except in the coarse heavy breeds.

in every variety, except in the coarse heavy breeds.

6258. Constitutional and hereditary causes operate on the feet. That a constitutional predisposition exists in the production of a particular form of foot, we know from the fact, that dark chesnut horses are more prone to contraction of the hoofs than any other coloured horse; and that the form of the foot is hereditary, may be gained from the known circumstance that some of the Lincolnshire stallions always get large flat-footed progeny; while some full bred entire horses entail small upright feet on all their

are more prone to contraction of the hoofs than any other coloured horse; and that the form of the foot is hereditary, may be gained from the known circumstance that some of the Linconshire stallions always get large flat-footed progeny; while some full bred entire horses entail small upright feet on all their offspring.

6259. Local situation will also affect the form of the feet. The effect of situation is remarkably exemplified in the horses which we used to obtain from Lincolnshire, Cambridgeshire, and some parts of Norfolk and Yorkshire, before the draining system was perfected. These horses had, almost invariably, large, flat, heavy feet; which, however convenient and natural they might prove to the animals while moving on the quaggy surface of marshy districts, yet were found very unfit for quick light movements in drier situations. Such horses go heavily and stumble: and as the horn of which these enormous feet are formed is always weak, the anterior or front part yields to the heat and inflammation brought on by exercise on hard roads, and falls inwards, which letting the weight of the body fall on the soles pushes that downward; and at last from a concave, it presents a convex surface. The feet cannot then bear sheeing, but with much art and difficulty: pain and tenderness bring on lameness and uselessness; and therefore horses with such feet should be rejected. Feet preternaturally small are equally objectionable, as betokening a disposition to contraction. Horses with a tendency to foundered feet stand with pain in the stable, first placing one foot before, and then shifting it to place the other in the same situation. The contraction usually begins in the heels, which are found higher than natural, and drawn inwards; the foot altogether is likewise narrower, and the sole hard and hollow. When a preternatural fulness is seen around the coronets, ring-bone may be suspected; and if heat and hardness be accompanied with any tenderness in going, its existence is certain. But although too much horn is to

wearing away of the shoe at the toe, while the other parts remain good, is a full proof of his going unserly and digging his toes.

6290. On a review of the conformation of the fore extremities, it may be remarked, that whereas the hinder may be considered as more particularly concerned in impelling the machine forwards with its requisite velocity; yet, that upon a proper form and a true direction of the various component parts of the fore legs should stand rather wides at the upper part, inclining a little inwards below; but when we view them latterly, they should present a perpendicular from the arm downwards; and the toe should place itself directly under the point of the shoulder, as it is called. If the foot should stand beyond this, which is seldom the case, the action will be confined, for the limb will have already passed over a point of its ground; such a horse, however, generally treads even, flat, and safe; and, in propriotion as it stands in the defect is considerable, by the removal of the centre of gravity too much forward, by which an increased tendency to stumble and fall is entailed; and as this in general accompanies a want of extent and obliquity in the shoulder, so it likewise lessens the speed.

6291. The hinder extremities. We have already described the thigh, correctly so

called, which is so concealed by muscles as frequently to escape this consideration of it, by which the part immediately below it popularly receives the name of thigh, but which is, in fact, the leg.

is, in fact, the leg.

6292. The leg (1, 2), commonly called the thigh, in well formed horses is powerfully furnished with muscles, and very extended in its figure; it should also make a considerable angle with the femur or real thigh, and form a direct line under the hip or haunch; for the same reasons that make it desirable to have a long arm in the fore extremities, it is also advantageous that the leg should be so likewise, and this is the form usual among all quadrupeds of speed.

6293. The hock (2) is the important joint immediately below the leg, or thigh commonly so called, and is interposed between the tibia and tarsal bones (fig. 830.), purposely to increase the extent of attachment, and to break the shock of great exertion; it may be considered as the most complex and important joint of the body; like the knee, it should be extended and broad; for, in proportion as the calcaneum or point of the hock (5), and which is the real heel, extends itself beyond the other bones, so the powerful tendo Achilles inserted into it, acts with a longer lever, and with a greater increase of power. This joint is subject to several important diseases, which, in the examination of a horse, require particular attention; when a soft puffy swelling is discovered in the ply or bend of the hock (3), it is termed a blood spain, which will be noticed among the diseases; it is, in fact, a similar enlargement with the windgalls before mentioned, and what has been said on them equally applies to these. When similar mucous capsules become enlarged on each side of the hock, the enlargement receives the name of thorough pin. A small bursal enlargement is sometimes found at the very point of the hock (5), and is then called a capplet; to all which what has been said on windgalls applies, that they are only to be deemed of consequence when so large as to interfere with the motion of the parts they are situated with or near; or, as indicative of an undue portion of work. The ligaments at the back of the hock sometimes become strained o

6294. The colour of horses does not depend on their real skin, as with man, but upon an exterior beautiful covering which nature has given them, called hair; nevertheless, the hair is, in some measure, influenced by the skin, as light-skinned horses have light hair, and when the hair is light, the eyes are usually so likewise: hair presents many varieties of tint, so horses are said to be of various colours. Buffon has conjectured that horses were originally of one colour, which he presumes to be bay; but such wild horses as have been seen, and which have been supposed to be pure originals, have not justified this This same author has divided the colours of the horse into simple, compound, and strange or extraordinary.

opinion. This same author has divided the colours of the horse into simple, compound, and strange or extraordinary.

6295. The simple colours are bay, chestnut, dun, sorrel, white, and black; bay is a very prevailing tint among European horses, and admits of many shades, but is admired in all; there are bright bays, blood bays, dark and danpled bays; brawn bay is a very esteemed colour, and consists of bay and black in unequal proportions in different horses: brown horses are highly prized; the darker varieties have usually beautiful tan markings, as about the muzzle, &c.: they have commonly also black manes and tails, with legs and feet of the same hue; and it may be here remarked, that horses of compounded colours, of whatsoever tint the mane and tail may be, will be found invariably formed of one of the compounding colours; thus light greys, which are a compound of black and white, have often white manes and tails; sorrels, again, which are formed of white, with a small proportion of red, have also frequently white manes and tails; chestnut, which is also a very common colour, admits of almost as many shades as the bay, from the lightest tint to the deepest tone. Very light chestnuts have frequently still lighter manes and tails, with mealy legs and light feet; so marked, they are certainly not be chosen for strength, durability, or pliancy of temper: the Suffolk punch, however, may be considered in some degree an exception, although the true breed is hardly so light as those hinted at here. Dark chestnuts are considered, and with justice, as fiery in their dispositions; they are also more subject to contracted feet than horses of any other hue. Dun is a colour that has several varieties; it is sometimes accompanied with a white mane and tail, at others they are seen even darker than the rest of the hair. In some, a list or line of deeper tint extends along the back, which is regarded by some as an indication of hardhood; a similar line is sometimes seen in the bay. Dun horses do not appear to be at all infl

have, however, all the extremes which the stage of the st

Now and then a third interferes; there are pies of all original colours with white, and all are held in

stimation.

6298. Colour, as a criterion of mental and personal qualities, is laid much stress on by many persons; and long experience has shown that certain tints are usually accompanied by certain qualities of person or disposition. As a general rule, dark-coloured horses are certainly the best; but, as before observed, it is peculiar that black, as the darkest of all, should form an exception to this rule. Light shades appear unfavourable to strength and durability; they are also accompanied frequently with irritability and perverseness of temper. Something like a general law in the animal economy seems to prevail, to make white a distinctive mark of weakness. Age, which is the parent of weakness, brings with it white hairs, both in man and in horses, and most other quadrupeds. The hair formed after a wound has robbed a part of its original covering is often white, because the new formed surface is yet in a state debility. It is likewise a fact well known among the observant, that the legs and feet when white are more obnoxious to disease than those of a darker tone. The Arabs remarks, that light chestnut horses have soft render feet. It is the observance of these peculiarities that has at length guided our taste, and formed our judgment of beauty. With us much white on the legs is considered as a deformity, and is expressively called foul marked, whereas pied markings in other parts are reckoned beautiful. In Africa, however, Captain Lyon informs us a superstitious dependence is placed on horses with legs and feet stockinged with white. It does not appear that climate has the same influence on the colour of horses as on that of other domesticated animals, in all latitudes in which the horse can live, he is black or white indiscriminately; but as he cannot endure extreme rigour, it is not necessary that he should vary.

The Bony Anatomy or Osseous Structure of the Horse.

6299. All quadrupeds are formed on an earthy base called bone, and the assemblage of bony parts is called a skeleton. Bones are formed of earth and membrane (1881.); they are covered also by an investure called periosteum. The earthy part is the last formed, and consolidates the bones as the animal becomes fitted to exert all his powers. deposit of earth in the bones appears to be hastened by any thing that perimanently quickens the circulation; heat does this, and hence the human and brute inhabitants of warm climates come to perfection sooner than those of northern regions; but they are generally smaller, for by preternaturally hastening the carthy deposit before the membranous part of the bones becomes fully evolved or grown, they do not attain the bulk they would be otherwise capable of. Undue exertion has the same effect; and thus we learn why horses too early and too hard worked become stinted in their growth. Pressure likewise occasions an early, and also a preternatural ossification: in this way the parts of the spine which bear heavy loads present large masses of bone, brought on by this cause alone. For the same reasons, horses early worked put out splints, spavins, and other bony concretions. Bones are all of them more or less hollow: within their caverns an oily fluid is secreted, called medulla or marrow, which serves for their support, and that of the constitution generally. The bones have nerves, blood-vessels, and absorbents. Bones are capable of reproduction, as proved by their uniting when broken; and also by the yearly renewal of the antlers of the deer, which are not horn as in the ox or sheep, but pure bone. Bones are connected together by articulation: when such articulation is moveable, it is termed a joint. In some cases bones articulate by suture or indentation of parts, as in the skull. We shall consider, in succession, the anatomy of the head, trunk, and extremities.

Subsect. 1. Osseous Structure of the Head.

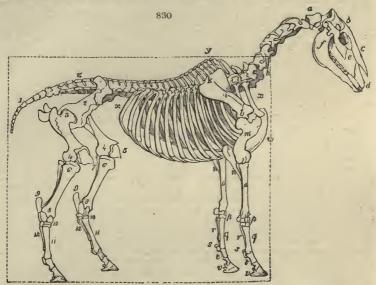

6300. The bones of the head are as follows. The occipital (fig. 830, between a & b), which is the largest bone of the skull, in the colt is composed of several pieces which unite by age; it articulates with the atlas (a) or first of the cervical or neck vertebræ. At its posterior surface it is perforated by a large hole, which gives passage to the spinal marrow. The two frontal bones (b) unite also by age; and behind them is lodged the anterior and inferior portion of the brain. A division of their bony surfaces forms two cavities called the frontal sinuses, which are lined by the nasal membrane throughout. The sagittal sature unites these two bones. The remainder of the bones of the skull are the two parietals, the two temporals, divided into a squamous and petrous portion, within the latter of which is situated the internal ear; and to the former the posterior or lower jaw articulates. The sphenoid and ethmoid bones are hollow and irregular, serving to intersect and attach the others; and also to assist by their cavities in extending the pituitary or smelling membrane.

membrane.

to intersect and attach the others; and also to assist by their cavities in extending the pituitary or smelling membrane.

6301. The bones of the face are ten pairs and two single bones. The nasal (c) pair, within their union, hold the séptum narium or long cartilaginous plate which separates one nostril from the other. These bones also greatly assist to extend the surface of the smelling organ. In the old heavy breeds, it was very common to see these bones arched outwards; but in the improved breed, particularly in those approaching full blood, it is not uncommon to find them slightly curved inward. The fosse within these bones are the principal seat of glanders. The two angulars form a considerable portion of the orbits of the eyes. The two malar, jugal, or cheek bones occupy also a portion of the orbits. The superior maxillary bones (c) are wanting in man, in whom the face is short: these bones concur with the former in forming alveoli or sockets for lodging the teeth. The superior palatines, the inferior palatines, the pterygoids, the two anterior, and the two posterior turbinated bones, with the vomer or plantines, the pterygoids, the two anterior, and the two posterior turbinated bones, with the vomer or plantines, the pterygoids, anterior edge is pierced to lodge the teeth; at the upper part it extends itself into two angular branches, each of which ends in two processes and an intermediate groove. The superior of these processes articulates with the upper jaw. This bone throughout shows the most admirable mechanism; the molar or grinding teeth, on which most is dependent, and whose exertions are greatest, are placed near the centre of motion: and as the upper jaw in most animals is fixed, or nearly so, it was necessary that the lower should have considerable extent of motion for the purpose of grinding; and it is exercisingly so formed as to admit of motion in every direction. The os hyoldes is a bone situated within the head at the root of the tongue, to which the serves as a support, and for the attac

twenty-four grinders, which numbers are equally divided between the two jaws. The teeth are inserted into indentations or sockets between the bony plates of the jaw, called alveoli, by cone-like roots. The bodies of the teeth are principally composed of two substances, one of the nature of common bone, giving bulk and form, and one of extreme hardness, called enamel, placed in man and carnivorous animals wholly

without the teeth, to give strength and durability; but in the horse and other Granivora, the latter particularly, it is placed in the grinders, in perpendicular plates, within the body of the teeth; by which contrivance, a rough grinding surface is kept up; for the mere bony parts wearing faster than the lamellæ of enamel, it follows that ridges remain to triturate the vegetable matter that passes between the teeth.

the teeth.
6303. There are two sets of teeth, a temporaneous or milk set, and a permanent or adult set, in which wise provision man and most brutes participate. The milk set are some of them, as the molars, apparent at birth; there being usually six grinders in each jaw, three on each side in the new-born foal, and which number of this set is never increased. The nippers begin to appear soon after birth, and follow a regular order of succession until the animal is three or four months old; at which time he begins to require support from herbage as well as milk. The temporaneous set remove gradually one after another; had they all been displaced at the same time, or even had several of them fallen out together, the animal must have suffered great inconvenience, and perhaps have been starved. This removal, which commences at the age of two years and a half, and is completed between the fourth and fifth year, is effected by the action of the absorbents on their fangs, and appears to be occasioned by the stimulus of the pressure received from the growing teeth under them. For although these two sets appear with an interval of some years between them; yet the rudiments of both are formed at nearly the same period, and both sets may be thus seen in a dissected jaw. Regulated by the stimulus of necessary there succeived from a pressure rediental removal of the colt's teeth is soon follows the necessity is evident; for a premature or accidental removal of the colt's teeth is soon followed by the appearance of the others. Dealers and breeders, aware of this, draw the milk teeth to make their colts appear as horses. It was necessary there should be two sets of teeth; for, as they grow slowly in proportion to the jaws, had there been but one only, the disproportion of growth between the teeth and jaws must have separated them.

separated them.
6304. The forms of the teeth vary more than their structure. The incisive or nippers are round, which is favourable for the pressure they undergo; the upper more so than the lower. On the upper surface a hollow is seen in the young tooth, which, not extending through the whole substance, naturally wears out with the wear of the tooth; and as a considerable degree of regularity occurs in this wearing away in all horses, it has gradually settled into the general criterion of age. The nippers are not all of them exactly similar; the corner teeth differ most in being nearly triangular, and in having an internal wall or side, which does not become level with the rest until long after those of the others. The cuspidate tusks or tushes are permanent, appearing at about five years or rather earlier; those in the front jaw are usually nearer the nippers than those below. Each presents a slight curve, which lows the direction of all the canine or pugnatory teeth of other Mammàlia. The pointed extremity wears away by age, leaving merely a buttomed process, which may serve as a guide to the age when a horse is suspected to be Bishoped, as it is called, from a man of that name who was peculiarly dexterous in imitating on old teeth the distinctive cavity of youth. The molar or grinding teeth are stronger in the upper than in the lower Jaw; which was necessary, as they form the fixed point in the process of grinding. The upper surface presents nearly a long square, indented from the alteration of the enamel with the bony portions; and as the interior or upper teeth hang over the posterior, so the ridges of the one set are received into the depressions of the other. of the other.

of the other.

6305. Wear of the teeth. The teeth, in a state of nature, would probably present a surface opposed to each other for mastication, to the latest period of the most protracted life; but the removal of the animal from moist food to that which is hard and dry, must occasion an unnatural wear in those organs; and hence, although the teeth of the horse, even in a domesticated state, are not subject to the caries of the human; yet the grinders are liable to become thus injured by continued exertion. In the young or adult horse, the upper and under grinders do not meet each other horizontally; on the contrary, they have naturally an inclination obliquely inwards; and those of the upper jaw present small spaces between each other, while those of the lower are more continuous; by which means, as the food, particularly its interrupted portions, as grain, becomes ground, it falls within the mouth to be replaced under the grinding sur-

face, if necessary, by the joint action of the tongue and muscles of the cheek. This arrangement becomes in a great measure frustrated in old horses, by the superior wear of the inner surface of the upper grinders, as well as by the general misapplication of the surfaces of both upper and under teeth, by constant attrition, when worn down nearly to the gums. The unfortunate animal felse sensible of this, and endeavours to remedy it by throwing the wear on the outer edge, by an inclination of the lower jaw and of the head in general; and which is so particular in its appearance as to engage the attention of the by-standers. This defect may be in a considerable degree remedied by casting the animal, and having opened and wedged the mouth so as to keep it so, removing the inequalities with a well tempered concave file, as much as may be. When the defect is considerable, and the horse is mild and quiet, it is better to file the inequalities every day, which will gradually but effectually wear them down. It however happens, that the inclination thus to wear is commonly resumed, and gradually the same loss of nutriment takes place: in which case, soft moist food, as carrots, mashes, soiling, or grazing, must be substituted for harder substances, and if corn be actually necessary, let it be bruised. Whenever an old horse betrays symptoms of want of condition, or weakness, and emaciation, that neither his mode of feeding, nor his ratio of work will account for, and particularly if whole grains should be found in his dung, his teeth should be examined carefully. This undue wearing of the teeth occasions another evil often, which is ulceration of the cheeks, by reason of the projecting ragged surface of the uneven teeth, which can only be remedied by the removal of such portions. These projecting portions are called by farriers wolves' teeth.

Subsect. 2. Bony Anatomy of the Trunk.

6306. The trunk of the skeleton consists of the spine, the pelvis, and the thorax or chest, composed of the ribs and sternum.

6307. The bony column called the spine is made up of seven cervical, eighteen dorsal, six lumbar, and five sacral vértebræ, with the addition of thirteen or fourteen small tail-bones. The spinal bones are thus divided on account of the varieties they present; they have, however, some characteristics in common. Each is composed of a spongy bony body, with protruded points called processes, which processes unite, to form a hollow through which the spinal marrow is transmitted; and by some of these processes the vértebræ are articulated with each other, as well as by their bodies, by which their strength as a column is much increased. Though but little motion exists between any two vértebræ, yet the flexibility of the whole spina is considerable.

of the whole spine is considerable.

of the whole spine is considerable. 6308. The cervical or nack vértebræ (g, h) are called, by farriers and butchers, the rack bones. It is remarkable, that, let the neck be long or short, the number of bones is the same in most quadrupeds. The first and second differ from the rest in figure, and present some other peculiarities. The first is the only one of them to which the great suspensory ligament of the neck does not attach itself, which would have interfered with freedom of motion. It articulates with the second by receiving its tubercular process within it, and from which process the second of these bones has been called denidia. Between these

only one of them to which the great suspensory ligament of the neck does not attach itself, which would have interfered with freedom of motion. It articulates with the second by receiving its tubercular process within it, and from which process the second of these bones has been called denital. Between these two neck bones is situated a part, where the spinal marrow is exposed from any bony covering; at which part butchers plunge a pointed kmfe into what they call the pith of the neck, when they want to kill their animals instantaneously, and without effusion of blood; whence it is called pithing. The remaining five neck bones are not very dissimilar from each other.

6309. The dorsal vértebræ (y) are now and then, though rarely, nineteen in number; they do not differ materially from each other, but in the length of the spinous processes of the first seven or eight. It is to these elongated spines that we owe the height of the withers; and as the intention of these parts seems principally to serve as levers for the muscles of the back inserted into them, so we can readily understand why their increased or diminished height is favourable or unfavourable to progression. These like the former articulate with each other by processes, as well as by the anterior and posterior surfaces of their bodies; between each of which is interposed a substance, semi-cartilaginous in its structure, which is most compressible at its sides, these permitting the motion of the spine.

6310. The six lumbar vértebræ differ from the foregoing in having a longer body, and very long transverse processes to make up for the deficiency of ribs in the loins. These bones often unite by the pressure of heavy weights, and sometimes spontaneously by age, and thus we need not be surprised at the stiffness with which some old horses rise when down.

6311. The five sacral vértebræ (z) are united into one to give strength to the column, and to serve as a fixed support to the pelvis, or basin, with which it is interwedged. From this detail it will app

SUBSECT. 3. Bony Anatomy of the Extremities.

6313. An examination of the bony parts of the limbs excites our admiration at the wonderful mechanism displayed in their formation: osseous portions also present themselves, which may be regarded as principally subservient in keeping up that vast chain of continuity and similarity observable throughout Nature's works. In the following explanation we shall have occasion to notice several of these.

6314. The scápula or shoulder blade (k,l), is a broad, flat, and rather triangular bone. It is very unlike the human scapula, having neither acromion, coracoid, nor recurrent process: neither is its situation at all similar to the human blade bone applied to the back; for, in this instance, the horse may be said to

have no proper back, but to be made up of sides and chest. In man, the scápula is in a direct angle with the humerus, but in the horse it does not pass out of the plane of the arm. Its superior surface is furnished with a considerable cartilage (l, m), by means of which its surface is augmented without weight. The posterior surface ends in a superficial cavity called glenoid, which receives the head of the humerus or arm bone. It is divided in its upper surface by its spine. The shoulder blade, as has been already shown in the exterior conformation, has neither bony nor ligamentous union, but is held in its situation by very powerful muscles, as the serrâtus mâjor, pectorâlis, and others. Its usual situation is to a plane perpendicular to the horizon, at an angle of thirty degrees; and it has a motion in its greatest extent of twenty degrees: hence, as it does not pass beyond the perpendicular backwards, so the more oblique its natural situation, the more extensive are its motions.

atural situation, the more extensive are its motions.

6315. The himerus or arm bone (m) is so concealed by muscles as to be overlooked by a cursory observer, and hence the radius or next bone is popularly called the arm. It extends from what is called the point of the shoulder, but which, in fact, is a protuberance of its own to the elbow, forming an angle with the scápula, and extending obliquely bac'wards as that does forwards. Near its upper extremity it sends off a very powerful head to articulate with the shoulder blade. The motions of the humerus are necessarily confined to a removal from its inclined point backward to the perpendicular line of the body. When this bone is too long, it carries the fore legs too much under the animal, and if this defect is joined to a shallow upright shoulder, the evil will be increased. It, however, fortunately happens that both the angle and extent of these two parts are usually regulated by each other.

6316. The fore-arm (n, n, o, o) is composed of the radius(o, o), and an appendage united to it, which, in man and some animals, forms the ulna(n, n), but which, as the leg of the horse requires no rotatory motion, was unnecessary in him. Here, however, to keep the link of resemblance in all her children of the higher order, Nature has stretched out a large process; which in the cott is really distinct, and may then deserve the name of úlna; and in the adult horse unites with the ràdius, and serves as an *ttachment to muscles. On the slightest inspection of the skeleton, it will appear how much the motions of the fore leg must depend on the length and obliquity of this process; which, acting on the principle of a lever in the extension of the arm, must necessarily, as it is either long or short, make all the difference between a long and a short purchase. The breadth of the arm, as it is called, at this part, will, from this reasoning, be seen to be very important. This bone articulates with the knee by its inferior portion. ferior portion.

ferior portion.

6317. The cdrpus, or wrist, called the knee (pp), is composed of seven bones, whose principal uses appear to be to extend the surface of attachment of ligaments and tendons, and by their interruptions to lessen the shocks of progression. It may be remarked that all hoofed quadrupeds have the anterior extremities permanently in the state of pronation, or with what is called the back of the wrist turned outwards. The carpal bones articulate with each other, and have one investing capsular ligament, by which means the smallest wound of the knee which penetrates this ligament has the effect of opening the whole joint: bence the quantity of synovia or joint oil which escapes in these cases, and hence also the dangerous consequences which ensure

sequences which ensue

sequences which ensue.

6318. The metacarpus (qq, rr), canon, or shank, is formed of one large metacarpal bone (q), and two small ones (r). Here the wide palm of the human, and the paw of the digitated animal, is formed into one solid cylindrical bone, and two small additamenta, called splint bones; which are united with it by strong ligamentary attachment, converted by age into a bony one. Although these additions may somewhat increase the surface of attachment, their principal use appears to be to keep up the connection with the digiti, of which they appear the rudiments. In the cow there are no splint bones, but the uniformity is more perfectly kept up by the divided hoof: in her, therefore, the canon branches at its inferior surface into condyles for the reception of the two claws.

6319. The pastern (tl). The rest of the extremity below the canon, consists of one phalange only, comissing all the mechanism, and a double portion of complexity of all the phalanges of the digitated tribes. Four bones enter into its composition with two small sesamoids (ss) to each fetlock; placed there not only to act as a spring and prevent concussion, but to throw the tendon of the foot which runs over them farther from the centre of motion. The pastern bone is situated obliquely forward, and on this obliquity depends the case and elasticity of the motion of the animal: nevertheless, when it is too long, it requires great efforts in the tendons and ligaments to preserve it in its situation; and thus long-jointed horses must be more subject to fatigue and to strains than others.

6320. The lesser pastern or coronary bone (t, v) receives the great pastern, and below expands into a considerable surface articulating with the coffin and navicular bones.

6321. The coffin bone (v v) forms the third phalange, and corresponds in shape with the hoof. It is

6321. The coffin bone (v v) forms the third phalange, and corresponds in shape with the hoof. It is very porous, and laterally receives two prominent cartilages. It is around the outer surface of this bone that the sensible laminar are attached; and the inferior surface receives the flexor tendon.

6322. The navicular mut, or shuttle bone, is situated at the posterior part of the coffin, and unites with that and the preceding bone.

6323. The posterior extremities differ much from the anterior, not only in their superior strength, and in the different lengths and directions of the parts, but also, in some degree,

in their uses.

6324. The femur, or thigh bone (3, 4) is the largest of the body, its vast indentations and risings, almost peculiar to it, show the great strength of the muscles inserted into it. It articulates with the acetábulum or hip joint by a strong head called the whirt-bone. In this situation it is held not only by a powerful capsular ligament, and still more powerful muscles, but by an admirable contrivance resulting from a ligamentous rope, which springs immediately from the middle of its head, and is firmly fixed within the socket of the joint. In its natural situation it is not perpendicular as the humar femur, but inclines to an angle of about forty-five degrees. This bone presents large protuberances for the attachment of very powerful muscles called trochanters. Throughout it exhibits a mechanism uniting the combined qualities of celerity and strength unknown to other animals. The inferior end of this bone is received by its condyles into depressions of the tibia, while the patélla, or knee-pan, slides over the anterior portions of both hones.

6325. The patélla (5), which is by farriers called the stifle, is nearly angular, and serves for the insertion of some of the strongest muscles of the thigh, which are then continued down to the leg. It thus appears

of some of the strongest musters of the time, whose men's language, called the thigh. It is a bone formed to act as a pulley.

6386. The tibia or leg bone (6,6) is usually, in horsemen's language, called the thigh. It is a bone formed of a large epiphysis, with a small attached part called the fibula (7), a long body, and an irregular inferior end, adapted to the peculiarities in shape of the principal bones of the back, with which it articulates. The obliquity in the situation of this bone corresponds with that of the femur, being as oblique backwards as the former is forwards. The length of the tbia is a prominent character in all animals of quick progression; in this respect it corresponds with the fore-arm, and the remarks made on that apply, with even more force, to this—that length is advantageous to the celerity, but less so to the case, of the

6327. The fibula (7,7) forms a prominent instance, in common with the splint bones, of what was remarked in the outset of our osteological detail of the extremities—that many parts, whose uses were not apparent, would be found to be organs of harmony, placed in the body to prevent interruption to the completing the general plan of animal organisation. In this way the fibula appears but a process springing from the posterior part of the tibia, forming but the rudiments of the human bone of that name.

In the ox it is wanting; in the dog and cat, as requiring numerous motions in their limbs, it is, on the

In the ox it is wanting; in the dog and cat, as requiring numerous motions in their limbs, it is, on the contrary, perfect.
6328. The tirsus, or hock of the horse (10, 10), is a striking instance of the perfect mechanism displayed in the bony structure of this admired animal. It is formed by an assemblage of six bones, and sometimes of seven; while in the ox, sheep, and deer, there are seldom more than five. Between these bones there is little motion, yet there is sufficient to give a spring to the parts, and to preserve the joints from the effects of shocks, &c. As the human anatomy is generally received as the standard of comparison, we must, in order to a proper consideration of the hock, consider it as the instep and heel; and all the parts beyond it as the foot. The human tarsus, and that of some beasts, as the monkey and some varieties of the bear, makes a right angle with the tibia and is far removed from the ground. In him, and the greater number of quadrupeds, all the bones, from the hock downwards, are much clongated, and form a part of the upright pillar of the limb. In the horse, therefore, the point of the hock, as already observed into it: but the appellation of tendo Achilles would be too forced here. A broad hock, as already observed in the exterior conformation, may be now still more plainly seen to be very important to strength and speed; for the longer the calcaneum or heel bone of the hock, the longer must be the lever that the muscles of the thigh act by; and a very elight increase or diminution in its length must be the lever that the muscles of the thigh act by; and a very elight increase or diminution in the mechanism, that, when the animal has inclined the angle between the canon and the tibia, or, in other words, when the extremities are bent under him in the gallop or trot, he is enabled to open it again. The bones of the hock, like those of the knee, are united together by strong ligamentous fibres; and it is to an inflammation of those uniting the calcaneum and cuboid bones, that th

Subsect. 4. General Functions of the Bony Skeleton.

Subsect. 4. General Functions of the Bony Skeleton.

6329. The skeleton of the borse must be considered as a mechanism of admirable wisdom and contrivance, which having considered in detail, we offer the following summary of its functions generally as a whole. It will be found to present nearly a quadrilateral figure, having an inclined cylinder resting on four supporting pillars. The spinal column, as the inclined cylinder, serves as a base for the soft parts, and is found not truly horizontal, but dipping downwards over the fore legs; by which the propelling force of the hinder extremities is relieved by the maximum of strength thus transferred. The increased weight of the hinder part of the cylinder is admirably counterpoised by the head and neck, which are projected forwards; by these means leaving the line of direction near the centre of the whole. The length of a cylinder may be such as not to support its own weight; Nature, therefore, has limited the length of the spines of animals: hence, ceteribus paribus, a long-backed horse must be weaker than a short one; and thus, likewise, small horses can carry proportionably more than larger ones. The four pillars which support this cylinder are not perpendicular partially; but they are so totally: for a perpendicular drawn from their common centre of gravity will be found to fall nearly in their common base, by which means they are supported as firmly as though their individual axes had been in a line perpendicular to the horizon. Had they been perpendicularly opposed to each other, there could have been but little classicity, and consequent ease in motion; every exertion would have proved a jar, and every increased effort would have produced luxation or facture. To increase our admiration of this mechanism, we need only turn our attention to the contra-disposition of these angles in the fore and hinder supporting pillars. Had these angles presented themselves in the same direction, the body must have been precipitated forward or backward; but each offering a c 6329. The skeleton of the horse must be considered as a mechanism of admirable wisdom and contrivance,

SECT. IV. Anatomy and Physiology of the soft Parts.

6333. We shall include under appendages to bone, the muscles and tendons, blood-vessels, absorbents, nerves and glands, integuments, head, ear, eye, nose, mouth, neck, chest, abdomen, organs of generation, and the foot.

Subsect. 1. Appendages to Bone, the Muscles, and Tendons.

6334. The appendages to bone are cartilages or gristle, periosteum, medulla or marrow, ligaments, and synovia or joint oil.

· 6335. Cartilages are of three kinds, articular (1887.), which cover the ends of the bones by a thin layer, enabling them to slide easily on one another; non-articular, or such as are placed between bones immoveably joined; unattached, as those of the ears and larynx; and temporary, as the ends of bones in very young animals before their earthy deposit is completed. The general nature of cartilage is smooth, white, solid, elastic, and hard.
6336. The periosteum is a ge

6336. The periosteum is a general uniting membrane to bones and their appendages (1882); on the skull it is called periorbinum; when it tovers ligaments, periotesmium; and periorbindrium, when it invests cartilage. Its uses appear to be to furnish vessels to the bones. It is little sensible, except under inflam.

cartilage. Its uses appear to be to furnish vessels to the bones. It is little sensible, except under inflammation, when it becomes highly so.

6337. Medalla, or marrow, is a soft fatty substance deposited in the cavities of bones.

6338. Ligaments (1891.) are close, compact, fibrous substances, of immense strength in the horse, necessary to bones as a connecting medium; ligament is also a common membrane in every part of the body. Ligament is considered inelastic; there are, however, many exceptions, of which the cervical and meta-carpal and metatarsal are instances. In some cases they are semicartilaginous. The suspensory ligaments attach and suspend parts, as that of the thigh bone to its socket, &c. Capsular ligaments surround the, two opposed ends of jointed bones, and form a complete cavity.

6339. The symbvia or joint oil, being secreted from the inner surface of the capsular ligaments, fills up this cavity, and affords a slippery medium, which enables the bones to slide readily over each other.

6340. Muscle is that part of the body of the horse which we term flesh, to distinguish it from skin, gristle, bone, ligament, &c. Muscles appear composed of bundles of reddish fibres, the ultimate division of which it is impossible to trace; and as the motions of an animal are very various, and as almost all motion is operated through the agency of the muscles; so the peculiar shape they take on is very varied. To the generality of muscles, particularly to those ending in bones, is added a portion of a very different nature, called tendon.

called tendon.

called tendon.

6341. Tendons are insensible, inelastic, tough, fibrous substances, of a whitish colour: expanded into thin layers, they are called aponeuroses. The tendons are eminently useful to muscles, diminishing their size without decreasing their strength. What would have become of the light elegant limb, had the large muscular masses been continued to their terminations below in equal dimension? Muscles are highly vascular, as their colour testifies; but the tendons are very little so, hence their powers of life are very different: one can regenerate itself with ease, the other with extreme difficulty. The muscles also possess a large share of nerves, and consequently of sensibility and irritability, to which properties the surprising phonomena they exhibit must be attributed; while their extreme vascularity furnishes them with powers to keep the energies requisite for these agencies. They contract and shorten at pleasure, acquire a power of acting dependent on their situation, and can change the fixed for the movable point, and vice versā.
6342. Muscles are voluntary and rivooluntary. The former are immediately under the influence of the will, as those of the legs, eyes, mouth, &c. Involuntary muscles are such as are not under the guidance of the will, and whose functions go on without control, as the heart, the respiratory and digestive muscular organs. Muscles are many of them covered by a cellular or membranous covering, called fiscal, and their tendons by another, but stronger investure, called théça or sheath. At the tendinous extremity there is usually a capsule containing a quantity of lubricating mucus, the diseased increase of which forms what is termed windgall.

Subsect. 2. Blood-vessels of the Horse.

SUBSECT. 2. Blood-vessels of the Horse.

6343. The arteries are long membranous canals, composed of three strata, which are called tunica or coats, as, an external elastic, a middle muscular, and an internal cuticular. Each of these coats is the cause of some important phenomena, as well in disease as in health. The clustic power enables them to admit a larger quantity of blood at one time than another, and thus they are turgid under inflammation; by this also they can adapt themselves to a smaller quantity than usual; otherwise a small hæmorrhage would prove fatal. The muscular tunic appears to exist in much greater proportion in the horse than in man, and this accounts for his greater tendency to inflammation, and also why inflammatory affections run to their terminations so much sooner in the horse than in man. The arteries gradually decrease in their diameter as they proceed from the heart. Our knowledge of the terminations of these vessels is very confined; we know they terminate by anastomosis, or by one branch uniting with another. They terminate in veins, and they terminate on secreting surfaces, in which case their contents become changed, and the secretion appears under a totally different form. Another common termination of the arteries is by exhalant openings, by which sweat is produced. The use of the arteries is evidently to convey blood from the heart to different parts of the body, and according to the part the artery proceeds from, or proceeds to, so does it receive an appropriate name.

6344. The abstra is the principal member of this system. Originating from the left ventricle of the heart it soon divides into two branches, one of which, the anterior, or abstra descendens (j.g., 833. p.), proceeds forward to be divided into two principal divisions: the carotids (g.), by which the head is furnished, and the axillaries, by which the fore limbs receive their blood, under the names of humeral, radial, and meta-carpal arteries; and the posterior, or abstra descendens (o), which is distributed to t

extremities.
63:5. The pulmonary artery is a trunk of five or six inches in length; arising out of the anterior ventricle of the heart, and continued by the side of the aorta. It soon divides and enters the lungs, through which it ramifies.
63:6. The veins are also membranous canals which begin where the arteries end, and return that blood which has been distributed by their means. They have less solidity, and possess two tunics or coats only. They usually accompany the airteise in their course, but are more numerous, being wisely divided into a superficial and a deep-seated set, to avoid the dangerous effects of interruption. To prevent the return of the blood they are furnished with valves also.
63:47. The original venal trunks of the horse are ten in number; the anterior cava, the posterior cava, and eight pulmonary, to which may be added the vena portæ.
63:48. The vena cava passes out of the heart by two trunks from separate parts of the right auricle. The anterior, or cava asseinates (fig. 83:3, n), opposite to the first rib, divides into four principal trunks; two axiliaries, and two jugulars, (fig. 83:3, r). The axiliaries furnish the fore limbs under the names of the humeral, the ulnar, and the metacarpals. The jugulars (r) run up one on each side of the trachea to return the blood of the head. The posterior, or cava descendens (o), returns the blood from the body and hinder extremities. hinder extremities.

hinder extremities.

6349, The vena porta is formed from the veins returning the blood from the viscera, which, uniting to enter a sac of that viscus, are ramified through all parts of the liver, where the blood having undergone some remarkable alterations is returned by the vena hepática, and enters the heart by the posterior cava.

6350, The blood is a homogeneous fluid, contained in the heart, arteries, and veins, and constantly circulating through the whole body. It appears formed with the body; is red in the arteries, and purple in the veins. The component parts of the blood are the croor or coágulum; the coagulable lymph, fibrin, or gluten; and the serum. The coágulum is composed of red globules, whose intensity of colour is less in the horse than in man. A red colour is not necessary to the essential properties of blood, seeing the blood of some animals is white; and even some parts of the horse's body are furnished with colourless blood, as the transparent part of the eye, &c. The coagulable lymph or fibrin (1941.) appears the most essential part of the blood, and that from which all the parts are former seems to dilute the whole. The quantity contained in the body is uncertain: young animals possess more than older, and hence bear bodily injuries better. It is less in quantity in fat than in lean animals; and in 5 Q. 4

domesticated than in those which run wild. An animal will lose one fifteenth before he dies. A borse lost forty-four pounds without apparent injury. Probably the quantity contained in the body may vary according to circumstances; between one eighth and one tenth of the whole mass is a fair medium.

6351. The pulse: From the contraction of the beart and consequent dilation of the arteries to receive the blood, and pass it onward to all parts of the body, which is called the diastole; so a dilatation of the heart and conferction of the arteries necessarily occurs, which is called the systole; and these two causes operating alternately produce the phenomena of circulation. The momentary increase in capacity in the diameter of the artery is called the pulse. As there is seldom disease present, without some alteration in the circulation also, so the pulse is attended to as an indication of health or disease. The circulation being carried on over the whole body; the pulse may be felt universally; but some situations are more favourable than others; as the heart itself, the pasterns, at the root of the ear, &c. but the most convenient of all is at the branch of the posterior jaw, where the maxillary artery may be readily detected (fig. 833, f). The natural pulse in the horse is about 45 beats in a minute; in the ox the same; in man 75; in the dog 90. When the pulse is mich accelerated, the circulation is accelerated also. If, with its quickness, fulness of ressels and hardness are apparent, the circulation is morbidly hurried, and inflammation general or partial is present.

Subsect. 3. Absorbents of the Horse.

Subsect. 3. Absorbents of the Horse.

Subsect. 3. Absorbents of the Horse.

6352. The absorbent system is a very extraordinary and a very important one; for if the blood builds up and repairs parts, the absorbents pull down, remove, and take them away again. They are composed of the hymphatics and facteals. Both kinds, although thin and transparent, are strong, and appear to have a contractile power: where very minute they are called capillaries. The lacteal absorbents are situated in the mesentery and intestings, whence they draw the chyle, or nutritious fluid by which the blood is nourished and augmented. The chyle is carried forward from the mesentery into a tube called the thoracic auct, which, passing up by the side of the adrea, pours its contents into the heart through the medium of the jugular vein. The hymphatic absorbents differ from the latter only in being situated over the whole body, and being the recipients of the various matters of the body; whereas the lacteals appear to absorb the chyle-only. From humerous facts, we know that the various organs are continually suffering a destruction and a removal of parts, and that what the absorbents take away, the arteries renew; and to this constant change, most of the alterations of the body are to be attributed with regard to the structure of parts. We use our power over these vessels in the horse medicinally. We stimulate the absorbents to take up diseased solutions of fluids from various parts of the body, as in watery swellings in the legs by mercury and by friction, or by pressure in the way of bandage. When deposits are made of hard matter, or ligament or bone, we stimulate them by blatering or by firing. It is by stimulating the absorbents that swelled legs are removed. Exercise is a very powerful stimulus to absorbents; thus it is that swelled legs are removed by half an hour's exercise. In the horse, the lymphatics are more liable to disease than the lacteals, but in man the reverse. Farcy diseases the lympha

Sursect. 4. Nerves and Glands of the Horse.

6373. The nervous system of the horse is composed of white medullary cords, springing from the brain and spinal marrow, whence they are generally distinguished into the cerebral and spinal nerves; the internal structure of these bodies is fibrous, and their ramifications extend to every part of the body; it is supposed that the brain is the seat of sensation and volition, and that the nerves are only the messengers of it. The sensibility of a part is usually proportioned to the number and size of its nerves; nervous influence occasions motion. From some cause, unknown to us, some motions are voluntary, and some involuntary; but both are brought about by nervous agency. As the nerves are the media of sensation; so a division of their cords has lately been attempted, with success, to relieve certain painful affections; the most prominent instance is, in the division of the pastern nerves for the relief of the painful affection of founder. Tetanus, or locked jaw, which seems a morbid irritation on the nerves, has been recommended to be treated in the same way.

mended to be treated in the same way.
6354. The cerebral nerves, arising in pairs immediately from the brain, are the olfactory, optic, motives
ceuli, pathétici, trigémini, abducents, auditory, lingual, par vagum, and the pair called the intercostal or
great sympathetic, from its extensive connection.
6355. The spinal nerves are those which arise immediately from the spinal marrow, as the cervicals, humerals, ulnar, nectacrapal, and pastern nerves; the dorsal, the lumbar, crural, sciatic, popliteal, sacral,
and the nerves to the posterior extremities, which correspond with those of the anterior.
6356. The glands are numerous, and placed in every part of the body; they may be characterised as secretory bodies, composed of all the different vessels enclosed in a membrane; their office appears to be to
secrete or form some fluid, as the liver secretes bile, and the kidney urine. They are classed into folliculose, globate, glomerate, and conglomerate; they also receive specific names according to their situations,
or according to the fluid they secrete, as lachrymal, salivary, &c.

SUBSECT. 5. Integuments of the Horse's Body.

6357. The common integuments may be considered as the hair, the cuticle, the epidermis, or insensible or outer skin, the rête mucosum, which is immediately under this, the cètis, sensible or true skin, the cellular membranes, which contain fat and other fluids, and the panniculus carnosus or fleshy pannicle; to these may be added, the únguis, nails or hoofs, which we shall describe separately.

6358. Hair is the clothing of brutes, and hence is very important to them, and as it enters largely into the arts, it is also important to us. (1851.) It appears to be a production of the true skin, arising from a bulbous end, which penetrates the rote and cuticle in the form of an elongate cone. In some parts hairs appear singly, as about the muzzle; in others in masses, as on the mane, tail, and over the body generally, as an inclined congregated mass; hair varies in colour, and therefore appears by nature intended both for crament, and use ornament and use.

ornament and use.

(359. The cuticle is situated immediately under the hair (1845.), and appears a hard insensible covering, purposely placed to guard or defend the sensible skin underneath. The cuticle lines many of the large openings of the body, as the mouth, whence it is continued into the stomach, lining one half of it. It is perforated by innumerable small vessels that give out and take in various matters; through these blisters act on the true skin, inflame it, and force it to secrete a quantity of fluid, which thus pushes the cuticle from the cutic. It exists before birth, and is speedily renewed after birth, when accidentally destroyed, and, like the true skin, thickens by pressure; it is constantly undergoing changes; it exfoliates in the form of powder, or little scales, over every part of the body, and is that substance called dandriff, which grooms are so careful to remove with the currycomb.

6360. The rite muchsum is a mucilaginous substance placed like a net between layers of cutile and cuties; and although every universal in animated nature; its use is unknown.

6500. The rète mucòsum is a mucilaginous substance placed like a net between layers of cutiel and cutis; and although very universal in animated nature, its use is unknown.
6361. The càtis, còrrium, or true skin. (1847.) This very general investure of the body is situated immediately under the two former; it is very vascular, and is furnished with innumerable small villous processes of exquisite sensibility, and which, without doubt, were intended to constitute it as the real organ of touch. It is much thickened by pressure; asses, from the beatings they are subjected to, have it of imanense thickness on the rump. It naturally also exists in various degrees of density according to the wants of the animal. Like the cuticle it is perforated by numerous openings which correspond with those of the latter membrane. Its composition appears principally gelatine, and hence it is employed in the manufacture of glue; its gelatine uniting with the matter called tannin, becomes insoluble

in water, and then forms leather; and the value of the horse's hide in this particular is sufficiently

known.

6362. Adipose membrane and fat. These form very considerable parts of the body of most animals. The adipose membrane is not so universal as the skin; some parts are completely without it, as the eyelids, ears, sheath, and some portions of the extremities. It is cellular, but the cells fortunately do not communicate or the fat would gravitate. The fat is the unctuous juice poured or rather secreted into these
cells. It appears in greater quantities in some parts than in others, and in different degrees of consistence; in the belly of some it is lard, and suct in others; within the bones it is oleaginous in all. Different
quadrupeds have their fat of different degrees of consistence, from the firm suct of the ox, and the tallow
of the sheep, to the soft lard of the hog, and the intermediate state of the horse; it guards the parts, it
preserves warmth; but above all, it is a depot against occasional want: thus a fan imaila can sustain itself
without food much longer than a lean one. The torpid bear comes from his hibernation emaciated, because his constitution has been subsisting on his fat.

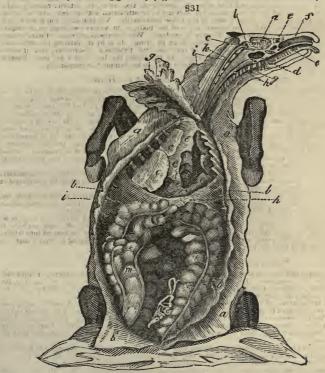

6363. Cellular membrane. (1842). This complete investure of the body enters every part, and is formed
of communicating cells; as we see by the practice of butchers who blow up their meat; and also by the
emphysematous effects of a fractured rib, and the gaseous distention in some putrid diseases. It exists in
different quantities, and under various modifications of density throughout the body, and is a very universal medium of connection in the form of ligament.

6364. Panniculus carnòsus. (1848.) The fleshy pannicle was kindly given to quadrupeds in lieu of hands,
to enable them to corrugate or pucker the skin, and thus to shake off dust and insects. It is a thin muscular expansion peculiar to brutes, but not to all; the swine family being denied it. By its attachments
it can operate variously, as we see by the uses the horse makes of it. It is very vascular and sensible, also,
from the numerous nerves wh

from the numerous nerves which enter it,

Subsect. 6. The Head generally.

6365. The parts of the head are external and internal; some of these have been touched on, as the integenents, &c. : such as have not will follow in the order of their magnitude or situation.
6366. The brain of the horse (fig. 831. a, b, c); contained within the hollow of the skull, is so similar to

that of man, that to describe the one is to portray the other. Like the human, it is composed of cérebrum (a), cercbéllum (b), and medúlla oblongàta (c). The medúlla spinalis is a direct continuation of the brain in the form of a medullary cord, called the pith or spinal marrow (k), which passes out of the skull through the occipital foramen. The brain appears to be the organ of consciousness, and the nerves which arise out of the medullary cord are the messengers by which sensation and volition are distributed to the various parts of the body.

Subsect. 7. The Ear.

6367. The ears of the horse are composed of inner and outer parts. The internal parts do not differ from those of the human, but the outer are adapted to his situation and habits. These exterior parts are composed of the skin, the outer hair, the cartilages, and the muscles by which they are moved. The skin within the ears is furnished with sebaceous glands, which secrete a bitter matter, noxious to insects: and further to guard against these, it is filled with hair; which the false taste of grooms induces them to remove, and thus to expose the animal to dust, hail, rain, and insects.

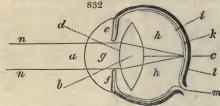

6368. The form of the ear is dependent on the concha cartilage, which is found pointed and small in the Arabian, but large and broad in the heavy breeds. The cavity within the concha is thrown into folds throughout, which increases its surface, and reflects the sonorous waves. This outer ear is attached to the internal, by connecting cartilaginous portions and appropriate ligaments. The parts of the internal ear are, the meatus auditorius intérnus, or passage; the membrana tympani, or separating membrane between the external and internal parts; the tympanum, drum, or barrel of the ear; and the labyrinth. The Eustachian tube is an opening at the upper and anterior edge of the hollow of the tympanum, forming a duct which is in part bony, and in part cartilaginous; extending from the tympanum to a large and peculiar cavity at the posterior part of the nasal fossa.

6369. The sense of hearing is formed through the medium of the expansion of the soft portion of the auditory nerve over the internal ear; sounds, therefore, entering the cavity of the concha, are reflected alternately from its sides into the týmpanum, whose oscillations are imparted to the brain.

The Eye and its Appendages. SUBSECT. 8.

Subsect. 8. The Eye and its Appendages.

6370. The appendages to the eye are, first, a funnel-shaped cavity formed by the concurrence of the bones of the skull, called the orbit, not placed directly in front as in man, but inclining laterally, to enable the animal to enbrace a larger field of view. The eyelids are an upper and under, of which the upper is the most considerable, and enjoys the greatest motion. United, they form an admirable curtain to defend the eye from dust, insects, and the light during sleep; and are moved by two appropriate muscles. Attached to the edge of each is a cartilaginous rim, called the tarsus. The cilia, or eyelashes, are not, as in man, above and below; the upper lid only is furnished with hairs, and these are not placed in one row, but in several smaller rows. The horse has no supercilia or eyebrows, unless we reckon as such the few long hairs over the orbits. The laterymal gland is a body lodged within the upper part of the orbit; it is furnished with five or six excretory duets, which secrete the lachrymæ or tears to lubricate the surface of the globe. The superfluous tears are carried off by two openings at the inner angle, called planeta lachrymalia, by which means the tears are at once carried into the nose, and not as in man first into a lachrymal sac. The carvincula lachrymalis is a small black substance in view at the inner canthus, whose office appears to be to direct the tears aright in this course. The have, or nictuting membrane, is an important part, seen when the eye is drawn inwards, but which is at all other times hidden within the fatty matter surrounding the globe of the eye. Though called a membrane it is cartiaginous, and when the eye is forcibly withdrawn into the socket, it is pressed out from the inner angle, and passes completely over the surface of the globe, to which its shape is adapted. A moderate pressure only shows about half of it; and it is thus seen in tetanus or stag-evil, by the action of the retractor muscle; and under inflammation of the eye these purposes.

6371. A diagram of the eye (fig. 832.) displays the transparent cornea in front of its globe (a), the crystalline lens (b), its posterior convexity (c), its anterior convexity (d), the iris, or curtain (e, f), the anterior chamber occupied by the aqueous humour of the pupil (g), the posterior chamber filled with the vitreous humour (h h), the retina (i), the choroid coat (k), the sclerotic coat (k), and optic nerve (m), rays of light showing the different degrees of refraction they suffer in passing through

rays of light showing the different degrees of refraction they suffer in passing through the humours of the eye (n n).

6372. The globe of the eye is composed of coats, chambers, and humours, and is operated on in its movements by muscles. It may be considered as forming a large cup-posteriorly, with a smaller cup applied to its margin anteriorly; or as though the segment of a large sphere were adapted to that of a smaller one. The substance which gives figure and consistence to the larger segment is the sclerotic coat (l), which is very firm and fibrous. The anterior cup or segment is supplied by the córnea, which is transparent, and formed of thin concentric plates of very different degrees of convexity in different animals, and often in similar animals; to a defect in which is ascribed the indistinct vision or starting of some horses. The córnea (a) is vascular and sensible, and in an inflamed state it admits the red blood, as we see by the universal redness over the whole; at other times it admits only the colourless parts of that fluid. Immediately within the selerotic coat is a thin vacular membrane, called the choröides (k), which is spread over it nearly as far as the córnea, where it turns in and expands into the ciliary processes. It also by a peculiar fold forms a ligament, after which it produces another projection into the cavity of the eye, termed the avea. It is here continuous, and presents a veil perforated in the ciliary processes. It also by a peculiar fold forms a ligament, after which it produces another projection into the cavity of the eye, termed the uvea. It is here continuous, and presents a veil perforated in the centre

the centre. 6373. The pupil of the eye (g) is the perforation which is seen annular in the human, oblong in the horse, ox, and sheep, and perpendicular in the cat. The anterior surface of the avea is covered with a membrane, termed iris, on which the colour of the eye depends: in man it is grey, brown, black, or blue; in the horse it is usually brown, but now and then white, when the animal is said to be wall-eyed. At the central margin of the Iris are seen, in a strong light, some little globular bodies or bags, covered with a black pigment. They are usually attached to the upper margin only, but when any exist on the lower they are small; they have been mistaken for disease. The Pris(e,f) is capable of accommodating itself to circumstances; that is, it can enlarge the diameter of the central aperture or pupil (g), so as to admit or shut out the rays of light. Over the central surface of the choroid expansion is spread a dark mucous substance, called nlgrum pigmentum. In animals, whose vision is distinct at night, this pigment is found of a lighter colour; in man it is very dark, and his crepuscular vision is, therefore, indistinct. In the grazing tribes it is of a greenish cast, lost in azure blue; in the predaceous tribes it is still lighter. Under this pigment is the mucous expansion, peculiar to quadrupeds, edd tapètum. The optic nerve (m) penetrates the sclerotic coat, and becomes expanded on its inner surface, in a membranous lamen of exquisite fineness, called retina. On this, it is supposed, objects are painted, and thus taken cognizance of by the brain. of by the brain.

of by the brain.
6374. The himours of the eye are the vitreous, the crystalline, and the aqueous. The vitreous humour (h h) is of a jelly-like consistence, and occupies all the globe, except those parts taken up by the other humours. The crystaltine humour forms a lenticular body of moderate consistence, and is, therefore, more properly called a lens (b). It is doubly convex (c, d), its posterior side resting in a concavity of the vitreous humour. It is not of equal consistence throughout, being much firmer in the middle. Different animals have the lens of different figures, to suit the purposes of their existence: in fisse it is nearly spherical, but in quadrupeds, lenticular. It is a diseased opacity of this body that forms cataract. The aqueous humour is a limpid fluid which fills up the spaces not occupied by those already described.
6375. The muscles of the eye. The motions of the eyeball are operated by seven muscles; four recti or straight, which elevate, depress, and draw to and from; two oblique, which rotate the eye; and a retractor

or choanoid, peculiar to quadrupeds, to draw the eye within the socket and thus preserve it from danger, which draws the globe inwards.

6376. The phenomena of vision. If the diagram oe examined, it will be evident that the eye of the horse presents an optical instrument of exquisite workmanship and mechanism, admirably fitted to collect the luminous rays from the various objects around, and to transmit them with truth othe brain. If the luminous rays reflected from objects passed through the eye in a rectilinear course, as they do through the atmosphere, no cognisance at all useful to the animal could be taken of them by the eye; all would be glare and indistinctness: but being refracted or bent by the media through which they pass, the rays finally meet at a point called their focus or focal point. Neither would one simple line of refraction have been sufficient to answer all the purposes of perfect vision, under its various modifications. It is necessary that the refraction should be increased in its passage by increased degrees of density in the media of its transit (n n). In the passage of the rays through the cornea and aqueous humour, they must encounter their first refraction; and it is evident, that the more convex the anterior portion of the eye may be, the more will this refraction be increased. We need not, therefore, be surprised that a goggler, or horse with this form of eye, should start. The next and largest degree of bending which the rays receive occurs in their passage through the crystalline lens, which from its leuticular form must necessarily be considerable; in their progress through the vitreous humour a farther refraction is effected, till meeting in a point on the rétina, a perfect representation of the object or objects viewed is oblined; the rays forming in their passage numerous cones, the bases of which will be the object viewed, and the apex of each a radiant point. Amidst the number of objects around, it appears that the eye has a capability of collecting rays from such only as a

It is becomes dilated, and the rays are then viewed through the edges of the lens, and their inclination is thereby lessened.

6377. The criteria of soundness in the eyes are gained by a careful examination of them; and which experience has shown to be best made by placing the horse within a stable, with his head nearly approaching the stable door, which should be fully open. Small eyes are found more prone to inflammation than large, and large goggling eyes are more liable to accompany a starting horse than lesser ones: and when the convexity is extreme, not only is the starting in proportion, but such eyes are more liable than others to become affected with the disease popularly called glass eyes, but medically guitta serena. It is not, however, to be understood that all starters have defective eyes; many are so from natural timidity, and still more from harsh usage. The eyes should be examined together, not only to observe whether each presents an equal degree of colarness in the transparent part and within the pupil, but also that an equal degree of contraction exists between each of the pupils. This is of much consequence: if any inequality in size or form be observable between the pupils, the least of them has been in some way affected, and will probably become so again. It is even more suspicious when a turbid milkiness appears on a part of the transparent portion; and equally so, when the inferior part looks other than clear; or, in a very strong light, with a lively buish tinge. When it is at all turbid, viewed under various aspects, regard it attentively, and there may probably be found an inward speck of perfect white; which is the nucleus or central point of an incipient cataract.

an incipient cataract.

6378. A glassy greenish cast in the eye should occasion suspicion, and the hand should be placed over such eye so as to exclude the light; remove the hand suddenly and watch the motions of the bris or curtain of the pupil. If it do not contract, carry the examination still further, and it will probably be found such eyes are totally blind. A blind horse usually carries his ears about, as though in alarm, on his leaving the stable; he also lifts his feet on such occasions, particularly in strange quarters, higher than a sound horse.

Subsect. 9. The Nose and Sense of Smelling.

6379. The organ of smell is, in most quadrupeds, the next in importance to that of vision, and in many points of view it is even of more consequence. With the herbivorous tribe, it forms their principal means of judging between the noxious and the innoxious. It is not therefore to be wondered at, that it should in these tribes form so large a portion of the head; nor that it should be so exquisitely gifted with sensibility, or so admirably formed to answer its important purposes. The external parts of the nasal organ are the two nostrils, and as much of their convolutions and linings as come into immediate view. Internally these two cavities are carried upwards into the pharynx, but completely divided by a cartilaginous septum (fig. 831./). In this course they communicate with numerous openings and cavities, formed within the bones of the skull (6300), the whole of which are lined by one continuous membrane of exquisite vascularity and sensibility; being largely furnished with blood-vessels, which gives them such a ready tendency to inflame and become red, as we witness under only a slight degree of exertion, and as we see more evidently when violent colds or inflammations on the chest are present. Its sensibility is derived from the olfactory nerves, which are spread over all its surface. It is this membrane which is the peculiar seat of glanders, becoming first inflamed, and next ulcerated throughout its extent; and as the membrane itself appears to be continued to the pharynx and largnx, so we need not wonder why the glanders proceeds to disease the lungs; nor why a common cold, which is at first a simple inflammation of this membrane, so readily degenerates into inflammation of the lungs. The common integruents or coverings of other parts are extended over the nose, but it is little furnished with fat. Of hairs it has a fine thin covering to the edges of the nostrils, and a longer set, which are carefully removed in trimming. By a fold of the skin, within which is a cartilage, the false nostril, as it is te

Subsect. 10. The Cavity of the Mouth.

A 6381. The external parts of the mouth are the lips, checks, and beard. The lips are made up of fleshy masses so disposed as to give them motion every way; they are covered over with a very fine expansion of skin almost devoid of hair, their exquisite sensibility forms them into an organ of touch; and in this point of view they may be considered as supplying the part of the points of the fingers in man. The checks are equally muscular and moveable, but are more furnished with hair; and the beard, in addition to this thin hairy expansion, has a set of long hairs.

6382. The internal parts of the mouth are the teeth already described (6260.), the gums, the alveolary edges, the palate, the tongue, and the parts of the great posterior cavity. The gums are a spongy substance which embraces and holds fast the teeth in their alveolary sockets. The membrane which covers the gums at the lower part of the channel forms a kind of fold to connect and
the gums at the lower part of the channel forms a kind of fold to connect and confine the tongue on each the gums at the lower part of the channel forms a kind of fold to connect and confine the tongue on each side. These folds are called the barbs, and are apt to be mistaken and cut off as excrescences. The bars are the spaces in the jaw left between the grinders and nipper teeth; and which man, ever ready to take advantage of for his own purposes, has made use of to ensure obedience by placing on its sensitive surface the pressure of the bridle-bit. The palate forms a bony arch, covered by membranous folds, which are apt, when the stomach is affected, to become swollen, in which case the horse is said to have the lampas or lampers. (6446.) By means of these rugose folds, the food is retained within the mouth. The curtain of the palate or vilum palatit, which is situated at the extreme end of the palatine arch, is stretched directly across the hinder mouth, and is not intercepted as in man by the penduous body termed vivula. This palate curtain is intended to shut out the communication between the mouth and the great cavity of the faces which it does at all times, except when the horse is savilowing at which it does at all times, except when the horse is savilowing at which it does at all times, except when the horse is savilowing at which it does at all times, except when the horse is savilowing at which it does at all times, except when the horse is savilowing at the former of the curtain.

directly across the hinder mouth, and is not intercepted as in man by the pendulous body fermed `vula.' This palate curtain is intended to shut out the communication between the mouth and the great cavity of the fauces, which it does at all times, except when the horse is swallowing, at which period the curtain is forced back and the food passes. I From this cause likewise the horse is prevented from breathing but by his nostrils; and when any air does pass by the mouth, as in coughing, crib-biting, &c., it is only effected by a forcible displacement of the curtain.

"6383. The tongue is a long fleshy mass (fig. 831. e), which adapts itself below to the form of the channel, and above to the arch of the palate: its external surface is rough by means of papillae, which are inclined backwards, and thus resist the loss of the food received within the mouth. In some animals, as the ox, bear, &c., they are very large, and in the cat pointed. The tongue is a very principal organ in mastication, carrying, by its great mobility, the food into every direction until fully acted upon, and finally passing it into the pharynx.

6384. Sense of tasting. It is not observed that this sense is so diversified in brutes as in man; but it is instinctively so correct, that it seldom errs in the herbivorous tribes; and when it does, there is reason to suspect some present defect in the organ, arising from morbid sympathy, which (as in the instance of salt-water, of which at some times horses will drink immoderately,) prompts then take in matters they are accustomed to refuse. Taste was given to brutes to regulate their other senses, and thus there are few plants or substances whose application to the tongue, under ordinary circumstances, produces an agreeable effect but such as are proper for food. Nature, therefore, stimulates have creatures to search for edibles by a double motive, the calls of hunger and the pleasures of taste; and these are usually in unison, for the nauses of repletion destroys the appetite of taste.

6385. The p

and which great membranous hollow is unknown in man and most quadrupeds (fig. 831. d.) Its use is not understood, but it is probably connected with the voice.

6336. The larynz is situated at the posterior part of the former cavity, and appears as a cartilaginous box between the os hyöldes, to which it is attached for support. This cartilaginous box, or entrance to the windpipe, is formed of several pieces, and is furnished with a kind of movable door, which, in ordinary cases, exactly fills up the cavity left by the arch of the plate curtain, thereby shutting the cavity of the mouth, and forcing the animal to breathe through his nasal openings. In extraordinary cases, as when the animal swallows food, this cartilage is forced down, and then it becomes a door to the glottis or funnel part of the trachea, and thus prevents the entrance of extraneous matter into the lungs. All these parts are operated on by numerous muscles.

the animal swallows food, this cartilage is forced down, and then it becomes a door to the glottis or funnel part of the trachea, and thus prevents the entrance of extraneous matter into the lungs. All these parts are operated on by numerous muscles.

16387. The voice. The larynx has also another important office in being the organ of the voice. The cartilages of the larynx are very movable on one another, and are furnished with nuscular cords, which tighten or relax them; besides which, they are also furnished with peculiar and appropriate sacs or cavities, independent of the tracheal opening, and which are of different magnitudes and directions in different animals. The cartilages of the larynx being acted on by the cordex ocales, produce different degrees of expansion in the laryngeal sacs; by which, either in expiration or inspiration, are produced different degrees of vibration, and consequent intonation. Neighing appears produced wholly by expiration through the nose, as are most of the tones of the horse's voice. This is proved by slitting the nasal cartilage, which wholly stops it. Knuckering, as it is termed, is only a lesser neigh, with shorter, deeper, and less forcible tones. The former sound is used as a call, the latter as either call or recognition. It is likewise, when used mildly, significant of joy and affection, and is then beautifully sonorous. The horse has an actue sound produced by inspiration, used as call, the latter in most other cases his intonations are accompanied by expirations; nor does it appear that the tongue or teeth of the horse are nuch concerned in the modulations of his voice.

6388. The parolia glands, or, in the language of farriers, the vioes, are two considerable bodies on each side of the head, extended from the base of the ear around the angle of the jaw. Each parolid is a conglomerate gland, furnished with numerous little ducts, which unite into one, and enter the mouth about the second molar tooth. These glands furnish saliva for the use of the mouth, and it is an

Subsect. 11. The Neck.

6389. The external parts of the neck are the common coverings which have been described; the cervical 6390. The external parts of the neck are the common coverings which have been described; the cervical ligament, the muscles, and the jugular or neck veins, &c. The evenucal ligament (fig. 831. 3), is a very strong substance, in some parts semimuscular, and in all extremely elastic, stretched from the occipital bone along the back of all the cervical vértebre except the first. Continued on the spinous processes of the dorsal vértebre except the first. Continued on the spinous processes of form the neck either into a plane, or an elegantly convex line upwards. By its extreme tenacity, the ponderous mass of the head is preserved in its situation, without the necessity of an immense mass of nuscle which would, without this contrivance, have been necessary. It is to an injury received at the upper and anterior part of this ligament, that the pole evil is owing. The nucles of the neck are too numerous to allow of particularisation; it is sufficient to say, they most of them run longitudinally. The jugular veins run one on each side of the neck superficially, on the side of the trachea and windpipe, and form the vessel usually bled from (fig. 833. r). A few inches before they reach the angle of the jaw, each divides to furnish the head.

6390. The internal parts of the neck are the vertebræ, within which passes the spinal marrow. The carolid arteries pass up under the jugular veins, near the cesophagus (fig. 833.s). The trachea or wind-

pipe (fig. 833.g), is a large canal for the transmission of air, formed by alternate rings of membrane and segments of cartilage, rendering it at once flexible and cylindrically hollow. The asophagus (figs. 831) h & 833.s) is the continuation of the funnel-like cavity of the pharynx. It is externally muscular, and internally membranous and cuticular, by which formation it is elastic, to allow of distention in the act of swallowing. The asophagus penetrates the chest within the mediasthum, and passing along the spine (fig. 833.l), through an opening in the diaphragm, terminates in the stomach. xpan ma, bas

The Thorax or Chest. 1 19 " ring has an aft 220 SUBSECT. 12.

6391. The chest of the horse is bounded anteriorly by the matters filling up the space between the two first ribs, posteriorly by the diaphragm, laterally by the ribs, above by the vertebra, and below by the sternum or breast bone. In dissecting the horse, after the interior-membranes, muscles, &c. are thrownback (fig. 331. bb b), there appear the lobes of the lungs (ccc) the heart (d) mediastnum or membranous division of the chest (ee); the sternum or breast-bone (f); the ensiform cartilage (g)); and tendinous centre of the diaphragm (h, i).

6392. When the chest is opened a smooth polished membrane is seen, which covers the surface, and then is reflected over its contents; this is called the plebra; and by a junction of the two plebra, a division of the chest into two nearly equal portions is effected, which membranous division is called the mediastnum. By this division of the chest into two parts, very important benefits arise; as when one-cavity is opened the lungs immediately collapse, but the respiration may be careful on by the other, all na similar manner ulceration may proceed to destroy the lobes of one side of the chest, as in glanders, but may be checked by the mediastnum from proceeding to the other. The plebra does not, as in man, appear to take on inflammation independently of the substance of the lungs; thus the horse is not subject pear to take on inflammation independently of the substance of the lungs, thus the horse is not subject to pleurisy. The thymus gland, which is a considerable body in the colt, and which forms the sweetbreat in calves, is hardly discernible in the old horse. It is situated between the folds of the mediastinum, but

to pleurisy. The thymus gaine, which is a considerance to a first content and the folds of the mediastinum, but its uses are unknown.

6393. The diaphragm or midriff (fig. 831. i, h) is a very important part of the body of the horse, dividing the chest from the belly by its disk, but which is far from elliptical, extending much. further backwards than forwards. Its fibres radiate from their origins to unite in one tendinous centre (k). In a state of rest it is anteriorly convex, and posteriorly concave; but at each inspiration these appearances are nearly reversed. (6398. It is perforated for the passage of the vine dava, the advita, the vine axygos, thoracic duct, and osophagus, all which pass through it by means of three openings. It has been found ruptured in some desperate cases of broken wind.

6394. The heart (fig. 831. d) is the great agent of circulation, and is made independent of the will; were, it otherwise, man and other animals might cease to live at their own discretion. The pericardium is first seen surrounding the heart so completely, that it swims within it by means of a little fluid termed, liquor pericardii. The heart (fig. 831. d) is the situated within the mediasthnum, so as to occupy a cavity of its own, distinct from either side of the chest. Its base is in a line with the dorsal vertebre, and its apex is directed to the left of the sternum, between the eighth and ninth ribs. Its two ventricles are immediately within its body, and its two auricles are rather without, appended to it. The left vertricle contains arterial blood, and from it originates all the arteries except the pulmonary. Within the ventricles are valves to prevent the return of the blood. The auricles are less muscular than the ventricles are valves to prevent the return of the blood. The auricles are less muscular than the ventricles. The left ventricle is the left, or pulmonary opens into the left ventricle can describe as originating with the light ventricle.

Into the right and larger auricle the anterior and posterior cavas enter by two openings, and into the left, the pulmonary veins pass.

6335. The circulation of the blood may be shortly described as originating with the left ventricle of the heart, which sends its blood, by means of the great vessel called the airta, to all parts of the body. The blood thus distributed is collected again by the veins from all parts, and is by them returned into the heart by means of the two cavas, which pour their contents into the right auricle, which immediately forces it, into the right ventricle. From the right ventricle it is again forced out into the pulmonary artery, which carries it throughout the lungs to undergo a change, and to be finally returned, by eight trunks into the left auricle, which immediately empties it into the left ventricle to renew the process

described.

described.

6396. The lungs are spongy masses divided into right and left, with less divisions called lobes. Their, colour varies according to age: thus, in the colt they are of a light lively pink; in the full grown horse they approach to a greyer tint; and in the very old subject they are of a still deeper tone. The brouchia are continuations of the trachea or windpipe, which, dividing on its entrance into the chest, ramifies throughout the substance of the lungs, giving these masses their spongy cellular structure, in which distribution the air vessels are accompanied by ramifications of the pulmonary artery and veins. From the extreme vascularity of these parts they are very liable to inflammation.

6397. The theory of respiration. By some extraordinary sympathy, the colt at birth gasps, and air rushes into the lungs before collapsed: having once felt this stimulus, by a common consent between the diaphragm and intercostal muscles, the cavity of the chest is diminished to expel the air received, and to inspire a fresh quantity; and which process is then continued through life. The body appears vitally nourished by two sources: the one through the medium of digestion; the other by means of the blood itself, which, in its progress through the body, gives out its vital principles of heat to the mass, and vitality to the muscular fibre, for unless the blood effect its part in the contractile phenomena it will be in vain for nervous influence to exert its power. Having given out these principles, it is returned by the veins, and is passed forwards into the lungs, circulating throughout their substance, and imbiling, by their contiguity or continuity with the air vessels, oxygen gas from the atmospheric air contained in them. In return for the oxygen received, carbon is given out, which passes off in the form of aqueous vapour, As the blood is renovated, so the air it acted on is deteriorated, and is therefore expired from the chest to make room for a fresh inhalation, to oxygenate a fresh quantity of blood, and vital powers subservient to its influence.

Subsect. 13. The Abdomen.

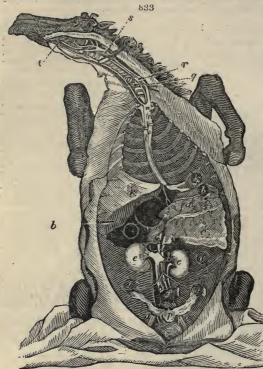

6398. The viscera of the abdomen include the stomach (fg, 833, a); lobes of the liver (bb); omentum or caul attached to the whole inferior curvature of the stomach (c); the spleen (d); the kidneys (e,e); the rectum (f); the ovarial (g,e); the atterus (h); the bladder distended with urine (f); the delaph ragm or muscular partition dividing the belly from the chest (kk); escophagus or gullet proceeding to the stomach (h); trachea (m); vena cava ascendens (n); aorta descéndens (o), which passes through the abdomen (a), as does the cava descéndens (b); to aortid arteries (g); jugular veins (r); escophagus (s); and maxillary artery, forming the most convenient situation for feeling the pulse (t); which completes the viscera and general appearances of the horse when laid open.

6399. The abdomen or cavity of the belty is the largest cavity of the body, and forms an extensive oval vault, containing very important viscera, which may be considered as the chylopoietic, the urinary, and the spermatic, all which are invested by a membrane called the peritoneum, which, after covering each of these organs separately, is reflected over the cavity of the belly itself. It is very strong, and very elastic, as we perceive by the effects of dropsy, great fatness, and likewise by the increase in pregnancy. The omentum or caul (c) is the fatty apron which first presents itself on opening an animal's

body, extending in some, as the dog, pig, &c. into the pelvis; but in the horse it is less considerable, from which he is not subjected to epiplocele as they are. Its uses are unknown.

6400. The stomach and its digestive functions. The horse has one stomach only, and that a very small one, drawing a very wide line of separation by this means between his family and the ruminants. In fact

the stomach of the horse may be regarded as intermediate between the triturating muscular one of fowls, and the mem-branous one of the Graminivora. It is peculiarly constructed to keep up this intermediate to keep up this intermediate character, being partly membranous, partly muscular, and partly cuticular; in which latter formation much of its peculiarity consists, and which it shares in common with asses, rats, and mice; whose habits of living on grain give them a like claim to this wise provision. In a state of rest, or only mode-rately distended, its direction is across the abdomen, with its two orifices directed upwards; but the cardiac or recipient orifice, to which the œsophagus is attached, the most so; while the pyloric or expellent orifice is rather lower, and more inclined backward. The situation of the stomach is immediately contiguous to the diaphragm or great breathing muscle (fig. 833. k k), from which we are at no loss to understand why a very full meal obstructs respiration; and why it is so across the abdomen, with its two respiration; and why it is so imprudent to gallop a horse very hard after drinking or eating fully. Small as the stomach is in a natural state, it is yet capable of great distention, as has been witnessed in stomach staggers, when upwards of half a hundred weight of undigested food has been extracted from it. The membranous portion of the stomach is gained from the peritoneum; within this is situated its muscular part, principally composed of longitudinal and transverse layers, by which its motions in digestion are re-gulated. Around the cardiac

cor recipient orifice, a strong band of circular fibres is very evident, which effectually constringes this part, and prevents regurgitation or vomiting in the horse, except under extraordinary circumstances of muscular relaxation and sympathy. It has been already shown that the anterior part of the alimentary canal, as the mouth, throat, and guillet, are lined with cuticle or skin. This cuticle is continued into the stomach, and lines nearly a half of its internal surface, whose office seems to be a more perfect comminution of the food, which the horse has no opportunity of remasticating like the ox, sheep, &c. The villous or sensible portion of the stomach is thrown into folds, so as greatly to increase its surface: here the comminuted food in its passage becomes saturated with the solvent gastric juice, and is then passed forward into the intestines

villous or sensine portion of the stomach is saturated with the solvent gastric juice, and is then passed forward into the intestines.

6401. The derangements of the stomach may be explained from its anatomy. Though small, and its sensible parts still smaller, yet it is subject to more diseases, and to more frequent derangement, than is generally supposed. It has been proved to be muscular, and that its digestive functions are performed by means of its muscularity. It has also been shown that the contractile energy of the muscular fibre, its mainly gained from the oxygen derived from the blood; whatever tends to interrupt this separation, as an unhealthy state of the lungs, too quick action of then, &c. must derange the action of the stomach also. The perfection of its digestive powers is also derived from its secreting healthy gastric juice, consequently whatever interrupts this process must likewise interfere with stomachic health; and that such health is more often impaired than is generally supposed, and that many ailments, attributed to other causes, are really dependent on an affection of this organ, experience and observation will fully evince. Out of condition is a most frequent complaint among horsemen; their horses are out of condition, and unfit for work: the appearances are various, but are all well known; yet it is seldom considered that it is owing, in every seven cases out of ten, to the stomach being morbidly affected. (6425). It is evident that too full feeding must derange it, not only by keeping it constantly distended, and thus weakening its capacity; but by entrenching too much on its secreting office, and requiring an inordinate quantity of gastric fluid to saturate an undue quantity of farinaceous matter. The bots, that are frequently found on its cuticular coat, and are there probably harmless, sometimes displace themselves, and settle on the villous part, where they must occasion uneasiness and probable inflammation.

inflammation.
6402. The intestines (fig. 831.k, t) in the horse may be considered not merely as secerning organs alone, as in man and many animals, but as really digestive organs, and continuations of the stomachic viscera. This is more particularly the case with the small intestines, and may therefore entitle them to the term of alimentary canal, and the large to that of the excremental; the former measure from twenty-one to twenty-three yards in length, and the latter from seven and a half to eight yards and a half, according to the size of the animal. The duodenum is the first of the small intestines, commencing at the pyloric orifice of the stomach; the jejunum, which is the next and larger portion, and the filum (fig. 831.e), which is still longer, form the remainder. The alimentary canal in its structure does not differ from the sensible part of the stomach, having like that two plans of muscular fibres, a circular and a longitudinal, by which its peristatic motions are regulated; the longitudinal shortening the canal, and the circular diminishing its size. The alimentary part of the intestinal canal ends with this small gut, which itself

terminates abruptly in the execum or first of the large intestines (fig. 834 a), and which intestine commences what has been termed the excrementitious canal. This entrance is effected in such a manner as to leave, by a protrusion of its surface inwards, a kind of valvular apparatus, which prevents the return of the contents.

contents.

6403. The large intestines (fig. 831.k k) in the horse are really descrying of that name, being very capacious; while in man and carnivorous animals they are little different from the small. They occupy and completely fill up the lower portion of the abdomen: the coccum occupies the right side, and carries its blind end towards the diaphragm, which is not furnished with an appendix as in man. A careful inspection of this intestine will show that the appellation of excrementitious canal does not wholly apply to it; but that, on the contrary, it performs some of the offices attributed to the smaller intestines. The colon commences small from the side of the base of the offices attributed to the smaller intestines. The colon commences small from the side of the base of the coccum; but soon enlarging, it makes a turn round the abdomen, when contracting it ends in the rectum, and passes backwards to the anus. Along the course of the large intestines are muscular bands, which throw their surfaces into folds, and also form them into a continuation of ceils (fig. 831. m). By these means, the matters are detained to be acted on more fully, and finally they are expelled in dry hardened balls.

and passes backwards to the anus. Along the course of the large intestines are muscular bands, which throw their surfaces into folds, and also form them into a continuation of cells (fig. 83). M). By these means, the matters are detained to be acted on more fully, and finally they are expelled in dry hardened balls.

6404. The digestive process in the horse is one of the most curious as well as one of the most important which goes on in the body. The various actions of an animal body produce relaxation and waste, which are indicated by fatigue and hunger. To restore the one, rest is required, and to restore the other, food becomes necessary. For the herbivorous tribes, vegetable matter is sought for, which being collected, is masticated by the grinders and mixed with salva, until it becomes a softened mass, when it is passed backwards by the tongue and molar musics, through the arch of the plate, in the form of a bolus. Received into the plarynx, which rises to receive it, and the action of which forces down the epiglicities, all impediment is removed to its falling in the open funnel that the soft in the cosphagus forcessure; but being further removed, it meets the action of the gastric fluid, by which it is reduced to a pulstaceous mass called chyme. In this state it is passed backwards within the stomach, as in man and many animals. The exertions of the horse require that she will cannot be stomach, as in man and many animals. The exertions of the horse require that she made a largely and nortitionsly, but the bulky viscera of the ox would have ill suited with his necessities; for he is not only strong, but his motions are designed to be quick also: it was therefore necessary that some speciality should occur to meet these seeming discordances. This consists in the mode of digestion, which being but partially completed in the stomach, requires a less bulk in that organ, the intestines participang in the above. A horse cannot fast long without injury and pain; jhis food does not produce a lasting effect in th

kidney.
6408. The spleen, or milt (fig. 833. d), is a spongy body situated at the greater extremity of the stomach.
Its use is likewise not clearly ascertained; but it has been supposed to be that of a reservoir of blood for the stomach

the stomach.

6409. The kidneys are two excremental glands (e e) situated in the lumbar region, the right more forward than the left. The structure of the kidneys exhibits an external reddish part, an internal whitish part, and a cavity called the pelvis. From this cavity passes out the duct called the ureter, and brings with it the urine which is secreted within the kidney. The urbers convey the urine to be bladder.

6410. The urine appears to be a faccal separation from the blood, and is in some measure connected with the skin in its oflice. Thus, when the perspiration is great, the urine is less; and on the contrary in winter, when the perspiration is small, the urine is more considerable. The kidneys of the horse are more easily shich would not appear potent act with violence on his urinary organs. Thus mow-burnt hay, kiln-dried oats, &c., will produce diabètes.

6411. The bladder of the horse (fig. 833. i) is a membranous sac for the reception of the urine. It rests on the pùbis, and is immediately under the rectum. It is in part muscular, by which it can expel its contents almost to the last drop. At its neck is a kind of sphincter to prevent the involuntary escape of urine, and at its posterior part it is pierced by the urèters. To the bladder is attached a membranous pipe called the urèthra, which passes through the penis, and by that means ejects the urine.

Subsect. 14. The Fætal Colt.

6412. The reproductive system is one of the most important of nature's works; and, whether we examine the subject anatomically or physiologically, we shall be convinced that the utmost wisdom and care have

been displayed to perfect the continuance of the species. The tender embryo, produced by the mutual sympathies of both parents, becomes placed in a situation the best adapted to its necessities and safety.

6413. Pregnancy and coolation of the factus. In the pregnant womb, the rudiments of the future animal are covered with expansions from the neighbouring parts; and derive neurishment from a communication with the mother by means of the umbilical cord, and farther, by a surrounding fluid. In this state a speciality is observed in the feetal sanguincous circulation; the whole of its abdominal blood passing through its liver (5733.) by which it gains a more early and perfect evolution to fit it at its first entrance into life for active exertions. Under these circumstances it daily acquires increase, until the distention it occasions becomes too great for the capacity, when the muscular fibers of the uterus, powerfully assisted by the diaphragm and abdominal muscles, contract, and thus force both the foal and the membranes into the world. membranes into the world.

membranes into the world.

6113. The new-born faul, on its entrance into active life, finds its organs of immediate necessity in a full state of capacity. Unlike the infant, it is far from indigent, but can run and perform the common phenomena of an animal with dexterity and ease. Its powers are, however, not sufficiently developed to enable it to live independent: it has therefore a necessity for seeking support from the mother, in the form of milk; and it may therefore be now considered in some measure as carnivorous. The milk is derived from a bag furnished with two nipples, having excretory outlets and valves to prevent the accidental loss of the fluid. These valves the instinct of the foal teaches it to displace by its nose. The milk of the mare being highly nutritious, its evolution rapidly increases and becomes fitted to perform all the

or the mare being nighty hutritious, its evolution rapidly increases and becomes fitted to perform all the more matured functions, and when fully able to counteract its own wants, it synthiese only with itself; when the parent's care being no longer necessary, the lactiferous secretion ceases.

6415. The period of gestation varies in different mares: one hundred and two mares were observed by Tessier, of which 3 foaled on the 311th day, 1 on the 314th, I on the 325th, 1 on the 326th, 2 on the 333d, 47 from the 330th to the 350th, 25 from the 350th to the 350th, 25 from the 350th to the 350th, 25 from the 350th to the 350th, 25 from
Subsect. 15. The Foot.

Subsect. 15. The Foot.

6416. The feet of the horse present in their united functions a series of springs with great complexity of structure. An unreflecting observer considers only the horny box, and perhaps attaches as little merit to its mechanism, as he would to a well turned wooden leg of a man. But a little examination will convince him that all the complexity, all the admirable mechanism displayed in the assemblage of four fingers and a thumb, are here concentrated within this horny box and its appendages. As the parts which compose the hind and the fore feet do not materially differ, a description of one foot will serve for the whole.

6417. On examining a perpendicular section of the foot, (c), the same tendon sliding over the navicular bone (d), the back sinew or great flex or tendon of the foot, (c), the same tendon sliding over the navicular bone (d), the sensible foot; the outer wall of the hoof, (d), the elastic matter of the extensor that (k), which includes the parts of the sensible foot; the outer wall of the hoof, (d), the elastic processes (m), the attachment of the extensor tendon of the foot, (d), and its attachment to the coronary bone (o), which completes the section.

6418. The coronary or small pastern bone (c), articulates with the coffin at its posterior part, and articulating also with both these is the navicular or nut bone (f), whose attachments to the form the tibia and in part from the femuniated substance.

6419. The coronary or small pastern bone (c), articulates with the coffin at its posterior part, and articulating also with both these is the navicular or nut bone (f), whose attachments to the made are effected by ligaments.

tnese is the nanucular or nut bone (f), whose attachments to them are effected by ligaments.

6120. The hoof is conical, or rather, as Clark observes, slightly truncated, and is a secretion as well from the vascular parts of the foot as from the skin, as our nails are from the portion of skin called the quick. The structure of the hoof is firm and fibrous; externally plane and convex, but internally concave and laminated. The quarters are the lateral parts. As the horn approaches the heels it becomes soft, and is reflected inwards. The heels are parted by the horny frog (fig. 836.6), and without the frog on each side, the hoof inflects its fibres to form the bars which are seen on the under surface (fig. 836.c). In a healthy foot (fig. 837), the heels are round, wide, and smooth (a a), the frog fully expanded (b), the bars or binders distinct (c), no corns in the usual angle (d), the sole broad and concave (d). In a diseased foot (fig. 837), the heels are high and drawn together by contraction (a a), the frog narrow and filled with the sole greatly shortened in its transverse diameter, which is morbidly counterbalanced by the increased heights in the truncated form (c). When the hoof is removed, the sensible

mediately lies, presents itself, covering the whole of the horny sole, except so much as is taken up by the sensible frog (h). This part is exquisitely sensible and vascular; and thus we learn why injuries to it from punctures produce such serious effects, and why very slight pressure from contraction of the hoof gives so much pain. The sensible frog and the sensible sole form the insensible frog and sole; but when from pressure, too much moisture, or other causes, the sensible frog, instead of forming horn, secretes pus or matter as in thrush, the structure of the whole becomes injured; and the horny frog, thus losing its support, gradually wastes and decays. It is, therefore, evident that no thrush can be entirely harmless, as is erroneously supposed. Above the sensible frog and sole is the great flexor tendon, or back sinew, inserting itself into the vaulted arch of the coffin (fig. 835. c.). This important tendon arising from its parent muscle above the knee, whose origin is taken from the humerus and ùlna, in its passage unites with an assistant flexor, but which latter is principally distributed to the pastern bones; while the pérforans, so called because it is perforated by the assistant flexor tendon, is inserted into the vault of the coffin. In the posterior extremities, the attachments of these two leading flexors, and a smaller lateral one, are from the femur and tibla. n the femur and tibia

6121. The sensible láminæ. Around the surface of the coffin bone it has been noticed that there are

ted b. יו כ לום "ודיוב

linear indentations, to which about five hundred semi-cartilaginous leaves are attached. Each of these is received between two of the horny lamella which line the interior of the horny hoof, and when it is considered what a vast surface of attachment is formed by these means, the strength of the union will not be wondered at. No common violence can separate these parts, and their use, as so many springs to support the actions of an animal, at once weighty, strong, and extremely agile, must be apparent. The vessels and nerves of the foot are derived from the metacarpal arteries, veins, and nerves, which pass behind the pastern, when the main trunks divide to proceed to cach side of the foot, and are ramified from thence throughout. It is a division of the metacarpal nerve on each side of the lesser pastern, or of the larger, as occasion suits, which forms the nerve operation, now in vogue as a remedy for founder. linear indentations, to which about five hundred semi-cartilaginous leaves are attached.

Sect. V. Diseases of the Horse.

6422. The diseases of the horse are as numerous and as important as its complicated structure, and the artificial state of his present mode of life, would lead one to expect. Until of late the treatment of these diseases was confined to the hands of ignorant farriers, presumptive grooms, or shoeing smiths; and the fate of the animals was commensurate with the wretched treatment they were subjected to. The establishment of a school for the veterinary art has disseminated an improved practice, and spread improved practitioners throughout the country; and we would earnestly recommend an application to one of established reputation in all cases of difficulty and danger. But as it is not always that such a one is within reach, to enable the agriculturist to have in his own hands the means of informing himself, or of being a check on others, we submit a concise view of the diseases of the head, neck, trunk, and extremities, preceded by some general observations.

General Remarks on the healthy and diseased State of the Horse. SUBSECT. 1.

Subsect. 1. General Remarks on the healthy and diseased State of the Horse.

6423. Condition of horses. Being in condition, in stable language, signifies not only perfect health internally, but such an appearance externally as the philosopher would call unnatural, or at least artificial; condition is denoted by a sleck, short, shining coat, with a degree of flesh neither bordering on fatness nor emacation. Even in this sense of the term, condition must be varied according to the user of the anima. In the cart horse, provided there be sleckness of coat, looseness of hide, sound wind, freedom from proase or swelled legs, with good digestion; a fulness and rotundity of bulk; instead of detracting from his beauty or impeding his exertions, will add to the one and assist the other. In the coach horse, the hole of the control
the effect is apt to be mistaken for the cause, and the symptoms for the disease. Hide bound and lampas are not in themselves any thing more than effects, or symptoms; the former being commonly, and the latter being always, dependent on a deranged state of the stomach: both are therefore, to be treated accordingly. Exactly the same will apply to all the other symptoms of morbid condition.

Subsect. 2. Inflammatory Diseases of the Horse.

6426. The inflammatory diseases of the horse are numerous, but his fevers are few; a febrile state being generally brought on by the inflammation of some important organ. Inflammation may be considered as general or diffused, and local or confined, and both seem to arise from an affection of the blood itself.

6427. General or diffused inflammation constitutes fever or extensive inflammatory affection, and appears to consist in an increased action of the heart and arteries, accompanied with an increase of heat. In some instances where the fever is purely symptomatic, and dependent on the inflammation of some important organ, as of the lungs or the intestines, the circulation appears retarded rather than increased, from interruption arising to its passage through the heart.

6428. Local or confined inflammation is also dependent on an affection of the blood-vessels, but con-

from interruption arising to its passage through the heart.

6428. Local or confined inflammation is also dependent on an affection of the blood-vessels, but confined principally to the blood vessels of the part affected. It is betokened by redness in the skin, tumour or swelling, heat, and tenderness, with pain. Inflammations, both diffused and local, are brought on by excitements, such as over-feeding, excessive heat, the reaction produced after cold, and the reaction produced by inordinate exertion. Those more exterior arise from injuries, the application of improper substances, &c. Inflammations terminate in various ways; but it is to be remarked, that in consequence of the very large circulatory system in the horse, his febrile affections rage higher, and terminate sooner, than in man. The usual termination of inflammatory affections in the horse is, by resolution, efforts a supportation, and cargreene. Schirus is not at all a common termination of inflammation in the borse.

of the very large circulatory system in the horse, his febrile affections rage higher, and terminate sooner, than in man. The usual termination of inflammatory affections in the horse by resolution, effusion, suppuration, and gangrene. Schirrus is not at all a common termination of inflammation in the horse. 6129. Inflammation of the brain (phrenkles), brain fewer, phrensy fever, staggers, mad and steepy. There are few diseases more likely to be mistaken by inexperienced farriers than this; it is not to be wondered at, therefore, if indifferent persons should be led into error by it. It appears in two forms, a violent frantic one, and a sleepy lethargic one; and the latter appearance is also common to a disease, not dependent, as this is, on idiopathic inflammation of the brain, but on a paralytic affection of the stomach, and thence it is called stomach staggers. This latter affection, however, may be distinguished from the former by attending to the colour of the eyelids, nose linings, mouth, &c., which, in stomach staggers, are usually more yellow than red; whereas, in sleepy staggers, they are more red than yellow. Inflammation of the brain shows itself, in general cases, by disinclination to food and motion, drowsiness, accompanied by a heaviness and closing of the eyelids, with moisture and redness of them; and also of the linings of the mouth and nose. Sometimes these symptoms increase until the horse becomes comatose, and after a few frightful struggles, he sinks to rise no more. In these cases the pulse is aptro be oppressed instead of increased; but most frequently after the first stages he becomes furious, plunges about, and is vicious to himself and others, approaching to a state of madness, in which state he continues till he sinks from his own exertions, when he rises again to renew his violence.

6430. The causes of staggers may be various: the immediate are either an original accumulation of blood within the brain, or the translation of the inflammation of some organ to the brain; as a remote ca

(Yet. Pharm. 6564.), blister the head, promote a current of free air in the stable, and treat altogether as directed under other febrile affections.

6432. Locked Jaw, Stag-evil, or tétanus, arises from cold, excessive fatigue, sometimes perhaps from worms, but more often from a wound of some part, as pricks in shoeing, &c. Such wound is seldom in a recent state, but after two or three weeks' continuance, sometimes after it has healed even; it follows docking, gelding, and nicking frequently, and is preceded by a flabby unhealthy, state of the wound. It is not always produced by an open wound; it is sometimes consequent on a bruise, strain, &c.; and is sometimes brought on by cold, violent exertions, &c. &c. It appears as an affection of the brain, which transmits its morbid irritation, particularly to the nerves attached to muscles, by which they become cramped, or may be considered as in a high state of action, giving the horse a peculiar look of energy, as though immediately stopped from full speed, with his nostrils extended, bis head raised, and nose carried forward; his legs straddle wide, and his tail is cocked and quivers, as after violent exercise. The jaws will now be found, if not closed, yet nearly so, when he is called jaw.set.

6433. The treatment is not often successful; but, however, it is sufficiently frequent that it is so, to deserve the utmost attention. Blaine informs us that enormous bleedings have succeeded; but he places his principal dependence on the application of cold by the means of ice, or of constant dashing with cold water, with an active blister applied the whole length of the spine. Balls of camphor and opium, to the amount of two drachms of each, may be given as a drink by means of a syringe; and even when the mouth is entirely closed, he informs us we may give a drink by the nostrils. Moorcroft used cold also. Fearon, on the contrary, has experienced benefit from a bath, heated to ninety degrees, and kept at the temperature for three hours. White recommends camphor and opium. only one, of giving support. days. (Vet. Pharm. 6566.)

days. (Vet. Pharm. 6566.)
6434. Catarrhal fever, epidemic catarrh, influenza, distemper, cold, morfoundering, &c. These names apply to one common disease, which often in rainy, variable seasons appears as an epidemic, and affects thousands of horses at once. It is observed to be particularly prevalent in this form in the spring of some years, more than of others. It is not contagious, like the more malignant form, but is brought on as an epidemic by the same causes being applied to nearly all subjects alike; which are alternations of heat with cold, moisture, and dryness, &c. In crowded cities and large towns it is more prevalent than in more open situations, and it is more frequently found in the young than in aged horses. Where it does not exist as an epidemic, it is brought on By an accidental cold taken. It is of great consequence to distinguish it from pure inflammation of the lungs, with which it is very apf to be confounded; and which mistake is often a fatal one, from the treatment being in some essential particular different. Inflammation of the lungs commences by a short cough, without much other disturbance to the health than the pain it gives the horse to cough; but which is often so considerable as to make him stamp his feet while coughing. If a horse in the distemper coughs early, it is not a hollow, harsh-sounding, and distressing cough of this kind; if he expresses uneasiness, it is principally from a sore throat, which is very common

in distemper, but by no means common in pneumonia. The sore throat in distemper gives the horse a disposition to refuse his food, or he chews it and lets the quid fall without swallowing it. He refuses water, particularly if it be placed on the ground. His cough is quick, short, and usually sounds more moist than harsh and dry; but though common, this is not invariably the case. His eyes are heavy and moist, his breathing is quickened, and his ears and legs are alternately hot and cold. His nose on looking into it is redder than usual, and sometimes his glands, as well submaxillary or jaw glands, as his parotid or vives, are tumified. On the second or third day excessive weakness comes on; the cough becomes more painful, the pulse is quickened, and the nose begins to run. After which the horse either runs off the disease by this suppuration, or it goes on to destroy him by the height of the fever, and degree of weakness produced, or by suffication from water in the chest. Now and then, although recovery takes place, an obstinate cough is left; and in a few cases the disease terminates in glanders.

6455. The treatment may in some cases be cut very short; for as in almost every instance a shivering fit begins the disease, so when many horses are in a stable, and the disease is very prevalent, those who have not been attacked should be watched, and the moment such an attack does take place, give of sweet spirit of nitre, or when not at hand of spirit of hartshorm, an ounce, in a pint of sound ale. Exercise the horse briskly, then well hand rub him, clothe him warmly, and it is more than probable that the disease will be cut short. But should it proceed, or should the disease have gone on unobserved to the appearance of the symptom detailed, begin by bleeding moderately, if the horse on on unobserved to the appearance of the symptom detailed, begin by bleeding moderately, if the horse on on the other proceeds. It will, however, in general cases, be advisable to avoid bleeding after the second day of the attack, or be given.

be given.
6436. Malignant epidemic, murrain, or pest. Now and then the distemper or influenza assumes a character of uncommon malignance; which is happily not frequent here, but not unfrequent in continental countries; sweeping off a third of the horses and kine, without any means being found sufficient to arrest its progress. In these cases it is highly contagious, attacking almost all the horses as well as a cattle within its sphere of action, or which communicate with each other. Dr. Layard, and Osmer, English writers of established reputation, noticed the appearances of this disease long ago; and their descriptions are not different from the milder kind noticed (6434.) but in degree. The throat is intensely sore, and the mouth ulcerated; the glands of the head swell, and sometimes these and other parts suppurate and burst. The matter from the nose is bloody, and the stench intolerable; the weakness is also reculiarly creat, and shows itself early.

purate and burst. The matter from the nose is bloody, and the stench intolerable; the weakness is also peculiarly great, and shows itself early.

6437. The treatment recommended by Blaine is the early use of malt mashes; even ale is indispensable. Green meat should be allowed, and a very cool stall is necessary, having a free communication with the open air. As medicine, three doses are necessary, every day, of the malignant epidemic fever drink (Vet. Pharm 6582.); half a pint of yeast with a pint of ale has been given, with good effect, three times a day; also, to prevent the infection from spreading, fumigate the stables and all the outhouses with the preventive fumigation. (Vet. Pharm. 6583.)

Subsect. 3. Diseases of the Head.

6438. Epilepsy, megrims, sturdy, or turnsick, are epileptic attacks of greater or less violence, and which are apt to be confounded with the accidental strangulation that sometimes takes place, from a collar too tight, or from driving a horse hard up hill, &c. The epileptic fit makes its appearance by a sudden stop; if the horse be in action he shakes his head, looks wild and irresolute, but after some time he proceeds; when more violent, he suddenly falls down, is convulsed, dungs and stales insensibly, and remains some time before he recovers. This disease, like staggers, is generally the consequence of too full a habit; and ignass should be allowed to alter the habit.

6439. The discusses of the horse's eyes are not numerous, but they are very destructive. The principal are ophthálmia and gutta serena.

6489. The diseases of the horse's eyes are not numerous, but they are very destructive. The principal are ophthalmia and gitta sereha.
6440. The ophthalmia, lunatic, or moon-blindness, is a very peculiar disease among horses, affecting their eyes generally about their full growth, but sometimes later, and seldom earlier. It is but little known among mules and asses, and unknown in oxen and sheep. It does not, however, appear to be a disease natural to the horse, as wild ones, or even those little subjected to artificial restraints, are not observed to be subject to it: but among others, it is become so common as to have the tendency handed down in the breed, the progeny of some stallions being more prone to it than others. It is often very sudden in its attack, the eyelids being found swelled and almost closed to avoid the light; they are also very red within, and the haw is half drawn over the surface; the tears flow down the face perpetually, and the whole head is hot: now and then these appearances come on gradually. The suddenness of the attack makes the complaint to be attributed to accident, as blows, hay-seeds within the eye, &c.; and it is frequently difficult to get the owner of such a horse to believe that a constitutional attack, as it usually is, can come on so suddenly. Sometimes as it comes on quickly, so it goes off, the eye, from being opaque and milky, in twenty-four hours becoming clear and almost well. When such an attack has taken place, even if nothing be done, the horse sooner or later amends, and the eye or eyes, for it is sometimes one, and sometimes both that are so attacked, — become again clear and well, and remain so an indefinite period, from five or six weeks to as many months. Another attack, however, sooner or later follows, to which others succeed, each leaving increased milkiness on the outer coats, and some dimness within the pupil, either speck-like or diffused; and finally the horse becomes blind from cataract. When one eye goes blind totally before the other, it is often th

by exciting evaporation will keep the part cool. A seton may be introduced under the eye or jaw. In some cases, blistering the forchead or cheek is found useful; but in every instance bleeding is proper, which should be repeated until the disease lessens. When the horse is very full and gross, physic and alteratives assist the cure. When blistering is used in any part near the eye, the greatest er requisite to prevent the blistering matter from being rubbed into it. A very peculiar ophthalmic affection is also sometimes occasioned, particularly to the horses of hot climates, by the entrance of a filaria or thread-worm into the globe of the eye, which swimming about in the aqueous humour, eventually occasions violent inflammation. The cure consists in letting out the aqueous humour with a lancet, when, the filaria escaping with the fluid recovery follows:

mation. The cure consists in letting out the aqueous humour with a lancet, when, the filaria escaping with the fluid, recovery follows.

6441. Gitta serina or glass eyes, so called from the peculiar glassy appearance of the eye, arise from a paralysis of the optic nerve. As the eye is not materially altered in appearance, a horse often becomes blind without its being noticed, until his cautious stepping, quick motion of his ears, &c., give notice of the case. On examination it will be found that the pupil remains dilated, however great the light, and the eye is irrecoverably lost. In the very early stages, blisters to the forehead and stimulants to the eyes (as white vitriol a drachm, water four ounces,) may be tried, but with faint hopes

of success.

6442. Pole evil. This complaint commonly requires the attendance of an experienced practitioner: but the prevention is often in the power of owners, and others about horses; and to this point we shall particularly direct their attention. Pole evil is commonly the effect of accident. Repeated small blows of the manger, or continued pressure from hanging back on the halter, &c., will, if not remedied, produce swelling at the nape of the neek, with some tenderness. In this early state, if the collar be removed, and the part be kept continually wet with vinegar and water, the swelling will often disperse; but if, in spite of this, it proceeds to suppuration, let a vent be made for the matter by a sotion (6537.) so that it may readily flow out. Introduce nothing healing, but encourage a free discharge, and it may yet heal at once. When such is not the issue, the disease attacks the ligaments, sinuses form, and the matter burrows under the skin and muscles, when a seton must be introduced from the opening above and should be brought out at the bottom: the seton should be then daily wetted with the liquid blister. (Vet. Pharm. 6562) Should this plan fail, escharotics will be required in the form of the scalding mixture. (Vet. Pharm. 6586.)

6443. Strangles, vives, or vives. This disease has been likened to the humans and the scalding mixture.

Pharm, 6562.) Should this plan tail, escharotics will be required in the form of the scalding mixture. (Vet. Pharm, 6586.)
6443. Strangles, vives, or tves. This disease has been likened to the human measles; because it usually attacks every horse, and most of them at a young period, between three and five years. It is fortunate when it attacks colts at grass, as it seldom occasions inconvenience, which has led some persons into error by turning their horses out as soon as attacked; but it is not found that stabled horses, thus turned out, pass through the disease more mildly, but the contrary, except the disease exists under its very mildest form. White has conjectured that colts breeding the strangles while at grass are afterwards exempt from glanders, but this wants confirmation. Prosser has also affirmed, that inoculation by the matter of strangles is good; because it mitigates the complaint, and renders the horse not liable to any future attack; but the practice has never gained ground. When the strangles occurs in the stable, and now and then also in the field, it proves a severe disease, and shows itself under the appearance of a cold, with cough, sore throat, and swelling of the glands under the jaws, or behind and under the ears. Sometimes there is not much external swelling, and the tumours break inwardly, and nature effects a cure; at others they break outwardly, and the disease runs off that way; and sometimes the swellings disperse either by nature or art, which breeders think unfavourable, as they suppose it renders the animal liable to a future attack, but many so treated pass the remainder of their lives without more affection.

6444. The treatment of strangles. When the swelling lingers, and neither comes forward nor recedes, poultices are preferable to fomentations, which, by leaving the horse wet, promote evaporation and produce cold. Peal recommends blistering the part, as the best means of promoting suppuration. The horse should be kept very cool, and bran maslies with warm water should be h

are proper.
6445. Viees, or tives, is supposed to be a relic of the latter complaint, and it does appear now and then that after the strangles the parotid or vive glands do remain enlarged (6463.), which occasions the disease in question: resolution may be attempted by mercurial frictions; suppuration should be avoided, otherwise the gland may be destroyed.

6446. Disease of the month, lamnas. All horses, but particularly very young ones, are liable to enlarge.

the giand may be destroyed.

6446. Discusse of the mouth, lampas. All horses, but particularly very young ones, are liable to enlargement of the rugge or ridges of the palate, dependent not on any local disease confined to the part itself, but occasioned by an affection of the whole passage of the mouth, throat, and stomach. It is usual to attend to the part only, which is scarified or burnt to little purpose, when a mild dose of physic, or gentle alteratives, would prove more certain expedients; to which may be added rubbing the rugge themselves with bay selection with purpose.

salt, or with vinegar.

6447. Bridle sores. When the bit in colt breaking, or in hard-pulling horses, has hurt the bars, care is requisite to prevent the bone becoming carious. Touch daily with ægyptlacum, and cover the bit with leather, unless total rest can be allowed.

6448. Diseases of the teeth are fully treated of under the anatomical description of the bones. (6305.)

Diseases of the Neck. Subsect. 4.

6449. Fistulous withers are brought on usually by pressure from a saddle with too low or narrow a saddle

6449. Fishdows withers are brought on usually by pressure from a saddle with too low or narrow a saddle-tree; and what has been said both with regard to prevention and cure on the subject of pole evil, will equally apply here also. (6442.) It is discovered by the horse chewing his hay, but instead of swallowing he drops it from his mouth, or, as it is called quids it. He likewise shows a disinclination to drink. In every case, the horse finds great difficulty in reaching every thing that stretches his neck downarwds or upwards; his water therefore should be held to him, and his hay should be pulled for him: omission of these services greatly aggravates the sufferings of horses labouring under sore throat.

6451. Swelled neck. A very serious swelling sometimes follows on bleeding with a rusty or poisoned lancet, or fleam, and sometimes also from causes not apparent. (6547.)

Subsect. 5. The Chest.

6452. Inflammation of the lungs is a disease to which the horse is peculiarly liable; as we might a priori suspect, from the vast dimensions of his circulatory system, and the vast alteration from a natural state to which we subject him, and thereby increase his pulmonary circulation.

6453. The causes are these deviations remotely, but the immediate attack is generally brought on by sudden cold, acting on a heated surface; and thus it is that knackers and collarmakers in frosty weather expect a glut of horses that die from this disease. Hard riding is a very common cause, and high feeding also. It often commences slowly, a hard dry cough has been slightly noticed, but which has occasioned no alarm for two or three days; gradually, however, the cough appears to give the horse pain; he occasionally shivers, and his ears and feet feel colder than the rest of his body; he heaves at the flanks, and the lining of his nose is found to be much more red than usual, in the worst cases it is seen of a purplish hue; the

inside of the cyclids also are tinged with the inflammation. The appetite now becomes affected; and although there is not much apparent pain, except when the horse coughs, yet there is much anxiety of countenance present. The pulse is usually small but quick. If in this state the horse accidentally or erroneously be taken out and subjected to considerable exertion, it is almost always fatal to him: it likewise happens that this complaint is sometimes mistaken for disterner, and, from a fear of profuse bleeding, the only remedy that is to be depended on is omitted, and the horse is lost. At the veterinary college, in these cases, a small dose of aloes is given every six hours, and after being bled and rowelled, the horse is turned out in the open air; and it is affirmed that many recover from this treatment. Certain it is, that the stable in which a horse is placed in this disease can hardly be too cool; but when entirely turned out, his feet and legs cannot conveniently be hand-rubbed, or bandaged up to promote circulation; neither can we blister a horse when turned out, so conveniently; and on blistering we depend as the second source of cure.

stable in which a horse is placed in this disease can hardly be too cool; but when entirely furned out, his feet and legs cannot conveniently and non bilstering we depend as the second source and we bilster a horse when turned out, so conveniently; and no bilstering we depend as the second source of the convenient of

6364. Sativation is also another mode of poisoning; and though not equally injurious to the stomach, it often proves distressing, and sometimes fatal. Whenever, therefore, mercurials are given, carefully watch the gums, and as soon as they look red, and the horse quids his hay, give him a mild purge instead of his mercurial.

6463. Feetable poisons also inflame the stomach; but by no means in an equal degree with the mineral poisons; nor is it supposed that it is the inflammation they raise that proves destructive, but by an effect

communicated through the stomach to the nervous system. Digitalis purpurea or foxglove, Taxus baccata or yew, Enauthe crocata or water dropwort, cicuta virosa or water hemlock, Phellandrium aquáteum or water parsley, Conium maculatum or common hemlock, are all poisonous in a high degree to horses, and may be taken accidentally by the animal as food, or given injudiciously as medicine. Nicotiana or tobacco, and the vegetable acid or vinegar, are also poisonous, and are sometimes productive of injurious consequences by over-doses, when intended as remedies. It is little known that a pint of strong vinegar has destroyed a horse. As we cannot remove the matters from the stomach, we must endeavour to neutralise their effects by acids and demuleents, as oil, butter, &c.: thus, when narcotics have been taken, a drachm of sulphuric acid or oil of vitriol may be given in a quart of ale; or six ounces of vinegar, with six of gin, and a quart of ale, may be tried. An excellent domestic remedy might be found in two ounces of flour of mustard mixed with ale or other fluid.

Vinegar, with six of gin, and a quart of ale, may be tried. An excellent domestic remedy might be found in two ounces of flour of mustard mixed with ale or other fluid.

6464. Stomach staggers. This peculiar complaint, which is even yet but little understood, appears dependent on a particular state of stomach, acting on particular foods; and not on what is taken in acting on the stomach, as was supposed by Coleman, White, and others. From later communications of White, he also now appears to consider it as originating in "a peculiar state of stomach." Blaine appears always to have characterised it as "a specific inflammation of the stomach." It appears among horses of every description, and at grass as well as in a stable; and there is reason to think it epidemic, as it is prevalent in some seasons more than in others. It may, perhaps, be regarded now and then as endemic also; under which circumstance it appears confined to low wet situations, where long marshy grass is abundant, and where noxious aquatic plants mix themselves with the grasses. When it occurs at grass, the horse is found stupidly dull or asleep with his head resting against something. This has occasioned the disease to be called the sleepy staggers: and it has often been confounded with the phreuits, or inflammation of the brain. (6429.) In the stable the horse dozes, and rests his head in the manger: he then wakes up and falls to eating, which he continues to do until the distention of the stomach becomes enormous; for the peculiarity of the complaint consists in the total stop that is put to digestion, and the uneasy feel of the distention consequent to such indigestion appears to deceive the horse, and by a morbid excitement to force him to take in more. In this way he continues acting until the distention prevents the return of the blood from the head, and the animal dies apoplectic, or his stomach bursts with over-distention. More frequently, however, the stomach becomes flably, inert, and paralytic, and after death presents marks of infla

quently, however, the stomach becomes flabby, inert, and paralytic, and after death presents marks of inflammation towards the pylorus.

6465. The treatment. When recovery has taken place, it has occurred only when the disease has been very mild, and has been assisted by stimulating the stomach into action by purgatives, at once active and invigorating, as an ounce of aloes dissolved in half a pint of gln. When a horse of extreme value is attacked, croton oil might be tried to the amount of 20 or 25 drops in two ounces of tincture of aloes. Warm water in small quantities, or mixed with common salt, should be frequently passed down. Remove every eatable; rake, clyster, and hand-rub; and, if the determination to the head be extreme, bleed, otherwise avoid it. wise avoid it.

6466. Inflammation of the bowels, enteritis, or red colic, is a very distinct disease from the gripes, gullion, or fret, with which it is, however, very apt to be confounded to the destruction of many horses. The peritoneal inflammation of the bowels, the one here treated on, is an affection of their outer

wise avoid it.

Gibb. Inflammation of the bowels, enterlis, or red colic, is a very distinct disease from the gripes, guillon, or fret, with which it is, however, very apt to be confounded to the destruction of many horses. The peritoneal inflammation of the bowels, the one here treated on, is an affection of their outer covering.

The causes are various. It is not unfrequently brought on by a sudden translation of cold after great heats, as swimming during hunting, or from the removal of a horse from grass at once into heated stables; neglected gripes, or long-continued costiveness, excessive riding, and the immediate drinking of cold water, have brought it on. It begins by restlessness, loss of appetite, and some uneasiness; the mouth is hot and dry; the inner membranes of the mouth, nose, and eyelids are often redder than natural. As the disease advances, the pain, before not violent, now increases so as to force the horse to lie down and rise again frequently; and when very violent, he kicks at his belly, or looks round at his sides, pawing his litter very frequently. The pulse is usually small, quick, or hard; sometimes it is more full and small, but always hard. Breathing is quickened, and the flanks heave; the extremities are alternately hand cold, but continue longer cold than hot; and the animal is costive; sometimes pain may force away a few hardened balls of faces, but the principal contents are retained. Blaine has given the distinguishing a considerable quantity of blood, from a large torse to be attended to the distinguishing deatures between this disease and colie, under which head we have stated them.

6488. The treatment must be active and inmediate, or a fatal termination may be expected. Begin by abstracting a considerable quantity of blood, from a large torse to be the mouth, if the expense he to considered an object, a pint of castor oil, mixed by means of the yolk of two eggs, with half a pint of broth or gruel. If the expense be objected to, give olive oil instead, following it up in half

following: — Powdered ipecacuanha, a drachm; powdered opium, a scruple; liquid arrow-root, eight ounces. Should this not check the evacuation, and should it continue as mucous as at first, again give castor oil, and then follow it up by either of the drinks directed for the cure of scouring or looseness.

(Vet. Pharm. 6552.)
6473. Diarrhæa or looseness. This complaint originates in an increased peristaltic motion of the intestines, with an increase of their watery secretion, and is distinguished from dysentery by the purging being complete from the first, and seldom occasioning much fever or disturbance in the general health, unless exceedingly violent. The stools are merely solutions of the aliment, and unmixed with membranous films as in dysentery or molten grease. It sometimes succeeds to over-strong physic; at others the food itself enters into new combinations, and forms a purge. Some horses have their bowels constitutionally weak, as lank-sided small-carcased ones, where the mechanical pressure hurries the contents forwards. Salt mashes and sea water will purge horses violently sometimes. In violent cases, horn down liquid starch, and throw up the same by clysters. Give astringents (Vet. Pharm. 6552. No.1) two or three times a day; keep the animal warm and quiet. In the milder cases and in habitual scouring change the food. The change should be generally from one more moist to one less os, abeans, &c. Barley will sometimes stop looseness; malt usually increases it. Buck-wheat is often a check to habitual diarrhæa. Efficacious astringents will be found in the Vet. Pharm. (6552.) Repeat either of these night and morning. Give but little water and that little warm. (Vet. Pharm. 6552.) 6473. Diarrhoa or looseness.

Give but little water and that little warm. (6932) repeat either of dress light and morning. 6474. Colic, flatulent or spasmodic, called also gripes, fret, or gullion, is an important, because a frequent, disease, and because it frequently destroys either quickly by its irritation, or by its degenerating into the red or inflammatory colic, when improperly treated or long continued. It is usually very sudden

in its attack.

into the red or inflammatory colic, when improperly treated or long continued. It is usually very sudden in its attack.

6475. The causes of colic are not always apparent. It is sometimes occasioned by intestinal stones, which accumulate to a great size, remaining for years in the cells of the colon, until some accidental displacement occasions an interruption to the peristaltic motion. Cold in its various forms is a parent of colic; but under the form of cold water given when a horse is hot it is most common. In some horses it is so frequent as to become a constitutional appendage.

6476. The distinguishing marks between colic and inflammation of the bowels are gained, according to Blaine, by attending to the following circumstances:— In gripes the horse has violent fits of pain, but they remit, and he has intervals of ease. The pain in red colic is more uniform and less violent. In gripes, the pulse is, in general, natural; in red colic it is quicker than natural, and commonly small. The extermities are not usually cold in gripes; in red colic they usually are. In gripes, the horse attempts to roll on his back, which in red colic he seldom does. There are no marks of fever with gripes, as red eyelids, inflamed nostrils, &c.; but in red colic they are always present. When spasmodic colic has continued some hours, it is always proper to bleed to prevent its ending in inflammation: bleeding in the mouth is quite useless. Back-rake, and throw up clysters of warm water, one after another, as fast as possible, which often overcomes the irritation. La Fosse recommends a curious remedy; but as it can always be obtained, and has the sanction of long experience, it may be tried. An onion is pounded and mixed up with some powdered savin; in default of which, use powdered ginger. This is to be introduced up with some powdered savin; in default of which, use powdered ginger. This is to be introduced up with some powdered savin; in default of which, use powdered ginger. This is to be introduced up with some powdered savin

of each a pint and a half: infuse these together, and keep for use. Give a quarter of a pint every hour until full relief is obtained; hand rubbing, wisping, or fomenting the bowels with hot water at the time.

6477. Inflammation of the intestines from wounds in the belly frequently occurs; and these injuries may happen in leaping over hedges or pale gates, or may be inflicted by the horns of a cow. Sometimes the strong tendinous covering of the belly is ruptured, while the skin remains entire; the gut then protrudes and forces out the skin into a tumour. The first thing to be done is to put the gut back, taking care at the same time, otherwise extensive inflammation follows, to remove any dirt or other matter that may be sticking to it; for which purpose, should it be found necessary, it may be washed with warm water, but with nothing stronger. If the gut cannot be returned, from its being full of air, and the opening in the belly be too small to put it back again, such opening may be carefully enlarged to the necessary size; but if the animal can be thrown upon his back conveniently, a great deal may be done that cannot otherwise be accomplished. After the gut is returned the skin only should be stitched up, and a cushion of several folds of old linen and tow being placed in the wound, it should be kept in its situation by means of a wide bandage rolled round the body, and carefully secured. The animal should then be copiously bled, and have his bowels emptied by clysters. The only food he should be allowed is grass, or bran mashes, and that only in moderate quantity. When the distention of the intestines wholly prevents their return, it would be prudent to puncture them with a very fine instrument, and thus to suffer the air to escape, which, although subjecting the horse to the risk of inflammation, is better than the certainty of death by having the intestines protruded.

6478. Worms of horses are of several kinds. First, bots in the stomach; but which, as they mostly attach themselves to the hard insensib

6479. The diseases of the liver are acute inflammation or hepatitis, and chronic inflammation or yellows.

Hepatitis is the acute inflammation of this organ, which, like the lungs, stomach, and intestines, may spontaneously take on the affection. The symptoms are not unlike those which attend red colic, but with

the bladder is the seat of the disease.
6482. The treatment must be active, and in most respects similar to what has been recommended for red colic, as regards emptying the bowels, and endeavouring to lessen the arterial action by bleeding; but here we must carefully abstain from irritating the kidneys by diuretics internally, or blisters externally. A newly stripped sheepskin placed over the loins, or active fomentations of hot water, are the only sources of counter-irritation that are proper; neither should diluting liquors be pressed, on account of the distention they occasion, but no evil can arise from frequent warm elystering.
6483. Inflammation of the bladder. When the body of the bladder becomes inflamed, there is frequent staling from the very first attack; but when the neck of the bladder is the seat of the evil, the squeezing out of a few drops will only take place when the bladder has become filled, which may be known by passing the hand up the rectum. The treatment will be alike in both cases, and is the same as recommended for the last affection. It must be evident, that warm, mild, and frequent clystering must here be peculiarly advisable.

liarly advisable,

for the last affection. It must be evident, that warm, mild, and frequent crystering must here be peculiarly advisable.

6434. Strangury or suppression of urine, incontineuce of urine, bloody urine. Strangury may arise from an injury done to the kidneys, or to the bladder, by strains, or by the absorption of irritating matters. In these cases, bleed if there be fiver, and if not, merely give the horse absolute rest; mash him, give gruel, and warm his water for drink. Bloody urine should be treated in the same way; some horses have such a natural or acquired weakness of kidneys, as to stale blood with their urine on every occasion of over-exertion: the means frequently used for relief are such as aggravate the complaint, and indeed are often the occasion of it, which are diureties. Strong diureties injure horses more than strong physic, and benefit them less than any other of the popular means made use of. In retentions of urine, but particularly in the case of bloody urine, they are absolutely improper.

6485: Diabetes, profuse staling, or pissing evil. This disease is more frequently forced on the horse by long-continued diureties, or from a similar effect brought on by kiln-dried oats, mow-burnt hay, and some green vegetables, than acquired from constitutional indisposition. The horse first stales often and profusely, he then becomes weak and faint, and sweats on any exertion. If it be at all constitutional, his hide is bound from the beginning, and his urine will have a sweet taste; but if his appetite were good, and his coat sleek, bright, and elastic when the urine was first observed to be immoderate, the evil arises from some fault in the feeding clothing, exercise, or other management of the borse. Examine into these matters, particularly hith the food, and next the water. Enquire whether diureties have been given, under an erroneous supposition of increasing the condition, and after what may be amiss. If this do not remove the complaint, try the following, after Blaine's directions:—Liver of sulphor, tw

6486. Stone and gravel: Calculous concretions are not uncommon in the large intestines of horses, where they grow sometimes to an enormous size, lodged in one of the cells usually, and where they occasion but little inconvenience, except a displacement occurs, when serious evils, as colic, inflammation, or total stoppage, follow. In the bladder, stone is very seldom found; and there is reason to believe, that though gravel is a common term in the farrier's list, that it seldom if ever occurs; injuries of the kidneys and bladder being usually mistaken for it.

Subsect. 6. Diseases of the Skin.

Subsect. 6. Diseases of the Skin.

6487. Mange is a contagious disease not uncommon among low-bred and badly kept horses, but which is seldom generated in those properly managed. When it is the effect of impoverished blood, a different course of feeding must be substituted, not heating, but cooling though generous; as, carrots, speared corn, malt mashes, stable soiling, &c. When it arises in full fed horses, bleed twice, lower the feeding, substituting for corn soilings, carrots, or barn mashes. Give a nightly alterative (Fet. Phorm. 6530. No. 1, or 2.), and dress with either of the mange dressings. (Fet. Pharm. 6539.). After a cure has been effected, carefully clean all the apartments with soap and water.

6488, Surficit will now and then degenerate into mange, but more generally it is brought on by a fullness of habit acted on by sudden transitions from cold to heat, or heat to cold; it is likewise not unfrequently the consequence of over-fatigue. If it show a disposition to spread, and the skin become scaly and scurfy, treat as under mange; otherwise treat as directed under want-of condition. (6425.)

6489. Warbies are of the nature of surfeits in many instances, in others they are brought on by the pressure of the saddle, which either suppurate and burst, or become indolent and remain under the name of silfasts. In the early state, bathe them with chamberlye or vinegar: if they proceed to suppuration, refrain; and when they neither go back nor come forward, put on a pitch plaster, and if this do not promote suppuration, let the siftast be dissected out.

1640. Warts are common to old horses, and had better be put up with unless they be situated in some inconvenient or very conspicuous part. In this case, tie a thread tightly around the root, and the wart will drop off, or it may be cut off. Blaine recommends the following, when warts are too numerous to be so removed:— Crude sal ammoniae, two drachms; powdered savin, one ounce; lard, an ounce and a half, 6491. Hide bound is a state of the skin, where the interstitial matter between that and the fleshy pan-

nicle is not in a state to allow of its pliancy and elasticity. The binding down of the hide thus closely acts on the hair, which it protrudes in a contrary direction to its naturally inclined position; and thus a staring coat usually accompanies hide binding. In considering the subject of condition (6425.), we have seen that it is not a disease of itself, but is in every instance a symptom only. sth. B at DE 1 3 -891 W. .

Subsect. 7. Glanders and Farcy.

6492. The glanders is the opproblum medicorum, for hitherto no attempts have succeeded in the cure of more than a few cases. By some peculiar anomaly in the constitution of the horse, although conclusive proofs are not wanting that this and farcy are modifications of one disease, and can each generate the other; yet the one is incurable, while the other is cured every day. When glanders has been cured, the time and labour necessary to accomplish the end has swallowed up the value of the horse; and has also, in many supposed instances of cure, left the animal liable to future lattacks which have occurred. The experiments on glanders, pursued at the veterinary college and by White of Exeter, have thrown great light on the disease itself, its causes, connexions, and consequences; but have done little more. From these we are led to conclude that glanders will produce farcy, and that farcy can produce glanders; that glanders is highly infectious, and that such infection may be received by the stomach, or by the skin when it is at all abraded or sore; and it is also probable, that it is received by the noses of horses being rubbed against each other. White's experiments go to prove that the air of a glandered stable is not infectious; but this matter is by no means certain, and should not be depended on without a greater body of evidence.

of evidence.
6493. The marks of glanders are a discharge of purulent matter from ulcers situated in one or both nostrils, more often from the left than the right. This discharge soon becomes glairy, thick, and white-of-egg-like: it afterwards shows bloody streaks, and is fetid. The glands of the jaw of the affected side, called the kernels, swell from an absorption of the virus or poison; and as they exist or do not exist, or as they adhere to the bone or are detached from it, so some prognosis is vainly attempted by farriers, with regard to the disease; for in some few cases these glands are not at all affected, and in a great many they are not bound down by the affection to the jaw. As there are many diseases which excite a secretion of matter from the nose, and which is kept up a considerable time, so it is not always casy to detect glanders in its early stages. Strangles and violent colds keep up a discharge from the nostrils for weeks cometines. In such cases a criterion may be drawn from the existence of upcation within the nose, whenever the disease has become confirmed. These glanderous chancres are to be seen on opening the nostril a little way up the cavity, sometimes immediately opposed to the opening of the nostril; but a solitary chancre should not determine the judgment. The health often continues good, and sometimes the condition also, until hectic takes place from absorption, and the lungs participate, when death soon closes the scene.

closes the scene,

solitary chancre should not determine the judgment. The health often continues good, and sometimes the condition also, until hectic takes place from absorption, and the lungs participate, when death soon closes the scene.

6394. The treatment of glanders, it has already been stated, is so uncertain that it is hardly worth the attempt; however, when the extreme value of the horse or the love of experiment leads to it, it may be regarded as fixed by experience, that nothing but a long course of internal remedies, drawn from the mineral acids, can effect it. These have all been tried in their endless variety: White recommends the middest preparations of mercury, as ethiops mineral; under the conviction that the more acrid preparations disturb the powers of the constitution so much, as to destroy as effectually as the disease. At the veterinary college the sulphate of copper (blue vitriol) has been long in use. Others have used the sulphates of from and zine. Clark recommends the daily administration of a drink or ball, composed of the following ingredients:—Sulphate of zine, 15 grains; powdered anthorides, 7 grains; powdered allspice of grains; of the utility of which he gives one or two extraordinary proofs, and Mr. Sewell still attaches much importance to its use, in such daily doses as the stomach will bear. Blaine appears but little sanguine as to any medical treatment, but recommends a union of the mineral acids in the same proportions, and with the same cautions, as are detailed under farcy. (6495.)

6495. The farcy is a disease more casily cured thun the glanders, of which our daily experience convinces us; farcy, or farcin, attacks under distinct forms, one of which affects the lymphatics of the skin, and is called the bud or butlon farcy: the other is principally confined to the hind legs, which it affects by large indurations, attended with heat and tenderness. A mere dropsical accumulation of water in the legs sometimes receives the name of water furcy by but his has no connection whatever which it affe was enabled to struggle to more; finally, he rose to extend his search, and perfectly recovered.

Subsect. 8. Diseases of the Extremities.

6497. Shoulder strains are very rare, most of the lamenesses attributed to the shoulder belong to other parts, and particularly to the feet. Out of one hundred and twenty cases of lameness in the fore extremities, Blaine found that three only arose from ligamentary or muscular extension of the shoulder. When a shoulder strain does happen, it is commonly the consequence of some slip, by which the arm is forced violently outwards. It is less to be wondered at than at first seems probable, that farriers mistake foot lameness for shoulder strains, when we reflect that a contracted foot occasions inaction, and a disposition to favour the limb by pointing it forward, which thus wastes the muscles of the shoulder. Seeing one shoulder smaller than the other, the evil is supposed to be there, and it is pegged, blistered, and fired,

or the horse is swam for it to his torture, and the increase of the foot's contraction by the confinement. or the horse is swam for it to his torture, and the increase of the foot's contraction by the confinement. In real shoulder strains, the toe is dragged along the ground while in motion; at rest it is planted forward, but resting on the point of the toe. When the lameness is in the foot, the horse points his foot forward also, but he does so with the whole limb unbent, and the foot flat. These differences are highly necessary to attend to, as well as the peculiar difficulty which is always apparent in moving down hill, which he does with reluctance, and by swinging his leg round to avoid flexing it. This lameness may be farther brought to the test by lifting up the fore leg considerably, which, if the evil be in the shoulder, will give great pain. The muscles between the fore legs are likewise tumefied and tender in these cases.

6498. The treatment consists, when it is recent, in bleeding in the plate vein, rowelling in the chest, and fomenting with hot water two or three times a day. When the heat and tenderness have subsided, first bathe daily with the astringent wash for strains (Vet. Pharm. 6555. No. 1.) for a week; and afterwards, if necessary, proceed to blister in the usual manner.

fomenting with hot water two or three times a day. When the heat and tenderness have subsided, first bathe daily with the astringent wash for strains (Vet. Pharm. 6555. No. 1.) for a week; and afterwards, if necessary, proceed to blister in the usual manner.

6499. Strain in the whirt bone. (6324.) This important joint is sometimes strained, or its ligaments and muscles unnaturally extended, from a greater force being applied to them than their structure is able to bear, or their powers to resist: a læsion takes place of some of their fibrillæ, or in lesser injuries their elasticity is injured by being put on the stretch beyond their power of overcoming again. In all such cases, the parts react, and inflammation follows; by which heat, tenderness, and swelling ensue.

6500. Treatment. The first indication is the same in this as in all ligamentary strains, which is to moderate the inflammation by fomentations, &c. &c., and when that has subsided, to endeavour by astringents and bracers to restore the tone of the parts: after which, if any seuling remains, from the extravasated blood becoming organised, to promote its absorption by mercurial frictions, and blistering. This applies to all strains, and will direct the treatment therefore of that of strain in the articulation of the thigh with the body also.

6501. Strain in the stiffe, is treated in the same manner.

6502. Strain or clap in the back sineus. This is generally an injury done to the sheaths of the tendons, or of the ligaments which bind them down. In very aggravated cases, it sometimes occurs that even the tendons themselves are extended beyond their capacity. The heat, swelling, and tenderness are first to be combated by fomentations, and if these be extreme, bleed also, and give a dose of physic. Next proceed to poultice with saturnine applications, until the heat and swelling are reduced: then use tonics, astringent weak (Vet. Pharm. 6555. No. 1. or 2); bandage and exercise very carefully. If swelling remain after leat, pain, and lameness are past;

may be considered as in a state of atony; and balluages junctiously applied are their project, particularly during the day.

6503. Rupture of the tendons and ligaments of the leg. It is very seldom that the tendons themselves are ruptured, but the suspensory ligaments are more often so, and the evil is called breaking down. It is usually very sudden, and the fetlock is brought almost to the ground. A perfect cure is seldom obtained; but the inflammation should be moderated by the means already described, and the heels should be raised. A laced stocking or firm bandage, when the inflammation has subsided, is necessary; and firing is often reaches a represent bandage.

prudent as a permanent bandage.

prudent as a permanent bandage.

6594. Strains of the ligaments of the fetlock and coffin joints often occur, and may always be distinguished by the heat, tenderness, and swelling. Treat as already described. In all strains of the leg, attended with inflammation, a goulard poultice is a convenient and useful application. The goulard water should be mixed with bran; and a worsted stocking being drawn over the foot, and up the leg, it is first tied around the foot; the poultice is then put in, and the stocking fastened around the leg above the injury. (6595. Mallenders and sellenders are scurfy scabby eruptions, affecting the back of the knee, and ply of the hock; common only in coarse, low-bred, and in cart horses. Wash with soft soap every day, after which anoint with an unguent formed of equal parts of mercurial ointment, tar, and calamine cerate.

6506. Broken knees. The usual cases of broken knees are referrible to wounds in general; and the treatment of them in purise differs therefrom with this caution, that here it is more immediately and the

666. Broken knees. The usual cases of broken knees are referrible to wounds in general; and the treatment of them in nowise differs therefrom, with this caution, that here it is more immediately necessary, both for appearance and safety, that if any flap of skin hang apart, to cut it off, or the wound will heal with rugosed edges. But when the joint of the knee is broken into by the violence of the injury, it becomes of a very different nature, and is known first by the extreme lameness and swelling that occur; and next, by the escape of a slippery mucus not unlike the white of an egg. If this continue to escape, violent inflammation follows, and either the horse or the joint are lost by it. Farriers are apt to attempt to stop the flow of the joint oil, as it is called, by oil of vitriol, or other escharotics, which treatment is usually followed by the most disastrous consequences. It is, however, necessary to stop the immediate flow, by other means; the best of which is by a fine budding iron heated. Should the laceration be considerable, this cannot be done; but the treatment must then consist of saturnine pultices, bleeding, low diet, and the other antifebrile remedies, until the swelling has subsided, when apply the astringent paste recommended by Clark, made of pipe-clay and alum, every day; but by no means introduce any escharotics. escharotics

escnarotics. Splints and bone spavins. The former are usually situated on the inner side of the canon or shank before; and as they are situated, so they are more or less injurious. When buried, as it were, within the tendons or back sinews, they are very apt to lame the horse seriously; but when situated on the plain bone, unless they be very large, they seldom do much injury. If a splint be early attended to, it is seldom difficult to remove. Blaine recommends the swelling to be rubbed night and morning for five or six days, with a drachm of mercurial ointment, rubbing it well in; after which to apply a blister, and at the end of a fortnight or three weeks to apply another. In very bad cases, he recommends firing in the largest few.

lozenge form.
6508. Bone spavin is an exostosis of the hock bones, the treatment of which in nowise differs from that of splint; except that as a spavin in general is more injurious than a splint, so it is more necessary to commence the treatment early, and to continue it energetically. From the greater complexity of structure in the hock, spavin is not so easily removed as splint, and more usually requires the application

of firing.
6509. Ling bone is of the same nature, being an exostosis or bony circle formed around the coronet, the treatment of which is the same with that of splint and spavin.
6500. Discovering how spaving and thoroughnin, are all of them originally of the nature of windgalls, treatment of which is the same with that of splint and spavin.

6510. Blood spavin, bog spavin, and thoroughpin, are all of them originally of the nature of windgalls, and are nothing more than enlargements of the bursal capsules described in the anatomy, as surrounding tendons, ligaments, and bones, to furnish them with a lubricating medium. By over-exertion or hard work these bursal bags become extended, and their contents increased and distended into puffy swellings in the hock, called, when on the ply, bog spavin. The pressure of this sometimes occasions a varicose state of the superficial vein, which passes directly over it on the inner side of the hock, and which enlargement then receives the name of blood spavin. When the bursal enlargement extends through the hock, it is called thoroughpin. When it is situated below, in the bursa of the flexor tendons, near the fetlock joint, it receives the name of windgall.

6511. The treatment of all these cases must be similar in principle, and consists in lessening the distended soc; not as was formerly practised, to the destruction of the horse often, by letting out the contents of these windgalls; but by strengthening the sides of the tumours by stinulants or by pressure. The more active stimulants are the liquid blister (Fet. Pharm. 6625), milder ones are found in the astringent wash. (Vet. Pharm. 6535. No. 1.) Bandages assist greatly, when well applied to the part, and in desperate cases firing has been resorted to, which is nothing more than a more violent stimulant, and a more permanent bandage.

manent bandage.

6512. Capulct is a bursal enlargement of the point of the hock, and is to be treated by friction, astringents,

and bandage.

and bandage.

6513. Curb is an inflammation of the ligaments at the back of the hock, and is usually removed by astringents. (Vet. Pharm. 6555.) When it does not give way to these, the sweating liquid blister may be applied. (Vet. Pharm. 6555.) When it does not give way to these, the sweating liquid blister may be applied. (Vet. Pharm. 6563.) When it does not give way to these, the sweating liquid blister may be applied. (Vet. Pharm. 6563.) When it does not give way to the same affection, and are commonly brought on by some neglect in all horses; but when they occur in any but the thick-heeled.low-bred animals, they are invariably so. Over-feeding or under-feeding, but much more frequently the former, will bring it on. A very frequent cause of it is the practice of washing the legs of horses, and suffering them to dry of themselves. In every case, without exception, washing the legs should be avoided, unless they be rubbed perfectly dry afterwards. When horses have long hairs about their heels, and are washed and then left wet, the evil must be doubled; as the evaporation going on, cools and chills the heels, and thus produces a species of chilblain: and we well know how difficult these are to heal when broken. Cracks in the heels every often occur in horses removed too suddenly into full keep from previous straw or

and then left wet, the evil must be doubled; as the evaporation going on, cools and chills the heels, and thus produces a species of chilblain; and we well know how difficult these are to heal when broken. Cracks in the heels very often occur in horses removed too suddenly into full keep from previous straw or grass, or from these to a hot stable; which, by the heat and moisture of the litter, occasions a determination of blood and humours to the legs, and they break out into cracks or scabs, from which issue a bloody lichor, or a more thick matter. Between the sores the hair stares and gets pen-feathered, and the horse finds difficulty and pain in moving.

6515. The treatment must depend on the state in which the animal is at present. If there be reason to suspect the horse to be full and foul, bleed, lower his food, soil him in the stable; or mash and give a mild dose of physic. But when some mismanagement is the sole cause, remove that, and if the case be a severe one, by means of an old stocking drawn over the foot, bury the whole heel in a poultice, made of scraped carrots or turnips; which will subdue the irritation, and bring the parts into a state to bear the application of the astringent paste (*Pet. Pharm. 6557. No. 2.), or if more convenient, of the astringent wash. (*Pet. Pharm. 6557. No. 2.) to 7.2). Moderate exercise should be continued, and the heels carefully cleaned from dirt by soft soap and water on each return therefrom; after which, always again apply the astringent.

6516. Grease is nothing more than an aggravated state of the same affection, and is more common to the hind than to the fore legs. Coarse fleshy-legged horses are peculiarly prone to the affection, from the great accumulation that takes place in their legs; and from the difficulty that the capillaries find in carrying the increased quantity of lymph upwards. In these, long stable confinement should be avoided, and when that is impossible, it should be counteracted by exercise frequently and judiciously administered. Many cart

Subsect. 9. Diseases of the Feet.

Subsect. 9. Diseases of the Feet.

6517. Founder of the feet is of two kinds, acute and chronic. Acute founder is a disease that, until lately, was less understood than almost any other. After a very severe day's work, or when very much heated, if a horse get a sudden chill by standing in snow or cold water, it is not uncommon for him to be seized with universal stiffness and every symptom of great fever. Such a horse is said to be body foundered. By degrees, however, it is observed that the animal has an extreme discliniation to remain on his feet; from whence it will appear that the whole of them are affected. When the horse draws his hind feet under him, his fore only are affected: and when he draws his fore feet under him, he hInder feet are the seat of the complaint; but which is seldom the case. On feeling the feet they will be found intensely hot, and the pastern arteries will beat with great violence. After a few days, unless the disease abate, a separation of the hoofs from the coronet takes place, and at last they fall entirely off.

6518. The treatment. At the commencement of the disease bleed largely, as well by the neck as from the toe of each affected foot, by paring, until the blood flows freely. After which immerse each foot in a goulard poultice (6536.), give the fever powder or drink (Vet. Pharm. 6578 and 6579.), litter up to the belly; and if amendment do not take place, renew the bleedings, and bister round the pasterns.

6519. Chronic founder, contraction or fever in the feet. The artificial life that horses lead subjects them to many diseases; one of the principal of which is that of contracted feet. Blain considers a neglect of sufficient paring of hoof, the application of artificial heat from bot stables, and hotter litter, the deprivation of natural moisture, constitutional liability, and the existence of thrushes, as among the principal causes of this evil. It is more common to blood horses than to others; and he observes, that dark chestnuts are of all others most prone to it. The app

affected.
6520. The treatment of contraction in the feet. It is better to prevent, than to be under the necessity of attempting to cure, the evil. Prevention may be practised by avoiding the acting causes. As soon as at all suspected to be likely to occur, keep the hoofs pared low; never suffer the horse to stand on litter, nor allow the stable to be too hot; feed moderately, and never allow the horse to go without daily exercise; whatever increases the general fulness of habit, flies to the feet. Above all, keep the feet moist by means of wet cloths tied loosely around the coronet, falling over the whole hoof, but not extending beyond the edge. Then moisten repeatedly, and stop the feet (6587,) every night. When contraction has already taken place, many plans have been recommended; as jointed shoes by Coleman, Clark, and others; but it is not found that mechanical expansion in this way produces permanent benefit. The most effectual mode is to obviate all previous causes of contraction; and then to thin the hoofs around the heels from each of the horn as is consistent with safety, from the coronet downwards. It is also prudent to put in a score or two from above downwards, drawn a quarter of an inch deep on each side towards the front of the hoof; but whether this be done or not, the front of the hoof should be rasped thin about an inch in width; by which means a hinge is formed, which operates most advantageously in opening the heels. After this is done, tips should be put on, and the horse should be turned out to grass, where he should remain three months, by which time the new formed heels will have reached the ground, and will bear a shoe. This process is fully described by Blaine in his Veterinary Outlines, where a plate completely elucidates the operation, and to which we would recommend the reader.

6521. The pumiced foot is a very common consequence of acute founder, in which the elasticity of the lamine becoming destroyed, the support of the coffin bone is removed, and it rests wholly on the sole, affected.

which it gradually sinks from a concave to a convex surface, drawing with it the front of the hoof inwards. In weak, broad, heavy feet, this evil comes on sometimes without founder; the treatment can be only palliative, a wide-webbed shoe exactly fitted to the foot, without at all pressing on it, prevents the lameness consequent to the disease. A shoe exactly the contrary to this has been tried in some cases with benefit, the form of which has been one with a web so narrow as only to cover the crust, but so thick as to remove the feet from accidental pressure. In other cases, no shoe answers so well as a strong bar

benefit, the form of which has been one with a web so narrow as only to cover the crust, but so thick as to remove the feet from accidental pressure. In other cases, no shoe answers so well as a strong bar shoe; (631), we the state of the

divided and the undivided parts of the hoof. With melted pitch close up the origin if the ozing be inoderate, and bandage tightly: Watch the foot, and if inflammation succeed this plan, remove the dressing.

632ê. Pricks or punctures in the feet are often very serious evils, either when received by nails in shoeing, or by one picked up on the road, &c. The danger arises from the inflammation, which is always great from any injury done to the sensible and vascular parts within the foot. This inflammation quickly proceeds to suppuration; and the matter is apt to make its way upwards, unless it find a ready vent below. When it does not break out at the coronet, it will often penetrate under the sole, and finally disease the bones, ligaments, or cartifages, and produce quittor. It is very seldom that a horse is pricked in shoeing, but that the smith is aware of it by the peculiarity of the feel on the hammer, and by the flinching of the animal. At such times were he to immediately withdraw the nail a little, enlare the opening, and introduce some spirit within the puncture, nothing would occur; but on the contrary, he sends the horse home to avoid trouble, who, the hext of following day, is found lame, and with his foot hot. If the nail be only driven too near the senisible lamina; it will only require to be removed, to free the horse from his evil; but if it have been driven through, and have wounded them, then suppuration ensues, and on examining the foot by the pincers when the shoe is removed, he will flinch at the pressure on the diseased part. It is probable, on the removal of the shoe, that matter will at once flow out at the immediate nail hole; if not, the drawing-knife will soon detect the injury. If the heat be great, and instead of matter bloody dark ichor flows out, wrap the foot up in a poultice; but if healthy matter flows out, this will not be necessary; sometimes it is requisite to detach all the horn that is underrun by the matter; but when the injury has not proceeded to this extent, apply over t as the case may be.

as the case may be.
6527. Quittor and canker are the consequences of these injuries when neglected, or originally extensive.
In these cases either the bones, ligaments, or cartilages, or all, become diseased; and a cure can only be obtained by removing the diseased parts by the knife or by caustic.
6528. Treads, over-reach, &c. A wound on the coronet is not uncommon from one foot being placed on the other; or the hinder foot may strike it, &c. First wipe away the dirt, and remove any loose edges that cannot unite: a woid washing, unless stones and dirt are suspected to be within, and bind up, having first placed over the wound a pledget of lint or tow moistened with balsamic tineture, or tincture of myrrh, or of aloes, &c. Over-reaching, or over-stepping, is often an injury done to the fetlock joint before, by the hinder foot, or to the back sinew higher up. Sometimes it is simply a violent bruise, at others the laceration is extensive, in which cases treat as a tread; and when no laceration has taken place treat as a bruise or strain. treat as a bruise or strain,

6529. Cutting is a defect to which some horses are liable from their form, as when they turn their toes

out, or have bent legs. Others cut only when they are lean, which brings their legs mearer together. Weak horses cut because they cross their legs when fatigued, and young unfurnished horses cut at youthful periods, and grow out of it afterwards. The part in which a foot interferes with the opposed limb is very different. When it strikes the shank high up it is called speedy cut, and is best remedied by wearing knee-boots or rollers. When it is at the fetlock the cutting is at the side, or rather backward, according to circumstances. Some horses cut by the edge of the shoe, others by the hoof at the quarters; and some by the point of the heels. It is to be remarked, that it is better to put up with the evil of cutting, than to do as is too frequently done, which is, to pare away the hoof until it excites contraction. The shoe may be feather edged, or it may be set a little within the cutting quarter; but by no means alter the size or the form of the hoofs themselves, and particularly avoid taking liberties of this kind with the fore feet. Boots, or rollers, are but little trouble to put on, and when not buckled too tight never injure: whereas, to allow a horse to continue to cut produces a callus, and often throws the animal down. animal down. d ess on the sol , but t en

SECT. VI. Veterinary Operations.

6530. The general practices to be here enumerated are chiefly the treatment of wounds, the application of fomentations, setons, blisters, clysters, and physicking; and the operations of castrating, nicking, bleeding, &c.

Subsect. 1. Treatment of Wounds.

Subsect. 1. Treatment of Wounds.

6531. A wound must be treated, in some measure, according to the part of the borse's body in which it happens; but there are some principles to be observed alike in all horse surgery. There are likewise a few, which, as they differ from the principles of human surgery, should be first noticed, and which should guide the practice of those who might be misled by analogy. The wounds of horses, however carefully brought together and confined in their situation, as well as shut out from the stinulus of the external air, are seldom disposed to unite at once, or, as it is called in surgical language, by the first intention. It is always, therefore, necessary to expect the suppurative process; but as the adhesive inflammation does now and then occur, we should never wash a mere laceration with water or other liquids, if no foreign matter, as dirt, &c., be suspected to be lodged within it, still less should we stuff it with candle tow, or tents of any kind. On the contrary, it should be carefully and smoothly brought together, and simply bound up in its own blood; and if it do not wholly unite at once, and by the first intention, perhaps some portion of it may; and, at all events, its future progress will be more natural, and the disfiguration less than when stuffed with tents, tow, &c., or irrited with heating oils or spirits. When an extensively lacerated wound takes place, it is common, and it is often necessary to insert sutures, or stiches, into the lips of the wound: and here we have to notice another considerable variation from the principles of human inflammation, which is, that these stitches in the horse, ox, and dog, soon ulcerate out, seldom remaining longer than the third or fourth day at farthest. It therefore is the more necessary to be careful, that by perfect rest, and the appropriation of good bandages, we secure the wound from distortion. In this we may be assisted by strips of sticking plaster, made with diachylon and pitch; but these strips should be guarded from to fomentations to the part itself.

Subsect. 2. Balls and Drinks.

6532. Mode of giving a ball. Back the horse in his stall, and being elevated on a stool (not a bucket turned upside down), gently draw the tongue a little out of the mouth, so as to prevent its rising to resist the passage of the hand; the tongue should however not be laid hold of alone, but it should be held firmly by the fingers of the left hand against the jaw. The ball previously oiled, being taken into the right hand, which should be squeezed into as narrow a shape as possible, must be passed up close to the roof of the mouth, and the ball placed on the root of the tongue, when both hands being withdrawn, it will readily pass down. This mode is much preferable, when a person is at all handy, to using a balling iron. At Long's, veterinary surgeon's instrument maker, is sold a clever machine for

this purpose.

6533. Mode of giving a drink. Exactly the same process is pursued, except that a horn holding the liquid matter is forced up the mouth; the passage being raised beyond the level line, the liquid is poured out from the larger end of the horn, and when the tongue is loosened it is swallowed. Clark, however, ingeniously proposes to substitute the smaller end of the horn, the larger being closed, by which, he says, the horn can be forced up the mouth between the teeth, and poured farther back so as to ensure its not

returning.

Subsect. 3. Fomentations and Poultices.

6534. Fomentations are very commonly recommended of various herbs, as rue, chamomile, St. John's wort, wornwood, bay leaves, &c.; but the principal virtue is to be found in warmth and moisture, which unload the vessels: but this warmth ought not to be too considerable, except when the inflammation is within, as in inflamed bowels. Here we foment to stimulate the skin, and cannot foment too hot; but when we do it at once to an inflamed part, it ought not to be more than of blood heat; and it should be continued long, and when removed the part should be dried or covered, or cold may be taken, and the inflammation increased instead of diminished. Anodyne fomentations are made of poppy heads, and of

inflammation increased instead of diminished. Anodyne forentations are made of poppy heads, and of tobacco, and are frequently of great use.

6335. The method of applying fomentations is conveniently done by means of two large woollen cloths wrung out of the heated liquors; as one is cooling the other should be ready to be applied.

6336. Poultices act in the same way as fomentations in allaying irritation and inflammation; but are in some respects more convenient, because they act continually. It is an error to suppose that poultices, to be beneficial, should be very hot; however hot they may be applied, they soon become of the temperature of the surrounding parts. When poultices are applied to the extremities, a stocking, as has been before stated, is a convenient method of application. When it is drawn over the leg and bound around the lower part of the hoof, or of the pastern, or otherwise, the matter of the poultice may be put within, and it may be then kept in its situation, if high up on the extremity, by means of tape fastened to one part of it, and, passed over the withers or back to the other side, and again fastened to the stocking, In this way, also, loose bandages may be retained from slipping down. Cold poultices are often useful in the inflammations arising from strains, &c. In these cases bran and goulard water form a convenient medium; but when the poultice is necessarily hot, a little linseed meal added to the bran will render it adhesive, and give it consistence. It is a very necessary caution in this, as in every natance where bandages are wanted around the extremities, to have them broad, and only so tight as to secure the matters contained, as in a poultice, or as in common bandaging.

Subsect. 4. Setons and Rowels.

6537. Setons are often useful in keeping up a drain to draw what are termed humours from parts; or by their irritations on one part, they lessen the inflammation in another part not very remote, as when applied in the check for ophthalmia or inflamed eyes. They also in the same way lessen old swellings by exciting absorption. Another useful action they have is to make a dependent or convenient orifice for the escape of lodged matter: thus a seton passed from the upper part of the opening of pole evil, through the upper part of the integuments of the neck, as low as the sinuses run, will often effect a cure without farther application. The same with fistulous withers, which sometimes run under the shoulder blade, and appear at the arm point; in which cases a blunt seton needle, of sufficient length to be passed down to that point, and to be then cut down upon, will form the only efficient mode of treatment. Setons may be passed in domestic farriery with a common packing needle and a skein of thread, or piece of tape; but in professional farriery they are made by a proper needle armed with tape or lamp cotton, or skeins of thread or silk smeared over with digestive ointment. When the seton needle is removed, the ends of the tape should be joined together, or otherwise knotted, to prevent them from coming out.

silk smeared over with digestive ointment. When the seton needle is removed, the ends of the tape should be joined together, or otherwise knotted, to prevent them from coming out.

6538. Rowels in their intention act as setons, and as irritating a larger surface, so when a general drain is required they act better; as in grease, &c.: but when their action is confined to a part only, setons are more convenient. Any person may apply a rowel by making an incision in the loose skin about an inch, separating with the finger its adherences around, and then inserting in the opening a piece of round leather with a hole in the middle smeared with a blistering ointment. Then plug the opening with tow; and in three days, when the suppuration has begun, remove it. The rowel leather is afterwards to be daily moved and cleaned.

Subsect. 5. Blistering and Firing.

Subsect. 5. Blistering and Firing.

6539. Blistering answers the same purpose as setons; and is practised by first cutting or shaving the hair from the part, when the blistering ointment (Vet. Pharm. 6559.) should be well rubbed in for ten minutes, or a quarter of an hour. Some of the ointment after the rubbing may be smeared over the part. The head of the horse should now be tied up to prevent his gnawing or licking. If a neck cradle be at hand, it may also for safety be put on; in which case the head may be let down the third day.

6540. A neck cradle for blistered horses is very convenient for other occasions also, when the mouth is to be kept from licking or biting other parts; or to keep other parts from being rubbed against the head. It is of very simple construction, and may be made by a dozen pieces of wood of about an inch and half in diameter, as old broom handles, &c. These bored at each end admit a rope to passed through; and as each is passed on, a knot may be tied to the upper part of the pieces of the cradle, two inches apart; and those which form the lower part, four inches: by which means the neck will be fitted by the cradle when it is put on; and the horse will be prevented from bending his head to lick or gnaw parts to be protected. When the lower parts of the legs, particularly of the hinder, require blistering, it is necessary to bear in mind that in gross hill horses, particularly in autumn, grease is very apt to follow blistering; and almost certainly if the back of the heels below the fetlock be blistered. First, therefore, smear this part over with lard or suet; and afterwards avoid touching it with the ointment. After blistering in summer, the horse is often turned out before the blistered parts are quite sound; in this case guard them from flies by some kind of covering, or they may become fly-blown: and likewise the fourth or fifth day rub into the blistered part some oil or lard to prevent the skin from cracking.

6541. Sweating or liquid blisters (Vet. Pharm. 6563.) are only more

in old strains and stiffnesses.

6542. Fring, as requiring the assistance of an experienced practitioner, we shall not describe; it will be only prudent to point out that it is a more active mode of blistering; and that it acts very powerfully as a stimulant, not only while its effects last as blisters do, but also after its escharotic effect is over, by its pressure; and in this way it is that it operates so favourably in bony exostosis, as splints and spavins; and in this way it is so useful in old ligamentary weaknesses; because by lessening the dilatibility of the skin it becomes a continual bandage to the part.

SUBSECT. 6. Clystering and Physicking.

Subsect. 6. Clystering and Physicking.

6543. Clystering should always be preceded by back-raking, which consists in oiling one hand and arm, and passing them up the fundament, and by that means to remove all the dung balls that can be reached. The large pewter syringe for clystering is neither a useful nor safe machine. A much better consists in a turned box pipe, to which may be attached a large pig or ox-bladder, by which four or five quarts of liquid can be administered at one time. (Vet. Pharm. 6564, to 6567.) The pipe should be previously oiled, by which means it passes more easily: the fupur should then be steadily pressed up; and when the pipe is removed, the tail should be held down over the fundament a little to prevent the return of the clyster. In some cases of a spasmodic nature, as gripes and locked jaw, great force is made by the bowels to return the clyster, and nothing but continued pressure over the fundament can enable it to be retained. Clysters not only act in relaxing the bowels, but they may be used as means of nutriment when it cannot be taken by the mouth; as in locked jaw, wounds of the mouth, throat, &c. &c. In locked jaw, it was observed by Gibson, that he kept a horse alive many days by clysters alone: and by clysters also many medicines may be given more conveniently than by the mouth.

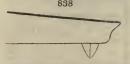

6544. Physicking of horses. It is equally an error to refrain altogether from giving horses physic, as it is to give it on every occasion, as some do. Neither is it necessary for horses to be bled and physicked every spring and autumn, if they be in perfect health, and the less so, as at this time they are generally weak and faint from the change going on in their coats. Nor is it always necessary to give horses physic when they come from grass or a straw yard; provided the change from the one state to the other be very moderately brought about. But on such a removal, it certainly expedies all the phenomena of condition (6423.), and such horses are less likely to afterwards fall to pieces, as it is

After the ball has been given two hours, a warm bran mash may be offered, and a very little hay. He should have walking exercise as usual, moderate clothing, and altogether he should be kept rather more warm than usual. At noon mash again, and give a little hay, which should be repeated at night, giving him at intervals chilled water. On the following morning the physic may be expected to work; which if it do briskly, keep the horse quiet; but should it not move his bowels, or only relax them, walk him quietly half an hour, which will probably have the desired effect. Continue to give mashes and warm water, repeating them every two or three hours to support him. When physic gripes a horse, give him a clyster of warm water, and hand-rub the belly, as well as walk him out. If the griping prove severe, give him four ounces of gin in half a pint of sound ale, which will soon relieve him. On the next day the physic will probably set, but should it continue to work him severely, pour down some boiled starch; and if this fail, turn to the directions under diarrhea. (6473.) The horse should return to his usual habits of full feeding and full exercise by degrees; and if more than one dose be to be given, a week should intervene. It is often requisite to make the second and third dose ather stronger than the first. A very mild dose of physic is likewise often given to horses while at grass in very warm weather, and without any injury. When worms or skin foulness are present, and mercurial physic is deemed necessary, it is better to give two drachms of calomel in a mash the previous night, than to put it into the purging ball.

Subsect. 7. Castration, Nicking, Docking, &c.

6546. The operations of castration, docking, nicking, and that of cropping (which is now seldom practised), all require the assistance of a veterinary surgeon; and it is only necessary to remark of them, that the after treatment must be the same as in all other wounds. To avoid irritation, to preserve a cool temperature and a moderate diet; and if active febrile symptoms make their appearance, to obviate them by bleeding, &c. &c. It likewise is proper to direct the attention of the agriculturist who attends to these matters himself, that the moment the wound following any of these operations looks otherwise than healthy, locked jaw is to be feared, and no time should be lost in seeking the best assistance that can be obtained. (6432.)

Subsect. 8. Bleeding.

Subsect. 8. Bleeding.

6547. Bleeding is a very common, and to the horse a very important operation, because his inflammatory diseases, on account of the great strength of his arterial system, run to a fatal termination very soon, and can only be checked in the rapidity of their progress by abstracting blood, which diminishes the momentum of circulation. Bleeding is more particularly important in the inflammatory diseases of the horse; because we cannot, as in the human frame, lower the circulation by readily nauseating the stomach. Bleeding also lessens irritation particularly in the young and plethoric, or those of full habit: hence we bleed in spasms of the bowels, in locked jaw, &c., with good effect. Bleeding is general or topical, General, as from the neck, when we mean to lessen the general momentum. Topical, when we bleed from a particular part, as the eye, the plate voin, the toe, &c. Most expert particitioners use a large lancet to bleed with; and when the habit of using it is acquired, it is by far the best instrument, particularly for superficial veins where a blow might carry the fleam through the vessel. In common hands the fleam (fig. 883), as the more general instrument, is best adapted to the usual cases requiring the agriculturist's notice. Care should, however, be taken not to strike it with vehremence; and the hair being first wetted and smoothed down, it should be pressed close between the hairs, so that its progress may not be impeded by them. A ligature should be first passed round the neck, and a hand held over the eye, unless the operator be very expert, when the use of the fingers will dispense with the ligature. The quantity of blood taken is usually too small. In inflammatory disease, a large horse, particularly in the early stage of a complaint, will bear to lose eight or ten quarts: and half the quantity may be taken away two or three times afterwards, if the violence of the symptoms seem to require it; and the blood should be drawn in a large stream to do all the good it is capabl

SECT. VII. Veterinary Pharmacopæia.

6548. The following formulæ for veterinary practice have been compiled from the works of the most eminent veterinary writers of the present day, as Blaine, Clark, Laurence, Peel, White, &c.; and we can, from our own experience also, confidently recommend the selection to the notice of agriculturists, and the owners of horses in general. It would be prudent for such as have many horses, and particularly for such as live at a distance from the assistance of an able veterinarian, to keep the more necessary articles by them in case of emergence: some venders of horse drugs keep veterinary medicine chests; and where the compositions can be depended on, and the uncompounded drugs are genuine and good, one of these is a most convenient appendage to every stable. The best arranged veterinary medicine chest we have seen was in London, at the veterinary elaboratory of Youatt of Nassau Street, Middlesex Hospital. Hospital

16549. The veterinary pharmacopæia for oxen, calves, and sheep has been included in the arrangement. When any speciality occurs, or where distinct recipes are requisite, they have been carefully noticed; it will therefore only be necessary to be kept in mind, that with the exception of acrid substances, as mineral acids, &c., which no cattle bear with equal impunity with the horse, the remedies prescribed require about the following proportions:—A large ox will bear the proportions of a moderate-sized horse; a moderate-sized cow something less; a calf about a third of the quantity; and a sheep about a quarter, or at most a third of the proportions directed for the cow. It is also to be remarked, that the degrees in strength in the different recipes are usually regulated by their numbers, the mildest standing first.

6550. Alteratives.

Levigated antimony, 2 drachms. Cream of tartar, Flower of sulphur, each half an ounce.

Cream of tartar, Nitre, of each half an ounce.

Acthiops mineral, Levigated antimony, Powdered resin, each 5 drachms. Give in a mash, or in corn and bran a little wetted, every night, or make into a ball with honey.

6551. Tonic Alteratives.

Gentian, Aloes, Ginger, Blue vitriol, in powder, of each 1 drachm. Oak bark in powder, 6 drachms.

Winter's bark, in powder, 3 drachms. Green vitriol, do., one and a half drachm. Gentian, do., 3 drachms. Make either of these into a ball with honey, and give every morning.

White vitriol, 1 drachm

Ginger or pimento ground, 2 drachms. Powdered quassia, half an ounce. Ale, 8 ounces.— Mix, and give as a drink.

Arsenic, 10 grains.
Oatmeal, 1 ounce.
Mix and give in mash or moistened corn nightly.

6552. Astringent Mixtures for Diarrhaa, Lax, or Scouring.

Powdered ipecacuanha, 1 drachm.
Do., opium, haif a drachm.
Prepared chalk, 2 ounces.
Boiled starch, 1 pint.

Suet, 4 ounces; boiled in Milk, 8 ounces, Boiled starch, 6 ounces, Powdered alum, 1 drachm.

The following his been very strongly recommended in some cases, for the lax of horses and cattle ! — Glauber's salts, 2 ounces. Epsom do., 1 ounces. Green vitrol, 4 grains. Gruet, half a pint. 4. 4.

When the lax or scouring at all approaches to dysentery or molten grease, the following drink should be first given: — Castor oil, 4 ounces. — Castor oil, 4 ounces. Powdered rhubarb, half a drachm. Powdered opium, 4 grains. Gruel, 1 piat.

6553. Astringent Balls for Diabetes or Pissing Evil.

Catechu (Japan earth), half an ounce. Alum powdered, half a drachm. Sugar of lead, 10 grains. Conserve of roses to make a ball.

6554. Astringent Paste for Thrush, Foot-rot, Foul in the Foot, &c.

Prepared calamine, Verdigris, of each half an ounce. White vitriol, Alum, of each half a drachm. Tar, 3 ounces: mix.

6555. Astringent Washes for Cracks in the Heels, Wounds, Sprains, &c. 1.

Sugar of lead, 2 drachms.
White vitriol, 1 drachm.
Strong infusion of oak or elm bark, 1
pint: mix.

Green vitriol, 1 drachm.
Infusion of galls, half a pint.
Mix, and wash the parts three times a

6556. Powder for Cracks, &c.

Prepared calamine, I ounce.
Fuller's earth, powdered,
Pipe clay, do., of each 2 ounces.
Mix, and put within gauze and dab the
moist surfaces of the sores frequently.

6557. Astringent Paste for Grease. 1.

Prepared calamine,
Tutty powdered,
Charcoal, do. of each 2 ounces.
Yeast enough to make a paste.

To the above, if more strength be required, add of alum and verdigris each a drachm.

6558. Astringent Wash for Do.

Corrosive sublimate, 2 drachms.
Spirit of wine or brandy, 1 ounce.
Soft water, 10 ounces.
Soft water, 10 ounces.
This is a strong preparation, and has often proved successful in very bad cases of grease, which have resisted all the usual remedies.

6559. Blisters.

Cantharides powdered, 2 ounces.
Venice turpentine, do.
Resin, do.
Paim oil or lard, 2 lbs.
Melt the three latter articles together, and when not too hot stir in the Spanish fise.

2.
6560. A strong cheap Blister, but not proper to be used in Fevers or Inflammations, as of the Lungs, Bowels, &c.

as of the Lungs, Bowels, &c.
Euphorbium powdered, I ounce.
Oil of vitriol, 2 scruyles.
Spanish flies, 6 ounces.
Falm oil or lard,
the state of the s

6561. A mercurial Blister for Splints, Spa-vins, and Ringbones.

Of either of the above, 4 ounces. Corrosive sublimate, finely powdered, half a drachm.

6562. Strong Liquid Blister. Spanish files in gross powder, 1 ounce.
Oil of origanum, 2 dr.chms.
Oil of turpentine, 4 ounces.
Olive oil, 2 ounces.
Steep the files in the turpentine three weeks, strain off, and add the oil.

5. 6563. Mild Liquid or Sweating Blister. Of the above, 1 ounce. Olive oil or goose grease, one and a half

6564. Clysters, a Laxative one. 1. Thin gruel or broth, 5 quarts. Epsom or common salts, 6 ounces.

6565. Clyster for Gripes.

Mash two moderate-sized onions.
Pour over them oil of turpentine, 2 ounces.
Capsicum, or pepper, half an ounce.
Thin gruei, 4 quarts.

6566. Nutritious Clyster.

Thick gruel, 3 quarts. Strong sound ale, 1 quart. or 4. Strong broth, 2 quarts. Thickened milk, 2 quarts.

6567. Astringent Clyster.

Tripe liquor, or suet boiled in milk, 3 pints. Thick starch, 2 pints. Laudanum, half an or or 6.

Alum whey, 1 quart. Boiled starch, 2 quarts

6568. Cordial Balls.

Gentlan powdered, 4 ounces.
Ginger, do., 2 ounces.
Coriander seeds, do., 4 ounces.
Carraway do., 4 ounces.
Carraway do., 4 ounces.
Oil of aniseed, a quarter of an ounce.
Make into a mass with honey, treacle,
or lard, and give one ounce and a half for a dose.

6569. Chronic Cough Balls.

Calomel, 1 scruple.
Gum ammoniacum,
Horse radish, of each 2 drachms.
Balsam of Tolu,
Squills, each 1 drachm.
Each all together, and make into a ball
with honer, and give every morning fast-

6570. Drink for the same.

Tar water, Lime water, of each half a pint. Tincture of squills, half an ounce.

6571. Powder for the same. 3

Tartar emetic, 2 drachms.
Powdered foxplove, half a drachm.
Powdered squill, half a drachm.
Calomel, 1 scruple.
Nitre, 3 drachms.

Give every night in a malt mash.

6572. Diuretic Balls.

Resin, yellow, 1 lb.
Nitre, half a pound.
Horse turpentine, half a pound.
Yellow soap, quarter of a pound.
Melt the resin, soap, and turpentine
over a slow fire; when cooling, add the

nltre. For a strong dose, an ounce and a half; for a mild one, an ounce. It should be kept in mind, that mild diuretics are always equal to what is required; and that strong diuretics are always hurtful.

6573. Diuretic Powders.

Yellow resin, powdered, 4 ounces.
Nitre, do., 8 ounces.
Cream of tartar, ditto, 4 ounces.
Dose – 6, 8, or 10 drachms nightly,
which some horses will readily eat in a

6574. Urine Drink.

Glauber's salts, 2 ounces. Nitre, 6 drachurs. Dissolve in a pint of warm water.

6575. Embrocations. — Cooling for Inflam-mations.

Goulard's extract, half an ounce. Spirit of wine or brandy, 1 ounce. Soft water, 1 quart.

Mindererus spirit, 4 ounces. Water, 12 ounces.

6576. For Strains. Bay salt, bruised, half a pound. Crude sal ammoniac, 2 ounces. Sugar of lead, quarter of an ounce. Vinegar, 1 pint and a half. Water, 1 pint.

6577. For the Eyes.

Sugar of lead, 1 drachm. White vitriol, 2 scruples. Water, 1 pint.

Brandy, 1 ounce. Infusion of green tea, 4 ounces. Tincture of opium, 2 drachms. Infusion of red roses, 4 ounces.

Rose water, 6 ounces. Mindererus spirit, 3 ounces.

Corrosive sublimate, 4 grains.
Alkohol, 1 ounce.
Lime water, 1 pint.

Alum, powdered, I drachm.
Calomel, half a drachm.
Mix and insert a little at one corner of the eye. The custom of blowing it in alarms the horse.

6578. Fever Powders.

Tartar emetic, 2 drachms. Nitre, 5 drachms.

Antimonial powder, 2 drachms. Cream of tartar, Nitre, of each 4 drachms.

6579. Fever Drink.

Sweet spirit of nitre, 1 ounce. Mindererus spirit, 6 ounces. Water, 4 ounces.

6580. Epidemic Fever Drink.

Sweet spirit of nitre, 1 ounce. Simple oxymel, 6 ounces. Tartar emetic, 3 drachms.

6581. Malignant Epidemic Fever.

Simple oxymel, Mindererus spirit, Beer yeast, of each, 4 ounces. Sweet spirit of nitre, 1 ounce.

6582. Fumigations for purifying infected Stables, Sheds, &c.

Manganese, 2 ounces.
Common salt, ditto.
Oil of vitrol, 5 ounces.
Water, 1 ounce.
Water, 1 ounce.
Water, 1 ounce.
Water, 1 ounce, ounces.
Water, 2 ounces.
Wate

6583. Hoof Liquid.

Oil of turpentine, 4 ounces.
Tar, 4 ounces.
Whale oil, 8 ounces.
This softens and toughens the hoofs extremely, when brushed over them night and morning.

6584. Purging Medicines Balls — very mild. Aloes, powdered, 6 drachms. Oil of turpentine, 1 drachm.

Mi'd. Aloes, powdered, 8 drachms. Oil of turpentine, 1 drachms. Strong.

Sirong.

Aloes, powdered, 10 drachms.
Oil of turpentine, 1 drachm.
The aloes may be beaten with treacle to a mass, adding, during the beating, the oil of turpentine. All spices, oil of tartar, cream of tartar, jalap, &c. are useless, and eften hurtful additions.

6585. Liquid Purge.

Epsom salts, dissolved, 3 ounces.
Castor oil, 4 ounces.
Castor oil, 4 ounces.
Wix.— The watery fracture of aloes is made by beating powdered aloes with the yolk of eggs, adding water by degrees; by these means half an ounce of aloes may be suspended in eight ounces of water; and such a purge is useful when a hall cannot be got down, as in partial locked law.

6586, Scalding Mixture for Pole Evil. Corrosive sublimate, finely powdered, 1 drachm.
Yellow basilicon, 4 onnces.

6587. Foot Stoppings. Horse and cow dung, each about 2 lbs. Tar, half a pound.

6588. Wash for coring out, destroying Fungus, or proud Flesh, &c. &c. Lunar caustic, 1 drachm.
Water, 2 ounces.

Water, 2 cunices.

Corrosive sublimate, 2 drachms.

Spirit of wine or brandy, 1 ounce.
Decoction of tobacco,

Ditto of white hellebore, of each 1 pint.

Dissolve the mercury in the spirit, and
then add the decoctions.

6590. Ointments for Healing.

Turner's cerate, 4 ounces.
White vitriol, powdered, half a drachm.

6591. For Digesting.

Turner's cerate, 2 ounces.
White vitriol, 1 drachments, forthe a portal Yellow basilicon, 5 ounces.

: 6592 For Manger bus yemuil Sulphur vivum, 8 ounces.
Arsenic in powder, 2 drachms.
Mercurial ointment, 2 ounces.
Turpentine, 2 ounces.
Lard, 8 ounces.

Mix, and dress with every morning.

6593. For Scale or Shah til Sheep, Mallenders and Sellenders in Horses, and fout Blotches and Eruptions in Cattle The general. 6552. Astrong nt .11

Camphor, 1 drachm. Sugar of lead, half a drachm. Mercurial ointment, 1 ounce.

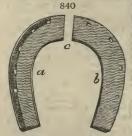

SECT. VIII. Shoeing of Horses.

Sect. VIII. Shoeing of Horses.

6594. The importance of the subject of shoeing to the agriculturist is sufficiently attested by the immense number of inventions which the ingenuity of philosophers and artists are every day devising, to render the system complete. Almost every veterinary professor has his favourite shoe; and we find one of the most ingenious of the present day endeavouring to force on our notice, and introduce into our stables, the French method; which, with the exception of the mode of nailing on, White observes, is the very worst he ever saw. The French shoe (j.g. 839 a) has a wide web towards the toe, and is concave above and convex below (b), on the ground (c); but the very worst he ever saw. The French shoe (j.g. 839 a) has a wide web towards the toe, and is concave above and convex below (b), on the ground (c); but the very worst he ever saw. The French shoe (j.g. 839 a) has a wide web towards the toe, and is concave above and convex below (b), on the ground (j.g. the very worst he ever saw. The French shoe (j.g. 839 a) has a wide web towards the toe, and is concave above and convex below (b), on the ground (j.g. the very worst he ever saw. The French shoe (j.g. 840), if he have he ground (j.g. 839 a) has a wide web towards the toe, and is concave above and convex below (b), on the ground (generally speaking) as a reoposed to it in an unshod state; and above all, to endeavour to preserve the original form of the foot, by framing the shoe thereto; but never to alter the foot to the defence. The shoe at tresten made at the forges of the most respectable smiths in the cities and large towns throughout the kingdom, if it have not all the requisites, has however, by degrees, been so improved, that with a few additional alterations, neither difficult to direct or adopt, it is the one we shall present to our readers; but so averse are the generality of smiths from having any improvements forced on them, and so obstinately determined are the generality of smiths from having any improvements forced

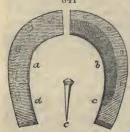

6395. The improved shoe for general use (fig. 840.), is rather wider than what is usually made. Its nail holes (a) extend no further towards the heels than is actually necessary for security; by which the expansion of these parts is encouraged, and contraction is avoided. To strengthen the attachment, and to make up for this liberty given to the heels, the nails should be carried around the front of the shoe (c). The nail holes, on the under er ground surface of the shoe (c), are usually formed in a gutter, technically called the fullering; but in the case of heavy treading powerful horses this gutter may be omitted, or if adopted, the shoe in that part may be steeled. The web should be quite even on the foot or hoof surface (b), and not only be rather wider, but it should also have rather more substance than is common: from half an inch to five eighths in thickness, according to circumstance, forms a fair proportion; when it is less it is apt, in waring, to bend to pressure and force out the clinches. A great error is committed in setting shoes out so much wider than the heels themselves; this error has been devised to correct another, which has been that of letting horses go too long without shoeing; in which case, if the heels of the shoe were not too wide originally, as the foot grew, they became lost within the heels; and were thus bruised and produced corns: but as we will suppose of the shoe should stand only wide enough to prevent the expansion of the quartery sushing the heels of the shoe should stand only wide enough to prevent the expansion of the quartery sushing the heels of the shoe should stand only wide enough to prevent the expansion of the foot; and which defect, will find only one third of its flat surface protecting the heels; the remainder projects beyond, and serves but to form a shelf to lodge dirt on; or as a convenient clip for another horse to tread on; or for the wearer to cut his own legs with; or to afford a more ready hold for the suction of clayer grounds to force off the shoe by.

to be impressed on the mind of every agriculturist, and guarded against by every one who possesses a horse. It is too frequently observed that the ground side of their shoe is convex, and that the inward rim, when the foot is on the ground, is the lowest part; on which it is evident the weight must first press; and by which pressure, the crust will be forcibly thrust on the extreme edge of the shoe; and the only resistance offered to its being forced from it, depends on the nails and clinches, instead of its just application to the ground, and the support derived from the uniform pressure of the whole. Every shoe should therefore be perfectly level on its ground surface: nor should any shoe be put on that has not been tried on a plane iron purposely made for such trial; which irons are kept in some smithles, but are absent from too many. The substance of the shoe should be the same throughout, forming two parallel lines of upper and under surface; in plain language, the heels, instead of being clubbed as is too frequent, should be the exact thickness of the toe. Neither should the width at the heels diminish in the proportion it usually does; on the contrary, for a perfectly formed foot, the web should present a uniform width throughout.

usually does; on the contrary, for a perfectly formed foot, the web should present a uniform width throughout.

G397. Varieties in form of foot, differences in size, weight, and uses of horses, will necessarily make deviations in the form and substance of shoes. The very shoe recommended may be considered as a variation from what would be immediately necessary, were the feet generally perfect; but it is to be considered that there are but very few feet but what have undergone some unfavourable alteration in their form, which makes them very sensible to concussion. It is for this reason, therefore, that it is recommended that a shoe be used, for general purposes, somewhat wider and thicker than the common one. In weak, tender, flexible feet, it will be found particularly advantageous; and here the benefit of wide heels to the shoe will be most apparent. Good as the roads now are, yet most horses are occasionally subjected to travel on bad ones; some know no other: to these the addition of one, or at the most, two ounces to each shoe is nothing; but the ease to the horse, and its superior covering, as well as support, is incalculable. In very young, very light, and very firm feet, the width and substance may be somewhat diminished at pleasure, and particularly in situations where the roads are uniformly good; but a very long and extensive experience has assured us, that the shoe portrayed is one well calculated to meet the ordinary purposes of travelling, and the present state of the art of horse-shoeing.

G393. An improved shoe on the present plan (fig. 341.), would be found to unite all the perfections of the modern English improvements, with some derived from our neighbours the French. What has since been called a seated shoe was introduced by Osmer; but from the obstinacy and ignorance of smiths, as it could not be brought into general use, it became little thought of until revived by Clark of Edinburgh; by whom it was patronised and recommended. It finally was taken up by Moortroft, and has ever since attrac

If to this shoe were added the French mode of fastening it to the foot, we think the improvement would almost shut out all others. amining the figure it will be seen that this shoe presents a flat surface opposed to the ground (a), but a concave one towards the sole (b); but that this concavity does not begin, as in some seated shees, near the outer edge, but embraces two thirds only of the web, leaving by this means a sufficient surface for the crust: but this bevelling is not

that this concavity does not begin, as in some seated shoes, near the outer edge, but embraces two thirds only of the web, leaving by this means a sufficient surface for the crust: but this bevelling is not intended to reach the heels; it stops short of them (c), leaving the web at this part plain for the heels to rest upon. The great advantages of this seating are, first, that as the crust rests on a flat surface instead of an inclined plane, as most of the common forged shoes present, so its position is maintained entire, and the inclination to contraction is in a great degree avoided. The nailing on of this shoe we would recommend to be after the French method, which consists in conical nail holes, punched with a square countersink (d), into which are received conical nails (e); which exactly fill up the countersink; by which means so long as any part of the base of the nail remains, the shoe must be held firmly on, and which is not the only advantage gained; for the nail holes being obliquely formed, and at some distance from the outer rim, act less detrimentally on the crust of the foot.

6599. To prepare the foot for the application of the shoe is also an important consideration. Avoid taking off more than one shoe at a time; otherwise the edges of the crust become broken away. Observe that the clinches are all carefully removed. Let the rough edges of the crust become broken away. Observe that the clinches are all carefully removed. Let the rough edges of the crust become broken away. Observe that the clinches are all carefully removed. Let the rough edges of the crust become broken away. Observe that the clinches are all carefully removed. Let the rough edges of the crust become broken away. Observe that the clinches are all carefully removed. Let the rough edges of the crust become broken away. Observe that control to stop a sole tends to heat and contraction, too weak a one will not require paring. In this paring into strong a sole tends to heat and contraction, too weak a one will not require paring.

6601. Varieties which necessarily occur in shoring. The bar shoc (fig. 842.) is the most important variety; and it is to be regretted that so much prejudice prevails against the use of this shoe, which can only arise from its supposed unsightly appearance as betokening unsoundness. As a defence to weak thin only arise from its supposed unsightly appearance as betokening unsoundness. As a defence to weak thin feet it is invaluable, as it removes a part of the pressure from the heels and quarters, which can ill bear it, to the frog which can well bear it; but a well formed bar shoe should not have its barred part raised into an edge behind, but such part should be of one uniform thickness throughout the web of the bar, which, instead of being the narrowest, should be the widest part of the shoe. The thickness of the bar should be greater or less (a), so as to be adapted to take only a moderate pressure from the frog. When the frog is altogether ulcerated away by thrush, the bar may be altogether plain; but this form of shoe is still the lest for these cases, as it prevents the tender surface from being wounded. In corns this shoe is invaluable, and may then be so made as to lie off the affected part, which is the great desideratum in corns. in corns, in corns, of the hunting shoe is made lighter than the common one, and it is of consequence that it is

made to sit as flat to the foot as it can safely do without pressing on the sole; by which the great suction in clayey grounds is much lessened. Hunting fore-shoes should also be as short at the heels as is consistent with safety to the foot, to avoid the danger of being pulled off by the hinder shoes; nor should the web project at all. It is the custom to turn up the outer heel to prevent slipping; which is done sometimes to both fore and hind feet, and sometimes only to the latter. As this precaution can hardly be avoided in hilly slippery grounds, it should be rendered as little hurtful as possible by making the tread equal; to which purpose, thicken the inner heel and turn up the outer. This is better than lowering the outer heel to receive the shoe, which still leaves both the tread and foot upeyer. and foot uneven.

and foot uneven.

6003. The racing shoe, or plate, is one made as light and slender as will bear the weight of the horse, and the operations of forging, grooving, and punching; to enable it to do which, it ought to be made of the very best Swedish iron. Three, or at most four, nails are sufficient on each side; and to avoid the interfering of the hind with the fore feet, the heels of the fore shoes are made as short as they can safely be. As racers are shod in the stable, the owners should be doubly careful that the plate is an exact fit. Many pairs ought to be brought and tried before any are suffered to be put on, and this is more important than is at first considered.

6604. Grass shoes or tips are very short pieces placed on the toe alone, in horse turned to grass in summer; at which time they are essentially necessary to guard the fore feet, which otherwise become broken away, and irretrievably injured. They should be looked at occasionally to see that they do not indent themselves into the soles.

ndent themselves into the soles.

6605. Frost shoes (fig. 843 a) have the ends turned up to prevent the foot from sliding; unless the turning up or calkin be hardened, they soon wear level and require to be renewed, to the injury of the foot by such frequent removals. To remedy this, many inventions have been tried; one of the best of these is that of Dr. Moore, in which the frost clip is made distinct and moveable by means of a female screw (b) worked in it, to which a knob or wedge (c) and male screw (d) are adapted; a key (e) being used for fixing or removing it.

6606. High cakins, or turn-ups, however objectionable in general shocing, yet, in precipitous counties, as those of Devonshire, Yorkshire, and of Scotland, &c., are absolutely necessary for their draught horses. It greatly obviates the evils of uneven pressure, if a calkin be also put to the toe; and it would be still better were these calkins steeled, particularly the fore ones.

6507. The shocing of discased feet is necessarily very various, and is too often left to the discretion of the smith, by which the evils themselves are greatly aggravated, if he be ignorant. The most prominent alterations for these purposes will be found described under the respective diseases of the feet requiring them.

66(8). Horse pattens are in use by some cultivators who occupy soft or mossy soils. Those esteemed the best are constructed of alder or elm, and are fixed to the hoof by means of three links and a staple, through each of which passes a leathern strap that goes twice round the hoof, and is fastened by a buckle. The staple is placed behind the patten, which is ten inches one way, by ten and a half the other. The links are about three inches in length, and rivetted through pieces of hoop iron to prevent the wood from splitting. After numerous trials, it has been found that pattens made in this way answer the purpose better than any other kind. (Farm. Mag.)

SECT. IX. Criteria of the Qualities of Horses for various Purposes.

6609. The general criteria of the qualities of a horse are derived from inspection and trial. His outward appearance among judges affords a pretty just criterion of his powers, and a moderate trial usually enables the same judgment to decide on the disposition to exercise such powers.

6610. The criteria of a horse derived from his colour have been already noticed. (6298.) As a general principle dark are preferable to light horses, except in the instance of black, which has fewer good horses within its range, particularly in the lighter breeds, than any other. Grey horses are also, in some degree, an exception to the rule; for there are many good greys. Bay and brown are always esteemed

The criteria of action are derived from a due consideration of the form generally, and of the limbs

6611. The criteria of action are derived from a due consideration of the form generally, and of the limbs particularly; as well as from seeing the horse perform his paces in hand.
6612. The criteria of hardthood are derived from the form of the carcase, which should be circular, or barrelled; by which food is retained, and strength gained to perform what is required. Such horses are also generally good feeders.
6613. The criteria of spirit, vigour, or mettle, as it is termed, are best derived from trial. It should always be kept in mind, that a hot fiery horse is as objectionable as a horse of good courage is desirable. Hot horses may be known by their disinclination to stand still; by their mettle being raised by the slightest exercise, especially when in company. Such horses seldom last long, and under acident are impetuous and frightened in the extreme. A good couraged horse, on the contrary, moves with readiness as well alone as in company; the carries one ear forward and one backward; is attentive and cheerful, loves to be talked to, and caressed even while on his journey; and if in double harness, will play with his mate. Good couraged horses are always the best tempered, and, under difficulties, are by far the most quiet, and least disposed to do mischief.
6614. The criteria of a race-horse, derived from form, are, that he have the greatest possible quantity of bone, muscle, and sinew, in the most condensed form. There should be a general length of parts to afford stretch, scope, and elasticity, with great muscles hardened by condition, to act on the length of these parts advantageously. In particular his hind limbs should be furnished with ample thighs and broad hocks, which should be low set. His fore-arm ought also to be broad, and the knee, like the hock, should be near the ground.

hocks, which should be low set. His fore-arm ought also to be broad, and the knee, like the hock, should be near the ground.

6615. The criteria of a hunter are, that he have somewhat similar proportions with the racer, but with more bulk to enable him to continue his exertions longer, and to carry more weight. In him, a good carcase is essentially necessary to fit him to go through a long chase; and the more, if he be required to hunt more than one or two days in the week. Some light carcased horses will do one day's hunting work a week very well, but knock up at more. The lunter should be well formed in his loins, and well let down in his thighs to propel him forward in his gallop, and give him strength to rise sufficiently to cover his leaps. It is also of great use to a hunter to be a good trotter; many such horses, when fatigued, break out of the gallop and relieve themselves by trotting, particularly over heavy ground.

horses, when fatigued, break out of the ganop and rener the heavy ground.

6616. The criteria of a hackney. If it be necessary that the hackney be well formed behind to give him strength, and to propel him forward, it is even of more consequence that he be well formed before; and in this kind of horse the hind parts are in some measure subordinate to the fore, as safety is preferable to speed. The head in the hackney should be small, and well placed on a neck of due length and substance to make a proper apput for the bridle, and that proper resistance to the hand, so pleasant to the feel, and 3 S 2

so necessary for ease and safety. The shoulders should be oblique and well furnished with muscle, but not heavy; and the withers in particular should be high. The elbows should be turned rather out than in, and the legs should stand out straight, and by no means fall under the horse, or it betokens a stumbler. The pasterns should neither be too oblique, which bespeaks weakness; nor too straight, which wears the horse out, and is unpleasant to the rider. The carcase should be round, or the horse will be washy and weak; the loins straight, wide, and ribbed home; the thighs of good substance; and although the being cat-hammed, or having the hocks turned inwards, is defective in beauty, it often bespeaks a trotter. 6617. The criteria of a cavalry horse are, that he have considerable extention of bulk or size, to enable him to carry weight, with good carcase to allow him to feed coarsely, and yet thrive at picket or on service. He should have also liberty of action; but great speed is not requisite. The best cavalry horses are those formed of the united properties of hackneys and very light draught norses.

6618. The criteria of road horses for quick draught, or coach, chariot, stage and post chaises, &c., are derived from the immediate purposes for which they are intended; as requiring either strength or speed in greater proportions. To make them safe, the fore-hand should rise, the back should be straight, the step should be short but quick, which fatigues least. As they approach the hunter in form, they are best fitted for quick work; and as they resemble the best kind of light agricultural horses, they are calculated for heavy draught, as coaches, &c. But in all, a portion of blood gives courage, durability, and econdenses strength into lessened bulk; by which activity is gained. It is of great consequence to a coach-horse that the neck and head be so formed as to be enabled to rein-in well to the bridle.

the neck and head be so formed as to be enabled to rein-in well to the bridle.

6619. The criteria of a dray-horse are, that he be very broad-breasted and muscular, and thick in the shoulders, which should not lie backward. Nor should the fore-hand be up, as recommended in the road-horse; for, by holding up their heads, such horses may be choked by the collar, as they would, if so formed, draw too much by the throat, and their wind being thus stopped, would be in danger of falling down. The neck of a dray-horse is not the better for being long, and the head should be proportionate to it. Like all horses, he should be chosen with short legs, and good strong hoofs. He ought to be thick in his thighs, and large in bone; but above all, he ought to be a steady collared horse, with courage to make him true to a severe pull; and yet, without a hot fiery spirit to make him fretly.

6620. The criteria of a unaggon horse are, in some respects, different from those of the dray-horse. He should be more weighty, and altogether larger. Rapidity of motion is greatly subordinate, in the heavy stage waggons usually seen on our roads, to strength. It is all collar work; nothing is gained from the momentum of the dragged mass, which, the instant the pul ceases, stands still. The waggon horse should be patient in the extreme; willing to lie to his collar up-hill, and yet settle into his share of work on level ground. As his exertions are constant, it is of the greatest consequence that he be a good feeder.

good feeder.

work on level ground. As his exertions are constant, it is of the greatest consequence that he be a good feeder.

6621. The criteria of a horse peculiarly adapted to the labours of agriculture, are thus given by Culley:—

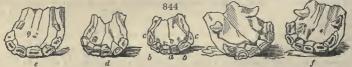

His head should be as small as the proportion of the animal will admit; his nostrils expanded, and mutzale fine; his eyes cheerful and prominent; his ears small, upright, and placed near together; his neck, rising out from between his shoulders with an easy tapering curve, must join gracefully to the liead; his shoulders being well thrown back, must also go into his neck (at what is called the points) unperceived, which perhaps facilitates the going much more than the narrow shoulder; the arm, or fore-thigh, should be muscular, and tapering from the shoulder, to meet a fine, straight, sinewy, and bony leg; the hoof circular, and wide at the heel; his chest deep, and full at the girth; his loins or fillets broad and straight, and body round; his hips or hooks by no means wide, but quarters long, and the tail set on so as to be nearly in the same right line as his back; his thighs strong and muscular; his legs clean and fine-boned; the leg-bones not round, but what is called Lathy or flat.

6622. The chief points in a farming cart-horse, in the opinion of the author of the New Farmer's Calendar, are, "neck not long, nor too thick; short legs, rather flat than round and gummy; fore-feet even, not too distant; wide chest; strong, but not high, shoulders; considerable length of waist, supported by a wide loin; quarters full, and rather raised; strong muscular thigh; size, fifteen hands one inch to sixteen hands high. Being somewhat forelow gives them an advantage in draught; and a moderate length of waist insures speed in the walk.

6623. The horse used in husbandary, according to the writer of the Experienced Farmer, ought to be larger, but in other respects like the road horse: and, instead of walking two or three miles an hour, be able to walk four or five. In that case he would be able both to

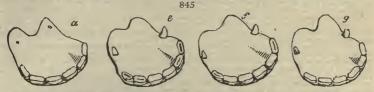

blood, therefore, is not disadvantageous. It is not size that confers strength, the largest horses being often soonest worn out. A quick even step, an easy movement, and a good temper, are qualities of the greatest importance to a working horse; and the possession of them is of more avail than big bones, long legs, and a lumpy carcase. To feed well is also a property of great value; and this property, as all judges know, depends much upon the shape of the barrel, deepness of chest, strength of back, and size of the hips or hooks with which the animal is furnished. If straight in the back, and not over short, high in the ribs, and with hooks close and round, the animal is generally hardy, capable of undergoing a great deal of fatigue, without lessening his appetite, or impairing his working powers; whereas horses that are sharp pointed, flat ribbed, hollow backed, and wide set in the hooks, are usually bad feeders, and soon done up when put to hard work.

6625. The criteria of a horse's age are derived from the appearance of the teeth. According to La Fosse the younger, there are these appearances. The horse is foaled with six molar or grinding teeth in each jaw (fig. 844 a); the tenth or twelfth day after, the two front nippers (a) appear above and below, and in

fourteen or fifteen days from this, the two intermediate (b,b) are pushed out; the corner ones (c,c) are not cut till three months after. At ten months the incisive or nippers are on a level with each other, the front less than the middle, and these again less than the corners; they at this time have a very sensible cavity (d). At twelve months this cavity becomes smaller, and the animal appears with four molar teeth on each side, above and below, three of the temporaneous or colts', and one permanent or horse tooth: at eighteen the eavity in the nippers is filled up, and there are five grinders, two of the horse, and three temporaneous: at two years (fg, 845.), the first of the colt's molar teeth in each jaw, above and below, are displaced: at two years and a half, or three years, the front nippers fall and give place to the permanent ones: at three and a half the middle nippers are likewise removed, at which period the second milk-molar falls: at four years the horse is found with six molar teeth, five of his new set, and one of his last: at four years and a half the corner nippers of the colt fall and give place to the permanent set

(fig. 844. e), and the last temporaneous grinder disappears; at five years old the tushes in the horse usually appear; at five and a half they are completely out, and the internal wall of the upper nippers, which

before was incompletely formed, is now on a level with the rest; at this period the incisive or hippers have all of them a cavity formed in the substance between the inner and outer walls ($f_{\mathcal{B}}, 844.f$), and it is the disappearance of this that marks the age; at six years those in the front hippers below are filled up ($f_{\mathcal{B}}, 845.f$), the tushes are likewise elightly blunted; at seven years the mark or cavity in the middle hippers is filled up, and the tushes a little more worn ($f_{\mathcal{B}}, 845.f$): at eight years old the corner hippers are likewise plain, and the tushes are round and shortened ($f_{\mathcal{B}}, 845.g$). In mare, the incisive or hippers alone present a criterion ($f_{\mathcal{B}}, 845.a$); at this period the horse is said to be aged, and to have lost his mark; but among good judges the teeth still exhibit sufficient indications. At nine the groove in the tushes in worn away nearly, and the hippers become rather rounded; at ten these appearances are still stronger; at twelve the tushes only exhibit a rounded stump, the hippers push forward, become yellow, and as the age advances, appear triangular and usually uneven.

6626. M. St. Bel, the late professor of the English Veterinary College, used to assert, that after eight years the cavities in the anterior or upper incisive teeth are filled up with equal regularity; thus from eight to ten the front ones were filled up, from ten to twelve the two middle, and from twelve to fourteen those of the corner; but though some pains have been taken to ascertain this, it does not appear that the disappearance of the cavities in these teeth is attended with sufficient regularity to warrant implicit confidence.

confidence.

the disappearance of the cavities in these teeth is attended with sufficient regularity to warrant implicit confidence.

6627. To make a cost appear older than he really is, both breeders and dealers very commonly draw the nippers, particularly the corner ones; by which means the permanent set which are underneath immediately appear, and the animal is thus fitted for sale before he otherwise would be.

6628. To make a horse look younger than he really is, dealers perform an operation on the teeth called bishopping (from the name of a noted operator); which consists in making an artificial cavity in the nippers, after the natural one has been worn out by age, by means of a hard sharp tool; which cavity is then burned black by a heated instrument. But no art can restore the tushes to their form and height, as well as their internal grooves. It is, therefore, common to see the best judges thrust their finger into a horse's mouth, contenting themselves with merely feeling the tush. To less experience judges other appearances present themselves as aids. Horses, when aged, usually become hollow above the eyes, the hoofs appear rugged, the under lip falls, and if grey, they become white. In this country, where horses are so early worked before the frame is consolidated, and where afterwards they continue to be exerted unceasingly on hard roads, it is not uncommon to find a horse at six years old feeble, debilitated, and exhibiting all the marks of old age, except in his mouth; on the contrary, when the animal falls into other hands, at ten or twelve he has all the vigour of youth, and his teeth are the only parts that present an indication of age: it is, therefore, more useful to examine the general appearance of the animal, than to be guided altogether by the marks in the teeth; a too strict adherence to which, Blaine observes, lead into greaterror on the subject of the age of horses. The commonly received marks, he says, grant not a criterion of a third of the natural life of the animal, nor of one half of the time the constitution, between the horse and man, under the ordinary circumstances of care towards each:—The first five years of the horse may be considered as equivalent to the first twenty of a man; a horse of ten as a man of forty; of fitners, and of first; of twenty-five as a man of sixty; of twenty-five as a man of seventy; of thirty as a man of eighty; and of thirty-five as a man of ninety. (Vet. Outlines, p. 35.)

SECT. X. Breeding of Horses.

Sect. X. Breeding of Horses.

6629. The general principles of breeding we have already laid down at length (2023.), and have here to notice what are considered the best practices in the choice of stallions and mares, and in the treatment of the latter during pregnancy. Unfortunately, however, much less attention has been paid to breeding horses, than to breeding cattle or sheep; though, as Brown has observed, a pound of horse-flesh is worth two of that of any other stock; and it costs just as much to breed a bad horse as a good one. Every one, an eminent writer observes, exercises some degree of judgment in regard to the stallion; but there are few breeders, comparatively, who hesitate to employ very ill-formed and worthless mares, and often solely because they are unfit for any thing else than bringing a foal. All the best writers on agriculture reprobate this absurd and unprofitable practice. "In the midland counties of England, the breeding of cart horses is attended to with the same assiduity as that which has of late years been bestowed on cattle and sheep; while the breeding of saddle horses, hunters, and coach horses is almost entirely neglected; or left almost wholly to chance, even in Yorkshire,—I mean as to females. A breeder here would not give five guineas for the best brood mare in the kingdom, unless she could draw or carry him occasionally to market; nor a guinea extraordinary for one which could do both. He would sooner breed from a rip, which he happens to have upon his premises, though not worth a month's keep. But how absurd! The price of the leap, the keep of the mare, and the care and keep of he progeny, from the time they drop to the time of sale, are the same, whether they be sold from ten to fifteen, or from forty to fifty pounds each." (Marshal's Economy of Yorkshire, vol. ii., p. 166.) A little consideration will show this error in a still stronger light, when we consider, that united with the characteristic marks common to the breed in general, the progeny of two individuals always ex

and rams, to a few eminent breeders. These stallions, which are shown at the different towns in the vicinity, sometimes sent to be exhibited at a considerable distance, are let out for the whole season, or sold to stallion men, or kept by the breeder himself, for covering such mares as may be offered, at a certain price per head; and this varies according to the estimation in which the horse is held, and sometimes according as the mare has more or less of what is called blood. For farm mares, the charge for covering by a stallion of the same kind is commonly about a guinea, with half-a-crown to the groom; and it is a common practice in the Notth, to agree for a lower rate if the mare does not prove with foal; sometimes nothing more is paid in that case than the allowance to the groom.

6631. In choosing the parents, or stallion and mare, regard must be had to the kind of stock desired to be bred. Whatever may be the particular purpose of the breed, a stallion ought first to possess all the general properties of a good horse, and next the characteristic criteria of the desired stock. The produce, whether a male or female, much more frequently acquires and retains the form, make, marks, and disposition of the sire than the dam. On this account, stallions with the least appearance of disease, blemish, or bodily defect of any kind, where there is the slightest probability of its being transmitted to the offspring, should be rejected as improper. And it is even considered by some necessary to descend to the minutiae of symmetry in the head, neck, shoulder, forehead, ribs, back, loins, joints, and pasterns, attending even to a strict uniformity in the form, make, and texture of the hoofs: it is also of importance to ascertain the temper and disposition of both sire and dam, in order to avoid the procreation of vices or imperfections. But provided either parents be free from hereditary infirmities, disorders which arise from accident are of no consequence. accident are of no consequence.

6632. The general properties required in a breeding mare, are a good shape, a gentle disposition, a large carcase conformably to her height, and belly well let down; she must be perfectly free from all sorts of blemishes and defects. The size, frame, bone, strength, and blood, will of course be regulated by the pur-

poses of the breeder.

poses of the breeder.

6633. The mare which is intended to supply draught colts should, according to the author of the Symposes of Husbandry, be large-limbed, close-jointed, short-docked, wide-chested, home-ribbed, with a capacious body; her eyes good, and her nostrils large and open; in disposition she ought to be gentle and tractable; of a constitution healthy and vigorous, free from any blemishes either hereditary or acquired. The horse should be bold and spirited, well made, and of a kindly disposition; his constitution should be strong, his temper good, and, in short, neither in mind or body ought he to be contaminated with vices or disease of any kind; since on the good qualities and strength of constitution in the sire and the dam depends, in a great measure, the future welfare of the colt.

6634. The age at which horses should be allowed to breed is not determined by uniform practice; and is made to depend, in some measure, on the degree of maturity, which, in animals of the same species, is more or less early, according to breed and feeding. Yet it would seem, in general, to be an improper practice to allow animals of any kind to propagate, while they are themselves in a raw unformed state, and require all the nutriment which their food affords, for raising them to the ordinary size of the variety to which they belong. It may, therefore, be seldom advisable to employ the stallion till he is about four years old, or the mare till she is a year older, and if the stallion to five also it is better, and still more so if he be six or seven. But the greater number of mares left for breeding are not very young; being in many cases not allowed to bring foals till 'they are in the decline of life, or otherwise unable to bear their full share in rural labour. full share in rural labour.

many cases not allowed to bring foals till they are in the decline of life, or otherwise unable to bear their full share in rural labour.

63.5. Three months before a stallion is sexually employed, he should be fed with sound oats, peas, or beans, or with coarse bread, and a little hay, but a good quantity of wheat straw; he should be watered regularly, and have long continued walking exercise every day, but he should not be over-heated. If he be not prepared and put in condition, the colts will be likely to be weakly, and the horse himself will become injured, begetting humours, or becoming broken-winded. If he be put to too many mares, he will not last long; his mane and tail will begin to fall off through weakness, and it will be difficult to get up his flesh again by the next year. The number of mares should be proportioned to his strength, and twelve, fifteen, or at the most twenty, are as many as a horse will well serve for in a season. This number, indeed, is thought by many too few, and in Suffolk, we are informed on the best authority, the stallions serve from fifty to seventy, and even eighty mares in a season.

663.6. The sund season for the generatine process is from the beginning of April to the beginning of July. The month of June is considered the best season in this country; although from the middle to the end of May is more approved of on the Continent, particularly in Normandy, where the farmers devote much of their attention to this branch of husbandry; and in which, especially in regard to useful farm horses, they have succeeded, perhaps, beyond those in any other part of Europe. This difference, as to the time when a mare should be allowed to take the horse, in the different countries, is easily reconcileable: a mare goes eleven months and a few days with foal; and the great object with all farmers, where practicable, is to have her covered at such a period as to ensure abundance of grass, and the return of warm and comfortable weather at the period of foaling. An early colt is always to be

their purpose, were they to follow the example of the Romans, and content themselves with one foal in the two years.

6637. At the season of parturition, there should be a suitable supply of food for the mother and young. The time of covering mares ought, therefore, to be partly regulated by a due regard to this circumstance, and may be carller in the south than in the north, where grass, the most desirable food both for the dam and foal, does not come so early by a month or six weeks. In Scotland, it is not advantageous to have mares to drop their foals sooner than the middle of April; and as the period of gestation is about eleven months, they are usually covered in May, or early in June. But if mares are intended to bring a foal every year, they should be covered from the minth to the eleventh day after foaling, whatever may be the time; and the horse should be brought to them again nine or eighteen days afterwards.

6638. In breeding horses on a targe scale it is easy to contrive so that all the foals may be brought forth at a time when there is plenty of grass. About the end of May the mares are to be put into an enclosure capable of feeding them as long as the stallion is to be with them, or that they are in season. In this enclosure all the mares are to be put together, as well those which are barren as others. The stallion's hind shoes are to be taken off, but the fore shoes should be left, or tips put on to preserve his feet; then lead him forth, and let him cover a mare twice in hand, to render him more tam agentle. After this take off the bridle and turn him loose among the rest, where he will become familiar with them, and not one of them will be horsed but when they are in season. There should be a little lodge built up in some part of the enclosure, and peas, beans, oats, bread, and other good food, put into the manger in it, that he horse may retire into it in the scorching heats, and each what he likes best. He must be thus entertained during the whole time he is with the mares, which is to be a

are very lat and gloss to not local success and ease.

6639. To bring a mare in season, it is a common thing to give her a quart of hemp-seed, or twice that quantity, night and morning for eight days before she is brought to the horse. If she refuse it alone, it may be mixed with beans or oats, and will go down; and if the stallion eat of it, it will force him also; but it must be remembered that these provocatives are unnatural, and often defeat their own purposes. They

are therefore seldom now resorted to among intelligent breeders. Still more improper is it to attempt an early horsing, by injecting stimulating fluids up the vagina as is sometimes done; for when it succeeds, the future progeny seldom answers the expectation.

6640. The treatment of a pregnant mare is in general little different from that of any other horse. Mares of draught are worked in summer as usual, and more moderately in the ensuing winter, till near the time of foaling; when, if the season be somewhat advanced, even though the pasture be not fully sufficient for their maintenance, they should be turned out to some grass field near the homestead, and receive what additional supply of food may be necessary under sheds adjoining. It is both inconvenient and dangerous to confine a mare about to foal in a common stable, and still more so to leave her loose in a close stable among other horses; and confinement is not much less objectionable after dropping her foal.

her loose in a close stable among other horses; and confinement is not much less objectionable after dropping her foal.

6641. Breeding mares are usually worked through the greatest part of the year, laying them aside only for a week or two before foaling, and during the summer season, when giving suck to the young foal. In this way, Brown observes, the strength and vigour of the mother is not only weakened, but the size and power of the foal stand a great chance of being diminished, by the exertions of the mother when kept at work. Under these impressions we are led to consider the working of breeding mares as an unprofitable practice. Were they suffered to remain at ease, to roam upon coarse pastures, where sheds were erected in which they might find shelter during inclement weather, we are almost certain that their progeny would enter upon action with increased abilities. The expense of a breeding mare kept in this way would not be great, whilst the advantages would be innumerable. In Yorkshire, and in those midland counties where the breeding and rearing of horses is better understood than in any other part of the island, they are often worked till the very time of foaling. Great care, however, is necessary in working and managing a mare heavy with foal: an over-heat, too severe exercise, a fright, or a sudden and violent jerk, are very apt to cause an untimely birth, whereby the foal is lost, and the life of the mare very much endangered.

endangered.

6642. In the mountains of Wales, and in the Highlands of Scotland, the breeding mares are never worked during the summer. They are driven to the hills and mountains at the close of the barley-seed season, where they remain till the inclemency of the weather forces them to return for shelter. But their scanty subsistence, the labour they are subjected to in procuring their food, and the moistness and coldness of the climate in the latter part of the season, render both themselves and their progeny of but little

value and importance.
6643. Farms, consisting chiefly of pasture land unfit for feeding, are the situations where breeding is generally carried on. Arable farmers may breed occasionally; but the inconvenience of wanting any part of their working stock at the time of foaling operates almost as a prohition to the breeding of horses. The greater number of horses are bred in situations where a small portion of arable land is attached to farms chiefly occupied with cattle or sheep; or where the farms are small as not to afford full and constant employment to the number of horses that must, nevertheless, be kept for the labour of particular assessors. particular seasons.

SECT. XI. Rearing of Horses.

SECT. XI. Rearing of Horses.

6614. Rearing includes the treatment of the foal till it is fit to work, or to be put in training for use, and also the treatment of the mother till she has weaned her foal.

6615. In regard to the treatment of the mother till she has weaned her foal in England, and in the improved parts of Scotland, a mare after having foaled is turned, together with the foal, into a pasture field, and is allowed two or three weeks' rest, before she is again worked, either in plough or cart; the foal being allowed to suck at pleasure during the time. After having had a few weeks' rest, he is again worked in the usual manner; the foal being commonly shut up in a house during the hours of working. In Yorkshire, some farmers are particularly careful not to allow the mare to go near the foal, after her return from labour, till her udder has been bathed with cold water, and not till most of the milk is drawn from it. These precautions are used with a view of preventing any bad consequences from the foal's receiving over-heated milk. Another practice, and which is superior to the above, is also common in Yorkshire, and in many parts of Scotland: — After the foal is a few weeks old, and has acquired strength and agility enough to follow its mother, it is allowed to attend her in the field during the hours of labour, and to suck occasionally. By this means, not only does the foal receive sufficient exercise; nor can any prejudicial effect happen from the over-heated state of the milk, as the foal is allowed to draw it off repeatedly, and at short intervals; but the little animal becomes hardy, and loses all timidity, and afterwards requires less breaking: these may be considered as the general modes of management in those parts of the kingdom mentioned above, during the period while the foal is allowed to suck its dam, which foals are generally weaned, or prevented from sucking. Breeding mares are evidently unable to endure the fatigue of constant labour, for some months before and after parturition: this

aways to noise the loais there during that season.

6648. During the first winter foals are fed on hay with a little corn, but should not be constantly confined to the stable; for even when there is nothing to be got on the fields, it is much in their favour to be allowed exercise out of doors. A considerable proportion of succulent food, such as potatoese, carrots, and Swedish turnips (oil-cake has been recommended), should be given them through the next winter, and beans and peas meal has been advantageously substituted for cats; but which, if allowed in a considerable quantity, are injurious to the thriving of the young animal, from their heating and astringent

6649. During the following summer their pasture depends upon the circumstances of the farms on which they are reared. In the second winter they are fed in much the same manner as in the first, except that straw may be given for some months instead of hay; and in the third winter they have a greater allowance of corn, as they are frequently worked at the harrows in the ensuing spring. (General Report of Scotland, vol. iii. p. 183.) When about three years old, the author of the New Farmer's Calendar advices

foals to be fed all winter with a little corn twice a day, with hay, oat-straw, &c. Where carrots can be procured, they form a most excellent feed for colts of every age, on which they will thrive surprisingly. With the use of carrots, no corn is necessary, nor any caution requisite against an over-heating effect from a more stimulating diet. Care should, however, be taken to cut them properly, allowing a well littered shed, or warm straw-yard. Colts fed at home with green meat, cut during summer, should have a daily range on a common, or elsewhere, for exercise. Yearlings to be carefully kept separate from the milet

shed, or warm straw-yard. Cots fed at home with green meat, cut during summer, should have a daily range on a common, or elsewhere, for exercise. Yearlings to be carefully kept separate from the milch mares.

6:50. The time for gelding colds is usually the same in both parts of the kingdom, which is, when they are about a year old; although, in Yorkshire, this operation is frequently suspended till the spring of the second year, especially when it is intended to keep them on hand, and without employing them in labour till the following season. Parkinson disapproves of delaying this operation so long, and recommends twitching the colts, a practice well known to the ram-breeders, any time after a week old, or as soon after as the testicles are come down; and this method, he says, he has followed himself with great success. (Parkinson on Live Stock, vol. it. p. 74.) Blaine's remarks on the subject of castration appear worthy of notice: he says, when the breed is particularly good, and considerable expectations are formed on the colt, it is always prudent to wait till twelve months: at this period, if his fore parts are correspondent with his hinder, proceed to castrate; but if he be not sufficiently well up before, or his neck be too long and thin, and his shoulders spare, he will assuredly improve by being allowed to remain whole six or eight months longer. Another writer suggests for experiment; the spanjing of mares, thinking they would work better, and have more wind than geldings. (Marshul's Yorkshire, vol. it, p. 169.) But he does not appear to have been aware that this is by no means a new experiment; for Tusser, who wrote in 1625, peaks of gelding fillies as a common practice at that period. The main objection to this operation is not that brood mares would become scarce, as he supposes, but that, by mecapacitating them from breeding in case of accident, and in old age, the loss in this expensive species of live-stock would be greatly enhanced. An old or lame remained to the process of the common of the pr

SECT. XII. Training of Horses.

6553. Horses are trained for various purposes, but principally for carrying our persons or drawing our burdens. Formerly, burdens were principally borne on the back by pack-horses, but the improvements in our roads have removed them from the back, to machines called carriages, drawn by means of barness applied over the person of the horse. Under saddle, we train horses as racers, hunters, hackneys, or troop horses. In harness we use them in coaches, stages, chariots, and various lighter vehicles, or we employ them in waggons, carts, ploughs, and various other agricultural or commercial machines. Horses are held in obedience by means of bridles, with appendages called reins, which are long or short, as used in riding or driving. Horses are directed and urged forward by whip, spur, and language, and they are chastised by the same means. by the same means.

by the same means.
6634. The directive language used to horses ought to be every where the same, which is the more easily accomplished, as words or phrases are sufficient for giving every requisite direction to a horse. The first of these words may be "on," or go on, or merely the common chuck of the tongue, &c. as used by all coachmen in the world; the second to make the horse go to the right-hand side, "right-hand;" the third, to the left-hand side, "left-hand," the fourth to make them stop, may be "stop," or "stand-still." Any attempt to modify these directions ought to be given in the correct language of the country, and not in provincial words, as go on, slowly, briskly, right-hand, a little round, or turn, left-hand, a little, or left-hand and round, stop, or stand gently, &c. As a proof that only four words are requisite for giving every requisite direction to horses, we may mention that foreigners in Stockholm, Petersburgh, and Moscow, who know nothing of the language, require only four corresponding words of Swedish or Russian to direct the native coachmen and sledge drivers to any street, house, or place, the situation of which they know by the maps, or otherwise.

know by the maps, or otherwise.
6655. The three natural and ordinary movements of horses are, walking, trotting, and galloping, to which some horses naturally add another, which is known by the name of "ambling," or "pacing,"
The trot is, perhaps, the most natural motion of a horse, but the pace, and even the gallop, are most easy

to the rider.
6696. In training saddle horses, the first thing is to make them familiar with man, and other general objects, and which is best effected at the earliest periods, which then saves almost all the trouble of breaking, and docility follows as a matter of course: to effect this, the greatest kindness should be used to the colts from the moment they are dropped: they should be accustomed to be handled, should be fed with bread patted in various parts of the body, have light matters put on their heads and backs, and subjects of different colours and forms should be shown them with caution. While at foot, the mare and foal should be led out into roads, and where carriages pass, during which time nothing should be allowed to intimidate the foal. By this management, the animal will be easily prepared for the future operations; and it is thus that the single foal the ploughed-land farmer breeds, and which daily follows the mother in her work as it were break itself.

and it is thus that the single to the ploughed-land farmer oreeds, and which daily flows are inches in her work, as it were breaks itself.

6657. Bucking is the next operation, and if the colt has been judiciously used, and taught familiarity and docility by early handling and kindness, it is by no means difficult. It should be commenced before the colt is two and a half or three years old. The first backing of a horse is a thing of great consequence, as his value afterwards very much depends of it. The application of the saddle should be gradually done, and without alarm to the horse. After a colt has become habituated to the saddle and bridle, and has been exercised some time, morning and evening in them, and become somewhat obedient, it is usually

recommended that he be taken to some ploughed land, where he is to be walked and trotted until he be slightly fatigued. If the colt he very high spirited or refractory, or if he be not inclined to lift up his legs sufficiently, it may be admissible to practise him on some very light-ploughed lands; but if otherwise, it is better to dispense with this, and a field and a road alternately used will, in general cases, be found preferable. It would be well that this preliminary practice should be performed in a cases on to ensure obedience. When he is perfectly tractable during his exercise, let a person used to him lay himself gently and by degrees across his back; and if he seem not to be alarmed, let him proceed at a foot-pace with his burden. When this occasions no alarm, let one leg gradually be slid over his back, the person at his head engaging his attention during the time, and encouraging him. The rider may then gradually raise himself up. The next step will be to mount him at once in the usual way, still having a judicious attendant at his head; this must likewise by no means be done suddenly, or at a jerk, but very gradually and slowly, by several risings and heavings. If he bear this patiently, the person is to seat himself firmly on his back; but if he be troublesome and not tame enough, the person is to forbear the attempt to mount, and he is to be trotted in the hand over the same ploughed lands or other ground again, till he is more fatigued, and willing to receive the rider quietly on his back: when this is done, the person who is on his back must encouraging him. The feet are to be fitted well in the stirrups, and the toesturned out; afterwards the rider is to shrink and movehimself in the saddle, and the person who holds his head is to withdraw his hand a little farther from the mouth. As the rider moves his toes forward, the holder must move him forward with the rein, till he is made to apprehend the rider's motion of body and foot, which must always got together, and with spirit, and will go for

in order.

**Bodden and the state of the different movements of walking, trotting, gattoping, and amoung, and one may observe, by the horse's lifting up its two legs on a side, the one after the other, beginning with the hind leg first. Thus, if he leads with the legs of the right side, then the first foot he lifts is the far hind foot; and in the time he is setting it down (which in a step is always short of the tread of his fore foot on the same side) he lifts his far fore foot, and ests it down before his near fore foot. Again, just as he is setting down his far fore foot, the lifts up his near hind foot, and sets it down again just short of his near fore foot, and just as he is setting it down, he lifts his near fore foot, and sets it down beyond his far fore foot. This is the true motion of a horse's legs in a walk; and this is the pace in which many things are best taught; for instance, when the horse is to be taught to turn to the right and left, or from one hand to another, he is first to be taught it on the walk, then on the trot, and finally on the gallop. The walk is a pace to which team, carriage, and road horses should constantly be well broke, as being of great use in all such cases and intentions. It is an excellent pace too in a saddle horse, when we well performed by being properly taught.

such cases and intentions. It is an excellent pace too in a saume noise, when the properly taught.

6000. In trotting, the limbs are diagonally employed; but their tenses or times, or rising and falling, are very different, as it is conducted slow or fast. In the slow trot the diagonal legs are elevated and replaced simultaneously; while those on the ground are preparing to elevate themselves, and the horse is for a moment on tiptoe; but until the original diagonal legs are set down, these are not whelly elevated; therefore the horse is during the moderate trot at no time without support. But it is very different when the trot is accelerated, as to nine or ten miles an hour; for then there is a period in every spring made by the diagonal members, when all the feet are in the air at the same time; and the body completely suspended from the ground by these means. Thus during this accelerated action, the off fore leg and near hind leg having been elevated in the air, before they meet the ground.

in the air, before they meet the ground, the near fore leg and the off hind one

in the air, before they meet the ground, the near fore leg and the off hind one are nor only prepared, as in the slow trot, to elevate themselves, but actually do so before the others are set down; consequently, the feet, at this precise time, must be all in air. (fig. 846.) To speed in the trot, it is necessary that a horse pick up his feet quick, and extend them far forward. To the safety also, it is necessary the development of the safety also, it is necessary the development of the safety also, it is necessary the same time the general elevation of the whole limb is operated by high withers and oblique shoulders.

6661. Three qualities are essenticilly necessary to make the trot useful. It ought to be extended, supple, and even, or equal: these three qualities mutually depend upon each other, so that you cannot pass to the supple trot without having first worked upon the extended trot; and you can never arrive at the even and equal trot without having practised the supple. The extended trot (fig. 846.) is that in which the horse trots out without retaining himself, going directly forwards; and this consequently is the kind of trot with which you must begin. The supple trot is that in which the hore, at every motion he makes, bends and plays his joints by the elasticity of the organs composing them; which no colts or raw horses can execute, who have not had their limbs suppled by exercise. The even or equal trot is that in which the horse; and when by exercise he has attained sufficient ease and suppleness to manage his limbs readily, you must insensibly hold him in still more and more, and by degrees you will lead him to the equal trot.

662. The manner of trotting a colt who has never been backed is as follows:—Put a plain snaffle in his mouth; if it a cavesson to his never been backed is as follows:—Put a plain snaffle in his mouth; if it a cavesson to his never been backed is as follows:—Put a plain snaffle in his

the equal trot."
6662. The manner of trotting a colt who has never been backed is as follows:—Put a plain snaffle in his mouth; fit a cavesson to his nose, to the ring of which tie a longe of a reasonable length. Let a groom hold this longe, who having got at some distance from the colt, must stand still in the middle of the circle which the horse will make. Let another follow him with a long whip or chambrière in his hand. The cold being alarmed, will be forced to go forward, and to turn within the length of the cord, the groom must hold it tight in his hand; by this means he will draw in, or towards the centre, the head of the colt, and his croupe will of consequence be without the circle. In working a young horse after this manner do not press or hurry him. Let him walk first, and alterwards put him to the trot. If you neglect this method his legs will be embarrassed: he will lean on one side, and be more upon one haunch than the other; the inner fore foot will strike against the outer one, and the pain which this will occasion will drive him to seek some means of defence, and make him disobedient. If he refuses to trot, the person who holds

the chambrière will animate him by trotting him, or striking the ground with it. If he offers to gallop instead of trotting, the groom must shake or jerk the cord that is tied to the cavesson, and he will fall into his trot. (Berenger's Art of Horsemanship, vol. i. chap. 4.) The value of this longing in a circle is incalculable, inasmuch as it supples the shoulders, and gives them a greater extent of action. It also increases the action of the whole limb downwards, and accustoms the horse to effect other movements, to be

performed with an elevated hand.

reases the action of the whole limb downwards, and accustoms the horse to effect other movements, to be performed with an elevated hand.

6653. The gallop is the swiftest natural pace of a horse, in which the two fore feet become elevated almost at the same moment, but one slightly takes the lead of the other, and must therefore be set down beyond and somewhat after it; previous to this, however, the hinder legs have become elevated, with also a little precedence in the leg of that side which has been led by the fore. Such is the natural gallop of the horse; when it is performed with its utmost velocity the limbs are simultaneous and synchronous, (6664.) In galloping the horse may lead with which fore leg he pleases; the most usual way is that with the right, in which case the gallop is said to be just; but whichsoever it be, the hind leg of the same side must follow it next, which forms an even or equal gallop; otherwise the legs are said to be disunited, and the gallop to be faise; to remedy which disorder, the rider must stay the horse at little on the hand, and help him on the spur on the contrary side to that on which he is disunited. However, this rule has not been always strictly observed; for hunting horses have been trained to lead indifferently with both legs, because it has been found, that a horse which has never been suffered to gallop hut with his right fore leg, has been worn out on one side, when he has been fresh and sound on the other. In order to make a stop in a gallop straight forwards, the rider should carefully put his horse together, without altering or disturbing the appui, and throw his body back a little to accompany the action, and to relieve the horse's shoulders. In doing this he should seize the time of making the stop, keeping the hand and body quite still, exactly when he feels the horse put his fore feet to the ground, in order that by raising them immediately by the next motion which he makes, he may be upon his haunches, when he is piuched, he should be kept in the hand. To p

the horse is confined always to lead with his fore leg within the turn; otherwise he is said to gallop false.

6364. The varieties of gallop may be reduced to the gallop of speed, the ordinary or hand gallop, and the canter: all others are but compounds of these. The gallop of full speed is the most simple of all the paces, being nothing more than a succession of leaps; but it requires repeated efforts to acquire its full celerity: the fore parts being first raised and thrown forwards are followed by the hinder immediately; as the velocity increases, the fore and the hind legs become opposed to the ground at almost the same instant, thus forming a repetition of leaps. The ordinary or hand gallop does not differ from the gallop (6363.), except that the leading leg being elevated still earlier, and being carried still more forward, is followed also by an earlier and a more considerable displacement of its fellow leg behind, which of course retards the velocity considerably, and lessens the exertion. The school gallop is formed of this, with the haunches drawn more under, and the fore hand more thrown up.

6363. The canter is different from the gallop in some essential particulars. Whether the gallop be fast or slow, still the legs are at one period wholly removed from the ground, and the horse is all in air. In the canter, on the contrary, at no period is the horse completely elevated from the ground but has always one or more points of contact with it. Blaine describes its operation thus: — When performed on the right, the horse commences by first placing his off hind leg a little beyond the other; at hearly the same instant he elevates the fore hand, and places first the near fore leg on the ground; the off doubling over and beyond, is placed in an instant after it. In the next movement the hind legs are thrown in, and, while elevated, the off fore leg becomes raised from the ground; but the near fore leg is not elevated until the hinder ones are replaced. The more fore leg is, therefore, the whole point of sup

fore can never be required of the farmer or breeder.

6698. The training of coach horses commences with taming, walking, trotting, and repeated longing; and next with yoking and driving in a break or four-wheeled frame, with no other load than that of the coach box or seat placed in the usual position, the driver and his assistant sitting on a board fixed to the perch or hind axle, in order to be ready at a moment's notice to descend and restrain or direct the horses. Coach horses, from fifteen to sixteen hands high, should walk light five miles an hour, and trot twelve. They should be first accustomed to this exercise in the country, next in the outskirts of a large city, and

lastly in the most crowded streets

lastly in the most crowded streets.

6639. The age at which a horse is fit to be worked in a coach is four and a half or five years; but by the fraudulent practice both of the country and town dealers, horses of three and four years old are frequently employed. The first business of the Yorkshire dealer, who has three or four years old colts to dispose of; is to draw their corner teeth, in order to make them have the mouths of those of five. The also undergo the operation of docking and nicking; and after having been kept two or three months on mashes, made of bran, ground oats, or boiled corn, they are sold to the London dealers, who, it is said, sell these three or four years old horses as if they were five years old. They are then taken into immediate work, either for the coach or saddle; and in a few months are completely destroyed by this premature and too severe labour. The drawing of the teeth is not a fraud practised on the London dealers; they know the deception, and insist upon its being done by the country dealers. It is requisite to be done some months before the London dealers finally sell them for use, or the tooth which denotes a horse to be five years old would not be grown, consequently the deception could not have taken place.

6670. The training of cart and plough horses commences with taming before they are a year old, with walking and rubbing them down in the stable when they are two, and with training to work when they are of three years' growth. They should be placed under the charge of a very steady careful servant, who

will teach them to back, and to go into the shafts. They ought not, however, to be made to draw any other than a very light empty cart till their fourth or fifth year; nor ought they to be put into the shafts of a threshing machine before their fifth year. The first work to which an agricultural horse may be applied is harrowing; but this during the fourth year only half a day at a time, or with a light harrow the whole day. Next he may be put to plough with similar care and caution in regard to strength. In general, agricultural horses require very little training; but one thing is too often neglected, and that is, teaching plough horses a quick step, and keeping them at that step ever after in working them. By not attending to this, and leaving the step to be regulated by lazy spiritless ploughmen, the loss to many farmers is very considerable.

SECT. XIII. The Art of Horsemanship.

Sect. XIII. The Art of Horsemanship.

6671. Horsemanship, as an art, is unquestionably of very ancient date, and it is curious how very different are the modes by which it is practised in different countries; but which differences are yet principally confined to the situation of the legs of the rider; for wherever the horse is used to carry the person, it is by the rider placing himself astride the animal. Horses were used in this way for centuries before any apparatus was used or applied to their bodies to spare fatigue to the rider; and we know that the first saddles were mere pads strapped round the body, but without the appendages of stirrups. In England, riding is systematically divided into two kinds, which are manege and jockey riding.

6672. Manege riding, called also riding the great horse, in the strict application of the term, was formerly more practised than at present; and required a system of education for both horse and rider long and severe. Horses perfectly broke for the manege were formerly taught several paces and motions, as ambling, pacing, passaging, yerking, capriole, and cornetti. The practice of these artificial cadences, it is supposed, injures the natural pace of the horse; and this circumstance, united to a particular form of horse (edective for other purposes) being required for the elasticity of these actions, has tended to bring manege riding, as formerly practised, into disrepute. Manege riding also taught the constant application of the seat of the body of the rider to the seat of the saddle, during all the motions of the horse; and as a severe education, and a particular form, had bestowed ease and elasticity to the rudeness of the manege horse, the inconveniences of this seat were not felt. But when another form of horse, capable of great speed over excellent roads, was in general use, this kind of riding was found hurtful to both horse and rider; fatiguing the one, and injuring the other.

6673. The art of proper riding, as practised among experienced horsemen, is derived fro

and a jockey seat.

6674. The use of the curb bridle is considered in the schools to be essential to good riding: by it the horse is not only restrained, but he is also aided and assisted. He is alternately thrown on his haunches, or forced on his forehand, by which changes fatigue is prevented to both. Great nicety, however, is required in the use of the curb; and without an inclination and ability to use it lightly and dexterously, a snaffle is the best and safest bridle. The curb is to be operated by a gentle turn of the wrist only; and the action of the band in this respect should be as fine and as pliable as the fishing rod and line. The force of the curb should in every instance be proportioned to the mouth of the horse.

6675. The best form of saddle for general riding is one in which the cantle is not so high as the military, nor so low as the racing saddle. The pommel should be no more raised than is necessary to keep the whole completely free from the withers. The stirrups should be substantial, not only to prevent breaking, but also that by their weight they may fall to the foot when accidentally slipped away; which is of more consequence than at first sight may appear. If they are of the spring kind, it is also desirable: but it is still more so, that the spring stirrup leather should be used; which prevents the danger arising from horses catching the leather in the projections of doors, gates, &c. Having saddled and bridled our horse, we will proceed to mount our rider.

proceed to mount our rider.

6676. If you would mount with case and safety, says Hughes, stand rather before the stirrup than behind it; then, with the left hand, take the bridle short, and the mane together, help yourself into the stirrup, with your right, so that, in mounting, your toe do not touch the horse. Your foot being in the stirrup rise yourself till you face the side of the horse, and look directly across the saddle; then, with your right hand, lay hold of the hinder part of the saddle be square, and the purchase of your bridle such as not to pull your shoulders: and let your body be in such an even posture as if you held a rein in each hand. In holding the bridle, grasp the reins with your hand, which should be held perpendicular with the reins passed, the lower within the hand, and the upper between the fore and next fingers (1/g. 847). The reins are then brought over the fore finger and firmly held by the thumb. It is often directed to place the little finger between the lower reins; the practice

Inger and army need by the future. It is often directed to place the little finger between the lower reins; the practice of this may be optional with the rider, and in a very fine hand is desirable. The bridle should be held at such a length as to enable you if your horse stumbles, to raise his head and support it with your arms; and by throwing your body backwards at the same time you frequently save a horse that would otherwise fall.

the same time you requently save a horse that would otherwise fall.

6677. A graceful and proper seat on horseback is greatly dependent on a right disposition of the legs and thighs, which from above; by placing the body flat and evenly on the saddle, and opening the knees, whereby the fork will come lower on the saddle. (fig. 848.) The thighs should be applied to the saddle and to the sides of the horse by their inner surfaces, so as to bring in the knees and toes; and although the line may be properly broken by some little irregularities, yet the foot, the knee, the hip, and shoulder, should deviate but little from one perpendicular line. The ball of the foot should rest within the stirrup, and should be even with the heel, or very slightly elevated above it. Avoid any stiffness in the legs, thighs, or body; all should be lax, but in a state to be able to embrace the horse, either for support, or as alds to lim. The loins, particularly, should be lax and pliable, as a coachman's on his box; and for the same reasons: for by sitting thus loosely, the rough motions of both are broken. To depend on the embrace of the knees for support is to lose the benefit of a true equipoise of body, and is rather to stick on a horse than to sit on one.

6778. When you are troubled with a horse that is vicious, which stops short, or, by rising or kicking, endeavours to throw you off, you must not bend your body forward, as is commonly practised in such cases; because that motion throws the breech backward, and moves you from your fork, or twists and casts you out of your seat; but the right way to keep your seat, or to

recover it when lost, is to advance the lower part of your body, and to bend back your shoulders and upper part. In flying or standing leaps, a horseman's best security is the bending back of the body. The rising of the horse does not affect the rider's seat; he is chiefly to guard against the lash of the animal's hind legs, which is best done by inclining the body backwards. But the usual method of fixing the knees in all cases of danger only serves, in great shocks, to assist the violence of the fall. To save yourself from being hurt, in these cases, you must yield a little to the horse's motion; by which means you will recover your seat, if displaced, or keep it at such times as would dismount an unskilful horseman.

**679. If your horse grows unraying, take the reins separately, one in each hand, put your arms forward, and hold him short, but do not pull hard with your arms low; for, by lowering his head, he has the more liberty; to throw out his heels: but if you raise his head as high as you can, this will prevent him from rising behind. Is it not reasonable to imagine, that, if a horse is forced towards a carriage which he has purring him on, with his face directly to it, he should understand as a sign to pass it? These rational queries are submitted to the serious consideration of such as are fond of always obliging their horses to touch those objects at which they are, or affect to be, frightened.

queries are submitted to the serious consideration of such as are fond of always obliging their horses to touch those objects at which they are, or affect to be, frightened.

6690. Indifferent horsemen, Lawrence observes, should never venture on horseback without spurs. Those who reflect upon the predicament of being placed between a deep ditch and a carriage, at which their horse shies, will see the necessity of this precaution.

6691. Previously to mounting, every person will find his account in examining the state of both horse and furniture with his own eyes and hands; for, however good and careful his groom may generally be, it is a maxim, that too much ought not to be expected from the head of him who labours with his hands. Besides, all such sedulously avoid trouble, particularly in nice matters. For example, see that your curb is right, that your reins are not twisted; that your griths, one over the other, still bear exactly alike; that the paid be not wrinkled up; but, above all, that your saddle lies exactly level upon the horse's back events.

back. On getting off the horse's back, hold the bridle and mane in the same manner as when you mounted, hold the pommel of the saddle with your right-hand; to raise yourself, bring your right leg over the horse's back, let your right-hand hold the hind part of the saddle, and stand a moment on your stirrup, just as when you mounted. But beware that, in dismounting, you bend not your right knee, lest the horse

the horse's back, let your right-hand hold the hind part of the saddle, and stand a moment on your stirrup, just as when you mounted. But beware that, in dismounting, you bend not your right knee, lest the horse should be touched by the spur.

638. The jockey mode of riding is practised in its fullest extent in racing. With some modification it is also in use by many who esteem themselves excellent fox-hunters. With still greater modification it is by its advocates practised also on the road. English post-boys unite these two kinds of riding in a manner at once easy to themselves and horses. True jockey riding consists in the use of a snaffle bridle, which is horse the proper pulls. To this end, the same writer recommends a firm seat, upright, and as you would sit in a chair, with the knees nearly as much bent, and turned inward; the toes somewhat out and upward; the leg falling nearly straight, and the foot home in the stirrup (fig. 849); elbows close to the sides; hands rather above the horse's withers, or pommel of the saddle; and the view directed between his cars. The same writer further advocates the jockey mode, by commenting on the decline of riding-house forms, and the universal preference given to expedition, which, as he says, fully confirm the superior use and propriety of a jockey-seat. Indeed, our riding-schools are now, he continues, considerably reformed from the stiffness of ancient practice in all respects. It was the custom formerly in the schools, and indeed pretty generally upon the road, to ride with the tip of the toe only in the stirrup; as if it were of more consequence to prepare for falling with safety, than to endeavour to sit securely. Those who preserve a partiality for this venerable custom, we would advise to suspend a final judgment, until they have made a few more essays upon a huge cock-tail half-bred, of that kind which 'cannot go, and yet won't stand still,' and will dart from one side of the road to the other, as if he really desired to get rid of his burden. Nor is the bal

toe, the one in, the other outward.

SECT. XIV. Feeding of Horses.

Sect. XIV. Feeding of Horses.

6683. The feeding of horses generally is an important feature in their management. In considering the food for horses, we are apt to locate our notions to the matters around us, without taking into account that every country has its peculiar products. White observes, that the best food for horses is hay and oats; and had he added for English horses, it might have been just, but without such notice the assertion is much too confined. "In some sterile countries, horses are forced to subsist on dried fish, and even vecetable mould; in Arabia, on milk, flesh bails, eggs, broth, &c. In India, horses are variously fed. The native grasses I judge very nutritious. Few, perhaps no oats are grown in India. Barley is not commonly given to horses; indeed, it is rarely grown. In Persia, barley is a common food for good horses. In some parts of India (in the Mahratta country), salt, pepper, and other spices are made up into balls, as big as billiard balls, with flour and butter, and thrust down the animal's throat. It is supposed to give them animation and fine coats: no doubt it promotes digestion. Meat broth (especially sheep's head) is also given to horses. English gentlemen sometimes adopt these usages. Different hists of grain are given to horses in different parts of India. In Bengal, a vetch, something like the tare, is used. On the western side of India, a sort of pigeon pea, called gram (Ciccr ariethum Z.), is the usual food; with grass in the season, and hay all the year. Indian corn or rice is, I think, seldom if ever given to horses in India as ordinary food. In the West Indies they are fed on maize, Guinea corn, and sugar-cane tops; and, in some instances, on the sugar itself, in the form of molasses. In France, Spain, and Italy, besides the grasses, the leaves of limes, vines, the tops of acacia, the seeds of the carob tree, &c. are used."

6885. The food of British horses may be divided into herbage, grain, roots, and mixtures. Of herbage, the principal kind is the proper gramina

wanted.

6666. Hay should never be given in large quantities at a time; horses breathe on it, become disgusted, and then waste it. They also, when it is good, eat too much, and distend their stomachs, and then become crib-biters. Hay should not be kept in the stable in great quantities, otherwise it becomes impregnated with the volatile alkali of the stable, and is then spoiled. As substitutes for hay, the strawof wheat, barley, oats, and rye are used; but these are much less nutritive, and rather serve to excite mastication by mixing them with other matters, than to be depended on for animalisation. On hay, when good, many horses subsist; and when no exertions are required of them they are sufficiently nourished by it.

6667. The wrain used as barse find is of various kinds, possessing, it is supposed different degrees of

by it. 6687. The grain used as horse food is of various kinds, possessing, it is supposed, different degrees of nutriment, according to their different proportions of gluten, sugar, or farinaceous matter. In South Britain, oats are almost exclusively used as horse grain; and which, according to the experiments of Sir Humphry Davy, as we have seen (\$ 5000.), contain 748 parts of nutritious matter out of 1000. In wheat, 955 parts of 1000 are nutritious; but wheat is seldom given with us except to racers and hunters, or on extraordinary occasions when great excitement is required, when it is sometimes given in the form of bread. Barley is more frequently given than wheat, and contains 920 parts in 1000 of nutritious particles. Made into malt, where its sugar is evolved, it becomes still more highly nutritious. Barley appears to have been the principal horse food of the ancients.
6688. The pulse used as horse food, are the seeds of beans, peas, vetches, &c. Beans are seldom given alone on account of their heating and astringent qualities, but are mixed with straw or hay, cut into chaff, either whole or broken.

either whole or broken.

6689. The roots used as horse food, are such as contain much sugar, but in which the gluten is in small proportion only. Carrots stand deservedly high on this list. They are favourable to condition, as the skin and hair always look well under their use. They are highly nutritious we know, from the fattening that occurs from them. They also generate good flesh, as we know horses can work on them, and have their wind increased by their use; indeed, so favourable are they to the proper action of the lungs, that a course of carrots will frequently remove the most obstinate coughs. The parsnep has similar properties. Swedish turnips, as having the saccharine particles in abundance, are also found good. Eventually the saccharine particles in abundance, are also found good.

root likewise, or mixed food, is formed of several kinds among agriculturists; and it possesses many advantages, as it can be varied to every taste, and made either cooling as an alterative, or nutritious and stimulating as a tonic. Although it is principally used for waggon, post, and farm horses, it would be better were its use more universal. Of this manger feeding, one of the best is formed from a chalf made of one part best meadow or clover hay, and two parts wheaten straw; to three bushels of this mixture add one of bruised oats. The importance of bruising or flattening the oats is every great. When used whole, the grains are apt to slip between the teeth or the chaff in mastication. In fact, corn when either given alone, or with chaff, would, in most instances, benefit by bruising. To horses mader great exertion, the stomach must be, to a certain degree, weakened also; in such cases, by bruising their corn, not only the work of mastication is much of it spared, but that of the stomach also. In old horses with worn teeth, bruised oats are of great consequence. Fast-eating horses do not properly masticate more than one half of their corn; much of it remains in the dung so perfectly unaltered, that it will afterwards vegetate; and an experienced agriculturist states, that during his residence in India, in a season of scarcity, half-famished wretches actually followed the cavalry, and drew their principal subsistence from the unchewed grains of corn extracted from the excrement of the horses. Of this manger took, free, four, five, or six pecks may be given daily, according to size and exertions required; and as but little hay is required, so hard-worked horses are enabled to lie down much more, instead of standing on their already fatigued limbs to eat hay. limbs to eat hay.

6691. Cooked food is also now much used by practical agriculturists for horses. The articles made use of are potatoes, carrots, turnips, or parsneps. To horses with their digestion weakened by hard work, old age, or other causes, food in sufficient quantities, thus already reduced to a pultaceous mass, resembling chyme, without the loss of time, or the waste of saliva, may be very important: for, as Curwen very judiciously observes, a horse will consume nearly six hours in eating a stone of hay, whereas he will eat a stone of steamed potatoes in twenty minutes. Horses are observed of themselves to lie down after eating

cooked food sooner than other times

cooked food sooner than other times.
6692. The quantity of food to be given to a horse must be regulated by circumstances, the principle of which is the exertions or nature of the work required of him. If this be simply laborious, as drawing of loads, or carrying of weights, all that is requisite is that the food be sufficiently nutritious. The bulk from whence such nutriment is gained is not a matter of import: but if such exertions are to be combined with celerity, as in our racers, hunters, &c., it is evident that such feeding is best adapted to the end required which combines nutriment without bulk; and which increases the durability by incressing the mental irritability, and thus giving tone and courage. These are found to be better derived from a proportionate allowance of grain or corn, than any other mode of feeding at present known. It remains only to add, that although experience has fully proved this, in all cases where the exertions are extreme, yet it has also led to another evil, by introducing a plan of treating all horses of value alike. Thus, most of the more valuable hackneys, the carriage horses of the wealthy, &c., are accustomed to be fed, not as though their exertions were moderate, but as though they were unceasing, to the destruction of a vast quantity of valuable corn. From thousands of such horses, at least one third of their hay and corn might be advantageously abstracted.

6693. Too great a quantity of food injures not only the community but the horse also. The stomach

6693. Too great a quantity of food injures not only the community but the horse also. The stomach becomes distended by over-feeding, and it then becomes weak and incapable of a healthy digestion; cribbiting, hide-bound, and pursiveness follow; or when the stomach does digest this undue quantity, it generate fulness, which shows itself in inflammations or foulness, appearing in the form of cracks and

grease.

6694. A horse in full work, of whatever kind, will require, according to his size, a peck of sound oats in twenty-four hours; and when the work is unremitting, as in post, stage-waggon, or other very large and hard-working horses, even more may be required. Some post horses have an unlimited quantity given them; but this practice is always erroneous. If they eat more, it serves only to distend the stomach unduly, and also to require stronger digestive powers: if they blow on it they leave it, and it is wasted, or a more greedy one swallows it up without mastication; and both stomach, horse, and master are thereby robbed. It is for consequence that the oats, as an important part of horse food, should be perfectly sweet, free from must, and not kiln-dried. The skin should be thin, but the grain plump and heavy, yielding from thirty-eight to forty pounds the bushel. To encourage a slow and thorough mastication, sprinkley them with water and spread them well over the manger. The quantity of hay required for saddle horses which are corn-fed is from six to eight pounds in twenty-four hours: if the quantity of corn be small, and whe horse large, ten or twelve pounds is not too much. This quantity is also sufficient for carriage or coach horses, as they usually have either corn or mixed food in sufficient plenty also. For waggon and the larger agricultural horses, from fifteen to twenty pounds may be requisited. When it can be conveniently done, the quantity of both hay and corn should be given at night; the ricx in quantity in the norm ing; the other two portions at noon, and about four in the alternoon. This, however, must depend on the work of the horse, and other circumstances.

6695. Watering of horses is an important part of their management, and many errors are committed relative to it. It is equally erroneous to debar then from it, as it is to allow them too much; and the former is much the most common evil. In summer, or when from great perspiration the animal juices

are wasted, it generates fevers, and wastes the strength and spirits. All horses prefer soft water, and as nature is unerring, there is no doubt but that it is the most wholesome. As some horses drink quicker

nature is unerring, there is no doubt but that it is the most wholesome. As some horses drink quicker than others, it is not a good custom to take riding horses to a pond, unless at night, when the quantity cannot injure them; or when not intended for early work the next morning, as hunting, &c. 6698. The necessary quantity of water for a horse should be regulated by circumstances, as the weather, the work, &c. In common cases, a large horse requires rather more than the half of a large stable pail full twice in the day. At night a full pail should be allowed. Horses should never be galloped after drinking; it has destroyed thousands, by gripes, inflammations, and broken wind. This custom also uses horses to expect they are to run away directly they are accidentally watered at any time. Others, expecting they are to be fatigued with a gallop, will avoid drinking at all. The most that should ever be done, is to suffer no horse to drink his fill at a river or pond; but having given him half what is necessary, walk him ten minutes, and then give him all that is required, and walk him again.

SECT. XV. Stabling and Grooming of Horses.

6697. The stabling of horses is likewise a most important point in their management, the more so as being wholly a deviation from nature; hence, under the most judicious management, it is liable to produce some departure from health; and as sometimes managed, is most hurful to it. Clothing, dressing, or combing, and exercise, are also highly important.
6698. Every stable should be large, cool, and airy. It is too common to suppose that many of the diseases of horses are attributable to the enervating effects of unnatural heat, and of an air breathed and rebreathed over again. Blaine says, Is it not alike repugnant to reason and experience, to expect to keep animals in health, that from stables heated to sixty degrees, and further protected by warm clothing, are first stripped, and then at once exposed to a temperature at the freezing point? If it be argued that habit and exercise render these less hurful, it will be easy to answer that their original hardihood is lost by confinement and artificial treatment; and that neither does exercise always tend to obvitate the effects of this sudden change; for our best carriage horses, and hackneves also, have often to wait hours in roads and streets the

and arthroid treatment; and that heither does exercise always tend to obviate the effects of this sudden change: for our best carriage horses, and hackneys also, have often to wait hours in roads and streets the convenience of their owners, or the pleasure of the groom.

6699. The heat of a stable should be regulated by a thermometer, and the heat shown by it should never exceed 50° of Fahrenheit in winter, or 62° or 63° in summer. To renew the air, the stable should be well ventilated; and which is best done by trunks or tubes passing from the ceiling through the roof.

6700. A stable should not only be well ventilated, but it should be light also; and the windows should be so constructed as to admit light and air, without producing a current of wind on the bodies of the horses. Darkened stables are very hurtful to the eyes; neither do they, as was formerly supposed at Newmarket, tend to the condition or rest of a horse. tend to the condition or rest of a horse,

6701. A stable should have a close ceiling to keep the dust and dirt from the hay-loft from entering the

6701. A stable should have a close ceiting to keep the dust and dirt from the hay-loft from entering the horse's eyes. It is also necessary to prevent the ammoniacal gases from ascending and lodging in the hay. It is preferable that the hay-loft be altogether removed from over the stable; and if a very high ceiling even to the roof were substituted, it would be for the benefit of the horses.

6702. The form of the rack and manger should be attended to. Sloping racks are disadvantageous, as encouraging dust in the eyes. They should therefore be upright, and by no means so high as they usually are, by which the head and neck are put injuriously on the stretch. As a proof that this is unpleasant to horses, many of them first pull out all the hay, and then leisurely eat it. The manger should be wide at the bottom, and of a proper height: care should be taken that no splinters are present to endanger the lips, nose, and mouth. The halter reins should, in good stables, be suffered to run within a groove within the manger post, to prevent the rein entangling the legs. It is become the practice in some stables appropriated to post, stage-waggon, and other hard-worked horses, to abandon hay-racks altogether; but the hay being placed on the ground before the horse encourages him to lie down and cat it; by which much rest is afforded to the weary limbs, and much improvement to the feet.

6703. The stable of a stable should be wide. Strains in the back, and sometimes even worse evils, are the consequence of the standings being too narrow. Balls are objectionable from the ease with which horses can kick over them; and also from the quickest feeder getting most food, when several horses stand together bailed.

ther bailed.

ther bailed.
6704. The acclivity of the stalls is a matter of much dispute: when too much raised, as in dealers' stables, they put the back sinews on the stretch, and fatigue horses much. It is more natural that they should be even; or that a very slight slope only be allowed to carry off the urine. The best mode, however, of carrying off the urine is by means of a small grating to each stall, communicating with a cesspool without doors, which should be closed up, that a current of air may not come through the grating. Such a contrivance will effectually carry off the water, and prevent the volatile alkali of the urine from impregnating the air around. For the same reasons, the dung should be removed, if possible, wholly without the stable as soon as dropped; for the exhalations from that are also ammoniacal, and consequently hurtful. To this cause alone we may attribute many diseases, particularly the great tendency stabled horses have to become affected in the eyes. The pungency of this effluvia is familiar to every one on entering a close stable in the morning, and when the long-soiled litter is removed, it is absolutely unbearable. unbearable

6705. The litter of horses should be kept dry and sweet, and should be often removed. When it is suffered to remain, under the notion of making better dung, the horse may be ruined; neither does the manure benefit as is supposed; for when it is removed to the dung pit, the close confinement does it more good than the open exposure in the stable, when it parts with its salts, on which its properties as manure

manure benefit as is supposed; for when it is removed to the dung pit, the close confinement does it more good than the open exposure in the stable, when it parts with its salts, on which its properties as manure partly depend.

6708. Horses should not stand on litter during the day, although very generally suffered to do so. Litter is thought to save the shoes and even the fect, by preventing the uneven surface of the stable from hurting them: but it holds the urine; it injures the feet; and is very apt to encourage swelling at the heels: as we know by removing it, when they immediately subside. A little litter may be strewed behind to obviate the effect of kicking, or the splashing of urine in mares.

6707. The clothing of horses is apt to be carried to as erroneous an extent as the heat of their stables. When horses go out in cold weather, and are intended to have merely a long walking exercise, then clothing is very proper: but it must be evident, that when taken clothed from a stable and exercised briskly so as to produce perspiration, it is erroneous; for not only are the clothes wetted and thus liable to give cold, but the horse is unfitted to go out afterwards with a saddle only. Saddle horses kept in condition stand clothed in a kersey sheet, and girted with a broad roller, with occasionally the addition of a quarterpiece; the breast-plate is sometimes put on when going out to exercise; the hood is used to race horses only, except in case of sickness. All horses, except racers, are best without clothing in the summer season; at the most a linen sheet only should be allowed to avoid the dust and flies.

6708. The grooming or dressing of horses is generally thus practised:—Having tied up the horse's head, take a currycomb, and curry him all over his body, to raise the dandriff or seurf, beginning first at his neck, holding the left cheek of the head-stall in your left hand, and curry him from the setting on of his head, all along his neck, to his shoulder, and so go all over his body to the buttocks, dow

raised. Then take a round brush, made of bristles, and dress him all over, both head, body, and legs, to the very fetlocks, always cleansing the brush from that dust which it gathers, by rubbing it upon the curry-comb. After that, take a hair-cloth, and rub him again all over very hard, both to take away the loose hairs, and to help to lay his coat; then wash your hands in fair water, and rub him all over with wet hands, as well head as body; for that will cleanse away all those hairs and dust the hair-cloth effect. Lastly, take a clean cloth, and rub him all over till he be very dry; for that will make his coat smooth and clean. Then take another hair-cloth (for you should have two, one for his body and another for his legs), and rub all his legs exceedingly well, from the knees and hocks downwards to his very hoof, picking and dressing them very carefully about the fetlocks from gravel and dust, which will lie in the bending of his joints.

6709. The curry comb should and he too know the statement of the curry comb should and he too known that the statement of the statement o

6709. The curry-comb should not be too sharp, or, at least, not used in a rude and severe manner, so as to be an object of torture and dread, instead of delight and gratification to the horse. It is too often the fate of thin-skinned horses to suffer much from the brutality of heavy-handed and ignorant fellows, who do not recollect that the unhappy animal is suffering, every time he writhes and attempts to escape from the comb or brush, the same tortures that they themselves experience when tickled on the soles of

their feet

their feet, 6710. The care of the legs and feet forms a most important branch of stable discipline. The legs must be kept perfectly dry and clean. Dirt suffered to form a lodgment, or wet remaining upon the legs in cold weather, will fret the skin, and cause cracked heels, grease, malienders and sellenders, rat's tail, crownscab, and such a train of stable plagues, as may baffle the most vigorous efforts during a whole winter. If any disposition to swellings, cracks, &c. make their appearance on the legs, particularly in winter, moderate bandaging, which every good groom knows how to perform, will contribute to remove the evil; if it, however, increase, have recourse to the veterinary directions. It forms a part of the constant attention of a good horse-keeper to see that the feet of his horses be well cleansed beneath the shoe with the picker from all small stones or gravel, at every return from abroad. The shoes must be examined that their of a good horse-keeper to see that the feet of his horses be well cleansed beneath the shoe with the picker from all small stones or gravel, at every return from abroad. The shoes must be examined, that their ends do not press into the crust, and that the nails be fast, and that the clinches do not rise to cut the horse. In these cases, instant application must be made to the farrier: horses ought by no means to remain in old shoes until the toe is worn away, or the webs become so thin that there is danger of their breaking, unless in case of brittle hoofs, when it is an object to shoe as seldom as possible. Upon the average, good shoes will wear near a month. Steeling the toes is, in general, a useful practice, but less necessary when the best iron is made use of. Where any tendency to dry hoofs exists, the feet should be stopped with equal parts of clay, cow-dung, and chamberlye every night; otherwise, twice or three times a week will be sufficient. A still better stopping is made by adding a little tar to the other matters. It is also prudent, when the hoofs have any tendency to hardness and contraction, to water the front part of the stall a little; and also occasionally, or constantly, to hang around the hoofs an apparatus, made by doubling a circle of woollen cloth over a tape, which should be tied around the fetlocks loosely: the two segments of the cloth will then fold around the hoof, and correspond to it in shape. This may be dipped in water, and will be found very convenient in keeping the feet moist and cool. Very brittle hoofs are greatly benefited by brushing them over with a mixture of whale oil and tar. It is considered as beneficial, in general, to take off the shoes of a horse who is necessitated to stand long in the stable, and who does no work, and to substitute tips; the growth of the crust and the enlargement of the heels being thereby promoted.

cial, in general, to take off the shoes of a horse who is necessitated to stand long in the stable, and who does no work, and to substitute tips; the growth of the crust and the enlargement of the heels being thereby promoted.

6711. The care of the furniture and trappings is another part of the duty of a horse-keeper. These are best kept in order by being instantly rubbed clean after use, and placed in a dry situation; by which method, neither oil nor scouring-paper is often found necessary. Great care should be taken to dry the pads of the saddles after journeys, and never to put a hardened and damp saddle upon the horse's back. The same is also necessary with regard to the body-clothes. The pads of the saddles ought to be kept perfectly soft, and free from dirt and sweat; and, after use, should be dried either in the sun or by the fire, and hung in a dry place: the body-clothes also should be washed much oftener than they generally are, and ever kept perfectly dry, and in a sweet state.

6712. The exercising of horses is essentially necessary for their health, as it counteracts the effects of the artificial life we force on them. High feeding, heated stables, and unnatural clothing are, particularly the first, counteracted by proper exercise; and without it, horses become pursive, fat, heavy, and greased; for, when the secretions do not find themselves natural vents by perspiration, &c., they will find themselves artificial ones. Exercise keeps down the fat, and it also hardens and condenses the muscles by drawing their fibres nearer together; it likewise enlarges the muscles. Thus the appearance, as well as the feel, when we handle the flesh of a horse in condition by proper exercise, is totally different from those of one merely full of flesh by fat, &c. Exercise increases the wind by taking up the useless fat, and by accustoming the lungs to expand themselves.

6713. The quantity of exercise necessary for a horse must be regulated by a variety of circumstances; as age, constitution, condition, and his ord

Sect. XVI. Management and Working of Horses.

6714. The working of horses includes the racing, hunting, and journeying of saddle horses; and the treatment in harness of coach, waggon, cart and farm horses.

Subsect. 1. Management and Working of Race Horses.

6715. In the managing and working of race horses, three things are to be considered, the preparation of the horse, the conduct of the rider, and the after-treatment of the horse. The preparation of a race horse for running a race is not the work of a few days, if there be any great dependence on the success. A month at least is required to harden his muscles in training, by proper food and exercise, and to refine his wind, by clearing his body to that degree of perfection that is attainable by art. It is first necessary to ascertain correctly the present state of the horse, as whether he be low or high fields in die hiter case a proper estimate should be formed of the time and means required to bring him into true running condition.

(6716. If a race horse be low in fiesh, it is necessary to judge of the cause of such state, and to act accordingly, the necessary proceedings for which were detailed in treating of condition. (6425.) It is to be remarked, that spices are less to be depended on for this purpose than generous food, as malt mashes; and if any thing of the kind be used, let it be the simple cordial ball. (Ict. Pharm. 6508.) Feed frequently, and by little at a time: while he is thus low, let his exercise be walking only, and by no means spare his water, or he will become hide-bound: carefully watch him, that full feeding may not disagree

by making his hoels swell, or his coat unthrifty; and if such appearances occur, mash him, and begin his scourings, otherwise abstain from physicking until he is in better health. As he improves in condition, increase his exercise, but not to such a degree as to make him sweat. His food must now be the best oats and beans, with wheaten or barley bread; the beans and oats are to be put into a bag, and beaten till the hulls are littleff, and then winnowed clean; and the bread, instead of being chipped in the common way is to have the crust clean of the state of the best of the

the hulls are full off, and then withnewed clean; and the breat, instead of being cupped in the common way, is to have the crust clean off.

6717. If the horse be in good fiesh and spirits when taken up for his month's preparation, cordials are altogether unnecessary, and the chief, business will be to cryitevithin good food and so much exercise as will keep him in wind, without over sweating or fatiguing him. When he takes larger exercise afterwards, towards the and of the monthly it will be project to have been horse the the place for run against him. This will put him upon his metale, and the heating them will give him spirits. This, howevel, is to be cattiously observed; that the has not an injustious; for if the language of joint place for the run for a forthight before the plate list of her run for; and that the last heat that is given him the day before the race must be in his cleakes with will make him run! with greatly more vigour when stripped for the race and feeling the cold wind on every part. In the second week, the horse should have the same food and more exercise; and in the last forthigh the mist have dried bats, that have been hulled by beatings after this lockeys we them with the whites of eggs, beaten up, and the laid out in the sun to strippid for the race; and feeling the cold wind on every part. In the second week, the horse should have he same food and more exercise; and in the last fortulat he must have dried bats, that have'been hilled by beating; after this jockeys wet them with the whites of eggs, beaten up, and then taid out in the sun fod rry; and when as dry as before, the horse is to have them: this sort of food being considered by their as very light of digestion, and very good for the creature's which the beans in this time should be the race and the read should be made of three parts wheat and one part beans, or of wheat and barley in equal parts. If he should become costive under this colume, he must their have bran, where and barley in equal parts. If he should become costive under this colume, he must their have bran, where the race, he should have his fill of hay; then he must have it given that in fits place! and every day, till the day before the race, he should have his fill of hay; then he must have it given that he digest a tip said in the morning of the frace day, the must have a toas for two of white bread's part of the race, he should have his fill of hay; then he must have it given that mid the read to the read to the read of the race, he should have his fill of hay; then he must have a day for two of white bread's part of the race of fedness and fasting are at this time to be equally avoided; the one stretting his wind, and the other occasioning a faintness that may make him lose. After he has had his food, the litter is to be shook up, and the stable kept quiet, that he may be disturbed by nothing till he is taked in the form, and the stable kept quiet, that he may be disturbed by nothing till he is taked in the form of the strip has a strip of the fill he is taked when the stable kept quiet, that he may be disturbed by nothing till he is taked in the form of the containing a race, it is not to be done by sticking the calves of the saidle skirts, and held firmly there; and the toes turned invarid, and his flood,

reserved for the greatest extremity.

spart his horse until there is great occasion, and then he will avoid striking him under the fore bowels between the shoulders and the girt; this is the tenderest part of it horse, and a touch there is robe, excerved for the greatest extremity.

6719. As to whipping the horse, it ought always to be done over the shoulder, on the near side, except in very bard running, and on the point of victory; then the horse is to be struck on the flank with a strong jerk? For the skin is the most tender of all there, and most sensible of the lash. When it have strong jerk? For the skin is the most tender of all there, and most sensible of the lash. When it have swinged and sparted, and is at the top of his speed, if he clap his ears in his pole, or whisk his tail, it is a proof that whis lockey treats him hard, and then he ought to give him as much comfort as he can by saving which will give the saving and them he ought to give him as much comfort as he can be saving which will give the saving and them he ought to give him as much comfort as he can be saving which will give the saving and them he ought to give him as much comfort as he can be saving which will give the saving and the saving him to goen the time of ridding, the artful jockey will let his adversary lead, holding hard belind him, fill he see an opportunity of giving a loose; yet, in this case, he must keep a close behind; that the other horse has keep the wind from him; and that he, sitting low, may at once shelter himself under him, and assist the strength of the horse. If the wind happen to be in their back, the expert jockey is keep directly behind the adversary, that he may have all the advantage of the wind to blow his horse along, as it were, and at the same time intercept it in regard to his adversary.

6720. When running on levels mooth ground, the jockey is to beat his horse as much as the adversary will give him leave, because the horse is an atturally more inclined to spend himself on this ground; on the conversal, or him and the proper had been any

speed in the creature's power.
6724. When the race is over, the horse is immediately to be clothed up and rode home; and immediately

on his coming into the stable, the following drink is to be given him: — Beat up the yokes of three eggs, and put them into a pint and a half of sound ale, made warm; and let it be given with a horn. After this, he is to be rubbed well down, and the saddle-place rubbed over with warm water and vinegar, and the places where the spurs have touched, with the same; after this he should have a feed of rye-bread, then a good mash, and at some time after these as much hay and oats as he will eat. His legs, after this, should be bathed some time with a mixture of vinegar and water.

Subsect. 2. Management and Working of the Hunter.

6725. The managing and working of the hunter includes his preparation for hunting, his condition, and his treatment while taking his regular day's work in the field, whether after buck, fox, or hare hounds. 6726. The preparation of the hunter must, like that of the race horse, be commenced by an estimate of his state and condition. If taken fresh from grass, it should be in due time: first, that he may be well prepared; and next, because the grass does not yield much nutriment in the heat of summer. A still better method is to continue to let him run out in the day and graze, having a shed to house himself from heat and rain. He is also to be fed and exercised, nearly as in the common training, for hunting condition. In this way he is sure to be free from cracks, hide-bound, or surfeit; and he will prove infinitely more hardy afterwards. It is even the practice with some of the best sportsmen to allow their horses to run out all the hunting season, unless the weather be very severe; when they are only stabled in a loose place. They are allowed as much corn as they can eat, and are found, if a little rougher in their coats, infinitely superior in hardihood, and exemption from the dangers of cold.
6727. A hunter taken from grass or in very low case should be treated as already fully detailed

6727. A hunter taken from grass or in very low case should be treated as already fully detailed under condition. (6424.) Great care must be taken that all the alterations in heat of stable, clothing, feeding, &c., are gradually brought about; by which means his flesh will harden gradually, and by using first walking exercise, and increasing it as he advances in flesh and strength, his wind also will become

excellent.

excellent.

6728. In the physicking of hunters, particularly when they are low in flesh, much caution is requisite that it be not over-done. It is the practice with some, and by no means a bad one, to give no physic; but to give more time in the preparation. Others, again, give mild grass physic, which is an excellent plan, when the weather is fine. (See Physicking, 5634.)

6729. The preparation of a hunter in full flesh and not from grass depends principally on regular exercise, and the best hard food; physicking him or not, according as he may be suspected to be foul, or as his wind may seem to want mending; but above all, whatever is done, should be done regularly; and his exercise should be rather long continued than violent. Oats with beans are the proper hard food for hunters, taking care that the beans do not constipate the bowels; which must be obviated by bran mixed with the other food, if such should be the case. Bread is not necessary, but for tender delicate horses; but every thing should be of the best.

6730. The day before a horse is to hunt it is common to treat him somewhat differently, but this is seldom necessary. It is evident he should be well fed, and that not late at night, that he may lie down early. Some feed in the morning, which others avoid; but when it is considered, as has been fully explained (604), how ill a horse bears fasting, it will be at once seen, that if very early in the morning, as by five o'clock, he could be fed with a moderate quantity of corn wetted, it would tend to support him through the day.

through the day,

through the day.

6731. On the return of a horse from hunting, the care bestowed on him should be extreme; as on it depends the immediate recovery of his strength. If he have fasted very long, and particularly if he be disinclined to eat of himself, horn down a pint of ale, with two pints of thick gruel. No prudent sportsman will bring in a horse hot; but if unavoidable accidents prevent this caution, let the horse be again led out for a few minutes, hooded and clothed; but he must have fresh clothes when afterwards dressed. Encourage him to stale as quickly as possible, after which proceed to hand-rub him all over carefully, placing before him a little of the best hay well sprinkled with water. If he refuse this, offer him three quarts of very clean chilled water. When perfectly cleaned, let his feet be carefully examined, that stubs have not pierced them, or that his shoes have not been forced awry by over-reaching, or by the suction of clayey ground; or that thorns be not lodged in his knees, hocks, and sinews. After all these matters have been well attended to, remove him from his stall to a loose box, well bedded up. A loose box is invaluable to a hunter; it gives room for stirring to prevent the swelling of the legs; and is better than bandaging when it can be avoided, which gives a disinclination to lie down. If the horse be off his food the next day, give him a cordial ball (*Fet. Pharm. 6568.*) and a malt mash, and afterwards a few cut carrots, which will assist to bring him round more speedily.

Subsect. 3. Working and Management of Riding Horses.

Subsect. 3. Working and Management of Riding Horses.

6732. The working and managing of hackney or riding horses include what is required for them as pleasure horses for ordinary airings; and what they require when used for purposes of travelling or long journeyings. It embraces also their stable management in general, with the proper care of horse and stable appointments: all which are usually entrusted to a servant, popularly called a groom, whose qualifications should be, moderate size, light weight, activity and courage, joined with extreme mildness and good temper; and above all, a natural love of horses, by which every thing required is done as a pleasure for the animal he loves, and not as task for those he is indifferent to.

6733. The hackney for gentlemen's airings should be in high condition, because a fine coat is usually thought requisite; and here the groom ought to be diligent that he may keep up this condition by regularity and dressing, more than by heat, clothing, and cordials. Whenever his master does not use his horse, he must not fail to exercise him but principally by walking) to keep up his condition, and to keep down useless flesh and swellings of the heels. The horse appointments are to be peculiarly bright and clean. The bridle should be hilletted and buckled, that the bits may be removed to clean them without soiling the leather, which cleaning ought not to be done with rough materials, but fine powder and polishing. On the return from exercise, they should be wiped dry and then oiled. Two pair of girths should be used, that a clean pair may always be ready, and the same if saddle cloths are used.

6734. The preparation for, and the care of a horse on, a journey involve many particulars which should not escape the eye of the master. The first is, is the horse in hard travelling condition? Next, Do his appointments all fit, and are they in proper order? The bridle for journeying should always be a double curbed one. The snaffle can be ridden with, certainly; but the snaffle can be ridd

Light carcassed horses, very young ones, and such as are low in flesh, require often baiting, particularly in hot weather; horses in full condition, above their work, and well carcassed, and such as are from seven to ten or twelve years old, are better when ridden a stage of fifteen or twenty miles, with a proportionate length of baiting time afterwards, than when baited often, with short stoppages: the state of the weather should also be considered; when it is very hot the stages should be necessarily shorter.

6738. To a proper consideration of the baiting times on a journey, the physiology of digestion should be studied, (6400.) Fatigue weakens the stomand; when we ourselves are tired, we seldom have much inclination to eat, and fatigue also prevents activity in the digestive powers. To allay these consequences, ride the horse gently the last two or three miles. If a handful of grass can be got at the road-side, it will wonderfully refresh your horse, and not delay you three minutes. In hot weather, let the horse have two or three go-downs (gulps), but not more, of water occasionally as you pass a pond; this tends to prevent excessive fatigue. Occasionally walk yourself up-hill, which greatly relieves him, and at such time remove the saddle, by shifting which, only half an inch, you greatly relieves him, and at such time remove the saddle, by shifting which, only half an inch, you greatly relieves him, and at such time remove the saddle, by shifting which, only half an inch, you greatly relieve him; and during this time, perhaps, he may stale, which also is very refreshing to him. It may be as well, in a finty country, to take this opportunity of examining that no stones are got into the feet likewise.

6731. When a horse is brought into an im from his journey, if he be very hot, first let him be allowed time to stale; let his saddle be taken off, and with a sweat knife draw the perspiration away; then, with a rug thrown over him, let him be led out and walked in some sheltered place il tool, by which means

for the purpose.

6739. The night baiting of a journeying horse should embrace all the foregoing particulars, with the addition of foot stopping; and care that his stable be of the usual temperature to that to which he is accustomed; and that no wind or rain can come to him. Give him now a full supply of water; if he has been at all exposed to cold, mash him, or if his dung be dried by heat, do the same; otherwise, let a good proportion of oats and beans be his supper, with hay, not to blow on half the night, but enough only to

afford nutriment.

afford nutriment.

6740. When returned home from a journey, if it has been a severe one, let the horse have his fore shoes taken off, and, if possible, remove him to a loose box, with plenty of litter; but if the stones be rough, or the pavement be uneven, put on tips, or merely loosen the nails of those shoes he has on; keep the feet continually moist by a wet cloth, and stop them at night if the shoes be left on; mash him regularly, and if very much fatigued, or reduced, let him have malt or carrots, and if possible, turn him out and hour or two in the middle of the day to graze: bleeding or physicking are unnecessary, unless the horse shows signs of fear. If the legs be inclined to swell, bathe them with vinegar and chamberlye, and bandage them up during the day, but not at night, and the horse will soon recover to his former state.

SUBSECT. 4. Horses in Curricles and Coaches.

6741. In working and managing horses in curricles, two-wheeled chaises, and similar cases, great feeling and nicety is required, not to overload or overdrive the animal; to see that the weight is duly proportioned between the wheels and horse's back, and that the harness does not pinch; but no directions on this head can be of much

use, unless the driver be a humane and considerate person, and one who sets a just value on the services of the noble animal committed to him. In Russia, drivers of two-wheeled carriages, as droscheys, sledges, and others, corresponding to our gigs and curricles, have a barbarous custom of teaching the horses to turn round their heads, the one to the left, and the other to the right (fig. 850.), the sight of which is very offensive to a

which is very offensive to a stranger.

6742. In working and managing coach horses, the same attention to grooming in all its departments is required as for saddle horses. Coach horses should never be brought into full work before they are five years old; when well fed on hard food, they may be worked at an average of thirty miles a day at twice. In general they should not be longer than five or six hours in the yoke at a time. Their principal meals should be in the morning and after their work is over for the day, as the action of trotting fast materially impedes digestion. impedes digestion.

Subsect. 5. Working of Cart, Waggon, and Farm Horses.
6743. In working and managing cart and waggon horses, a similar attention is requisite as for coach horses, though perhaps in a somewhat less degree, the animal being hardier.
6744. The working and managing of farm horses includes the age at which they are put to work, the quantity of work they should perform, and their feeding and general management.
6745. The age at which horses are put to full work, in the labours of a farm, is usually when four or five years old, according to the nature of the soil, and the numbers of the team; but they are always understood to be able to pay for their maintenance after they are three years old, by occasional work in ploughing and harrowing. Brown thinks it probable they might be put to work at four years old, were the same attention paid to their breeding and rearing that is paid to cattle and sheep.
6746. The work which a farm horse cught to perform is evidently a question of circumstances, which does not admit of any precise solution: a two-horse plough may, on an average, work about an English acre a day throughout the year; and, in general, according to the nature of the soil, and the labour that has been previously bestowed on it, a pair of horses, in ploughing, may travel daily from ten to fifteen

miles, overcoming a degree of resistance equal to from four to ten hundred weight. On a well made

miles, overcoming a degree of resistance equal to from four to ten hundred weight. On a well made road, the same horses will draw about a ton in a two-wheeled cart for twenty or twenty-five iniles every day; and one of the better sort, in the slow movement of the carrier or waggoner, commonly draws this weight by himself on the best turnpike roads. In some places horses are in the yoke, when the length of the day permits, nine hours, and in others ten hours a day; but for three or four months in winter, only from five to eight hours. In the former season they are allowed to feed and rest who hours from mid-day, and in the latter they have a little corn on the field, when working as long as there is day light, but none if they work only five or six hours. (Sup. Enc. Brit. art. Agr.)

6747. The feeding of farm horses is a subject of great agricultural inportance, and has excited considerable discussion among speculative agriculturists, who have generally urged the great expenses attending it as an argument against horses, in favour of oxen. Others, without preferring oxen to horses, have, instead of corn and hay, proposed to feed them on roots, leaves, whins, and even haws from the hedges. The latter have been given in large quantities by West of Hampshire, and, it is said (Complete Furmer, art. Team), were found to answer. That horses as well as men may live on very inferior food is evident; but that either will be able to perform their work under such treatment, as well is stift by were properly nourished, is contrary to reason and experience. It is observed by the judicious writer so often quoted, that horses can never perform their labour, according to the present courses of husbandry, on carrots, turnips, potatoes, or other roots alone, or as their chief food. They will work and thrive on such food; but they will work as much more, and thrive as much better, with oats or beant addition, on shally to repay the difference in expense. One of the three meals a day, which farm horses usually receive, may consist

that has actually occurred.

attention, that flesh once gained ought never to be lost, but that every animal whatever should be kept in a progressive state of improvement, and not suffered to take a retrograde course, which afterwards must be made up by extra feeding, or a loss be sustained, in a direct proportion to the degree of retrogradation that has actually occurred.

6789. The learness of a farmer's working cattle, and their reluctant movements, clearly mark his unprosperous condition. There are particular operations, indeed, such as turnip-sowing, seeding, fallows, harvest-work, &c., which require to be executed with so great despatch in our variable climate, that une most careful treatment, to prevent the animals from losing flesh, sonetimes even when their spirit and vigour are not perceptibly impaired. Such labours, however, do not continue long, and should always be followed by a corresponding period of indulgence. It is particularly dangerous and unprofitable to begin the spring labour with horses wom down by bad treatment during winter. (Sup. Enc. Brit. art. Agr.) 6750. Donaldson observes, that the coarse garbage with which farm horses are commonly stuffed, profitably or otherwise, is the real cause of the frequent occurrence among them of blindness, grease, and colic; more particularly the last, which, with care, might be prevented from happening so frequently. The remedy lies in physic, once or twice a year; either the regular alocid cose, or salts given in pails of warm water, or sulphur and cream of tartar, one third of the latter mixed in the corn. All horses kept in the benefited with others by purging physic.

6751. The cleaming and dryssing of farm horses was formerly very little attended to; but at present its importance to the health of the animal is better understood. Donaldson recommends that the heels, legs, bend of the knee, and hock, the twist under the fanks; in short, all parts out of sight, of cart horses, whilst standing in the house, should be kept perfectly free from dirt and scurf, and the skin supple; t

. 6754. The expense of feeding a horse throughout the year may therefore be estimated, in regard to quantity, as follows :

Oats, fifteen quarters.
Soiling, one acre of clover and rye-gress, and tares.
Hay part of October and November, March, April, and
May, 1½ ton.

Straw for other four months, half the price of hay. Potatoes, yams, or Swedish turnips, \(\frac{1}{2} \) acre. (Sup., \(\delta_{C} \), acre. (Sup., \(\delta_{C} \), acre.

May, 14 ton.

6755. The extent of land required for a horse's maintenance, supposing the soil to be of a medium quality, may be about five acres; that is, for oats three acres, soiling one, and one more for hay and roots. On rich soils four acres will be sufficient; but on poor soils, and wherever horses are kept at pasture, the produce of six acres and a half, or seven acres, will be consumed by one of them, when worked in the manner already mentioned. The straw of about two acres must be allowed for fodder and litter, the last of which has not been stated above; because, at a distance from towns, what is allowed for litter must, at any rate, be converted into dung. If sixty acres, therefore, should be assumed as the average extent of land that may be kept in cultivation by two horses, according to the best courses of modern husbandry, the produce of ten acres of this will be required for their maintenance; or, a horse consumes the produce of one acre out of every six which he cultivates, according to a four or six years' course, and something more than one acre out of every five which he ploughs annually. The Ass. - E'quus Asinus L. Ane, Fr.; Esel, Ger.; Asno, Span.; and Asino, Ital.

6756. The ass is a native of the mountainous deserts of Tartary, of Arabia, Persia, and other parts of the Asiatic continent; and at present is very generally domesticated throughout most civilised countries. The wild ass feeds chiefly on the most saline or bitter plants of the desert, as the kalis, atriplices, chenopodium, &c.; and also prefers the saltest and most brackish water to that which is fresh. Of this the hunters are aware, and usually station themselves near the ponds to which they resort to drink. Their manners greatly resemble those of the wild horse. They assemble in troops under the conduct of a leader, or sentinel; and are extremely shy and vigilant. They will, however, stop in the midst of their course, and even suffer the approach of man, and then dart off with the utmost rapidity. They have been at all times celebrated for their swift-Their voice resembles that of the common ass, but is shriller.

descriptive writers on the history of animals; and of none with more happy effect than those of the elequent Buffon, and the ingenious Abbé la Pluche. The ass, in his natural temper, is humble, patient, and quality of his food, contenting himself with the most harsh and disagreeable herebs, which other animals will scarcely touch. In the choice of water he is, however, very nice; drinking only of that which is perfectly clear, and at brooks with which he is acquainted. He is very serviceable to many persons who are not able to buy or keep horses; especially where they live near heaths or commons, the barrenest of which will keep him; being contented with any kind of coarse herbage, such as dry leaves, stalks, thistles, briers, chaff, and any sort of straw. He requires very little looking after, and sustains labour beyond most others. He is seldom or never sick; and endures hunger and thirst longer than most other kinds of animals. The ass may be made

other kinds of animals. The ass may be made use of in husbandry to plough light lands, to carry burdens, to draw in mills, to fetch water, cut chaff, or any other similar purposes. The female (fig. 851.) is also useful in many cases for her milk, which is excellent; and she might be of more advantage to the farmer if used, as in foreign countries of the heritage. The skin of the ass is extremely hard, and very elastic, and is used for various purposes; such as to cover drums, make shoes, or parchment. It is of the skin of this animal that the

horse, 6758. The ass attains his full growth in three or four years, and may then be put to work. Like the horse, he will live to 25 or 30 years: it is said the female lives longer than the male; but, perhaps, this happens from their being often pregnant, and at those times having some care taken of them, instead of which the males are constantly worn out with fatigue and blows. They sleep less than the horse, and do not lie down to sleep, except when they are exceedingly tired. The male as also lasts much longer than the stallion; the older he is, the more ardent he appears; and, in general, the health of this animal is much better than that of the horse; he is less delicate, and not nearly so subject to maladies. Ophthalma, which may be reckoned among the indigenze of the cultivated horse, is almost unknown to the ass. Contraction of the feet also is very seldom observed in him.

6759. The different breeds or reaces of the ass are much less known than those of the horse; because in

6760. In breeding from the ass, the same general rules should be attended to as in the horse breeding. The male ass will procreate at the age of two and a half years, and the female still earlier. The stallion ass should be chosen from the largest and strongest of his species; he must at least be three years old, but should not exceed ten; bis legs should be long, his body plump, head long and light, eyes brisk, nostrils and chest large, neck long, loins fleshy, ribs broad, rump flat, tail short, hair shining, soft to the touch, and of a deep grey. Those are reckoned the best shaped that are well squared, have large eyes, wide nostrils, long necks, broad breasts, high shoulders, a great back, short tail, the hair sleek, and of a blackish caller. blackish colour.

-n -10 - 4 - 4 - 4 - 1 - 11

the fire and a serior to below the so a military and the second beauty and the second
wide nostrifs, long necks, broad breasts, high shoulders, a great back, short tail, the hair sleek, and of a blackish colour.

6761. The best time for covering is from the latter end of May to the beginning of June, nor must the female be hard worked whilst with foal, for fear of casting; but the more the male is worked, in moderation, the better he will thrive. She brings forth her foal in about a twelvemonth, but, to preserve a good breed, she should not produce more than one in two years. She should be covered between the months of March and June. The best age to breed at is from three years old to ten. When the foal is cast, it is proper to let it run a year with the dam, and then wean it by tying up and giving it grass, and sometimes milk; and, when it has forgot the teat, it should be turned out into a pasture; but if it be in winter, it must then be fed at times, till it be able to shift for itself.

6762. The ass may be broken and trained at the end of the second year; but should not be worked sooner than the third year. Breaking is easily effected when two years old, or it may be let alone still longer, as till three years. It is easily done by laying small weights on his back, and increasing them by degrees; then set a boy upon him, and so increase the weights as may be proper, till they are sufficiently heavy.

6763. The age of the ass is known by his teeth in the same manner as the horse. At two years and a half old, the first middle incisive teeth fall out, and the other on each side soon follow; they are renewed at the same time, and in the same order.

6664. The anatomy and physiology of the ass do not differ from those of the horse essentially. The concha cartilages of the ears are, however, considerably more elongated; the spinous processes of the dorsal vertebre forming the withers are less extensive; and the bones of the extremities in general are less angularly placed, from whence results his inferiority in speed. It is also to the unbending lines of the spine, that his motions are rendered

The Mule and Hinny, Hybrids of the Horse and Ass.

6767. The mule (E'quus Asinus var. γ Mulus L. Grand Mulet Fr.; Grosser Maulessel, Ger.; Mula, Span. and Ital.) is the hybrid produce of an ass with a mare;

having a large clumsy head, long erect ears, a short mane, and a thin tail.
6768. The hinny (E'quus Asinus, var. & Hinnus L. Bardeau or Petit Mulet, Fr.;
Kleiner Maulessel, Ger.; Mulo, Span. and Ital.) is the hybrid produce between the sheass and a stallion; the head is long and thin, the ears are like those of a horse, the mane is short, and the tail is well filled with hair. The hinny is much less common than the mule; because, being less hardy and useful than the other, he is never cultivated.

6769. The mule, commonly so called, is much valued for the saddle, and for drawing carriages in Spain, Portugal, Italy, and the East, and in the warmer parts of America. In those countries where great attention is paid to the breed, it is as tall as the horse, exceedingly well limbed, but not so handsome, especially about the head and tail. These animals are mostly sterile; some, indeed, have thought that they are altogether incapable of producing their kind; but some few instances have occurred in which female mules have had foals, and in which even the male has impregnated females both of the ass and horse species, though such instances are exceedingly rare.

horse species, though such instances are exceedingly rare.

6770. The mules made use of in the southern parts of Europe are now brought to an astonishing perfection as well as great size. (fig. 853.) They are usually black, strong, well-limbed, and large, being mostly bred out of fine Spanish mares. They are sometimes fifteen or sixteen hands high, and the best of them worth forty or fifty pounds. No creatures are so proper for large burdens, and none so sure-footed. They are much stronger for draught than our horses, and are often as thickset as our dray-horses, and will travel several months together, with six or eight hundred weight upon their backs. Some think it surprising that these animals are not more propagated here, as they are so much hardier and stronger than horses, less subject to diseases, and capable of living and working to twice the age of a horse. Those that are bred in cold countries are more hardy and fit for labour than those bred in hot; and those which are light made are fitter for riding than horses, as to the walk and trot; but they are apt to gallop rough; though these do it much less than the short-made ones. The general complaint made against them is, that they kick and are stubborn; but this is owing to neglect in breeding them, for they are as gentle as horses in countries where they are bred with proper care.

6771. In the breeding of mules, mares that are of a very large breed and well made should be employed. They should be young, full of life, large barrelled, but small limbed, with a moderate-sized head, and a good forchand. It is found of advantage to have the foals from the time of their being dropped often

handled, to make them gentle: it prevents their hurting themselves by skittishness and sudden frights; and they are much easier broken at the proper age, and become docile and harmless, having nothing of

that viciousness which is so commonly complained of in these animals. They may be broken at three years old, but should never be permitted to do much hard work till four, as they are thus secured from being hurt by hard labour, till they have acquired strength enough to bear it without injury. An expert breeder of these animals found, that feeding them too well while young, was not only incurring a much larger expense than was any way necessary, but also made them wonderfully nice and delicate in their appetitos ever after. He therefore contented himself with giving them food enough to prevent their losing flesh, and to keep up their growth without palling their

licate in their appetites ever after. He therefore contented himself with giving them food enough to prevent their losing flesh, and to keep up their appetites with delicacies, or making them over fat: he also took care to defend them from the injuries of the weather by allowing them stable-room, and good litter to sleep on, besides causing them every day to be well rubbed down with a hard wisp of straw by an active groom. This was carcely ever omitted, particularly in cold, raw, wet weather, when they were least inclined to exercise themselves. When three years old, mules are proper for use.

6772. The shoe for the mule is by some made not unlike the bar shoe before, and the common shoe behind; by some both fore and hind shoes are made to project considerably beyond the toe, under an idea of increasing the points of contact with the ground: but the most usual shoe is one formed between the usual horse and ass shoe.

CHAP. IV.

Neat or Horned Cattle. — Bós L.; Mammàlia Pécora L., and Ruminàleæ Cuv. Bétes à corne, Fr.; Vich, Ger.; Ganado, Span.; and Bestiame, Ital.

6773. The neat or horned cattle used in agriculture are included under two species of Bôs; the B. Taurus or ox, and the B. bubulus or buffalo; the latter less used in Britain than on the Continent and in other countries. These animals are more universally used as beasts of draught and burden than the horse, and have the additional advantage of furnishing excellent food and other valuable products. There is scarcely a country in which the ox or the buffalo is not either indigenous, or naturalised and cultivated; while in many parts of the world the horse is either wanting, or reserved for the purposes of war or the saddle.

SECT. I. The Ox. - Bos Tawrus L.; Ochs, Ger; Bauf, Fr.; Buey, Span.; and Bue, Ital.

6774. The male ox is the bull (Taureau, Fr.; Stier, Ger.; Toro, Span. and Ital.) and the female the cow (Vache, Fr.; Kuh, Ger.; and Vaca, Span. and Ital.). The bull and cow inhabit various parts of the world, and, as already observed, are domesticated every where. In most countries, however, they are the mere creatures of soil and climate, the same attention in breeding and rearing that is bestowed on the horse being withheld; the natural habits little restrained or the form little improved for the purposes of milking, fattening, or for labour. It is almost exclusively in Britain that this race of animals has been ameliorated so as to present breeds for each of these purposes, far superior to what are to be found in any other country. Notwithstanding this, however, much certainly remains to be known regarding the nutriment afforded by different kinds of herbage and roots; the quantity of food consumed by different breeds, in proportion as well to their weight at the time, as to the ratio of their increase; and the propriety of employing large or small animals in any given circumstances. Even with regard to the degrees of improvement made by fatting cattle generally, from the consumption of a given weight of roots or herbage, no great accuracy is commonly attempted; machines for weighing the cattle themselves and their food, from time to time, not being yet in general use in any part of Britain. We shall consider this valuable family as to variety, criteria, breeding, earing, feeding, working, fattening, and milking: the manufacture of milk will be reated of in a succeeding chapter.

Subsect. 1. Varieties and Breeds of the Bull.

6775. The varieties of the wild ox are the bonasus and the bison (fig. 112.); the first with a long mane, and the last with a gibbous back. They inhabit the woods in Madagascar and many other countries of the East; and the bison is even said to be found in Poland.

ature is such, that they have been formed into many diversities of shape, and various qualities have been given them, very different from the original stock. The uris, or cows of Lithuania, are almost as large as the elephant; while some of those on the Grampian hills are little above the size of a goat; and cows are found of every diversity of size between the one and the other. They are not less varied in their shapes. The bison, which is a species of the cow family, and which readily propagates with our cows, wears a strong shaggy mane, like the lion; a beard, like the goat; as much hair under its neck and breast as covers its fore legs; a hump upon its shoulders, nearly as large as that worn by the camel (sometimes forty or fifty pounds in weight), with a tail that scarcely reaches the top of its buttock; and it resembles the lion much more than it does our domesticated cows, or other varieties of its own species. (Atton.)

6777. The diversity of qualities in the cow family is also very great. Our cows are so grovelling and inactive, that they scarcely know the road from their stall to their pasture; while those of the Hottentots are so tractable as to be intrusted with the charge of other animals, and keep them from trespassing on the fields of grain, or other forbidden ground. They also fight their master's battles, and gore his enemies with their horns. Our dairy cows are so feeble and inactive, that they are hurt by travelling twice a day, even slowly, one mile from the byre to their pasture; while those of Tartary are used as riding animals, and in drawing carriages. Those of Hindostan draw the coaches, and maintain their rates with horses at the full trot; and the Hottentots teach their cows to hunt down the elk antelope. Cows of the wild neglected breed can with difficulty be removed from one enclosure or one hill to another; while those, on whom due attention has been bestowed are docile, and submit to perform all sorts of labour. Some cows the full trot; and the Hottentots teach their cows to hunt down the elk antelope. Cows of the wild neglected breed can with difficulty be removed from one enclosure or one hill to another; while those on whom due attention has been bestowed are docile, and submit to perform all sorts of labour. Some cows will yield upwards of twenty Scots pints of milk per day, while others will not give so much in ten, perhaps not in twenty days. These are not so many different species of animals, but all of them one and the same species, all capable of generating with each other a perfect offspring. All these varieties have been formed from the parent stock, partly by the diversity of soil and climate, or other accidental or adventitious circumstances; and partly of late by human skill and industry. (Dairy Husbandry, p. 17)

6778. The varieties of the cultivated or are the European, Indian, Zebu, Surat, Abyssinian, Madagascar, Thian, and African. From the European variety have been formed the different breeds cultivated in Britain. They are very numerous, but we shall only notice such as are in most esteem. These different breeds expensively distinguished by the length of flexure of their horns; by the absence of horns; by the districts where they are supposed to have originated, or in which they abound, or exist in the greatest purity; or by the name of the breeder.

6779. The long-horned or Lancashire breed of cattle (fig. 853.) is distinguished from others by the length of their horns, the thickness and firm texture of their hides, the length and closeness of their hair, the large size of their horns, and their coarse, leathery, thick necks: they are likewise deeper in their fore quarters, and lighter in their hind quarters, than most other breeds; narrower in their shape, less in point of weight than the short horns, though better weighers in proportion to ties quantity. They are more varied in their bind quarters, than most other breeds; hut, whatever the colour be, they have in general a white streak along their back, w

which the breeders term finched, and mostly a white

spot on the inside of the hough. (Culley, p. 53.) In gular efforts that have been made towards its improvement, remains with little alteration; for, except in Leicestershire, none of the subvarieties (which differ a little in almost every one of those counties where

almost every one of those counties where the long horns prevail) have undergone any radical change or any obvious improvement. The improved breed of Leicestershire (fig. 854.) is said to have been formed by Webster, of Cauley, near Coventry, in Warwickshire, by means of six cows brought from the banks of the Trent, about the beginning of the present century, which were crossed with bulls from Westmoreland and Lancashire. Bakewell of Dishley, in Leicestershire, afterwards got the lead as a breeder, by selecting from the Cauley stock, and the stocks of several other eminent breeders have been traced to the same source. (Mar hal's Midland Counties, vol. 1, 9. 318) p. 318.)

6780. The short-horned, sometimes called the Dutch breed (fig. 855.), is known by a variety of names, taken from the districts where they form the prin-

the districts where they form the principal cattle stock, or where most attention has been paid to their improvement: thus, different families of this race are distinguished by the names of the Holderness, the Teeswater, the Yorkshire, Durham, Northumberland, and other breeds.

The Teeswater breed, a variety of short horns, established on the banks of the Tees, at the head of the the North in the highest set in the North in the North in the highest set in the North in the N

the reswater breed, a variety of short horns, established on the banks of the Tees, at the head of the vale of York, is at present in the highest estimation, and is alleged to be the true Yorkshire short-horned breed. Bulls and cows from this stock, purchased at most extraordinary prices, are spread over all the north of England, and the border counties of Scotland. The bone, head, and neck of these cattle are fine; the hide is very thin; the chine full; the loin broad; the earcase throughout large and well fashioned; and the flesh and fatting quality equal, or perhaps superior, to those of any other large breed. The short-horns give a greater quantity of milk than any other cattle; a cow usually yielding twenty-four quarts of milk per day, making three firkins of butter during the grass season: their colours are much varied, but they are generally red and white mixed, or what the breeders call fleeked. The heaviest and largest oxen of the short-borned breed, when properly fed, victual the East India ships, as they produce the thickest beef, which, 3 T 4

by retaining its juices, is the best adapted for such long voyages. Our royal navy should also be victualled from these; but, from the jobs made by contractors, and from other abuses, it is feared our honest tars are often fed with beef of an inferior quality; however, the coal ships from Newcastle, shields, Sunderland, &c., are wholly supplied with the beef of these valuable animals. These oxen commonly weigh from 60 to 100 stone (14 bts. to the stone); and they have several times been fed to 120, 130, and some particular ones to upwards of 150 stone, the fore quarters only. (Culley, p. 48)—
16781. In comparing the breeds of long and short horned cattle, Culley observes that the long-horns excel in the thickness and firm texture of the hide, in the length and closeness of the hair, in their beef being finer-grained, and more mixed and marbled than that of the short-horns, in giving a less quantity of milk; in weighing more in proportion to their size, and in giving richer milk; but they are inferior to the short-horns, in giving a less quantity of milk; in weighing more in proportion to their size, and in giving richer milk; but they are inferior to the short-horns, in giving a less quantity of milk; in weighing more in proportion to their size, and in giving richer milk; but they are inferior to the short-horns, in giving a less quantity of milk; in weighing more in proportion to their size, and in giving richer milk; but they are inferior to the short-horns, in giving a less quantity of milk; in weighing more in proportion to their size, and in giving richer milk; but they are inferior to the short-horns, in giving a less quantity of milk; in weighing more in proportion to their size, say, the head, have a proportion of beef, atlow when killed, in being generally advantages in different situations? Why not threed has long had, not probably may have, its particular advantages in different situations? Why not the thick firm hides, and probably may have, its particular advantages in different situations? Why no

south, has been stated at about 40 stone, avoirdupois; and some of them, fattened in England, have been brought to nearly 100 stone.

6787. The general properties of this breed are well known in almost every part of England, as well as in Scotlands. They are sometimes sent from their native pastures directly to Smithfield, as distance of four hundred miles, and sold at once to the butcher; and in spring they are often shown in Norfolk, immediately after their arrival, in as good condition as, or even better than, when they begin their journey; with full feeding, there is perhaps no breed that sooner attains maturity, and their fielsh is of the finest quality. Culley was misinformed about the quantity of milk they yield, which, though rich, is by no means abundant. It is alleged not to be more than seventy or eight years since the Galloways were all horned, and very much the same in external appearance and character with the breed of black cattle which prevailed ever the west of Scotland at that period, and which still abounds in perfection, the largest-sized, ones in Argyleshire, and the smaller in the Isle of Sky. The Galloway cattle at the time alluded to were coupled with some hornless bulls, of a sort which do not seem now to be accurately known, but which were then brought from Cumberland, the effects of which crossing were thought to be the general loss of horns in the former, and the callargement of their size; the continuance of a hornless sort being kept up by selecting only such for breeding, or perhaps by other means, as by the practice of graciating with the knife the horns in their very young state. (Coventry on Live Stock, p. 28.).

6788. The Suffolk duns, according to Cultey, are nothing more than a variety of the Galloway breed. He supposes them to have originated in the intercourse that has long subsisted between the Scotch drovers of Galloway eartile, and the Suffolk and Norolk graziers who feed them. The Suffolk are chiefly light duris, thus differing from the Galloways, and are considered a

under similar soil, climate, and relative circumstances; but also in feeding for the shambles. They are,

under similar soil, climate, and relative, circumstances; but also in feeding for the shambles. They are, in fact, is breed of rows that have, by crossing, coupling, feeding, and treatment, been improved and brought to a state of perfection, which his them, above all others yet known, to answer almost in every diversity of state of perfection, which his them, above all others yet known, to answer almost in every diversity of state of perfection, which his them, above all others yet known, to answer almost in every diversity of levels. Advance of a state of the county of for fattening them to be county of the state of the county of the state of the county of Ayr. I mproved in the state of the county of Ayr, and principally by those of the state of the county, and principally by those of the state of the county of Ayr is of mixed white and brown colours.

6791. The size of the dyrshire improved dairy cours "varies from 90 to 40 stones English, according to the quality and abundance of their food. If cattle are too small for the soil, shey will soon rise to the size if can maintain; and the reverse, if they are larger than it is calculated to support." (Atlan).

6792. The shapes mast approved of are as follows:—" Head small, but rather long and relative the state of the stat

dairy breed of Ayrshire is, that, after they have yielded very large quantities of milk for several years, they are as valuable for beef as the Galloway cow, or any other breed of cows known in Scotland. They fatten as well, and their beef is not inferior to that of any other breed of cattle known in Scotland. They fatten as well, and their beef is not inferior to that of any other breed of cattle known in Scotland. (Alton.) 6795. The cattle of the Highlands of Scotland are divided into a number of local varieties, some of which differ materially from others, probably owing to a difference in the climate and the quality of the herbage, rather than to their being sprung from races originally distinct, or to any great change effected either by selection or by crossing with other breeds. It is only of late that much attention has been paid to their improvement, in any part of this extensive country; and in the northern and central Highlands the cattle areyet, for the most part, in as rude a state, and under management as defective, as they were some centuries ago. These cattle have almost exclusive possession of all that division of Scotland, including the Hebrides, marked off by a line from the Frith of Clyde on the west, to the Murray Frith on the north, and bending towards the east till it approaches in some places very near to the German Ocean. Along the eastern coast, north of the Frith of Forth, the Highland cattle are intermixed with various local breeds, of which they have probably been the basis. There are more or less marked distinctions among the cattle of the different Highland counties; and, in common language, we speak of the Inverness-shire, the Banffshire, &c., cattle, as if they were so many separate breeds; but it is only necessary in this place to notice the two more general varieties, now clearly distinguishable by their form, size, and general properties.

6796. The most valuable of these are the cattle of the Western Highlands and Isles, commionly called the Argyleshire breed [the Hebrides ar

in their progress to the south, the kyloes or ferries in the mainland and Western Islands, where these cattle are found in the greatest perfection (General Report of Scouland, vol. iii. p. 26.)

Scouland, vol. iii. p. 26.)

6797. The cattle of Orkney and Zetland are of a most diminutive size; an ox weighing about sixty pounds a quarter, and a cow forty-five pounds. They are of all colours, and their shapes are generally bad: yet they give a quantity of excellent milk; fatten rapidly when well trained to the yoke, and so plentifully fed as to enable them to support labour.

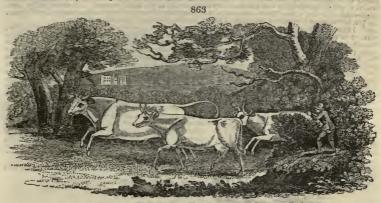

6798. Of the Fifeshire cattle, Culley observes, "You would at first imagine them a distinct breed, from their upright white horns, being exceedingly light-lyered and thin-thighed; but I am pretty clear that it is only from their being more nearly allied to the kyloes, and consequently less of the coarse kind of short horns in them. (Culley, p. 69.) Notwithstanding this opinion, the cattle of the north-eastern counties of Scotland require, for every useful purpose, to be mentioned separately from the Highland herds; and as all of them have a general resemblance, it will only be necessary in this place to notice the Fife cattle in particular. There are various traditions about the origin of this praticy. It is said to have been much improved by English cows sent by Henry VII. to his daughter, the consort of James IV., who usually resided at the palace of Falkland, in that county; and as there is some resemblance between the cattle of Fife and Cambridgeshire, they are supposed to have been brought originally from the latter county. Others ascribe the origin of the present breed to bulls and cows sent by James VI. (James I. of England), in payment of the money which his obliging neighbours in Fife are said to have advanced for his equipment, when he went to take possession of the English throne. (Report of Nairra and Moray, p. 505.)

6799. The prevailing colour of the Fife cattle is black, though sometimes spotted or streaked with white, and some

6801. Of the Welsh cattle (fig. 862.) "there seem to be two distinct kinds. The large sort are of a brown colour, with some white on the rump and shoulders, be two distinct kinds. The large sort are of a brown colour, with some white on the rump and shoulders, denoting a cross from the long-horns, though in shape not the least resembling them. They are long in the legs, stand high according to their weight, are thin in the thigh, and rather narrow in the chine; their horns are white and turned upwards; they are light in flesh, and next to the Devons, well formed for the yoke; have very good hoofs, and walk light and nimbly. The other sort are much more valuable; colour black, with very little white; of a good useful form, short in the leg, with round deep bodies; the hide is rather thin, with short hair; they have a likely look, and a good eye; and the bones, though not very small, are neither large nor clums; and the cows are 6802. The Alderney cattle are to be met with only about the seats of a few great landholders, where they are kept chiefly for the sake of their milk, which is very rich, though small in quantity. This race is considered, by very competent judges, as too delicate and tender to be propagated to any extent in Britain, at least in its northern parts. Their colour is mostly yellow or light red, with white or mottled faces; they have short crumpled horns, are small in size, and very ill-shaped; yet they are fine-boned in

general; and their beef, though high-coloured, is very well flavoured. I have seen, says Culley, some very useful cattle bred from a cross between an Alderney cow and a short-horned bull. 6803. The Irish cattle, Culley thinks, are a mixed breed between the long-horns and the Welsh or Scotch, but more inclined to the long-horns, though of less weight than those in England. 6804. The last variety of cattle we shall mention is one entirely of luxury, it is the wild breed (fig. 863) which is found only in the parks of a few great proprietors, who preserve the animals as curious and

ornamental, or for the sake of their high-flavoured beef. Those kept at Chillingham Castle, in North-umberland, a seat belonging to the Earl of Tankerville, have been very accurately described in the Northumberland Report, and in Culley's book on live stock, so often quoted. Their colour is invariably of a creamy white; muzzle black; the whole of the inside of the ear, and about no third of the outside, from the tips downward, red; horns white, with black tips, very fine, and bent upwards; some of the bulls have a thin upright mane, about an inch and a half or two inches long. The weight of the oxen is from thirty-five to forty-five stone, and the cows from twenty-five to thirty-five stone the four quarters (fourteen pounds to the stone). The beef is finely marbled, and of excellent flavour. From the nature of their pasture, and the frequent agitation they are put into by the curiosity of strangers, it is scarcely to be expected they should get very fat; yet the six years old oxen are generally very good beef, from which it may be fairly supposed that, in proper situations, they would feed well.

6805. The habits of these animals are entirely rude; at the first appearance of any person they set off in full gallop, and at the distance of about two hundred yards, make a wheel round and come boildly up again, tossing their heads in a menacing manner; on a sudden they make a full stop, at the distance of forty or fifty yards, looking wildly at the object of their surprise, but, upon the least motion being made, they all again turn round, and fly off with equal speed, but not to the same distance, forming a whorter circle, and again returning with a bolder and more threatening aspect than before; they approach much nearer, probably within thirty yards, when they again make another stand, and again fly off: 'this they do several times, shortening their distance, and advancing nearer and nearer till they come within such a short distance, that most people think it prudent to leave them, not choosing to provoke them fa

farther.

farther.

6806. When the cours calve, they hide their calves for a week or ten days in some sequestred situation, and go and suckle them two or three times a day. If any person comes near them, the calves clap their heads close to the ground, and lie like hares in form, to hide themselves. This is a proof of their native wildness, and is corroborated by the following circumstance that happened to the writer of this narrative (Bailey of Chillingham), who found a hidden calf, two days old, very lean and very weak:—On stroking its head it got up, pawed two or three times like an old bull, bellowed very loud, stepped back a few steps, and bolted at his legs with all its force; it then began to paw again, bellowed, stepped back, and bolted as before; but knowing its intention, and stepping aside, it missed him, fell, and was so very weak that it could not rise, though it made several efforts: but it had done enough; the whole herd were alarmed, and, coming to its rescue, obliged him to retire; for the dams will allow no person to touch their calves without attacking him with impetuous ferocity.

without attacking him with impetuous ferocity.

6807. When a calf is to be castrated, the park-keeper marks the place where it is hid, and when the herd

6807. When a calf is to be constrated, the park-keeper marks the place where it is hid, and when the herd are at a distance, takes an assistant with him on horseback; they tie a handkerchief round the calf's mouth to prevent its bellowing, and then perform the operation in the usual way, with as much expedition as possible. When any one happens to be wounded, or is grown weak and feeble through age or sickness, the rest of the herd set upon it and gore it to death. (Culley, p. 73.)

6808. The mode of killing them was, perhaps, the only remains of the grandeur of ancient hunting. On notice being given that a wild bull would be killed on a certain day, the inhabitants of the neighbourhood came mounted and armed with guns, &c. sometimes to the amount of a hundred horse, and four or five hundred foot, who stood upon walls or got into trees, while the horsemen rode off the bull from the rest of the herd, until he stood at bay, when a marksman dismounted and shot. At some of these huntings, twenty or thirty shots have been fired before he was subdued. On such occasions, the bleeding victim grew desperately furious from the smarting of his wounds, and the shouts of savage joy that were echoing from every side; but, from the number of accidents that happened, this daffgerous mode has been little practised of late years, the park-keeper alone generally shooting them with a rifled gun at one shot. gun at one shot.

Subsect. 2. Criteria of Cattle for various objects and purposes.

6809. The criteria of a well-made bull, to whatever breed he may belong, are, according to Culley, as follows:—The head should be rather long, and the muzzle fine; his eyes lively and prominent, his ears long and thin, his horns wide, his neck rising with a gentle curve from the shoulders, and small and fine where it joins the head; the shoulders moderately broad at the top, joining full to his chine or crops and chest backwards, and to the neck-vein forwards; his bosom open, breast broad, and projecting well before his legs; his arms or fore-thighs muscular, and tapering to his knee; his legs straight, clean, and very fine-boned; his chine and chest so full as to leave no hollows behind the shoulders; the plates strong, to keep his belly from sinking below the level of his breast; his back or loin broad, straight, and flat; his ribs rising one above another in such a manner that the last rib shall be rather the highest, leaving only a

small space to the hips or hooks, the whole forming a round or barrel-like carcass; his hips should be wide placed, round, or globular, and a little higher than the back; the quarters from the hip to the rump long, and instead of being square, as recommended by some, they should taper gradually from the hips backward; and the turls or pott-bones not in the least protuberant; rump close to the tail, the tail broad, well-haired, and set on so high as to be in the same horizontal line with his back. Bulls should be constantly well fed, and kept in proper enclosures, never being suffered to ride before they are three years old, as when the contrary is the 'practice they never attain so perfect a growth. It is observed by Lawrence, that the above description delineates that barrel-shape which Bakevell supposed most advantageous for all kinds of animals intended to be fed for slaughter, or even used for labour.

6310. The criteria of excellence in neat cattle in general are thus given by John Wilkinson of Linton, near Nottingham, an eminent breeder. (Hemarks on Cattle, &c. 1820). "The head ought to be rather long, and muzzle fine; the countenance calm and placid, which indicates a disposition to get fat; the horns fine; the neck light, particularly where it joins the head; the breast wide and projecting well before the legs; the shoulders moderately broad at the top, and the joints well in, and when the animal is in good condition, the chine so full as to leave no hollow behind it; the fore flank well filled up, and the girth behind the shoulders deep; the back straight, wide, and flat; the ribs broad, and the space between them and the hips small; the flank full and heavy; the belly well kept in, and not sinking low in the middle, but so formed that a cross section of it would resemble an oval, whose two ends are of the same width, and whose form approaches to that of a circle, or of an ellipsis whose eccentricity is not great (the whole forming, not a round or barrel-like carcass as some have expressed it, for this

po t re din was

She's fine in her bone, and silky of skin, on the she's a grazier's without, and a butcher's within.

Shi? Culley's marks of a good com are these. —Wide horns, a thin head and neck, dewlap large, full breat, broad back, large deep belly; the udder capacious, but not too fleshy; the milk-veins prominent, and the bag tending far behind; teats long and large, buttocks broad and fleshy; tall long and pliable, legs proportionable to the size of the careass, and the joints short. To these outward marks may be added a gentle disposition, a temper free from any vicious tricks, and perfectly manageable on every occasion. On the other hand, a cow with a thick head and a short neck, prominent back-bone, slender chest, belly tucked up, small udder or fleshy bag, short teats, and thin buttocks, is to be avoided as totally unit for the purposes either of the dairy-man, the suckler, or the grazier. The most valuable cows are those which are bred in Yorkshire, Staffordshire, and upon the strong lands in other part of England, and in Ayrshire in Scotland.

Soil. The criteria of excellence in calle, as derived from colour, are of no importance; and all that can be said is, that white and red cattle are less hardy than the black haired.

Soil. The criteria of age in cattle are derived from the teeth and horns. At the end of about two years they shed their first four teeth, which are replaced by others, larger, but not so white; and before five years all the incisive teeth are renewed. These teeth, are at first equal, long, and pretty white; but, as the animals advance in years, they wear down, become unequal, and grow black. These animals, according to soine, likewise shed their horns at the end of three years; and they are replaced by other horns, which, like the second teeth, continue; this, however, is totally or partially denied to in the "damerican Jeamer."

The manner of the growth of these horns is not uniform, nor the shooting of them equal. The first year, that is, the fourth year of the aminal lives. These buttons becom

only or ce a day tril they ar Subsect. 3. Breeding of Horned Cattle.

1. T 1/0 - Diniti 11

6818. The objects to be kept in view in breeding cattle are, forms well adapted for fattening, for producing milk, or for labour. These three objects have each of them engaged the attention of British agriculturists; but experience has not hitherto justified the expectation that has been entertained of combining all these desirable properties, in an eminent degree, in the same race. That form which indicates the property of yielding the most milk, differs materially from that which we know from experience to be combined with early maturity and the most valuable carcass; and the breeds which are understood to give the greatest

weight of meat for the food they consume, and to contain the least proportion of offul, are not those which possess, in the highest degree, the strength and activity required in the beasts of labour.

6819. A disposition to fatten, and a tendency to yield a large quantity of milk, cannot be united. The form of the animal most remarkable for the first, is very different from that of the other; in place of being flat in the sides, and big in the belly, as all great milkers are, it is high-sided and light-bellied: in a word, the body of the animal well adapted to fatten is barrel-formed, while that of the milker is widest downwards. It is not probable, therefore, that the properties of two breeds of cattle, so oposite in form and general appearance, can ever be united in the same animal.

6820. The long and short horned breeds have hitherto been in possession of the best part of the island; but various others, as the Ayrshire, the Galloway cattle, and kyloes, might be bred with advantage in many situations, so as to be more profitable than either the short-horns or the long-horns. If These breeds of cattle, as true quick feeders, and being kindly-fleshed, or excellent eating beef, have established their character in the first market in the island. The Scotch or kyloes are better adapted to cold, exposed, heathy, mountainous situations, than any other breed we have. Particular breeds are probably best adapted to particular situations; on which ground, breeders of cattle should endeavour to find out what breed is the most profitable and best suited to their situations, and to improve that breed to the utmost, rather than to try to unite the particular qualities of two or more distinct breeds by crossing. The latter is a precarious practice; for we generally find the produce inherit the coarseness of both breeds, and rarely attain the good properties which the pure distinct breeds individually possess. In order to have good cattle of any breed, particular regard must be paid in selecting those that are the most compl

6822. The best bulls are either let out for the season, or cows are brought to them at a certain rate per head. The practice of letting bulls is said to have originated with Bakewell (Marshale Middland Counties, vol. i. p. 334.), who, early in his career, let a bull for one hundred and fifty-two guineas, to be used only four months (Parkinson, vol. ii. p. 499.); and five guineas per cow were about that time commonly paid to him and other eminent breeders.

him and other eminent breeders.

6822. The age at which bulls should begin to be employed, and the number of seasons they should be allowed to serve, as well as the age at which the females should begin to breed, are points regarding which practice is by no means uniform. In the midland counties, the bulls are pretty commonly allowed to leap while yearlings; and if good stock-getters are kept on as long as they will do business, perhaps till they are ten or twelve years old. In other places they are employed only three casens, for the first time at two years old. The females, in many instances, bring their first calf at the age of two years, but more commonly, perhaps, not till they are a year older; and in some of the Highland districts, where, owing to a want of proper nourishment in their infancy, they are later in coming to their full growth, the females do not often become mothers till they are about four years old.

6824. The period of gestation with cowe has been found, upon an average of a great number of experiments, to be about forty weeks. M. Tessier communicated to the National Institute of France the following observations on this subject:—Of 160 cows, It calved from the 241st to the 266th day; 3 on the 500th; 50 on the 280th; 68 on from the 280th to the 290th; 90 on the 800th; and 5 on the 308th. Cows seldom bring more than one calf at a time. When they produce twins, one of them a male and the other a female, the latter, which is called a free martin, is commonly considered to be incapable of procreation; yet there seem to have been well authenticated instances to the contrary. (Farmer's Magazine, vol. vii. p. 462.) and vol. viii, p. 463.)

yet there seem to have been well authenticated instances to the contrary. Craimer's augmentage 19,462.; and vol. viii. p. 466.)
6325. The most desirable period for putting cows to the bull is midsummer, in order that they may be dropped in spring, and have the whole of the grass season before them. Where no regular system is followed, and cows are sent to the bull merely because they are in heat, calves will be dropped at all seasons; but, except in those districts where the fatting of calves is an object of importance, spring is probably the most advantageous time; as the calves, having all the grass season before them, become sufficiently strong for enduring the change to a less agreeable food in the ensuing winter. A calf newly weaned seldom thrives well during that period, unless it is pampered with better food than usually falls to the share of young animals. By midsummer the cows are readier to take the bull than at any other season, and will bring calves in proper time. If a cow goes till after May before she calves, the calf will be too weak in the winter following; and the dam will not be so ready to take the bull again, but will often grow barren.

barren.
6896. It is not always the best mileh cow that has the best calf, even though the external circumstances should be similar; and vice versa, a sorry cow may have a good calf. These remarks apply to this breed as well as to others. The immediate progeny of a good milker may be an indifferent milch cow; but in the second remove, the good milking quality of the grandam returns. This has often been observed, and without any of the causes being imputable to the size. (Robertson, p. 571.)

Subsect. 4. Rearing of Horned Cattle.

t t fourt

6827. The mode of rearing calves is various. There can be little doubt but that the best and most natural mode is that of allowing them to suck their dams, at least for some length of time after they are brought forth.

forth.

6528. In Yorkshire, and most parts of Scotland, the usual method is to give them milk to drink, there being few instances where they are allowed to suck. For the first two or three weeks, they mostly get milk warm from the cow; but for the next two or three weeks, half the new milk is withdrawn, and skim-milk substituted in its stead; and at the end of that period, the new milk is wholly withdrawn: they are then fed on skim-milk alone, or sometimes mixed with water, till they are able to support themselves by eating grass, or other food of that sort.

6829. In Cheshire, the practice is to allow the calves to suck for the first three weeks. They are then fed on warm new whey, or scalded whey and buttermilk mixed; with the green whey water is frequently mixed, and either oatmeal or wheat and bean flour added. A quart of meal or flour is thought sufficient to mix with forty or fifty quarts of liquid. Oatmeal gruel and buttermilk, with an addition of skimmed milk, are also used for the same purpose. Some one of these prepared kinds of food is given, night and morning, for a few weeks after the calves are put on that diet, but afterwards only once a day till they are three months old or more. three months old or more.

6830. In Gloucestershire the calves are not allowed to suck above two or three days; they are then fed on skim-milk, which is previously heated over the fire. When they arrive at such an age as to be able to eat a little, they are allowed split beans, or oats and cut hay, and water is mixed with the milk.
6831. In Sussess it is common to allow the calves to suck for ten or twelve weeks, or to wean them at the end of three or four, and give them a liberal allowance of skim-milk for six or eight weeks longer.
6832. In Middleses it is usual, in rearing calves, to give them a paifful, containing about a gallon, of milk warm from the cow, morning and evening, for eight or ten weeks; or, which is certainly the most

agreeable to nature, and therefore to be preferred to any other that can be adopted, to allow the calf to suck its dam, as it is sometimes done in the county of Sussex, and generally in Wigtonshire.

6833. According to Marshad, the best method is this:—The calves suck a week or a fortnight, according to their strength (a good rule); new milk in the pails, a few meals; next, new milk and skim.milk mixed, a few meals more; then, skim.milk alone, or porridge made with milk, water, ground oats, &c. and sometimes oil-cake, until cheese-making commences; after which, whey porridge, or sweet whey, in the field; being careful to bonse them in the night, until warm weather be confirmed. (Midtand Counties, vol. 1), p. 588). This method of suckling is not, however, free from objection; and, in the ordinary practice of rearing calves, it is held to be a preferable plan to begin at once to teach them to drink from a pail. The calf that is fed from the teat must depend upon the milk of its dam, however scanty or irregular it may be; whereas, when fed from a dish, the quantity can be regulated according to its age; and various substitutes may be resorted to, by which a great part of the milk is saved for other purposes, or a greater number of calves reared upon the same quantity. (General Report of Scolland, vol. iii, p. 51.) Yet it would seem to be a good practice to allow calves to suck for a few days at first, if there were no inconvenience to be apprehended, both to themselves and their dams, from the separation afterwards skim. (SSA: Where ealness are recreat with skim.milk, it should be boiled, and suffered to stand until it cools to the temperature of that first given by the cow, or a trilling degree more warm, and in that state it should be given to the cilf. Milk is frequently given to calves warm only; but that method will not succeed so well as boiling it. If the milk be given over-cold, it will cause the calf to skit or purge. When this is the case, put two, or the calf is capathe or each will always to be underst

preserve the liquor or broth, and mix it with milk for the calves.

6858. In summer, calves may sometimes be reared on whey only; but, when reared in winter, they must be fed with hay; and clover-hay is probably the best of any for this use. Calves may also be raised with porridge of different kinds, without any mixture of milk. It is sometimes a good and convenient plan, the author of the New Parmer's Calendar says, to bring up calves under a step-mother; an old cow, with a tolerable stock of milk, will suckle two calves, or more, either turned off with her, or at home, keeping them in good-condition, until they are old enough to shift: they ought to suck the first of their mother's milk for two or three days, although many are weaned without over being suffered to suck at all. Calves, whether rearing or fattening, should also always suck before milking, the cow being milked afterwards, as the first and thinnest of the milk is sufficiently rich. Old milk will, perhaps, scour a very young calr; but the effect will go off without any ill consequences. He observes, that the Duke of Northumberland's recipe is to takeo one gallon of skimmed milk, and to about a pint of it add half an ounce of common treacle, stirring it until it is well mixed; then to take one ounce of linseed-oil cake, finely pulverised, and with he hand lettif fall gradually, in very small quantities, into the milk, stirring it in the mean time with a spoon or ladle, until it he thoroughly incorporated; then let the mixture be put into the other part of the milk, and the whole be made nearly as warm as new milk when it is first taken from the cow; and in that state it is fit for use. The quantity of oil-cake powder may, from time to time, be increased as occasion may require, and as the calf becomes inured to the flavour of it. Crosk's method is to make a lelly of one quart of linseed, boiled ten minutes in six quarts of water, which jelly is afterwards mixed with a small quantity of the best hay tea. On this he rears many calves without milk: he

jelly of one quart of linseed, boiled ten minutes in six quarts of water, which jelly is afterwards mixed with a small quantity of the best hay tea. On this he rears many calves without milk: he thinks many calves are annually lost by artificial rearing, and more brought up with poor and weak constitutions.

6837. When calves are dropped during the grass season, Donaldson observes, they should be put into some small home-close of sweet rich pasture after they are eight or ton days old, not only for the sake of exercise; but also that they may the sooner take to the eating of grass. When they happen to be dropped during winter, or before the return of the grass season, a little short soft hay or straw, or sliced turning, should be laid in the trough or stall before them.

6838. *Castration* is performed both on male and female calves, when neither are intended for procreation. On cow calves, however, it is generally omitted: but in Norfolk no distinction is made as to sex; males and females are equally objects of rearing, and are both occasionally subject to castration, it being a prevailing custom to spay all heifers intended to be fatted at three years old; but such as are intended to be finished at two years old are, it is believed, pretty generally left "open," as are, of course, those intended for the dairy. There are two reasons for this practice: they are prevented from taking the bull too early, and thereby frustrating the main intention; and by this precaution may lie more quietly, and are kept from roving at the time of fatting. This may be one reason why spayed heifers are thought to fatten more kindly at three years old, and to be better fleshed, than open heifers.

6839. The time of performing the operation of castration in horned cattle, as in all kinds of live stock, is while the animals are yet very young, and just so strong as to endure this severe operation without any great danger of its proving fatal. The males, accordingly, are cut commonly when about a month old, and the females at the age

to their pasture, milk-pottage should be carried to them at each of their feeding hours. For the first month or six weeks, the calves ought every night to be brought out of the meadow, and lodged in the pens; but after this time they may be left in the pasture as well in the night season as in the day; and at this time their, food may be lowered by degrees, till it be at length reduced to simple water only; for, when the calves get to the age of twelve or fourteen weeks, they will no longer require the aid of this sustenance, but will be able to satisfy their appetites with grass. Care, however, must be taken throughout the summer that they be frequently shifted from one pasture to another, in order that they may be kept up in good flesh, and enabled to grow away with the utmost celerity. At Michaelmas, or soon after, the calves should be taken into the yard; and if they were allowed the indulgence of a small close to themselves it would be still better. still better.

be taken into the yard; and if they were allowed the indulgence of a small close to themselves it would be still better.

6841. The treatment of young cattle, from the time they are separated from their dams or are able to subsist on the common food of the other stock, must entirely depend upon the circumstances of the farm on which they are reared. In summer, their pasture is often coarse, but abundant; and in winter all good breeders give them an allowance of succulent food along with their dry fodder. The first winter they have hay and turnips; the following summer coarse pasture; the second winter straw in the fold-yard, and a few turnips once a day, in an adjoining field, just sufficient to prevent the straw from binding them too much; the next summer tolerably good pasture; and the third winter as many turnips as they can eat, and are in every respect treated as fatting cattle. (Culley, p. 47.)

6842. The method of managing young cattle during the first winter is, according to Donaldson, pretty generally the same in every part of the island. They are generally housed: sometimes bound up to the stall; but more frequently allowed to remain at freedom. The way of feeding them in England is chiefly with hay or hay and straw mixed; and in Scotland sometimes with hay, but more frequently straw and turnips. They are mostly turned out on some of the inferior pastures on the farm in the following summer, and maintained the second winter on straw in the straw-yard, or in louses or sheds erected for the purpose. Some farmers in the more northern parts of the kingdom, from being situated at a distance from any market at which they can dispose of stall-fed beef, ever frequently give a considerable part of their turnip-crop to their young cattle. This is, he thinks, an excellent practice; and one that ought to be followed, even by those who, from being better situated with regard to markets, can adopt other methods of using turnips to advantage. The benefit of green winter food for live-stock is so great, that there is

Subsect. 5. Fattening Calves by Suckling.

6843. The most advantageous stock for suckling calves for the butcher is that sort of cow which gives the greatest quantity of milk, richness of quality being not so great an object, or so well adapted to the desired purpose. The Holderness cows are to be preferred in this view; not, however, to suckle calves of the same, but of a smaller breed: perhaps Devon calves surpass all others as sucklers, whether for quickeness of proof, or beauty of the veal; they are not, however, to be procured but in or near their own

same, but of a smaller breed: perhaps Devon calves surpass all others as suckiers, whether for quickness of proof, or beauty of the veal; they are not, however, to be procured but in or near their own country.

6844. The method most commonly employed in fattening calves is, to allow them to suck; as by this method the object is probably not only sooner, but more effectually attained than by any other means. The period which is necessary for fattening calves in this way must be different, according to circumstances, but it is generally from seven to nine weeks; however, in the dairy districts, where milk is considered a valuable article, scarcely half that time is allowed. These is another method, which is, to give them the milk to drink; and when that is done, it is given them morning and evening warm from the cow, and the quantity increased according to their age and strength. In whatever way they may be managed, they should be kept in pens in a close house, and well littered. The allow of the Synopsis of Husbandry observes, that as it is necessary that the calves should lie always quiet, in order that they may indulge in sleep at those times when they are not employed in sucking, it seems proper that the cowhouse should be situated in the most retired part of the yard, and that the pens should be kept as dark as possible. But notwithstanding this caution, the calves should by no means be suffered to lie too hot in the summer time, which would be apt to produce a sickness amongst them. To admit, therefore, an occasional draught of fresh air, let a window be cut in each pen, with shutters adapted to the same, and let these windows be opened whenever the closeness of the atmosphere indicates it to be necessary. In the summer season, they should rarely, if ever, be closely shut; and when it is required, the stream of air may be increased by opening the cow-house door at the opposite end of the building. Each calf should have a collar round his neck, with which the attendant may direct him in his sucking, but shou be conveniently united.

beconveniently united. But he whole make hay be scheduly as the darly and the lattering of calves by stacking cannot be conveniently united.

6845. The only advantage which suckling can have, over giving calves milk to drink, is, that the action of sucking induces "a greater secretion of saliva, which, by promoting digestion, accelerates the growth and fattening of the young animal, cannot be doubted; but the secretion of that fluid may be likewise promoted, by placing an artificial teat in the mouth of the calf, and giving it the milk daily and at the natural temperature. In the dairy districts of Scotland, the dairy-maid puts one of her fingers into the mouth of the calf when it is fed, which serves the purpose of a teat, and will have nearly the same effect as a natural teat, in inducing the secretion of saliva. If that, or an artificial teat of leather, be used, and the milk given slowly before it is cold, the secretion of saliva may be prometed all the extent that can be necessary; besides that secretion is not confined to the mere period of eating, but, as in the human body, the saliva is formed, and part of it swallowed at all times. (Atton's Dairy Husb. p. 87.)

6846. Young cathes, when permitted to suck their fill, are often selzed with a lax or souring: to prevent which, the calves for the first fortnight or three weeks may be stinted in their allowance; and at the same time due care should be taken that they do not pine or decrease in flesh for want of milk. But after this age they should be allowed to suck as long as they choose; and every means ought to be made use of to increase their appetite, and render them more eager after their food. Chalk may be given for this purpose, as well as for giving to the flesh a delicate whiteness. An excellent astringent remedy has been already given. (6559.) Salt sprinkled in the trough will likewise act as a stimulus to the appetite; besides which, it is a common practice with some people to cram their calves with balls compounded of flour, pounded chalk, and mi

two, about the size of a walnut, once a day, or oftener, to each calf. These balls, being very nutritions, in some degree supply the place of milk, and at the same time the spirituous mixture operates on the creatures as a soporific, and thus, by composing them to sleep, increases their disposition to fatten; but where milk can be had in sufficient abundance, it is never worth while to have recourse to these factitious aids. When the demands of the calf, however, are beyond the ability of the cow, these balls come seasonably to their relief. In order that the calves may be provided with sufficient store of milk, the pastures should be changed, whenever the cows are found to be deficient in this particular; and in the winter time, such food as is of a succulent nature, as grains, turnips, &c., should be always at hand to supply the want of grass; and these, with a due allowance of the sweetest hay, should be their constant aliment during the time that the cows are confined to the yard.

6847. The prices of suckling calves vary according to the goodness of the young animal, and the time of

time, such food as is of a succulent nature, as grains, turnips, &c., should be always at hand to supply the want of grass; and these, with a due allowance of the sweetest hay, should be their constant alliment during the time that the cows are confined to the yard.

6847. The prices of euckling cadves vary according to the goodness of the young animal, and the time of year wherein the purchase is made. In general, sucklers fetch the largest price in summer, when veal sells the cheapest; and the reason of this arises from the smaller number to be net with at that time than in the spring. When calves are slaughtered at six weeks or two months old, the veal is seldom of a god colour; neither has the flesh of these young calves a taste equal to that of animals suffered to live a few weeks longer. To attain colour and flavour, it is necessary that the calves should be maintained with plenty of milk, and managed as before directed, till they arrive at the age of eight or ten weeks, according to the season of the year, the more or less kindly state of the calf, the particular demand of the markets, or other accidental circumstances. In the summer season, it may be proper to dispose of them at an earlier period than in the winter; not only on account of their growing away with greater celerity in warm weather, but likewise because of the increased demand for small veal, which is then most saleable. During the last three or four weeks, blood should frequently be drawn from the calf, which will be a likely means towards rendering the veal of a colour delicately white; a circumstance so much attended to by the butcher, that he will commonly depreciate such calves as, from the appearance of their eyes, are likely to die black, as they term it, though in other respects not to be despised.

6849. Calves suckled on their our dams will, generally speaking, fatten in a shorter time than those afterwards brought in to supply their places. The first obvious reason for this difference in their favour its, their having been permit

Subsect. 6. Fattening Horned Cattle.

6852. The fattening of cattle demands considerable and constant attention, and the grand object is to fatten quickly. An animal when in a state of rearing may be considered as a vessel open at both ends, in which the supply and the waste being nearly equal it can never be filled: fattening an animal may be considered as an attempt to fill the vessel, and this can only be done by excess of supply. The waste being the same as before, this excess must be great; if it is not so, the vessel may be filled to a greater height than before without ever becoming full. An important hint might be taken from this simile by many farmers, who know little of the difference between feeding and fattening. We have known cattle, sheep, and swine kept for months, and fed with a view to fattening them, without their gaining a pound of meat. 6853. The food on which cattle is fatted in summer is grass, commonly on pastures, but, in a few instances, cut and consumed in feeding-houses or fold-yards: in winter by far the greater number are fatted on turnips, along with hay or straw; oil-cake, carrots, potatoes, and other articles of food, are used occasionally, and in particular districts, oil-cake chiefly for feeding the larger animals; but few, comparatively, are fatted on any of these without the addition of turnips of one or other of the varieties generally cultivated. A considerable number of cattle are also fatted on the offals of distilleries, when distilling from corn; a source of supply, the frequent interruption of which has been much felt in those situations where the soil does not permit the extensive cultivation of turnips. It is seldom or never the practice of the best managers to fatten cattle with roots or other winter food on the field, during that season; but to confine them to houses or fold-yards, where they are well littered, regularly fed, not liable to be disturbed, and sheltered from the inclemency of the weather, and where the manure they make is an object of very considerable importance, and of much greater valu

over a whole field.
6854. The age at which cattle are fatted depends upon the manner in which they have been reared; upon the properties of the breed in regard to a propensity to fatten earlier or later in life; and on the circumstances of their being employed in breeding, in labour, for the dairy, or reared solely for the butcher. In the latter case, the most inproved breeds are fit for the shambles when about three years old, and very few of any large breed are kept more than a year longer. As to cows and working oxen, the age of fattening must necessarily be more indefinite; in most instances the latter are put up to feed after working three years, or in the seventh or eighth year of their age. In general, it may be said, that the small breeds of cattle are fatted on pastures, though sometimes finished off on a few weeks' turnips; and that large cattle, at least in the north, are chiefly fatted in stalls or fold-yards, by means of turnips, and the other articles before mentioned articles before mentioned

6855. Stall-feeding is the most common, and, when judiciously conducted, probably the most eligible method, in regard to the cattle themselves, the economy of food, and the expense of farm buildings. The small shed and fold-yard, called a hammel (2831.), are used only for the larger breeds; but they do not

seem well calculated for an extensive system of fatting by those who do not breed, but purchase stock every year from different parts. (Sup. E. Brit. art. Agr.)
6856. The two great points in feeding animals to proof, according to the author of the Farmer's Calendar, are, regularity, and a particular care of the weaker individuals. On the latter account there ought ever to be plenty of trough or rack room, that too many may not feed together; in which very common case the weaker are not only trampled down by the stronger, but they are worried, and become cowed and spiritless, than which there cannot be a more unfavourable state for thriving; besides, these are ever compelled to shift with the worst part of the meat. This domineering spirit is so remarkably prevalent amongst hoursed cattle, that he has a hundred times observed the master-beasts running from crib to crib, and absolutely neglecting their own provender for the sake of driving the inferior from theirs. This is, much oftener than suspected, the chief reason of that difference so visible in a lot of beasts, after a winter's keep. It is likewise, he says, a very common and very shameful sight, in a dairy of cow, to see several of them gored and wounded in a dozen places, merely from the inattention of the owner, and the neglect of tipping the horns of those that butt. The weaker animals should be withdrawn and fed apart; and, in crib-teeding in the yard, it is a good method to tie up the master-beasts at their meals.

6357. Fattening cattle, Donaldson observes, are usually put to grass, the nature of the pasture, and many others; but, in ordinary cases, an ox will be completely fattened in three months. There is, he says, one method of fattening, connected with the grazing system, that the farmers in England are, from the superior excellence of the climate, enabled to adopt with success, which can never be attempted with propriety in Scotland. It is very common, at the close of the grass season, when the fattening stock happen not to be fully in conditi

sometimes be seen several hundred head of cattle.

6800. The method of fattening cattle with oil-cake, corn, cut chaff, &c. is practised in many of the English counties, with a degree of success sufficient to warrant farmers in other parts of the island to follow the same practice. The cattle are commonly put up to fatten at the end of the grass season. The usual allowance of oil-cake, after it is broken in a large mortar, or, in the fruit districts, in a cyder-mill, is about half a peck per day, one half in the morning, and the other in the evening; to which is added hay, and in some cases ground corn, that is, oats or barley of inferior quality, and cut strap, provincially "chaff." As bullocks fattened in this manner get regularly five, and sometimes six, meals a day, it is sufficiently evident that, although it may be, upon the whole, an expensive mode of fattening, yet it must be both expeditious and effectual.

expeditions and effectual.

6881. Bookh establishment for futlening calle at Brentford is one of the most extensive in the neighbourhood of London. It was formed for the purpose of consuming on the spot the grains and wash of the extensive distillery of that family. The building is 210 feet long, and 180 feet wide; and calculated to contain 600 head of cattle. It cost 8500%. The side walls are about at each end, not glazed, and a few glazed skylights in the roof. The roof forms one ridge, and the centre part of it affords space for an ample hay-loft; it is supported by castion and wooden pillars, so numerous as to have the appearance, on first entrance, of a forest of columns. A passage of six for the control of the centre of which is paved with plates of cast-iron, is even of cartle are presquest of the same width and description. The whole is lighted by thirty-six gas-lights. The cattle stand in stalls seven feet and a half wide; and the space from the manger to the gutter behind the cattle is about ten feet: the gutters have an inclination to one end, and there are also underground drains having a similar inclination, into which the liquid from the gutters runs through from gratings. Therefore, the bottom of which is on a perfect level. The periton of this manger contained in every double stall has a second bottom, with two ends let into it, the second or upper bottom descending to within three inches of the bottom common to the whole manger. In the upper trough so formed, and which, in length, occupies about half of the length of the portion of their solid food; the common manger being for the re-

ception of the wash, or other liquid food or drink. The immense quantity of wash produced by the distillery is kept in a cistern or tank above the level of these mangers, and in a different part of the premises; but pipes from this tank are conducted under the surface and communicate with each of them, so that by turning a cock the whole of the cattle in any one of the ranges are instantly supplied with wash. This particles of the ground mait, and the greater part of the barley meal used in the mashing process. The grains are kept in deep pits about twelve feet square, and ten or twelve feet deep, somewhat narrower at bottom than at top, lined with brick set in cement; and when the grains are trodden in, and raised like the ridge of a house, they are covered with road stuff to exclude the ridge of a house, they are covered with road stuff to exclude "is used, and neither green food nor hay uncut is ever given." Oil-cake is used, hut not always; it being found that rough clover chaff mixed with the grains and wash will fatten to any extent.

tent.
6862. This building, though crected at great expense, is very unsightly, and far from complete. It is much too cold in winter from the openness of the roof, and, exteriorly, very unpleasing to the eye. f. om its great height.
18 utterly distingured by seemingly innunerable posts, three fourths of which are of little or no use. For one third part of the cost an equally useful, and much handsomer structure might have been erected. It has never paid a profit to its owners, who, if they could sell their wash and grains at the present market price, calculate that their profits would be considerably greater than by consuming it on the premises.

Subsect. 7. Management of Cows kept for the Dairy.

6863. Milch cows are kept for the manufacture of butter and cheese, for the suckling of calves for the butcher, and for the immediate use of the milk.

6864. The kind of cow used by the dairyists who supply the London market is chiefly the Holderness, a variety of the short-horned breed, with large carcasses and short horns. They are bred chiefly in Yorkshire and Durham; but in part in most counties. The Edinburgh dairies are supplied by short-horned cows from Roxburghshire, and other pastoral districts in the south of Scotland. For private dairies, the variety bred in Ayrshire (fig. 864,) have a decided preference, as giving a rich milk and large proportion of butter; and the cheese made from the milk of this breed, known as Dunlop, is decidedly celebrated. In Lancashire, the native long-horned breed is said, in the Report of that county, to obtain the general preference: but in Hodgson's the native long-horned breed is said, in the Report of that county, to obtain the general preference: but in Hedgson's dairy at Caton, in the same district, it was found that a short-horned cow, upon an average of twelve months, will yield nine quarts of milk in the day, and four and a half pounds of butter in the week; and a long-horned cow gives eight quarts of milk in the day, and four pounds of butter in the week, for the same period. The cows of both kinds had constantly the same kind of food; but, in order to have the clear result, the quantity of food consumed by each cow of the different breed should have been fully ascertained. The produce of milk and butter is on the side of the short.

3 U

horned sort; but it is not ascertained whether the neat balance is in favour of the short or long-horned; (Lancashire Rep. 551.) The Guernsey breed is valued by some for the richness of the cream and butter; but, both for the dairy and butcher, it is very unprofitable.

6865. Where butter is the principal object, such cows should always be chosen as are known to afford the best milk and cream, and in the largest quantity, of whatever breed they may be. But the weight of butter to be made from a given number of cows must always depend on a variety of contingent circumstances: such as the size and goodness of the beasts; the kind and quantity of the food; and the distance of time from calving. As to the first, it need scarcely be mentioned that a large cow will give greater store of milk than one of a smaller size; though cows of equal size differ as to the quantity of cream produced from the milk of each: it is, therefore, on those cows whose milk is not only in large abundance, but which, from a peculiar inherent richness, yields a thick cream, that the butter dairyman is to place his chief dependence; and where a cow is deficient in either of these, she should be parted with, and her place supplied by one more proper for this use. As to the second particular, namely, the kind and quality of the food, those who would wish to profit by a dairy ought to provide for their cows hay of a superior goodness, to be given them in the depth of winter, and this in an unlimited degree, that they may always feed till they are perfectly satisfied; and, when the weather will permit, the cows should be indulged with an outlet to marshes or low ineadow-grounds, where they may feed on such green eyestables as are precent; which is far preferable to the practice of confining them the whole day on dry meat, will enable them to yield greater plenty of milk, and will give a fine yellow colour to the butter even in the winter season.

season.

6866. In the vales of Buckinghamshire and Oxfordshire, very great numbers of cows are kept for the purpose of butter. These fertile lands maintain a breed of large cows, which yield great store of milk; so that it is no uncommon circumstance for one farmer to keep a herd of fifty or sixty, and to collect a quantity of cream sufficient to fill a barrel-churn of sixty gallons in a week. The butter made from this cream is sold by the farmer or dairyman to persons who make it their business to purchase this article at a stated price from Michaelmas to Lady-day, and at an inferior rate from Lady-day to Michaelmas. The butter thus collected is sent to London every week in waggons. It is consigned to the dealers, who retail it to the consumer; and no small profit from this traffic accrues to the waggoner and the butter-merchant. This butter is mostly made up in lumps of two pounds each, and for that reason it has obtained the name of lump-butter. Its flavour is peculiarly sweet and agreeable, which is chiefly owing to the goodness of the pasture whereon the cows are fed; for this intrinsic merit would in vain be sought for in butter made from ordinary pastures, how great soever may be the skill of the dairy-woman. Though the grass should be equally luxuriant, the cows of the same breed, and the cream in like abundance, yet would a decided preference still remain in favour of the vale-fed cows; for, as a fattening beast on rich land will thrive much quicker than on thin soils, though the herbage be shorter on the former than on the poor ground, so will cows give a larger store of milk, and that of a more nutritious quality, when fed on deep fertile meadows, than if depastured on those of inferior goodness or quality.

6867. Epping butter has long been held in the highest estimation; and great quantities are manufactured in Cambridgeshire and the adjoining counties. The Cambridge butter is sent in small pans; it has an additional quantity of salt mixed with it, to insure its keeping for ten days or a fortnight;

tubs for the southern markets.

tubs for the southern markets.

6868. Where cheese is the principal object, the management in respect to the cows must be the same.

6869. When the object is the suckting of calves, the farmer should provide himself with a breed of cows suited to the quality of his land. Where the farm abounds with fertile pastures, watered with wholesome streams, and not far distant from the yard, so that the cows may be turned immediately out of the suckling house upon their feed, the benefit will be in every respect superior to what can be expected from an arable farm, or where the green land is in a small proportion to the ploughed; for, in this latter case, the cows must depend for their sustemance chiefly on artificial fodder; such as clover, rye-grass, turnips, and other roots and herbage.

6870. The combours should be of a size adapted to the number of the beasts. Each cow should be

farm, or where the green land is in a small projection to the ploughed; for, in this latter case, the cows must depend for their sustenance chiefly on artificial fodder; such as clover, rye-grass, turnips, and other roots and herbage.

6870. The cow-house should be of a size adapted to the number of the beasts. Each cow should be driven into the house at suckling-time, and her head confined in a proper manner, having some fodder lying constantly before her, and a space left between every beast. When they become accustomed to this kind of restraint, they will without any trouble come into the places destined for them, when the calves may be suckled with the greatest case and facility.

6871. The time cows should become dryb before their calving is not agreed on, some contending that they may be milked almost to the time of their dropping the calf without injury; while others maintain that it is absolutely necessary that they should be laid dry from one month to two, both for the advantage of themselves and their calves. It is probable that much in this business must depend on the manner in which they are kept; as when well fed they may be continued in milk till within a week or two of their calving, without suffering any injury from it; but in the contrary circumstances it may be better to let them run dry for a month, six weeks, or more, according to their condition, in order to their mone fully recruiting their strength. It appears not improbable, but that the longer the milking is continued, the more free the cows will be trom indurations and other affections of the udder; which is a circumstance deserving of attention. Where only one or two cows are kept for the supply of a family, it is likewise useful to know, that by good feeding they may be continued in milk without any bad consequences till nearly the time of calving.

6872. Cows sometimes slip their calves before they are sufficiently grown. Where this occurs, it is essentially necessary to remove such cows immediately from the cow-yards, or from mixin

of gestation is accomplished, assumes, in some degree, the appearance of milk, and may be drawn from the teats. To spring at the bearing, is when this part is more than ordinarily large and distended. Heifers are said to spring soonest at bearing, and old cows at the udder. Some cows are peculiarly given to abortions; and where this happens, they should never be continued long in the herd, as being unlikely to yield any considerable degree of profit to their owners.

6876. Cows which are expected shortly to cabee ought to be lodged at night in a large convenient outhouse, or some other place, for a week or two previously to calving, as it may be the means of saving the life of the calf, and perhaps that of its dam: for, when a calf drops in the yard or field under such circumstances, the hazard of its perishing through the inclemency of the weather is very great, and it may considerably endanger the life of the cow. But if, from inattention or other causes, the creature should eath cold by calving abroad in sharp winter nights (which may be perceived by a refusal of her food, and by her trembling joints), she ought immediately to be driven into a warm shed, together with her calf, and fed with sugar-sops and ale, and with the best and sweetest hay, and should not be suffered to drink any cold water. By this treatment she will mostly recover in a few days; but should the disorder hang about her, balls composed of aromatic cordial substances may be given.

6877. A milch cow is in her prime at five years old, and will generally continue in a good milking state till ten years old or upwards; but this depends greatly on the constitution of the animal, some cows, like other animals, exhibiting marks of old age much earlier than others.

6878. Cows of large size yield great store of milk when turned on pastures where the grass is in sufficient abundance, or fed with a constant supply of such food as, from its succulency, conduces much towards the nutriment of the creature, and enables her to give large quartities of m

shire or Staffordshire breed, which, having been bred on the best kind of land, would be starved where a Scotch or a Welsh cow would find an ample supply of food.

6879. Those who would make the utmost advantage from cows, either as calf-sucklers, dairymen, or milk-sellers, should always provide a bull to run in the herd, to obviate the perpetual trouble of driving them perhaps a mile or more to the bull, and in order to prevent the loss and inconvenience of their becoming frequently barren. One bull will generally be sufficient for twenty cows. These animals are in their prime at two years old, and should never be suffered to continue longer in a state of virility than to the fifth year; as, after that time, bulls which before were gentle and lay quiet in the cow pastures, are mostly apt to contract vicious dispositions, and become very unmanageable. Whenever this happens, they should be immediately castrated. In the principal town dairies of Scotland, such as Edinburgh, Glasgow, &c. the cows are never allowed to take the bull, but are sold off, after being kept a year or less, to the butcher, and fresh cows bought in their place. This is one very remarkable difference between the management here and in the town dairies of England.

6850. For feeding of stalled cows, the following directions are given to the cow-feeder in an improved dairy establishment near Farnham, in Surrey:—"Go to the cow stall at six o'clock in the morning, winter and summer; give each cow half a bushel of the field beet, carrots, turnsy, or potatoes cut; at seven o'clock, the hour the dairy-maid comes to milk them, give each some hay, and let there be plenty of fresh water in the troughs; at nine o'clock give each cow thay and let there be plenty of fresh water in the troughs; at nine o'clock give each cow three gallons of a mixture composed of eight gallons of grains and four gallons of bran or pollard; when they have eaten that, put some hay into the stally gallons of grains and four gallons of bran or pollard; when they have eaten tha

feed, at noon, a quart of malt dust."

6851. Directions to the dairy-maid: — "Go to the cow stall at seven o'clock; take with you cold water, and a sponge, and wash each cow's udder clean before milking; dowse the udder well with cold water, winter and summer, as it braces, and repels heat. Keep your hands and arms clean. Milk each cow as dry as you can, morning and evening; and when you have milked each cow, as you suppose, dry, begin again with the cow you first milked, and drip them each; for the principal reason of cows failing in their milk is from negligence in not milking each cow dry, particularly at the time the calf is taken from the cow. Suffer no one to milk a cow but yourself, and have no gossiping in the stall. Every Saturday night give in an exact account of the quantity of milk each cow has given in the week." (Farm. Mag. vol. xv. n. 314)

p. 314.)
6882. Harley's dairy establishment at Glasgow has been celebrated since 1813. The object of the proprietor, who is engaged in various extensive concerns, is to supply the public with new milk free from adulteration, and to have the cow-house, cows, and milk kept in a more cleanly state than by the usual

mode.

6885. Harley's com-house is fitted up upon a new construction. The cartlet stand in rows, twelve in arow, across the house, head and head, and tail and tail, alternately; there is a passage behind for cleaning, and one in front for feeding. In front of each cow is a wire grating, hung like a window sash, which flee up when giving the soft food and cleaning the cribs, and fifth up when giving the soft food and cleaning the cribs, and washing the cribs, collecting the urine, ventilating the house, &c., give peculiar advantages to the establishment, which may be summed up in the following, items:—The health of the cattle; the preservation of the timbers; the diminished danger from fire, there being no hay-loft above the cattle; the preservation of the timbers; and the flavour of the milk. The servation of the provender; and the flavour of the milk. The be produced, so as to keep the cattle comfortable in the horiest weather, by which their health is promoted. The ventilation also prevents the timber from rotting; makes the cows eat their fodder better, as their breath is allowed to escape, instead of being thrown back upon the food, as is the case when their beads are placed opposite a wall. It is well known that milk east are placed opposite a wall. It is well known that milk cow-house is filled with had air, the milk, while passing from the text to the pail, and during the time it may stand in the house, will be impregnated with the food atmosphere.

6884. In Redwing and preparing the food, Harley has made many experiments: and by the mode he now follows, the cattle fatter and milk better, than by the ordinary process; and the substantial and the mode of lock-clean milked, and also prevents fraud; and the mode of lock-clean milked, and also prevents fraud; and the mode of lock-clean milked, and also prevents fraud; and the mode of lock-

ing up the milk, and at the same time of admitting air, prevents adulteration by the retailer. The cows are not farmed out to milkmen as in London.

6886. The stock of come for some time back has been 190, averaging eleven English quarts each per day; but both quality averaging eleven English quarts each per day; but both quality as decided preference to the Ayrabire breed of cows. They are bought chiefly at country fairs, either newly calved, or a few weeks before calving, and never turned out till they go to the butcher.

weight chiefly at country fairs, etther newly calved, or a few weeks before calving, and never turned out till they go to the butcher.

6887. The food of the come during nummer consists of cut grass of the come and the come an

6891. The advantage of irrigating grass lands with the con's urine almost exceeds belief. Last sesson some small fields of old grass were cut six times, averaging fifteen inches in length at each cutting, and the sward very thick. The soap-suds of a public washing-house are applied to the same purpose with considerable advantage.

6892. The advantage of this system to the owner of the cattle is shown by the following abstract, in Harley's own words; but the benefit of a liberal supply of gentnie milk to the community at large, particularly to children, it is not easy to estimate:—

To the general health of the cattle by ven To the general network of the states of thation remains of the second of 15 per cent. do

6896. The London dairies of most eminence are the two at Islington, belonging to Mr. Laycock and Mr. Rhodes, and the Metropolitan Dairy in the Edgeware Road. From 1822 to 1829, a number of other dairies sprang up, and made a conspicuous figure for a time; but, like other bubbles of those years, they have nearly all burst, and none now remain worth notice. We examined the Islington and Metropolitan dairies in October 1830, and the following is a brief outline of the result:—

dairies sprang up, and made a conspicuous figure they have nearly all burst, and none now remain with a construction of the co

common to all such establishments, which it is not necessary to describe.

6898. The cows in Rhodes's dairy are purchased newly calved in the cow market held in Islington every Monday. They are kept as long as they continue to give not less than two gallons of milk a day, and are then fattened on oil-cake, grains, and cut clover hay, for the butcher. The short-horned breed is preferred, partly for the usual reason of being more abundant milkers than the long horns, partly because the shortness of their horns allows them to be placed closer together, and hardly account. The Arrhive level his been tried to the number of 150 at a time, and highly approved of, as affording a very rich cream, as fattening in a very short time when they have left off giving milk, and as producing a beef which sold much higher than that of the short horns. The difficulty,

To saving of timber in the building, as they will last more than double the time 50 per cent.

6893. Harley has a steam-engine for driving the following nachinery: --

nosob. Harvey are a tream-engine for criving the following machinery:

A structure:
A turnly and potato silcer.
The churning apparatus.
Pumping water, &c.
The same boiler that drives the engine steams the food,
which is now brought to such a state of perfection, that it receives the cordial approbation of all who have seen it; furnishing the community with genuine milk at a comparatively low
price. It is admitted, that the greater part of the system is
criginal, and is not to be met with in any part of the kingdom.
(Form. Mag. xv. 1859). Here ye system are now considered to be
greatly exaggerated in the above account. Taking the system
altogether, it may be described as essentially that employed by
the dairy-farmers in Holland and the Nether ands, described
at length by Radcliff and sinclair, and noticed in preceding
sections of the present work from the above and other writers.

for a time; but, like other bubbles of those years, brief outline of the result:—

however, in procuring this breed was found to great, that Mr. Rhodes was obliged to leave it off. The length of time during which a cow, treated as in this establishment, continues to give milk, varies from six months to the almost incredible period of two years. We were assured of there being at this moment several cows among the 390 which we saw, that had stood in their places even more than two years, and continued to give upwards of one gallon of milk daily.

In the place were more than two years, and continued to give upwards of one gallon of milk daily.

In most other establishments if not in all, stall-fed cows or cattle are let out at least once a day to drink; but these animals have clear water continually before them. They are kept very clean, and the sheels are so remarkably well ventilated, by means of than that of any cowhouse we had ever before examined; probabily from its direct perpendicular entrance through the toof, this, in moderate weather, being certainly far preferable to its horizontal entrance through the side walls.

6900. The principal flood off the convar in Rhodes's dairy, as in all the other London establishments, consists of grains; that is, the brewing seasons are chiefly autumn and spring, a stock of grains is laid in at these seasons sufficient for the rest of the grains are generally laid in pits bottomed and lined with brickwork set in cement, from ten to twenty feet deep, about twelve or sixteen feet wide, and of any convolent length. In the context of
woo'uncess and cow a day. It is mixed with the grains which are supplied before milking, about three o'clock in the morning; and in the afternoon, about two o'clock, just before milking.

6902 Of green food or roots portions are supplied alternately with the grains; and in winter, when tares or green grass cannot be procured, after the turnips, potatoes, or mangold wurzel have been eaten, a portion of dry hay is presently will and cream for private families and for public hospitals and other institutions. A number of the public establishments are supplied directly from the dairry, by contract; but private families are principally supplied by milk dealers: these have what are called milk-walks; that is, a certain number of customers whom they call upon with supplies twice a day; their customers consume, and to contract with Messrs. Rhodes for this average. The latter calculate the number of cowa sufficient to give the dealer the supply wanted, and this number the dealer undertakes to milk twice a day; to wil, at three o'clock in the morning and at three o'clock in the afternoon. The milk is measured to the dealer, and should he have milked more than his quantity it readed to the contracts of the dealer are continually varying, it often happens that considerable quantities of milk remain on the dairy-man's hands, frequently, we are told, as much as sixty or seventy gallons a day. This quantity are formed in the dealer and the demand of the dealers are continually varying, it often happens that considerable quantities of milk remain on the dairy-man's hands, frequently, we are told, as much as sixty or seventy gallons a day. This quantity are the cows and the demand of the dealers are continually varying, it often happens that considerable quantities of milk remain on the dairy-man's hands, frequently, we are told, as much as sixty or seventy gallons a day. This quantity are the cows and the demand of the dealers are continually varying, it often happens that considerable quantities of milk remain on the dairy-man

6904. The management of Rhode's dairy is committed to three persons:—A clerk, who kreps the books, collects debts, pays and receives; a man, who superintends the feeding and the treatment of the stock, and has the general care of the premises; and a dairy-woman, who sees the milk measured to the dealers, and superintends the dairy. The cows are purchased and sold by regular salesments of the sees the milk measured to the dealers, and superintends the dairy. The cows are purchased and sold by regular salesments of the sees that the same from 400 to 700; but there are open sheds sufficient to shelter from 900 to 9000 head of cattle, and these sheds are accordingly appropriated to taking in cattle for the sights previous to the days on which Smithened the stabilishment differs from that of Messrs. Rhodes. The cows are fed in the same manner, with the exception of not receiving any salt among their grains; but the hay is salted when put into the rick. They are turned out once a day to drink from troughs in the yards, remaining out from half an hour to three From the end of June till Michaelmas, the cows are turned into the fields from six o'clock in the morning till eleven o'clock, and from two o'clock in the afternoon till about three o'clock in the following morning. The remaining hours of the twenty-four they are in the cow-houses for the purpose of being milklews stabilishment. Those which become barren are fattened in the same manner on grains, oil-cake, and, what is rather uncommon, boiled linseed. This linseed is boiled in a common boiler, and when reduced to a pulp, let out by tubes into large wooden clsterns, where it is mixed with clover-chaff roughly wooden clsterns, where it is mixed with clover-chaff roughly che cattle. Those cows which are good milkers are allowed to take the bull, for which purpose eight bulls are kept. The usual period of keeping the cows is three or four years; the caves are sold in Smithfield, when only a few days old, to those whose business it is to take them to the country and

woman.
6906. The Metropolitan Dairy establishment is situated in the
Edgeware Road; it was founded by the late Mr. Rhodes fifteen
years ago, and after undergoing various changes, and among
others being possessed by one of the bubble companies, from

which its present name is derived, is now the property of Mr. Wilberforcs. It stands on less than an acre of ground, and is well arranged. It is calculated for 500 cows, on the new contains 520, most of which are in milk, but some are fattening. The cowhouses are in parallel ranges twenty-four feet wide, the side walls eight feet high, the space allowed for each cow about three feet nine inches, and the greater number of cowhouses without stalls. There is one found that the latter is very apt to make the cows stamble, when turned out upon any occasion. It is true, these occasions are rare, for the cows here, as in Messrs. Ahode's establishment, are never untied from the day they are put into the milking shed till they are removed to the fattering sheds, or till fluely are it in the control of the control

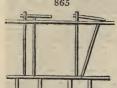

6907. The defects of the London dairy establishments appear to us to be chiefly want of cleanliness, and imperfect ventilation. The first is to be removed by under-ground gutters, covered with oak plank pierced with numerous holes; and by the more abundant supply of litter: the second by openings in the roof as at Messrs. Rhodes's establishment, which, as we have said before, seems the most perfect in that respect of the three just examined. Compared with the Dutch and Gernan dairies (p. 525. 587. and 611.), and with that of Harley of Glasgow (p. 6882.), they are very deficient both in original design and in management. It is a great mistake to suppose that they are lucrative concerns; and the idea is by no means pleasing of consuming milk chiefly manufactured from grains and distiller's wash, and produced by cows deprived of all exercise in the open air. Not more agreeable is the knowledge of the fact that the London market is supplied with so large a proportion of cattle fattened chiefly no il. cake. According to a calculation we all exercise in the open air. Not more agreeable is the knowledge of the fact that the London market is supplied with so large a proportion of cattle fattened chiefly on oil-cake. According to a calculation we formed, the three establishments mentioned must supply, at an average of the year, nearly thirty fat cattle weekly. Booth's establishment, already described (6861.), probably furnishes half that number at the average of the year; and taking into consideration other establishments for fattening on oil-cake and grains, local and provincial, we shall probably not be far wrong in estimating that this description of beef is at all times the prevalent one in the London market. The cattle fed in pairs in hammels, (§ 2831.) that is, permitted to walk about in an open shed, as in Berwickshire and East Lothian, must produce a very different description of beef. The time will no doubt arrive when oil-cake beef will not find a market in England, but when the cattle so fed will be sent alive in steam boats to the Continent, or other parts of the world, where the taste of the inhabitants in the article of butcher's meat is less refined. Already country dairies have sprung up at the distance of from five to twenty miles from London, and the milk and cream are sent to town in close vessels in spring carts, which go at a rapid trot. When, instead of these spring carts, rail-roads are established, on which carriages may go at the rate of thirty miles an hour, the milk and butter used by the commonest people of London will be of as good a quality as that now used almost exclusively by gentlemen who have country seats. now used almost exclusively by gentlemen who have country seats.

SUBSECT. 8. Working of Horned Cattle.

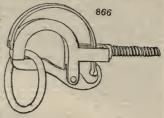

6008. The arguments for and against the working of oxen have been already stated. (4828.) Though horned cattle are gradually disappearing as beasts of labour, it is probable they will in many places be occasionally used as a substitute for horses, or to get up one or two additional teams on extraordinary occasions. Indeed we see no objection to the occasional use of both oxen and cows for this purpose; more especially in cases likely to occur in the farming of an extensive proprietor, such as breaking up his park, or cutting down and carting away timber, earth, gravel, &c. to a greater extent than can be readily performed by the ordinary teams of the establishment. For these and similar purposes of anateur farmers, and probably for some purposes on the farms of rent-paying cultivators, the borned cattle of the farm may afford a valuable resource. For these reasons, it seems fitting in this work not to consider the working of oxen as altogether an obsolete practice; and we shall, therefore, notice the training, harnessing, shoeing, age of being put to work, and general treatment of these animals so employed.

(300). The training of the calf intended for labour, according to some, should commence at an early period; and after being accustomed to be handled, he should be taught to present his foot to the shoeing smith, as readily as the horse, which is partially the practice in some places. No animal, however, is so easily broke as the ox at any age; and in most countries, where they are used in labour, they are never handled till harnessed and put in the plough, or to drag a tree. This is the case both in Devonshire and

Herefordshire, and as they are only worked a few years it does not seem desirable to be at any great expense in their training. The Roman practice, in this particular, may deserve imitation. (99.) 6910. Working ozen when kept in a house are generally confined to their places by the same sort of fastening used for cows, (fig. 865), in which their neck has free play between two upright spars; but in some establishments a ring

of a particular description (fig. 866.) is used, to which they are tied by a halter attached to a head strap or bridle. The ring is gene-rally screwed into the front of the manger or eating trough. The cattle fasten-ing used in Devonshire is

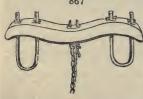

ang used in Devonshre is a wooden bow put on their necks and fastened to a round post. The bow consists of two pieces; the yoke, which has two slits terminating in round holes; and the bow, which is made of split ash, and has a knob at each end. These knobs being put through the round holes, the elasticity of the bow forces it along the slit

has a knob at each end. These knobs being put through the round holes, the elasticity of the bow forces it along the slit and prevents it from returning.

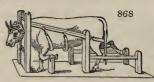

6911. Harness for labouring cattle is of three kinds: that for bearing as saddles some sorts of oxen yokes; that for drawing or pushing, as traces, brechins of saddles, &c.; and that for guiding the animals, as bridles, halters, reins, &c. These articles are of considerable expense, but when taken care of, kept dry, and the iron joints and leathers oiled occasionally, they will last a long time. In making all harness for beasts of labour great care ought to be taken to avoid superfluous materials which only encumber, and ornaments which only add to the expense. The London harness is much too heavy for agricultural purposes; that of Berwick or Newcastle is much more light and sufficiently strong.

6912. The most approved kind of harness for the ox is little different from that of the horse, except in the shape of the collar. In many places however, and especially on the Continent, the ox draws solely by the withers, by means of what is called a yoke and bow. (fig. 567.)

6913. The shoeing of oxen is a practice which is yet far from being performed in a perfect manner. Clark says, that in many parts of France, where the ox is used for draught, it is sometimes necessary to employ eight shoes, one under each nail; or four, one under each foat are generally made use of, being mostly fixed on, especially in the northern districts, with three or four large-headed nails to each shoe. They are fitted on in a similar manner to those of the horse, But, as the shoes of these animals from the smallness of the pieces are so liable to break, it has been suggested to have them shod with whole shoes in the manner of the horse; but how far this practice would answer, must depend upon future trials. As there is much trouble in the shoeing of oxen, from the necessity for casting them each time, it has been found requisite to have recourse to contrivances for shoeing them standin

recourse to contrivances for shoeing them standing (fig. 868.) 6914. An ox shoe (fig. 869.) consists of a flat piece of iron, with five or six stamp holes on the outward edge to receive the nails; at the toe is a projection of some inches, which, passing in the cleft of the foot, is bent over the hoof, so as to keep the shoe in its proper place. This projection is not, however, employed in the general practice of making these shoes. these shoes.

feels are at which an ox may be worked is from two and a half to three and a half ears. Some begin at two, but it ought to be for very light operations, and such as report of long duration. The period to which the ox is worked varies from his fifth vears.

are not of long duration. The period to which the ox is worked varies from his fifth to his tenth year.

6916. Parkinson's father used to make up occasionally an ox team for the plough of four oxen and one horse as a leader, which he found did about two thirds of the labour of two horses. There are, he says, great objections to ox-teams in the plough. He has, however found them useful in some sorts of farmwork, from their slow, steady pace; as in scarifying, leading dung, &c., as the work suits them from its being easy, and having a great deal of standing: they are, says he, much more cheaply kept than horses, and eat straw in the winter, and are valuable for making dung. He never saw this practice injure their growth. They may be worked from two till five years old, without any loss of time, as they grow to that age, and are then both larger and better beef than three-year-old steers. He therefore recommends ox-teams for leading dung and the other odd jobs, but not to plough and harrow. If they are worked to the farmer.

(8017. Bakewell used to work his heifers moderately, whilst exercise the surface of the surfa

6017. Bakewell used to work his heifers moderately, whilst carrying their first calves; an unobjectionable practice, provided they are well fed. Bulls are generally allowed to be good labourers, and capable, if high fed, of vast exertions.

0 0 0

if high fed, of vast exertions.

6918. The length of time per day which an ox is kept in the yoke varies according to the kind of labour, and the age and keep of the ox. If an ox is fed on hay, oats, and some roots, he will plough four days a week; but if on straw and roots only, not above three days. In the former case he is worked two whole days and two half days, and in the latter case as ix half days. The latter is the best plan, for which reason, where oxen are regularly worked, two pairs should be kept for each ploughman.

6919. The most desirable breeds of oxen to work are the Devonshire and Herefordshire varieties, which are long-legged, quick-stepping animals. Lord Somerville, who has carried the working of oxen to greater perfection than any one else, prefers the Devon breed, which most cultivators consider the quickest walkers in England. When horned cattle are only worked occasionally, whatever sort of animals are on the farm, whether bulls, cows, or oxen, of good or bad breeds, will necessarily be employed.

6920. The food of horned cattle employed in labour must be substantial. It is agreat mistake to suppose they can work on straw alone. Unless they have roots added to straw in winter, and green food in summer, it will be an idle attempt to harness animals so nourished. The best and indeed the only way is to feed them well with straw, coarse hay, roots, green herbage, or pasturage, as the season and other circum-

them well with straw, coarse hay, roots, green herbage, or pasturage, as the season and other circumstances may indicate.

Subsect. 9. Anatomy and Physiology of the Bull and Cow.

6921. The general structure of the bull and cow presents some peculiarities when compared with the horse, whose anatomy having been fully explained, will be taken as the subject of comparison. The ox, as an animal machine, displays less complexity of structure than the horse; but the principal differences between the two will be found to arise from the evident intention of nature to bound the locomotion of horned cattle: the limbs of the ox are therefore not found favourable to speed; nor does his general mass betray that symmetrical proportion and mechanical composition that would fit to be acted on to advantage, as it regards quick motion, by the powerful muscles he evidently possesses; for strength alone will not produce speed.

6922. The skeleton of the ox is formed under the above view; and though the number of his bones differs little from that of the horse, the general form differs materially;—the frontal, the occipital, and indeed most of the bones composing the skull are broad and extended, while to the former are appended the horns. These, as we have seen (1859.), partake of the nature of true bone, placed within a membranous envelopment of a mixed nature between cuticle and cartilage. The ox has no upper nippers; the grass being cropped into a tuft by means of the tongue, is cut off by the under nippers; the grass being cropped into a tuft by means of the tongue, is cut off by the under nippers; the grass being cropped into a tuft by means of the tongue, is cut off by the under nippers; the grass being cropped active the constitution of both incisive teeth.

6923. The vertebræ or neck bones are the same in number and form as in the horse; but from the diminished elevation of the head, and the peculiarity of attachment of the great suspensory ligament, the ox has no cervical crest. The dorsal vertebræ are thirteen, with spinous processes, or withers less high. The lumbar vertebræ are six, and the sexaral four; the ecceyx or bones of the tail a indefinite in number, from eighteen to twenty-five. The pe

materially differ from those of the horse.
6924. The fore-limb bones are, the arm, and the fore-arm, which, as in the horse, is composed of the radius and fulna, and bears a general resemblance to that of the horse. The knee is composed of four bones in the first row, and two in the second, which renders that joint inferior to that of the horse in complexity and elasticity: the same holds good with regard to the hock, where the bones entering its composition are also less numerous than in the horse. The canon or shank has no splint bones attached to it, but it is lower, and enlarges into two articular portions corresponding with the metacarpal bofere, and metatarsal bones behind: thus, from the pastern downwards, the limb is double, and ends in two separate hoofs, which present, individually, a similarity of structure and design to the single hoof of the horse, but less developed; to the posterior part of each are appended two imperfect phalanges or claws, thus keeping a connection with the digiti with the digiti.
6925. The hinder limbs present nothing remarkable, but preserve the same increased simplicity of structure with the fore.

ture with the fore.
6926. The viscera of the chest offer no peculiarities from those of the horse to deserve notice; neither is
the economy of the organs concerned different.
6927. The viscera of the belty of the ox have some specialities, the principal of which consist in the
digestive organs, which differ in form, structure, and economy, in some essential particulars, from the
same system in the horse.
6928. The ox has four stomachs, in which formation the goat, sheep, camel, and deer participate. As
it is necessary that these animals should collect much herbage for their support; and as it would fatigue
and keep them too long in motion to gather and masticate such a quantity at the same time, so a peculiar
provision has been made for them, by which they first hastily collect their food, pass it into a reservoir,
and afterwards commence the mastication of it at their leisure.
6929. The first stomach raimen, or naunch, is a very large membranous and muscular bag, principally

and keep them too long in motion to gather and masticate such a quantity at the same time, so a peculiar provision has been made for them, by which they first hastily collect their food, pass it into a reservoir, and afterwards commence the mastication of it at their leisure.

(6929. The first stomach, riemen, or pannch, is a very large membranous and muscular bag, principally occupying the left side, and extending, when full, from the middle of the ribs to the haunch, into which the unruminated food is received; consequently, it is the over-distention of this which occasions the malady called hover: it is in this stomach also that the concretions called hair balls are found. It presents number of the honey-comb, and which is well known to the eaters of tripe. The esophagus, or gullet, enters at the junction of this with the first stomach, and is continued in the form of a muscular ridge, or segmental rube along the line of junction between these two stomachs, which is thenee continued into the many-plics. In the hornless ruminants, the second stomach is exclusively designed as a reservoir for water, and is capable of holding and preserving a vast quantity of it. A little of this water is passed up, as wanted, to be mixed with the dry matters chewed during rumination. In the deserts of Arabia, where water is met with only at long distances, this reservoir is peculiarly advantageous to the camel and dromedary; and the Arabian travellers, when famishing for water, save themselves frequently at the expense of their camels, by killing of which, and taking out this stomach, they find a supply.

(693). The third stomach is named after its foliated structure many-plies; there are about eighty or ninety of these septa or folds, which are covered with cuttlet, in common with the two former stomachs, by which some resemblance is kept up between the digestive processes of the horse and ruminants. By the comparative insensibility of these stomachs, they can also bear potent medicines, which would be destructive to the side

6935. The liver of the ox is large, and presents a gall-bladder, which that of the horse does not. This gall blad is furnished by several hepatic ducts leading into the neck of the gall duct. By the existence of a gall bladder the bile is evidently more concentrated; but it is difficult to understand why this should be

gall bladder the bile is evidently more concentrated; but it is difficult to understand why this should be necessary to the runniants and not to the horse.
6336. The pincreas of the ox is of a lozenge form. The spleen is very large, and is placed on the left side of the paunch. The biliary and pancreatic ducts unite together. The principal fold of the omentum is very large, and incloses the four stomachs, and part of the intestines. The renal capsules are flat and triangular. The kidneys are lobulated.
6337. The organs of generation in the cow differ but little from those of the mare and other Mammàlia. The penis of the bull is more pointed and taper than that of the horse. The vesículæ seminales are wanting, but have a small ligamentous bridge instead. The prostate are two.

Diseases of Horned Cattle. Subsect. 10.

6938. Cattle are subject to some very dangerous diseases; but as their life is less artificial, and their structure less complex, they are not liable to the variety of ailments which affect the horse. The general pathology of the horse and the ox being little different, the fundamental rules for veterinary practice, and the requisite medicines, when not particularised, will be found in the Veterinary Pharmacopoxic,

and the requisite medicines, when not particularised, with be found in the *Peterinary Pharmacopeia*, already given. (6548).
6939. Mild fever, pantas or pantàsia. Cattle sometimes appear affected with heat, redness of the nostrils and eyelids; they refuse food, are dull, evacuate and stale with difficulty; and the urine is high coloured. These symptoms are often aggravated every other day, giving it the appearance of an intermittent affection. The complaint is often brought on by over-driving in very hot weather, occasionally by pushing their fattening process too fast. If there be no appearance of malignancy, and the heaving be considerable, bleed, and give half an ounce of nitre in a drink night and morning; but unless the weather be sold do not house the avined.

be cold do not house the animal

be cold do not house the animal.
6940. Inflammatory fever is called, among farriers, cow.leeches, and graziers, by the various names of black quarter, joint felon, quarter evil, quarter ill, showing of blood, joint murrain, striking-in of the blood, &c. Various causes may bring this on. It is sometimes epidemic, and at others it seems occasioned by a sudden change from low to very full keep. Over-driving has brought it on. No age is exempt from it, but the young oftener have it than the mature. Its inflammatory stage continues but a few days, and shows itself by a dull and heavy countenance, red eye and eyelids: the nostrils are also red, and a slight mucus flows from them. The pulse is peculiarly quick; the animal is sometimes stupid, at others watchful, particularly at first; and in some instances irritable. The appetite is usually entirely lost at the end of the second day, and the dung and urine either stop altogether, or the one is hard, and the other red. About the third day a critical deposit takes place, which terminates the inflammatory action: and it is to the various parts on which this occurs that the disease receives its various names. The deposit is, however, sometimes universal, in the form of a bloody suffusion throughout the whole skin. In others, swellings form on the joints, or on the back or belly; and in fact, no part is exempt from their attack. Sometimes the animal swells generally or partially, and the air being suffused under the skin, crackles to the feel. After any of these appearances have come on, the disease assumes a very malignant type, and is highly contagious. contagious.

contagious.

6941. Treatment of inflammatory fever. Before the critical abscesses form, or at the very outset of the disease, bleed liberally, and purge also: give likewise a fever drink, (6579.) If, however, the disease be not attended to in this early stage, carefully abstain from bleeding, or even purging; but instead, throw up clysters of warm water and salt to empty the bowels, and in other respects treat as detailed under malignant epidemic. (6436.) It may be added, that four drachms of muriatic acid in three pints of oak bark decoction, given twice a day, has proved useful. The swellings themselves may be washed with warm vinegar, both before and after they burst. The cowhouse should be fumigated daily. 6942. Catarrh or influenza in cattle, also known by the name of felon, is only a more mild form of the next disease. Even in this mild form it is sometimes epidemic, or prevalent among numbers; or endemical by being local. Very stormy wet weather, changing frequently, and greatly also in its temperature, are common causes. We have seen it brought on by change of food from good to bad; and from too close pasturage. It first appears by a defluxion from the nose; the nostrils and eyelids are red; the animal heaves, is tucked up in the flanks, and on the third day he loses the cud. There is a distressing and painful cough, and not unfrequently a sore throat also, in which case the beast almost invariably holds down his head. The treatment does not at all differ from that directed under the same disease in horses. (6434.) Bleeding only the first two days, carefully sheltering, but in an open airy place, and littering well up.

down his head. The treatment does not at all other from that directed under the same usease in horses. (6434.) Bleeding only the first two days, carefully sheltering, but in an open airy place, and littering well up.

6943. The malignant epidemic influenza is popularly called the murrain or pest; and has at various times made terrible havoc among cattle. Ancient history affords ample proof of its long existence; and by the accounts handed down, it does not seem to have varied its types materially. In 1757 it visited Britain, producing extreme fatality among our kine. From 1710 to 1714 it continued to rage on the Continent with unabated fury. (Lancist's Disputatio Historica de Bovilla Peste.) The years 1730 and 1731, and from 1744 to 1746, witnessed its attack, and produced many written descriptions of it, among which stand pre-eminent that of Sauvages, the celebrated professor of medicine at Montpelier. The British visitation of the malayd in 1757, elicited an excellent work from the pen of Dr. Layard, a physician of London, which was afterwards translated into several other languages.

6944. Symptoms of the murrain. Dr. Layard describes it as commencing by a difficulty of swallowing, and itching of the earrs, shaking of the head, with excessive weakness and staggering gait, which occasioned a continued desire to lie down. A sanious fetid discharge invariably appeared from the nostrils, and eyes also. The cough was frequent and urgent. Fever exacerbating, particularly at night, when it usually produced quickened pulse. There was a constant scouring of green fetid dung after the first two days, which tainted every thing around: even the breath, perspiration, and urine were highly fetid. Little tumours or boils were very commonly feti under the skin, and, if about the seventh or ninth day these eruptions become larger, and boils or buboes appeared with a lessened discharge of faces, they proved critical, and the animal often recovered; but if, on the contrary, the scouring continued, and the breath became cold, a

the spine and withers was also a characteristic, with emphysema, or a blowing up of the skin by air discharged underneath it.

6945. Dissections of those that have died of this disease, according to Sauvages, have shown marks of great inflammation, and of a great putrid tendency; but the solid parts seldom ran into gangrene. The fluid secretions, however, always were sufficiently dissolved and broken down by putridity. The paunch, he says, was usually filled with undigested matter, and the other stomachs highly inflaned; the gall bladder was also commonly distended, with acrid thick brown bile. Goelich, who likewise dissected these subjects, describes the gall as particularly profuse and intolerably fetid. According to him the whole alimentary canal, from the mouth to the anus, was excordated; and Lancis; contrary to Sauvages, found the viscera of the chest and belly, in some cases, sphacelated and gangrenous. Gazola describes the murrain as accompanied with pustulous sores; and so great was the putrid tendency, that even the milk, before it dried up, which it usually did before the fourth day, became fetid.

6946. The treatment of the murrain. In the very early stages, all eminent authors recommend bleeding; but which should not only be confined to the very early periods, as to the first two days, but also to such subjects as by their previous health and condition can bear it. The animals should be placed in an open airy place; the litter should be frequently renewed; and the place itself should be funigated with the preventive fumigation. (6582.) It has been recommended to burn green boughs with pitch as a substitute: even charcoal fires occasionally carried round the place would be useful. Dr. Layard advised the body to be washed with aromatic herbs in water; but vinegar would have been better. In the early stages, saline purgatives, as from ten to twenty ounces of Epsom salts, are to be invariably used. If the scouring have already come on, still, however, purge; but with only half the quantity: an artificial purge will carry off the morbid bile; and if excessive weakness do not come on, the same may be advantageously repeated. Setons are also recommended in the dewlap. When abscesses appear, they may be opened, and their contents discharged, washing the wound with brandy or vinegar, if putrid sloughing takes place. The emphysematous swellings or cracklings may also be opened, and their discharged. The other essentials of medical treatment, as detailed under malignant epidemic among horses, is here applicable in every particular. When recovery takes place, it is usually a very slow process, and requires care to prevent other diseases supervening. The animals should continue to be housed, and neither exposed to sun or wind for some time, and the feeding should be nutritious.

ticular. When recovery takes place, it is usually diseases supervening. The animals should continue to be housed, and neither exposed to sun or who as some time, and the feeding should be nutritious.

6947. The presention of the murrain, or the prevention of its spreading, in many respects is even more important than its medical treatment. Where it has already appeared, all the out-buildings, but particularly the ox-lodges or stalls, should be daily fumigated with the preventive fumigation (6582.); and even the whole of the infected districts should have frequent fires of green wood made in the open air, and every such district should be put under a rigorous quarantine. The cattle on every farm should be carefully examined three or four times every day, and the moment one is found to droop, he should be removed to a distance from the others. In very bad weather, while it is prevalent, the healthy cattle should be housed, and particularly well fed; and their pasture should also be changed. The bodies of those who die of the disease should be buried with their skins on, very deep in the earth, and quick-lime should be strewed over them.

6943. Phrenzy fever, or inflammation of the brain, called also sough, now and then, but by no means frequently, attacks cattle. The symptoms differ but little from those which attack horses. The treatment must be exactly similar.

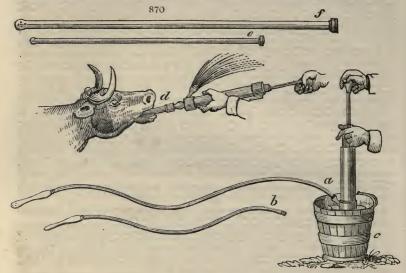

6949. Inflammation of the lungs occasionally occurs in cattle, in which also the symptoms, progress, and proper treatment are similar to those detailed under that head in horse pathology.

6950. Inflammation of the stomach sometimes occurs from poisonous matters; and in such cases, when the nature of the poison is discovered, the treatment detailed under poison in horse pathology must be pursued. But there is a species of indigestion to which cattle are liable in the spring, from eating voraciously of the young sprouts of wood; to which some woods are more conducive than others. The symptoms are heat, thirst, costiveness, lessened urine, quick and hard pulse, with heat and redness in the mouth and nose; the belly is hard and painful, and the stools, when they appear, are covered with glair. When the mouth and nose discharge a serous fluid, the animal usually dies.

crously of the young sprouts of wood; to which some woods are more conducive than others. The symptoms are heat, thirst, costiveness, lessened urine, quick and hard pulse, with heat and redness in the mouth and nose discharge a serous fluid, the animal usually due to the mouth and nose discharge a serous fluid, the animal usually discharge and the mouth and nose discharge as the works by saline purgatives. (6585.) After this give large quantities of nitrated energy and plate to be one of the proper of

uncture left side

abdomen, which would occasion an equal distention. As soon as the air is perfectly evacuated, and the paunch resumes its office, the trochar may be removed; and, in whatever way it is done, the wound

should be carefully closed with sticking plaster or other adhesive matter. It is necessary to observe, that this operation is so safe, that whenever a medical assistant cannot be obtained, no person should hesitate a moment about doing it himself. After relief has been afforded by means of either the probang or the paunching, a stimulant drink may yet be very properly given, such as half a pint of common gin; or one ounce of spirit of hartshorn in a pint of ale, or two ounces of spirit of turpentine in ale, may any of them be used as an assistant stimulus. When also the cud is again chewed, still some relaxation of the digestive organs may remain; at first, therefore, feed sparingly, and give, for a few mornings, a tonic. (6551. No. 1.)
6854. Inflammation of the bowels, or red colic, is by no means unknown in cattle pathology; the symptoms of which do not differ from those common to the horse, and the treatment also is in every respect the same. (6165) should be carefully closed with sticking plaster or other adhesive matter. It is necessary to observe, that

Seed. Inflammation of the cowers, or rea core, is by no means unknown in case, partners, a symptoms of which do not differ from those common to the horse, and the treatment also is in every respect the same. (6465.)

6955. Inflammation of the liver, or hot yellows, sometimes occurs, in which case, in addition to the symptoms detailed under hepatitis in the horse (6478.), there is, from the presence of eystic bile in the ox, a more determined yellowness of the eyelids, mouth, and nostrils; the treatment must be similar. (6479.)

6956. Inflammation of the kidneys, called red water by the cow-leeches, is not uncommon among cattle, and is, perthaps, dependent on the lobulated form of these parts in them. The annual, to the other symptoms of fever, adds stiffness behind, and often straddles, but always shrinks on being pinched across the loins, where frequently increased heat is felt; the urine is sometimes scanty, and now and then increased in quantity, but it is always first red, then purple, and afterwards brown or black, when a fatal termination may be prognosticated. The treatment has been fully detailed under nephritis, in the horse pathology (6481.), and it consists in plentiful bleedings, &c., carefully abstaining from the use of diurctics, as advised by ignorant cow-leeches.

6957. The black water is only the aggravated and latter stages of the above.

6958. Inflammation of the bladder also now and then occurs, and in nowise differs from the cystits of the horse in consequences and treatment. (6483.)

6959. The colics of cattle arise from different causes: they are subject to a spasmodic colic, not unlike that of horses, and which is removed by the same means. (6474.) Costiveness also brings on a colic in them, called clue bound, fardel bound, &c. which often ends in the red colic, unless early removed; the treatment of this we have fully detailed. (6476.) Another colic is accompanied with relaxation of bowels.

bowels.

6860. Diarrhea, scouring, or scouring cow, is common in cattle, and is brought on by exposure to rain, improper change of food, over-driving, and other violences. It is essentially necessary that the animals be taken under cover, kept warm and dry, and have nutritious food allowed them. The medical treatment has been detailed. (6473.)

6961. Dysentery, or braxy, bloody ray, and slimy flax, differs from simple scouring, in a greater degree of fever attending it, and in its being an inflammation of a particular kind, and part of the intestines. It is frequently dependent on a vitiated putrid state of the bile, brought on by over-driving in hot weather, low damp pastures in autumn, &c. The discharge is characterised by its bad smell, and by the mucous stringy patches in it, and also by its heat and smoking when voided: all which are very different from the mere discharge of the aliments in a state of solution in diarrhoza, and which differences should be carefully marked to distinguish the one from the other weaths and which differences should be carefully

marked, to distinguish the one from the other: treat as under dysentery in the horse. (6470.)
6902. Yellows. When active fever is not present, and yet cattle are very dull, with great yellowness of eyelids, nostrils, &c., it arises from some biliary obstruction, to which oxen and cows are more liable than horses, from their being furnished with a gall bladder; it is a more common complaint in some of the cold provinces on the Continent, where they are housed and stall-fed all the year round, than it is in England. The treatment is the same as detailed for chronic inflammation of the liver in horses, (6480.) adding in every instance to it a change of pasturage, and if convenient, into salt marshes, which will alone

adding in every instance to it a triange of pasturage, and it convenient, the same massive often effect a cure.

6903. Loss of the cud. This enters the list of most cow-leeches' diseases, but is less a disease than a symptom of some other affection; indeed it is evident that any attack sufficient to destroy the appetite, will generally occasion the loss of the cud. It is possible, however, that an occasional local affection or paralysis of the paunch may occur, particularly when it is distended with unhealty substances, as acorns, crabs, the tops of some of the woody shrubs, &c. The treatment, in such cases, consists in stimulating

the stomach by tonics, as aloes, pepper, and gin mixed; though these, as liquids, may not enter the stomach in common cases, yet in this disease or impaired action of the rumen they will readily enter there.

6964. Staggers, daisey, or turning, are sometimes the consequences of over-feeding, particularly when from low keeping cattle are suddenly moved to better pasturage. Treat with bleeding and purging.

6965. Tetanus, or tocked jaw, now and then attacks cattle, in which case it presents the same appearances and requires the same treatment as in horses. (6422.)

6966. Cattle surgery is in no respect different from that in practice among horses, the wounds are treated in the same manner. Goring with the horns will sometimes penetrate the cavity of the belly, and let out the intestines: the treatment of which is the same as in the horse. (6477.) Strains, bruises, &c. are also

the intestines: the treatment of which is the same as in the horse. (6477.) Strains, bruises, &c. are also to be treated like those of horses.
6867. Foul in the foot. This occasionally comes on of itself, but is more often the effect of accident: cleanse it well, and keep it from dirt:—apply the foot paste, (6587.)
6808. Wornals, or puckeridge, are tumours on the backs of cattle, occasioned by a dipterous insect which punctures their skin, and deposits its eggs in each puncture; these tumours are erroneously attributed to the fern owl or goat-sucker (Caprimulgus europæ'us L.). When the eggs are hatched, and the larvæ or maggots are arrived at their full size, they make their way out, and leave a large hole in the hide, to prevent which the destruction of the eggs should be attempted by nipping the tumour, or thrusting in a hot wire a hot wire.

6069. Cattle obstetrics are not very varied; young cows of very full habits have sometimes a superabundant secretion of milk before calving, which produces fever and heat; sometimes, from cold taken; the same will occur after calving also: in either case, give mild dry food, or hay; bathe the udder also with vinegar and water: in some cases, warm fomentations do best. If the fever run high, treat as under

with vinegar and water; in some cases, warm fomentations do best. If the fever run high, treat as under fever in horse pathology.

6970. The process of calving is usually performed without difficulty; sometimes, however, cross presentations take place, and sometimes a constriction of parts prevents the natural passage of the calf. To act properly on these occasions, great patience is required, and much mildness: many cows have been lost by brutal pulling; we have seen all the men and boys of the farm mustered to pull at a rope affixed about a calf, partly protruded, which, when it was thus brought away, was forced to be killed, and the mother soon died also from the protrusion of parts this brutal force brought with the calf. A steady moderate pull, during the throes of the animal, will assist much; having first directed the attention to the situation of the calf, that the presentation is such as not to obstruct its progress; if it does, the calf must be forced back, and turned or placed aright.

6971. Whethering, or retention of the after-birth or burden.—It sometimes happens that this is retained; for which no better remedy has been hitherto discovered than warm clothing and drenching with ale, administered as a forcer.

6972. The diseases of calves are principally confined to a species of convulsions which now and then

administered as a forcer.

6972. The diseases of calves are principally confined to a species of convulsions which now and then attacks them, and which sometimes arises from worms, and at others from cold. When the first cause operates, it is then relieved by giving a mild aloetic purge, or in default of that, a mild dose of oil of turpentine, as half an ounce, night and morning. In the second, wrap up the animal warm, and drench with ale and laudanum a drachm. Calves are also very subject to diarrhœa or scouring, which will readily yield to the usual medicines. (6552.)

SECT. II. The Buffalo. - Bos bubulus L. Buffle, Fr.; Buffalo, Span.; Bufflochs, Ger.; and Bufle, Ital.

6973. The buffalo is found wild in India, America, and various parts of the globe, and is in some degree domesticated in many countries. He is gregarious, docile, alert, and of surprising strength; his carcass affords excellent beef; and the horns, which are jet black, and of a solid consistence, take a polish of wonderful beauty: they can be converted into fabrics of use and ornament, such as mugs, tumblers, knife-handles, &c. this way they sometimes apply them; and when ornaments of silver or mother-of-pearl are employed, the contrast with the polished black of the horn is agreeably striking. The boss on the shoulders is, as well as the tongue, extremely rich and delicious, and superior to the best English beef. It is usual to cure the tongues for sale. The buffalo far surpasses the ox in strength. Judging from the extraordinary size of his bones, and the depth and formation of his chest, some consider him twice as strong as the ox; and, as an animal of labour, he is generally preferred in Italy. In this country the ingenious physiologist, Hunter, has caused buffaloes to be trained to work in a cart. At first they were restive, and would even lie down; but afterwards they became steady, and so tractable, that they were driven through the streets of London, in the loaded cart, as quietly and steadily as in Italy or India.

6974. The buffalo is kept in several gentlemen's parks as an object of luxury, and has been trained and worked by Lords Sheffield, Egremont, and some other amateur agri-Many prefer his flesh, and some his milk, to that of the bull family.

6975. The breeding, rearing, and general treatment of the buffalo may be the same as those of the bull family.

CHAP. V.

The Dairy and its Management.

6976. The manufacture of butter and cheese is of necessity carried on where the milk raw material is at hand. The subject therefore forms a part of farm management, or raw material is at hand. more or less on every farm; and the principal one in dairy farms. In most of those counties where the profit of the cow arises chiefly from the subsequent manufacture of the milk, the whole care and management of the article rests with the housewife, so that the farmer has little else to do but to superintend the depasturing of his cattle; the

milking, churning, and in short the whole internal regulation of the dairy, together with the care of marketing the butter, where the same is made up wholly for home consumption, falling alone upon the wife. In this department of rural economy, so large a portion of skill, of frugality, cleanliness, industry, and good management, is required in the wife, that without them the farmer may be materially injured. This observation will indeed hold good in many other parts of business which pass through the hands of the mistress in a farm-house; but there is none wherein he may be so greatly assisted, or so materially injured, by the good conduct or want of care in his wife, as in the dairy. The dairy husbandry is more extensively and successfully pursued in England than in Scotland or in Ireland. " As to dairy husbandry on any thing like an improved plan," says Aiton, "it is still confined to a mere corner of Scotland." This corner is the district of Cunninghame, in Ayrshire, of which he observes: "The excellence of the improved breed of cows in Ayrshire, as well as the superior quality of Strathaven veal, the Glasgow butter and milk, and Dunlop cheese, to all others in Scotland, are things that cannot be disputed." (Aiton's Dairy Husbandry, Pref. p. 18.) We shall in giving the dairy husbandry of England glance, at the same time, at the peculiarities of the Ayrshire dairy husbandry, as given by the author last quoted.

husbandry, as given by the author last quoted.

6977. The operations of the dairy in all its branches are still conducted perhaps more empirically than those of any other department of husbandry, though it would appear that science, chemistry in particular, might be applied to discover the principles, and regulate the practice, of the art, with facility and precision. We have heard it admitted, an eminent author observes, even by experienced dairymen, that the quality of their cheeses differs materially in the same season, and without being able to assign a reason. Every one knows how different the cheese of Gloucester is from that of Cheshire, though both are made from fresh milk, the produce of cows of the same breed, or rather, in both counties, of almost every breed, and fed on pastures that do not exhibit any remarkable difference in soil, climate, or herbage. Even in the same district, some of what must appear the most important points are far from being settled in practice. Marshal, in his Rural Economy of Gloucesterishire, has registered a number of observations on the heat of the dairy-room, and of the milk when the rennet was applied in cheese-making; on the time required for coagulation, and the heat of the whey after, which are curious, only because they prove that no uniform rule is observed in any of these particulars. The same discrepancy is observable in all the subsequent operations till the cheese is removed from the press, and even afterwards in the drying room. One would think the process of salting the cheeses the most simple of all; and yet it is sometimes, as in the west of Scotland, mixed with the curd; in other instances poured into the milk, in a liquid state, before being coagulated; and still more commonly, never applied at all till the cheeses are formed in the press, and then only externally. In treating of the dairy, we shall first offer a few remarks on the nature of milk, and the properties of that of different animals; and next consider the dairy house and its furniture, milkin

Sect. I. Chemical Principles of Milk, and the Properties of the Milk of different Animals.

Sect. I. Chemical Principles of Milk, and the Properties of the Milk of different Animals.

6978. The milk used by the human species is obtained from various animals, but chiefly the cow, ass, ewe, goat, mare, and camel; that in most general use in British dairying is the milk of the cow, which in modern times has received great improvement in quantity as well as quality, by ameliorations in the form of milch cows, in their mode of nourishment, and in the management of the dairy. Whatever be the kind of animal from which milk is taken, its external character is that of a white opaque fluid, having a sweetish sate, and a specific gravity somewhat greater than that of water. Newly taken from the animal, and allowed to remain at rest, it separates into two parts; a thick white fluid called cream, which collects on the surface in a thin stratum; and a more dense watery body, which remains below. The quantity and quality of cream, and the time it requires to separate from the milk, vary according to the nature of the milk and the temperature of the atmosphere. Milk which has stood some time after the separation of the cream, first becomes accseent, and then coagulates. When the coagulum is pressed gently, a serous fluid is forced out, and the remainder is the caseous part of milk, or pure cheese.

6979. Butter, or solidified cream, one of the most valuable products of milk, is obtained artificially by churning; an operation analogous in its effects to shaking or beating, by which the cream separates from the caseous part and serum, in a more solid form than when left to separate spontaneously. It is afterwards rendered still more solid by beating with a wooden spatula.

6980. Cheese is obtained by first coagulating the milk, either with, or deprived of, its cream, and then expressing the serum or whey; the consolidated curd so produced forms cheese. The milk may be coagulated in various ways, but that effect is chiefly produced by the use of reunet, which is prepared by digesting the coad of young ruminating animals

the butter is white and soft, and equally copious, and so is the curd, which is of a firmer consistence than that of the cow, and retains less whey.

6987. Mare's milk produces a very fluid cream, similar in colour and consistence to good cow's milk before the cream appears on the surface; the butter made from it has but little consistence, and is readily decomposed. The eurol is similar to that obtained from woman's milk, and the whey has little colour, and contains a large proportion of saccharine matter, and of saline substances.

6988. Camet's milk throws up little cream, which is whitish and thin, affording insipid whitish butter; the curd is small in quantity, and contains but little whey, which is colourless and somewhat saccharine.

6989. Sov's milk. In China, especially about the city of Canton, no other milk can be had but that of the sow. It is rather sweeter than cow's milk, but very similar in all other respects.

6990. In the use of these milks, that of the came is chiefly confined to Africa and China, and that of the mare to Tartary and Siberia. In India the milk of the buffalo is preferred by the natives to that of the domestic cow. The milk of the goat is more generally used in Italy and Spain than in any other countries in Europe; they are driven into Leghorn, Florence, Madrid, and other towns, in flocks early in the morning, and milked in the streets. The goat will allow herself to be sucked by the young of various other animals, and a foal which has lost its mother has been suckled by a goat, placed on a barrel to iacilitate the operation. As the butter of goat's milk contains a larger proportion of gelatine, and less of than that cheese; but it is an error to suppose that the Parmesan (a skin-milk cheese) is made from it. Ewe's milk is gradually wearing out of use, though it makes excellent cheese, and some milking ewes as well as goats might be kept for that purpose, by those who have extensive upland grass-lands. The milk of the ass comes the nearest to that of the woman, and being the li Britain, is that of the cow.
6991. Lactometers for ascertaining the value of milk, relatively to butter and cheese, will be described

among the utensils of the dairy in the succeeding section.

Sect. II. The Darry House, its Furniture and Utensils.

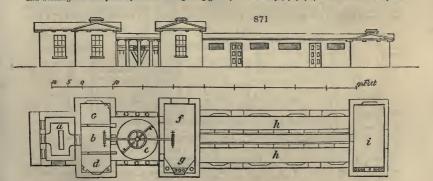

6992. The dairy house, for general purposes, consists of at least three separate apartments, the milk room, the dairying or working room, and the cheese or store-room. The two former are generally separated by a passage or lobby; and the latter is very frequently a loft over the whole, entered by a stair from the lobby.

693. The properties requisite in a good milk-house are, that it be cool in summer, and moderately warm in winter, so as to preserve a temperature nearly the same throughout the whole year, or about 45 degrees; and that it be dry, so as to admit of being kept clean and sweet at all times. For these reasons a northern exposure is the best, and this as much under the shade of trees or buildings as possible; if it can be so situated that the sun can have no influence either on the roof or walls, so much the better. 6994. A well constructed butter dairy should consist of three apartments; a milk-house, a churning-house, with proper boiler, as well as other conveniences for scalding and washing the implements, and a room for keeping them in, and for drying and airing them, when the weather will not permit of its being done without doors.

done without doors.

6995. The cheese dairy should likewise consist of three apartments; a milk-house, a scalding and pressing-house, and a salting-house. It is essential to the cheese dairy to have a command of heat during the cold season. When milk is exposed to a degree of cold below 50° at any time, from the moment it is drawn from the convex to the cheese will not only pressed, but, to a great extent, dried, the cheese will not be good. "It is not enough that the milk be again heated; it must never be allowed to become too cold at any time, not even in the press; or if it is, the quality of the cheese will be much injured." (Aidor's Dairy Husb. p. 82.) To these should be added a cheese-room or loft, which may with great propriety be made above the dairy. This is, however, generally separate from the dairy. But a milk dairy requires only a good milk-house, and a room for scalding, cleaning, and airing the utensils. The size of the milk-house, according to Aiton, ought to be sufficient to contain one day's milk of all the cows belonging to it. 6996. A dairy for the private use of any farmer or family need not be large, and may very economically be formed in a thick walled dry cellar, so situated as to have windows on two sides, the north and east in preference, for ventilation; and in order that these windows may the better exclude cold in winter, and heat in summer, they should be fitted with double sashes, and on the outside of the outer sash should be a fixed frame of close wire netting, or hair cloth, to exclude flies and other insects.

6997. Of dairies for dairy farmers there are different sizes and shapes. 6998. A dairy-house connected with a cow-house, and mill for preparing food for the cows, churning, and washing the family linen, is thus arranged. (fig. 871.) The dairy (a, b, c, d) is at the north end, has

hollow walls, double doors, double sashed windows, and an ice-house under. The milk room (a) is surrounded by milk coolers, and has a butter slab and jet in the centre. The jet is supplied from a cistern over the steaming house (f,g), to which the water is raised from a well by a forcing-pump worked by the

gin wheel. Besides supplying the jet, it furnishes, by cocks and pipes, water for the usual dairy purposes, the steaming or boiling of food for the cows, their drink, and washing out the cow-house, the washing machine, &c. The churning room (b), is separated from the milk-room by double doors, as is the latter from the cheese-room (c) and store closet (d). The gin wheel (e) is worked by one or two horses, or oxer or asses, according to the work to be done. The steaming and washing room (c) is a lower

is worked by one or two horses, or oxen or asses, according to the work to be done. The steaming and washing room (f,g) is a large roomy apartment properly fitted up, and furnished with two boilers, a machine for steaming cattle food, another for washing linen by steam; one impelled by the gin wheel operating on an axle with beaters or lifters (f,g,872.), and a cylinder of open spars, which turns round in a box of water for washing potatoes or other roots. The cow-house (h,h) is calculated for forty cows to be fed from a broad passage in the centre. At the south end is a large apartment (h) one to the roof for hay straw, green bethage for soiling

a broad passage in the centre. At the south end is a large apartment (i) open to the roof for hay, straw, green herbage for soiling, turnips, and other food; and under it is a urinarium vaulted, and from which the liquid is drawn by a Buchanan pump (4494.) outside of the building, and some yards distant.

6999. The dairy-house recommended by Dr. Anderson is surrounded by double walls, the inner of brick or stone, nine inches or a foot in thickness; and the outer about two feet distance, built of stone or turf; or a bank of earth faced with turf may be placed against the inner walls.

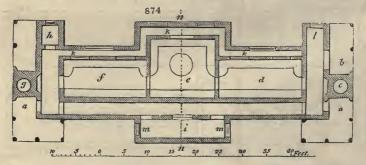

7000. The size of the dairy house should vary according to that of the number of cows. Marshal found in Gloucestershire one for forty cows to be twenty feet by sixteen, and one for one hundred, thirty by forty. The North Wiltshire dairy-rooms have in general, he says, outer doors, frequently opening under a pent-house or open lean-to-shed; which is a good conveniency, affording shade and shelter, and giving a degree of coolness to the dairy room. In one instance he observed two doors: a common close-bearded door on the hiside, and an open-paled gate-like door on the outside; giving a free admission of air in close warm weather, and, at the same time, being a guard against dogs and poultry. A conveniency which, he thinks, would be an improvement to any dairy room in the summer season. The inside wall may be seven or eight feet high in the sides, on which may be placed the couples to support the roof, and the walls at the gables carried up to the height of the couples. Upon these should be laid a roof of reeds, or thatch, that should be produced downward till it covers the whole of the walls on each side to the ground: but here, if thatch or reeds be not in such plenty as could whole of the walls on each side to the ground: but here, if thatch or reeds be not in such plenty as could be wished, there is no occasion for laying it quite so thick. In the roof, exactly above the middle of the be wasned, there is no occasion for laying it quite so thick. In the root, exactly above the middle of the building, should be placed a wooden pipe of a sufficient length to rise a foot above the roof, to serve occasionally as a ventilator. The top of this funnel should be covered, to prevent rain from getting through it, and a valve fitted to it, that by means of a string could be opened or shut at pleasure. A window also should be made upon one side for giving light, to be closed by means of two glazed frames, one on the outside, and the other on the inside. The use of this double sash, as well as the great thickness of the wall, and of the thatch upon the roof, are to render the temperature of this apartment as equal as possible at all seasons of the year, by effectually cutting it off from having any direct communication with the external air. external air.

at all seasons of the year, by effectually cutting it off from having any direct communication with the external air.

7001. The dairy-house made use of by Wakefield of Liverpool contains three apartments; a milk house, churning-room, and the room for the utensils. In the milk-house were the coolers; a slab for laying butter on after it is made up; cocks for drawing off the milk from the coolers; a large cock to throw water on the floor, which slopes a little from that part; cocks at the back part of the coolers, for letting in water; a door, latticed; and another door most commonly used, but panelled. In the churning-room is a fire-place, a boiler, a large copper, also used when brewing. The room for drying or airing the utensils is also used occasionally as a laundry.

7002. A very neat dairy for a private family may be made under the shade of two or three tall trees, in the following manner: — Build the walls of bricks, and hollow in Silverlock's manner, by which every course of brick-work is laid on edge, and forms oblong cavities (fig. \$75.3.a), the bricks of the one course being laid alternately lengthways (b), and crossways (c), and those of the next breaking joint with these, by the cross ones being placed on the middle of the long ones (d). The elevation of such a wall, and nature of the foundations. The plan of a dairy with such walls should contain the three usual apartments for milk, churning, and utensils (b), and should have double doors and windows: the latter guarded by flywire. The elevation (i) may be of any style of simple architecture.

e deb d 7003. As a complete dairy on a large scale, we submit the following. The plan (fig. 874.) is of an oblong form, and consists of the three usual principal apartments, enclosed by walls of four inches in thickness, and surrounded by a passage two feet wide to the north, and three feet to the south, which is again surrounded by a nine-

inch wall. The passages communicate with the roof by covered openings, in the ridge of which and by the windows ventilation is completely effected. In detail, the plan exhibits two principal entrance porches (a), back entrance (b), copper for heating water (c), churning-room (d), milk-room (c), utensits

and cheese-press (f), boiler for heating milk (g), store closet or butter-room (h), cheese-room (i), passage surrounding the whole (k), water-closet (l), and windows to cheese-room (m).

709. A section (fig. 37.5) taken across the milk-room (fig. 874. n n) exhibits the ventilating funnel in the roof (a),

projecting eaves (b, c), cheese-room (d), passage on the north side (e), raised part of the roof for ventilation (f, g), fountain in the centre of the dairy (h), and south

Joseph Passage (t). 7005. The elevation (fig. 876.) presents a simple shed roof, varied, however, by projections and recesses: it presents no windows or doors to the south, and therefore that side, if other circumstances permit, may be covered with vines or other fruit-trees, or with ornamental creepers.

The fixtures of the dairy are, in the scalding-room, a copper boiler fixed over a

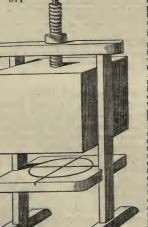

fire-place, for boiling water to wash and scald the utensils; next, some benches and shelves in this room and the cheese-room; and a bench or table not more than two feet wide surrounding the milk-room. It is very desirable, also, that there should be a jet, or fountain, or pump, or spring, in the centre of the milk-room, in order to cool down the air in summer, and to supply clear water at a moderate temperature at all times.

7007. The utensils of the dairy are, pails for milking into; sieves of hair-cloth or silver wire-cloth for passing the milk through, to free it from hairs and other impurities; milk dishes, or coolers, for holding the milk till it throws up its cream; a cream-knife of ivory for separating, and skimming dishes of willow or ivory for removing, the cream; bowls and barrels for holding it, or other preparations of milk-churns, butter-makers, butter-prints; one or more tubs for hot or cold water, in which to immerse vessels that require extraordinary purification; and a portable rack for drying dishes in the open air. All these utensils are requisite where butter only is to be produced.

All these utensils are requisite where butter only is to be produced.

7008. The utensils requisite if cheese is to be made, are the cheese-tub, in which the curd is broken, and prepared for being made into cheese; the cheese-knife, generally a thin spatula of wood, but sometimes of iron, used for the purpose of cutting or breaking down the curd while in the cheese-tub. The cheese-cloth is a piece of thin gauze, like linen cloth, in which the cheese is placed in the press; the cheese-board is circular, and on it the cheeses are placed on the shelves of the cheese-room; their diameter must be somewhat less than that of the interior or hoop part of the vat. The vat is a strong kind of wooden hoop with a bottom, which, as well as the sides, is perforated with holes to allow the whey to escape while the cheese is pressing: the size of vats must depend on that of the cheese and the number required, as of most of the other implements on the extent of the dairy. The cheese-press (fig. 871.) is a power generally obtained by a screw, though sometimes by a dead weight, and is used for forcing the whey from the curd while in the vat. The cheese-tub, when the vat is set on it in order to drain the whey from the curd while in the vat. The cheese-tub, when the vat is set on it in order to drain the whey from the curd while in the vat. The cheese-tub, when the vat is set on it in order to drain the whey from the curd while in the vat. The cheese-tub, when the is some add a lactometer, one kind of which (fig. 878.), is a glass tube a foot long with a funnel at top.

The upper two inches of the tube are marked in small divisions, and when the instrument is filled to the height of one foot with milk, the depth of cream it yields is noted by the gradations on the upper part. Another lactometer "for ascertaining the richness of milk from its specific gravity, by its degree of warmth taken by a thermometer.

richness of milk from its specific gravity, by its degree of warmth taken by a thermometer on comparing its specific gravity with its warmth," was invented by Dicas, of Liver-

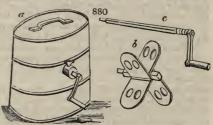

on comparing its specific gravity with its warmth," was invented by Dicas, of Liverpool, but never came into use. Another invention for the same purpose was made by Mrs. Lovi, of Edinburgh, in 1816. It consists of acreometric beads, by which the specific gravity of the milk is tried first when new.milked, and next when the cream is removed. When milk is tried as soon as it cools, say to 60°, and again, after it has been thoroughly skimmed, it will be found that the skimmed milk is of considerably greater gravity; and as this increase depends upon the separation of the lighter cream, the amount of the increase, or the difference between the specific gravity of the fresh and skimmed milk, will bear proportion to, and may be employed as a measure of, the relative quantities of the oily matter or butter contained in different milks. The specific gravity of skimmed milk depends both on the quantity of the saccharo-saline matters, and of the curd. To estimate the relative quantities of curd, and by that determine the value of milk for the purpose of yielding cheese, it is only required to curdle the skimmilk, and ascertain the specific gravity of the whey. The

whey will, of course, be found of lower specific gravity than the skimmed milk, and the number of degrees of difference affords a measure of the relative quantities of the curd. According to this hypothesis, the aereometric beads may be employed to ascertain the qualities of milk, relatively both to the manufacture of butter and cheese. (Trans. of the High. Soc. sect. v. part i.)

7009. In milk coolers and churns there is considerable variation of form. Milk coolers are generally made of earthenware or wood; but of late years they have been formed of lead, marble, slate, and castiron. Their general form is round, and diameter from one to two feet; but in extensive dairies they are often made several feet or yards in length, and from two to three feet wide, with holes at one or more corners to admit the escape of the milk after the cream is removed. The safest dish is wood, though it requires most labour to keep it sweet; next is earthenware or China, though on the leaden glaze of the former the acid of the milk is apt to operate. Leaden dishes or troughs, though very general in Cheshire, are the most dangerous; and the objection to slate coolers is the joinings of the plates, which are always unsightly, imperfeet, and liable to be operated on by the lactic acid. The annealed and tinned cast-iron dishes of Baird's invention (in 1905), and which are now becoming universal in Scotland (Aiton's Dairy H., p. 81.), are perhaps the best for such as do not choose to go to the expense of China dishes. They are durable from the nature of the material, not liable to be broken by falls by being annealed, easily kept clean from being turned smooth, and also very economical, and said to throw up more cream from a given quantity of milk than any other.

7010. Besides the common plunge and barrel churns, it in motion either by a man or horse. The Derbyshire churn (fig. 880.), which works on the principle of the barrel churn, is an excellent implement on a large scale. The bottom is a segment of a circle, and the advantage of t

the plan is, that when the butter is made, the lid (a) being

removed, the beaters (b) may be taken out at pleasure by withdrawing the spindle (c) to admit the removal of the butter, or the cleaning and scalding of the churn.

7011. The Lancashire plunge churn (fig. 881.) is a simple and effective implement, worked by the operator standing on the levers (a, b), throwing his whole weight alternately on each, so as by means of the line (c, d) connected with the churn stand alternately.

and lower it and turn it round alternately.

7012. The most exquisite cleanliness in the dairy is an essential requisite, as to the walls, floor, shelves, henches,

and in the different utensils.

and in the different utensils.

7013. The milk coolers and all the dishes in which milk is put, as well as the churn, must be scalded, scrubbed, rinsed, and dried every time they are used. Scalding is less frequently requisite in the cheese utensils, but they also must be almost daily washed in hot water, dried, and aired. When any vessel becomes tainted with the acidity of milk, it operates like leaven on what is put into it: if this taint cannot be removed by ordinary scalding, it may by boiling or immersing in water impregnated with alkali; but afterwards it must be well holled, or a day or two immersed afterwards it must be well boiled, or a day or two immersed in pure water.

SECT. III. Milking and the general Management of Milk.

7014. The times of milking vary greatly in different districts. In most places cows are milked twice in twenty-four hours throughout the year; but in the best managed dairies where they are abundantly fed, they are milked at morning, noon, and the approach of night: the additional quantity thus obtained is very considerable, but according to the experiments of Parmentier it must be inferior in quality; for he found twelve hours requisite for the due preparation of the milk in the cow. Where quantity of milk or cheese is an object, three times milking must be decidedly preferable; but it is certain that in the best butter districts of England the cows are only drawn twice a day, between five and six o'clock morning and evening. Whatever may be the times of milking, it is essential that the milk be drawn off clear; for if the milk which the cow can be made to yield at the time be not completely taken away, the quantity left will be reabsorbed into the system, and no more will be generated than is necessary to supply the quantity actually drawn off.

7015. The operation of milking is performed by men in many districts, but taking Britain generally it is more commonly the work of women. The milker, whether a man or woman, ought to be mild in manners and good tempered. If the operation be performed harshly, it becomes painful to the cow, who in this

case often brings into action her faculty of retaining her milk at pleasure; but if gently performed, it seems rather to give pleasure, as is exemplified on a large scale in Tiviotdale, and Switzerland, where the cows come to be milked at the call of the milkers. Many instances have occurred, Dr. Anderson observes, in which cows would not let down a single drop of milk to one dairy-maid, which let it flow in abundance whenever another approached them; exhibiting unequivocal marks of satisfaction in the one case, and of sullen obstinacy in the other. For the same reason, when cows are ticklish, they should be treated with the most soothing geutleness, and never with harshness or severity; and, when the udder is hard and painful, it should be tenderly fomented with luke-warm water, and stroked gently, by which simple expedient the cow will be brought into good temper, and will yield her milk without restraint. Lastly, as it sometimes happens that the teats of cows become scratched or wounded, so as to produce foul or corrupted milk, whenever this is the case, such milk ought on no account to be mixed with the sweet milk, but should be given to the pigs, without being carried into the milk-house; lest, by continuing there, it should taint the atmosphere, and consequently prove injurious to the rest of the milk.

7016. To promote cleaniness in regard to milking, own are in some places curried, combed, brushed, and clothed like horses; before milking, their udders and teats are washed and dried, and their tails trussed up. It would be well if a part of this refinement were adopted in all dairies; that of using the comb and brush, and washing the udder, is indispensable in every establishment where clean milk is an object. According to Mowbray, snuff-takers, sluts, and daudles are unfit to be dairy-women, and no milker should ever be suffered to enter the dairy in a dirty apron covered with hairs from the cowhouse.

7017. The following aphorisms respecting the management of milk in the dairy are from the "Recreations" of Dr. Anderson, one of the most scientific writers on this subject.

I. Of the milk drawn from any cow at one time, that part which comes off at the first is always thinner, and of a much worse quality for making butter, than that afterwards obtained; and this richness continues to increase progressively to the very last drop that can be obtained from the udder.

2. If milk be put into a dish, and allowed to stand till it throws up cream, the portion of cream rising first to the surface is richer in quality, and allowed to stand till it throws up cream, the portion of cream rising first to the surface is richer in quality, and greater in quantity, than that which rises in a second equal space of time; and the cream, which rises in the second interval of time, is greater than that of the fourth, and so of the rest; the cream that rises continuing progressively to decrease in quantity, and to decline in quality, so long as any rises to the surface.

3. Thick milk always throws up a much smaller proportion of the cream which it actually contains than milk that is thinner; but the cream is of a richer quality; and if water be added to that thick milk, it will afford a considerably greater quantity of cream, and consequently more butter than it would have done if allowed to remain pure; but its quality is, at the same time, greatly debased.

4. Milk, which is put into a bucket or other proper vessel, and carried in it to a considerable distance, so as to be much agitated, and in part cooled before it be put into the milk-pans to settle for cream, never throws up so much, or so rich cream, as if the same milk had been put into the milk-pans directly after it was milked.

was milked.

was milked.

7018. From these fundamental facts, the reflecting dairyist will derive many important practical rules. Some of these we shall enumerate, and leave the rest to be discovered. Cows should be milked as near the dairy as possible, in order to prevent the necessity of carrying and cooling the milk before it is put into the creaming dishes. Every cow's milk should be kept separate till the peculiar properties of each is so well known as to admit of their being classed, when those that are most nearly allied may be mixed together. When it is intended to make butter of a very fine quality, reject entirely the milk of all those cows which yield cream of a bad quality, and also keep the milk that is first drawn from the cow at each milking entirely separate from that which is last obtained, as the quality of the butter must otherwise be greatly debased without materially augmenting its quantity. For the same purpose, take only the cream that is first separated from the first drawn milk. Butter of the very best quality can only be economically made in those dairies where cheese is also made; because in them the best part of each cow's milk can be set apart for throwing up cream, the best part of this cream can be taken in order to be made into butter, and the remainder, or all the rest of the milk and cream of the dairy, can be turned into cheese. The spontaneous separation of cream, and the production of butter, are never effected but in consequence of the production of acid in the milk. Hence it is that where the whole milk is set apart for the separation of cream, and the whole of the cream is separated, the milk must necessarily have turned sour before it is made into cheese; and no very excellent cheese can be made from milk which has once attained that state. that state.

SECT. IV. Making and Curing of Butter.

7019. The milk from which butter is to be made may either be put at once into the churn, and left there till it send up the cream; or it may be made to cream in milk dishes, and the cream alone churned.

dishes, and the cream alone churned.

7020. The last is generally considered the best mode, and in carrying it into effect, the milk being drawn from the cow, is to be strained into the creaming dishes, which should never be more than three inches deep, and of about a gallon and a half or two gallons in capacity. In general the best cream will be fit for removal in seven or eight hours, though for ordinary good butter it may stand twelve hours; but where the very best butter is wished, and such arrangements are formed as admit of converting the milk to cheese, or some other use while it is sweet, it may be separated after standing only two or three or four hours. In performing the operation, first pass the cream knife round the edges of the vessel, to separate the adhering stratum of cream, and then draw it to one side, lift it off with the skimming dish, and put it in the cream bowl to be carried to the cream barrel.

7021. Cream may be kept from three to seven days before it is churned. Where quantity more than quality is desired, the whole of the milk is churned, without separating any cream; the milk is kept in the churn or in large barrels for two or three days, till it begins to get sour. The operation of churning, where the cream and milk are both to agitate, is necessarily tedious and laborious; but a great weight of butter is undoubtedly obtained, the quality and flavour of which will depend a good deal on the peculiar properties of the milk. The milk of Galloways, Ayrshires, and Alderneys, so treated, makes excellent butter.

7022. In the process of churning great nicety is required; a regular stroke in plunge or pump churns, and a regular motion in those of the barrel or turning kind, must, if possible, never be deviated from. A few hasty irregular strokes or turns has been known to spoil what would otherwise have been excellent butter.

7023. The process of churning regular commends the selection of a churner of a cool phlegmatic temper, of a sedate disposition and character; and advises never to al

it should remain during the whole time of churning; which will very much harden the butter. During winter, from the equality of temperature, which (if it be properly managed) will generally prevail in a dairy, it will very rarely, if ever, be necessary to churn near the fire. Should any circumstance, however, require this, care should be taken not to churn so near the fire as to heat the wood; as it would impart a strong rancid taste to the butter. As soon as the butter is made, it must be separated from the milk, and be put into a clean dish; the inside of which, if of wood, should previously be will rubbed with common salt, to prevent the butter from adhering to it. The butter should then be pressed and worked with a flat wooden ladle or skimming-dish, having a short handle, so as to press out all the milk that may be lodged in the cavities of the mass. A considerable degree of dexterity, as well as of strength, is requisite in this manipulation: for, if the milk be not entirely removed, the butter will infallibly spoil in a short time; and if it be much worked, the butter will become tough and gluey, which greatly debase its quality. In some places it is the practice to beat up the butter with two flat pieces of board, which may, perhaps, answer very well. In this operation, some persons pour cold water upon the butter, for the purpose of washing it: this practice, however, is not only useless, for the butter can be perfectly cleared of the milk without it, but it is also permicious, and debases the quality of the butter in an astonishing degree. Nothing is so detrimental in a dairy as water improperly used; which, if mixed in any way, either with milk or

without it, but it is also pernicious, and debases the quality of the butter in an astonishing degree. Nothing is so detrimental in a dairy as water improperly used; which, if mixed in any way, either with milk or butter, tends greatly to debase the quality of the latter.

7024. The best temperature for churning butter has been very satisfactorily determined by a number of experiments, sanctioned by the Hightand Society of Scotland, and published in their Transactions. From these experiments it is concluded, that the most proper temperature at which to commence the operation of churning butter is from 50° to 55°; and that at no time in the operation ought it to exceed 65°; while, on the contrary, if at any time the cream should be under 50° in temperature, the labour will be much increased, without any proportionate advantage being obtained; and a temperature of a higher rate than 65° will be injurious, as well to the quality as the quantity of the butter. (Highl. Soc. Trans. vol.vii, p. 198.)

7025. The making up of butter is the next process.

7026. Before being sent to table or market, sweet or fresh butter is made up into various forms; sometimes into rolls or cylinders, six or eight inches long, and from half an inch to two inches in diameter; at other times into small round figures, or casts, with impressions in relief from butter moulds. When the butter is too soft for the last purpose, it may be put into small wooden vessels, which may be allowed to swim in a tub or cistern of cold water; or they may be set in an ice-house for an hour or two; or the water in which the small vessels float may be iced. At all events, whatever mode is adopted, no water ought to be allowed to touch the butter. When formed into the desired shapes, it may be placed in dishes, and set in the margin of the central cistern of water till wanted.

7027. In salting or curing butter the use of wooden vessels is preferable; and these vessels should be made from timber which has been previously boiled for four hours, to free it from the pyroligneous acid; or they should be formed from the lime tree, which is confidently asserted (Highl. Soc. Trans. vol. vii. p. 355.) to be without this acid. Whatever description of casks are used, they should previously be rendered as clean and sweet as possible, well rubbed with salt, and the cavity between the bottom and sides filled in with melted butter.

sweet as possible, well rubbed with salt, and the cavity between the bottom and sides filled in with melted butter.

7028. An excellent composition for preserving butter may be made, by reducing into a fine powder, and carefully mixing together, sugar and nitre, of each one part, and two parts of the best common salt. Moir to each pound weight of salt adds four ounces of raw sugar. Of this composition, one ounce should be thoroughly mixed with every sixteen ounces of butter, as soon as the latter has been freed from the milk; and the butter must be immediately put list to the firkin, being pressed so close as to leave no air-holes, or any kind of cavities, within it. The surface must be smoothed; and, if a day or two be expected to elapse before more can be added, the vessel must be closely covered up with a piece of clean linen, upon which should be laid a piece of wetted parchment, or (if this be not procurable) with a piece of fine linen dipped in melted butter, that is exactly fitted to the edges of the vessel all round, so as to exclude the air as much as possible. When more butter is to be added, these coverings are to be removed; the butter is to be applied close upon the former layer, pressing it down, and smoothing it as before, till the vessel be full. The two covers are then to be spread over it with the greatest care; and a little melted butter is to be poured all round the edges, so as to fill up every part, and effectually to exclude the air. A little salt may then be strewed over the whole, and the cover be firmly fixed down. Butter thus cured does not taste well till it has stood at least a fortnight after it has been salted; but after that period it acquires a rich marrowy taste, and will continue perfectly sweet in this climate for many years. As, however, its quality is liable to be impaired by being improperly treated while it is using, it will be necessary, when the firk in so pened, first to pare off a small portion of the wole surface, especially mear the edges, in case the air should, by

7031. As winter-made butter is mostly pale or white, and, at the same time, of a poorer quality than that made during the summer months, the idea of excellence has been associated with the yellow colour: hence, various articles have been employed in order to impart this colour. Those most generally used, and certainly the most wholesome, are the juice of the carrot, and of the flowers of the marigold, carefully expressed, and strained though a linen cloth. A small quantity of this juice (and the requisite proportion is soon ascertained by experience) is diluted with a little cream, and this mixture is added to the rost of the cream when put into the churn. So small a quantity of the colouring matter unites with the butter, that it never inparts to it any particular tasks. that it never imparts to it any particular taste.

that it never imparts to it any particular taste.
7052. The butter most etermed in London is that of Epping and
Cambridge: the cows which produce the former feed during
summer in the shrubby pastures of Epping forest, and the
leaves of the trees and numerous wild plants which there
abound are supposed to improve the flavour of the butter. It
is irrought to market in rolls from one to two feet long, weighfrom the milk of cows that feed one part of the year on chalky
uplands, and the other in rich meadows or fens; it is made up
into long rolls like the Epping butter, and generally salted, not
curred, before brought to market. By washing it, and working
the salt out of it, the London cheesemongers often sell it at a

10.55. The Suffilik and Yorkshire butter is often sold for that of
Cambridgeshire, to which it is little inferior. The butter of
Somersetshire is thought to equal that of Epping; it is brought
7055. In marking fresh butter, or butter salted only

to market in dishes, containing half a pound each, out of which it is taken, washed, and put into different forms by the buttermen of Bath and Birstol. The butter of Gloucestershire and of Oxfordshire is very good; it is made up in half-pound packs or prints, packed up in aquare baskels, and sent to the London market hy wargon.

7051. The butter of the mountains of Wales and Scotland, and the moors, commons, and heaths of England, is of excellent quality, when it is properly managed; and though not equal in quantity, it often is coalessedly superior to that produced from of mismanagement, want of cleanlines, and institute is successful to the coalessed of the produce the finest butter in the empire, were it not for the intolerably fifthy state of their cows, and the want of cleanlines, and institute.

Somerseshire is thought to equal that of Epping; it is brought

7055. In packing fresh butter, or butter salted only for immediate use, the leaves of cabbage, white beet, or of the garden orache (A'triplex horténsis) are to be preferred. The bottom of the basket should be bedded with a thick cloth, folded two or three times; then a thin gauze, dipped in cold water, spread over it, on which the prints or rolls of butter are to be placed, each with one or more leaves beneath, and smaller once over it. The lowermost layer being adjusted, fold half of the gauze cloth over it, put in another layer in the same way, and then cover with the remainder of the gauze. The butter should be put into the basket, as well as taken from thence, without being touched.

7036 Whey butter, as its name implies, is butter made from the whey which is taken from the curd, after the milk is coagulated for the manufacture of cheese. It is chiefly made in those counties where cheese is manufactured, and where it forms no inconsiderable part of the profits of the dairy. In the county of Derby more butter is said to be made from whey than from the cream of milk, or from milk churned altogether.

7037. Whey is divided into two sorts, green and white, the former escaping readily from the curd, while

churned altogether.

7037. Whey is divided into two sorts, green and white, the former escaping readily from the curd, while
the latter is freed from it by means of pressure. "There are different methods of extracting the whey.
In some dairies the whole whey, when taken from the cheese-tub, is put into pails or other vessels, where
it remains for about twenty-four hours; when it is creamed, and the whey is applied to the use of calves
and pigs, which are said to thrive as well on it, after the cream has been taken from it, as before. The
cream, when skimmed off the whey, is put into a brass pan and boiled, and afterwards set in pans or jars,
where it remains till a sufficient quantity for a churning be procured, which, in large dairies, happens
generally once, but sometimes twice, in the week." In Ayrshire whey is given to horses.

7038. Butter forming an important article of commerce as well as food, the legislature has passed various statutes respecting its package, weight, and sale. The principal of these are the 36th and 38th of Geo. III.

Sect. V. Process of Cheese-making.

7039. The production of cheese includes the making of rennet, the selection of a colouring matter, the setting of the curd, and the management of the cheese in the press.

7040. The milk fresh drawn from the cow is to be immediately strained into the dishes or shallow troughs, if these are used, in order to promote cooling, as the surest guard against fermentation. The same object may be attained by repeatedly drawing off the milk from the coolers, and pouring it back

7041. To understand what rennet is, and its uses, it is necessary to premise that milk is no sooner taken into the stomach, than it becomes curdled by the operation of the gastric juice, as every one who has seen much of infant children must have observed. What is called rennet is nothing more than the stomach of an animal in which the gastric juices are preserved by means of salt.

7042. The application of any kind of acid will cause milk to coagulate, as well as the infusion of several plants, as ladies' bedstraw (Galium verum), butter-wort (Pinguicula vulgaris), and others. With the former plant, the Jews coagulate the milk for all their cheese; the Mosaic law prohibiting them to mingle

meat with milk, and rennet they consider as meat.

former plant the Jews coagulate the milk for all their cheese; the Mosaic law prohibiting them to mingle meat with milk, and rennet they consider as meat.

7043. The maw or stomach of ruminating animals, which admit of obtaining the gastric juice in a less mixed state than those of others, and chiefly of a young calf that has been killed before the digestion is perfected, is almost universally preferred as rennet. This bag or maw is cleaned and salted in different ways in different districts; but the following method, described by Marshal in his Rural Economy of Norfolk, is considered as one of the best. "Take a calf's bag, maw, or stomach; and having taken out the curd contained therein, wash it clean, and salt it thoroughly inside and out, leaving a white coat of salt over every part of it. Put it into an earthen jar, or other vessel, and let it stand three or four days; in which time it will have formed the salt and its own natural juice into a pickle. Take it out of the jar, and hang it up for two or three days, to let the pickle drain from it. Re-salt it, place it again in a jar, cover it tight down with a paper pierced with a large pin, and in this state let it remain till wanted for use. In this state it ought to be kept twelve months; it may, however, in case of necessity, be used a few days after it has received a second salting; but it will not be so strong as if kept a longer time."

7044. In order to prepare this remnet for use, Marshal gives the following directions: — "Take a handful of the leaves of sweet-briar, the same quantity of the leaves of the dog-rose, and the like quantity of bramble leaves; boil them in a gallon of water, with three or four handfuls of salt, about a quarter of an hour; strain off the liquor, and, having let it stand till perfectly cool, put it into an earthen vessel, and add to it the maw, prepared as above. To this is added a good sound lemon, stuck round with about a quarter of an ounce of cloves, which give the rennet an agreeable flavour."

7045. The strength of the

liness and sweetness; for if it be kept too long, so as to become foul or tainted, the cheese will invariably become affected by it, and will prove unfit for use.

7046. In Holland a small quantity of the muriatic acid is used instead of rennet; and it is the use of this article which gives to the Dutch cheese that pungent relish which induces so many persons to prefer it.

7047. Colouring matter. As cheese in its native state, that is, such as is well manufactured, being put together in proper time, the milk being of a proper degree of warmth, and in all other respects properly pressed, salted, and dried, is uniformly of a bright yellow cast, the idea of excellence is generally attached to cheese of such a colour. Hence it has become necessary for the dairyman, who would dispose of his cheese to advantage, to impart a light yellow orange colour to it by artificial means.

7018. Turmeric, marigolds, hawthorn buds, and other vegetables, were formerly employed for this purpose; but these have long since been rejected for the Spanish Arnotto, which is unquestionably the best ingredient of the kind that can be used for the colouring of cheese. It is a preparation of the roucon or arnotto tree (Biza Orellana Lin., fig. 163.), which is a native of America. The red pulp, that covers the seeds of this tree, is suspended in hot water, and allowed to subside, and when dry, is formed into cakes or balls, which are further set aside, until they become completely dry and firm. One ounce of this substance, when genuine, will be sufficient to colour an hundred weight of cheese; and this is the common allowance in the county of Gloucester; in Cheshire, the weight of a guinea and a half is considered to be sufficient for a cheese of sixty pounds weight. The usual mode of applying the arnotto is to dip a piece, of the requisite size and weight, in a bowl of milk, and rub it on a smooth stone until the milk assume a deep red colour. This infusion is to be added to the milk, of which cheese is intended to be made, in such a quantity as will impart to the whole a bright orange colour, which will become the deeper in proportion to the age of the cheese. The mixing of the arnotto in no respect affects either its taste or smell.

smell.

7049. In the county of Cheshire, however, a somewhat different practice obtains. There, when the colouring matter is wanted, it is usual to tie up as much of the substance as may be deemed sufficient in a linen rag; putting it into half a pint of warm water, to let it stand over night. In the morning, immediately before the milk is coagulated, the whole of this infusion is mixed with it in the cheese-tub, and the rag is dipped in the milk, and rubbed on the palm of the hand, until all the colouring matter is completely extracted. A more simple method is directed by Parkinson: — "Take," says he, "a piece about the size of a hazel nut, put it into a pint of milk the night before you intend to make cheese, and it will dissolve. Add it to the milk at the time the rennet is put in. The quantity will suffice to colour a cheese of twenty pounds weight." (Parkinson on Live Stock, vol. i. p. 62.)

The proper season for making cheese is from the beginning 7050. Setting the curd. of May till the close of September, or in favourable seasons till the middle of October. Very good cheese, however, may be made in winter, provided the cows be well fed. certain elevation of temperature is requisite to the coagulation of milk, and it may naturally be supposed to be nearly that of the stomachs of milk-taking animals. Marshal is of opinion that from 85 to 90 degrees of heat, and two hours of time, are the fittest for coagulation.

is of opinion that from 85 to 90 degrees of heat, and two hours of time, are the fittest for coagulation.

7051. Cimale, scason, weather, and pasture may require that these limits should sometimes be violated. Milk produced from poor clays will require to be coagulated at a higher temperature; but the most approved practice is to mix boiling water in such a proportion as shall render the milk of a proper degree of heat to receive the rennet; this the thermometer should be used to determine. In hot weather the milk in the cows' udders is liable to become very much agitated by their running about, or being driven to too great a distance: so that if rennet be put to it in this state, the curd, instead of coming in one two hours, will require three, four, or five hours, and will be so spongy, tough, and in every respect so imperfect, as to be scarcely capable of being confined in the press or vat; and when released from the state, which perhaps can scarcely be avoided during very hot weather, where cows are pastured abroad, in unsheltered grounds, or where water is not within their reach; it will be advisable to add some cold fresh spring water to the milk as soon as it is brought into the dairy. The quantity to be mixed, in order to impart the proper degree of heat, can in this case only be regulated by experience and the use of the thermometer. The effect of the water thus added will, in both cases, be to make the rennet take effect much sooner, and consequently to accelerate the coagulation of the milk.

7052. The proportion of rennet and time requisite for coagulation have been already mentioned (7045, 7050). It to much rennet ought not to be put in, otherwise the cheese will be ready to heave, as well as become rank and strong; the same effects will also be produced if the rennet be made with bad or foul materials, or if it be too strong to operate in the given time (two hours). During the process, the milk ought to be covered so as not to lose more than five or seven degrees of its original heat. One or two h

possible. During this part of the process salt is scattered over the curd, and intimately mixed with it; the proportion, however, has not been correctly ascertained, and is regulated by experience.

7054. Management in the press. The breaking and salting completed, a cloth is spread over the cheese vat, and the broken curd being packed into it, and covered up with the cloth, a smooth round board is laid over the vat, which is usually filled to the height of one inch above the brim, to prevent the curd from shrinking below its sides, when the whey is squeezed out.

7055. The whole is then put into a press for two hours, and as it is of the utmost importance that every drop of whey should be expressed, skewers are thrust into the cheese through the holes in the lower part of the vat to facilitate its escape. The two hours expired, the cheese is taken out and put into a vessel of warm or hot whey for an hour or two, in order to harden its skin. On taking the cheese out of the whey it is wiped dry, and when it has become cool, is wiped in a clean dry cloth, of a finer texture, and again submitted to the press for six or eight hours. The cheese is now turned a scoon dime, and is taken to the salting room, where it is rubbed on each side with salt; after which it is wrapped in another dry cloth, of a finer texture than either of the preceding cloths, and is again pressed for twelve or fourteen hours; if any edges project these are paired off, and the cheese being laid upon a dry board, is turned every day. In the salting-room cheese should be kept warm until it has had a sweat, or has become regularly dry and somewhat stiff; as it is warmth that ripens cheese, improves its colour, and causes it when cut to have a flaky appearance, which is the surest sign of superior excellence.

7056. Management in the cheese-room. After the processes of salting and drying are completed, the cheeses are deposited in the cheese-room or loft, which should be airy and dry; but on no account should hard and soft cheeses be placed in the same room, for the dampness or moisture arising from the latter will cause the hard cheese to chill, become thick coated, and often spotted. Throughout the whole process of cheesemaking, the minutest attention will be requisite; for if the whey be imperfectly expressed, or the rennet be impure, or the cheese be not sufficiently salted, it will become rank and pungent. For this defect there is no remedy. The imperfect separation of the whey will cause cheese to heave or swell, as well as to run out at the sides.

7057. In order to prevent as well as to stop this heaving, as well as to full out at the sites.

7057. In order to prevent as well as to stop this heaving, the cheese must be laid in a moderately cool and dry place, and be turned regularly every day. If the heaving be very considerable, the cheese must be pricked on both sides in several places, particularly where it is most elevated, by thrusting a skewer into it: by this pricking, though the heaving will not be altogether prevented, a passage will be given to the confined air, the heaving or swelling will consequently be considerably reduced, and the cavities of the cheese will be less offensive to the eye. Another remedy for heaving in cheese consists in applying a composition of nitre and bole armoniac, which is vended in the shops under the name of cheese-powder. It is prepared by mixing one pound of saltpetre with half an ounce of their the name of cheese-powder. It is prepared by mixing one pound of saltpetre with half an ounce of their be to be rubbed on a cheese, when put a second and third time into the press, half on each side of the cheese at two different meals, before the salt is rubbed on, that the cheese may be penetrated with it. This preparation is very binding, and sometimes proves serviceable, but the nitre is apt to impart an acid taste; and if too much be applied, and the cheese should be exposed to too great heat, the quantity of air already confined in it will be increased by fermentation, and the cheese will swell much more than it would if no powder had been rubbed on the cheese will swell much more than it would if no powder had been rubbed on the cheese will swell much more than it would if no powder had been rubbed on the cheese will swell much more than it would if no powder had been rubbed on the cheese will swell much more than it would if no powder had been rubbed on the cheese will swell much more than it would if no powder had been rubbed on the cheese will swell much more than it would if no powder had been rubbed on the chee

and the cheese should be exposed to too great near, the quantity of air aiready commed in t will be increased by fermentation, and the cheese will swell much more than it would if no powder had been rubbed in. The greatest care, therefore, will be necessary whenever this remedy is adopted.

7058. Hard and spoiled cheese may be restored in the following manner: take four ounces of pearlash, and pour sweet white wine over it, until the mixture ceases to effervesce. Filter the solution, dip into it clean linen cloths, cover the cheese with them, and put the whole into a cool place, or dry cellar. Repeat this process every day, at the same time turning the cheese, and, if necessary, continue it for several weeks. Thus the hardest and most insipid cheese, it is affirmed, has frequently recovered its former flavour.

Sect. VI. Catalogue of the different Sorts of Cheeses and other Preparations made from Milk.

7059. Of cheeses, we shall first enumerate the British sorts, and next those peculiar to foreign countries: the description of each will be such as to enable any ingenious dairyist to imitate them.

Togo. The brick-bat cheese is so named from the form of the mould; it is formed of new milk and cream in the proportion of two gallons of the former to a quart of the latter. It is principally made in Wiltshire, in the mouth of September, and should not be cut until it is twelve months old.

Togo. Chedder cheese, so named from the vale of that name in Somersetshire, where it is exclusively made. It is made in cheeses about thirty pounds each, which have a spongy appearance, and the eyes are filled with a limpid and rich, but not rancid oil.

Togo. Cheshire cheese is in universal esteem; it is made from the whole of the milk and cream, the morning's milk being mixed with that of the preceding evening, previously warmed. The general weight is sixty pounds each cheese.

Togo. Dunlop cheese (so called from its having been first brought to the Glasgow market by a carrier who lived in the parish of Dunlop, in Ayrshire,) has been made in the district of Cunningham in Ayrshire, from time immemorial. The quality of this cheese has certainly not been equalled in any other part of Scotland, and scarcely surpassed in England. According to Aiton, it is "milder in its taste, and fatter, than any English cheese whatever." The following directions are from this author's Dairy-Hussbandry. Husbandry.

Husbandry.

7064. When as many cone are kept on one farm as that ther milk will form a cheese of any tolerable size every time they are milked (trice a day), the milk, as it comes from the cows, is passed through a sieve (provincially termed a milked) to remove impurities into a bow (val), and when the whole is collected, it is formed into curd by a mixture of rennet. As milk requires to be, coagulated as nearly as possible at the temperature of animal heat, and as it must cool considerably during the operation of milking from several cows, and in passing through the step is a necessary for those who set their cut in the nature attention of the condition of the

have been described, and placed in the milk-house till as much is collected as will form a cheese of a proper size. When the cheese is to be made, the cream is skimmed from the milk in the coolers, and without being heated is, with the milk that is drawn from the cows at the time, passed through the sieve into the curd-vat; and the cold milk from which the cream has been taken is heated, so as to raise the temperature of the whole mass to near blood heat; and the whole is congulated by means of remet careful that its oily parts may not be melted, and the skimmed milk is heated as much as to raise the whole to near animal heat. The utmost care is always taken to keep the milk in all stages of the operation free, not only from every admixture or injunity, but also from being hurt by foul air arising from acidity in any milks substance, putrid water, the

stench of the byre, dunchill, or any other substance; and likewise to prevent the milk from becoming sour, which when it he was a state of the property of the substance and the substance is and likewise to prevent the milk from becoming sour, which when it he field. The temperature at which the milk is kept from the time it is drawn from the cows till it is formed into cheese, ready to be put up to dry, is a matter of great importance, and should be carefully attended to. The milk, when taken from the cow, ought to be as soon as possible cooled to below 55% or between that and 50% on Fahrenheld's scale: to cool it speedily, and to facilitate the separate is generally mixed with the milk in each cooler; and when the stone or from coolers that have been described are used, the milk will cool in them much sooner than in the wooden dishes formerly in use. If the milk is kept warmer than 55% of temperature, it will not properly cast up the cream, which it is thought necessary it should do even when the whole is to be formed into cheese, and the milk is mought to near that degree of temperature; but if it gets into a lower temperature than about 50% the milk acquires an inspired and unpleasant taste, of which it cannot be again divested; it does not coagulate nearly so well, and the cheese made from it is soft and inadhesive, the curd difficult to be separated from the whey, and the milk and cheese are never well itsaed.

**The drawn from the cow, or from 90 to 95 degrees of temperature, and for that pupose a thermometer ought to be used in the milk-house. If coagulated a marryl it natural heat when drawn from the cow, or from 90 to 95 degrees of temperature, and for that pupose a thermometer ought to be used in the milk-house. If coagulated much warmer, the curd is the milk-house. If coagulated much warmer, the curd is the milk-house. If coagulated much warmer, the curd is the milk-house. If coagulated much warmer, the curd is the milk-house. If coagulated much warmer, the curd is more milk-house. If coagulated, he

and it is only for a few minutes at first that the whey is too and it is only for a few minutes at first that the whey is too for so coplously now on that a first, as when the curd is more minutely broken.

7059. When the coagulum has been formed at a proper temperature, neither too cold not on hot, breaking the curd minutely, but gently and sofily, seems to be most proper: for though the whey is a little too white at first, that is soon over; it comes off abundantly pure in a few minutes after; and if flows the soft abundantly pure in a few minutes after; and if flows the soft and the sound of a speed discharge of the whey, as it saves time, and prevents the curd from becoming too cold and acquiring any bad taste or flavour (which it often contracts when neglected at that stage of the operation), is an ample compensation for any small quantity of the oily parts that may come off a first breaking.

It is a summary to the sound of the sold o

thin canvas, and put under the press.

7081. Gloucester cheese is in very considerable demand from its mild taste, which suits most palates, especially those of the young and of simple habits: there are two kinds, double and single, the first made from the milk and cream, and the latter with the milk deprived of about half the cream: the latter are of course the least valuable; but as they may be often mistaken for the former, upright dairymen, Marshal observes, impress a heart-shaped stamp upon them to distinguish them from the former. They are made of various sizes, from twenty to seventy, or even eighty pounds weight, but generally from fifty to sixty pounds.

7082. Green, or sage-cheese, is made by steeping over night in a proper quantity of milk, two parts of sage, one part of marigold leaves, and a little parsley, after they have been bruised. On the following morning, the greened milk is strained off, and mixed with about one third of the whole quantity intended to be run or coagulated. The green and white milks are run separately, the two curds being kept apart until they be ready for vatting: these may be mixed, either evenly and intimately, or irregularly and fancifully, according to the pleasure of the manufacturer. The management is the same as for common cheese. Green cheeses are made in the vale of Gloucester, as also in Wiltshire.

7073. All these operations ought to be carried on with the least possible delay, and yet without precipitation. The sooner the whey is removed after the cosquidation of the milk, so much the better. But if the curd is soft, from being set too cold, it requires more time, and to be more gently dealt with; as otherwise much of the curd and of the fat would go off with the whoy. And when the curd has been formed too lot, the same whoy. And when the curd has been formed too lot, the same roughly, would add to its toughness, and expel still more of the oily matter: and, as has been already mentioned, but water or whey should be put on the curd when it is soft and cold; and cold water put on when the curd is set too hot. 7074. After the cheese is put into the press it remains for the first time about an hour, or less than two hours, till it is first time about an hour, or less than two hours, till it is cloth put round it every four or six hours till the cheese is completed; which is generally done in the course of a day and a half, two, or at most three days after it was first put under the press.

irst time about an hour, or less than two hours, till it is taken out, turned upside down in the cheese-vat, and a new cloth put round it every four or six hours till the cheese is aken out, turned upside down in the cheese-vat, and a new cloth put round it every four or six hours till the cheese is completed; which is generally done in the course of ady and a half, two, or at most three days after it was first put under the course of the press. If the process of shelling is very differently conducted in the Scotch dairles from what it is in England. In Scotland, the sait is minutely mixed into the curd after it has been rendered as dry as possible, and cut very small by means of the cheese-kinfe, as has been already mentioned. This seems to answer the purpose just as well as the mode pursued in England, to be afterward secribed, which is far more troublesome, and must, and in labour. The greatest defect 1 can perceive in the satistic pare and the said is generally applied to the cheese merely by guess, whereas it ought to be more carefully regulated. Half an ounce of said to every English pound of cheese, or at most thirteen ounces to twenty-four pounds English, is a sufficient quantity. Too much sait renders the cityen, the cheese will become putrid. The content of the course of th

7083. Lincolnshire cheese is made by adding the cream of one meal's milk to that which comes immediately from the cow; it is pressed gently two or three times, and is turned for a few days previously to being used. It is chiefly made in spring, but the richest is that made in autumn. It will not keep above being used. three months.

being used. It is chiefly made in spring, but the richest is that made in autumn. It will not keep above three months.

7084. Norfalk cheese is made from the whole of the milk and cream; the size is from thirty to fifty pounds; it is generally coloured yellow, and is reckoned a good keeping cheese.

7085. Saft, or slip-coat cheese, is made from new milk hot from the cow, and the afterings; and what is required to make one pound of butter, will, in general, make one pound of cheese: this is a small soft rich echeese, which must be used immediately.

7085. Siltion cheese, which, from its peculiar richness and flavour, has been called the Parmesan of England, is made in the following manner: — The night's cream is put to the morning's milk with the rennet; when the curd is come, it is not broken as is usual with other cheese, but is taken out whole, and put into a sieve to drain gradually; while draining, it is gently pressed till it becomes firm and dry, when it is placed in a vat, a box made exactly to fit it; as it is so extremely rich, that without this precaution it is apt to bulge out, and break asunder. It is afterwards kept on dry boards, and urned faily, with cloth binders round it, which are tightened as occasion requires. After being taken out of the vat, the cheese is closely bound with cloth till it acquires sufficient firmness to support itself; when these cloths are removed, each cheese is brushed once every day for two or three months, and if the weather be moist, twice every day; the tops and bottoms are treated in a similar manner daily before the cloths are removed, each cheese is brushed once every day for two or three months, and if the weather be moist, twice every day; the tops and bottoms are treated in a similar manner daily before the cloths are removed, each cheese is brushed once every day for two or or three months, and if the weather be moist, twice every day; the tops and bottoms are treated in a similar manner daily before the cloths are removed. It is a similar manner daily before of the cheese.

of the cheese.

7087. Cottenham checse, from the town of that name in Cambridgeshire, is a thicker kind of cream cheese than the Stilton: its superior delicacy and flavour are attributed to the fragrant nature of the herbage on the commons on which the cows are pastured, and, according to Professor Martyn, to the prevalence of Poa aquática and praténsis.

7088. Suffilk, or skim cheese, is made of skimmed milk; it forms a part of every ship's stores, not being so much affected by heat as richer cheese, nor so liable to decay in long voyages.

7089. Wiltshire cheese is made of new milk coagulated as it comes from the cow: sometimes a small quantity of skimmed milk is added. In some dairies it is manufactured in winter as well as summer; in the former case it is liable to become scurfy and white coated; the last of which defects is frequently concealed by a coat of red paint. cealed by a coat of red paint.

7090. Of foreign cheeses, the most common is the Dutch cheese; this is prepared much in the same manner as the Cheshire cheese, excepting that muriatic acid is used instead of rennet, which renders it pungent, and preserves it from mites; that of Gouda is preferred.

7091. Parmesan cheese (formaggio di grana, cheese used in a granular form,) is made in the Duchy of Parma, and in various places in Lombardy. It was formerly supposed to be made from the milk of goats, but it is merely a skim-milk cheese, the curd hardened by heat, well salted, pressed, and dried, long kept, and rich in flavour from the rich herbage of the meadows of the Po, where the cows are pastured.

keet, and rich in flavour from the rich herbage of the 7092. The process, according to Pryce, (Bath Papers, vol. vii.) is as follows: —The evening's milk, after having been skimmed in the morning, and standing till ten o'clock, and the morning, and the standing till ten o'clock, and the morning, and the standing till ten o'clock, and the morning to the standing till ten o'clock, and the morning time to the standing till th

e meadows of the Po, where the cows are pastured.

off, water poured round the bottom of the anddowniestle to cool it, so as to admit of a cloth only peed below this condition of the cool of the coo

allowed to subside; three fourths of the whey is then drawn

7093. Swiss cheese is of several varieties, mostly of skimmed or partially skimmed milk, and manufactured like the Parmesan. Its varied and rich flavour is more owing to the herapse of the pastures than the mode of making; and some sorts, as the Gruyère (so called from the bailwick of that name in the canton of Fribourg), are flavoured by the dried herb of Melilàtus officinalis (fig. 43) in powder, Gruyère cheeses weigh from forty to sixty pounds each, and are packed in easks (fig. 43) in powder, Gruyère cheeses weigh from forty to sixty pounds each, and are packed in easks (fig. 43) in powder, Gruyère cheeses weigh from forty to sixty pounds each, and are packed in easks (fig. 43) in powder, Gruyère cheeses weigh from forty to sixty pounds each, and are packed in easks (fig. 43) in powder, Gruyère cheeses weigh from forty to sixty pounds each, and are packed in easks (fig. 43) in powder, Gruyère cheeses weigh from forty to sixty pounds each, and are packed in easks (fig. 43) in powder, Gruyère cheeses weight of the weight of the cheese requires to be kept in a damp place, and should frequently be washed with white wine, to present the depredations of insects. Neufchâted is celebrated for a very fine sort of cheese made there, which, in shape, resembles a wash. hand ball. 7094. Westphalia cheeses is in the cheese is of the skim—milk kind, and of a different character from any of those hitherto described. The cream is allowed to remain on the milk till the latter is in a sub-acid state; it is then removed, and the milk placed near a fire spontaneously to coagulate. The curd is sten put into a coarse bag, and loaded with ponderous stones to express the whey: in this dry state it is rubbed between the hands, and crumbled into an empty delam milk vat, where it remains from three to eight days, according as the cheese is intended to be strong or milk. During this part of the process, which is called mellowing, the curd undergoes the putrid fermentation, an

7096. Polato cheese is a German manufacture, of which there are three sorts. One of the best is thus prepared:—Select mealy potatoes, and only half dress them in steam; for by bursting their flavour and efficacy are diminished. Peel them, and then grate or beat them into a fine pulp. To three parts of this mass add two parts of sweet curd, knead and mix them, and allow them to stand three days in warm, and four or five days in cold, weather; form into small pieces like the Westphalia cheeses, and dry in the same manner. A still better sort of potato cheese is formed of one part of potatoes and three of the curd of sheep's milk. This sort is said to exceed in taste the best cheese made in Holland, and to possess the additional advantage that it improves with age, and generates no vermin.

7097. The preparations of milk, which can neither be included under butter nor cheese, are various, and constitute a class of wholesome luxuries or rural drinks. We shall do little more than enumerate them, and refer for further details to the cookery books.

7098. Curds and whey is merely coagulated new milk stirred up, and the curd and whey eaten together, with or without sugar and salt.

with or without sugar and salt.
7099, Curds and cream; here the whey is removed and cream substituted, with or without sugar. The
milk coagulated is often previously skimmed.
7100. Sour cream; cream allowed to stand in a vat till it becomes sour, when it is eaten with fresh cream
and sugar, or new milk and sugar, and is found delicious.
7101. Corstorphin cream; so named from a village of that name, two miles from Edinburgh, from which
the latter city is supplied with it. The milk of three or four days is put together with the cream, till it
begins to get sour and coagulated, when the whey is drawn off and fresh cream added. It is, therefore,
simply sour curd and fresh cream. It is eaten with sugar as a supper dish, and in great repute in the
north.

7102. Devonshire oreum is a term applied in the county of that name, sometimes to sour curd, and sometimes to sour cream; in either case mixed with new milk or fresh cream, and eaten with sugar like the

Corstorphin cream.

Tion. Devonshire oream is a term applied in the country of that hame, sometimes to sour crain; in either case mixed with new milk or fresh crain, and eaten with sugar like the Corstorphin cream.

Tios. Devonshire scalded or clouted cream. The milk is put into tin or earthen pans, holding about ten or twelve quarts each. The evening's meal is placed the following morning, and the morning's-milk is placed in the afternoon, upon a broad iron plate heated by a small furnace, or otherwise over stores, where, exposed to a gentle fire, they remain until after the whole body of cream is supposed to have formed upon the surface; which being gently removed by the edge of a spoon or ladle, small air bubbles will begin to rise that denote the approach of a boiling heat, when the pans must be removed from off the heated plate or stoves. The cream remains upon the milk in this state until quite cold, when it may be removed into a churn, or, as is more frequently the case, into an open vessel, and then moved by hand with a stick about a foot long, at the end of which is fixed a sort of peel from four to six inches in diameter, and with which about twelve pounds of butter may be separated from the buttermilk at a time. The butter in both cases being found to separate much more freely, and sooner to coagulate into a mass, than in the ordinary way, when churned from raw cream that may have been several days in gathering, and at the same time will answer a more valuable purpose in preserving, which should be first salted in the usual way, then placed in convenient.sized egg.shaped earthen crocks, and always kept covered with a pickle, made strong enough to float and buoy up about half out of the brine a new-laid egg. This cream, before churning, is the celebrated clouted cream of Devon. Although it would be reasonable to suppose that the scalded skin-milk is much richer and better for the purposes of suckling, and makes far better cheese than the raw skin-milk does. The ordinary produce of milk per day, for the first twenty weeks

eaten with sugar. Both sorts may be formed by those who have no cow, by warming the sweet or new milk, and squirting it into the wine or sour milk.

7107. Skim.milk is milk from which the cream has been removed. When this has been done within twelve or fifteen hours from the time of milking, it is sweet and wholesome, and fit either for being heated or coagulated in order to make cheese, &c., or used as it is with other food; but if allowed to remain twenty or thirty hours, it becomes sour, coagulates spontaneously, the whey separates from the curd; and if it remain a certain period, generally three weeks longer, in a warm temperature, the vinous fermentation takes place, and a wine or a liquor, from which ardent spirit may be distilled, is produced.

7108. Buttermilk is that which remains in the churn after the butter has been taken off. When butter has been made from cream alone, it is seldom of much value; but where the whole milk has been churned, and no water poured in during the process, it is a very wholesome cooling beverage. Some prefer it when it has stood a few days and become sour. In England it is chiefly given to pigs; but in Ireland it forms a very common diluter to porridge, potatoes, oat cakes, peas cakes, and other food of the labouring classes, and especially of the farm servants. In the Orkney Islands and other northern parts of Britain, as well as in Ireland, buttermilk is sometimes kept till it undergoes the vinous fermentation, when it is used to procure intoxication.

procure intoxication.

procure intoxication.

7109. Sour milk, Aiton observes, requires considerable care in the manufacturing, and the use of the thermometer ought never to be omitted. "When the operation is carried on at a low temperature, the milk swells when agitated in the churn, appears of a white colour, throws up air bubbles, and makes, when agitated or churned, a rattling noise. But when it is in proper temperature the milk does not swell or rise in the churn, it is of a straw or cream colour, emits a much softer sound, and does not cast up air bubbles so plentifully as when colder. When milk is either overheated or churned too hastily, the butter is always soft and of a white colour. From two to three hours is a proper time for performing the operation of churning. In the manufacture of sour milk, and in every branch of dairy husbandry, the utmost attention to cleanliness is indispensably necessary. The milk must no doubt become sour, and even coagulate before it is churned; but if that souring is not natural, but brought on by any foulness in the vessels through which the milk passes, or by any sort of admixture, or even by the milk being kept in a damp place, in one too hot or too cold, or even by exposure to an impure atmosphere, the acidity will not be a natural one, nor the taste of the milk or butter agreeable, but acrid and unpalatable. Every vessel through which the milk passes must be as clean, and every part where it is kept before being churned must be as free from dampness, and every species of impurity or bad air, as if it were intended to keep the
